**trochilus** is also a name used by Aristotle, Pliny, and others of the ancient naturalists, for the *regulus cristatus*, or, as we call it, the golden-crowned wren.

**trochilus** is also the name of a remarkable water-bird, being very long-legged, yet web-footed.

It is a very swift runner on the ground, and is thence called by the Spaniards *coriza*. Its beak is straight and black at the end, and the opening of its mouth very wide; it has black eyes surrounded by a white naked membrane, and that by a brown one. On its under part it is white; its back, shoulders, and wings, are of a ferruginous colour; its running is so very swift, as to equal the flight of most birds. Aldrovand, de Avib. lib. xix. c. 35.

**trochich.** The small branches on the top of a deer’s head.

**trochitæ, or trochites, in Natural History, a kind of figured fossil stones, resembling parts of plants; vulgarly called St. Cuthbert’s beads.**

They are usually of an opaque, brownish colour: they break like spar, glossy and shining, and are easily dissolved in vinegar. Their figure is generally cylindrical, sometimes a little tapering, the circumference smooth, and both the flat sides covered with fine radii drawn from a certain hole in the middle to the circumference.

Two or three, or more, of the simple trochites, joined together, constitute what the naturalists call an *entrochus*.

In these the trochites, or single joints, are so set together, that the rays of the one enter into furrows in the other, as in the futures of the skull. They are found in great plenty in the bodies of the rocks at Braughton and Stock, two villages in Craven, at all depths under ground; also in Mendip-hills, &c. sometimes only sprinkled here and there, and sometimes in large strata, or, beds, of all magnitudes, from the size of the smallest pin, to two inches about.

They are often found round or branchy, several rudiments of large branches arising from the stem, or cylinder, and sometimes still smaller from these. The branches being deeply inserted into the stem, the tearing them off leaves great holes in them. See Entrochus Ramusus.

Dr. Liferay has discovered a sort of little fragment among them, which he takes to have been the apices of them; and another sort, which he imagines to have been the roots: for he supposes them to be a sort of rock-plants.

M. Beaumont, in the Philosophical Transactions, assures us, that he has found, that all the cliffs in some mines are made up of these entrochi, some of which have been converted into a reddish matter; while others, becoming white spar, compoze bodies of that substance: and considering that all the cliffs, for a very large circumference in some places, consist almost wholly of these stones, it has been thought by some, who supposse them plants, that there have been, and still are, whole fields or forests of these under ground, as there are of coral in the Red sea. In the courses between the cliffs are found of these fossils, at all stages and degrees of maturity, growing up in the gritty clay, and rooted in the rake-mold stones, many of them of the form and dimensions of a tobacco-pipe, with the evident beginnings of circles and futures; and others full-grown, formed of perfect spar, and at their point of maturity.

The central matter, in many, continues still white and soft, as the whole substance is, by some, thought to have been at first; and is continually refreathed by the mineral streams and moifture, which have free access to it through five hollow slots, or feet, in the figured roots, or through the mafs of clay usually lying under the plain roots.

From the curiosity of their make, and from this accidental resemblance of plants, many have thought them to be such; and affirm, that they may vie with most of the vegetable kingdom, and are shaped and formed like them; having stem, branches, roots, an inward pith, as likewise joints and runnings in their grit, and sometimes cells to supply the place of veins and fibres.

Others have thought it highly probable, these rock-plants are lapides sui generis, and not parts of animals or plants petrifled, as many authors have imagined. If the figured roots, on which they sometimes grow, give any sufficience they might have belonged to an animal, particularly a species of the *Bella arboreus*, the trunks seem to them to evince the contrary: nor are they reducible to any known species of vegetables. M. Beaumont tells us, that he had by him above twenty different species of trochites, all of them wonderfully regular, and not to be paralleled by any vegetable he knows of in nature; and it is inconceivable how to many species, diffused through many parts of the earth, should come to be lost. They are certainly, indeed, not vegetable remains, but are truly parts of the *Bella arboreus* petrifled. See farther, Keppellus Effai de Entroch. and the articles Entrochus, Star-fish, and Star-fone.

**trochitifer glans.** See Glans Trochitifera.
TROCHLEA, προξελα, one of the mechanical powers, usually called a pulley; which see. TROCHLEA, in Anatomy, a name given to some articular emanations of bones, which resemble in form the groove of a pulley; viz. that of the humerus, adapted to the ulna. TROCHLEARIUS, a muscle of the eye. See EYE. TROCHMI, in Ancient Geography, the name of one of the three Gaulish nations, which, according to Strabo, established themselves in that part of Galatia which respects the Euxine sea, and that which touches on Cappadocia. TROCHOSCARPA, in Botany, from τροχος, a wheel, and ΚΣΟΤΟ, fruit, serving to express the orbicular depressed form of the nut, like a little wooded wheel.—Brown Prodr. Nov. Holl. v. i. 548.—Cf. and order Perastria Monogynia. Nat. Ord. Epacridae, Brown. Gen. Ch. Cal. Periathan inferior, of five equal, erect, ovate leaves, with two smaller ones, of the same shape, at the base, permanent. Cor. of one petal, funnel-shaped; tube cylindrical, more or less than the calyx; limb in five deep, ovate, spreading segments, bearded on the upper side. Neotaxy cup-shaped, five-lobed, surrounding the base of the seed. Stam. Filaments five, thread-shaped, the length of the tube, inserted into its lower part; anthers oblong, incumbent, included within the tube. Pfl. German inferior, ovate; style very short; stigma simple. Peris. Drupa globosha, depressed, juicy. Seed. Nut orbicular, with ten lobes, finally separating into as many distinct cells, with a kernel in each. Eff. Ch. Outer calyx of two scales. Corolla funnel-shaped, with a pervious naked tube, and a five-eleft, spreading, bearded limb. Stamens within the tube. Drupa pulpy. Nut wheel-shaped, ten-lobed, ten-celled. 1. T. laurina. Laurel-leaved Trochoscarpa. Br. n. l. (Cyathodes laurina; Rudge 77. of Linn. Soc. v. 8. 293. t. 9.)—Found near Port Jackson, New South Wales. A small tree, smooth in every part, with very hard wood. Leaves scattered, on short flanks, elliptic-lanceolate, acute, entire, many-ribbed, with somewhat of the aspect of a Rhus, each near two inches long. Spikes rather lax, terminal and axillary, shorter than the leaves. Flowers white, small. Fruit less than a pea. TROCHOID, τροχοειδς, or Trochoides, formed from τροχος, a wheel, and οιον, form, in Geometry, a curve, whose generis may be thus conceived: if a wheel or circle be moved with a two-fold motion at the same time, the one in the right line, and the other circularly about its centre, and these two motions be equal, i.e. describe two equal lines in the same time: and if in the radius, which at the beginning of the motion reaches from the centre of the wheel, or the first point of the line which describes the circumference: if, I say, in this radius, a point be taken any where, except in the centre, this point will describe a curve, one part of which will be below the line described by the centre, and the other above it. This line, thus described by the point taken in the radius, is called the trochoid. The right line which joins the two extremities of the trochoid, and which is either the path the wheel makes, or a line parallel to that path, is called the base of the trochoid. The axis of the trochoid is the diameter of the wheel, perpendicular to the base in the middle of the motion; or that part of the radius between the trochoid and its base. The point, in which the axis is cut into two parts by the line described by the centre of the wheel, is called the centre of the trochoid; the uppermost point of the axis the vertex of the trochoid; and the plane comprehended between the trochoid and its base, the trochoidal space. The trochoid is the name with what we otherwise call the cycloid; for the properties, &c. of which, see Cycloid. TROCHOIDES LACUS, or Trochoid Lake, in Ancient Geography, a lake in the isle of Delos. It was on the borders of this lake, that, according to the mythologists, Latona was brought to bed of Apollo and Diana; and here the first of these deities had a temple. TROCHTELFINGEN, in Geography, a town of Wurtemberg, lately imperial; 16 miles N.W. of Buchau. N. lat. 48° 16'. E. long. 9° 18'.—Also, a town of Germany, in the county of Oettingen, on the Eger; 4 miles S.W. of Nordlingen. TROCHUS, in Antiquity, denotes the exercise or game of the hoop. The hoop was of iron, five or six feet in diameter, set on the inside with a number of iron rings. The boys and young men used to whirl this along, as our children do their hoops, directing it with a rod of iron, having a wooden handle: which rod the Grecians called σφεις, and the Romans radius. The clattering of the ring served partly to the diversion, and partly as a notice for pedlans to keep out of the way. Horace de Art. Poët. ranks this exercise among other manly sports: "Ludere qui necit, campdfribus ablinet armis, Indocutile, pile, dilicie, trochive quicfet." TROCHUS, in Natural History, the name given by authors to a genus of shells: some of the species of which resemble the figure of the trochus, or top, which boys play with. As there are many species of this shell, however, which are flattened and have nothing of this form, the whole series of them are much better named, by a denomination taken from the shape of the mouth, which is of an oval figure, and is alike in all these species, and different from all other shells. They are therefore aptly characterized by a late French writer under the name of cochlea oro depriffo. The trochus, or tops, form the fifteenth family of shells in Da Costa's arrangement; and he defines them to be shells of a conic or pyramidal shape, the top being broad and flat-tish, and gradually tapering thence to a very sharp point; the aperture or mouth is most generally angular, low, and narrow. This is a numerous family, and abounds with curious and fine shells. See Trochus, under Conchology. There is a fossil species of trochus, not yet discovered recent. It is a large kind, flat-tish, and like a cochlea helix, generally about two inches in diameter, much wrinkled, with sharp prominent edges like plates, which are spiked at regular distances, running across the spires; and the whole shell is likewise iridated. This trochus is found in the limestone of Coalbrook-dale in Shropshire, and Dudley in Staffordshire. TROCKENBERG, in Geography, a town of the duchy of Stitia; 4 miles N.N.W. of Rein. TROCOT, a small island in the East Indian sea, near the coast of Queda. N. lat. 6° 30'. E. long. 99° 33'. TROCTUS, in Ichthyology, a name given by Arickote, Alani, Athenæus, and others of the Greek writers, to the fish called amia by Pliny, and moll other of the later, as well as ancient Latin writers; but by some, lebœia and glaueus. It is properly a species of the stomor; which see. TROCZENIECZ, in Geography, a town of Poland, in the palatinate of Braslaw; 20 miles S. of Braslaw. TRODEN, a town of Germany, in the principality of Querfur; 8 miles S.E. of Juterbock. TRODENA,
TRODEN^, a town of the county of Tyrol; 16 miles
S.S.E. of Bolzano.

TREZEN, or TREZEN, Danala, in Ancient Geography,
a town situated towards the S.E. extremity of the peninsula
of the Argolidse, at a small distance from the sea, and at
the junction of the two rivers, the Charybdis and the
Hydrcus. This town took its name from a hero, the son
of Pelops, and the brother of Pitheus. The last reigned
there, and was admired for his virtues and the mildness of
his government. The veneration which his conduct had ex-
cited, remained to the time of Paulinas.

Trezzen abounded with a variety of monuments; among
which we may reckon the tomb of Pitheus in a temple con-
structed in honour of Diausa Confervatrix by Theleus, after
his return from Crete, as an acknowledgment of his having
escaped the fury of the Minotaur; a portico ornamented
with the statues of women and children; a chapel confe-
crated to the Muses, and a great number of temples. The
habitants of Halicarnassus, in Caria, regarded Trezen
as their capital. A great part of the territory of Trezen
was an illusim extending into the sea, and as far as Her-
mone to the W. The port lay N. of the town, and was
called "Pogonis portus."1

TREZEN, a town of the Peloponnesus, in the interior
of Messenia. Ptolomy.

TROZENE, a town of A尹a Minor, in Caria.
Strabo.

TROGEN, in Geography, a town of Switzerland, and
chief place of the Protestant part of the canton of Appen-
zell, celebrated for its manufacture of cloth. Near it is
a mineral spring, containing copper, sulphur, and alum,
used externally for several complaints; 7 miles S.E. of
St. Gall. N. lat. 47° 14'. E. long. 9° 33'.

TROGILUM, in Ancient Geography, a promontory
of A尹a Minor, in Ionia, W.S.W. of mount Mycale, and
S.S.E. of the promontory Podium.

TROGILUS, a country of Macedonia. Steph. Byz.

TROGLODITAE, formed of TEnggd, caverns, and
by G, I enter, a people of Ethiopia, said to have
lived in caves under ground.

Pomp. Mela gives a strange account of the Troglo-
dytes.

—He says, they did not go properly speak or shriek; and
that they lived on serpents, &c. Tzetzes calls them Itbby-
ophagi. Mountanus takes them to be the same with thole
called in Scripture Ghananim. Pintianus in Strabo will
have the name written without the I, Trogodite.

These Trogloodytes, so called by the Greeks from their
primeval habitats in natural caverns, or in mountains
excavated by their own labour, were probably, as sir
William Jones conjectures (Works, vol. iii. p. 166, 8vo.)
the first inhabitants of Africa, where they became in time
the builders of magnificent cities, the founders of oneiarias
for the advancement of science and philosophy, and the in-
ventors (if they were not rather the importers) of symboli-
ical characters. Upon the whole he concludes, that the Ethiopians
of Meroe were the same people with the first Egyptians,
and hence likewise, as might be easily flown, with the
original Hindoos. We have already, aided by the conjectures
and historical details of the learned Bryant, and of the indef-
attagible traveller Bruce, traced the probable origin of these
people under the article CUSH. Having accompanied the
Cushites or Cushites in their migrations to Abyssinia, and
suggested the reason of their forming excavations in the
mountains and rocks for their habitats, we shall now at-
tend them in their peregrinations towards the south. Be-
sides other arts, with which they seem to have been
acquainted, they employed themselves in astronomical ob-
servations; and accordingly wished to difengage themselves
from the tropical rains and cloudy skies, that hindered their
correspondent observations with their countrymen, defecled
from the fame aneclors, who had ellablifhed themselves
at Meroe and Thebes. But upon advancing within the
southern tropic, they still found rains; and, therefore, con-
structed houses, such as the fears of a deluge had induced
them to prepare. They found solid and high mountains in
a fine climate; but, more fortunate than their countrymen
to the northward, they found gold and silver in large quan-
tities, which determined their occupation, and constituted
the riches and confluence of their country. In these
mountains, called the "mountains of Sofala," large quan-
tities of both metals were discovered in their pure and un-
mixed state, lying in globules without alloy, or any necel-
licity of preparation or separation. The balance of trade, fo long
against the Arabian and African continents, turned now in
their favour, from the immense influx of these precious
metals, found in the mountains of Sofala, jilt on the verge
of the southern tropical rains. The northern colonies ad-
vanced gradually from Meroe to Thebes, intent upon the
improvement of architecture and building of towns, which
they began to substitute for the caves which they and their
ancestors, the Cushites, originally occupied; and they thus
became traders, farmers, artificers in various branches, and
even practical astronomers, from having a meridian night
and day free from clouds, for such was that of the Thebaïd.
As their brethren, who still inhabited the mountains, did not
enjoy similar advantages, being confined by six months'
continued rain to their caves, we may naturally imagine
that their sedentary life would render them useful in re-
ducing to practical purposes the observations daily made by
those of their countrymen who lived under a purer sky.
Letters too, or at least one fort of them, and arithmetical
characters, as we are informed, were invented by this middle
portion of the Cushites; while trade and astronomy,
the natural history of the winds and feaons, were employing
that part of the colony which was established at Sofala,
more to the southward. The very nature of the commerce
of the Cushites, the collecting of gold, the gathering and
preparing of spices, necessarily fixed them permanently
at home: but his profit depended on the disperion of these
spices through the continent, otherwise his mines, and the
trade produced by the possession of them, would be of little
avail. A carrier was necessary for the disperion of their
dispensable commodities; and such they found in their own
vicinity. These carriers were denominated Berbers or
Shepherds, as well as distinguished by other appellation
of similar import. These shepherds of the Thebaïd and
Ethiopia were wholly employed in the disperion of the
Arabian and African goods all over the continent; and
they rose to be a great people. As that trade increa-
ed, their cattle multiplied, and consequently they increased
in number, and the extent of their territory was enlarged.
Nothing was more opposite than the manners and life of the
Cushite, and his carrier the shepherd. The first, although
he had forsaken his caves, and now lived in cities which he
had built, was necessarily confined at home by his commerce,
amassing gold, arranging the invoices of his spices, hunting
in the seaon to provide himself with ivory and with food
through the winter. The mountains, and the cities he after-
wards built, were situated upon a loamy, black earth, so
that as soon as the tropical rains began to fall, he was de-
prived of his cattle, by swarms of flies (fice ZIMB) which
appeared wherever that loamy earth was; which made him
S1 absolutely
absolutely dependent upon the shepherd, who was himself also affected by this circumstance. The shepherd, as a carrier, was enabled to perform his long and toilsome journeys across Africa by the means of the camel, emphatically called by the Arabs "the ship of the desert." When Carthage was built, the carriage of this commercial city fell into the hands of the Lebhim, or Lubim, the Libyan peacants, and became a great accession to the trade, power, and number of the shepherds. For a further account of the shepherds, see Shepherds of Egypt.

As the Abyssinians of the Arabian flock had no symbols of their own to represent articulate sounds, they borrowed those of the Troglodytes above mentioned; and to them we may with probability trace the origin of the Abyssinian written language, or the Ethiopic, which is a dialect of old Chaldæan, and a filter of Arabic and Hebrew; and many improvements in science and the arts, as well as in commerce, at an early period, were introduced into Africa, and through Abyssinia and Ethiopia into Egypt, by these people. It has indeed been suggested that the Gypsies (see the article) were Troglodytes from the rocks near Thebes, where a race of banditti still resemble them in their habits and features; but it seems more probable that the Gypsies, whom the Italians call Zingaro and Zinganos, were no other than Zinganians, who might, in some piratical expedition, have landed on the coast of Arabia or Africa, where they might have rambled to Egypt, and at length have migrated, or been driven into Europe.

Troglodytes is also an appellation given to a feclt of Jewish idolaters.

The prophet Ezekiel relates, chap. viii. ver. 8, 9, 10, &c. that God, among other abominations of the Israelites, which he set before him, sentenced him seventy old men, who, with their centers in their hands, adored secretly all kinds of animals and reptiles painted on the wall.

Philastrians, on this vision of the prophet, erect these idolaters into a feclt of Israelites, who, hiding themselves under ground, and in caves, adored all kinds of idols.

And yet the prophet plainly shews, that it was in secret parts of their houses, and not in subterraneous caverns, that these seventy Israelites idolatized. The name Troglodytes, then, is feigned; and so probably is the feclt.

Troglodytes, in Ornithology. See Wren.

Trogodos, Trobodos, or Trebos, in Geography, a name given by the Greeks of the present day to mount Olympus, which divides the island of Cyprus longitudinally. In order to distinguish it from another mountain of the same name in Natalia, and from another more famous in Macedonia, the ancients gave this the name of "Little Olympus." On its summit they had built a temple dedicated to Venus, the entrance of which, by a regulation very strange for a spot consecrated to the goddesses of Love, was prohibited to women: they were even forbidden to look at it. To this temple, an elegant and faced reeves, where were celebrated the enjoyments of nature, had succeeded retreats erected for privations. Numbers of convents were built on the same ground. There, laborious Cenobites embellished the steep of the mountain with gardens, and plantations of all sorts, laid out with taste. This was the most charming abode in the island; and the rich Cypriots went thither, during the summer, to enjoy the coolness of agreeable groves, watered by limpid streams, directed with considerable art. Ineffable to a happy harmony of nature and industry, the Turk has carried his ferocity and ravages into this beautiful district: the monasteries have been demolished, and cool and cheerful spots have been clothed with the rugged garb of ITERITY. Somnini.

Trogon, CURUCAI, in Ornithology, a genus of the Pica; the characters of which are, that the bill is shorter than the head, cultrated, hooked, and serrated at the margin of the mandibles; the nostrils are covered with bristles; and the feet, short, timple, covered with down, are formed for climbing, having two toes forward, and two backward.

The birds of this genus are mostly inhabitants of South America: they feed on fruits, and all agree in their general habits of life. In Guiana they are denominated Cozrocuoos, or Curucui, from their notes being very much like that word.

Species.

Strigilatus. Cinereous, with a fulvous abdomen; wings frizzled with white; tail-feathers black, the three lateral ones outwardly banded and tipped with white. The cinereous curucui of Latham. Inhabitats Cayenne and Guiana.

Curucui. Golden-green; of a fulvous red beneath; throat black; wing-coverts and the three exterior tail-feathers white, striped with black. Red-bellied curucui of Latham. Of this species there are several varieties, viz. one mentioned by Marchgrave, which had the wing-coverts plain brown, the bill ah-coloured, irides fawn-coloured, and without the bare spot under the eye mentioned by Brifon in his description; another, with a yellow abdomen; the green yellow-bellied curuco of Edwards; another, described and figured by Buffon, of a cinereous-grey, with very flight traces of green-gold, especially on the back and middle tail-feathers; the lower part of the belly and the vent only being red; the tail very long, having the outer web of the three lateral feathers and the tips plain white; the three outer quills are also marked with black and white on the exterior webs. This species is a very solitary bird, being found only in the thickest forests; and in pairing time never more than two are found together, when the male has a very melancholy note, never uttered except whilst the female is sitting. They pair in April, and lay three or four white eggs. The male, during the incubation of the female, supplies her with food, and by his song helps to pass away the time. The young, when first hatched, are altogether without feathers, and are fed by the old birds with small worms, caterpillars, and insects; but are deferred by them, when they are able to shift for themselves; and the parent-birds return to their solitary haunts, till August or September, when they are prompted to produce another brood. At St. Domingo and in other islands these birds are called "Demoiselle," or "Dame Angloise," where attempts have been made to tame them, but ineffectually, as they refuse to eat, and consequently die. They are also found in Cayenne, Peru, Brazil, and Mexico.

Viridis. Golden-green; beneath yellow; throat black; with the three lateral feathers on both sides obliquely destitute of white. The yellow-bellied curucui of Latham. Of this species there is a variety, viz. the lefs, with white abdomen; the white-bellied curucui of Latham. This species inhabits Cayenne.

Rufus. Rufous, with the body beneath yellow; wings frizzled with black and grey; the three lateral tail-feathers frizzled with black and white, with white tips. The rufous curucui of Latham. Found in Cayenne.

Violaceus. Violet-coloured, with a green back; wing-coverts and secondaries quills spotted with white; the three lateral tail-feathers barred with black and white, with white tips.
The violet-headed curucu of Latham. Found in Cayenne.

Maculatus. Striped with dusty and brown; crown green; wing-coverts and secondary quill-feathers green, white at the tips; tail dusky, with white bars. Spot at curucu of Latham; inhabiting Ceylon.

Fasciatus. With a ferruginous back; body beneath fulvous red; head and neck dusky, with a white face on the breast; wings fuscated with black and white; apex of the tail black. Fuscated curucu of Latham; inhabiting Ceylon, but rare, and called by the inhabitants "Rautvankonda-cuckoo".

Asiaticus. Green, with the forehead, crown, and hind part of the neck red; throat blue, with a red spot; quills and tail-feathers black. Blue-cheeked curucu of Latham; inhabiting India.

Indicus. Dusky, with ferrugineous spots above; beneath yellowish, striped with dusky; head black, with white stripes; tail very long, and barred. Indian curucu of Latham; called in India by the natives "Bungummi".

Narina. Above green, with a red belly. Male, with the head, neck, back, throat, jugulum, breast, and wing-coverts green, which last are greyish behind; quills black, bordered externally with white. Female, with the throat, jugulum, and wing-coverts brown; abdomens in front cinerascents. Le Vaillant says, that this bird is an inhabitant of Caffaria, and the country of Auteniqua to the river Gantoo, and that the name Narina, in the Hottentot language, signifies a flower. The female lays four nearly round eggs, and during her incubation the male has a melancholy note, but at other times he is silent.

Trogus Pompeius, in Biography, a Latin historian, flourished in the time of Augustus, and wrote 44 books, under the title of "Philippicis," so called from their subject, which was the Macedonian empire, originating with Philip, the father of Alexander. An epitome of this work by Julius is extant. Julius denominates Trogus a man of antique eloquence, and Pliny, who often refers to him in his Natural History, distinguishes him by the appellation of "feverifimus auctoris," as a most exact author.

TROIA, or Trojan Games, Ludi Trojanii, were games instituted by Ascanius, son of Æneas; and which afterwards passed to the Romans, and were celebrated in the Circus by the youth of Rome.

One of the number, who presided over the solemnity, was called princeps juvenatis; and was always of one of the six families in Rome.

At first, it is supposed, they only engaged on foot, and on horseback; because Virgil, who describes these games in the Æneid, lib. v. only speaks of horse and cavaliers, without any mention of biga or quadriga, which were not in use in Rome till long after Ascanius. And yet Dion, speaking of Cæsar's games, says, the youth there combated in chariots; but it is thought by some, that these were not the Trojan games, but races and combats of a different kind, proper for young people, of a more advanced age.

The Trojan games were renewed by Augustus, after the victory at Actium, A.D. 726; began to decline under Tiberius, and terminated under Claudius.

TROIA, in Ancient Geography, a town of Chonisia, in Cilicia. Steph. Byz.—Allo, a town or rather village of Egypt, in the vicinity of mount Troicus. This was the ancient habitation of the Trojans, who followed Memelus to his captivity. Strabo.—Allo, a town of Italy, at the bottom of the Adriatic gulf, in the country of the Veneti. Steph. Byz.—Allo, a town of Asia, in Cilicia.—Allo, a place of Italy, in the territory of the town of Larentum. According to Livy, it gave name to the place where Æneas landed, on his arrival in Italy; situated, according to Dion. Halic., four stadia from the sea.

TROJA, or Troy, a celebrated city of Asia Minor, and capital of the small country called Troas, or Tronde (which see), and Phrygia Minor, situated to the north-west. See PHRYGIA Minor.

TROJA, in Geography, a city of Naples, in Capitanata, on the river Chilar, the seat of a bishop, containing six churches and six convents. It was built on an eminence, out of the ruins of Æneas, a city destroyed by Conflans II. It is said to have been founded by Bajianus, catapar or viceroys of the province in the eleventh century, by order of the emperors Basil and Constantine, as a bulwark against the inroads of the Norman adventurers, and to have had its name in commemoration of the famous city, which, by its fall, immortalized the heroes of Greece. It was long accounted a key to the Apennines, and as such was exposed to many assaults and sieges; 33 miles S.W. of Manfredonia. N. lat. 41° 24'. E. long. 15° 18'.

TROIA, a small island in the Mediterranean, near the coast of Italy. N. lat. 42° 43'. E. long. 11° 5'.

TROJAN, a town of Servia; 16 miles S. of Sabaceq. TROIL, among Tinners, denotes a feath., or occasion of merriment, by eating and drinking; called also a duggle. TROILINSAKAIA, in Geography, a town of Ruffia, in the country of the Caffacks, on the Don; 80 miles E. of Azoph.

TROIS-CINQUE, in the French Distillation, a term used to express their brandy, when of a peculiar strength, consisting of five parts alcohol and three parts phlegm.

The method of distilling the wines into brandy in France, is exactly the same with that used with us to draw the spirit from our wine or fermented liquor of malt, treacle, sugar, or whatever other kind. They only observe more particularly to throw a little of the natural lee into the still along with the wine; and the poorest wines are sure to succeed best on the trial, making by much the finest brandies. We are apt to wonder that we cannot, from the wines of particular countries, distil their particular brandies; but the whole mystery consists in this, that they do not send us over the same wines which they use in distilling, because these latter would not be liked as wines, nor would keep in the bringing over. Sometimes in Scotland they meet with the poor and pricked wines, the fame that the French distil their brandies from; and from these they distil a spirit, not to be known from the brandy distilled in France.

The lea which the French add in the distillation gives the brandy that high flavour for which we so much esteem it; but they themselves like it so much the worse for it. The French notion of a proof strength, determined by the chaplet or crown of bubbles, is the fame with ours; and all their fine spirits are found of this strength.

But they have one particular expedient for those brandies which prove foul and feedy, or retain the taste of certain weeds which grow among the wines; they draw them over again, with a design to free them from that adventitious flavour. In this operation they always leave out the faints, or rather they change the receiver as soon as ever the stream comes proof; then mixing together all that ran off before, they make a brandy stronger than the ordinary kind, and this is what they call trois-cinque.

The distillers in France scarcely ever bring their brandies higher than this; for they have the art to persuade the foreign merchant, that the phlegm of French brandy is so natural...
natural and essential to it: but the truth is, that the spirit alone contains the flavour and excellence of the brandy, and it might as well be reduced to half its bulk for exportation, and fent over in the state of alcohol, and then lowered with common water to the proof strength.

The French use no art in colouring their troisi-cinque, any more than their common proof-brandy, nor do they add any thing to give them an additional flavour; the thing which they principally value themselves upon, both in regard to brandies and wines, being to make them perfectly natural: so that all the colour we find in their brandies, is acquired from the cask, and the time they are left in it. This is often twelve or eighteen months, sometimes two or three years; in this time they acquire a brown colour, and lose their acid taste.

The greatest adulteration of brandies is in England: the French have no temptation to do it, they having no cheaper spirit, since the prohibition of molasses in their country. The Dutch are in the same condition, having no molasses-spirit, and only a very coarse and nauseous sugar-spirit, and a yet worse malt-spirit of their own manufacture; a single gallon of which would spoil a whole piece of brandy. The French brandy also paying no duty in Holland, is as cheap, or nearly so there as in France itself. The duties being high upon brandy in England, it is greatly adulterated, and that with all sorts of spirits; as malt, molasses, cider, and sugar spirits; and when this is done in a dexterous and spurious manner, the cheat is not easily detected. Shaw's Essay on Distillery.

TROIS MARIES, Let, in Geography, a town of France, in the department of the Mouths of the Rhône, by the inhabitants of the country held a sacred place, as having been, according to tradition, the residence of the three Maries, and Lazarus after our Saviour's crucifixion; 15 miles S. of Arles.

TROIS RIVIÈRES, Let, a town of the island of Martinico. TROIS RIVIÈRES, a town of Canada, on the river St. Lawrence, lying nearly midway between Quebec and Montreal, and so called from three rivers, into which the river St. Maurice is divided by two islands, whole streams unite about a quarter of a mile below the town, and afterwards fall into the great river of St. Lawrence. It was formerly the capital of the French government in New France, and much reforted to by several nations which come down those rivers to it, and trade in various sorts of furs. The town contains about 270 or 300 houses, and ranks as the third town, in respect of size, in the provinces. It is one of the most populous settlements in the country, and its founder, it is said, calculated upon its becoming in a short time a city of great extent. It has hitherto, however, increased but very slowly in size, nor can it be expected to improve much, at least until the country bordering upon the river St. Maurice becomes settled. The bank of iron-ore in its vicinity, which promised opulence, is nearly exhausted. The fur-trade also, from which great benefit was expected, is now almost wholly transferred to Quebec and Montreal; and it is merely the small quantity of furs brought down the St. Maurice, and some of the northern rivers that fall into the St. Lawrence, nearer to the town of Trois Rivières than to Quebec or Montreal, that is shipped there. These furs are laden on board the Montreal ships, which float opposite to the town as they go down the river. The streets of Trois Rivières are narrow, and the houses in general small and indifferent, many of them being built of wood. In the town are two churches, an English Episcopal, and a large Roman Catholic parish-church, formerly served by the Recollets, or Franciscan friars, but the order is now extinct in Trois Rivières. The old monastery of the order is defunct, and the houses near it lie uninhabited. The college or monastery of the Jésuits, a large old stone-building in the same neighbourhood, has been converted into a gaol. The only religious order at present existing in the town is that of St. Ursula, the friary of which is as numerous as the convent can well allow. This was founded by M. de St. Vallier, bishop of Quebec, in the year 1677; the building is spacious, and situated near that formerly belonging to the Recollets; and annexed to it under the same roof is an hospital, attended by the nuns, and containing about twelve or fourteen beds, for the convenience of patients, who are well accommodated. The filters of this convent are particularly distinguished for their curious work made of the bark of the birch-tree, and of which they manufacture pocket-books, work-baskets, dressing-boxes, &c. which they embroider with elk-hair, dyed of the most brilliant colours. They also make models of the Indian canoes, and various warlike implements used by the Indians. Almost all the birch-bark canoes in use on the St. Lawrence and Utawa rivers, and on the nearer lakes, are manufactured in Trois Rivières, and its vicinity, by Indians. These canoes are constructed very neatly, and on the water they appear very beautiful. The canoes are so light, that two men can easily carry on their shoulders one that is capable of containing six people. Their size varies, some being sufficient for only one person, and others capable of accommodating any number as far as twenty. They are navigated with paddles, and move with surprising velocity. The country in the vicinity of Trois Rivières has been represented by some French travellers as wonderfully fertile, and as one of the most agreeable parts of Canada; but, according to Mr. Weld (Travels through Lower Canada, vol. ii.) it is totally the rever. It is a level barren tract, and so sandy, that in walking along many of the streets of the town, and the roads in the neighbourhood, you sink into the land at every step above the ankles. The air also swarms with mosquitoes, indicating the low damp situation of the place; 44 miles W.S.W. of Quebec. N. lat. 46° 24'. W. long. 72° 20'.

TROIS RIVIÈRES, a bay on the E. coast of the island of St. John, in the gulf of St. Lawrence.—Alfo, a river of St. Domingo, formed by the union of three streams, and running into the sea on the N. coast of the island, near Port Paix.

TROISSEREUX, a town of France, in the department of the Oise; 4 miles N.W. of Beauvais.

TROYTZ, or TROTSKOE MONASTIR, that is, The Convent of the Holy Trinity, a convent of Russla, which is so large, as at a little distance to have the appearance of a small town; and, like many convents in this country, is strongly fortified, according to the ancient mode of defence, being surrounded with high brick walls, strengthened with battlements and towers. Beside the convent or habitation for the monks, the walls inclofe an imperial palace, and nine churches, constructed by different sovereigns. The convent is a large range of building encircling a court, and is far too spacious for the present inhabitants. It formerly contained 300 monks, together with a proportionate number of students; and was the richest ecclesiastical foundation in Russla. The fraternity possessed considerable estates, upon which were at least 100,000 peafants: these estates, as well as all the other church-lands, being now annexed to the crown, the members receive small penions. With their revenues their number has been greatly diminished, and they fearfully amount
amount of present to 100 monks. Their habit is black, with a veil of the same colour; they eat no meat, and the discipline of the order is very strict. This convent is distinguished in the annals of this country as the asylum for the Russian sovereigns, in cases of infirmary or danger; and is more particularly known to foreigners for the refuge it afforded to Peter the Great, when he put an end to the administration of his brother Sophia; 40 miles from Moscow.

TRÖTZK, a town of Russia, in the government of Penza; 76 miles W.N.W. of Penza. N. lat. 54°. E. long. 49° 32'.

TRÖTZKOE, a town of Russia, in the government of Ufa; 200 miles E. of Ufa. N. lat. 54°. E. long. 61° 44'.—Alfo, a town of Russia, in the government of Ufa; 16 miles N.E. of Sergievsk.

TRÖTZKOI, a town of Russia, in the government of Simbirsk; 20 miles N. of Sizran.—Alfo, a town of Russia, in the government of Archangel; on the Pinn; 28 miles S.E. of Pinn.—Alfo, a town of Russia, in the government of Ufa; 40 miles N.W. of Belovecz.—Alfo, a town of Russia, in the government of Tobolfsk, on the Ob; 204 miles N. of Tobolfsk. N. lat. 61° 24'. E. long. 42° 50'.—Alfo, a town of Russia, in the government of Tobolfsk; 40 miles N.W. of Narim.—Alfo, a town of Russia, in the province of Ulug; 32 miles S. of Lasf. Alfo, a town of Russia, in the government of Koltrom; 40 miles S. of Vethluga.—Alfo, a town of Russia, in the government of Koltrom; 12 miles N. of Vethluga.—Alfo, a town of Russia, in the government of Tobolfsk; 14 miles N.E. of Talievskoi.

TRÖK, or TROI, a town of Lithuania, and capital of a patinate to which it gives name. This town was built by the great duke Gedim in, the year 1321, and is situated among lakes; it was formerly the residence of the great dukes, who afterwards removed their seat to Wilna. In the year 1655, it was demolished by the Russians; 16 miles W. of Wilna. N. lat. 54° 33'. E. long. 24° 44'.

TROLHETTA, a town, or rather village, of Sweden, in West Gothland; 15 miles E.S.E. of Uddevalla. For an account of the canal of Trolhetta, see CANAL.

TROLLING, among Anglers. To troll, is to fish for pikes with a rod whose line runs on a reel. See Pike-Fishing.

TROLLUS, in Botany, a name given to this plant, our Globe-flower, by Conrad Gesner, which, though of barbarous etymology, has been universally retained. This might be attributed to respect for its illustrious author, were there not so many bad reasons for which barbarous names have been admitted. The derivation of Trolleus is laid to be from an obsolet German word tröll, or tröllen, expressing any thing globular. Hence it is synonymous with the English name of this flower; as well as with the French one, boule d'or. Professor Martyx says, after Haller, "Trolhume, in German, seems to signify a magical flower."

Gen. Ch. Cal. none. Cor. Petals about fourteen, sometimes fewer, roundish-ovate, concave, converging, diminutive, three in each outer row, five in the innermost. Neftaries about nine, linear, flat, incurved, perforated at the base within. Stam. Filaments numerous, linear, much shorter than the corolla; anthers linear, erect. P.PB. Germens superior, numerous, sessile, columnar; fyles short; fligma pointed, shorter than the flaments. Peric. Capsules numerous, collected into a head, oblong, compacted, curved, pointed, burring at the inner edge, of one cell. Seeds numerous, obovate, angular, polished, inferted along the inner edge of each valve.

Obs. Linnaeus erroneously in Gen. Pl. calls the capsules ovate and single-feeded.

1. T. europeus. European Globe-flower. Linn. Sp. Pl. 782. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 28. Fl. Dan. t. 133. Lightf. Scct. 295. (Ranunculus globosus).—Geer. Em. 955. R. fexs. Camer. Epit. 385. Globe Crawfoot; Pétiv. Herb. Brit. t. 43. f. 2. —Petals closely converging. Neftaries the length of the flaments. Native of mountainous, rather moist, meadows and pastures in the north of Europe, especially Lapland, Sweden, Germany, Switzerland, Wales, the northern counties of England, and Lowlands of Scotland, flowering in May and June. The root is perennial, of many stout fyrines. Herb smooth. Stem erect, two feet high, round, leafy, branched in the upper part. Leaves deeply divided into many wedge-shaped, deeply cut and toothed, acute, spreading lobes; the radical ones on long falks; the refl nearly sessile, alternate. Flowers solitary at the naked summits of the branches, erect, globular, above an inch wide, of an elegant bright uniform yellow. Neftaries obtuse. Seeds black. Höller and Lightfoot say the flowers are fragrant, which we have not observed. The Scotch call them Lucken-gowans, or Cabbage-daifes. In Westmoreland we have seen these flowers gathered by the peafants, with great fertility, and made into garlands for the young men and women, as well as to decorate the porches of their cottages. Linnaeus mentions them as ufed in Sweden to trow the floors on holidays.

2. T. afaticus. Asiatic Globe-flower. Linn. Sp. Pl. 782. Willd. n. 2. Ait. n. 2. Curt. Mag. t. 235. (Helbor us asci folio, flore globo croceo). Ann. Ruth. 76. n. 101. —Petals spreading. Neftaries nearly equal to them in length. Native of the banks of rivers in Dauria. Annum.—A hardy, but not very common, perennial in our gardens, flowering in May or June. It requires a mixture of loam and bog earth, in a northern exposure, and must have due supplies of water in dry summers, for want of which we have, after several years successful cultivation, lost the plant. This species is very like the former in habit, though somewhat larger, with more copious and acute teeth, or serratures, to the leaves. The flowers however are distinguished by their spreading petals, of a rich orange-colour, and the full deeper hue of their large and numerous neftaries, almost, or quite, equal to the petals in length. The flower being much more open than in T. europeus, the neftaries, as well as flaments and pettis, are displayed in full view, and the whole makes a very handsome appearance.

—Petals spreading, slightly concave. Nectaries hardly so long as the flammes. —Native of Pennsylvania, flowering in May. Specimens and seeds were sent us in 1793, by the late Rev. Dr. Muhlenberg, under the above name, by which he has published the plant in his Catalogus Plantarum America Septentrionalis. This name is so singularly apt, one species of this genus being appropriated, as it appears, to each of three quarters of the world, that, though we by no means approve of specific names taken from particular countries, on a limited scale, we cannot reject this: fill less can we allent to an arbitrary change of the other two. On this subject we have the universal suffrage of botanists in our favour. The species before us is smaller than either of the other two, and seems to have scarcely more than five petals, which are obvate, and of a yellow, not orange, colour. Their spreading position sufficiently distinguishes the plant from T. europaeus, as the thornettes of the nectaries does from asfaticus. The capsules are short and abrupt, crowned by the rather elongated styles.

Mr. Donn mentions two other American species, by the names of intermedium and hybridus, which we preume to be varieties of americanus. We have observed a difference of appearance, with respect to size and colour, in plants raised from our original parcel of seeds, and Dr. Muhlenberg makes but one American species. The date of the introduction of T. americanus ought to be 1794, not 1805.

T. patulus, Salis. Tr. of Linn. Soc. v. 8. 303; Helleborus ranunculus, Sm. Plant. t. 379, is most evidently no Trollius, on account of its tubular nectaries.

Trollius, in Gardening, comprises some hardy, heraceous, flowery, perennial plants, as the globe ranunculus, or globe-flower, among which the species cultivated are the European globe-flower (T. europaeus); and the Asiatic globe-flower (T. asfaticus).

These two plants are of a rather tall hardy growth, affording considerable ornamental effect in their large flowers, which grow in the first fort in a particular converging manner, or turn in an inward direction, or somewhat revolute mode, so as to give them a perfect globular form, from which they derive the name of globe-flower. They appear in both forts in the beginning of summer. Those in the Asiatic or latter kind, however, are not connivent, but spread out and shew some of the inner parts, which are of a fine faffron-colour, and display a flanking elegant singularity in their appearance, which renders them highly valuable for their use in the flower-garden. They are both definable flower-plants.

Method of Culture.—The means of propagation and increase in these plants are occasionally by sowing the fresh seeds of them, and the parting of their roots.

In the former method, the seeds should be sown in shallow drills, in a somewhat shady border or other place, in the autumn or spring seasons, covering them to the depth of nearly half an inch, when they readily grow and produce plants for setting out in other parts.

In the latter mode, the roots should be taken up in the autumn season, when the leaves decay and fall off, or very early in the spring months, and be divided into several parts, but not by any means into too small slips, and then be planted out either where they are to remain, or in nurseries, where they are to continue for twelve months, when they will be ready to set out finally.

The seedlings should be set out in summer, or towards the autumn season, in rows about five inches asunder, where they are to continue about six or eight weeks, to become perfectly strong, and be finally planted out in the places where they are to remain.

And the root-plants, which are set out in rows, may be removed in the autumn or spring seasons to the spots where they are finally to grow and continue.

As these plants are natives of moist and shady situations, they are generally the most successfully planted in places where the circumstances are the same in this climate, though they will commonly grow very well in any border or compartment of the garden which is not over dry, or without moisture.

These plants multiply extremely fast by the roots, and are of a great many years duration.

They are highly deserving of a situation in all curious collections in the flower-gardens and pleasure-grounds, where they have a fine effect in the clumps, borders, and other compartments.

TROMBA, in Geography, a small island near the coast of Iltia. N. lat. 45° 3'. E. long. 13° 52'.

TROMBA, in the Italian Music, either denotes the common trumpet, the buccina of the ancients, or the modern facbat, but more properly our trumpet.

TROMBETAS, in Geography, a river of Brazil, which runs into the river of the Amazons at Pauxis.

TROMBETTA, in Ichthyology, a name given by the Italians to the fish commonly called foispolax by authors. See Trumpet-Fish.

TROMBETTA, in the Italian Music, a small trumpet, being the diminutive of tromba.

TROMBONE, a wind-instrument blown by the mouth, and resembling in form the military trumpet, of which it is the bafe, the name implying the great trumpet. It differs, however, from the trumpet in being divided into two branches or parts fitted to sockets, giving the performer power to lengthen and shorten the general tube at his pleasure, according to the different tones which he wishes to produce. On which account it is called in Latin, tuba ductilis. The Germans call it paufaune, and the French faquebute.

Zarlini has described this instrument under the title of trombone movibile, and the quantity and quality of the sounds is capable of producing, very exactly.

"The trombone," says he, Supplimenti Musicales, lib. iii. cap. 5. "is an instrument truly worthy of consideration, which I have seen and often heard by good performers, beginning at the lowest sound which it is capable of producing; when, being closed in all the joints, it can produce no sound less than the octave; then from the octave to the fifth; and from that can it produce a less interval than the fourth; and from the fourth to the third major, then the third minor, after which another fourth, the key-note, from which it can form a complete series of eight notes. No other sounds than these can be produced without altering, moving, and lengthening the instrument."

Pere Merfenee, in his experiments on this instrument, (Harmon. Instrum. lib. ii.) found it capable, by lengthening or shortening the lower part of the instrument, of forming a regular series of fifteen sounds, from double C in the bafe, to C on the fifth line.

The instrument is made of brans, of which there are five forts: canto, alto, tenor, bafe, and doubl-bafe. It is much used in the large churches of Germany. They can produce all the tones and semitones in gradation. The manner of writing for them is the fame as for different voices, and on the same staff of five lines.

Canto.
The double-bafe of this instrument goes a 5th lower than any other bafe. It has the finest effect in funeral proce-
sions, and in general in melancholy strains. We never hear
it with more pleasure in England than in Handel's dead
march in Saul. Its use should be rare, and its effects would
be more striking. But tromboni and double-drums are now
so frequently used at the opera, oratories, and in symphonies,
that they are become a nuisance to lovers of pure harmony
and refined tones: for, in fact, the vibrations of these in-
struments produce noise, not musical sounds.

TROMELIA, in Ancient Geography, a town of the
Peloponnesus, in Achaia Propria.

TROMNES, in Geography, a small island in the North
sea, near the coast of Lapland. N. lat. 68° 5'. E. long.
15° 26'.

TROMP, MARTIN HARBERTZON, in Biography, a
famous Dutch admiral, was born at the Brill in 1597. At
the age of eight years he was defined for the sea-service,
and was sent on board a ship bound for the East Indies.
Whilft he was very young he was taken prisoner by an
English pirate, with which he continued for two years, ac-
quainting himself with the slrattages and manevures prac-
ticed in that kind of service: and being afterwards employed
in the service of the States, he accompanied the famous
Peter Hein in his various expeditons, and being his favourite,
fought by his side when he was killed. By various gra-
dations he was advanced to the rank of admiral, and in
February 1639, he pursued a Spanish squadron, and in
an engagement off Graveline, captured and destroyed five men
of war and four frigates. In October of the same year he
engaged another Spanish fleet in the Downs, and obtained
a glorious victory, taking or destroying the greater part of
the fleet, though effected by the English. On this occa-
sion he saved the life of Oquendo, the Spanish commander,
by sending a frigate to his relief, when his own ship was
finking. His name now became famous through Europe,
and the king of France enrolled him by patent among the
French nobility. In 1652, Tromp and Blake, the English
admiral, had a rencontre in the Downs, in consequence of
which the Dutch fleet, after having sustained some los,
was obliged to retire. Having on another occasion met
with a disappointment in fulfilling his orders for attacking
Blake by reason of a storm, he was disgraced and recalled,
and De Ruyter was appointed to supercede him; but his
command was restored to him in the same year. In No-

deember he attacked Blake, commanding an inferior force, in
the Downs, and after a severe engagement, obliged him to
retire into the Thames, with the los of five ships. Tromp
with some degree of arrogance triumphed, and fixed a
broom on his top-mast, intimating vain-gloriously that he
would sweep away the English from the Channel. This
triumph, however, was of no long duration. In Febru-
ary 1653, the two powerful fleets of Holland and
England had an engagement which lasted three days; one
of which terminated in the los of eleven men of war to the
Dutch, but it is said that Tromp lost no reputation in this
action. This engagement was succeeded by another off
Nieuport, in which Tromp and De Ruyter mutually re-

cued each other from imminent peril; but the termination
of the contest was unfavourable to the Dutch, who suffered
considerable los. These two Dutch commanders made
complaints to the States of the insufficiency of their equip-
ment, and great exertions were made to supply them with
both ships and men. In July, Tromp with eighty-five ships
decreed the English fleet with ninety-four; but before they
could come to an engagement, which was prevented by a
storm, the Dutch fleet was augmented to 120 sail. On the
6th of August the containing fleets rushed to action.
The first day was indecisive: the second was unfavourable to
Tromp, who, according to his usual practice, pierced the
enemy's line, and was surrounded, being defeated by his
own squadron. Whilft he was fighting with desperate
valour, he fell by a musket-shot, as he was giving orders
on the deck; exclaiming, before he expired, "Take
courage, my lads, I have run my course with glory!"
The Dutch seamen, having lost their commander, could not
be re-animated, and a disfavour, though dearly bought,
defeat closed the day, and also the war. The remains of
Tromp were interred with funeral honours in the church at
Delft, and a magnificent mausoleum was erected to his

TROMP, CORNELIUS, the second son of the preceding,
was born at Rotterdam in 1629, and having been educated
with a view to the navy, he was appointed, at the age of
19, to the command of a ship of war against the Corsairs
on the Barbary coast. When the war broke out between
England and the United Provinces in 1665, he was one of
the admirals in the sea-fight off Solbay, when the
Dutch fleet was defeated, though by his masterly retreat
the victors were prevented from making the most of their
successes. In some subsequent engagements Tromp distin-
guished himself by his valour, though not always unblended
with temerity, and seldom with any great successes.
Complained of by De Ruyter, who was superior in command,
he was superceded; nor was he again employed till the year
1673, when the two rival admirals, being reconciled, fought
in concert and mutual assistance in the engagements with the French and English, off the Dutch coast, in June and August. After peace with England had taken place, Tromp, in 1675, visited London, and being honourably received, was made a baronet by Charles II. Having this year conducted a fleet to succour Denmark in its war with Sweden, he was invested by the king with the order of the Elephant. Upon the death of De Ruyter, in 1677, he was appointed his successor as lieutenant-admiral-general of the United Provinces. He continued, however, in the service of Denmark, and at the peace withdrew from the navy; but in 1691, when the war with France was renewed, he resumed his command. Whilst a fleet was fitting out, he was seized by a disease which terminated his life at Amsterdam, on the 29th of May, in his 62d year. His remains were deposited in the magnificent tomb of his father at Delft. Un. Hist. Moreni.

TROMPE, in the Range. See Received.

TROMPERWICK, Gulf of, in Geography, a bay of the Baltic, on the north-east coast of the island of Usedom; a dangerous road for vessels which are driven thither by the wind, or misguided by darkness. N. lat. 54° 40'. E. long. 13° 40'.

TROMSOE, an islet on the coast of Lapland, near the Storfennifs, or Great Rocky Cape; flor, in the Scandinavian dialect, signifying great, and hence probably are derived our words flor and flor-house. Here, in the latitude of 69° 38', a village has been lately founded under the protection of the Danish government, and endowed with peculiar privileges and immunities; being intended to facilitate the exchange of commodities, and to diffuse the benefits of civilization over these fequestered regions. For two whole months at Tromsø the sun never sets; and as he wheels his oblique apparent course, he skirts the northern horizon at midnight, and again attends with fiercer beams in progress of the day, the sky being, with little variation, bright and cloudless. The change of temperature is confined to a very narrow range. The great heat, on the 15th of July, was observed at 2 o'clock in the afternoon, when the thermometer rose to 61° or 62° of Fahrenheit, and the greatest cold at 1 o'clock in the morning, when the thermometer stood at 50° or 52°. This low islet is covered with birches, though the prospect is saddened by patches of snow lying still unmelting in the streets, the gardens, and the fields. Von Buch's Travels in Norway and Lapland.

TRONAGE, TRONIUM, an ancient cemetry, or toll, paid for the weighing of wool.

The word comes from trona, an old name for a beam used in weighing.

TRONATOR, an officer of the city of London, whose business it was to weigh the wool brought into that city.

TRONCHIN, THEODORE, in Biography, a celebrated physician, was born at Geneva in 1750, and being disappointed in his expectations from Lord Bolingbroke when he visited in England, he repaired to Leyden in order to study under Boerhaave, whose Elements of Chemistry he had perused; and after passing through a course of medical instruction, he graduated M. D. in 1750, publishing on the occasion a dissertation "De Nymphae," patronized by Boerhaave. He settled at Amsterdam, and became a member of the college of physicians and an inspector of hospitals. Here he distinguished himself as a zealous promoter of inoculation. In 1754 he returned to Geneva, and ranked among the most distinguished practitioners in Europe, not only on account of his established reputation, but from the number and quality of his patients. His native city erected in his favour a chair of medicine, and the Society of Physicians admitted him into their body. He was employed by the duke of Orleans in the inoculation of his children, and by other personages of rank at Paris; and in 1763 he went to Parma, for the purpose of inoculating the family of the duke. Although he declined to comply with the invitation of the empress of Russia to spend two years at Petersburg, he accepted, in 1766, the offer of being principal physician to the duke of Orleans. His practice was simple, administering few medicines, and relying chiefly on diet and regimen, with the regulation of the passions and affections. In nervous complaints abounding in a luxurious capital, he recommended temperance and exercise. With the practice of inoculation, he patronized the cool treatment in the natural small-pox, and also the free admission of air in other diseases. On mothers he urged the stringency of their children. In the exercise of his profession he was exemplary for his humanity and charity. In conversation he was mild and modest, and in his manners agreeable and polite. He had little time for writing; but besides his inaugural dissertation already mentioned, he published a treatise "De Colica Pictonum," in 1757, and he contributed several articles to the "Encyclopædia," and to the "Memoirs of the Academy of Surgery." Of the works of Bailly, he gave an edition in 1762, with a preface on the state of medicine. He had the honour of being enrolled as a member of the chief medical and scientific societies in Europe. He died in Paris in 1781, in the 73d year of his age. Nouv. Dict. Hist. Gen. Biog.

TRONCO, in the Italian Music, the French called coup de grace, is used to intimate to the voices as well as instruments, that they are not to draw out the found to its natural length, but cut it short; that is, only continue it long enough to be heard, by which means there is a small silence between each sound; which has a very good effect in expressions of grief, to make signs; and also in expressions of wonder and surprize, &c.

TRONCONNE, or TRONCONN, in Heraldy, denotes a croissant or other thing, cut in pieces, and dismembered; yet so as that all the pieces keep up the form of a croissant, though cut at a small distance from one another.

TRONE, in Agriculture, a term applied provincially to a drain or small trench of that kind, in some places.

TRONE, in Geography, a town of Sweden, in Helsingland; 7 miles N.W. of Soderhamn.

TRONE Pound, in Scotland, contains twenty Scotch ounces. But because it is usual to allow one to the score, the trone pound is commonly twenty-one ounces.

TRONE Stone, in Scotland, according to Sir John Skene, contains nineteen pounds and a half.

TRONE Weight was the same with what we now call troy weight.

TRONECKEN, in Geography, a town of France, in the department of the Serre; 12 miles S.S.E. of Traarbach.

TRONINGE, a town of Sweden, in the province of Halland; 8 miles E. of Halmstad.

TRONIS, in Ancient Geography, a country of Greece, in the Phocis, which contained many ancient monuments.

TRONQUIERE, LA, in Geography, a town of France, in the department of the Lot; 12 miles N. of Figeac.

TRONTO, a river which forms a boundary between the marquisate of Ancona and the province of Abruzzo Ultra, and runs into the Adriatic, N. lat. 43° 52'. E. long. 13° 59'.

TRONUM, in Ancient Geography, a place on the route from Dyrrachium to Salone, between Pons Piliris and Bludium. Antonini.

TRONZAN,
or παραθανώ, a warlike trophy. This fanciful but elegant name was chosen by Linnæus, in Hort. Clifl. 143; for the
present singular and striking genus, because he conceived the
shiel-like leaves, and the brilliant flowers, shaped like
golden helmets, pierced through and through, and dined with
blood, might very well justify such an allusion. Particularly
when the plants are oftentatively trained over the trellis or
aloeve of a garden, as is commonly the case. The names of
Naffiurtium indicum, Cardamium, and Acrióvla, given by
preceding botanists, in reference to the cleft-like flavour
of the herbage, are all liable to exception, for various rea-
sons, explained in the Philosphia Botanica. It is remark-
able that the first of these has remained, as the popular
appellation of this genus; though Indian Cref, conveying
the same idea in English, with more precision, is preferrable.
Juf. 250. Lamark Illurj. t. 277. Gert. t. 79. (Car-
damidum ; Tourn. t. 244. Acrivola; Boer. Lugd-
Bat. ed. 2. v. i. 244.)—Chaf and order, Otandria Mo-
Rather, in our opinion, totally undetermined.

Gen. Ch. Cal. Perianth inferior, of one leaf, five-
cleft, slightly spreading, acute, coloured, deciduous; two
inferior segments narrowest; bafe elongated behind into a
straight, tubular, awl-shaped, closed, &c.; the longer than the
segments. Cor. Petals five, roundish, inserted between
the segments of the calyx; the two uppermost stellig; 
three lower with oblong fringed claws. Stam. Filaments
five, awl-shaped, short, unequal, declining; anthers ob-
long, straight, ascending. Pfl. German inferior, roundish,
three-lobed, fracted; style simple, erect, the length of
the flaments; stigma in three acute segments. Peric. Berries
three, combined, dry and leathery; externally convex,
depthfully furrowed and wrinkled; internally angular. Seeds
solitary, roundish, agreeing nearly with the shape of the
berries; their coat simple, very thin.

Eff. Ch. Calyx of one leaf, with a nectariferous lip
behind. Petals five, unequal. Berries three, dry, coria-
ceous.

Obf. Willdenow and Hort. Kew. have, by miiftake,
“petals four.”

1. T. minus. Small Indian-crefs or Naffurtium. Linn.
(Carodium minus et vulgare; Peiull. Peru. v. 3. 14.
Em. 252.)—Leaves petalate, slightly wavy; their angles
bristle-pointed. Petals acute.—Native of Peru, from
whence its seeds were brought very early to Europe.
Gerarde cultivated this fpecies, but it has been fupplicant
the following in our gardens. The writer of this found
it in general cultivation about Geneva, in 1787, and
restored it to the English collections. Like the reft of the
premif genus, this plant is a hardy annual in the natural
climate of Europe, though perennial, if sheltered from
frost. The flers are branched, lax and twining, many
feet in length, round, smooth, leafy. Leaves scattered,
roundish, somewhat laterally peltate, wavy, angular, entire,
smooth; their ribs radiant from the fpot where the long
wavy footstalk is inserted. Flowers axillary, foltary, on
long fimple flalks resembing the footstalks; their colour a
deeep yellow, variegated and fleared with orange and red.
The calyx is coloured like the petals; its fpur near an inch
and half long. Petals about an inch. Fruit greenish.
The whole plant has a hoit pungent taffe, resembing crefles
of various kinds. The flowers are flightly fragrant.

2. T. major. Great Indian-crefs or Naffurtium. Linn.
Sp.
(Cardamundum amphiior, folio, et majori flore; Feuill. 
Peruv. v. 3. t. 14. f. 8. f. 1. Viola indica scandens, nauturri 
sapore, maxima odorata; Herm. Lugd.-Bat. 628. t. 629.) 
—Leaves peltate, wavy, with blunt naked angles. Petals 
obtuse.—From the same country. Introduce into England 
in 1686, as appears by the manuscripts of Peter Collinson. 
This is now the most commonly cultivated species, seen in 
every cottage garden; as it rises, without any care, from 
self-sown seeds. The flowers are abundant from June till 
the whole plant perishes by the autumnal frosts. This 
species is larger than the foregoing, especially its petals, 
which are also much more rounded and obtuse. A daughter 
of Linneus is recorded as having observed a kind of flaming 
light from these flowers in an evening. We have watched 
for this phenomenon, but know not whether we ever 
perceived it, or whether our eyes were merely dazzled by 
the brilliancy of the colours. The seeds are hot and 
pungent, much used for pickles; and the flowers are often 
temixed with fallad herbs, both for ornament and flavour.

There is a double-flowered perennial variety of this 
species, common in greenhouses, and readily increased by 
cuttings.

Another variety, with small jagged petals, called T. 
pinnatum in Andr. Repof. t. 535, and Ait. Epit. 375, 
came up under our inspection in a bed of the common T. majus, 
and having been immediately sent to Meffrs. Lee and Kennedy 
at Hammersmith, in 1800, was preferred, and dispersed by 
cuttings all over the kingdom. It fearlessly ever attempts 
to form any seed, and is cultivated just like the double kind, 
whose botanical history, and origin, it appears to throw 
considerable light.

3. T. hybridum. Mule Indian-cres or Nauturrtum. 
1765. 32. t. 1."—Leaves wedge-shaped, five-lobed, entire, 
scarcey peltate.—A variety of the past, which, according to 
Linneus, sprung up accidentally in a garden at Stockholm. 
It rarely produced seed in the Upfal garden, but 
was propagated by cuttings. A seedling plant however is 
preferrved in the Linnean herbarium. The leaves are 
palmate, but wedge-shaped at the bafe, deflexed, on very 
long slender footstalks, which infection is quite at the bottom, 
and, nor do we find a single leaf in any degree peltate. The 
nectary is said to be obtuse; the corolla scarcely ever of 
any determinate form. We retain this as a species, merely in 
conformity to our predecessors. Its history is presumed to 
be authentic; but a few varieties are more extraordinary.

4. T. peregrinum. Fringed Indian-cres or Nauturrtum. 
Diff. 12. Willd. n. 4, excluding the synonym of Jacquin, 
and perhaps of Feuillée.—Leaves peltate, palmate, deeply 
five-lobed. Petals all jagged and fringed. Nectary straight, 
about twice the length of the corolla.—Native of New 
Granada, from whence it was sent by Mutis and his pupils 
to Linneus, who also received a garden specimen from his 
friend Duchefne. This species is not known in England. 
The leaves are all slightly, but uniformly, peltate, with five, 
rarely seven, deep lobes, various in breadth and acuteness, 
the middle one sometimes three-clft, the two next occasion-
ally having a lateral external lobe. Flowers rather smaller 
than in T. minus, though the nectary is as long, and of the 
fame taper form, scarcely curved, and by no means hooked. 
Petals unequal in size, all deeply and irregularly laciniate, 
with five capillary segments. We find these segments 
variable in breadth, like the foliage, in our numerous native 
specimens, but their general aspect is the same. Lamarck's 
t. 277. f. 3, represents this plant. Feuillée's plate and de-
scription, if good for any thing, must belong to a different 
species, or variety, three of whose petals are very small, 
and quite entire. His nectary is too imperfectly drawn for us 
to determine any character from thence. We have seen in the 
foregoing species how liable the petals are to the most extra-
ordinary variation, so that we dare not, from Feuillée's figure 
alone, attempt to define his as a distinct species.

5. T. adunca. Hooked Indian-cres or Nauturrtum. 
Sm. Tour on the Continent, ed. v. 1. 158. ed. 2. v. 1. 
165. (T. peregrinum; Willd. n. 4. Ait. n. 3. Jacq. 
Curt. Mag. t. 1351.)—Leaves peltate, palmate, deeply 
five-lobed. Two petals jagged; three smaller fringed. 
Nectary hooked, the length of the larger petals.—Native of 
Peru. Cultivated in the open air at Gibraltar, where it is 
called the Canary-bird flower, and perhaps in other parts 
of Spain. In Germany, England, and even the south of 
France, this is a greenhouse plant, very tender with us, 
and seldom ripening seed. The leaves do not much differ 
from the real T. peregrinum, but the flowers are constantly 
very distinct, nor do any specimens or figures, that we have 
seen, shew them to be variable in any degree worthy of 
notice. Their calyx is pale green, with a remarkably 
hooked spur, hardly an inch long if it could be straightened. 
Petals lemon-coloured; the two uppermost deeply jagged, 
rarely hair-pointed; three lower much smaller, oblong, un-
divided, copiously fringed. Jacquin's figure displays a 
luxuriance of foliage greater than we have met with, some 
leaves having seven, more or less pinnatid, lobes. There 
can be no doubt of this being a very distinct species. 
A figure of it was drawn for the 30th plate of our Species 
Botanica, but that work never proceeded to a third 
saceiculus, and the figure would now be superfluous.

6. T. pentaphyllum. Five-leaved Indian-cres or Nauturrtum. 
Lamarck Dict. v. 1. 612. Illustr. t. 277. f. 2. 
Wildd. n. 5. (T. quinatum; Hellen. Diff. 20. t. 1.)— 
Leaves quinate; leaflets ovate, entire, stalked. Petals un-
divided, shorter than the segments of the calyx.—Gathered 
by Commeron at Buenos Ayres, where this elegant and 
singular species climbs amongst Indian figs, and other 
shrubs, according to a manuscript note before us. The 
flora is slender, cloathed with numerous, irregularly scattered, 
leaflets, on footstalks an inch or an inch and a half long; 
leaflets on short partial stalks, acut, all undivided; the 
central one an inch in length; the two nearest the stalk not 
half so large. Flowers numerous, solitary, on axillary 
stalks extending rather beyond the leaves. Tube of the 
calyx above an inch long, conical, deep orange-coloured, 
contracted towards the end, which is oval; segments about 
the quarter as long, ovate, acute, green towards the point, 
two of them prominent, and rather larger than the rest. 
Petals not discernible in the flowers we have examined. 
Professor Hellenius describes them, "ovate, entire, nearly 
serate, a quarter the length of the segments of the calyx;", 
which answers to Lamarck's definition.

Three more species of this genus are described in the 
Flora Peruviana, one of them having only two petals; but 
of these no specimens have fallen under our inspection.

Tropæolum, in Gardening, furnishes plants of the 
herbaceous, annual, and perennial, trailing and climbing 
kinds, among which the species cultivated are the small In-
dian cres or nauturrtum (T. minus); and the great Indian 
cres or nauturrtum (T. majus).

In the first sort, there are varieties with deep orange-
coloured flowers inclined to red, with pale yellow flowers, 
and with double flowers.

And in the second kind, there are varieties with pale 
yellow
yellow flowers, orange-coloured flowers, and the doubleflowered.

It may be noticed that they are both natives of Peru, and commonly esteemed to be annual plants, though they may be continued through the winter, if they are kept in pots, and sheltered in a greenhouse or glass-cave, in the same manner as the variety with double flowers.

The stalks will climb fix or eight feet high, when they are trained up, and thus the flowers make a good appearance; but when they trail upon the ground, they will spread over the neighbouring plants and become unprofitable: the flowers are frequently eaten in fallads; they have a warm taste, like the garden cress, and hence the plant has its common name natterrium; they are likewise used for garnishing dishes: the seeds are pickled, and by some are preferred to moist pickles for sauce, under the false name of capers.

Method of Culture.—These plants, in all the single varieties, may be increased by seeds, which should be sown in the spring in patches where they are to grow in the borders, or in drills in the garden.

They afterwards only require to be kept free from weeds, and to be well supported by sticks.

The double variety may be increased by planting cuttings of the branches in pots of light mould in the early part of the summer, placing them in the shade, and giving frequent light waterings, but not too freely in the winter months; those planted early may be rendered more forward by being plunged in a moderate hot-bath.

It requires to be protected in the greenhouse in the winter, being well supported with sticks.

Both the forks are cultivated in the garden as flowering plants, and for culinary uses in fallads and pickles, being often in the former year trained against fences and walls, or to run on trellisses, rafterings, palings, hedges, the sides of arbours, and some other kinds of supports. Allo to run on branchy sticks set in the borders and other parts.

In the latter intention, the common single forks and varieties are often grown, which supply young tender leaves and berries that are much esteemed for some of the purport of eating, the former as a warm relishing agreeable fallad article, and the latter as a very pleasant fork of pickle while young and fresh. The flowers are also warm in their taste, and afford a very ornamental garnish, in many cases, both for fallad dishes and those of the next kind. When the plants are raised in these ways, the seeds should be sown in the small compartments of the kitchen garden in the later spring months, in small patches or shallow drills to the depth of an inch, and the plants when up have the support of a few branchy sticks, by which means they afford supplies in each of these ways for two or three months.

They all afford variety in the borders, clumps, &c. in the summer, and the double forks among potted plants.

TROPEUM Q. Fabii Maximi Emilianii, the trophies of Fabius, &c. in Ancient Geography, were situated, according to Strabo, near the place where the Ifere discharged itself into the Rhone, and on this spot 35,000 Romans, commanded by Fabius, defeated 200,000 Gauls, in commemoration of which, the general caused to be erected on the field of battle a trophy of white stone.

TROPEUS, in Mythology, a name given to Jupiter, for the same reason that Tropea was given to Juno.

TROPATENA, in Ancient Geography, a country of Asia, extending according to Ptolemy, from the territory of the Gelli-Margare to that of the Amaraici.

TROPE, a word or expression used in a different sense from what it properly signifies.

Or, a word changed from its proper and natural significance to another, with some advantage.

As when we say an affinity, for a flupid person; thunder-bolt of war, for a great captain; to wash the blackamoor white, for a fruitful undertaking.

This change of sense is never to be used, but where it gives a force and dignity, or renders the discourse more significant, weighty, and graceful.

It is called tropes, τροποι, from the Greek, τρόπος, a change; because the words are here transferred from the things they properly import, to others which they only import indirectly: and that tropes only signify the things they are applied to, by reason of the connection and relation those things have with those others, whose proper names they are.

This change, or inversion, is performed various ways; but chiefly four: whence arise four principal tropes; viz. the Metaphor, Metonymy, Synecdoche, and Irony; which see respectively.

Some authors confound trope with figure; but they are very different things. Most authors, as F. de Colonius, &c. make figure the genus, and trope a species; defining figure to be, an ornament in discourse, by which it is raised above the common language; and trope to be that peculiar kind of ornament which consists in the change of the sense, &c.

But Voluins makes trope and figure to be two collateral and independent things; defining trope to be the change of the sense, &c. and figure to be any ornament, except what becomes so by such change, &c. See Figures.

With regard to the difference between tropes and figures we may observe, that tropes mostly affect single words, but figures whole sentences: a trope conveys two ideas to the mind by means of one word; but a figure throws the sentence into a different form from the common and usual manner of expression; and besides, tropes are chiefly designed to represent our thoughts, but figures our passions. The reasons which have occasioned the introduction of tropes are, according to Quintilian, three: viz. necessity, emphasis, and beauty. Tropes were first introduced from necessity, because no language contains a sufficient number of proper words to express all the different conceptions of our minds. Tropes do also on many occasions express things with greater force and evidence than can be done by proper words; thus when Virgil (Efin. lib. vi. v. 842.) calls the Scipios two thunderbolts of war, he gives us a more lively image of the rapid force and speedy successe of their arms, than could have been conveyed by a long description in plain words. And moreover, beauty and ornament have been another cause of the use of tropes: and it is the business of an orator to entertain his hearers, at the same time that he instructs them. Accordingly some subjects require a more florid and elegant address than others, and variety of expression is also pleasing in a discourse.

The following directions, however, are proper to be observed in the choice of tropes. As every trope gives us two ideas, one of the word expressed, and another which by means of that the mind connects with it; it is necessary that the relation between these two should appear very plain and evident; for an obscure trope is always faulty, unless where some particular reason makes it necessary; and therefore tropes ought not to be too far-fetched, left they should thus be rendered obscure.—Again, as a trope ought to be very plain and evident, so likewise should it bear a due proportion to the thing it is designed to represent, to as much as its natural idea of it. Poets, however, are allowed a greater liberty in this respect than orators. Further, as a moderate use of tropes, judiciously applied, beautifies
beautifies and enlivens a discourse, so an excess of them causes obscurity, by running it into abstruse allegories and riddles. Moreover, as one use of tropes is plesurability and entertainment, we should endeavor to make use of such as are smooth and easy; and if it should be necessary to use a harsh trope, it is proper to soften it by some preface. Finally, care should be taken how we transfer tropes from one language into another. It was customary for the Roman soldiers to carry their money in their girdles; hence it was the same thing with them to say, *a person had lost his girdle* (Hor. Ep. lib. ii. ep. 2.), as that he *had lost his money.* And because the Romans wore the toga in time of peace, and a different garb when engaged in war, their writers sometimes use the word toga to signify peace. But as neither of these customs is in use among us, so neither would the tropes suit our language, or be generally understood by us. There is also a beautiful trope in the account of St. Paul's shipwreck, in the use of the word *αντωναλμαι* (Acts, ch. xxvii. v. 15.) which we translate to bear up into the wind, but which properly signifies to look or keep its eyes against it: to this purpose Plutarch says of Demosthenes, that he could not *αντωναλμαι των εργων, look against or resist the power of money.* Ward's Orat. vol. i. lect. 25. See also on this subject, Blair's Lect. vol. i. lect. 14.

Besides the four capital tropes above-mentioned, there are several inferior ones. When the trope is too bold, it is called an *hyperbole,* when continued, it is an *allegory,* when too obscure, an *enigma,* when it shocks us, or is too remote, a *catachresis.*

Add to these, other tropes: as the *metalepsis,* *anomalous,* and *litotes,* or *exaptnation.* See *Metaphor,* &c.

Some also refer the six kinds of scoffing, or derision, to the tropes: *wit,* the farcasm, *dialyse,* *charieintum,* *aleism,* *myterium,* and *mimesis,* but this without sufficient reason. See *Sarcasm,* *Irony,* &c.

**TROPEA,** in *Geography,* a town of Naples, in Calabria Ultra, built on a rock near the sea-coast, the see of a bishop, suffragan of Reggio. It contains five parish-churches, eleven convents, and about 4000 inhabitants, of whom the most wealthy and the handcraftsmen reside within the walls, whilst the husbandmen and labourers dwell in the outkirts, on the lands which they cultivate. Its situation is admirable, on the point of a lofty rock impending over the sea, and joined to the main land by an isthmus that is almost cut through at the gates, and thus leaves only a small passage to the town. A little to the N. lies a large island, on which some sheep are turned to graze, and a small one, with a hermitage placed on its summit, in a most romantic position. The streets of Tropea are narrow, the houses high, and built of stone, with great solidity. Two gates give admittance, one to those who come up the hill from the bay, and the other to such as approach along the high plain, on which is a pleasant walk near two miles long. This level is half a mile broad between the sea and a chain of mountains so steep and rugged, that they apparently cut off all communication by land with the rest of Calabria. The whole flat, and sides of the hills, yield abundance of grapes, mulberries, olives, pule, vegetables, and garden-fruit. Cobious streams run from the mountains, and after watering the orchards, are collected into one body, and turn a great number of mills. In 1783, it suffered greatly from an earthquake; 37 miles N.N.E. of Reggio. N. lat. 38° 40'. E. long. 16° 13'.

**TROPER,** in our *Old Writers,* is used for a book of alternate turns and responses in singing mas. Linndewode calls it *liber sequentiarum.*

Female on a separate tree, Cal. inferior, of one leaf, undivided or two-lobed. Cor. either wanting, or of four corona, roundish petals, closely embracing the germen. *Petals* seven, of four cells; style short, thread-shaped; stigmas two, oval-shaped, spreading. *Pericarp* nearly globular, corrugated, of one cell. *Seeds* from one to four, roundish, with a brittle skin.

Female, Calyx of one leaf. Petals four, or none. Stigmas two, oval-shaped. Berry superior. Seeds one to four.

Ob. Nothing can be more obscure or uncertain than the history of this genus, nor do we feel, by any means, confident that the plants assembled under it agree in natural, or essential, characters. We must content ourselves with giving the best account of them in our power, after having so far new-modelled the generic character as to avoid palpable contradictions.

1. *T. americana.* Ramoon Tree of Jamaica, or West Indian Trophis. Linn. Sp. Pl. 1451. Am. Acad. v. 5. 416. Willd. n. 1. Ait. n. 1. Swartz Obs. 372. (T. foliis oblongo-ovatis glabris alternis, floribus malacinsis spiratis ad alas; Browne Jam. 357. t. 37. f. 1. Bucephalon racemosum; Linn. Sp. Pl. 1661. B. frut. racemoso rubro; Plum. Lc. 55. t. 67. f. 1.)—Thorns none. Leaves ovate, pointed, entire, smooth. Berry oval, furrowed, with a simple point, and solitary feed. Native of dry exposed situations in the West Indies, flowering in spring. *Swartz.* A tree, about twenty feet high. *Leaves* alternate, on shortish furrowed stalks; rounded at the base; about four inches long, with one rib and several transverse interbranching reticulated veins. *Spikes* axillary, falcit, solitary, many-flowered, much shorter than the leaves, something downy, pale; the female ones shorter. *Berries* spiky, sessile, the size of large grapes, oval, with four furrows, and of a pleasant flavor. *Swartz* says, the trunk and branches, when wounded, discharge a very white, viscid, milky juice. He, as well as Browne, affe the foliage and young shoots to afford an agreeable wholesome fodder for all sorts of cattle.

2. *T. laurefolia.* Laurel-leaved Trophis. Willd. n. 2. —Thorns none. Leaves elliptic-oblong, acute at each end, smooth, entire. Berry with two horns, and two or four seeds.—Native of Quito and New Granada. A tree, with thick, nearly round, *branches.* Leaves alternate, falcit, three inches or more in length, tapering at each end, coriaceous, smooth on both sides; shining above; pale beneath. *Cliffers* axillary, the length of the fruit. *Fruit* globose, crowned with two dintant, oval-shaped, infixed horns, rather longer than the fruit itself. *Seeds* obvate; two only, according to Willdenow; four in a drawing sent by Mutis to Linneus, which the latter has marked Bucephalon, and which answers to exactly to Willdenow's description of the plant gathered in Quito by Humboldt and Bonpland, that we can have no doubt of its being done from the same species. In contemplating Willdenow's specific characters
of this and the foregoing, we cannot help thinking that he
took for the fruit of *Trapa americana*, the nut of *Trapa bicornis*,
(see *Trapa*), which Burmann has subjoined to Pluver’s

Native of Java. *Branches* round, greyish-brown, armed with
glabrous axillary thorns, which are incurved when young,
but become subeurrently frawned. *Leaves* frawned, larger
than the leaf, and very frawned on both sides; paler beneath.
*Female* flowers two or three together, frawned, concave.
*Male* not observed. The wood is used to dye yellow,
and, with the addition of indigo, green. The berries are
described by Rumphius about the fize of a strawberry, with
several seeds, and of a yellowish yellow. By his account
also, it should seem that this fruit is involved with a permanent
hardened *corolla*, evincing the generic affinity of the present
species to the last; though their belonging to *Trophis* must,
for the present, remain very doubtful.

TROPHONIUS, Oracle of, in Ancient Mythology, a
famous oracle in Boeotia, which was consulted with greater
ceremony than those of any deity, and subfitted long after
all those of Greece ceased. Trophonius, from whom the
oracle took its name, was the son of Erginus, king of the
Orchomenians, who, as well as his brother, were famous ar-
chitects, and built the temple of Apollo at Delphi. The
tomb of Trophonius had been altogether disregarded and
forgotten, when the Boeotians, on occasion of a great
drought, consulting the oracle of Apollo, were directed to
have recourse to Trophonius at Lebadea. They purified the
direction of the oracle, and obtained an answer, that
suggested the means of removing their calamity. In con-
sequence of this event, they confebrated to Trophonius the
wood in which he was interred, and in this wood erected a
temple to him, with his statue executed by Praxiteles.
The oracle of Trophonius was upon a mountain, within an
enclosure of white stones, upon which are elevated obelisks
of bronzes. In this enclosure there was a cavern, in the form
of an oven, cut out of the mountain by human art and
labour. Within this was another small cavern, with a very
straight entrance, into which those who consulted the oracle
were to pass, with a variety of ceremonies.

TROPHY, TROPESM, along the Ancients, a pile or
heap of arms of a vanquished enemy, raised by the con-
queror in the most eminent part of the field of battle.
The word is formed from the Latin *tropeca*, or *tropism*,
which Vellius deduces from the Greek *tropos*, the flight
of an enemy.

The word is also used for an artificial representation of
such a pile in marble, stone, or other matter. Such were
the trophies of Marius and Sylla, in the Capitol, &c.
The ancient trophies consis of Greek and Roman arms;
and the modern ones of arms of the various nations now in
use: as in those inscribed ones near Blenheim, in the Faus-
burg S. Antoine, and in the castle of Verailles. Some are
done in baso-relievo; as those of the Trojan column,
and the Attic of the court of the Louvre. The form of
these trophies cannot be better described than in Virgil’s
second Aeneid. Of those which Marius raised after the
Cimbrian war, still remaining at Rome, Fabricius has given
the following account. They are two trunks of marble
hung round with spoils; one of them is covered with a feally
corset, with shields and other military ornaments. Just be-
fore it is set a young man in the posture of a captive, with
his hands tied behind him; and all round were winged
images of victory. The other is set out with the common
military garb; having a shield of an unequal round, and
two helmets, one open and adorned with crests, the other
closed, without crests. On the fame trophy is the shape of
a soldier’s coat, with several other designs, which, by reason
of the decay of the marble, are no discovered without
great difficulty. These two trophies now adorn the front
of the Capitol.

Trophies are likewise frequently exhibited on medals of
the emperors, struck on occasion of victories; wherein, be-
sides arms and spoils, are frequently seen one or two captive
by the fides of the trophy.

Trophies, M. Vaillant observes, were, originally, nothing
but trunks of trees, which the victor planted on the mos
t eminent part of the conquered province, and hung them
with the spoils of the enemy, to perpetuate the memory of
the defeat.

Trophy, in Architecture, an ornament which represents
the trunk of a tree, charged or encompassed all round
about with arms or military weapons, both offensive and
defensive.

TROPHY-Money, a duty paid annually by the hou-
keepsers, in the several counties of England, towards pro-
viding harquebus, drums, colours, &c. for the militia.

TROPIANA, in Ancient Geography, a town of Italy, in
Calabria.

TROPICS, Tropic, in Astrology, two immovable
circles of the sphere, drawn through the solstitial points,
parallel to the horizon.

Such are the circles M E and N L, Plate XVI. Astro-
logy, fig. 140.

The tropics may be defined, two circles parallel to the
horizon, at such distance from it, as is equal to the sun’s
greatest reced from the equator towards the poles; or to
the sun’s greatest declination; or the obliquity of the
ecliptic.

Of the two tropics, that drawn through the beginning of
Cancer E, is called the *tropic of Cancer*. And that through
the beginning of Capricorn, the *tropic of Capricorn*.

They have their name from the Greek *tropos*, turn, con-
version; as being the limits of the sun’s way, or declination

towards north and south; so that when the sun is arrived at either of them, he turns the other way.

Hence, 1. Since the declination of the ecliptic is the arc $E\alpha$, or $L\alpha$; $EN$ will be the distance of the tropics; which is double the greatest declination.

2. Wherefore, if the sun's meridian altitude be observed, both in the winter and summer solstices, and the latter be subtracted from the former; the remainder will be the distance of the tropics; half of which is the greatest declination of the ecliptic.

Tropics, in Geography, are two lesser circles of the globe, drawn parallel to the equator, through the beginnings of Cancer and Capricorn.

Thee tropics are the planes of the celestial tropics, and at the distance of $23^\circ 29'$ from the equator, which is the sun's greatest declination.

Tropical Bird, in Ornithology, a species of the phaeton, called $lepturus$ by Buffon, on account of the slenderness of its tail. See Phaeton.

Tropic Keys, in Geography, small islands or rocks among the Virgin islands, in the West Indies, between Great Paffage island and Porto Rico.

Tropical Winds. See Trade-Winds and Wind. Tropical Year. See Year.

Tropino, in Geography, an ostruz of Russia, in the government of Tobolik, on the river Plazida. N. lat. 72° 36'. E. long. 90° 14'.

Tropists, or Tropici, the name of a sect. St. Athanasius, in his letter to Serapion, gives this appellation to the Macedonians, who were also called Pneumatomachi in the East, and Patrippines in the West.

The reason of the name Tropist was, that they explained the scripture altogether by tropes and figures of speech.

The Romans also gave the appellation Tropists to those of the reformed religion; in regard to their constraining the words of the eucharist figuratively.

Tropites, Tropites, a sect who, according to Philastrius, maintained that the Word was turned or converted into flesh, or into man.

This opinion they founded on that passage of St. John, in the Saviour, The Word was made flesh; as if it imported, that the Word was converted into flesh, and that he was clothed with our flesh and our nature.

Troppau, or Oppau, in Geography, a principality of Silicia, bounded on the N. by the principality of Oppeln, on the E. by Katober and Telchen, on the S. and W. by Moravia. The soil is good for corn and pasture, and abounds in fruit. It contains eleven cities or towns. The principality of Troppau once formed a part of Moravia, and with that marquisate came to Bohemia. It is now divided between the house of Avalria and the king of Prussia.

Troppau, or Oppau, a city of Silicia, and capital of the principality so called. It is situated in a fruitful country on the river Oppen, being walled, and containing an ancient palace of the princes, with three parochial churches, a college, three convents of monks, a monastery, and a commandery of the order of St. John; besides which, it is also the seat of the regency for the Bohemian part of Silicia. In 1758, the greatest part of this town was destroyed by fire. It belongs to Avalria; 45 miles S. of Oppeln. N. lat. 49° 50'. E. long. 18° 36'.

Troppowitz, a town of Silicia, in the principality of Troppau; 70 miles N.N.W. of Troppau. N. lat. 50° 1'. E. long. 17° 31'.

Troques, a bay on the S.E. part of lake Huron.

Trosa, a sea-port of Sweden, in Sudermanland, on the Baltic; 18 miles S.W. of Stockholm.

Trosburg, a town of Upper Bavaria; 13 miles E. of Waffeburg.

Trossachs, a tract of rugged rocks or mountains of stupendous height, situated about 10 miles W. from Callander, in the shire of Perth, Scotland, and accessible by a carriage-road. They exhibit an assemblage of wildnefs and rude grandeur, which fills the mind with the most sublime conceptions. It seems as if a vast mountain had been torn in pieces, and frittered down by a convulsion of the earth, and the huge fragments of rocks, woods, and hills, scattered in confusion for two miles on the fides of Loch Catherine. A huge column of these rocks was some years ago torn with thunder, and lies in very large blocks near the road. Where there is any foil their fides are covered with aged birch-trees. The fensible horizon is bounded by these trees on the fummit of every hill. On the north fide, the road is cut in some places through the solid rock, which rifes upwards of 200 feet perpendicular above the lake: at others the road is at the foot of lofty cliffs, and trees are growing where no earth is to be found.— Beauties of Scotland, vol. iv. Berthshire. Gazetteer of Scotland, 1806.

Trossuli, among the Romans, a name given by some to the guards that attended the kings of Rome, otherwise called celers.

Trossulium, in Ancient Geography, a town of Italy, in Etruria, in the vicinity of the country of the Volsci, according to Pliny.

Trot, in the Manage, one of the natural paces of a horse, performed with two legs in the air, and two on the ground, at the same time, crosswise, and continuing fo alternately, to raise the hind-leg of one fide, and the fore-leg of the other fide at once; leaving the other hind and fore-leg upon the ground till the former come down.

This action of his legs is the same as when he walks, except that in this trot his motions are more quick.

In this motion, the nearer the horse takes his limbs from the ground, the opener, the evener, and the shorter his trot will be. If he takes up his feet slovenly, it is a sign of stumping and lameness; if he treads narrow, or crofs, it betokens interfering or falling; if he treads long, it bews over-reaching; if he steps uneven, he indicates toil and weariness.

Three qualities are essentially necessary to make the trot useful. It ought to be extended, supple, and even or equal; these three qualities mutually depend upon each other; so that you cannot pass to the supple trot, without having first worked upon the extended trot; and you can never arrive at the even and equal trot, without having practiced the supple. The extended trot is that in which the horse trots out without retaining himself, being quite straight, and going directly forwards; and this, consequently, is the kind of trot with which you must begin. The supple trot is that in which the horse, at every motion he makes, bends and plays all his joints, viz. those of his shoulders, his knees and feet, which no colts, or raw horses, can execute, who have not had their limbs limped by exercise, and who always trot with a surprising lightness and awkwardness, without the least spring or play in their joints. The even or equal trot is that in which the horse makes all his limbs and joints move so equally and exactly, and his legs never cover more ground one than the other, nor at one time more than another. To do this, the horse must necessarily walk and collect all his strength, and, if the expression may be allowed, distribute it equally through all his joints. To go from the extended trot to the supple, you must gently and by degrees hold in your horse; and when by exercise he has attained sufficient ease and suppleness to manage
manage his limbs readily, you must insensibly hold him in still more and more, and by degrees you will lead him to the equal trot. All horses that are inclined to be rambing
should be kept to the extended trot. A horse of a sluggish
and cold disposition, which has, nevertheless, strength and
bottom, should likewise be put to this trot: as he grows
animated, and begins to go free, keep him together by little
and little, in order to lead him insensibly to the supple trot;
but if, while you keep him together, you perceive that he
slackens his action and retards himself, give him the aids
briskly, and put him forward, keeping him, nevertheless,
gently in hand; by this means he will be taught to trot
freely and equally at the same time.

The only proof, or rather the most certain sign of your
horse's trotting well is, that when he is in his trot, and you
begin to put him a little, he offers to gallop. The principal
effects of a trot are to make a horse light and active,
and to give him a just appui.

The manner of trotting a colt who has never been backed
is as follows: put a plain fishtail in his mouth; fit a cavesson
to his nose, to the ring of which tie a longe of a reasonable
length. Let a groom hold this longe, who, having got at
some distance from the colt, must stand full in the middle
of the circle which the horse will make. Let another follow
him with a long whip or chambriere in his hand. The colt,
being alarmed, will be forced to go forward, and to turn
within the length of the cord; the groom must hold it tight
in his hand; by this means he will draw in, or towards the
centre, the head of the colt, and his course will of confe-
quence be without the circle. See FOAL, and Backing of a
House.

In working a young horse after this manner, do not pref
or hurry him. Let him walk first, and afterwards put him
to the trot. If you neglect this method, his legs will be
embarrassed; he will lean on one side, and be more upon
one haunch than the other; the inner fore-foot will strike
against the outer one, and the pain which this will occasion
will drive him to seek some means of defence, and make
him disobedient. If he refuses to trot, the person who
holds the chambriere will animate him, by trotting him, or
striking the ground with it. If he offers to gallop instead
of trotting, the groom must shake his cord that is tied
to the cavesson, and he will fall into his trot. Berenger's
Art of Horsemanship, vol. i. ch. 4.

TROTHY, in Geography, a river of England, in the
county of Monmouth, which runs into the Wye, near
Monmouth.

TROZTA, a river of Ruffia, which runs into the
Kama, 16 miles N. of Kofa, in the government of Viatka.
TROU, L.e, a settlement in the N. part of Hifpaniola.
N. lat. 19° 35'. W. long. 72°.

TROUBADOURS, a name given to the ancient poets
of Provence, who wrote, set, and sung their own veres.
See Provencal Poets.

Some will have the word borrowed from troubier, to find,
by reason of their inceptions, whence they are called trou-
veres; though others take them to have been called trob-
adores; by reason they sung their poems to an instrument
called a trompe or trompe.

The poetry of the troubadours consisted in sonnets, psy-
torals, fongs, syrventes, or stafires, which were much to their
taste; and in tenons, which were love-dithuses.

Jean De Notre Dame, commonly called Noitradamus, a
procurer in the parliament of Provence, wrote an ample
discourse of these poets. He makes their number seventy-
fix.

Pufquier tells us, he had an extract of an ancient book,
belonging to cardinal Benoits, entitled "Los Noms da-
quels qui firent Tenfons & Syrventes," which made their
number ninety-six; among which was an emperor, viz.
Frederic I. and two kings, viz. Richard I. of England, and
a king of Arragon: with a dauphin, several counts, &c.: not
that all these had composed entire works in Provengal;
some of them had not brought forth any thing beyond
epigrams.

Pufquier tells us, he had an extract of an ancient book,

Petrarch speaks, with applause, of several troubadours
in the fourth chapter of the Triumph of Love. The Ita-
lian poets are said to have borrowed their best pieces
from the troubadours. Pufquier declares expressly, that Dante
and Petrarch are, indeed, the fountains of Italian poetry; but
fountains which have their sources in the Provengal poetry.

Bouche, in his History of Provence, relates that, about
the middle of the twelfth century, the troubadours began
to be esteemed throughout Europe; and that their credit
and poetry were at the highest about the middle of the four-
teenth. So that they flourished in Europe about two hun-
dred and fifty years, viz. from 1120 or 1130 till the year
1382. He adds, that it was in Provence that Petrarch
learned the art of rhyming, which he afterwards practifed,
and taught in Italy.

Strolling musicians, under the appellation of Jongleurs,
(which see, ) abounded in France fo early as the time of
Charlemagne, who forbids their admission into convents;
and in the first capulitary of Aix-la-Chapelle, this prince
speaks of them as perfons branded with infamy. They
continued, however, to amuse the great in private, as well
as the people in public, as a distinct body of men, till the
troubadours introduced poetry into France, in the dialect
of that country. Their licentiousnes was frequently re-
pressed, and their conduct regulated, by the police; and
during the reign of Philip Augustus, the troubadours and
minstrels, or jongleurs, were involved in the same disgrace,
and for some time banished the kingdom; which left such
a stigma upon their order, as no efforts of genius, or au-
terity of manners, could entirely eflace, though they were
afterwards recalled, and in some degree restored to public
favour.

It is observed by a late elegant French writer, that though
the proscriptio of music and poetry, and the kind of
inquisition which Philip eftablifhed against the jongleurs
in France, may have originated from the laudable intention
of repressing those disorders, which the abuse of their pro-
feffion had occasioned; yet, if he had reflected that the
fate of letters was at that time in the hands of the trou-
badours, and that among every people approaching towards
civilization, the progress of virtue is generally propor-
tioned to the cultivation of arts and literature; he would
have inflicted a less ignominious punishment on the objects
of his displeasure; for such is the empire of prejudice, that
the anathema it pronounces against the abuse of a profeffion
remains in full force, even after the reformation of those who
exerice it. This author ventures to pronounce the jong-
leurs, or troubadours and minstrels, notwithstanding the con-
tempt with which they are named at present, to have been
the fathers of literature in France: they, says he, banished
scholastic quarrels and ill-breding, and polished the manners,
eflablifhed the rules of politefns, enlivened the conver-
sation, and purified the gallery of its inhabitants. That
urbanity, continues he, which distinguishes us from other
people, was the fruit of their fongs; and if it is not from
them we derive our virtues, they at least taught us how to
render them amiable. Tableau Historique de Genes des
Lettres, par l'Abbe de Louvichamps, tom. v. cited by
Mr. T. Warton (Hist. of English Poetry) is of opinion that there were two forts of French troubadours who have not been sufficiently distinguished. If we diligently examine their history, we shall find that the poetry of the first troubadours consisted, as we have already intimated, in satires, moral fables, allegories, and sentimental sonnets. So early as the year 1180, a tribunal called the "Court of Love," was instituted both in Provence and Picardy, at which questions in gallantry were decided. This institution furnished ample matter for the poets, who threw the claims and arguments of the different parties into verse, in a style that afterwards led the way to the spiritual conversations of Cyprian and Chloia. Fontenelle does not scruple to acknowledge, that gallantry was the parent of French poetry. But to sing romantic and chivalrous adventures was a very different talk, and required very different talents. The troubadours, therefore, who composed metrical romances form a different species, and ought always to be considered separately. And this latter class seems to have commenced at a later period, not till after the crusades had effected a great change in the manners and ideas of the western world. In the mean time, as Warton conjectures, the art of the troubadours, commonly called the "Gay Science," was first communicated from France to the Italians, and afterwards to the Spaniards. If this be true, it is at the same time highly probable, as the Spaniards had their "Juglares," or convivial ballads, very early, because from long connection they were intimately acquainted with the fictions of the Arabsians, and were naturally fond of chivalry, that the troubadours of Provence in great measure caught this turn of fabling from Spain. The communication, without mentioning any other obvious means of intercourse, in an affair of this nature, was easy through the ports of Toulon and Marfeilles, by which the two nations carried on from early times a constant commerce. Even the French critics themselves universally allow, that the Spaniards, having learned rhyme from the Arabsians, through this very channel conveyed it to Provence. Tasso preferred "Amadis de Gaul," a romance originally written in Spain by Vafo Lobeyra, before the year 1500, to the most celebrated pieces of the Provençal poets. The early universality of the French language very much contributed to facilitate the circulation of the poetry of the troubadours in other countries; and thus they contributed in a very considerable degree to the revival and diffusion of literature in Europe. See Jongleurs, Minstrel, Mystery, Provençal Poets, Romance.

TROUBLES, in Geography. See Coal.

TROVE, in Law. See Treasure-Trove.

TROVER, an action which a man hath against one that, having found any of his goods, refuseth to deliver them upon demand, but converts them to his own use; from which finding and converting, it is called an action of trover and conversion.

Actions and detinue are frequently turned into actions upon the case, far trover and conversion.

The injury in this case lies in the conversion: and, therefore, the fact of the finding, or trover, is now totally immaterial; for the plaintiff needs only fugget (as words of form) that he lost such goods, and that the defendant found them; and if he proves that the goods are his property, and that the defendant had them in his possession, it is sufficient. But a conversion must be fully proved; and then in this action the plaintiff shall recover damages equal to the value of the thing converted, but not the thing itself; which nothing will recover but an action of detinue or repelvin. See Restitution of Stolen Goods.

TROUGH, a hollow wooden vessel for kneading dough in, or to beat apples in for cyder; also a piece of the trunk of a tree made hollow, to feed swine in; or an open pipe or channel, made of boards, for the conveyance of water.

TROUGH of the Sea, is the hollow cavity made between two waves, or billows, in a rolling sea.

When a ship lies down there, they say, she lies in the trough of the sea; in which case she rolls heavily, because the letting of the sea is always produced by the wind, and, consequently, the waves, and the trough between them, will be at right angles with the direction of the wind.

TROUP HEAD, in Geography, a cape of Scotland, on the north coast of the county of Banff; 10 miles W. of Kinnaid's Point. N. lat. 57° 39'. W. long. 2° 11'.

TROUPESBURGH, a township of New York, in the United States, situated in the S.W. corner of Steuben county, 25 miles S.W. of Bath village, erected in 1808, from the S. part of Canisteo and a small part of Addison, and extended to Allegany county in 1811; bounded N. by Canisteo, E. by Addison, formerly Middletontown, S. by the state of Pennsylvana, and W. by Allegany county. It is 18 miles long E. and W., and about 10 miles wide. The inhabitants were in 1810, consisting of 292 persons and 36 feclusion electors.

TROUS de Loup, in Field Fortification, are round holes, about six feet deep, and pointed at the bottom, with a flake placed in the middle. They are frequently dug round a redoubt, to obstruct the enemy's approach. At top they are circular, and about four feet and a half in diameter.

TROUSSEQUE, in the Manuge. See Dock.

TROUSSEQUIN, a piece of wood, cut archwise, raised above the hinder bow of a great sledge, and serving to keep the bolters firm.

TROUT; Salmo fario of Linnaeus, in Ichthyology, a very valuable river-fish. See Salmo Faro.

The colours of the trout, and its spots, vary greatly in different waters, and in different seasons; yet each may be reduced to one species. In Llyndivi, a lake in South Wales, are trouts called cach y dael, mentioned by Pennant. See Salmo Faro.

In Lough Neagh, in Ireland, are also trouts called budding, some of which weigh thirty pounds; and others of a much superior size are taken in Hulse-water, a lake in Cumberland, supposed to be the same with the trouts of the lake of Geneva. In the river Honyn, not far from Machynlleth in North Wales, and in one of the Snowden lakes, is found a variety of trout, naturally deformed, having a strange crookedness near the tail.

The Hon. Mr. Daines Barrington suggests, that gillaroo, the name given to certain trouts in the Irish lakes, (see Salmo Faro,) may be either a corruption of Killala, the name of a town near which these trouts are caught, or formed of the Welsh cylla, q. d. flamach, and the Irish raath, q. d. strong; so that gillaroo may be the same as strong flamach. From the observations both of Dr. Watson and Mr. J. Hunter, there is no reason for considering the flamach of these trouts as gizzards, but as true flamachs. That of the English trout is of the same kind with the flamach of the gillaroo trout, but its coat is not so thick by two-thirds; and, therefore, the difference in the thickness of the flamachs, which may be occasioned by the nature of the waters, or adapted to the purposes of containing a greater quantity of flesh-fish than the flamachs of our trouts, does not warrant its being clasped as a different species. The flamach even of the gillaroo trout can pollute fearfully any power of grinding, as the whole cavity is lined with a fine villous coat, the internal surface of which appears everywhere to be digestive, and by no means fitted for mastication.
TRO

tification. Thse stomachs are sometimes served up at table
in Ireland, under the name of grizzards. See on this sub-
ject, Phil. Trans. vol. lixiv. part i. p. 116. 121. 310.
Trouts are a very voracious fish, and afford excellent di-
version to the angler (see Trout-Fishing); they shift their
quarters to fpawn, and, like a salmon, make up towards the
heads of rivers to deposit their roes. The under jaw of the
tout is subj ect, at certain times, to the same curvature as
that of the salmon.

Mr. Pennant has described a species that migrates out of
the sea into the river Ef, in Cumberland, from July to Sep-
tember, and called from its colour the cubiting. When
dressed, its flesh is red, and most delicious eating. On their
first appearance from the salt-water, they have the salmo-
lofhe adhering to them. They have both melt and fpawn,
but no fry has as yet been observed. The Scots call this fish
phinos; they never exceed a foot in length; the upper jaw
is a little longer than the lower; in the first are two rows of
teeth, in the last one; and on the tongue are fix teeth; the
back is straight; the whole body of an elegant form; the
lateral line straight; the colour between that and the top of
the back, dusky and silvery intermixed, beneath the line of
an exquisite silvery whitenefs; first dorsal fin spotted with
black; the tail black and much forked; the third dorsal fin
has eleven rays; the pectoral thirteen; the ventral nine,
Trout, Salmon. See Salmo Trutta.
Trout-Fishing. See Trout-Fishing.
Trout-Coloured. A horse is faid to be of this colour,
when he is white, and speckled with spots of black, bay, or
ferr; especially about the head and neck.

Trout Creek, in Geography, a souther branch of Sal-
mon creek, in Franklin county, New York, on which are
mills in Erazville, Dickinson, and Confiable.
TROUTBECK, a river of England, in Westmoreland,
which runs into the Eden, 3 miles below Appleby.
TROW, a kind of boat, sometimes with fquare and
upright head and stern.

TROWBRIDGE, in Geography, a confiderable market
and manufacturing town in the hundred of Melkham
and county of Wilt, England; is situated at the distance of 28 miles
N.W. from Salisbury, and 98 miles W. by S. from London.
Neither the etymology of its name, nor the period of its origin,
can be ascertained with accuracy; but as it is not mentioned
in Domesday book, we may conclude that it had no existence
when that work was compiled. The earliest notice of it in
history occurs in the reign of king Stephen, about the year
1150, when it appears that Trowbridge was occupied by
the partisans of the empress Maud, and was besieged and
taken by Stephen; but whether there was any town at that
era does not appear. It is certain, however, that the lordship
of Trowbridge formed part of the estates of Henry, duke of
Lancaster, whose daughter Blanche married John of Gaunt,
son of Edward III. When Lancaster was constituted a
county-palatine, this manor, as part of the dukes's property,
was recognized in the charters as one of the honors
attached to it: and here it is probable the court of Chanery
for the duchy was held, as the rents for the same are paid at
Trowbridge to this day. As the entire duchy of Lancaster
was vested in the king in the reign of Henry VII., this town,
as belonging thereto, became a royal demeine. In the next
reign it was granted to Edward, earl of Hereford, after-
dwards duke of Somerset, at whose attainder it again reverted
to the crown. It was restored to his son by queen Eliza-
beth, and continued the property of his collateral descendants
till the reign of Charles I., when Sir Francis Seymour was
created baron Seymour of Trowbridge. It afterwards passed
Vol. XXXVI.
to the family of Manners, by the marriage of lady Frances
Seymour with John, marquis of Granby; and from him de-
cended to the present duke of Rutland, who sold it in 1809
to Thomas Timbrell, esq.

Like the generality of manufacturing towns, Trowbridge
is very irregularly built. None of the streets seem to have
been formed on any regular plan, but have been construct-
ed according as private interest or convenience suggested.
Hence, though there are several handsome houses in the
town, yet they appear to disadvantage from the narrow-
ness of the streets, and the intermixture of old and mean
buildings. The extent and importance of Trowbridge may
be he best determined by the parliamentary report of 1811,
by which it appears to have then contained 1170 houses,
and 6175 inhabitants. Of the latter, the greater part was
engaged in the woollen manufacture, which was first esta-
blised here in the early part of the reign of Charles VII.
then, who lived in that reign, gives the following account of
this town. "From Bradeforde to Thoroughbridge, about a
two mile by good corn, pasture, and wood, I entered to the
towne by a fone bridge of three arches. The townve
standeth on a rokky hille, and is very well buildyd of fone, and
furnisht by drapery. Of later tymes, one James Terumber,
a very rich clothier, buildyd a notable faire house in this
towne, and gave it at his deth, with other landes, to the found-
ing of two Cantuaries preltes ys Thoroughbridge churche.
This Terumber made also a litle alme-hone-forsy Thorough-
bridge churche, and yt he be a fite poore folkes, having a three-
pence by the week towards their finding. Horton, a clothier
of Bradeforde, buildyd of late dayes dyvers fyne houses in this
town. Old Baylie buildyd of late in this town; he was a
rich clothier; Baillie's fone now drapeth the town, and
also a two miles out of it, at a place yn the way to Farley
castle. One Alexandre is now a great clothier in the towne."
The cloths now principally manufactured here are superfine
broad-cloths and kerseymeres; the weekly produce is el-
minated at ninety pieces of the former, and four hundred
and ninety pieces of the latter. Trowbridge not being incorpo-
rated, its government is vested in the county magistrates, who
hold the petty seions for the Trowbridge division of the
hundred alternately here and at Bradford. A court-leet and
a court-baron are also annually held; in the former the con-
fables, tything-men, and cornets of the market are appointed.
The duty of the last-mentioned officers is to inspect the pro-
visions brought to the market, and to see that the weights
and measures accord with the proper standards. The market-day
is Saturday; and a fair is held annually, at which consider-
able quantities of woollen goods, cattle, cheese, &c. are sold.
In the market-place formerly stood a stone cross, which was
taken down towards the end of the last centurie, on the pre-
sence of its obstructing the communication of the High-
street, and injuring its appearance. It is thus noticed by
Leland: "There is a fair standing place for market-men to
stand up in the harte of the towne, and this is made viij fquare,
and a pillar in the midle, as there is one made in Malmyby
far fairer than this." The church of Trowbridge, though
upwards of four hundred years old, is still characterized by
the appellation of New Church, which implies that another
must have previously existed here. By whom the new struc-
ture was raised is not distinctly recorded; but it appears
probable, that a great part of the expense was incurred by
James Terumber, the rich clothier mentioned by Leland,
and the remainder by other benevolent individuals connected
with the town. This opinion is founded on the contents of
a deed of frowstment by Terumber, dated January 11, 1483,
and preferred in the vestry-room; by which he directs that,
out of his elates therein enumerated, ten marks should be
paid
paid yearly to a priest to pray for his soul, and the souls of all other benefactors whose names should be inscribed in a table hanging at the high altar. Considered in an architectural point of view, this church is deserving of notice. Leland styles it "light and fair," and tells us that one Molines, "a man well-learned," was parson there in his time. It is a spacious edifice, and consists of a nave, chancel, two side-aisles, with chapels attached, a north and south porch, and a large tower at the west end, surmounted by a taper spire. The nave and aisles are embattled, and are ornamented with crocketed pinnacles. Both porches are unusually lofty. The nave has a flat ceiled roof, highly decorated with flowers: it is separated from the aisles by five arches on each side, supported by clustered columns with ornamented capitals. Some of the windows contain fragments of painted glass, particularly the east windows of the chapels, which are large, and display seven days of lights, separated by mullions. The font is lofty, and covered with a profusion of tracery and panelling, with sculptural representations on shields, emblems of the crucifixion. The living is a rectory, in the gift of the duke of Rutland, he having reserved the advowson when he held the manor: the present rector is the Rev. Mr. Crabbie. This church is the only place of religious worship on the establishment in the town; but there is a chapel of ease dependent upon it at Staverton, a hamlet within the parish. Like most manufacturing towns, Trowbridge abounds with Dintferers, and consequently contains several meeting-houses. The charitable institutions in Trowbridge are an almshouse, and a school for the education of thirty boys. The former was founded by a person of the name of Verbury. The school-house stands in the church-yard, near the spot where the almshouse erected and endowed by Termper was placed, which has been recently taken down, and the funds appropriated to the use of the parish poor generally. Of the nave no part is now standing; but its site is distinguishable by the remains of the most and vault by which it was surmounted. It is more elevated than the town, and still retains, in the apellation Court-hill, a marked allusion to its ancient appropriation. As there are no data to determine by whom the cated was erected, so the period of its demolition is equally uncertain; but it must have occurred previous to the reign of Henry VIII., for Leland says of it, "The caeller floode on the fouthe side of the toone. It is now clene down. There was in it a feuen gret towres whereof peaces of two yet flande." The college was formerly approached from the town by a drawbridge over the moat, which has given occasion to a plausible conjecture that the name Trowbridge is a corruption of Drawbridge, near which the retainers of the college might probably have built their houses in the infancy of the town. This supposition derives some support from the fact, that some of the buildings adjoining Court-hill posses considerable marks of antiquity.

Among the distinguished natives of this town is George Keate, a writer of considerable eminence in the last century. He was descended from the ancient and opulent families of the Hungerfords and Seymour. He died June 27, 1797, aged 67.

About two miles to the south-east of Trowbridge is Rodw Aflton, the seat of Richard Godolphin Long, esq. one of the present representatives of the county of Wilts. The house is large and commodious, and has lately undergone considerable alterations and improvements, under the superintendence of Jeffry Wyatt, esq. architect. The park is extensive and well wooded.—Beauties of England and Wales, vol. xv. Wiltshire, by John Britton, F.S.A. 1815.

TROWEL. See BRICK-Layer.

TROWEL, Garden, a tool of the trowel kind, which is made of iron, in a hollow or scooped form, and is an useful implement in taking up numerous sorts of small plants and bulbous roots, and replanting them in pots, fowing in patches, and various other similar light works: it should be from six to twelve inches long in the plate, and half as broad, and fixed on a short handle, to hold with one hand. From its being hollowed semicircularly, it is remarkably handy in removing many sorts of small plants with a ball or lump of earth whole about their roots, so as not to feel their removal; lifting several sorts of bulbous flower-roots, after the flowering is past in summer; planting bulbs in patches or little clumps about the borders, as also for digging small patches in the borders for sowing hardy annual flower-seeds on; likewise for filling mould into small pots in planting any sort of plants, stirring the surface of the mould in pots, and from earthing them when necessary: it is also highly useful for filling in earth about plants in hot-beds, and under frames, or any small compartments where a spade cannot be readily introduced.

They should be had of different sizes to suit different purposes.

TROWERT, Island, in Geography, a small island in the East Indian sea, near the south coast of Java. N. lat. 7° 2'.

TROWERYN, a river of North Wales, which rises from a lake in Merionethshire, and runs into the Dee.

TROLE, or TROLE, the Bowl, in English Antiquity, was a common phrase in drinking for passing the vellum about, as appears from several of our old catches.

TROERS, among Sailors, a fort of loose breeches of canvas, worn by seamen, &c.

TROXIMON, in Botany, from τροχόειαν, eateable, a name chosen by Gartner, without much propriety, for this genus, which he very justly distinguished from TRAGOPOGON: see that article, as well as ARNOPOGON, thereunto subjoined.

Gen. Ch. Common Calyx simple, ovate, of numerous lanceolate equal scales, in two rows. Cor. compound, imbricated, uniform. Florets various in number, all perfect, of one petal, ligulare, longer than the calyx, abrupt, with five teeth. Stam. Filaments, in each floret, five, capillary; anthers united into a long furrowed tube. Pist. Germen, in each floret, oblong; style thread-shaped, the length of the flaments; fligmas two, revolute. Peric. none, except the permanent, finally spreading, calyx. Seeds solitary, oblong, slender; seed-filile, capillary, roughish. Recept. naked, dotted.

Obst. We do not find the calyx ever "imbredicated with unequal scales," as Gartner says it sometimes is. Such a character belongs to Sonchus. Neither is it perfectly simple; for, as far as we can discern in every known species, the scales, or leaves, stand in a double row, or circle, the outer ones alternate with, and overlapping the inner, at their base. The simple feed-down effectually distinguishes this genus from Tragopogon, nor are the habits of the plants similar.

—Native
Native of the banks of the Missouri. Biennial, with bright-yellow flowers. Purb. Dr. Sims says perennial.

The original specimen was sent by Clayton from Virginia, in 1734, to Gronovius, who communicated it to Linnaeus, inferred "Dandelion with undivided leaves." Hence the latter took his specific name, the meaning of which he probably did not investigate, and he might perhaps call it *Dandelion*. The name is, at any rate, as bad as can possibly be, and we are happy in getting rid of it, by discovering the plant to be Mr. Pursh's first species of *Troximon*. Of this indeed neither this author, nor any one else, was aware; but though we have seen no specimen from Mr. Pursh, his specific character leaves no doubt in our mind, and Gartner originally suggested that this Linnaean *Tragopogon* was a *Troximon*. The leaves are radical, glaucous, very smooth, even, quite entire, four or five inches long, taper-pointed, with a foliary mid-rib, and some flight longitudinal veins. *Flower-flalks* half as long in our specimen, but they probably are incomplete; Gronovius says twice as long; they are simple, clothed in the upper part with prominent, tawny, glandular bristles, most crowded just under the *flower*, which is yellow, above an inch wide. Calyx smooth and glaucous, shorter than the corolla, its leaves folding over one another as described in our general character, but of equal length, not truly imbricated. The point of each is pale, a little dilated and membranous, or, as Pursh says, *cuspidate*. *Seed-down* serrate and rough, not feathery. Gronovius rightly noted this circumstance. We can scarcely doubt the figure in Curtis's *Magazine* being our plant, though a larger specimen. The roughness of the flower-slalk indeed is wanting, and the points of the calyx not shown.

2. *T. lanatum*. Woolly *Troximon*. (*Tragopogon lanatus*; Linn. Sp. Pl. 1111. Willd. Sp. Pl. v. 3, 1495. Leontodon lanatus; Linn. Am. Acad. v. 4, 287; excluding the reference to Rauwolf, 117, not 217, which rather belongs to *Scorzonera tuberofa* see that article, n. 12.)—Leaves linear-lanceolate, undulated, clothed with fibby hairs, as well as the radical flower-slalks and calyx.—Native of Palestine, from whence, if we mistake not, the Linnaean specimen was brought by Haffel quitt. The root has a perennial aspect, its crown bearing several tufts of upright, narrow, thrashing leaves, three or four inches long, considerably undulated, entire, loosely clothed, on both sides, with long, soft, fibby, woolly, or rather silky, hairs: the bases of the outer ones pale, dilated, membranous and smooth. *Flower-slalks* radical, foliary, from the centre of each tuft of leaves, and rather exceeding them in height, angular, covered with similar hairs to those of the foliage. *Flowers* foliary, eret, yellow, nearly the size of the fall, but with fewer *flowers*. Calyx hardly so long as the corolla, very fibby at the base, its leaves eight or ten, in two rows, lanceolate, equal, straight, hairy, somewhat membranous at the edges. We can just perceive, in the flowers, that the *seed-down* is simple and rough. Gartner has indicated the true genus of this species, as well as of the foregoing. It appears nearly related to *Scorzonera tuberofa*, a plant we have never seen; but whole puhescence is not described as at all like that before us; and the recurved or revolute points of its *calyx-flake*, which moreover are unequal, and truly imbricated, in Palas's figure, remove all ambiguity.

3. *T. virginicum*. Virginian *Branching Troximon*. Pursh n. 2. (*Tragopogon virginicum*; Linn. Sp. Pl. 1111. Hyoferis prunainoides; Wild. Sp. Pl. v. 3, 1615. H. amplexicaulis; Michaux Boreal.-Am. v. 2, 87.)—Smooth and glaucous. Stems erect, somewhat leafy, with several flowers.—In meadows and moist shady woods, from Pennsylvania to Carolina, flowering in July and August. Root perennial. Herb about a foot high, with handsome yellow flowers. Purh. The radical leaves are either obtuse or lyrate, oblong, or toothed, tapering down into thrashing membranous *foot-flanks*, together with which they measure about four inches; those of the stem few, ovate-oblong, feathery, the uppermost diminished to one or two *bracteas*, at the base of the long partial *flower-flanks*, three or four of which together compose a fort of umbel. *Flowers* erect. Calyx of eight or ten glaucous smooth leaves, half an inch in length. *Florets* twice as long, not very numerous. *Seeds* few, smooth. *Receptacle* small, dotted, naked.—Specimens from Kalm and others from the late Dr. Muhlenberg differ widely in their foliage, that of the former being deeply lyrate, the latter fearly toothed; yet the plants are so alike in other respects, that we cannot, without further information, distinguish them as species.

4. *T. cuspidatum*. Pointed-flaked *Troximon*. Pursh 742. "Stalk radical, single-flowered; rather downy in the upper part. Leaves linear, downy and wavy in the margin. Calyx- scales imbricated, pointed, smooth."—Found by Mr. Bradbury, in Upper Louisiana. Perennial. *Flowers* large, yellow. Reflembles *T. glaucum*. Purh. By the specific character, we should be inclined to fulfill this might be the *Leontodon Dandelion* of Linnaeus, our first species of *Troxim*, were not the size of the flowers against it.

TROY, or ILIUM, in Ancient Geography, a city of Troas, or Phrygia Minor (which sec.), rendered immortal by the inimitable poems of Homer and Virgil, was built by Troy, king of that country, who called it Troy from his own name, and Ilium from that of his son Ilius. It was placed on a rising ground near mount Ida, and about five miles from the shore. Of this city, there subjected feantry any remains in the time of Strabo; and most of the ancient as well as modern writers have confounded the old and new Ilium. The new city, built nearer the sea-coast, was reduced to a village in the time of Alexander the Great, and was remarkable for nothing but a temple of Minerva, which that prince visited, after having defeated Darius on the banks of the Granicus, and enriched with offerings, bestowing ample privileges on the place, and honouring it with the title of city. He likewise ordered the buildings to be repaired, and the whole city to be embellished by Lyfimachus, one of his generals, who surrounded it with a wall of forty furlongs in circumference. It was again reduced to the condition of an inconsiderable village, when the Romans first entered Asia. As they pretended to be the genuine offspring of the ancient Trojans, no cost nor pains were spared to restore it to its ancient lustre, especially in the time of the Caesars. Augustus sent thither a colony, embellished the city with many flatly buildings, and enriched it with ample privileges and exemptions. Belloniuss tells us, that in his time the walls were yet standing, with the ruined monuments of their turrets; and that he spent four hours in compassing them, partly on horseback and partly on foot. He observed round the walls a great many marble tombs of exquisite workmanship, with their covers entire. Two of these were still remaining when M. Spont visited those places; who informs us, that they were in the style of the ancient Romans, and not unlike thse that are to be seen at Arles; whence he concludes them to be the remains of that Troy which was rebuilt by the Romans. Belloniuss likewise observed the ruins of three great towers, one on the top of a hill not far from the shore, another about the middle, and the third at the bottom, with a great many large cisterns to receive the rain-water. Spont observed on the south of the haven three columns lying among the briars, of which two were entire, and each of one single piece, being
TROY.

The monuments and, as is now generally believed, the First Monuments to the Ancients, were erected by the ancient Greeks in honor of their gods. The temple of Apollo at Delphi was the most famous of these monuments, and the temple of Zeus at Olympia was the most important. The temple of Hera, at Eleusis, was also very famous.

The temple of Athena at Pergamum was one of the most magnificent buildings of its kind, and the temple of Artemis at Ephesus was another famous monument. The temple of Minerva at Carthage was also famous, and the temple of Dionysus at Athens was another important building.

The temple of Jupiter at Rome was one of the most famous of its kind, and the temple of Venus at Vicenza was another famous monument. The temple of Vulcan at Mantua was also famous, and the temple of Neptune at Naples was another important building.

The temple of Minerva at Alba Longa was one of the most famous of its kind, and the temple of Apollo at Corinth was another important building. The temple of Fortuna at Rome was also famous, and the temple of Ceres at Tarentum was another important building.

The temple of Diana at Ephesus was one of the most magnificent buildings of its kind, and the temple of Bacchus at Carthage was another famous monument. The temple of Jupiter at Rome was also famous, and the temple of Apollo at Corinth was another important building.

The temple of Minerva at Alba Longa was one of the most famous of its kind, and the temple of Apollo at Corinth was another important building. The temple of Fortuna at Rome was also famous, and the temple of Ceres at Tarentum was another important building.
TROY.

siege promised little hopes of succors; the Greeks being unacquainted with any military engines fitted to make an impression on the Trojan walls. With such a numerous army, they might have converted the siege into a blockade; but scarcity of supplies compelled the greater part of them to quit the camp. The refoule of ravaging the adjacent country soon exhausted itself. Many betook themselves to cultivating the rich vales of the Chersonesus, whose indulgent inhabitants had recently been expelled, or destroyed, by the fierce incursions of the barbarous Thracians. Others had recourse to piracy, scouring the neighbouring seas, ravaging the unprotected coasts of the Hellespont and Ægean, and plundered or demolished such unfortified places as acknowledged the dominion, or afflicted the arms of Troy. These ravages excited the rage of the Achaians, and rendered them more hearty in the caufe of their confederates. In this manner nine summers and winters elapsed, without affording the nearer prospect of a decision to the confest; but, in the tenth year of the war, the feeming misfortunes of the Greeks precipitated the downfall of the proud city of Priam. A dreadful pestilence invaded the camp of the besiegers, and long continued to rage with unabating fury. This calamity was followed by the well-known quarrel between Agamemnon and Achilles, which deprived the Grecian army of its principal strength and ornament. The Trojans derived new spirits from the misfortunes of their enemies; they ventured to abandon the protection of their walls, boldly affailed the Grecian camp, and rifked several engagements, in most of which they were victorious. In the laft of theft, the beloved friend of Achilles was slain by the arm of Hector, the bravest and molt generous of the Trojan race. This event, which was infinitely more dreadful than death to the affectionate ardour of the Grecian chief, rifed his hitherto inexorable reftament against the proud tyranny of Agamemnon. His return to the camp restored the declining fortune of the Greeks; and the indignant furv of his rage was quenched in the detefted blood of Hector, whose patriotic valour had long been the firmest bulwark of his father's kingdom. The destruction of Troy soon followed the death of her darling hero. The city, whether taken by florm or by surprife, was set on fire in the night; most of the citizens perished by the sword, or were dragged into captivity; and only a miserable remnant escaped through the confufed horror of raging flames and expiring kifsen.

The burning of Troy happened eleven hundred and eighty-four years before the Christian era. Neither the city nor territory ever anew, in any succeeding age, the dignity of independent government. The sea-coast was planted, eighty years after the Trojan war, by new colonies from Greece; and the inland parts submitted to the growing power of the Lydians, whose arms overspread and conquered all the finest provinces of Lesser Asia.

The Greeks had recovered possession of the admired beauty of Helen; they had taken complete vengeance on the family and nation of her unhappy seducer; but the misfortunes which were the natural confequence of the Trojan expedition, left them little reafon to boast of their victory. Of five Boeotian commanders, only one remained, and the fiege had been proportionately fatal to the leaders of other tribes, as well as to their warlike followers. Thofe who lived to divide the rich spoils of Troy, were impatient to fet fail with their newly-acquired treafure, notwithstanding the threatening appearance of the fikes. Many of them perihed by shipwreck; the reft were long tufhed on unknown feas; and when they expected to find in their native country the end of their calamities, they were exposed to fuffer greater calamities there, than any which they had yet endured. The thrones of feveral of the abfent princes had been usurped by violence and ambition; the lands of various communities had been occupied by the invasion of blowfif tribes; even the least unfortunate of those adventurers found their domains uncultivated, or their territories laid waste; their families torn by discord, or their cities shaken by fedition. And thus the moft celebrated enterprise of combined Greece tended to plunge that delightful and once happy country into barbarism and misery. Gillies's Hist. of Anc. Greece, vol. i.

All the Roman writers affure us that Æneas fettled in Italy, and there founded the kingdom of Alba. From him the Cæsars affected to derive their pedigree. Livy alone feems to betray fome fort of doubt as to this particular, in- fluating, with a great deal of referees, that he has not fufficient grounds either to admit or reject the common opinion. But, notwithstanding the unanimous consent of the Latins, there are not wanting arguments of great weight, which the learned Bochart has carefully collected, to prove the arrival of Æneas in Italy to be a mere fable.

Dr. Gillies having carefully examined the evidence given by Bochart (Epift. num Æneas unquam fuit in Italia), and by Mr. Wood (Eflay on the original Genius of Homer), to prove that the defcendants of Æneas reigned in Troy, observes, that notwithstanding the learned ingenuity of a profound, and the plausible arguments of an elegant fcholar, the matter feems ftill too doubtful to warrant contradicting the popular opinion. Some few writers, both ancient and modern, have regarded Homer's account of the siefe of Troy as a mere fiction, or the refult of a poetical imagination. Thus Dion Chrysifollon (Orat. xi.) attempts to prove that the siege and defeftion of Troy by the Greeks is altogether fabulous, and deftitute of any foundation in truth. But his performance has been generally regarded as a mere jeu d'esprit, since the author elsewhere (πίστις ἀκρίβειας, p. 229) disproves that he endeavours to establish in the place before cited. Indeed the siege and capture of Troy are tranafions so well attested, and form so remarkable an epocha in history, that they cannot be justly questioned. Nevertheless the learned Bryant, not long ago, published two pamphlets with a view of refuting the generally received opinions respecting the eXistence of Asiuic Troy, and the authenticity of the leading facts in the history of the Trojan war: but his arguments and conclusions have been examined, and, in our opinion, satisfactorily refuted, by Mr. G. Wakefield, in his "Letters to Jacob Bryant, Esq. concerning his Difertation on the War of Troy," and J. B. S. Morritt, eq. in his "Vindication of Homer, and of the ancient Poets and Historians, who have recorded the Siege and Fall of Troy," as well as the testimonies of Le Chevalier, and other modern travellers. See Olivier's Travels in the Ottoman Empire, &c.

TROY, Epochia of the Destruction of. See EPOCHA.

TROY, FRANCIS DE, in Biography, was born at Toulouse in 1645. He was the son of Nicolas de Troy, a paitener of little celebrity, from whom he received the firit rudiments of design; but he was fent to Paris when young, where he acquired the finefl rudiments of painting, and became a member of the Academy in 1674. He afterwards attached himself to the more lucrative profession of portrait painting, and became celebrated in that line. He was flent by Louis XIV. to the court of Munich, to paint the portrait of Maria-Christiana of Bavaria, afterwards dauphine of France. His own portrait is placed in the gallery of Florence. Among the historical pictures which he produced, one of the most renowned was painted for the church of St. Genevieve, in which the magnificats of Paris were represented in voicing that faint. He died at Paris in 1730.
TROY, John de, was the son of Francis, and born at Paris in 1676. After receiving the instruction of his father in the art of painting until he had made considerable progress, he travelled to Italy, where he studied some years, and soon after his return to Paris he was made a member of the Academy. He was employed by Louis XIV., for whom he painted a series of cartoons for tapestry, representing the history of Esther; and several large allegorical subjects for the Hotel de Ville. The king appointed him director of the French Academy at Rome, where he resided great part of his life; and he acquired himself in the administration of his office in a most respectable manner. His majesty conferred upon him the order of St. Michael, and honoured him with other marks of his particular esteem. He was not less distinguished as a painter of portraits than of history. He died in 1752, aged 76.

Troy, in Geography, a post-township, the capital of Rensselaer county, on the E. bank of the Hudson, six miles above Albany; bounded N. by Lansingburgh, E. by Brunswick, S. by Greenbush, W. by the Hudson, or the county of Albany. The flourishing village of Troy is in this township, from which it has its name. Along the river are extensive flats, and the river-hill is mostly arable. In the S. where the hills approach nearest the river, are some fine streams for mills, and falls of a great height. There are few places on the Hudson, of the same area, that combine more advantages for a populous town. The soil is good, and here are excellent facilities for water-works; and near the head of sloop-navigation on one of the best rivers in America. In 1818, the whole population was 3895, including 89 slaves, and the number of electors was 334.

The village of Troy is agreeably situated on a gravelly plain, on the E. bank of the Hudson, six miles N. of Albany; it is regularly laid out in streets and squares, and contains 660 houses and stores, five places of worship, two banks, the court-house and prison for the county, a market-house, and many other buildings. Many of the houses, though built of wood, are large and elegant, and those of brick form a considerable number of the whole. The streets are wide, with sufficient side-walks, but unpaved. River-street, the principal avenue, extends about a mile along the river, and receives all the other streets that run N. and S. as well as E. and W. in right lines, forming the rear space into perfect squares, and the straight streets are fifty feet wide. The manufactures are considerable, and trade is extensive, as it employs a great number of floors, &c. on the Hudson. In wealth and trade Troy takes the third rank in the state, among its populous towns. The places of worship belong to the Presbyterians, Baptists, Episcopalians, Quakers, and Methodists: and here are several school-houses, as well as two banks, with an aggregate capital of $500,000 dollars. The River-hill, that rises in the rear of Troy, is very appropriately called mount Ida, and its fine sides and summits present elegant sites for building that command an extensive view of Troy and the surrounding country. Troy was incorporated in 1801, and is governed by a president and several trustees.

Troy, a town of Massachusetts, in the county of Bristol, containing 1296 inhabitants.—Alto, a town of Vermont, in the county of Orleans, containing 23 inhabitants.—Allo, a town of the county of Athena, in the district of Ohio, containing 778 inhabitants.—Alto, a township of Tumult county, in the district of Ohio, containing 239 inhabitants.

Troy, White, White of Orleans, or Spanish White, is a name given to a preparation of chalk, which is finely powdered, formed into cakes, and used in the arts. This chalk is found in great abundance at a village called Villeloup, about four leagues from Troyes in France. It is dug out of the earth in small lumps, and after having been exposed to the air, is bruised and reduced into a gross powder, which is puffed through a sieve: when it is perfectly dry, it is diluted with soft water, and formed into a kind of paste, which, being well tempered, is ground very fine in a mill, and used by painters, gilders, &c.: the qualities that particularly recommend that substance are, its being very white, friable, and free from all mixture of adventitious earth and florne. The white of Orleans is prepared at Cavereau, a small village about nine leagues from Orleans, and is reckoned inferior in value to the former. Mem. Acad. Sc. 1754. Ephemeris. Troyennes, an. 1759.

The artificial Troy white, called also Spanish white, is chalk neutralized by the addition of water in which alum is dissolved, and afterwards washed over. It is used by some in water-colours as a white, and may be thus prepared: Take a pound of chalk, and soak it well in water; then wash over all the fine part; and having poured off the first water, add another quantity, in which two ounces of alum are dissolved. Let them stand for a day or two, stirring the chalk once in six or eight hours: wash the chalk again over, till it be rendered perfectly fine, and pour off as much of the water as can be separated from the chalk by that means, taking off the remainder of the dissolved alum, by several renewed quantities of fresh water. After the last water is poured off, put the chalk into a cullender-filter, with a linen cloth over the paper; and, when the moister has been sufficiently drained off from it, lay it out in lumps to dry on a proper board. Handm. to the Arts, vol. i. p. 137.

TROY Weight, anciently called Trone Weight. See Weight.

TROY Pound. See Weight.

TROYES, in Geography, a city of France, and capital of the department of the Aube, on the Seine: before the revolution the capital of Champagne, and the seat of a bishop. It contained fourteen churches, four abbeys, ten convents, a college, and an hospital. The inhabitants carry on a considerable trade in linen, flax, hemp, cotton, fustians, &c. The environs produce grain, legumes, and fruit in abundance; 18 posts N.W. of Dijon. N. lat. 48° 18'. E. long. 4° 10'.

TRSCHITZ, a town of Moravia, in the circle of Olmutz; 10 miles S.S.E. of Olmutz.

TRSEBON. See Wittgenau.

TRSEMESCHNO, a town of the duchy of Warsaw; 10 miles S.E. of Gnefna.

TRUCE, TRENGA, a suspension of arms; or a cession of hostilities between two parties at war, which does not terminate it, but merely suspends its operations.

The word, according to Menage, &c. comes from the Latin trenga, which signifies the name; and which Caenenge derives further, from the German trure, or truce, which signifies truth.

A truce is either particular or universal: by the former, hostilities cease in particular places, as between a town and a besieging army; by the latter, they are to cease generally, and in all places between the belligerent powers. Particular truces may also admit of a distinction with regard to the acts of hostility, or to the persons; that is, it may be agreed to abate for a time from certain hostilities, or two armies may conclude a truce, or suspension of arms, without respect to place. A general truce made for many years, differs from a peace in little else than in leaving the original question of the war undecided, as they found it.

Accordingly
Accordingly, truces are frequently concluded between princes, in order to come to a peace; and truces of many years serve in lieu of treaties of peace between princes, whose differences cannot be finally adjusted.

All truces and pacts of arms are concluded by the authority of the sovereign, who commits some of them to his own immediate person, and to others through the ministry of his generals and officers. The truce binds the contracting parties from the moment of its being concluded; but cannot have the force of a law with regard to subjects on both sides, till it has been solemnly proclaimed. A ship being on the open seas at the time of publishing the truce, meets with a ship of the enemy, and sinks her; as in this case there is no guilt, the ship is not liable to any damage. If the ship has made a capture of the vessel, all the obligation she lies under is to restore it, as not retainable by the truce.

If one of the contracting parties, or any person by his order, or with his consent only, commit any act contrary to the truce, it is an injury to the other contracting party; the truce is dissolved, and the party offended is entitled to take up arms, not only for renewing the operations of the war, but also for revenging the recent injury offered it.

Sometimes a penalty on the infractor of the truce is reciprocally stipulated, and then the truce is not immediately broken on the first infringement; if the party offending submits to the penalty, and repairs the damage, the truce subsists, and the party offended has nothing farther to claim. If an alternative has been settled, that in case of infringement the delinquent shall suffer a certain penalty, or the truce be broken, the party injured may chuse whether he will demand the penalty, or make use of his right to take up arms again.

The time of the truce should be well specified in order to prevent any doubt or dispute from the moment of its beginning to its period. If no term has been specified for the commencement of the truce, as it binds the contracting parties immediately upon its conclusion, it concerns them to cause it to be published immediately, in order to the observance of it; for it becomes binding on the subjects only from the time of its proper publication; and it begins to take effect only from the moment of its publication, unless the agreement be otherwise. The rules that concern a truce during its continuance are such as follow: Each party may do, within its own territories, what it has a right of doing in time of full peace: advantage is not to be taken of doing what could not be done during the hostilities, e.g. continuing the works of a siege, or repairing breaches, and introducing succours. Nothing is to be undertaken in confined places while the truce continues, but every thing is to be left as it was; e.g. if the enemy does not relinquish a port, town, or village, the truce forbids an invasion of it: subjects inclined to revolt against their prince are not to be entertained, much less incited to treason; persons or effects of enemies are not to be seized during the truce. Intercourses may be allowed during a truce. At the expiration of the truce the war is renewed without any fresh declaration. See Vattel’s Law of Nations, book iii. ch. 10.

Truce of God, Tréve de Dieu, is a phrase familiar in the histories of the eleventh century, when the disorders and licences of private wars between lords and families obliged the bishops of France to forbid such violence within certain times, under canonical pain.

Those intervals they called tréve de Dieu, truce de Dieu, q. d. truce of God, a phrase frequent in the councils since that time. The first regulation of this kind, was in a synod held in the diocese of Eliso in Rouffillon, anno 1072, where it was enacted, that, throughout that country, no person should attack his enemy from the hour of none on Saturday, to that of prime on Monday, that Sunday might have its proper honour; that nobody should attack, at any time, a religious priest walking unarmed, nor any person going to church, or returning from the same, or walking with women; that nobody should attack a church, or any house within thirty paces around it. The whole under penalty of excommunication, which, at the end of three months, was converted into an anathema.

These quarrels had prevailed even in the time of Charlemagne, and much more after his death; so that the church found it necessary to interpose. The most early of these interpositions, now extant, is towards the end of the tenth century.

In 990, several bishops assembled in the south of France, and published regulations to restrain the violence and frequency of private wars, ordaining that the transgressor should be excluded from all Christian privileges during his life, and be denied Christian burial after his death. To the same purpose a council was held at Limoges, A.D. 994, and several other councils issued their decrees for restraining the evil. But the authority of councils was insufficient; and, therefore, a bishop of Aquitaine, A.D. 1032, pretended that an angel from heaven had appeared to him with a writing, enjoining men to cease from their hostilities, and be reconciled to each other. Accordingly, a general cessation took place, and lasted for seven years; and a resolution was formed, that no man should attack or molest his adversaries from the evening of Thursday in each week, to the morning of Monday in the week ensuing, the intervening days being peculiarly holy; our Saviour’s passion having happened on one of them, and his resurrection on another. This sudden change was considered as miraculous, and the respite from hostilities subsequent to it was called the true of God.

This from being a regulation in one kingdom became a general law in Christendom, and was confirmed by the authority of the pope, and the violators were subjected to the penalty of excommunication. The council of Toulouges in Rouffillon, A.D. 1041, issued an act, containing all the stipulations required by the truce of God. The nobles, however, disregarding the truce, pursuaded their quarrels without interruption. Toward the end of the twelfth century, a new revelation was pretended, and, in consequence of it, an association formed under the title of the “Brotherhood of God.” At length Philip Augustus, or St. Louis, published an ordinance, A.D. 1245, prohibiting any person to commence hostilities within forty days after the offence which caused the quarrel, and the transgressor was to be tried and punished by the judge as a traitor. This was called the royal truce, and the regulation was productive of good effects. This was further enforced by an ordinance of Philip the Fair, A.D. 1296. See Robertson’s Hist of Charles V. vol. i. p. 335, &c. 8vo.

TRUCHMAN, Dragoman, or Dragman, in the countries of the Levant, an interpreter.

TRUCHMENIANS, or ancient Turkmants, called by the Russians Turkmenian Tartars, are those tribes whose parent stock still nomadizes on the eastern coasts of the Caspian, where their territory extends as far as the lake Aral and Persia. The Truchmennians, in particular, posses on the western side of the Caspian that part of the Caucasian mountains
mountains which stretches from that sea as far as the province Kakhett in of the Georgian state. The generality of the districts have their own common princes; others form particular states, and some are under foreign sovereignty. In the former half of the 18th century a part of these hordes fell under the yoke of the Torgotan prince Ayuka, and on that occasion many Truchmenian families withdrew to the Tartars of Orenburg, Ufa, and Astrakhan. In the year 1770, the remainder of these people, who had not been before under the dominion of the Kalumus, set themselves at liberty, and at present nomadise as free subjects of the Russian empire about the mouth of the Kama. Their number is continually increasing by such as escape from the Kirghizes, and are found though singly among the Tartars of Orenburg and Ufa, yet to no small amount. See Turkomans.

TRUCHTERSHEIM, in Geography, a town of France, in the department of the Lower Rhine; 7 miles W. of Strasbourg.

TRUCKING, in Commerce. See Permutation, Exchange, and Commerce.

TRUCKS, in a Ship, pieces of wood of various shapes, and used for different purposes. Carriage-trucks are cylinders, the breadth or thickness of which is always equal to that of the fide-pieces; but the height of the fide-pieces and diameter of the truck must always depend upon the height of the gun-ports above the deck. Flag-flags-trucks are circular flat pieces of elm, with a small scavage at least on each side. They are fixed by a mortice upon the upper end of flag-flaps, and are used to receive the halels. Parrel-trucks are round balls of elm, or other wood, and have a hole through the middle, in which a rope is reeved, to form the parrels. Seizing-trucks are similar to parrel-trucks, but have a score round the middle, to admit a seizing. They are used to lead ropes through. Shroud-trucks are short cylindrical pieces of elm, &c.; they have a hole through the middle, lengthways, a groove down the side the fize of the shrouds, and a score round the middle to admit a seizing. They are fized to the shrouds to lead ropes through, that they may be more readily found. Vane-trucks are small ornamental pieces of wood like an acorn, &c. and are fixed on the uppermost point of the spindle, above the vane on the mast-head. Their use is to prevent the vane’s unshipping.

Trucks, among Gunners, round pieces of wood, in form of wheels, fixed on the axle-trrees of carriages, to move the ordnance at sea, and sometimes also at land. See Carriage.

Trucks are also a very large kind of wheel-barrows, with high wheels moving on planks, used for conveying stuff down a flight declivity in digging canals.

Truck-Barrows are used in rope-making of different fizes; they have three wheels, and are used to take hauls of yarn from the yarn-house, and remnants of yarn, coils of rope, &c. from the ground to the rope-house.

TRUDENAU, in Geography, a town of Pommeria; 9 miles S.E. of Dantizck.

TRUE, something agreeable to the reality of things, or to truth.

In this sense we say, the true God, the true religion, true gold, &c. in opposition to false or pretended ones.

True Place of a Planet, or Star, in Astronomy. See Place.

True Altitude, Anomaly, Asphm, Horizon, Propofition, Recovery, Ribs, and Suture. See the several articles.

TRUENTUS, Tronto, or Otranto, in Ancient Geography, a river of Italy, in the southern part of P台词, which passed by Asculum. At its mouth was a fortified place called "Castrum Truentinum."

TRUFFLES, formed from truffle, or truffle, of the Latin tuber, or tuberculum, tabula terre, in Natural History, a sort of subterraneous vegetable production, or a kind of mushroom, the characters of which are these: they are of a fungous fleshy ftructure, and are of a roundish figure, growing sometimes single, sometimes many together, and always remaining under ground. See Tuber.

Bradley calls them under-ground edible mushrooms, or Spanish trubbes, and under-ground deer's-balls, or mushrooms.

The ancients, it is evident from their writings, were not acquainted with the sort of truffles which we have in use at present; they describe theirs to have been of a reddish colour, and smooth on the surface; we at present know this kind very well; it is common in Italy, and is called the wild truffle, and disregarded. They had indeed the white African truffle, sometimes brought to them, and held it in great esteem for its flavour. The Romans called it the Lybian tuber, and the Greeks the Cyrenian misy.

Avicenna recommends those truffles as the best, which were of a whitish colour within; and this not being a clear white, he expresseth himself by a word which signifies fand-coloured, alluding to dusky-white sand, in common use at that time.

It is certain that the finest truffles were called by some authors by this epithet arenofs, with a very different meaning, only expressing that they were produced in sandy countries; the European truffles both then and now are, mostly produced in dry ground on the fides of hills; but the Lybian were produced only in the burning sands of that country, and these were therefore called sand-truffles. Serapio tells us, that the belft of all truffles were those produced in sand; and Martial alludes to these, where he describes the finest truffles as breaking the surface of the earth into cracks, and by that means directing people where to search for them. To which purpose Leo Africanus says of the Lybian truffle, that the places where they are may be known by the earth’s being railed into hillocks, and breaking into numerous cracks.

The truffle is most abundantly produced in dry fields of a reddish loamy earth, not too poor, according to Pliny, chiefly after rains and thunders in autumn; and they are found to flourish most near the roots of elms, the ilex, and some other trees. They do not well bear the severity of hard winters, but are usually scarce all the seafon after fuch. The smallest are found about the bignefs of a pea, reddish without and whitish within, and they grow from this fize sometimes to a pound weight, but fuch are not common; what are taken up in the spring are diftinguifhed by their white colour and infipidity to the taste, and are commonly called white truffles; those taken up in autumn are of a variegated colour within, and are called marble truffles; the inner fubflance having swelled extremely and changed colour, and the white part now remaining only in form of a number of pipes or tubules, which feem in many places to run to the extremity, and terminate in the chaps and wrinkles of the back. The greyfih fubflance, which is wrapped up among these tubules, when examined by the microscope, appears to be a transparent parenchyma, composed of little bladders or hollow veffels, in the midft of which may be seen fmall round bodies, which are unquestionably the feeds of the truffle.
What confirms the opinion of their coming from feed is, that there have been truffles discovered in England, and this, at first, only in Northamptonshire, and even only in one place of it, viz. Ruthton, a place flocked with trees formerly brought from Languedoc; and it is only since then, that any truffles have been there observed; whence it is concluded, that the feed of these truffles was brought from France among the roots of the trees brought thence.

These English truffles were first discovered by Dr. Hatton. Dr. Tancred Robinson affirms us, they are the true French truffles, the Italian tortuffi, or tortufoli, and the Spanish turmas de tierra, being not before noted by Mr. Ray as ever known on English ground: he adds, that he has found them thrice at large at Florence, Rome, &c.

Those observed in England are all included in a studded bark or coat, and the inner substance is of the consistence of the fleshly part of a young chefnt, of a palte-colour, a rank or hircine smell, and unfavourably.

When the truffles are arrived at such a degree of maturity as to yield feeds, which is generally in August, they are of a fine high flavour and agreeable smell; and the heat and rains at this season greatly promoting their growth, has been the occasion of the old error, that thunder produced them; after this they continue good till the middle of winter, and sometimes even till March; but those gathered from this time till the end of July are small, and only white, never marbled, nor of their high taste.

If the truffles are not taken up when fully ripe, they always rot and burst; whence it is plain, that they are an annual plant, which lives no longer than till they have perfected their feeds. And if the place where the old ones have rotted and burst be examined, the seeds will be found after some time to have vegetated, and a great number of young truffles to be produced in the place: these, if not destroyed by the frosts, are what in the ensuing spring furnish the younger white truffles.

The truffle is very apt to be pierced and eaten within by a worm, and this, though a damage to the particular truffle, is of some service to the people who make it their business to seek for them: for this worm, after a proper time passed in that state, changes into a chrysalis state in the body of the truffle; whence he soon after comes out, in the shape of a beautiful violet-coloured fly; and wherever these flies are found, they are an indication that there are beds of truffles near, as they are never bred in any other root.

These communicate a bitterness to the whole truffle, and make it unfit for the table; though if the whole be carefully searched into, the part eaten by the worm, and the hole by which it made its way in, will be found to be in reality the only bitter parts, and the rest of the truffle, when these are cut out, as good as ever: but, besides these destroyers, the microscope usually discovers on the surface of the truffle a multitude of other devourers, which are small animalcules, continually eating, and searching the cracks of the bark, as the places where the pulp is most easily come at; these somewhat resemble mites.

The earth that produces truffles rarely affords any other plants, these taking up all the nourishment it can afford: the earth all about them smells very strongly of them, that they are easily found out by it, by the animals which carry their noses near the ground; and those who sought after them soon found the way of using hogs to search them out; but these being a sort of unmanageable animals, dogs were found which would supply their place with more certainty, and much less trouble. Mem. Acad. Scien. Paris, an. 1771.

By a chemical analysis, truffles are found to abound in a volatile alkali salt, mixed with oil, upon which their smell, &c. depend. They never rise out of the ground, but are found, usually, half a foot beneath the surface of it.

Dr. Hatton has observed several little fibres issuing out of some truffles, and infusing themselves within the soil, which, in all probability, do the office of roots. The truffles grow tolerably globular, as receiving their nourishment all around them; which they suck in through the pores of their bark or rind.

They are tenderest and best in the spring, though easiest found in autumn; the wet swelling them, and the thunder and lightning disfiguring them to send forth their scent, so alluring to the swine: hence some of the ancients called them ceramia, q. d. thunder-roots.

The ancients were exceedingly divided as to the use of truffles; some affirming them to be wholesome food, and others pernicious: Avicenna, particularly, will have them to cause apoplexies. For my own part, says M. Lemery, I am of opinion, they have both good and evil effects: they restore and strengthen the stomach, promote the fermen, &c.; but when used too freely, they attenuate and divide the juices immediately, and, by some volatile and exalted principles, occasion great fermentations, &c. though the pepper and salt, with which they are ordinarily eaten, do doubtless contribute greatly to these effects: their rich taste is owing to their not putting forth any fault; in effect, their principles being united, and, as it were, concentrated into a little bulb, must yield a richer and more delicious flavour than if the juices were dispersed by vegetation through the several parts of the common plant. Some count truffles under saffrons, and others mix them in saucis.

In Italy, France, England, &c. they eat them as a great dainty, either in fried slices, with oil, salt, and pepper, or boiled thoroughly in their own broth. The hogs are exceedingly fond of them, and are frequently the means of discovering the places where they are; whence the common people call them fuisse-bread. See MISV. and UPSON.

TRUFFLE-WORMS, a species of fly-worm which is found in truffles, and lives in and feeds on them, till the time it undergoes the common metamorphosis of these creatures, for the production of a fly, like that from the egg of which it was hatched.

They are very small, and have two brown spots, easily distinguishable near their hinder end, which are the two posterior ommata. They are all over white, and very transparent; and may very easily distinguish the two black stalks of their two hooks, with which they tear the substance of the truffle, as the other species do their food: when they have arrived at their full growth, which is usually in a few days, then they leave the truffle, and go to seek some proper place, where they may rest during the time of their transformation; they enter the earth for this purpose, and twelve hours after they have gone into it they are transformed into an egg-shaped shell, of a chefnt-brown, of the same fort with that of the blue flesh-fly.

These are the worms in a manner peculiar to the truffles; but, besides these, they, often furnish nourishment to another species, very common in mushrooms of the ordinary cultivated kind, and which has a yellow body, and a black crustaceous head. Reaumur’s Hist. Inf. vol. IV. p. 374.

TRUFTLORN, in Geography, a town of Bavaria; 13 miles S.S.W. of Vilhofen.

TRUG, or Trug-Corn, Truga Frumenti, in our Antient Cufpons, denotes a measure of wheat. "Tres trug frumenti vel avenæ faciant due buhlers, inter præbendam de Hunderton ecclesia Heref." Ms. de Temp. E. III.

At Lempster, the vicar has trug-corn allowed him for officiating.
TRU

officiating at some chapels of ease; as Stoke and Dockley, within that parish.

TRUC, is also a country word for a milk-tray, or hod to carry mortar in.

TRUHTCHEVSK, in Geography, a town of Ruffia, in the government of Orel, on the Dclina; 80 miles W.S.W. of Orel. N. lat. 52° 35'. E. long. 33° 34'.

TRULLIZATION, in the Ancient Architecture, the art of laying on slats or layers of mortar, gypsum, or the like, with the trowel, in the inside of vaults, ceilings, &c.

TRULLO, in Geography, a small island on the east side of the gulf of Bothnia. N. lat. 63° 54'. E. long. 27°.

TRULLUM, a barbarous word, formed from trulla, cap, and signifying dome; chiefly used in the phrase, council in trullo.

This was a council assembled, in the year 692, against the Monothelites, in the dome of the palace of Constantinople. called trullum; the name of which it has retained. It was also called the quinquextum.

The trullum was properly a hall in the palace of the emperors of Constantinople, where they usually confined of matters of State. This council, held in trullo, was the sixth ecumenical or general council.

TRUMAU, in Geography, a town of Austria; 5 miles E. of Baden.

TRUMBULL, a county of the district of Ohio, bordering on lake Erie, and containing 19 townships and 8671 inhabitants.—Also, a post-town of Connecticut, in the county of Fairfield, containing 1241 inhabitants; 156 miles N.E. of Philadelphia.

TRUMENAU, a town of Prussia, in Oberland; 16 miles S.E. of Marienwerder.

TRUMAN, a town of Hindoostan, in Maravar; 40 miles S.W. of Tanjore. N. lat. 10° 15'. E. long. 78° 45'.

TRUMP, in Ichthyology, a name given by some of the English writers to that species of whale, called by the generality of authors cetes, and balaena major. This is the physeter micros of Linneus, or blunt-headed cachalot. The Dutch call it the pot-whale fis.

TRUMPET, a musical instrument, the most noble of all portable ones of the wind-kind; used chiefly in war, among the cavalry, to direct them in the service. Each troop of cavalry has one. The cords of the trumpet are of crimson, mixed with the colours of the facings of the regiment.

The word is formed from the French trompette. Menage derivates it from the Greek τρομπητα, turbo, a shell anciently used for a trumpet. Du-Cange derivates it from the corrupt Latin trumpa, or the Italian tromba, or trombetta; others from the Celtic trampil, which signifies the same. It is usually made of brass, sometimes of silver, iron, tin, and even wood. Mofes, we read, made two of silver, to be used by the priests (Numb. x.); and Solomon made two hundred like those of Mofes, as we are informed by Josephus (lib. viii.); which shews abundantly the antiquity of that instrument.

As to the invention of the trumpet, some Greek historians ascribe it to the Tyrrhenians; but others, with greater probability, to the Egyptians, from whom it might have been transmitted to the Israelites. The trumpet was not in use among the Greeks at the time of the Trojan war; though it was in common use in the time of Homer. According to Potter (Arch. Grac. vol ii. cap. 9.), before the invention of trumpets, the first signals of battle in primitive wars were lighted torches; to these succeeded shells of fishes, which were founded like trumpets. And when the trumpet became common in military use, it may well be imagined to have served at first only as a rough and noisy signal of battle, like that at present in Abyssinia and New Zealand, and perhaps with only one found. But even when more notes were produced from it, so noisy an instrument must have been an unfit accompaniment for the voice and poetry; so that it is probable the trumpet was the first solo instrument in use among the ancients.

In the 96th Olympiad, before Christ 396, a prize was instituted at the Olympic games for the best performer on the trumpet; and the first person who gained the prize was Timaeus of Elis; and Herodotus of Megara, a famous trumpeter, who lived about the 120th Olympiad, or 300 years before Christ, was victor at the different games of Greece no less than ten, or, as some say, fifteen several times. These performers on the trumpet appear to have been heralds and public criers, who not only gave the signals at the games for the combatants to engage, and announced their successes, but proclaimed peace and war, and sounded signals of sacrifice and solemnities, at religious ceremonies. Burney's Hist. of Mus. vol. i, p. 376.

Among the Romans, there were various instruments of the trumpet kind: as the tuba, cornua, bucina, and litus. The tuba is supposed to have been exactly like our trumpet, widening gradually in a direct line to the orifice; the cornua was bended almost round; and the bucina was somewhat lopsided. The litius, which was almost rightangled, but crooked at the extremity, in the form of the auricular staff, whose name was, a species of clarion, or octave trumpet, made of metal, and extremely loud and thrilling, used for horse, as the straight trumpet was for foot. Horse-distinguishes it from the tuba or trumpet. See Litus.

The tuba, or long trumpet, called by the Hebrews the trumpet of the public, may be seen in several pieces of ancient sculpture at Rome, particularly on the arch of Titius, on Trajan's pillar, and in a baso-relievo at the Capitol, representing the triumph of Marcus Aurelius.

The modern trumpet consists of a mouth-piece, an inch broad, though the bottom be only one-third so much. The pieces which convey the wind are called the brasses; the two places where it is bent, potence; and the canal between the second bend and the extremity, the pavilion; the places where the branches take a sudden, or are folded, the knots; which are five in number, and cover the joints.

If an ellipse (says Dr. Young, Lecture xxxi.) be prolonged without limit, it will become a parabola: hence a parabola is the proper form of the section of a tube, calculated for collecting a found which proceeds from a great distance, into a single point, or for carrying a found nearly in parallel directions to a very distant place. It appears, therefore, that a parabolic conoid is the best form for a hearing-trumpet, and for a speaking-trumpet; but for both purposes the parabola ought to be much elongated, and to consist of a portion of the conoid remote from the vertex; for it is requisite, in order to avoid confusion, that the found should enter the ear in directions confined within certain limits: the voice proceeds also from the mouth without any very considerable divergence, so that the parts of the curve behind the focus would in both cafes be wholly useless. A trumpet of such a shape does not very materially differ from a part of a cone; and conical instruments are found to answer sufficiently well for practice. It appears, however, unnecessary to fuppose, as Mr. Lambert has done, that they differ essentially in principle from parabolic trumpets. It is not yet perfectly decided whether or not a speaking-trumpet has any immediate effect in strengthening the voice, independently of the reflection of sound.
When the sound of the trumpet is well managed, it is of a great compass. Indeed its extent is not strictly determinable; since it reaches as high as the strength of the breath can force it. A good breath will carry it beyond four octaves, which is the limit of the usual keys of spinets and organs.

The usual sounds of the trumpet are represented by the following musical notes.

```
```

Here the loudest sound being denoted by 1, the pitch of the ref, or the number of their respective vibrations, during the time that C vibrates once, will be expressed by the numbers denoting the order of their sounds, 2, 3, 4, 5, &c. The sounds expressed by the musical numbers, that is, by 2, 3, 5, and their composites, which are, 4, 6, 8, 9, 10, 12, 15, 16, are all perfectly in tune; but the sounds expressed by numbers not musical, as 7, 11, 13, 14, are false.

Three of these, viz. B♭, its octave, and A, distinguished by f placed over them, are too flat; and the remaining note F, marked with an S, is too sharp. See Musical Numbers.

The reason of which is, that B♭ ought to be a tone major below C: that is, its pitch to that of C will be as 8 to 9; but the proportion given by the trumpet is as 7 to 8; which being a less proportion than that of 8 to 9, follows that B♭ will be too flat. The same holds true of its octave.

And A being a tone minor above G, it ought to be to G as 10 to 9; but in the trumpet, it is to G as 13 to 12; which being less than the proportion of 10 to 9, it follows that A will be too flat. On the other hand, F ought to be a semitone major above E: that is, F ought to be to E as 16 to 15; but in the trumpet, F is to E as 11 to 10; which being a greater proportion than that of 16 to 15, it follows that F is too high or too sharp.

This system of trumpet-notes is an effectual confusion of those who are for introducing 7, 11, 13, and other primes into music.

In war there are eight principal manners of sounding the trumpet: the first, called the caracollet, used when an army approaches a city, or parries through it in a march. The second the bontefille, used when the army is to decamp, or march; at which time the drums beat a general, when the troopers boot, faddle, and get ready. The third is when they found to horse, when the amble begins to beat, on which the troopers mount; and then to the standard. The fourth is the charge, in the day of battle. The fifth the watch. The sixth is called the double caracollet. The seventh the chamade: and the eighth the retreat. Besides these, there are various flourishes, voluntary, &c. used in rejoicing.

There are also people who blow the trumpet so softly, and draw so delicate a sound from it, that it is used not only in church-music, but even in chamber-music; and it is on this account, that, in the Italian and German music, we frequently find parts entitled tromba prima, or 1a, first trumpet; tromba IIa, segonda IIIa, tenza, second, third trumpet, &c. as being intended to be played with trumpets.

There are two very great defects in the trumpet, observed by Mr. Roberts, in the Philological Transactions for 1692, No. 195. The first is, that it will only perform certain notes within its compass, commonly called trumpet-notes: the second, that though its ordinary compass is from double C-flat to C-flat in alt., yet there are four notes, the 7th, 11th, 13th, and 14th, in this progression, viz. B♭, f, a, and b♭, which are not exact in tune. The same defects are found in the trumpet-marine: and the reason is the same in both. Phil. Trans. Abr. vol. i. p. 667.

Trumpet-Marine, is a musical instrument, consisting of three tables, which form its triangular body. It has a very long neck with one single string, very thick, mounted on a bridge, which is firm on one side, but tremulous on the other. It is struck by a bow with one hand, and with the other the string is pressed or stopped on the neck by the thumb. Plate XXIV. Miscellany, fig. 4.

It is the trembling of the bridge, when struck, that makes it imitate the sound of a trumpet, which it does to that perfection, that it is scarcely possible to distinguish the one from the other. And this is what has given it the denomination of trumpet-marine, though, in propriety, it be a kind of monochord. Of the six divisions marked in the neck of the instrument; the first makes a fifth with the open chord, the second an octave, and so on for the rest, corresponding with the intervals of the military trumpet.

The trumpet-marine has the same defects with the trumpet, viz. that it performs none but trumpet-notes, and some of those either too flat or too sharp. This Mr. Fr. Roberts (ubi supra) accounts for, only premising the common observation of two unison strings; that if one be struck, the other will move; the impulses made on the air by one string setting another in motion, which lies in a disposition to have its vibrations synchronous to them; to which it may be added, that a firing will move, not only at the straining of an unison, but also of that of an 8th or 12th; there being no contrariety in the motions to hinder each other.

Now in the trumpet-marine you do not stop close, as in other instruments, but touch the string gently with your thumb, by which there is a mutual concurrence of the upper and lower parts of the string to produce the sound. Hence it is concluded, that the trumpet-marine yields no musical sound, but when the stop makes the upper part of the string an aliquot part of the remainder, and consequently of the whole; otherwise the vibrations of the parts will stop one another, and make a sound suitable to their motion, altogether confused. Now the aliquot parts, he shews, are the very stops which produce the trumpet-notes.

Trumpet, Harmonical, is an instrument which imitates the sound of a trumpet, and which resembles it in every thing, excepting that it is longer, and confounds of more branches. It is usually called a Jacob's.

Trumpet, Listening or Hearing, is an instrument invented by Joseph Landini, to afford the ear in hearing of persons who speak at a great distance, without the assistance of any speaking-trumpet.

Instruments of this kind, represented in Plate XXIV. Miscellany, fig. 5. and 6. are formed of hollow conical tubes from eight to sixteen inches in length, with a wide mouth from about two to four inches in diameter, and terminating in a small canal,
TRUMPET.

canal, whose aperture is not above one-fourth of an inch in diameter, which is applied to the ear. These tubes are often bent in a manner somewhat resembling the letter C, except that in general the small end is bent much less than the other. The construction of these instruments evidently shows how they contribute to affill the hearing; for the weak and languid pulses of the air being received by the large end of the tube, and reflected several times from its sides in passing to the small end, are condensed, and entering the ear in this condensed state, strike the tympanum with a greater force than they could have done without the intervention of the tube: the found is louder, but less distinct. Hence it appears, that a speaking-trumpet may be applied to the purpose of a hearing-trumpet, by turning the wide end towards the found, and putting the ear to the narrow end.

TRUMPET; Speaking, is a tube from six to fifteen feet long, made of copper or of tin allied-plates, perfectly straight, and with a very large aperture; the mouth-piece being big enough to receive both lips. The edge of the narrow end is generally covered with leather or cloth, in order that it may more effectually prevent the passage of any air between the trumpet and the face of the speaker. The mouth being applied to it, carries the voice to a very great distance, so that it may be heard distinctly a mile, or more; hence its use at sea. A person who is not in the direction of the trumpet will hear the sound of it both weaker and less distinctly, in proportion as he is more or less distant from the direction of the sound; which is the direction straight before the trumpet.

The words which are spoken through a speaking-trumpet may be heard much farther and louder, than not so distinctly, as without the trumpet.

A speaking-trumpet has also been applied to the mouth of a gun or pillar, by which means the explosion has been rendered audible at a vast distance. Such contrivances may be used as signals in certain cases.

The invention of this trumpet is held to be modern, and is commonly ascribed to Sir Samuel Moreland, who called it the tuba Stentorophonica.

Of this instrument an account was published at London in 1671, in a work entitled "Tuba Stentoro-phonica," in which the author relates several experiments made by him with this instrument; the result of which was, that a speaking-trumpet constructed by him, five feet six inches long, twenty-one inches diameter at the greater end, and two inches at the smaller, being tried at Deal castle, was heard at the distance of three miles, the wind blowing from the shore.

But Ath. Kircher seems to have a better title to the invention; for it is certain he had such an instrument before ever Sir S. Moreland thought of his.

Kircher, in his "Phonurgia Nova," published in 1673, says, that the tromba, published last year in England, he invented twenty-four years before, and published in his Mufurgia: he adds, that Jac. Albinus Ghibbifius, and Fr. Eschinardus, ascribe it to him; and that G. Scottus testifies of him, that he had such an instrument in his chamber in the Roman college, with which he could call to, and receive answers from the porter.

Indeed, considering how famed Alexander the Great's tube was, with which he used to speak to his army, and which might be distinctly heard a hundred stadia or fur- longs, it is somewhat strange the moderns should pretend to the invention; the Stentorophonic horn, or tube of Alexander, of which there is a figure preferred in the Vatican, being almost the same with that now in use. See STENTOROPHONIC.

The principle upon which this instrument is constructed is obvious: for as found is stronger in proportion to the density of the air, it must follow, that the voice passing through a tube or trumpet, must be greatly augmented by the conflat reflection and agitation of the air through the length of the tube, by which it is condensed, and its action on the external air greatly increased at its exit from the tube.

In a speaking-trumpet, the sound in one direction is supposed to be increased, not so much by its being prevented to spread all round, as by the reflection from the sides of the trumpet. But as the real action of the instrument, or the true motion of the air through it, is not clearly understood; different persons, according to their particular conceptions of the cause, have recommended peculiar shapes for the construction of such trumpets: some having recommended a conical shape, others that which is formed by the rotation of certain curves round their axes; others, again, have recommended an enlargement or two of the cavity in the length of the trumpet, &c. That which has been more commonly recommended as the bell figure for such trumpets, is generated by the rotation of a parabola about a line parallel to the axis.

In order to estimate the effect of this instrument, let us suppose A B (Plate XXIV. Mifcellany, fig. 7.) to be such a length of tube as admits of reflection of the found, emitted by the speaker, from the side B B; let A F be another length, in which the found or voice is reflected five times by the sides, viz. in B, C, D, E, and F: the found striking the metal tube in B is the same as that at F; but the number of parts forming the periphery of the circle in B is to that in F, as the diameter B B is to the diameter F F; and therefore the intensities with which the parts of the metal will be moved in these peripheries, will be in the inverse ratio of the peripheries, or of the diameters B B, F F. But the parts of the metal move the air contained within the peripheries of the circle, or constituting their respective areas, which are as the figures of the diameters: i.e. the air agitated in B is to that agitated in F, as B B to F F; and consequently, the intensity of the sound found in the tube of the length A B is to that in the length A F, as B B to F F; and the inverse ratio of the diameter B to F: or, the intensity in A B is to that in A F :: FF × BB²; BB × FF; i.e. dividing the last ratio by BB × FF :: BB: FF. But the intensity of the sound increases the more frequently it is reflected from the sides: let then the number of reflections of the found in B be n, in F it will be 5 n, and therefore the whole intensity of the found in B is to that in F as n × B B to 5 n × F F. Consequently, the longer the tube the more numerous will be the reflections, and the greater will be the increase of the found, and the farther it may be heard.

A man speaking through a tube four feet in length, may be understood at the distance of 500 geometrical paces; with a tube of 16 feet, at the distance of 1800 paces; and with a tube 24 feet long, at a greater distance than 2500 geometrical paces.

The found will be also heightened by having the remotest aperture of the tube wide, more than if it were narrow. However, the effect of the tube in magnifying found, either for speaking or hearing, depends principally upon its length: nevertheless some advantage may be derived from its particular form and shape.

Some have proposed the figure which is made by the revolution of a parabola about its axis, as the bell; where the mouth-piece is placed in the focus of the parabola, and conve-
consequently the sonorous rays will be reflected parallel to the axis of the tube. But Mr. Martin observes, that this parallel reflection is by no means essential to the magnifying of sound; on the contrary, it prevents the infinite number of reflections and reciprocations of sound, in which, according to Sir J. Newton, its augmentation principally consists: the augmentation of the impetus of the pulses of air being proportional to the number of repercussions from the sides of the tube, and therefore to its length, and to such a figure as is most productive of them. Hence he infers, that the parabolic trumpet is the most unit of any for this purpose.

He observes, that there is one thing more which contributes to the augmentation of the agitations of air in the tube; viz. the proportion which the several portions of air bear to each other when divided by transverse sections, at very small, but equal distances, from one end of the tube to the other.

Thus, let those several divisions be made at the points \( a, b, c, d, e, \&c. \) (fig. 8.) in which let the right lines \( ak, bl, cm, dn, \&c. \) be taken in geometrical proportion. Then will the portions of air contained between \( B a, a b, b c, c d, \&c. \) be nearly in the same proportion, as being in the same ratio with their bases, when the points of division are indefinitely near together. But it is known, that when any quantity of motion is communicated to a series of elastic bodies, it will receive the greatest augmentation when those bodies are in geometrical proportion. Therefore, since the force of the voice is impelled upon, and gradually propagated through a series of elastic portions of air in a geometrical ratio to each other, it will receive the greatest augmentation possible.

And since by construction \( B a = a b = b c = c d, \&c. \) and \( ak : bl : cm : dn, \&c. \) the points \( k, l, m, n, o, p, q, r, s, \&c. \) will form the logarithmic or logitic curve: whence Mr. Martin concludes, that a trumpet formed by the revolution of this curve about its axis, will augment the sound in a greater degree than any other figured tube whatever.

Caffegran also is of opinion, that an hyperbola, having the axis of the tube for an asymptote, is the best figure for this instrument. Mufchenb. Lit. ad Phil. Nat. tom. ii. p. 296, 410. Martin's Phil. Brit. vol. ii. p. 248, 30 edit.

For other constructions of speaking trumpets by Mr. Conyers, see Phil. Trans. N° 141. for 1678.

Trumpets, Feasts of, in Ecclesiastical History, one of the menstral feasts among the Jews, kept with greater solemnity than the rest, on the first day of the month Tifi. (Numb. xxii. 1—6. Levit. xxiii. 24, 25.) The day of this feast was the new-year's day of the Jews, in which the people were solemnly called to rejoice in a grateful remembrance of God's benefits to them through the last year, which might be intended by blowing the trumpets, as well as to implore his blessings upon them for the ensuing year, which was partly the intention of the sacrifices offered on this day.

The modern Jews have a notion, which they derive from the Mifchna, that on this day God judges all mankind; and therefore, according to Bafnage, their zealots spend, some a whole mouth, others four days, and especially the eve of this feast, in confounding their fins, beating their breasts, and some in lashing their bare backs, by way of penance, in order to procure a favorable judgment on this decisive day.

Trumpet-Fish, Scelopax, in Ichthyology, a fish called also the bellows-fish. In the Linnaean system it is a species of the centrifus; but in the Ariduan, a species of balistes. Pliny calls it ferr. See Centrisus Scelopax.

Trumpet-Flower, in Botany. See Bignonia and Lo-nicer.

Trumpet-Honeysuckle. See Lonicera.

Trumpet-Shell, or Whelk, Buccinum, in Natural History, the name of a large genus of shells, the characters of which are these: they are univalve shells of the form of a trumpet, according to old pictures, with a wide belly, and a large, broad, and elongated mouth; they have a distinct and regular tail, usually long, though sometimes short; they have a hooked beak, and the clavicle is often elevated, though sometimes depressed and contorted. In the Linnaean system, the characters of this genus are, that its animal is a flag, the shell univalve, spiral, and gibbous, the aperture oval, ending in a short canal or gutter. Linnæus enumerates fifty-one species. See Conchology.

The family of the buccinum, when examined ever so strictly, is very large; but according to the general custom of authors, of confounding together several genera under the same name, it is usually made to appear much larger than it really is. Linnæus has comprehended a vast number of shells, by confounding it with the families of the murex and purpura.

It is not indeed peculiar to this author, to have confounded thefe genera: those who went before him have done the same; and Pliny has comprised the buccinum, murex, and purpura, under the general name cerry.

To avoid the general confusion, which arises from not distinguishing the families of the buccinum, murex, purpura, and vis, or screw-shell, it will be proper to observe, that there are regular characters, which distinguish them all, one from another: the characters are these: the buccinum differs from the purpura, in that it has a very long mouth of an oval figure, and has an elevated head; whereas the purpura has a round mouth, and a head somewhat flattened; the tail of the purpura is also usually furrowed, and is shorter than that of the buccinums. The buccinum differs also from the murex in having a longer tail, by the smoothness and variety of colours of its coat, and by having a larger mouth less furnished with teeth; the murex having a smaller and longer-shaped mouth, its surface covered with points or spires, and several teeth.

It is easier to distinguish the buccinum from the screw-shell, as this is always more long and slender than the buccinum; it has also a flat mouth, and has rarely any tail.

The most singular species of the buccinum class, is one that has its mouth turned the contrary way to all other shells: this has been thence called by authors, the unique and the fans pareille.

The buccinum generate in the warm months, and some species of them are seen very frequently remaining in pairs together, upon the rocks defiled by the tide on that occasion. These bee thence supposed to be of a different genus, and have been called buccinum littorale; they are usually found in copulation early in the morning. Rumphius de Telt. Aldrovand. de Telt. lib. iii. cap. 231.

The species of the buccinum being very numerous, they are arranged under several distinct heads, according to certain obvious distinctions, and are as follows: of the buccinum, with long distinct tails and oblong mouths, there are thirteen species; of those with a short tail and a wide mouth, we have twelve species; of those with long erect clivicles, there are
are eleven species; and of those with less erect clavicles, and crooked rostra, there are also eleven species.

It appears from the writings of the ancients, that the famous purple dye, which they obtained from a shell-fish, was not peculiar to any one species; but was found in several of the smaller kinds of Buccinæ; some of which they called marices, from the hollow spines, or long and slender proceffes, which run in different directions from their shells. See Pupíra.

M. Reaumur, when on the coasts of Poitou, found certain eggs of fishës arranged in regular order, and in great numbers, on the rocks and salted banks, which had the fame property with the purple-dyeing liquor of the buccinum; it is not yet known to what particular fish they belong, or what uses they may hereafter be brought to serve. Mem. Acad. Par. 1711.

Pliny seems to derive the name buccinum from buccina, a kind of musical instrument; but it is more probable that instrument took its name from the shell to which it bore resemblance, and of which it might probably have been anciently made. Plin. Hift. Nat. lib. ix. cap. 36. Phil. Tranf. N° 282. p. 1277.

Buccinum lapidifum is a figured stone, shaped like the former, and probably only a petrifaction of the shell above-mentioned.

Ray speaks of a buccinum which was not only petrified, but after petrifaction was converted into a pyrites.

TRUMPERET, in Ornithology, a name given in England to a particular species of pigeon, called by Moore the columba tibicen.

This species is of the middle size of the common pigeon, and made considerably like it; but it is nearly self-colored; is of a mottled black, is feathered down the legs and feet, and is turn-crowned like the nun, and some of the other species; sometimes like the finickin, but much larger: this seems to be the best sort, as being the most melodious. The best character to know them by, is a tuft of feathers growing at the root of the beak; and the larger this tuft is, the more they are esteemed; the reason of their name is, that they imitate in their cooing the sound of the trumpet; but to be often entertained with their melody, it is necessary to feed them frequently with hemp-seed. Moore's Columbarium, P. 45.

Trumperet is also a name given by Mr. Pennant to the phafia of Linneus; because it makes a strong noise with its mouth, which it answers by a different noise from its belly, as if it came from the anus.

TRUMPERET, in a Man of War, one whose office is always to attend the captain's command, and be ready at the entertainment of strangers. In the time of an engagement his proper station is on the poop.

TRUN, in Geography, a town of France, in the department of the Orne; 7 miles N.N.E. of Argentan.

TRUNCATED LEAF, among Botanists. See Leaf.

Truncated Pyramid, or Cone, is one whose top or vertex is cut off by a plane parallel to its base. See Pyramid and Cone.

The word is formed of the Latin truncare, to cut off a part from the whole; whence also truncus, truncum, &c. In Heraldry, they lay truncated.

A truncated cone, or the frustum of that body, is sometimes also called a curtys-cone. See Frustum. See also GAUGHING.

TRUNCATED Roof. See Roof.

TRUNCHEON, of the French trancon, and the Latin truncus, a batton; or a kind of short flaff used by kings, generals, and great officers, as a mark of their command. See Batton.

In our military language, it denotes a flaff of command borne by a general officer.

TRUNCHEON, in Rural Economy, a fort of small framed contrivance with two handles at one end, and two low wheels at the other, which is troubled before the performer using it. It is found convenient in conveying many forts of weighty matters that are in small bulks.

TRUNCHEON, Shot, is an iron shot about seventeen inches long, sharp-pointed at the ends, with a round bowl of lead cast upon it, about an hand-breadth from each end.

TRUNGIBIN, in Natural History, a name given by Rauwolf, Tournefort, and others, to a fort of manna collected from the allagis maurorum, as the common manna is from the aii; and used in the eastern parts of the world as a purge. It is what we call the manna Pericum, and though in itself a very fine and clean kind of manna, yet it is usually so carelessly collected, and mixed with so much filth, that it requires to be given in three times the dose of ours in order to purge. The name seems very evidently to be a corruption of tenenabin or tenenabin of the Arabian, which was the word used by all their authors to express the manna Pericum.

TRUNK, a strong chest or box of a roundish form, at least on the upper side.

TRUNK, in Anatomy, is used for the buttock of the human body, exclusive of the head and limbs.

The trunk is divided into three parts; vis. one common, called the spine, and two proper, viz. the thorax or breast, and the pelvis; which see respectively.

TRUNK, Truce, is also used for the main body of an artery or vein, in contradistinction to the branches and ramifications of it.

The word is particularly applied to certain parts of the aorta and cava.

TRUNK, in Architecture, is used for the fulfl or shaft of a column. Also for that part of the pedestal between the base and the cornice, otherwise called the dye.

TRUNK, in Gardening and Planting, the common name of the boll, body, or principal item in all plants of the tree-kind, and of the stalk in those of all the other sorts. It is that part which rises immediately from the root, and is properly the fock or chief body of the plant or vegetable from the root of which it proceeds, and which ramifications itself into the various branches, branches, buds, leaves, flowers, and fruit which contribute to it, and are the production of it.

The trunks of moss trees, and some other kinds of plants, are of a hard ligneous nature, but in others soft, and in the former are constituted of several different original parts, such as an outermoist coat or thin layer of hard matter of a fibrous quality, the fibres crossing each other in all directions; and the texture of which in some cases is so very thin and clear, that the direction or net-work of them can be seen by holding the substance up against the light. The use of this finely woven tunic or coat is that of defending the true bark of the trunk, or the layer which lies immediately below or underneath it, from the action and injurious effects of the atmospheric air; the protecting and keeping open, by its elastic nature, the fine pores of the exhalating and inhaling syfilids of vessels; the modifying the various impressions which are made by external objects upon the plant or vegetable; the securing and giving protection to the extreme ramifications of the aerial or aqueous vessels; and the covering of the
of the cellular sub stance, in which the several fluids of it are elaborated and prepared.

A true and somewhat inner bark is situated next to the above in the trunk of the tree, and is of a hard texture, but adhering only loosely in trees to the covering which lies below it. In tender plants this covering is often of a soft pulpy nature, and has the denomination of skin.

A still more inner layer, which is often called fiber, forms a third part or covering of the trunk in trees, which is of a membranous and flexible nature, being sometimes altogether separable from the true bark above it, and the white lamina which lies below it. This and the former coat of the trunks in trees are formed of different lamina, as is evident from macerating them in water, by which the cellular substance is destroyed, and the laminated appearance becomes fully displayed. These seem to be parts which are very essential to the life of the plant or vegetable, as in them the chief or principal functions of it are carried on; such, for instance, as those of nutrition, digestion, secretion, and some others. This is plainly proved and shown to be the case, by those trees which have hollow or rotten trunks, the infides being wholly destroyed, and by such plants as are kept in vigour by the perfectly good state of their barks, although the internal parts of their trunks or stalks are wholly rotten and destroyed.

The next part, lamina, or coat, which affords a covering or portion to the trunks in trees, is that which has the title of alburnum or lapwood commonly given to it, and which is situated immediately upon the ligneous or woody part, being most profusely composed of a rather soft white substance that is scarcely perceptible in some sorts of trees, but which in others is hard and perfectly visible, as in those of the oak, elm, and some other kinds. This coat or part forms an imperfect coat of wood in the trunk, not having yet put on the confluence which is proper for perfect wood, the former of which must be arrived at before the latter can be put on. The hardiness and solidity of this part of the trunk are somewhat in proportion to the vigour of growth in the particular tree or plant.

The succeeding or ligneous part, is that which is compose of a compact fibrous substance, disposed in concentric layers, and which surrounds the middle or pithy part of the trunks. It seems as if it were constituted or made up of a conglomerates or collection of dried vascular parts; and in plants of the annual and biennial kinds commonly receives the denomination of flesh.

The fast, middle, or pithy part of the trunks of trees or plants, is that which is situated in and runs through the hearts of them, and which is of a soft vascular nature, differing from that of the cellular textured kind in the perfect whiteness of its colour. It is in the greatest abundance while the trees or plants are in their young state of growth, diminishing in quantity as they advance in age and size, and at length not unfrequently wholly disappearing. Hence it is obviously necessary to them in the beginning of their lives and growths, but not for the continuance of them. It has been suggested as probable, that nature may reserve a superfluous nourishing fluid in this pithy part, if from any cause the young tree or plant should become dry, that then it may be taken up and converted into its food and support.

It must be evident, that what has been said concerning the trunks of trees and plants, must be equally applicable in every respect to the branches and other ramifications, as having the same parts continued from such trunks, of which they in fact form a part in the ways which have already been pointed out.

The trunks of trees and other vegetable productions during their growths are enlarged in their size and thickness throughout their whole lengths, as well as in their heights, and not at any one particular point or part only, as has been fully proved by numerous and repeated trials of various kinds. And in those which are of an annual or one year's growth and duration, the enlargement or expansion in length continues simply until they have protruded and completed their flowers and flowering proics, when the constituent parts of the trunks, limbs or stalks begin to take on a hardened form, and at length, in a gradual manner, become quite dry and rigid.

But in those which are of a perennial nature, or of some years' growth and duration, this enlargement or increase in the trunks, limbs, or stalks, continues until such times as the leaves decay and fall off in the autumnal season, when a germ or bud protrudes and fixes itself in the place which contains the basis or rudiment of a new trunk or stem, that by degrees during the winter months increases in size until the advance of the vernal season, when, throwing off its former covering, it continues the enlargement or increase of the new trunk or stem, in the same manner as the inferior or lower part was augmented during the former year; as in the place where a bud is situated, a swelling-out takes place and extends itself, which is so continued with the new trunk or stem, as fearlessly to leave any mark or veigle where it was. The increase of the trunks or limbs in breadth, however, does not proceed from the dilatation or enlargement of the woody layers of them, but from the generation and production of new laminae or layers, which are every year deposited and added to them, by the vessels which are contained in the barks of them, as has been sufficiently shown by different experiments.

It has been further shown by observation and experience, that the trunks or limbs of trees and some other plants are augmented every year by two woody laminae or layers, but that the size or thickness of them is by no means each year exactly the same, this depending in some measure upon the vigour of growth, age, and state of the climate, whether it is the best or when the rate of growth is the most, the age in the middle degree, and the heat of the situation moderate; for the warmer the summer, the more slender the bark, or outward covering.

The trunks, or limbs and stalks, in trees and plants, are of several different kinds, and distinguished by many different names. Some trees have trunks or limbs which are very short and thick, others have long large clean ones; and some again have them long, small, and clean, others more knotty; some are very crooked, others quite straight; and there are still many further differences in these and several other respects. Trees of the oak, ash, beech, and elm kinds, and the several forts of the fir-tribe, have, in general, the largest, thickest, and cleared trunks or bolts; but there are many other varieties of trees which furnish good useful trunks and limbs, such as the lime, the walnut, the willow, the poplar, the chestnut, &c. in particular situations. The trunks of trees are valuable as timber, according to the particular uses and purposes for which they are designed, and to which they are put. Thus in ship-building, their being properly crooked is a great recommendation; while in many works of carpentry and other descriptions, their being perfectly straight renders them of the most estimation. In fact, their having a straight clean growth is in general a favourable property, and a circumstance which makes them readily disposed of in the markets.

In plants of other kinds the trunks are often small, so as more properly to deserve the title of limbs; and at other times
times they are of a soft and pulpy nature, so as to demand the name of stalks. See Plant, Stalk, and Stem.

In these sorts of plants the stalk is the most common part of trunk or stem, both among small plants of the tree kind, and those of the nature of herbs, as producing and supporting the leaves, flowers, and fruit. The name of stem is given to trunks or stalks of the straw or haulm kind, which are peculiar to grasses and grain, and equally bear the leaves, flowers, and produce or fruit. Frond is a term which is constantly applied to the trunks or stems of plants of the palm and fern kinds or tribes, which are of a compound nature, as being formed of a branch and leaf united or blended together, and not unfrequently the flower and fruit together. The pedicle is a term signifying that part of trunk or flowering-stalk which rises sometimes from the root, but more commonly from the branches, raising or elevating the flowers and fruit, but not the leaves. The peduncle is a term implying that part of trunk or leaf-stalk which bears the leaves only, and not the flowers.

The term fronds is a name which is applied to herbaceous naked stems or trunks which serve to elevate and raise up the fructification only, as in thistles of the hyacinth and daffodil kinds.

The term fronds is applied to that part of trunk or stem which is found in some kinds of fleshy plants, such as those of the common mushroom, and others of the fungus tribe. See these terms respectively.

Trunk is therefore a term which has a very extensive application in the cultivation of garden vegetables of the culinary and flowery ornamental kinds, as well as in planting, as trees of the timber and other sorts, as more fully shown and explained in speaking of stalk, stem, timber, and tree. See thes terms.

Trunk, in Canals, denotes a wooden culvert sometimes made under cauls.

Trunk and Valve, is a trunk of wood laid through the bottom of the bank of a canal, by which water can be let out of the canal, by drawing of the valve at its inner end.

Trunk, in Mining, is a flare or frakes (q. d. stream) with a very small stream or dribble of water, to wash the slime of tin or copper ore, by which the lighter earthy parts are carried off with the water. The operation is called trunking the flumes.

Trunk is also popularly used for the snout of an elephant, by naturalists called the proboscis.

Trunk, in Natural History, is pointed, hollow, slender, and oblong body; joined to the fore-part of the heads of many insects, and serving them for sucking the blood or juices of the animals, or vegetables, on which they feed.

The trunks of flies serve for distinguishing many genera of those little animals, from their different form and other accidents. Some of these are a tube formed all of one simple piece, and others composed of several shorter pieces, nicely joined together; some are thin and as it were flabby, others thick and fleshy; those of some flies are terminated by a foot of broad foot, or by a foot of thick lips; and those of others have no lips, or at least no tenable ones; and others are made in form of a spindle hollowed at the end.

It is often necessary to have recourse to the microscope, to distinguish with nicety and exactness between these.

Without the assistance of glases, however, it is easy to distinguish among the flies of different genera, three different manners of carrying this organ when in a state of imitation. Many flies have trunks which they can shorten, when they are not using them; these are fixed in the fore-

part of the creature's head, where there is a cavity defined to receive them when they are not in use. In many species, this cavity is no more than a mere pinus, or hole, in the fore-part of the head; but in others it is more nicely contrived, the anterior part of the head lengthening itself, and forming a kind of arched vault for its reception. Other flies have trunks which in the time of imitation are turned, or somewhat folded from above downwards: the trunks of bees are of this kind.

There are others also, which have their trunks contained entirely in a sort of case, where they lie straight at length, without being either turned or folded; but they are able to incline them in any direction, in regard to the position of their legs: of this kind are the trunks of the cicadas, gnats, &c.

Among the butterfly clafs, a great number are furnished with a trunk; but there are also a great number that have it not: the fly of the silk-worm, and many, as well larger as smaller kinds, are without this organ. Those species which have it, shew it to the first view; it is placed in the middle of the head, directly between the two eyes. And though in several species it is very long, yet it takes up even in theb but very little room; when it is not in use, it is always rolled up in a spiral form, in the manner of the spring of a watch; and even the shortest of them are thus turned as well as the longest.

There are among the butterflies, some which never settle upon any thing, but are eternally upon the wing, in the manner of swallows: these feed on the wing as those birds do. We often see them buzzing about a flower in the manner of a bee, and in that case they fulfil themselves in the air with their wings, while they unroll their trunk, and thrust its extremity into the flower, to suck from its bottom the honey-dew, which is the common food of them, of the bees, and of many other insects. It has been much disputed, among the curious observers of nature, whether the trunk be originally composed of two parts, or two trunks laid close to another; or whether it were owing to its slender structure, that it was easily split by breaking its parts.

Mr. Bonani was of the first opinion, and Mr. Riget agreed with him at first, but he afterwards became of the contrary sentiment; and thought that they really broke in this splitting, being originally only one; but Réaumur has determined the question in favour of Bonani: having by repeated observations, found them composed of two parallel trunks, nicely and evenly laid sidewise together.

The action of the trunk in sucking is easily seen on giving a piece of sugar to a butterfly that has been kept without food for some days, after its being produced out of the chrysalis; many of the species will in this case feed on the sugar in the same manner that they would on the juices of flowers, and will shew that the use of their rolling up their trunk at times, is the swallowing what they have received into it. The trunks of the several species of butterflies are as different in colour as in shape: some are black, others reddish, many of a cheetin colour; some are also of a pale brown, and some of a beautiful yellow; many of them also are hairy on the under side, and many are smooth. The thicker trunks are always shorter than the flat ones, and have only one canal. Réaumur, Hist. Inf. vol. i. p. 287. 293. 309.

Trunk of Gnats, the instrument by means of which the gnat strikes the flesh, and sucks the blood from animal bodies.

This is a machine well worth an attentive observation. As fine and small as this instrument appears, it is neverthe-

less of a very complex structure. The piercer, or more pro-

Edward has Baker's feen travelling the complex, the is wet is the a introduced, and fuffer magnifying-glas others now vale 2482, upon its neither by will parliament town the be for great creature, obferve to aperture, have part remains trunks trate feeble depth, of trunks they the the other afford mur, Thunk-oo/^ Trunk, the trunk, the cafe the fixed, has not occafion have three. fnure of cyhndric, makes number to this, which is partly doomed animals. of places, is included, and protruMed of a immense animals. of the field afford them a ftuftinent nourishment; for these, like many other of the insect tribes, are partly carnivorous, partly otherwife, and feed equally on flees and vegetables. Reamur, Hift. Infect. vol. iv. p. 586, seq. Baker's Mier.

TRU

These are of two kinds: 1. Such as vegetate by a direct defect, the place of their eruption being sometimes all along the trunk, as in mints, &c. and sometimes only in the umfif point, as in some other plants and trees.

2. Such as neither ascend nor descend, but foout forth at right angles to the trunk, which, therefore, though, as to their office, they are true roots, yet, as to their nature, are a medium between a trunk and a root.

TRUNKED, among Herald, is applied to trees cut off at each end, which are said to be trunked or truncated.

TRUNIONS, or TRUNIONS, of a piece of ordnance, thofe knobs or bunches of metal in a gun, mortar, or howitzer, which project from the piece, and bear it upon the cheeks of the carriage.

TRU-NNI-ON Ring, is a ring about a cannon, next before the trunnions.

TRU-NI-ON Plates, are two plates in travelling carriages, mortars, and howitzers, which cover the upper parts of the fide-pieces, and go under the trunnions.

TRUN, in Geography, a town of the Grifons, where the independence of the Grey League was firft rafied, and an alliance concluded between the chiefs and the communities, on the Rhine; 7 miles W. of Hantz.

TRUNTZ, a town of Pruffia, in Ermeland; 9 miles N.E. of Elbing.

TRURO, a large market-town and borough in the western division of the hundred of Powder, and county of Cornwall, England; is situated in a vale at the conflux of the two small rivers Kenwyn and St. Allen, 22 miles S.S.W. from Bodmin, 46 miles S.W. by S. from Launcelton, and 257 miles W.S.W. from London. It is called in ancient records Trevery, Treraun, and Truro-burgh. It was one of the decayed market-towns for the repairs of which an act of parliament was paffed in 1549; but it has now become a place of considerable trade. Its central situation with refpect to the commerce and chief products of the county, its improved and still improving flate, the regularity and handfome appearance of the buildings, with its increafing population, pufh the title to pre-eminence among the towns of Cornwall. Leland fays, "This is a caftle, a quarter of a mile by well out of Truro longing to the criles of Corawale, now clene down. The fite therof is now ufed for a ftoating and playing place, out of the town of Truro." This caftle is not mentioned in Domesday book, and was therefore erected after the Conquett. William of Worceftre fpeaks of it as being in ruins in the time of Edward IV. It stood on an eminence on the more westerly fide of the two currents: its only remains are a wafe area, and an artificial mount or keep, the earth of which is daily decreasing by its being applied to other purpofes. From the increafe of the buildings from the time of Leland, the fite is now included within the town, which appears to have derived its origin from the caftle; but was foon nearly coeval with it, that it is noticed as exifiting within a century after the Conquett, and as having a charter in the reign of Henry I. The corporation of Truro, as eftablifhed by a charter of queen Elizabeth, bearing date 1589, confifs of a mayor, four aldermen, and twenty capital burgofies. In thefe twenty-five perfun, the right of electing two members to parliament (poffefled by the borough ever since the reign of Edward I.) is vefted; though the number of inhabitants, as aftarined by the population return of the year 1811, is 2482, when the houses were enumerated at 400. The burgoftes of Truro have many privileges by grant of their ancient lords; and the mayor's jurifdiction extends even over Falmouth. This laft mentioned privilege, which is said to have been granted

Vol. XXXVI.
by king John, and is recorded in the herald’s visitation of 1629, was lost in the early part of the last century; it having been then contested by, and decided in favour of, the inhabitants of Falmouth, who now enjoy the jurisdiction of their own port. This town is situated in the three parishes of St. Mary, St. Clement, and Kenwyn. St. Mary’s church is a spacious edifice, of the architecture which prevailed in England about the reign of Henry VIII. It consists of two aisles of equal size, and a smaller one; and has a modern fleecy, which does not correspond with the body of the church. In the windows are several fragments of painted glass; and in one of them, on the south side, is the date 1518, the year when the church was erected. Here are seven meeting-houses for the accommodation of dissenters of various denominations. Truro is one of the original coinage towns; and here only, and at Penzance, with the exception of a few times at Helston for the convenience of the merchants, have the coinages of late years taken place. Most of the tin is coined here, and more is exported hence than from any port in the county. The blocks lie in heaps about the streets, and are left entirely unguarded, as their great weight renders it difficult to remove them without immediate detection. Here is a coinage-hall; and Hals, in his Parochial History, mentions the town polishing one so early as king John’s reign. Here is also a manufactory for converting block-tin into bars and ingots: the weight of the former is from eight ounces to one pound; that of the latter, from sixty to seventy pounds each. The bars are exported to the Mediterranean and Baltic; the ingots are sent to the East Indies. Considerable quantities of copper-ore are exported from this town to Wales. A manufactory for carpets has been recently established, which is carried on with great success, and forms a material addition to the export trade. The improvements made in Truro of late years have been very considerable, and particularly since the year 1794, when an act of parliament was passed for lighting and paving the town. The principal street was formerly contracted, and disfigured by a row of houses stretching along the middle from the coinage-hall to the market-place. These have been removed, and a spacious opening formed, from which a new street is built, diverging from the other at right angles. A literary society and a county library were established here in the year 1792. A theatre and assembly-room have also been erected in that part of the town called the High-Crofts: and on the 12th of August, 1799, a county infirmary, a spacious stone building, was opened in Kenwyn parish, under the patronage of the prince of Wales. A free grammar-school was founded at an early period: and there are two exhibitions, of 30l. per annum, at Exeter college, Oxford, for scholars of Truro school, founded by the trustees of the charitable bequests of the Rev. St. John Eliot, who died in 1760. A central school on Dr. Bell’s plan was established in 1813, in which there are 130 boys and 70 girls. An hospital for ten poor housekeepers in St. Mary’s parish was built in 1632, pursuant to the will of Mr. Henry Williams, who endowed it with lands which now produce 120l. per annum. The corporation make widows the exclusive objects of this charity, and allow them a pension of four shillings each per week and clothes. The market at Truro is held by subscription: the claim to it having been certified and allowed in the reign of Edward 1. Here are now two market-days, Wednesday and Saturday, both well supplied with butcher’s meat, fish, and other provisions. A corn-market is also held on Wednesday. Four annual fairs are likewise kept for cattle. About a mile from Truro, on the road to Falmouth, at Calinnick, is a large smelting-house for tin. It consists of ten reverberatory furnaces, six feet in height, and about twelve feet in length, each. Culm-coal is used as the flux, in the proportion of about one-eighth to the ore, of which nearly 600 cwt. is smelted within six hours, and yields about 330 cwt. of tin.—Beauties of England and Wales, vol. ii. Cornwall; by J. Britton and E. W. Brayley, 1802. Lysons’s Magna Britannia, vol. iii. 1814.

TRURO, a town of Nova Scotia; 40 miles N. of Halifax.—Allo, a town of Barnstable county, in the state of Massachusetts, on the E. side of Cape Cod bay, containing 1200 inhabitants. N. lat. 42° 11′. W. long. 70° 2′.

—Allo, a township of Franklin county, in the district of Ohio, containing 672 inhabitants.

TRUSAM, a river which rises in the Brisgau, passes by Friburgh, &c. and joins the Eltz, near Riegel.

TRUSS, TRUSSE, a bundle, or a certain quantity of hay, straw, &c.

A truss of hay is to contain fifty-six pounds, or half a hundred weight: thirty-six trusses make a load.

In June, July, and August, a truss of new hay must weigh sixty pounds. The truss of straw is likewise to weigh a certain weight, but this is various, in some degree, in different places. In other matters, the trusses differ greatly according to custom or other circumstances.

A truss of forage is as much as a trooper can carry on his horse’s crupper.

TRUSS, or Bunch, among Florists, is a term applied to the tuft of flowers which is formed at the top of the main stem or stalk of some plants of that kind, and which, in the auricula and polyanthus fort, consists of a small bunch of flowers, to which the title of pips or blossoms is given, and which are supported by as many little foot-lands, proceeding from out of the top part of the main stem: some of the properties of which are these: the pips or blossoms, which are the flower parts, consist of the disk or outer rim, the eye or inner rim, the tube or pipe, and the thrum, chives, or apices. The pips or blossoms, of these kinds of flowers, should always be rich, and of a lively good colour or colours, as such as may immediately strike and captivate the mind of the beholder with the idea of real beauty; as this is the property which is the foundation of all the others in these sorts of flower-plants: consequently, where the colours of the flowers in them have a faint or dead appearance, or are of an ordinary and inelegant tinge or hue, they are good for nothing, even though the whole of their other properties should be the most excellent.

In all the painted or striped flowers of these sorts, the colours should constantly be so equally distributed over the rim or disk, as that there may be an equal uniformity amidst the whole variety; in order that, upon the whole, the fight may not be in the leaf disfracted or offended with any sort of disproportion, or perceive one side to be of a brighter or darker hue or shade than that of another. The edges of the rims should be round, or at least to near it, that the indentures may bear but a small proportion to the disk; as when these are deep, and the points of the petals stand in somewhat the far-form, greatly divided, the largeness of the vacancies will affect the fight with an evident deficiency: and the edge is still worse in those pips or blossoms which are liable to run out into a greater breadth on one side of the eye than the other; such irregularities and disproporions are very disturbing in these flowers. The eye, which is the iris or little ring that environs the tube or pipe, and which ought to be formed in the manner of the disk, either perfectly or nearly round, and of an entire clear colour; and of a snowy or pure white, in all painted or striped flowers; and of either a white, bright yellow, or good straw-
TRUSS.

Black colour, in self or plain-coloured flowers. The farina, mealy, or dusty property should also be fine; as, if coarse, it will be unpleasant to the eye, or in appearance. The eye of the flower should appear entire, though not separate from the disk or rim; that is, it should be blended with or shaded into it in such a manner, as not to occasion any indistinctness between the edges of the one and the other: as, in flowers where these two properties of the eye are imperfect, the lively contrast or difference between the rim and the eye, which otherwise reciprocally display and show each other off to the belt and most advantage, is, in a great measure, lost and destroyed. The face of the whole pip, rim, and eye, should likewise be so opened as to lie perfectly or very nearly flat; as when it either inclines inward, which is termed cupping, or throws itself backwards, as in particular flowers, such as the martagon lily, the true form as well as colours are in some degree obscured by being covered and put out of sight. See TUBE and TURBON.

The length of the pedicles which support the pips or blossoms in the trufis, should be proportioned to the number and size of the pips which they buttress; as, if they be very long, and the pips small, there will be unsteadily vacancies in the trufis; or if they be short, and the blossoms many and large, they will be too much crowded together, so that neither the colours can be fully viewed, nor the other properties of the pips be displayed. The pedicles should also be sufficiently elastic, firm, and strong, in order that they may not droop by the weight of the pips or blossoms, and fall loose and in a disarranged manner, but buttress the trufis firmly and closely, without either vacancy or crowding. They should, too, be nearly all of the same length, so that the pips may stand together at the same height, and form a regular umbel, or rather corymb, which is the formal perfection of the trufis. The pips should also be nearly of the same size and colour, so as not to be readily distinguished from each other; as otherwise the unity and harmony of the trufis will be destroyed, and though ever so plentifully formed, would appear as if taken from different sorts of these flowers. P. A plant of these kinds should blow freely, and expand all its pips or blossoms at the same time; as, by this means, the colours in them all will appear equally fresh and lively; whereas in those which do not blow some of the pips until others have puffed their prime, the whole appearance of the trufis falls much short of that beauty which would otherwise be conspicuous.

The item or stalk which supports the trufis, and which is mostly termed the main stalk, should be elastic, straight, and sufficiently strong for bearing it without drooping. It is also an excellency in it to be erect and lofty, as thereby the trufis, and of course the whole flower, will make a more stately, commanding, and handsome appearance.

Such plants of these kinds as have these properties or qualities can hardly fail to please the curious florist; yet as, on the one hand, some plants may be somewhat deficient in several particulars of less consideration, and still be juicily deemed fine and valuable flowers; so, on the other hand, it will be an additional excellence, in such as have all these properties, that they naturally stand long in bloom, and wear their colours without alteration or fading in any way. The trufis or bunch is probably so named by florists, in consequence of its having naturally something of that appearance about it.

TRUSS, in the language of Surgery, is a particular sort of bandage, or apparatus, employed in cases of ruptures, (see HERNIA,) for the purpose of keeping up the reduced parts, and hindering a fresh protrusion. It must of course be adapted to the situation and nature of the rupture. As a truf is of all the inventions of surgery one of the most important, and highly essential to the health of a large portion of the human race, the most advantageous modes of constructing and applying it are objects which it is as much the duty of the surgeon to know something about, as about any other means of curing or lessening the danger of so serious and common a disease as a rupture.

A truf which fulfils its intention properly, should compress the neck of the hernial sac, and the ring or external opening of the hernia, in such a manner, that a protrusion of any of the contents of the abdomen will be prevented with complete security. Hence, it is the indispensable quality of a good truf, first, to make effectual and equal pressure on the parts indicated, without causing pain or inconvenience to the patient; secondly, not easily to flip out of its right situation, in the varying motions and positions of the body.

The different kinds of hernial bandages may be reduced to the two classes of elastic and inelastic. The latter are composed of leather, satn, dimity, or similar materials. These cannot be at all depended on, and should, therefore, be entirely banished from surgery. Since (as Mr. Lawrence has remarked) the size of the abdomen varies according to the different states of the viscera, and to the motions of its parietes in respiration, a non-elastic bandage must vary constantly in its degree of tightness, and keep up either too great or too little pressure. The omentum, or intestine, easily slips out when the opening is not exactly closed, and the patient who wears such a bandage, must be in a state of constant insecurity. Those who lead an active life, or are obliged to use laborious exertions, will be more particularly exposed to risk. If the patient, after experiencing these defects, endeavours to remedy them by drawing the bandage tighter, he may confine the viscera, but he produces other inconveniences. The increased pressure injures the peritoneal chord, and may affect the testicle: the integuments become red, painful, and excoriated; and the bandage must be entirely laid aside, until the parts have recovered. Richter has often seen painful tumefaction of the testicle, hydrocele, and even cirrhosis, produced from this cause, and entirely disfigured by the employment of a proper truf. Traité des Hernies, p. 24.

He also law the pad of a non-elastic bandage excite, in the region of the abdominal ring, a considerable inflammation, which terminated after a few days in suppuration. The hernia never appeared again after the cure of the abscess. The inflammation had extended to the neck of the sac, and obliterated that part. Lawrence on Ruptures, edit. iii. p. 69, 79.

Every truf consists of a pad, for compressing the ring or aperture through which the hernia protrudes, and of another piece, which surrounds the abdomen. To these are sometimes added a thigh-flap, which passes under the perineum, and a cephalic, which is applied over the shoulder. The use of the two latter appendages is to keep the pad from slipping up or down, an inconvenience which it is difficult to prevent in certain cases, unless a cephalic or thigh-flap be worn. In the inelastic trufis, the piece which extends round the body, is a simple girdle or band; but in every elastic trufis, this part is constructed with a spring, which is the most important thing of the whole instrument.

Elastic trufis, when they are well made, and fit properly, are to be preferred to the inelastic, in regard to security. They yield to the varying motions of the body; are less liable to flip off the part upon which they are intended to pref;
The valuable properties of this instrument (says Mr. Lawrence) depend entirely on its spring, which keeps the pad constantly prefixed against the hernial opening; and gives it a power of reaction, by which an uniform pressure is maintained under varying attitudes. This elasticity can be attained only by the employment of steel. In the first attempts at procuring something better than the non-elastic bandages, iron was used; and the instruments fabricated by Blegny at Paris were constructed of this metal. It is obviously inadequate to accomplish the ends which we have in view, in treating herniae; yet it is only at a comparatively recent period that its defects have been discovered. Arnaud, whose writings contain much valuable information on this subject, recommends for the spring of a truss a mixture of malleable iron and steel, so that the instrument may be moulded by the hand to any particular shape which the patient may require; and he is followed on this point even by Richter. A truss which admits of such management, must in effect be exposed more or less to the objections which apply to the non-elastic bandage; and the only material which possesses the requisite qualities of firmness and elasticity, is well-tempered steel.

The most important part, then, of an elastic truss, consists of a flat and narrow piece of steel, adapted to the form of the body, and called the spring. This plate is attached to the back of the trunk, terminates anteriorly on an expanded plate of iron, to which it is riveted, placed over the mouth of the face, and extends behind to various distances beyond the spine. The posterior surface of the plate is furnished with a convex cushion, termed the pad, and adapted in form and size to the opening which it is designed to close. The spring is covered externally with leather, and that it may fit easily on the body, its inner face is lined with some soft substance; a strong strap, extending from its posterior end, passes round the found side of the trunk, and is fastened to a hook on the front of the plate. This strap, being perforated by several holes, enables the patient to tighten or loosen the truss at pleasure.” Lawrence on Ruptures, p. 71, 72. edit. 3d.

In a note, this gentleman observes, that the spring of the truss has commonly been a semicircle, with the posterior end resting on the spine. Camper proposed to carry it round to the anterior superior spine of the ilium on the found side; and Scarpa very much approves the plan. Trusses of this form fit with a firmness which cannot be given to the others by tightening the strap. They keep up the rupture much better than a stronger spring of the other kind. Hare-skin, with the hair outwards, is considered the best article for covering the spring, with a view of keeping it from the ill effects of the perspiration.

When it is necessary to make a strong compression, as in large old ruptures, and in persons who cannot avoid labour and exercises, the elastic spring should be made accordingly thicker and broader. But an object of the first-rate importance is to make the spring press equally upon every point of the body which it touches. This is what demands the earnest attention both of the surgeon and the instrument-maker, especially as the hips of some individuals are flat and narrow, while those of other persons are broad and prominent. A thick, flexible, metallic wire, accurately applied round the pelvis, will serve to take the measure and proper shape of the spring, which may afterwards be altered a little, if found necessary. The wire, however, should be somewhat longer, on account of the length of the spring being diminished in the construction of it. Callifen disperses the springs which extend quite round to the opposite side; but he thinks a certain bend of the spring downward, near the pad, is useful in trusses for inguinal ruptures, as, by this means, the part of the instrument which goes round the pelvis can be made to fit more closely, and is placed at a convenient distance from the trochanter, so as to be less liable to derangement. The neck of a truss for a femoral hernia should be shorter, and, in general, the instrument requires in this case the employment of a thigh-strap to keep the pad from slipping into the bend of the groin.

The pad of a truss is frequently composed of a piece of cork covered with leather, with the intervention of some wool or horse-hair. Proposals have been made to use pads which are formed of bladder or elastic gum, filled with air, but we know nothing of the real merits of such contrivances, nor should we expect them to answer. Callifen gives a general preference to pads which have a flat and not a conical surface, which last form not only produces less equal pressure, but is more liable to slip. The shape and size of the pad should of course correspond to the figure and dimensions of the ring, or opening, at which the rupture protrudes. In the inguinal hernia, the pad should be long and oblique; in the crural, shorter; in the umbilical, round; and in the ventral, for the most part, oval. In large old ruptures, the pad should be large accordingly; and in small recent cases, it should be small in proportion. For fat subjects, the pad should be firm and prominent; but for thin persons, it should be flatter and softer. Nay, it has even been found sometimes necessary to accommodate the shape of the pad to the various degrees of convexity or flatness of the os pubis.

Trusses are sometimes fabricated with a pad moveable on the spring, instead of being riveted to it. This may be inclined upwards or downwards, according to the form of the abdomen; and it is retained at the desired point by a spring fitting into the teeth of a rack. In others, the plate contains a screw, by which the cushion is pulled farther inward, or allowed to recede, at pleasure. Although there cannot be a doubt that some of these inventions possess considerable merit, and, in certain instances, superiorly useful, it must be confessed that, in general, their utility is not so much greater than that of common pads, as to make amends for the want of simplicity and the increase of expense. We should be sorry, however, to say anything that would unfairly discourage all such ingenious endeavours to improve so difficult an instrument to make perfect as a truss; and we therefore repeat our belief, that there are particular cases, in which pads, with racks, screws, springs, &c. may be employed with great advantage.

Notwithstanding every care, sometimes even elastic trusses cannot be hindered from slipping away from the part which they are designed to compress. Sometimes they slip downwards, which in fat subjects is generally caused by the projection of the abdomen. Occasionally, the fault consists in the instrument becoming displaced in the direction upwards, which mostly happens in thin persons, and is produced by the flatness of the abdomen. In the first case, the displacement is to be prevented by the use of an elastic scapulary; in the second, the slipping of the pad upwards is to be prevented by the employment of a thigh-strap.

When a patient is afflicted with a rupture on each side, the two protrusions may be very well kept up by means of a single truss, made with two pads, which are joined together, at the exact distance of the rings from each other,
by a piece of felt, applied over the convexity of the symphysis of the pubes, and proportioned in length to the space between the two openings through which the viscera descend. In such cases, however, it is absolutely necessary to have the spring stronger, than if there were only one rupture. The truss should also be made to put on that side of the body, upon which the hernia, most difficult to retain, is situated. There are some practitioners, who give the preference to the use of two single trusses, joined together in front and behind with suitable straps.

With respect to the application and use of trusses, the following instructions seem to merit attention.

1. A truss should never be first applied, or changed, except when the patient is in the horizontal posture, and it is known with certainty that all the contents of the rupture are completely reduced.

2. The first applications of a truss should always be made under the superintendence of the surgeon himself; and care should be taken to put on the instrument in such a manner, that the lower third of the pad will comprefs the neck of the hernial sac against the os pubis, while the upper portion will comprefs the abdominal ring. The surgeon should also make the patient acquainted with the right manner of applying the truss; the principles on which it keeps up the bowels, and affords a chance of a radical cure; the requisite cautions to be observed, &c. When a patient first begins to wear a truss, he should be particularly careful not to be guilty of any imprudent exertions, and it behoves him to observe most attentively, that the instrument does not slip from its proper situation. It will also be necessary for him to pay attention to the instrument being neither too tight, nor too loose.

3. The patient ought to be provided with at least two trusses, which should be changed every morning in bed. In order to save the trusses, especially in fat persons, who periphrize a great deal, it is a good plan to lay a soft piece of linen under the pad.

4. An uneasiness about the ring, which always gives rise to a suspicion that a portion of intestine, or omentum, is protruded, makes it proper to take off the trusses, carefully examine the parts, and reduce them if they have defected.

5. When the skin is excoriated by the trusses, the part may be cured by sprinkling upon it the powder of acetie of lead, fuller's-earth, &c. and washing the part with the faturnine lotion. It will also be right to protect the excoriated place with a piece of linen put under the trusses.

6. When the preflure of the trusses excites affections and swellings of the spermatic cord and testicle, either the thighstrap must be relaxed, or the lower part of the pad made less prominent.

7. In children a very tight truss is altogether hurtful, and may be the cause of various curvatures and deformities; but the erroneous opinion, that they ought not to wear a spring truss, we have noticed in another place. See Hernia.

8. Sometimes very old large ruptures cannot be securely kept up by means of a truss, and even when the pad is extremely large, not more success is often experienced. Should they be retained, it may happen that the ill effects of the compression will be felt in the strained state of the cavity of the abdomen, or in the speedy appearance of another hernial tumour on the opposite side. Ruptures totally irreducible, and various disorders of the testicle and cord, do not admit of the use of a steel truss. Whoever wears a truss, should be careful to employ it day and night, without interruption, so that there may be no opportunity for the hernia to protrude again. If, under the employment of a truss, the rupture once defends again, either a strangulation happens from the narrowness of the neck of the sac; or, at all events, the hope of a radical cure, which may have been entertained for months and years, vanishes in a moment. For experience has put it beyond all doubt, that, by the continual unremitting use of a truss, and the steady retention of the contents of the hernia, the neck of the hernial sac, and the ring, may be gradually leffened in diameter, until they are entirely closed, and a radical cure of the rupture effected. This is more frequently observed in young subjects; seldom in adults; and hardly ever in persons of advanced years. But trusses must be worn a long while, nor should the patient venture to lay aside their use till after many cautious attempts; beginning the experiment at first only in the night-time, and not making it in the day, till after a considerable period from the time when he first thinks himself safe. The longer and more attentively a truss is worn, the greater is the hope of a radical cure. Callifen, Syll add. Chir. Hod. tom. ii.

Representations of various kinds of trusses may be seen in Plate IX. Surgical Plates. Fig. 1. exhibits a common truss. Fig. 2. the spring terminating in front in the expanded plate of metal, often termed the head of the truss. Fig. 3. represents a truss for a double rupture, with two pads affixed to one spring, and furnished with two thigh-strap{s}, which, in each a cafe, would be almost indispensible. Fig. 4. exhibits Dr. Hulme's palm truss, so named by its inventor, from its acting continually like the pressure of a hand. Its particularity consists in its springs not being placed in that part of the truss which goes round the body, but in thePad itself; where there are three spiral springs. A full description of this truss may be found in the Transactions of the Medical Society of London; but as the construction of this instrument does not make much provision against the flipping and displacement of the pad, it can afford very little security to the patient, and does not therefore appear to us to be deserving of recommendation. Fig. 5. represents a very good ordinary truss, made by Mr. Whitford, a surgeon's instrument-maker in Smithfield. Fig. 6. exhibits Mr. Salmon's patent truss, with the additional springs, all three of which together are capable of exerting a force equal to nine pounds weight. A is the spring, made so as to exert a positive force on the cushion at each end. At the front and back ends are different holes, to which the plates and cushions may be instantly shifted by the wearer, so as to admit of being correctly accommodated to the parts. B, C, the additional springs detached, either, or both, of which may be added, so as to increase the power of the truss, if requisite. These springs are simply flipped into a loose leather or other case. D, the front plate with its cushion. This plate will apply to either of the holes in the spring, and is kept on the ruptured part by the pin, on which it turns in all directions; so that whatever be the shape or inclination of the body, the plate adapts itself to such changes, not being confined in its direction by any power of the spring. The cushions are simple cafes stuffed with the softest materials. E, the back plate and cushion. F F a strap is to be used, if occasion require, to prevent a forcible removal of the cushions.

Fig. 7. represents a fection of the pelvis, round which the truss is to be applied. Mr. Salmon contends, that if the spring only passed round to the point diametrically opposite that from which it commenced, it would not remain stationary, as both extremities would rest on planes inclined to their action. For a full explanation of this figure, however,
ever, we must refer to Mr. Salmon’s Mechanical Analysis of Truffles.

Fig. 8. a trufs for a navel-rupture, invented by the late Mr. Marrifon, of Leeds. It conflits of two pieces of thin clafic fleee, which surround the fides of the abdomen, and nearly meet behind. At their anterior extremity they form conjointly an oval ring, to one fide of which is//fastened a fpring of fleee, of the form reprefented. At the end of this fpring is placed the pad, or bolifer, that prefides upon the hernia. By the elefticity of this fpring, the hernia is reprefented in every pofiren of the body, and is thereby con-ftantly retained within the abdomen. A piece of calico, or jean, is fastened to each fide of the oval ring, having a con-tinued loop at its edge, through which a piece of tape is put, that may be tied behind the body.

When there is a great projection of the abdomen below the navel, as is often the cafe in women who have borne many children, the oval ring (epecially if made wide) is thrown into an oblique direfireion, and then does not give the pad so true a bearing upon the hernia. To prevent this inconvenient, Mr. Marrifon made the lower bow of the ring to project more than the upper one; and instead of the calico skirt surrounding the ring, he ufed a belt faftened to the lower bow only, as is reprefented in Mr. A. Cooper’s work on hernia, part ii. plate 9. fig. 6.

Afterwards Mr. Marrifon uſually made his trufles with the lower bow of the ring only; forming this to pojet fo as to fuit the pendulous flate of the abdomen. To the round end of the fpring, which supports the pad, he affixed a frap, in which were contained spiral wires, for the purpofe of regulating the degree of prefire upon the hernia. In a flate abdomen he invented the pofiren of the trufs, dif-recting the bow to be placed above the navel.

Fig. 9. reprefents a new trufs for a navel or ventral rupture, invented by James Execland, trufs-maker at Leeds. The trufs consists of two femicircular bows of bow; of which, at its anterior extremity, is faftened by a diftinct brafs hinge, placed vertically, to the outer fide of an inter-mEDIATE plate of block-tin. This plate is somewhat con-cave on its inner fide. The concavity is filled with a piece of blanket, which is covered with leather. This lining causeds the leather covering to project a little; but in so small a degree, that when the concave fide of the plate is ap-plied to the abdomen, the prefire of the bows brings the rim of the plate, in every part of its circumference, into contact with the skin.

The pofterior part of each bow, for about an inch and a half from its extremity, is turned backward, fo as to form a flat surface, where it refts upon the back of the patient. To the inner fide of this flattened part is fewed a soft leather fuffion, lined with blanket, to prevent the patient from being hurt by the ends of the bows.

A frap of leather is fewed to the covering of the trufs, near the pofterior end of one bow; and a buckle is fixed, in like manner, near the end of the oppofite bow, but refting upon it. By means of this frap, the patient can keep the ends of the bows steady, without being hurt by the buckle. See Hey’s Practical Observations in Surgery.

Fig. 10. fhews a back view of Execland’s navel trufs, and of Salmon’s patent inguinal trufs, applied.

Fig. 11. reprefents a front view of the fame instruments applied.

Besides trufles for ruptures, there are alfo trufles for an other purpofe, namely, supporting the ferotum in cafes of hydrocele, inflamed teftile, farcocele, &c. These lat are commonly called bag-trufles, or futpenfory bandages. In cafe, they fimpfly confift of a linen bag, for the reception of the ferotum, and of a girt which goes round the body, and to which the bag-part of the trufs is faftened by means of little hooks, fo as to afford the requeft degree of support to the ferotum. Many persons who hunt, and are accu-tomed to take violent horfe-exercife, make use of bag-trufles, in order to keep the ferotum from being hurt by contuions againdt the pumme! of the faddle.

TRUSSES, in a Ship, a machine employed to pull a yard home to its refpective mat, and retain it firmly in that pofiren. As the trufs is generally used instead of a parrel, it is rarely employed, except in flying top-gallant-fails, which are never furnished with parrels. It is no other than a ring or traveller, which encircles the maft, and has a rope faftened to its after-part, leading downward to the top or decks; by means of which the trufs may be ftraightened or fackened at plefire. The haliards of the top-gallant-fail being passed through this ring, and the fail being hoifted up to its utmost extent, it is evident that the yard will be drawn clofe to the maft, by pulling down the trufs close to the upper part of the fail. For, without the trufs, the fail and its yard would be blown from the maft, fo as to fwing about by the action of the wind, and the rockling of the veffel; unlefs the yard were hoifted clofe up to the pulley in which the haliards run; which seldom is the cafe in flying top-gallant-fails, becaufe they are ufually much fhallower than thofe which are fixed or fanding. Falconer.

TRUSSES, short pieces of ornamental carved work, mostly in small fhips fitted under the taffarel, in the fame manner as the term-pieces.

TRUSS-Parrel. See PARREL.
TRUSS-Pendants. See PENDANTS.
TRUSS-Tackles. See TACKLE.

TRUSSED, in the Manage. A horfe is faid to be well-trufled, in French bien ficte, when his thighs are large, and proportioned to the roundnefs of the croupe. On the contrary, a horfe with thin thighs, that bear no proportion to the breadth of the croupe, is faid to be ill-trufled.

TRUSSES, in Rope-Making, have a back with flout pin and four legs braced together. They are ufed at the upper end of a rope-ground, or put under ropes of a short length, when the frands cannot be put on the flake-heads.

TRUSSING, in Falcorv, is a hawk’s raifing any fowl or prey aloft, foaring up, and then defcending with it to the ground.

TRUST. See CESTUI que TRUST.
TRUSTEE, one who has an efteate, or money, put or trufled in his hands for the ufe of another. See FIDES commiffam.

TRUSTRA. See Tristra.

TRUTH, VERITAS, a term used in opposition to falfe-

hood; and applied to propositions which afferm or accord to the nature and reality of the thing of which something is affirmed or denied.

Thus, when we fay, that four is the fourth part of twice eight, that proposition is true, becaufe agreeable to the nature of thofe numbers.

Truth, according to Mr. Locke, consists in the joining or separating of figns, as the things signified by them do agree or differ one with another. Now the joining or separating of figns, is what we call making of propositions.

Truth, properly, belongs only to propositions, of which there are two farts, mental and verbal; as there are two farts of figns commonly made ufe of, viz. ideas and words.

Mental propositions are thofe in which the ideas in our underftanding are put together, or separated, by the mind perceiving or judging of their agreement or difagreement.
Verbal propositions are words put together or separated, in affirmative or negative sentences. So that proposition consists in joining or separating of signs; and truth consists in putting together or separating those signs, according as the things they stand for agree or disagree.

Truth, therefore, as well as knowledge, may come under the distinction of verbal or real; that being only verbal truth, where terms are joined according to the agreement or disagreement of the ideas they stand for, without regarding whether our ideas were such as really have, or are capable of having, any existence in nature. But it is then they contain real truth, when these signs are joined as our ideas agree; and when our ideas are such as we know are capable of having an existence in nature: which, in substances, we cannot know, but by knowing that such have existed.

Truth is the marking down in words the agreement or disagreement of ideas, as it is. Falsehood is the marking down in words the agreement or disagreement of ideas, otherwise than it is: and so far as these ideas, thus marked by sounds, agree to their archetypes, so far only is the truth real.

The knowledge of this truth consists in knowing what ideas the words stand for, and the perception of the agreement or disagreement of those ideas, according as it is marked by those words.

Besides, it is taken in the strict sense before mentioned, which is also called logical truth, there are other sorts of truths; as,

**Truth, Moral**, which consists in speaking things according to the perfunction of our own minds, or the conformity of our expressions to our thoughts, called also veracity; and in a more general sense, comprehending also faithfulness, which is a conformity of our actions to our words. Whereas lying or falsehood, as opposed to truth, is generally a mean, selfish, or malevolent, and always an unjustifiable, endeavour to deceive another, by signifying or affirming that to be truth or faë, which is known or believed to be otherwise; and by making promises, without any intention to perform them.

**Truth, Metaphysical or Transcendental**, which is nothing but the real existence of things conformable to the ideas which we have annexed to their names.

In which sense a clock may be said to be true, when it answers the idea or intention of the person who made it. Others will have metaphysical truth to consist in the agreement of a thing with the idea thereof in the divine understanding.

**TRUTINA Hermetis is used, among Astrologers, for an artificial method of examining and rectifying a nativity, by means of the time of conception.**

**TRUTINATION, formed from trutina, a pair of scales, the act of weighing or balancing a thing.**

**TRUTTACEOUS, in Ichthyology, the name of a genus of fish, of the trout kind, which are distinguished from all other fish by a small fat fin, which they all have near the extremity of the back, and which has no rays or nerves. Of the fish of this genus, some live only in fresh waters, never entering the sea or salt rivers; others frequent both the fresh and salt waters, and are therefore called anadromous.**

The trout which have, and those which have no teeth. Of the edentulous kind, or such as have no teeth, are the lavaretus (for, thymallus, oxyrinchus, and albula); and of the toothed kind, are the salmo, umbra, trutta, carpio, &c. In diñction, the truttaceous fish have all apophyses to the pyrilius, and are all a high-tailed and fine fish for the table.

Ray's Ichthyology, p. 182.

**TRUTULENSIS Portus, in Ancient Geography, a port of the isle of Albion, according to Tacitus, in his life of Agricola. The situation of this port has not been factually ascertained; but it has with the greatest probability been fixed at Richborough or Rutups, in the county of Kent.**

**TRUXILLO, in Geography, a town of Spain, in Eifremadura, defended by a citadel; the birth-place of the celebrated Francis Pizarro, the conqueror of Peru; about 40 miles N.N.E. of Merida. N. lat. 39° 15'. W. long. 5° 12'.**

**TRUXILLO, a city of South America, in the viceroyalty of Peru, and seat of a bishop. It was built in the year 1535, by Don Francisco Pizarro, in the valley of Chimo. Its site is pleasant, notwithstanding the fundame of the soil, the general inconvenience of all the towns in the valleys. It is surrounded with a brick wall, and from its circuit may be classed among the cities of the third order. It stands on a small river, about half a league from the sea; two leagues to the northward is the port of "Guanchaco," the channel of its maritime commerce.**

**Truxillo**, the houses make a creditable appearance. The generality are of brick, with little balconies, and superb porticoes; but the others are of baxareques. Both, however, are low, on account of the frequent earthquakes, and few of them have so much as one story. The corregidor of the whole department resides in this city, and also a bishop, whose diocese begins at Tumbes; with a chapter, consisting of three dignitaries, namely, the dean, archdeacon, and chaplain, with four canons, and two prebendaries. Here is an office of revenue, affixed by an admitted and treasurer, of which resides at Lambayeque, several convents, a college, and an hospital. The inhabitants consist of Spaniards, Indians, and all the other calls. Among the ladies are several rich and distinguished families. The women in their draperies and costumes follow nearly those of Lima. About a league from the city is a river, the waters of which are conveyed by various canals through this delightful country. The dioce of comprehends eight juridictions, viz. Truxillo, Sana, Piura, Casamarca, Chachapayas, Lulia and Chilcas, Patan or Casamarquina, and Jean de Bracamoros; the last is situated in the province of Quito; the rest in the viceroyalty of Peru. The jurisdiction of Truxillo is situated on the coast of the Pacific ocean, and extends twenty leagues in length, and as much towards the interior part of the country, composed throughout of beautiful valleys. In this climate there is a sensible difference between winter and summer; the former being attended with cold, and the latter with excessive heat. The country of this whole valley is extremely fruitful, abounding with sugar-canes, maize, fruits, and garden vegetables, as also with vine and olive yards. The parts nearest the mountains produce wheat, barley, and other grain; so that the inhabitants enjoy not only a plenty of all kinds of provisions, but likewise make considerable exports to Panama, especially of wheat and fuggars. This remarkable fertility has been improved to the great embellishment of the country; so that the city is surrounded by several groves and delightful walks of trees. The gardens also are well cultivated,
TRY

TRYBLION, TRYBERG, TRYAL.

TRYGUM, in Ichthyology, the Greek name given by Aelian, Athenaeus, and Appian, to the fish which we call the paffinae marina, or fire-faire. Aristote and some others write it trugum.

TRYING, in Pharmacy, the purifying of fat substances by means of melting, and separating them from their membranes, &c. See Suet.

In the College Dispensatory, the method laid down for the purifying of lard, sue, &c. was this: melt them at a gentle fire, with the addition of a little water intermixed, and, when melted, strain them from the membranes. The addition of water in this keeps the fat from burning and becoming black, which it would otherwise do; for the water not being capable of receiving any greater degree of heat than that of boiling, will keep the bottoms of the vessel from growing too hot, much better than the nicest management of the fire could do.

TRYING, in Sea Language, denotes the situation in which a ship lies nearly in the trough, or hollow, of the sea, in a tempest, particularly when it blows contrary to her course. In trying, as well as in scudding, the sails are always reduced in proportion to the increase of the storm. Thus, in the former state, the ship may lie by the wind under a whole main-fail, a whole fore-fail, or a whole mizen; or under any of those sails, when diminished by the reef or balance. As the least possible quantity of sail used in scudding is the goose-wings of the fore-fail, so, in trying, the smallest portion is generally the mizen-stay-fail, or main-stay-fail; and in either state, if the storm be excessive, she may lie with all the sails furled, or, according to the sea-phrase, under bare poles.

The intent of spreading a sail at this time is to keep the ship more steady, and, by preliting her side down in the water, to prevent her from rolling violently; and also to turn her bow towards the direction of the wind, so that the shock of the waves may fall more obliquely on her flank than when she lies along the trough of the sea. While she remains in this situation, the helm is fastened close to the lee-fide, or, in the sea language, hard-a-lee, to prevent her, as much as possible, from falling-off. But as the ship is not then kept in equilibrio by the effort of her sails, which at other times counterbalance each other at the head and stern, she is moved by a slow but continual vibration, which turns her head alternately to windward and leeward, forming an angle of three or four points in the interval. The part where the flops, in approaching the direction of the wind, is called her coming-to, and the contrary excess of the angle to leeward is termed her falling-off. Thus, supposing the wind northerly, and a ship trying with her starboard fide to windward: if, in turning her head towards the source of the wind, she arrives at N.W. 45° N. or N. 50° W. and then declines to the leeward as far as W. 45° S. or S. 45° W. the former will be called her coming-to, and the latter her falling-off. In this position she advances very little, according to the line of her length, but is driven considerably to leeward.

Falconer.

TRYLISIA, in Geography, a town of Ruffian Poland; 10 miles E.N.E. of Zyтомiers.

TRYON, a county of the state of New York.

TRYON Mountains, mountains of North Carolina, west of Salisbury, bordering on Tennessee.

TRYPETHELIUM, in Botany, from τρυπη, a perforation, and ἄνθος, a nipple, on account of the mammillary orifices of the warts containing the receptacles; a genus of the great family of Lichenes. (See that article.)—Achar.

Lichenogr.

Eff. Ch. Crust somewhat cartilaginous, flat, uniform, fixed. Warts of the substance of the crust, coloured, prominent. Receptacles several, concealed in the substance of each wart, of a thick, black, spongy texture, at the orifice nipple-shaped, projecting as far as the surface of the wart, the globular cellular nucleus being altogether internal.

Professor Acharius defines eight species, all found on the banks of different tropical trees. They are nearly allied to his Theothema. See that article.

TRYPHALIA, in Ancient Geography, a maritime country of the Peloponnesus, between Messenia and the Elide, according to Polybius.

TRYPHERA, τρυφερα, in Pharmacy, a denomination given to divers medicines, especially of the opiate kind. The great tryphera is composed of opium, cinnamon, cloves, and several other ingredients: it is used to fortify the stomach, to stop fluxes, and is good for some diseases of the womb.

The word is formed from the Greek τρυφερά, delate, on account of their gentle and pleasant operation, or, according to others, because they make those who use them reft.

The Saracenic tryphera, and Perian tryphera, thus called, because first introduced, the one by the Saracens, and the other by the Persians, were both of them gentle purgatives.

TRYPHIDORUS, in Biography, a Greek poet, was a native of Egypt, and commonly referred to the reign of the emperor Aenæus, in the commencement of the fifth century. Of his history little is known; but he was designated a grammarian, and wrote many works, the titles of which are given by Suidas. Of these, none are extant besides his poem on the destruction of Troy, ἡ Ἰλιανή, in about 700 lines, without any disarranging merit besides it’s being a relic of Greek literature. It was first printed by Aldus, and has passed through subsequent editions by Merrick, Oxon. 1741; Bandini, Florent. 1765; and Northmore, Oxon. 1791, which are the most esteemed. Volusius. Moreri. Gen. Biog.

TRYST'S, CATTLE, a term applied to fairs in some of the northern parts of the island.

TRYSUNDA, in Geography, a small island on the W. side of the gulf of Bothnia. N. lat. 63° 9'. E. long. 18° 35'.

TRIVET, a village of Ireland, in the county of Meath. This place was rebuilt by Hugh de Lacy, and peopled by a colony of English; after which it became a considerable town, but is now fallen to decay; 8 miles S.E. of Navan.

TSABA, a town of Asiatic Turkey, in Natolia; 10 miles E. of Bolı.

TSABA-CHOU, a town of Corea; 43 miles S.S.E. of Koang-techeou.

TSAKATHURN. See CSAKATHURN.

TSAKTELU, a town of Asiatic Turkey, in Caramania; 28 miles N.E. of Akheher.

TSALGO, a town of Georgia, in the province of Carduel; 50 miles S.W. of Telifs.

TSAL-HASSAR, a town of Arabia, in the province of Hadsjar; 45 miles N.N.W. of Catham.

TSANG, a city of China, of the secon rank, in Petcheli; 102 miles S. of Peking. N. lat. 38° 21'. E. long. 116° 34'.

TSANG-CHIN, a town of Corea, near the sea; 35 miles S.S.W. of Han-techeou.

Vol. XXXVI.

TSANPOU. See SANFOO.

TSANTE-AGHISI, a town of Asiatic Turkey, in Natolia; 12 miles N.W. of Eregeri.

TSAO, a city of China, of the second rank, in Chantong; 72 miles W.S.W. of Yeng-techeou. N. lat. 35° 22'. E. long. 115° 16'.

TSÄO-SU, a small island near the coast of China. N. lat. 25° 22'. E. long. 119° 42'.

TSAO-TCHANG, a town of Corea; 20 miles N. of Han-techeou.

TSAPHARI, in the Materia Medica of the Ancients, a name given by some to the cadmia, called by Dioscorides placitis; and by others of the Greek writers, sonitis and onychitis. It was a flat kind, forming a sort of crust or crust on the walls or sides of the furnace; hence it had the name placitis, or crustaceus; and it was called onychitis and sonitis, because, when broken transversely, it appeared made up of several successive plates, which had the appearance of so many belts or zones. Scalp tells us, that this and the botryoid cadmia were dug out of the mines; that is, that they were natural productions; but this is erroneous, and contrary to all the accounts of the ancients.

TSASMA, in Geography, a town of Crimea; 8 miles E. of Ivanitz.

TSATSORKEN, a town of Thibet; 501 miles E.S.E. of Laffa.

TSCHAGATAY, or Dschagata, a name given to the Mongolian state, which was assigned to one of the sons of Tchingis-khan, so called after the name of its founder, to whom his father assigned the Greater and Less Bucharia, Turfan, the country of the Igers, and part of the present Kalmuckey.

TSCHA-HAFFER, a town of Arabia Deserta; 80 miles W. of Cathem.

TSCHAMA-CALAB, a town of Persia, in Adirbeyzan; 66 miles S.E. of Tauris.

TSCHARSHEBEH, a town of Asiatic Turkey, in Natolia, on the Meinder; 20 miles N. of Degniuzl.

TSCHASCHWITZ, a town of Silisia, in the principality of Neifie; 4 miles W. of Neifie.

TSCHASLAW. See Czsaslau.

TSCHASTOLOWITZ, a town of Bohemia, in the circle of Konigigratz; 14 miles E.S.E. of Konigigratz.

TSCHAVAT. See JAYAT.

TSCHAEHENDORF, a town of Silisia, in the principality of Neifie; 9 miles N.N.E. of Pachtkhan.

TSCEKENAGAR, a town of Asiatic Turkey, in Caramania; 50 miles N.N.E. of Cogni.

TSCHELENSTACH, a town of Austrian Poland, in Galicia; 28 miles N. of Cracow.

TSCHENGRA, a town of Bulgharia, near the Daphne; 50 miles W.S.W. of Varna.

TSCHENSTOCHOWA, a town of Austrian Poland, in Galicia; 46 miles N.N.W. of Cracow.

TSCHEREMISSES, or Tschermisses, a tribe of Finns, who dwell in the governments of Viatka, Kazan, Simbirsk, and Ufa, on both shores of the Volga, especially the left. They call themselves MARI, i.e. men. Although their language is mixed with Tartarian and Russian words, it is easily distinguishable as a Finnish dialect. The Supreme Being they call Yuma. In the time of the Tartars they were subject to them, and dwelt more southerly, between the Volga and the Don; but at the downfall of the Tartarian dominion, they fell to the Russian empire, and even in this state they long retained their own khans, which, however, ceased upon the
the extinction of the princely race. They were formerly a pastoral people, but under the Russian government they are gradually becoming husbandmen. The present amount of them is not known; but they have been estimated at 20,000.

**TSCHERIKOV.** See Tschcherikov.

Tschcherikov's Island, an island in the North Pacific ocean, so called by Capt. Vancouver, after the companion of Beering. In the point of view in which Capt. Vancouver saw the south-west, southern, and eastern sides of this island, it appeared to form a somewhat irregular four-sided figure, about ten leagues in circuit; having from its western part, which is low and flat, and which had the appearance of being infular, a remarkable high, flat, square rock, lying in a direction S. 66° W. at a distance of two miles, between which and the island is a ledge of smaller rocks. The centre of the island appeared to be in N. lat. 55° 49'. E. long. 205° 4'.

**TSCHERKASK.** See Tscherkask.

**TSCHERKASSIANS.** See Tscherkasses and Circassians.

**TSCHERNEMBL.** See Zernembl.

**TSCHERNOYAR.** See Tschernoiyar.

**TSCHERSK, or Czersk.** See Czersko.

**TSCHESCHENGIANS, or MISCHSCHIANS.** A tribe of vaffals to Russia, living in the eastern part of the great Kabardia, who in time of war can raise 5000 horsemen.

**TSCHESME',** a small town of Alta Minor, situated almost opposite to the isle of Scio, at the head of a spacious road, to which art has no occasion to add, in order to make it a good harbour. A citadel somewhat extensive, constructed by the Genoese, runs sloping to the sea-thore, and seems intended to secure from all infult both the town and the harbour. Tschefm is built on the ruins of Cyillus. This road is famous for the victory which the Roman fleet gained there over that of Antiochus, and also for the burning and total destruction of the Turkish squadron by the Russians in 1770. Geographers place at the head of a bay, two or three leagues to the N. of Tschefm, the ancient Erythrae, celebrated for the oracles of the Sibyl. The territory of Tschefm furnishes grain and fruit in abundance; a little oil and a great many raisins are also produced here. It is from this harbour that the isle of Scio draws a great part of its subsistence, and by means of it frequently keeps up an intercourse with Smyrna.

**TSCHETCHES,** the name of a colony of strangers and Chrlitans, who are secluded from the world in a most sequestered part of the wilds of Caucasus, so called in the language of the country. These poor people are said to lead lives of the most exemplary piety, and to exhibit a primeval simplicity of manners. They are totally ignorant of their origin, any farther than knowing that they are strangers, and their being considered as such by the scattered neighbouring nations. From an affinity in their language, and some other circumstances, they are supposed to be descended from a colony of Bohemians, who, flying from religious persecution in their own country towards the close of the fifteenth century, found at length a refuge from oppression in the district from the rest of mankind which these remote deferts afforded.

**TSCHIGRI, a town of Russia, in the government of Kurik; 48 miles E. N. E. of Kurik.**

**TSCHILLA, a town of Bohemia, in the circle of Rakonitz; 8 miles S. W. of Rakonitz.**

**TSCHIRNE, a town of Silezia, in the principality of Glogau; 20 miles E. of Gros Glogau.—Alo, a river of Silezia, which runs into the Bober, two miles below Sagan.**

**TSCHIRHAUSEN, EHRENFRIED WALTER VON,** in Biography, an ingenious mathematician, was a descendent of a noble Bohemian family, and born at Kilplingwald, in Upper Lusatia, in 1651. Having studied for some time at the university of Leyden, directing his particular attention to mathematics and philosophy, he entered into the Dutch army in 1672, and for the purpose of further improvement visited France, Sicily, Italy, and Malta. He also established three glas-houses in Saxony, with a view to the improvement of the science of optics, and having shewn how porcelain might be made from an earth found in that country, he may be regarded as the founder of the Dresden porcelain manufactory. As to his claims on the invention of caustic curves, we refer to the article Caustic Curve. His account of them was communicated to the Academy of Sciences at Paris in 1682. See also the fame Memoirs for 1703. For the construction and powers of his burning-glasses, contrived about the year 1687, we refer to the article Burning-Glafs. Heedless of the fame which he so justly acquired, Tschirnhausen took delight in encouraging the researches of others, who were engaged in pursuits similar to his own, and was at considerable expense in printing works of public utility. He died, highly esteemed and much regretted, in the month of September 1758. He furnished the Leipzig Translations with many articles; and also the Memoirs of the Academy of Sciences with the following: viz. "Observations on Burning-glasses of three or four Feet Diameter," in the vol. for 1693; "Observations on the Glass of a Telecope convex on both Sides, and of thirty-two Feet focal Distance," 1700; "On the Radius of Curvatures, and finding the Tangents, Quadratures, and Rectifications of many Curves," 1701; "On the Tangents of Mechanical Curves," 1702; and "On a Method of Quadratures." The only work published separately was his "Medicina Mentis," resembling Malebranche's "Recherche de la Verite," but much more extensive; first published in 1687, and again with improvements in 1695. Montucla, Hist. des Mathem. Hutton's Math. Diet. **TSCHIRNAUSIANA QUADRATRIS.** See Quadratrix Tschirnhausiana.

**TSCHOPA, in Geography, a river of Saxony, which rises near Weifenthal, on the borders of Bohemia, and runs into the Mulda, between Dobele and Leisping.**

**TSCHOPA, or Zichapou, a town of Saxony, in the circle of Erzegiburg, celebrated for its blue manufacture; 7 miles S. E. of Chemnitz. N. lat. 50° 4'. E. long. 13° 2'.**

**TSCHUDI, AEGID, in Biography, an eminent Swis historian, was descended from a noble family, and born at Garus in 1503. After completing his school education, he went to Basel, and accompanied his preceptor Glarancus to France, with a view to farther improvement. Upon his return to his native place, he was employed, in 1528, on a million respecting the Reformation, in which he conducted himself to the satisfaction of both Reformers and Catholics; and in the following year he was chosen chief magistrate of Sargans. By his discharge of the duties of this office, he gained incrasing reputation, and more extended truits of a similar kind. His great object was to enlurge his acquaintance with the Helvetic history; nor did he cease to pursue it, even in the military service of France, or in any of the honourable stations which he was appointed to occupy. Towards the close of his life he was severely afflicted with the stone, but death terminated his pains and labours in the year 1572, and 60th year of his age. His principal works were "A Description of the ancient Rhetaia," published at Bale in 1538; the "Helvetic Chronicle," commencing with the year
TSHUKOTSKOI Noss, or Cook's Straits, in Geography, a part of the shores of the government of Irkutsk, walked by the Eastern or Pacific ocean, extending to the frontiers of China; or in other words, from the mouth of the river Aimakan; i.e. from about 65° to 45° N. lat.

TSHUKTCHES, a people who occupy the north-eastern point of Siberia, towards the Frozen ocean and the Eastern ocean, which is called the Tschuktschy-cape, and in all respects so much resemble the Koriaks, that one might be induced to take the two nations for relative items. They may be computed at 4000 heads. We may naturally suppose that they are the primitive poiffleurs of these coasts, who either came over from the continent of America, or were divided by the probable infraction of the sea, and the consequent separation of the two quarters of the world. They, as well as the Koriaks, Kamchadales, Tunguses, and Lamutes, bear a great likeness to the nearest Americans beyond the straits.

TSHUVASSES are a very numerous nation of Finns, paying the tax for more than 200,000 heads. They reside principally on both sides of the Volga, in the governments of Tobolsk, Viatka, Nizhnei-Novgorod, Kazan, Simbirsk, and Ufa. Their language at present borders more upon the Tartarian than that of the Finns, and hence from will not allow them to belong to this flock; nevertheless, their manners and customs are very much resemble those of the Finns, particularly those of the Votaks and Tscheregimies. These three tribes dwell together in villages, but never in towns; they are inured to agriculture, and have abandoned their nomadic way of life; they are fond of horse-flies; they are mostly heathens, and they have among them enchanters, and a sort of place for divine worship, which they denote by the generic name of Keremet. At their meetings they sacrifice a horse, in which their principle religious solemnities consists. See Tscheremisses.

TSE, a town of China, in Shan; 300 miles S.S.W. of Peking. N. lat. 35° 30'. E. long. 112° 26'.

TSEBID, or Taeberit, a town and district of Africa, in the country of Sugulmeua; 75 miles E. of Sugulmeula. N. lat. 31° 46'. E. long. 1°.

TSELGA, or Tschelga, a town of Abyflinia; 30 miles N. of Gondar.

TSEMURITZU, a mountain of Croatia; 20 miles S. of Bihacs.

TSENA, a river of Malacca, which runs into the Chineese sea. N. lat. 7° 33'. E. long. 101° 21'.

TSERKESB, a town of Asiatic Turkey, in Natalia; 36 miles N. of Angura.

TSHAC, a mountain of Little Bucharia; 80 miles S.S.W. of Hotun.

TSHANI. See Tchani.

TSHARISKOI MOUNTAINS, a very extended branch of the Altai mountains that fall to the shore of Russia, in the range of Kolbychan. They comprise the whole space between the highest sources of the Ulba, Ouba, and the Ko-kofun (to the point where the Thuya falls into the Koko-fun), and between the course of this latter river and the Kama, and carries its powerful forked ridges along both sides of the Thaari, from its origin to its disemboosing into the Oby. The direction of these mountains is from E. to W. and N.W., and on the S. they are parted, by a rude valley, from the Oubinfiok snow-mountains. In several places this range rises to a great height, having up enormous pinnacles, which in some parts are covered with never-failing snow, and which, for the most part, consist of granite, porphyry, Jasper, and flint breccia. One of these, viz. the Tjeeretzkoi, to a considerable height consists of marble, which contains a multitude of sea-shells. These in general are found to be 4392 Paris feet higher than the Shlangen-burg. One of the highest points is the Kojfikpina-Sopka (the Ragged-head), consisting of monstrous blocks of hoary granite. In several places of these wild and extensive mountains, iron, copper, and lead ores have been dug up, but no regular works have been established.

TSHATSHI, a town of Little Bucharia; 30 miles N.E. of Afu.

TSHEGULA, an island belonging to the class called Fox islands, and arranged by Muller under the appellation Kavalaag.

TSHENIKE, a town of Asiatic Turkey, in the government of Sivas; 20 miles N.E. of Amaseh.

TSHETCHINA, one of the islands comprehended under the name of Andreaofskiye oflrova, on which a high white mountain overtops the reef, which is apparently an extinct volcano, as there are still hot springs on this island.

TSHETGIVEN, one of that class or division of the islands that lie between Kamtschatka and America, called Chao.

TSHIBUK-ABAD, a town of Asiatic Turkey, in Natalia; 18 miles N.E. of Angura.

TSHIGAMA, one of the class of islands called Fox islands, distinguished in Mr. Muller's arrangement under the name Kavalaag.

TSHI-KOI, a river of Russia, which runs into the Selengu, 12 miles S. of Selenginfuel.

TSHI-KOTA, one of the Kurile islands, distant from Kunaffy island 70 veris, 120 veris long, and 40 broad. It has lofty mountains, with similar forests to those of Kunaffy, with lakes and glooms of wholesome water.

TSHILLIENI, a town of Walachia; 7 miles S. of Caracalla.

TSHINKA, in the Materia Medica, a name by which some authors have called the clove-tree, the tree which produces the spice of that name.

TSHIRINKUTAN, in Geography, one of the Kurile or Kunilki islands, about 30 veris from Ikarma. The island is round, and its diameter is about fifteen veris. A mountain nearly upon the island is continually emitting smoke, and very frequently large stones roll down one of its sides, by which a valley has been excavated from top to bottom. The coal round about is mountainous and rocky. It has a great number of wild fowl, and in other respects very much resembles Ikarma.

TSHIRPO-OI, one of the Kurile islands, may be estimated in length and breadth at 15 veris. This island has had a volcano, that has discharged stones from the whole face of it. Instead of forest-woods, it presents to view merely bushes of the forbus sylvetris, but no trees, and one small saline lake. In one spot is a salt-spring of that kind called acidula, the water of which洛杉矶 its acidity by boiling. On an adjacent island is also a volcano.

TSHLUCHOW, a town of Prussian Pomerelia; 44 miles S.S.W. of Danzig.
TSIA, in Botany, a name taken from the Japanese, and used by some authors for the tea-tree.  
TSJAKELA, H. M.—Ficus Malabarica, fémel in anno fruitífera, frutíá miníma, a species of fig-tree growing in Malabar. Of the bark of this tree they make strings for their bows, and prepare a red colour for dyeing the Cambavan cloths.  
TSIAM PANGAM, a name used by some authors for the tree whose wood is the log-wood, used in dyeing, and in medicine.  
TSIAMAJA, in Geography, a town of Laos; which see.  
TSIAMA. See CHAMPA.  
TSIANA EVA, a name given by some authors to the coitus root.  
TSIAO, in Geography, a city of China, of the second rank, on the south coast of Corea; 35 miles S.S.W. of Kiong-teou. N. lat. 36° 45'. E. long. 105° 16'.—Alfo, a town on the west coast of the island of Corea, about 60 miles in circumference; 42 miles S.W. of Nang-king.  
TSIAO-TING-CHAN, a town of Corea; 50 miles E.N.E. of Koang-teou.  
TSIAO-TONG, a town of Corea, on an island of the same name. N. lat. 37° 48'. E. long. 124° 14'.—Alfo, an island in the Hoang-hai, or Yellow sea, near the coast of Corea, about 35 miles in circumference; N. lat. 37° 44'. E. long. 124° 54'.  
TSIASSEM, a kingdom of the island of Java, on the north coast, E. of Carawang.  
TSIBBA, a town of Japan, in the island of Niphon; 30 miles E.S.E. of Jedo.  
TSI-CHU, in Botany, the name of a Chinese tree, which furnishes the liquor of which they make their celebrated varnish.  
TSIEN, in Commerce, a weight in China. The Chinese weigh gold and silver by the gin or catty, of 16 liyang or tales; and the liyang is subdivided into 10 tsions or maces, 100 fenwans or candareins, and 100 lis or cafs. The gin is the Chinese denomination for this weight, and the catty that of the European. See TALE.  
TSIEN-UEY, in Geography, a town of Chinese Tartary; 40 miles S.W. of Ning-yuen.  
TSIERIBON. See CHERIBON.  
TSIHA, a town of Thibet; 48 miles W. of Conchbudong.  
TSIKUMA, a town of Japan, in the island of Niphon; 88 miles W. of Meaco.  
TSILI, a town of Corea; 35 miles W. of Sing.  
TSILKANI, a town of the principality of Georgia, in the province of Carduel; 20 miles N.W. of Teflis.  
TSILON-PALHASIN, a town of Chinese Tartary, in the country of the Monguls; 13 miles S. of Oulan.  
TSIM-YUEN, a town of Corea; 650 miles E.N.E. of Peking. N. lat. 42° 28'. E. long. 120° 54'.  
TSIN, a city of China, of the second rank, in Chen-fi; 620 miles S.W. of Peking. N. lat. 34° 35'. E. long. 105° 24'.—Alfo, a city of China, of the second rank, in Hou-quant; 645 miles S.W. of Peking. N. lat. 26° 36'. E. long. 109° 2'.  
TSIN, or Tsin, a town of Corea; 188 miles S.S.E. of King-ki-tao. N. lat. 34° 52'. E. long. 127° 44'.  
TSIN, in Natural History, the name given by the Chinese to a stone which they make very use of in their manufacture of porcelain ware. It is of a deep blue colour, much resembling Roman vitriol in appearance, and is found in lead-mines, and supposed to contain some particles of lead; its effects being the same in the porcelain manufacture as those of cerufs, or white lead, in making the other colours penetrate into the substance of the veflils. The deep violet colour that we see so beautiful on the china-ware, is usually made with this stone. They find it about Canton and Peking; but the latter place affords the best, and it sells at greatly the best price.  

The painters in enamel melt this stone in their way, and use it very much; they form many beautiful works, by laying it upon silver; but it is apt to come off in time. When the tsin is used in the porcelain manufacture, it is only used to the vases that pass a second baking, and are intended as the beft kinds.  

The tsin is prepared by only beating it to powder, not rolling it in the common way. They mix the powder with large quantities of water, and flirring it together, they let it subfide a little, to separate any earthy or extraneous matter that might be among it. They then let the powder subfide. The water which is thrown away has no colour from this matter, and the powder itself is not of that fine blue it was in the lump, but of a pale afh-colour; but this recovers all its beauty when it is laid on the china and baked. The settlement taken from the water is dried and preferred in powder, and when it is to be used, they only mix it up with gum-water, or a solution of glue, and lay it on with a pencil. Obfer, fur les Coutumes de l'Asie.  

TSIN-NAN, in Geography. See TSI-NAN.  

TSINCHAN, a town of Corea; 13 miles N.W. of Sing.  

TSIN-CHOUI, a river of China, which runs into the Yuen, near Meyang.  

TSINEH, a town of Asiatic Turkey, in Natolia; 16 miles W.N.W. of Mogila.  

TSING, a city of China, of the second rank, in Chan-fi; 267 miles S.S.W. of Peking. N. lat. 36° 42'. E. long. 112° 24'.—Alfo, a lake of China, in Kiang-nan, 22 miles in circumference; 45 miles N. of Hoai-ngan.  

TSING-HING, a city of China, of the second rank, in Yen-nan; 1162 miles S.S.W. of Peking. N. lat. 24° 47'. E. long. 102° 36'.  

TSING-KIANG, a town of China, in Kiang-nan, on the Yang-tze river; 50 miles S.E. of Yang-teou.  

TSING-LAN-OUEI, a town of China, in Hou-quant, near the source of the river Yuen; 25 miles S.W. of Hoang.  

TSIN-KIEN, a river of China, which runs into the Hoang; 12 miles E.S.E. of Yen-chou.  

TSIN-NING, a city of China, of the second rank, in Chen-fi; 585 miles W.S.W. of Peking. N. lat. 35° 36'. E. long. 103° 25'.  

TSINO, a town of Japan, in the island of Awafi; 10 miles N. of Awafi.  

TSINRAMA, a town on the west coast of the island of Celebes. S. lat. 4° 40'. E. long. 119° 14'.  

TSIN-TCHUEN, a town of Corea; 40 miles S.E. of Hoang-teou.  

TSIN-YANG, a river of China, which rises near Tch'i-hia, in Chan-tong, and runs into the Eastern fea, near Fou-chia.  

TSIN-YUEN-OUEI, a fortrefs of China, in Chen-fi, near the great wall, on the river Hoang; 75 miles N. of Lingtao.  

TSISA-
TSISAGATA, a town of Japan, in the island of Nippon; 110 miles W. of Meaco.
TSISIR, a town of Thibet, now in ruins. N. lat. 34° 14'. E. long. 96° 19'.
TSITA, a lake of Thibet, 45 miles in circumference. N. lat. 33° 32'. E. long. 99° 39'.
TSITCHICHAR. See TICCHICAR-HOTUN.
TSIURAC, a river of Natalia, which runs into the Meinder, at Tarharbeh.
TSO, a city of China, of the second rank, in Pe-teche-li; 22 miles S.S.W. of Peking. N. lat. 39° 32'. E. long. 115° 39'.—Allo, a city of China, of the second rank, in Quang-fi; 930 miles S.S.W. of Peking. N. lat. 22° 42'. E. long. 106° 49'.
TSO-CHOU, a town of Corea; 55 miles S.E. of Kang-tcheou.
TSOKAMA, a town of Japan, in the island of Nippon; 170 miles W. of Meaco.
TSOL-ABAD, a town of Asiatic Turkey, in Caramania; 32 miles S.W. of Akhehr.
TSONDUE, a town of Thibet; 7 miles W. of Painom-Jeung.
TSONG-HE, a town of Corea; 10 miles N. of Hoang-tcheou.

TSONG-KING, a city of China, of the second rank, in Se-tchuen; 837 miles S.W. of Peking. N. lat. 30° 38'. E. long. 103° 23'.
TSONG-MING, a town of China, in the island so called. N. lat. 31° 45'. E. long. 102° 51'.

TSong-Ming, or Ts'ing-ming, an island near the coast of China, in the Eastern sea, at the mouth of the Yang-tfe river, belonging to the province of Kiang-nan, about 50 miles in length, and 10 in breadth. This island was formerly a place of banishment for criminals, to whom some poor Chinese families resorted, and they divided the lands amongst them; but not being able to clear all the land they had appropriated to themselves, called other families from off the continent to their assistance, and yielded to them for ever a part of the lands, on condition that they should pay annually, in divers goods, a rent proportionable to their harvest. The country is divided by an infinite number of canals, that have high banks to defend it from inundations, for the land is level, having no hills; the air is healthful and temperate, and the country agreeable. Here are large towns scattered about the island, at convenient distances, wherein is a great number of shops, well furnished with all manner of necessaries and conveniences of life; and, diversified between each town, there are as many houses about the country as there are families employed in tillage. The highways are very narrow, and are bordered with little shops that sell refreshment to travellers; and, indeed, one would imagine the whole island to be one exceeding large village. Here are no wild fowl, but great numbers of large geese, ducks, hens, hogs, and buffaloes, but these latter are used only for tillage. The land is not alike throughout the island, the produce of it being very different; that towards the north is not cultivated, but the reeds which grow here naturally produce a considerable revenue; as there are no trees in the whole island, they use part of these reeds to build houses in the country; the other part serves to burn, and supplies fuel not only for the whole island, but also for some parts of the neighbouring continent. The second fort of land is that which extends from the first quite to the sea on the south side; this produces two crops every year; one of grain, which is generally in the month of May, the other of rice, or cotton; of rice, in September; of cotton, a little later:

TSU, a city of the first clafs in China, in the province of Fo-kien, and reckoned one of the most beautiful cities in China, on account of its situation, extent, trade, triumphal arches, temples, and its well-paved streets. It has in its district seven cities of the third clafs. In its neighbourhood is a bridge remarkable for its extraordinary size, and the singularity of its construction. It was built at the expense of one governor. It is wholly built of the same kind of blackish stone, without arches; but it has above 600 large stone pillars, which terminate on each side in an acute angle, the more easily to break the violence of the current. Five arches of equal size, laid transversely from one pillar to another, form the breadth of the bridge; of these there are 1000, all of the
fame size and figure. On each side there are buttresses or props, constructed of the fame kind of stone, on the tops of which are placed lions on pedestals, and other similar ornaments. This is merely one part of the work,—that which is between the small city of Lo-yang and the castle built upon the bridge: for beyond the castle there is another part, equally stupendous with the first.

TSUGARA, a town of Japan, in the island of Niphon; 45 miles W.N.W. of Nambu.

TSUGARA, a town of Japan, in the island of Niphon; 60 miles N. of Jedo.

TSU1-TSANG, a town of Corea; 40 miles W.S.W. of Sing.

TSUKUKI, a town of Japan, in the island of Niphon; 36 miles N.N.E. of Jedo.

TSUNTNITZ, a town of Croatia; 16 miles W. of Damianovitz.

TSUN-Y, a city of China, of the first rank, in Setchuen; 860 miles S.W. of Peking. N. lat. 27° 38'. E. long. 106° 35'.

TSUR. See TSB.

TUA, in Ancient Geography, an estuary on the south-eastern side of the island of Albion, between the estuary Varis, or Firth of Tyne in Sunderland, and the mouth of the river Cenius, and the Spaï, in the shire of Elgin. The Tua was therefore Cromarty, or Murray Firth.

TUA, in Geography, a river of Portugal, which runs into the Duero, 15 miles N.W. of St. Joao de Pefiqueira.

TUABO, a town of Africa, in the kingdom of Jaen, on the side of the Senegal. N. lat. 14° 56'. W. long. 10° 8'.

TUACA, a town of Africa; 10 miles S. of Mombasa.

TUAK, a small island in the Red sea, about 12 miles from the coast of Arabia. N. lat. 5° 58'. E. long. 41° 58'.

TUAM, a post-town of the county of Galway, Ireland, which is represented in the "New Traveller's Guide for Ireland," as "a large, populous, well-built town;" but which Dr. Beaumont calls, though an archiepiscopal see, a very poor city. It may have been improved since the publication of Dr. Beaumont's work, but the other account must be received with caution, especially when it speaks of "byelanes and alleys thickly inhabited by an industrious populace and working mechanics." It may, however, have a considerable retail trade, and may have derived great advantage from the introduction of the linen manufacture into its neighbourhood. The archbishop's palace is a spacious, venerable structure. The cathedral is a neat, but not extensive, edifice, which serves also for the parish-church. Tuam lost its privilege of being represented in parliament at the Union. It is 93 miles W. from Dublin, and 16 miles N. by E. from Galway.

TUAM, an archiepiscopal see in Ireland, being the lowest in dignity of the four, and having the smallest jurisdiction; the number of benefices in this province being only 87, whilst in Armagh there are 419, in Dublin 252, and in Cashel 362. The fee of Tuam contains the greatest number of acres of any fee in Ireland, extending over a great part of the counties of Galway and Mayo, and including a part of Roscommon; yet such is the want of cultivation, and the poverty of the country, that it was found necessary to unite the bishopric of Ardagh in the province of Armagh, to enable the archbishop to support the dignity of his office. The number of parishes is 89, forming 23 benefices, and having 24 churches. The chapter consists of a dean, a provost, an archdeacon, and eight prebendaries. The infragran biphories are those of Clonfert, Elphin, and Killalla.

TUAP, a town of New Navarre; 160 miles S. of Cote Grande.

TUARIK, a people of Africa. The west and south of Fezzan, says Mr. Horneman, is inhabited by the Turak, a mighty people, who border south-west on Bornou, south on Bornou, Soudan, and Tombuctoo, eastward on the country of the Tibbou and Fezzan, northward on part of Fezzan and the Arabs who live behind the regions of Tripoli, Tunis, and Algiers, and westward on the great empire of Fez and Morocco; of whom a few colonies are found in Sockna, Angala, and Siwwah; in such places, the language of the Turak is the only one spoken by the inhabitants. The Turak are divided into many nations and tribes, who all speak the same language. The Turak of Hagara and Kolluvi are thin in growth, rather tall than short, their walk swift but firm; their look stern, and their whole demeanour warlike. Cultivated and enlightened, their natural abilities would render them perhaps one of the greatest nations upon earth. Their character, particularly that of Kolluvi, is much esteemed. The western tribes are white, as much as the climate and manner of living will admit. The Kolluvians who reached the region of Asien, and conquered Agades, and mixed with the nation, are of different colours, many of them black, but their features are not like those of negroes. The Hagara and Muktara tribes are yellowish, like the Arabs: near Soudan there are tribes entirely black. They are not all Malomctans. In the neighbourhood of Soudau and Tombuctoo live the Tegama, who are white and pagans: they carry on a commerce between Soudan, Fezzan, and Gadamess. Their caravans give life to Mourzouk, which without them is a desert; for they love company, song, and music. The greater part of the eastern Turak lead a wandering life.

TUAT. See TWAT.

TUB, is used as a kind of measure to denote the quantity of divers things. A tub of tea is a quantity of about 60 pounds. A tub of camphor is a quantity from 56 to 80 pounds. A tub of vermillion from 3 to 4 cwt.

TUB, Cheesfs, in Rural Economy, that fort of large tub which is employed in the making of cheese, which, in some districts, is wetted or washed with cold water before it is used, to prevent the milk from flicking to the wood.

TUBS, in Gardening, a sort of strong upright boxes, calculated for containing large green-house exotics, and other potted plants and trees, when grown too large for the pots. These tubs are made by the cooperers proper for this purpose, somewhat in the garden-pot form, a little wider at top than at bottom, from a foot and a half to two feet and a half deep; the width in proportion; constructed of the strongest, thickest planks and bottoms, and well hooped with iron, and with two iron handles at top, by which to remove them; the handles being strong, and generally hooked, especially in very large tubs, in order to receive a pole in each occasionally, that the tube and plant together may be more readily moved. The bottom of the tubs have auger-holes bored in different parts, at regular distances, by which to discharge the superfluous moisture, after watering, &c.

In tabbing large-grown plants, they should be removed from their present pots, with the balls of earth about their roots entire; and having earthed the bottom parts of the tubs, the plant should be set in with its whole ball of earth, filling up properly around, and an inch or two over the top of the ball, with more fresh mould, and then watering. See SHIFTING OF PLANTS, and POTTING. 
TUBA, in Geography, a river of Russia, which runs into the Elbe, 16 miles S.W. of Abakan, in the government of Kolivan.

TUBAI, one of the small Society Islands, in the South Pacific ocean; about 12 miles from Bolabola. S. lat. 16° 12', W. long. 151° 44'.

TUBANSKA, a town of Russia, in the government of Irkutsk; 44 miles N.W. of Irkutsk.

TUBANTES, in Ancient Geography, a people of Lower Germany, on the other side of the Rhine. According to Cluver, they at first inhabited the country now called the counties of Ruvenberg and Lippe; and from hence they traversed the territory which lies between the Rhine and the Sela.

TUBAON, in Geography, a town on the north coast of the island of Java. S. lat. 5° 50'. E. long. 112° 14'.

TUBBAULEH, a town of Hindoostan, in Lahore; 10 miles S.S.W. of Callanore.

TUBBER, in Mining, a name given in Cornwall to that mining instrument, which is in other parts of England called a becle.

TUBBER-Men, in Cornwall, the people who work with this tool, and who are, from its other name of becle, called in other places becle-men.

TUBBERMORE, in Geography, a post-town of the county of Londonderry, Ireland, which is 90 1/2 miles N. by W. from Dublin.

TUBE, TUBUS, pipe, conduit, or canal; a cylinder, hollow within and outside, either of lead, iron, wood, glass, or other matter, for the air, or some other fluid, to have a free passage or conveyance through.

The term is chiefly applied to those used in physics, astronomy, anatomy, &c. On other ordinary occasions, we more usually say pipe.

In the Memoirs of the French Academy of Sciences, M. Varignon gives a table of the proportions necessary for the diameters of tubes, to give precisely any determinate quantities of water. The result of his piece turns upon these two analogies; that the diminution of the velocity of water, occasioned by its friction against the sides of tubes, are as the diameters; the tubes being foppoped equally long; and the quantities of water issuing out of the tubes, are as the square roots of their diameters, deducting out of them the quantity each is diminished.

For the tubes of barometers and thermometers, see Barometer and Thermometer. For the ascent of liquors in capillary tubes, see Ascent and Capillary.

Tubes, in Astronomy, are sometimes used for telescope (which see); but more properly for that part of it into which the lenses are fitted, and by which they are directed and used.

The goodness of the tube being of great importance to that of the telescope, we shall here add its structure.

The Construction of a Draw-tube for a Telescope. — The chief points to be regarded here are, that the tube be not troublesome by its weight, nor liable to warp and disturb the position of the glass; so that any kind of tube will not serve in every case: but,

1. If the tube be small, it is best made of thin brass plates covered with tin, and formed into pipes or draws, to slide within one another.

2. For long tubes, brass or iron would be too heavy; for which reason, some chafe to make them of paper, thus: a wooden cylinder is turned, of the length of the paper to be used; and of a diameter equal to that of the smallest draw. About this cylinder is rolled and pasted paper, till it be of a sufficient thickness; when one tube is dry, provide others after the same manner; still making the last serve for a mould for the next, till you have enough for the length of the tube desired. Lastly, to the extremes of the draws are to be glued wooden ferris, that they may be drawn forth the better.

3. Since paper draws are apt to swell with moist weather, so as to spoil their sliding; and in dry weather to shrink, which renders them loose and tottering; in both which cases, the situation of the lenses is easily disturbed; the best method of making tubes is as follows: glue parchment round a wooden cylinder, and let the parchment be coloured black, to prevent the reflected rays making any confusion. Provide very thin flits of beech, and bending them into a cylinder, glue them carefully to the parchment; cover this wooden case with white parchment, and about its outer extreme make a little ring or ferris: after the same manner make another draw over the former; and then another, till you have enough for the length of the tube.

To the inner extremes of each draw, fit a wooden ferris, that the furious rays, striking against the sides, may be intercepted and lost. In those places where the lenses are to be put, it will be proper to furnish the ferris with female screws. Provide a wooden cover to defend the object-glares from the dust, and putting the eye-glares in its wooden ferris, fasten it by the screw to the tube. Lastly, provide a little wooden tube of a length equal to the distance the eye-glares is to be from the eye, and fit it to the other extreme of the tube.

Tub, or Pipe, among Florists, is that part of a fine flower which has something of a straw-like pipe or opening; and which, to constitute a good flower, in some sorts, as those of the auricula and polyanthus, should stand exactly in the centre of the blossom, and have a truly round or circular form; be well filled with chives or little thread-like parts, something in the manner of a brush at their points, rising even with the face of the pip or blossom; as when only the styme or pointal rives like a pin, without being surrounded or encompassed with the chives to the fame height, the flower is said to be pined, and displays a chasm or vacancy, which is so very unpleasant to the eye of the curious in flowers, that though, in many other respects, such flowers may have good properties, yet falling in this central perfection and beauty, nothing else can atone or make up for it; and such flowers are, of course, held in but small estimation by the florist. See THUMB and TRUSS.

Tubes, in Artillery, are instruments used in quick firing, made with us of tin; their diameter is two-tenths of an inch, so as just to enter into the vent of the piece; their length is about five or six inches, with a cap above, and cut slanting below in the form of a pen, and the point is strengthened with some folder, that it may pierce the cartridge. Through each tube is drawn a quick-match, and the cap is furnished with mealed powder, moistened with spirits of wine. To prevent the mealed powder from falling out by carriage, a cap of paper is tied over it, which is taken off when used; but of late this cap is made of flannel, steeped in spirits of wine, and with saltpetre dissolved in it; and
there is no occasion to take it off, because it takes fire as quick as loose powder.

The French use a small reed, to which is fixed a wooden cap, and they are about two inches long, filled with meal powder, moistened with spirits of wine, and a small hole is made through them of the size of a needle, through which the fire darts with great violence, and gives fire to the cartridge, which must be pierced before-hand with the priming-iron.

These tubes may be kept a great while without being spoiled; but piercing of the cartridge retards the quickness of firing. Muller's Art. p. 293.

TUBE, Alimentary. See Duct.

TUBE, Euftachian, or Trumpet, in Anatomy, a canal of communication between the throat and the tympanum. See EAR.

TUBE, Euftachian, Disease and Obstructions of, in Surgery. These are often a cause of a considerable degree of deafness, because it is necessary for perfect hearing, that air should be conveyed from the mouth through this passage into the cavity of the tympanum, which now can no longer happen.

A degree of deafness generally attends a severe cold, which is accounted for by the Euftachian tube being obstructed with thickened mucus. Mr. Saunders tells us, that the obstruction most frequently arises from syphilitic ulcers in the throat, or sloughing in the cymalge magna. The deafness comes on when such fores are healed, that is, when the obstruction is complete. The deafness of a nasal polyposis into the pharynx, and enlarged tonsils, have also been known to close the tube.

When the Euftachian tube is obstructed, the patient cannot feel the membrane tympani crackle, as it were, in his ear, on blowing forcibly with his nose and mouth flopped. Previous ulceration, or disease, of the throat, will sometimes aid in facilitating the diagnosis.

When the Euftachian tube is obstructed with mucus, it has been proposed to employ injections, which are to be thrown, by means of a syringe and catheter, into the guttural orifice of that canal. This operation, however, is alleged to be always attended with trouble; and when the os sphenoidum inferius happens to be situated near the floor of the orbit, the introduction of any instrument like a female catheter would be impracticable. Richerand Nofographie Chirurgicale, tom. ii. p. 131. edit. 2.

Mr. A. Cooper had noticed, that hearing was only impaired, not lost, when suppurations in the tympanum had injured, and even destroyed the membrane tympani; and that the degree of deafness by no means equaled what resulted from an obstruction of the Euftachian tube. Hence, when the tube was permanently obliterated, he conceived that a small puncture of the membrane tympani might be the means of enabling the patient to hear. Mr. A. Cooper practised the plan with success, and others have imitated him with the same result.

The operation consists in introducing an instrument, resembling a hydrocele trocar, but curved, into the meatus auditorius externus, and pushing it through the anterior and inferior part of the membrane tympani; a place rendered most eligible, on account of the situation of the chorda tympani and manubrium of the malleus, patts which should be left uninjured. The instrument must not be introduced far, lest it should wound the vascular lining of the tympanum, and cause a temporary continuance of the deafness, by an effusion of blood. When the puncture is made, in proper cases, and in a judicious manner, hearing is immediately restored. A small hole in the membrane tympani now conveys the air into the cavity of the tympanum, answering the same purpose as the Euftachian tube.

The surgeon will be able to operate with more cafe, if he take care to lessen the curvature of the meatus audito-rius, by drawing upward the external ear.

There is some chance of a relapse, in consequence of the opening closing up. This consideration has led Richerand to propose making the aperture with cautie, so as to destroy a part of the membrane. (Nofographie Chirurgicale, tom. ii. p. 132. edit. 2.) The suggestion is not, however, likely to be adopted, on account of the inconveniences of applying cautie within the ear. Mr. Saunders is an advocate for making the opening large. This gentleman relates, that he instantaneously restored hearing in one case, in which the patient had been deaf thirty years, in consequence of a loss of part of his palate by syphilis. Mr. A. Cooper's cases are in the Philosophical Transactions for 1802.

Puncturing the membrane tympani has been attended with some degree of success in France, as well as this country. It is not to be disembarrassed, however, that there are numerous failures. We are informed that professor Dubois has done the operation in four instances, without success. Richerand Nofographie Chirurgicale, tom. ii. p. 132.

In most cases, the patients who have been benefited, are said to have experienced pain just after the trocar was withdrawn. The organ, in consequence of not being accustomed to sound, had become so extremely sensitive, that it could not bear the gentle impression of the parasporous vibrations; and the patient's first request, after the perforation was made, was that they who were near him might speak softly. This excessive tenderness of the sena gradually subsides.

TUBES, Fallopian, or Trumpets, in Anatomy, two small canals, forming communications between the cavities of the uterus and abdomen, and serving to convey the germs of the new beings, in generation, from the ovaries to the uterus. See GENERATION.

TUBE, Glafs. See GLASS-TUBE, LAMP-BLOWERS, AND HERMETICAL SEAL.

In order to bend a glass-tube, if the glass is pretty thick, and the bore narrow, it may be held in the weaker part of the lamp-flame, and softened for about an inch or two of its length, and then bent slowly into any required shape. But if the tube be wide, and the glass thin, this mode of bending will entirely destroy the cylindrical form of the bore at the part that is bent, making a double flattening. In order to avoid this, first seal up one end of the tube, and then, whilst bending it at the required part, blow steadily and gently into the open end; and the preльure of the breath will counteract the falling in of the sides of the bending portion, and keep the bore cylindrical. The closed end is then cut off by the file; for which purpose, make a deep scratch with one edge of a fine three-cornered file on the part intended to be cut, then break the tube with a smart pull in that direction in which the scratched part will be outermost; and it will in general separate accurately at this point.

In order to join two tubes, heat them both in the flame, and apply them together, when quit hot, turning them round to finish the condensation; or else, to avoid the thick ring of glass which this produces, previously close one end of one tube, and when the two ends are fully joined, blow into the open end of the other tube, and pull them out a little at the point of juncture, till an equal cylinder is formed.

To form a bulb (e.g. of a thermometer), chuse a tube of
of a very equal bore, seal the end in the usual manner, and
to collect a greater mass of glafs at the end, press upwards
on it while quite hot with any iron instrument, so as to con-
solidate and shorten it a little; let it remain in the hottest
part of the flame, till the lump of glafs is quite white hot;
then remove it, put your lips to the open end without loss of
time, holding it with the hot part lowest, and blow moder-
ately and readily. The lump of hot glasfs will immediately
open into a bulb, the fize of which may be regulated at
pleafure.

TUBE, Stenatorphonic and Torricellian. See the adjectives.

TUBEIPILLY, in Geography, a town of Hindooftan, in
Myföre; 20 miles W. of Chinhala Balabarun.

TUBEL, a word used by some chemical writers to ex-
press scales of copper or brads.

TUBELDIE, in Geography, a town of Dar-Fur; 180
miles S. of Cobbe.

TUBER, or Tuberole, in Botany, a kind of round
turgid root, in form of a knob or turnip.
The plants which produce such roots are hence de
dominated tuberofls, or tuberous plants. See Tuberous Roots.

Tuber, an old Latin name for a fort of excercifence,
appropriated alfo to several things of the fungus tribe.
Its derivation is from tumeo, to fwell. Botanists have
retained this name for the preuent genus, to which it originally

Sm. Prodr. Fl. Græc. Sibth. v. 2. 351. Jüff. 3. Lami-
arch. Lull. t. 887.—Clafs and order, Cryptogamia Fungi.

Nat. Ord. Fungi.

Eff. Ch. Roundifh, fhefy, folid, clofed; its fubfcance
variegated with veins bearing feeds.

(T. brumale, pulpa obfcura odorata; Mich. Gen. 221.
t. 102. Tubera; Tourn. Infl. t. 333. T. terræ; Ger. Em. 1583.)—Blackift, rough with prominent warts.—
Found under the surface of the ground in molt parts of
Europe, where the fof is light and dry; as well as in Japan,
and the East Indies. Dogs are taught to find this fungus
by the fcm, and to scratch out of the earth. It is
brought to table, either simply boiled, or flewed in
various forms. The French and Italians introduce tubules into
different made dishes, sauces, pies, &c.
They are reported to have a stimulating, or aphrodisfical quality, which,
whether imaginative or not, perhaps renders them more po-
pular than their flavour, which is trifling. The fize of this
fungus is about that of a walnut in its outer coat, but the
surface is irregularly tumble, and harph to the touch from
innumerable sharp warts. The inner fubfcance is grayift,
or pale brown, with numerous curved branching veins,
lodging the minute feeds. No figns of a root are obser-
vable. They are faid to be several varieties of colour in this
species.

t. 479. Perf. n. 2.—Blackift, fmoofh. —Native of France.
Like the foregoing in fize, and general figure; but its
surface is smooth, the inner fubfcance rather soft, and the
fcent musky. By drying the coat becomes wrinkled.

Bulliard.

3. T. grifum. Grey Truffle. Perf. n. 3. (Truffle
grie; De Borch Truffles du Piemont, 7. t. 1. 2.)—
Roundifh, irregular, smooth, foft, grayift-afhcoloured.
—Native of Piedmont, in a light, moderately moift, fof.
The fize of the two preceding, but more irregular in fhape,
of a foapy texture and light colour, with a frong fcent of
garlick.

Vol. XXXVI.

Perf. n. 4. With. n. 2. Soweb. Fung. t. 310. (Bi-
anchetti; De Borch Truffl du Piemont. 6. 7.) Lycopoldon
bibboum; Dickf. Crypt. falc. 2. 269.)—Light reddifh-
brown, roundifh, half above ground; veins rufty-coloured.

—In woods, in England and France, also in Greece, but
partly furk in the earth. The outside is smooth, turning
more yellow in drying; the inner fubfcance refembles rhu-
bras. Its flavour is laid to be disagreeable.
Dr. Withering describes a variety, or more probably, as
he observes, a different species, whose internal fubfcance is
uniform, like cork, of the hue of tanned leather; the sur-
face knobby and pitted, hairy in the pits. The whole mafs
perforated by items of glasfs; fo that it must have been
above ground in a soft flate.

(T. album); Perf. n. 4. Lycopoldon effumum; Wulf.
in Jacq. Coll. v. 1. 349.)—Nearly globular, smooth,
brown, or blackift; fpongy within; entirely subterraneous.
—Plentiful in Carinthia and Carniola from May to Auguft.
These have little fette or fmall, but are used much for the
table. When young the surface is whithif and fcaly, but
gradually becomes brown or blackift. Their fize is equal
to a chefut or walnut. Perhaps, as Perfoon thought, this
may not be a different species from the laft.

6. T. cernum. Baltard Truffle. With. n. 3. (Tu-
bera cernum; Lob. Fc. v. 2. 276. Lycopoldaltrum tu-
berum arifon fulvum, cortice duro crefto et granulato,
medullā ex albo purpuraceore, femine nigro caffro
Mich. Gen. 220. t. 99. f. 4.)—Globular, finely granu-
lated, rather fold, finally burting; powdery in the centre.
—Found barelely funk in the ground, in several parts
of England, as well as in Bohemia and Silefia, about Sep-
tember. The diameter is about an inch and a half; the
outside tawny; inner fubfcance, or nucleus, purplifh.

7. T. folidum. Hard Truffle. With. n. 4. (Lyco-
perdon cepae facie; Vaill. Parif. t. 16. f. 5. 6.)—
"Glo-
bular but compressed, (rather depreffed,) brown, reticu-
lated, very firm; blue-black within." — Found in Dr.
Withering's park at Edgbaston, near Birmingham, under
an oak-tree by the pool, in Auguft. This had a short
root, as Vaillant represents it, and appears to be, as Mr.
Sowerby fuppofes, only a nearly felfile variety of his Lyco-

8. T. radicatum. Rooted Truffle. With. n. 5. (Lyco-
perdon cernum; Bolt. Fung. v. 3. t. 116. L. fpadie-
ceum; Dickf. Crypt. falc. 1. 25. Lycopoldaltrum effu-
crum, altius radicatum, pulpa atro-purpurae, cete lacera,
veluti punctata; Mich. Gen. 220. t. 99. f. 3.)—Roundifh,
depreffed, cracked in the surface, with a thick fhort root.
—Found on heaths, and in woods, in Italy and England in
the fummer, but rare. Two or three inches in diameter,
solid, never burting, nor becoming internally powdery.
The outer skin is brown, or olive, craking into angular
portions, but not wary. Inner fubfcance purplifh, veined
with black; finally quite black. Apparently different from
Lycopoldon aurantiacum of Bulliard, t. 270; fo that the fine
infone in his figure may not be altogether, as Bolton fays,
"conjeftural," it may reprefent the powdery feeds, eloping
from holes eaten by insects, as Bolton himfelf fuppofes.

Tuber, or Tuberefty, in Surgery, is used for a knob or
bumb growing naturally on any part; in opposition to
tumours which rifé accidentally, or from a difeafe.

The fame term is also used for a knot in a tree.

TUBERA TERRÆ. See Truffles.

TUBERAN, in Geography, a town of Perfia, in the
province of Kerman; 171 miles N.E. of Schiras.
TUBERCLE, a small, hard, superficial tumour, circumseribed, and permanent, or suppurating partially.—Bate- 
man’s Synopsis of Cutaneous Diseases.

TUBERCULA QUADRIGEMINA, in Anatomy, a part of the 
brain. See Brain.

TUBERCULARIA, in Botany, so called from its small 
tuberculat figure.—Tode Fung. Mecklern. f. 1.18. Per. 
Syn. Fung. 111. Obf. Mycol. f. 1. 78.—Nata and 

Eff. Ch. Roundish, compact, smooth, permanent, solubile 
in wet.

Mycol. n. 138. f. 1. 79.—Burfting from the cuticle 
of trees, crowded, even, red; with a difcoide permanent 
base.—On decayed branches of Maple.

t. 4. f. 30. Perf. n. 2. (Tromella purpurea; Lion. Sp. 
Pl. 1626. Hudf. 565. Licheniobes tuberculatam amoeni 
purpuream; Dill. Mufc. 127. t. 18. f. 6.)—Aggregate or 
feattered, bright red, corrugated, with a thick pale base.

Very common on dead or dying branches of trees, efpe- 
icially currant-bushes, where it becomes conspicuous by its

n. 3.—“Roundish, dull red, with a corrugated granulated 
surface.”—On the branches of Sycamore, or other species 
of Acer, but rare. Its colour is brownish and opaque; 
yellowish within. Perfon.

“Crowed and confluent, of a flefly red brick-colour, small, 
oblong, angular or flatthiff.”—On dry branches of the 
Common Maple. Coloured much like T. vulgaris, but smaller, 
and lofter.

“Scattered, small, funk in the bark, flatthiff, very smooth, 
bright red.”—On the bark of the chefnead-tree. Half the 
size of T. vulgaris, and fearcely projecting out of the 
cuticle of the bark. Its colour externally is like that of a straw-
berry, of the infide yellowish, firm.

Mycol. n. 137. f. 1. 78. (Lichen roseus; Schreb. Lfp. 
140.)—Scattered, loose, irregularly globofe, rofe-coloured.

—On trees, especially adhering to Lichen flcllarius, parietius, 
&c. We have found it on the former at Hetherfet, near 
Norwich. The bright-pink little maffes, of which this fpe- 
cies confifts, might be taken for the tubercules of fome Lichen; 
but they diffolve in wet.

TUBERCULUM ANNULARE, in Anatomy, a part of 
the brain. See Brain.

TUBERCULUM Loweri, a small eminence in the right au-
ricle of the heart. See Heart.

TUBERNICENSE OFFIDUM, Tubernoke, in Ancient 
Geography, a town of Africa, built in form of a crescent, 
between the fummits of a mountain, 7 leagues S.W. of 
Tunis.

TUBERNOBI, in Geography, a town of Tunis, anciently 
the fee of a bishop; 21 miles S.E. of Tunis.

TUBEROS, in Botany, See POLIANTHES. This Eng-
lish name is not compounded of tube and rofe, as most people 
would naturally conceive, but originates in the old ap- 
pellation of Tubero, or Tuberosus, Hyacinth, Hyacinthus tu-
berofus; alluding to the tuberous root, and the reemance 
of the flower to a Hyacinth.

TUBEROUS Roots, in Gardening and Agriculture, 
such as conflit of one or more swelled or knobbled tubers, of a 
solid flefly fulblance. In this tribe are comprifed many plants 
of the ornamental flowery kind, and fome efeulents of the 
kitchen garden; as in the former, amone, raphan, 
filpenula, many forts of iris, aconitum, prony, oricho, cy-
clamen, winter-aconit, day-lyl, &c.; fome alfo with bulbo-
tuberous roots, as gladiolus, polianthes or tuberofe, opyrs, 
&c; and of the efeulent tuberous roots are the potatoe and 
Jerufalem artichoke: all of which plants are principally per-
ennial in their roots, being perpetuated annuallly by offsets, 
or cuttings for fets. See Root.

It has lately been fugged, and in many meafure con-
formed by experiment, that, in cultivation, the root of this-
kind, called the potatoe, is liable to have the difeafe termed 
the curl produced in crops of it, by the tubers which are 
ufed for feed-flock or fets having been allowed to become 
too ripe the preceding year; and that this praftice of over-
ripening, being repeated year after year, is the real caufe 
of the difeafe, the vegetative power in the tubers being in 
this way exhausted.

It has been long known to all cultivators of this fort 
of crops, that the usual method of reproducing any particular 
variety of the root is by cuts or fets of the tubers; and that 
this manner of propagation is continued from year to year, 
as long as that particular fort is fifted for, without ever 
thinking of reinvigorating the feed-flock, or tubers for 
planting, by raifing new plants from the real feed; the 
fitness being reproduced only by fowing the true feeds of 
the plant. It is only thus that new varieties are obtained.

But if fets be taken from any particular variety which is 
fifted to be preferred, and if care be exercised that the 
plants fhall have no communication with the farina of any 
of the plants of the fame species in flower, then the produce 
of thefe feeds will probably be the fame with that variety 
from which the feeds were faved; and from the feed-flock 
being renewed, and reinvigorated in this manner, it feems 
likely that the variety fo obtained may, by obferving a pro-
per management, be preferved from this difeafe, or any other 
kind of degeneracy, for any length of time.

This opinion of the over-ripening of the feed-flock for 
the supply of the ensuing year, by allowing it to remain too 
long in the ground, efpeially when planted early, and of the 
repetition and continuance of it rendering the tubers wholly 
uflit for producing vigorous healthy plants, by exhaufting 
their power, being the chief caufe of this difeafe, has however 
been almost uniformly objeented to, as being quite contrary 
to experience in regard to feeds in general, as full ripenefs 
has been confidered the best recommendation of them. It is 
notwithstanding apprehended, that this objeetion arises from 
the taking of an improper view of the matter. For though 
它是 true, that all of what are properly called feeds are im-
proved by being thoroughly ripened; the cuts or fets taken 
from the tubers of this fort cannot, strictly speaking, be con-
lidered as feeds. The planting cuts of this kind of tuberous 
root, is analogous, it is fuppofed, to budding or grafting of 
tubs, being only a fecondary mode of propagation, and con-
sequentially that such an objeetion cannot hold good. Besides, 
the fuggelion is illuftrated and supported by different other 
circumstances and confiderations, as well as by the well-known 
powerful caufe which weakens the vegetative power in the 
tubs,—that of allowing the plants that are intended for the 
supplying of feed-flock for the ensuing year to run to flower, 
and produce feed. This, it is thought, fhould in all caufs 
be prevented, by cutting off the flowers as they appear in 
their embryo flate. In this way, by turning nature from her 
ordinary course, to force her to exert herfelf in another di-
rection, and to throw back into the tubers that portion of 
the vital principle of the plant, which would have been ex-
haufted in the formation of flowers and feeds. Nothing will, 
it is fuppofed, contribute more to prevent degeneracy in this 
fort
sort of tuberous root, and especially of the disease to which it is so liable, than this treatment. See the first volume of the Transactions of the Scotch Horticultural Society.

TUBERSOKE, in Geography, a town of Tunis, anciently the seat of a bishop; 48 miles S.W. of Tunis.

TUBIG, a town on the E. coast of the island of Samar. N. lat. 12° 13'. E. long. 135° 27'.

TUBILUSTRIUM, composed of tubus, trumpet, and tubera. I purify, in Antiquity, a feast or ceremony in use among the Romans. This denomination was given to the day on which they purified their sacred trumpets, as also to the ceremony of purifying them. It was held on the fifth and last day of the feast of Minerva, called quinquatrus, or quinquatria, which was performed twice a year.

TUBINGEN, in Geography, a town of Wurtemberg, situated in a valley on the Neckar, between two hills. An university was founded here in the year 1477, and refounded in the year 1770. Here is a seminary for the study of divinity, and a college for the nobility. The foundation of the town is unknown, but assuredly of great antiquity. It is the origin of the pfalzgrave of Swabia, and though the descent of the ancient palatines of Tubingen be unknown, yet they had their pfalz or palatium, which stood on the spot of the present castle. One of the elder pfalzgraves known at present, lived in the year 1080; and the last of them, W., George Eberhard, died in the year 1631. The two pfalzgraves, Gobs and William, in the year 1342, sold the town to count Ulrich of Wurtemberg. In 1555, duke Ulrich, pulling down the old castle, caused that of Hohen Tubingen, which is the present residence, to be erected, with fortifications. In 1540 the town was damaged by fire. In the thirty years' war it was frequently besieged and taken; and in 1688, was considerably injured by the French; 16 miles S.S.W. of Stuttgart. N. lat. 48° 33'. E. long. 9° 10'.

TUBIPORA, Red tubular Coral, in Natural History, a name given by Linneus to a genus of Zoophyta, in the class of worms; the characters of which are, that its animal is a mereis, and that it is a coral, consisting of cylindrical, hollow, erect, and parallel tubes.

In Gmelin's edition of the Linnean System we have the following species.

Musica. With falciculated combined tubes; the transverse partitions membraneaceous and distant. This is the purple tubipora of Pallas, of which he mentions a variety, or the flexuoso tubipora. It is found in the American, Indian, and Red seas, affixed to other corals or rocks; and is used by the Indians as an antidote to strangury and wounds inflicted by poisonous animals.

Catenula. With parallel tubes, connected into a lamina anamorphosing with a folded wreath. Found on the shores of the Baltic sea.

Serpenis. With cylindrical, erect, very short, distant, axillary tubes; diversiforated at the dichotomous base: the Millepora lilacea of Pallas. Found in the Mediterranean and Northern seas, and on the shores of the Baltic.

Fascicularis. With filiform falciculated tubes; the sides anamorphosing. Found on the shores of Gothland.

Ramosa. With roundish interspaces, and simple, flexuosae, aggregate, confluent tubules of the confluent branches. Found in the White sea.

Pinnata. Dichotomous, erect, with tubules distributed in the form of small feathers. Found in the Mediterranean sea.

Penicillata. Stalky; the top incrustated, and formed of tubules connected towards the base. Found in the Greenland sea, affixed to teftaceae.

Flabellaria. Depressed, flabelliform, with parallel conjoined tubes. Found as the former.

Stellata. With separate tubes, combined in layers or tables, many of these tables being remote, horizontally tubulous, and radiated with sreel on the surface. Found among foraminifers.

Striae. With distant diverging tubes, loose behind and often bent; with tubules small, simple, and horizontal, combined. Found among foraminifers.

TUBNA, in Geography, a town of Algiers, anciently called Thubana. The Arabs bury their treasures under the ruins; 116 miles S.S.W. of Constantina. N. lat. 35° 8'. E. long. 5°.

Tubo, a town on the south coast of Mindanao. N. lat. 7° 49'. E. long. 124° 32'.

TUBOEUF, a town of France, in the department of the Mayenne; 6 miles N.E. of Laflay.

TUBOR TERRAE, a name used by some botanical authors for the cyclamen or low-bread.

TUBUG, in Geography, a harbour on the west coast of Mindanao, much frequented by pirates. Near it is the house of a rajah, strongly palisaded, and defended with twenty swivel guns; 10 miles N. of Pollock harbour.

TUBUHACAN, a town of Africa, in the country of Sugulmeffa; 9 miles from Sugulmeffa.

TUBULARIA, in Zoology, a genus of the Zoophyta class of worms; the characters of which are, that the animal is vegetating and radicated; the head crested with tentacles, generating small eggs; and that the item is tubulous, horny, very simple, or branched, affixed at the bottom, and the animal thralls out at the apex. Among the following species are included several of the tubular corallines of Ellis.

Species.

Ramosa. With branched flanks, and wreathed joints; one of Ellis's. Found in the European sea. The loft tubules fiercely grey.

Fragilis. With dichotomous flanks, and compressed joints. Found in the American sea. White or greenish.

Papyracea. With a very large papyraceous tubule, alternately ramose. Found in the Indian ocean.

Penicillus. With aggregate, simple, radicated tubes, profliurous and penicillated at the apex. Found in the American sea. It is doubted whether this and the last be of this genus.

Acetabulum. With filiform flanks; the terminal pelta or shield inflated, radiated and calcareous. Found in the Mediterranean and American seas. White and soft, and affixed to teftaceae.
**TUB**

**SPLANCHNEA.** With capillary very simple stalks; the terminal pelta smooth and membranaceous. Found in the Mediterranean sea. Of horn-colour.

**CORYNLA.** Sub-ramose, filiform, papyraceous, jointed with ovato-acuminate capsules, and dilatable mouth, and terminated with cylindrical armed tentacula. Found on the shores of Holland and England. Anercaneous and reddish.

**AFFINITIS.** Simple, sub-anastomosed, soft; with the tentacula of the mouth encompassing the papilla attenuated. Found on the English coast, adhering to fuci, and akin to the lani.**

**FABRICATION.** Stellated, with pinnated cirri, and six rays encompassing the mouth. Found on the shores of Norway and Greenland, often in the fissures of rocks. Grey, green, or white.

**LONGICORNIS.** With two fætaceous cirri, longer than the tubule. Habitation unknown.

**MULTICORNIS.** With more than twenty cirri centrally white; body round and hyaline, tubule mace-like. Habitation unknown.

**CAMPANULATA.** With lunated cret; orifices of the vagina annulated; body concealed within the vagina. Found in the flagrant waters of Europe.

**REPENS.** Creted, with cirri on both sides radiated; vagina extended, tubule opaque, procumbent. Found in the flagrant waters of Northern Europe.

**REPTANS.** With lunated cret; body tractile beyond the vagina. Found in the flagrant waters of Europe. Hyaline, soft, with about sixty cinas.

**SULTANA.** With infundibuliform cret, ciliated at the base. Found in the pools of Gottingen.

**STELLARIS.** Creted, with pectinated cirri, brown, annulated cret tubule. Found in the focus of the Baltic sea.

**SIMPLEX.** With eight linear cirri, and conic hyaline tubule. Found in the focus of the Norwegian sea.

**SPALLANZANI.** With five plume cirri, pectinated on both sides, and cylindrical, horny tubules, below incurvated. Found in the Mediterranean sea.

**MEMBRANACEA.** With a double concentric range of fitiones tentacula, and a membranaceous, contractile, vilcid, cylindrical tubule inclosing the inhabitant. Found in calm parts of the Mediterranean; but doubted whether it belongs to this genus.

**TUBULARIA Fossilis, in Natural History,** the name of a species of coral found very often fossil, in Germany and Italy, and composed of a great number of tubes, or longitudinal pipes, often resembling so many worms ranged perpendicularly in the mafs.

They are usually found either in mafses of a lax flone, or in fngle tubules in thofe of the harder and firmer texture. In these two dises this fossil makes two very different appearances; and, according to the different directions in the mafs, or the different views of them that the sections of it place them in, they make a number of very elegant figures.

**TUBULATED FLOWER, Tubulatus flocculus, in Botany,** a term used by authors to express those fmall flowers, a great number of which go to compose one large compound flower. These are called tubulated, by way of distinction from another kind of them, which are, from their shape, called ligulated. The tubulated floccules generally compose the disk, and the ligulated ones the radius of the compound flowers. The tubulated ones are formed into a hollow cylinder, which expands into a mouth at the top, and is divided into five equal segments, which flatten expanded, and in some meafures bent backward.

**TUBULI CONCAMERATI, in Natural History,** the name of a genus of the Tubulus marinus, distinguished abundantly from all the others by its figure and inner structure. They are long shelly bodies, usuallv either of a conic or cylin- dric form, or else resembling the dentes in shape; and sometimes, but that very rarely, they have their smaller end bent and twisted round. They are composed within of a number of hollow compartments, each of which communicates with the next by means of a siphunculus, which runs through the whole length in the manner of the thick nautilus, or the cornu ammon. We know not these in their recent flate at this time, but frequently meet with them fossil in the flones brought from Sweden for pavements, and in some others.

Some authors have called thefe by the name alveoli, confounding them with the conic body found in the belemnite. See ALVEOLUS.

Others have called them pyramidal entrochi, others abelisci marmorei alveolares; and they are the bodies described by Gehrner and Aldrovand, under the names of lapides cuneo cancri, or cancri. Some late authors have called them also polythalamii, and others cone-flones. Klein. de Tubul. p. 7.

**TUBULI Fossilis,** the name given by authors to the cafes or tubes of sea-worms, found buried in the earth.

They are in their native flate of very various kinds, but by different accidents attending them in their accidental one, they are subject to a multitude of other appearances. They are found of very various sizes, sometimes complete, and buried in the flata of earth or fone; sometimes they are more or less perfect, and are immerfed in mafses of the ludus Helmontii, or septaries, and in this flate they make one kind of lapis siringoides, or pipe-flone; but the most beautiful siringoides, or pipe-flones, are the parts of the bottoms of thips, or pofts fixed in the fia, which have been pierced, in their original flate of wood, by these cafe-worms, and afterwards petrifed with the cafes or tubuli of the worms remaining in them.

Of these there are many beautiful specimens on the shore of the island of Sheppy, and in our clay-pits about London and Richmond.

Thole tubuli called dentalia et entalia, are not lefs frequent, and found of various kinds in the clay-pits about London and the hills of Yorkfliire; but they are more frequent in similar places in France and Italy.

**TUBULI Lattigferi, or Calicophori, in Anatomy,** the canals in which the milk is secreted. See BREAST.

**TUBULI Seminiferi,** the innumerable minute canals com- posing the body of the teifs. See GENERATION.

**TUBULI Uriniferi,** the small tubes terminating on the papilla of the kidney. See KIDNEY.

**TUBULI Vermicularis,** a name sometimes used by naturalists for certain small oblong and hollow sea-flones remem- bring worms.

**TUBULUS Marinus, or Canalis, in Natural History,** the name of a genus (according to fome writers) of univalve shell-flies; the characters of which are these: it is of an ob- long figure, terminating in a point, and hollow within, so that it remembles a tube or horn. Thofe are also called by the old writers dentalia, from their remembing the tooth of a dog. See DENTALIUM, CONCHILOGY, AND SHELLS.

It has been a common error of authors to confound under the general name of tubulus marinus, these flones, and thofe very different ones of the vermiculi marini, which make a number of pipes or tubes joined together; thofe, by their number and joinings, have induced a late French author to place them among the multivalve flones, while the canalis are usually single and separate, and can have no title to any clas but the tubular univalve one. Aldrovand obferves, that the tubuli
In Botany, a diminutive, from tubus, a tube, expressing the structure of the fungus in question.—

TUBULINA, in Botany, a diminutive, from tubus, a tube, expressing the structure of the fungus in question.—

1. T. falax. Doubtful Tubulina. Perf. n. 2. Obs. Mycol. fse. 2. 28.—"Opaque, indeterminate, brownish. Receptacles combined at the top into an uniform bark."—

2. T. fragiformis. Strawberry Tubulina. Perf. n. 2. Obs. Mycol. fse. 2. 29. (Tubulifera arctonicae; Jacq. Mie. Anh. v. 1. 144. t. 15. T. Ceratum; Fl. Dan. t. 369. f. 2.)—Nearly globular; first red; then brown; receptacles rather swelling upwards, distinct at the top.—

Found on the trunks of trees, after heavy rains in summer, attracting notice by its likenesses to a large strawberry. When arrived at maturity, it becomes opaque, of a rusty brown. The author above quoted mentions in his Observationes Mycologicae, fse. 2. numerous fungi allied to this, partly observed by himself, and partly described by other authors, which he was doubtful whether to consider as species or varieties. His doubts seem to have been rather increased than diminished when he wrote his Synoq, and therefore we cannot presume to remove them. Among these obscure productions are Spherocephorus fragiformis, Buliard t. 384; and S. cylindricus, t. 470. f. 3, which appear to answer well to the generic character of Tubulina, and to be specifically distinct from T. fragiformis, as represented by Jacquin. Perfon also mentions a Reticulaira multipolosa of Sowerby's Fungi, t. 169, which is an altogether erroneous reference; nor shall we attempt to guess whether it alludes to any thing in that author's t. 399, or any other.

TUBULOSE LEAF, among Botanists. See LEAF.

TUBURBO, in Geography, a town of Africa, in the kingdom of Tunis, supposed to be the ancient Tuburbum. Mahomet, a late bey of this kingdom, planted a great number and variety of fruit-trees in the neighbourhood of this town, which were ranged in so particular a method, that each species was confined to one grove, and thereby removed from all influence of another. In the adjacent valley, where the Mejerda conveys its stream, the fame curious and generous prince erected out of the ruins of a neighbouring amphitheatm, a large mafs

bridge or dam, with proper fufces and flood-gates to raise the river to a convenient height for watering and refreshing thefe plantations. But this, which was too laudable an invention to be fubmit long in Barbary, was soon entirely broken down and destroyed; 16 miles W.N.W. of Tunis.

TUBUS COROUM, in Botany, the inferior, more or less cylindrical, part of a monopetalous corolla, supporting the Limbus; see that article. The tube differs in length, in different genera or species of plants, as well as in shape. A rotate, or wheel-shaped, corolla has the tube necessarily very short, or scarcely any; a funnel-shaped one has the same part elongated, and dilated upward. Sometimes the tube conceals the flamines, which are inferred either into some part of itself, or more rarely into the receptacle; sometimes, indeed very frequently, the flamines project, with the fyle, out of the tube. Its mouth is usually pervers; sometimes hairy; in several genera of the tribe Asperifolius, that part is closed by arched or converging valves, covering the others. The claws of the petals, in a polypetalous corolla, stand in the place of the tube of a monopetalous one, and in some instances are so far connected, at an early period, as really to constitute a tube, subsequently splitting into claws. Examples occur in the order of Proteaceae, which have caused some perplexity, and difference of opinion, in the characters given by different botanists of the plants of that order.

TUCABATH, in Ancient Geography, a town of Africa, in the interior of Libya. Ptolemy.

TUCANA, in Ornithology, a name given by fome to the toucan.

TUCAPEL, in Geography, mountains of Chili, S. of Concepcion. S. lat. 37° 30'.

TUCAYAN, a town on the W. coast of the island of Negros. N. lat. 11° 12'. E. long. 122° 57'.

TUCCA TEREBINTHINA, Sheelab, in Ancient Geography, a town in the interior of Africa, near Affaraus and S.W. of it. Ptolemy.

TUCCABAR, in Geography, a town of Tunis, on the Mejerda; 24 miles W. of Tunis.

TUCCABATCH, a town of the flate of Georgia; 10 miles S.W. of Oakfukee.

TUCCI, Marins, in Ancient Geography, a town of Spain, in Betica, S. of Calulu.

TUCHAN, in Geography, a town of France, in the department of the Aude; 12 miles S. of La Gaffe. TUCHEL, a town of Prufia, in Pomerelia; 25 miles N.W. of Culm.

TUCK of a Ship, a name given to that part of the ship where the ends of the bottom planks are collected together, immediately under the stem or counter. When this part, instead of being incurvated, and forming a convex surface, assumes the fhape of a vertical or oblique plane, it is said to be square; and a square tuck is accordingly terminated above by the wing-tranfon, and below, and on each fide, by the fahion-pieces. Falconer.

Tuck-Rail, the rail which is wrought well with the upper fide of the wing-tranfon of ships, &c. and forms a racket for the purpose of caulkmg the butt-ends of the planks of the bottom.

TUCKABATCH, in Geography, a town of the Creek nation of Indians.

TUCKAHOC CREEK, a branch of the river Choptank, in Maryland.

TUCKAHOL, in Botany, the North American Indian name of a very extraordinary production, found in various parts of the United States, which appears to be a subterraneous fungus, nearly allied to the genus Tuber; see that article.
article. The Tuckahoe is found in irregular, more or less globular or oblong, lumps, from an ounce to thirty pounds in weight, having a brown corrugated bark. Its internal substance is uniform, solid, snow-white, farinaceous, with little or no taint or smell; and has been used by the natives as food. This production is generally found attached to the roots of some tree, especially of the genera Pinus and Quer-
cus, the fibres of which are interwoven with part of its texture, but in process of time are obliterated. Its growth appears to be very slow. In decay the inner substance affumes an acid flavour, and brown colour. Such are some of the particulars of the history of this fungus, for so we preface it to be, which we have received from Dr. Mac
bride of Charlestown, South Carolina; who has lately given a more ample and detailed account of it, with specimens, to the Linnean Society of London.

TUCKAREAH, in Geography, a town of Africa, in Sahara, anciently called Tigava; 166 miles S. of Algiers.

TUCKATPOUR, a town of Hindoostan, in the circuit of Ruttnapour; 18 miles S.W. of Ruttrnapour.

TUCKEA, a town of Hindoostan, in Goondwana; 10 miles W. of Nagpour.

TUCKER, in Rural Economy, a term sometimes applied to a person employed in the business of fulling.

TUCKER, Josia, D.D., in Biography, a controversial writer, was the son of a small freeholder in Wales, and born in the year 1711. Having completed his education at St. John's college, Oxford, and taken orders, he served a curacy at Bristol, and was promoted by bishop Butler, who made him his chaplain, to the rectory of St. Stephen's in that city. His residence at Bristol drew his particular attention to commercial matters, in reference to which he published, about the year 1747, "A Brief Essay on the Advantages and Disadvantages which Respectively attend France and Great Britain with regard to Trade," which was followed by "Reflections on the Expediency of a Law for the Naturalization of foreign Protestants," published in two parts, 1751—2, and advocating liberal and enlarged prin-
ciples. In these principles he espoused the cause of the Jews in two "Letters to a Friend concerning Naturalizations," 1753. The part he took on this occasion exposed him to much obloquy, and was the occasion of his being burnt in effigy by the populace. However, in 1755 he obtained the degree of D.D., and was made a prebendary of Bristol. His activity in promoting the election of Mr. Nugent, afterwards lord Clare, as a representative for Bristol, was recom-
pensed in 1758 by the deanship of Gloucester. In the controversy occasioned by the petitioning clergy in 1771, he took a part, and published in 1772, "An Apology for the present Church of England, as by Law established," in which, whilst he opposed their claims, he expressed his wish for the omission of the Athanasian creed in the church ser-
cvice, and for excusing students of the universities upon ma-
triculation, and graduates in lay faculties, from subscription to the article. In the same year he published "Six Ser-
mons," on doctrinal points that were then much agitated. In 1773 appeared his Letters to Dr. Kippis's "Vindication of the Protestant Diffident Ministers with regard to their late Application to Parliament," which were written with moderation and candour, and in which he seems disposed to unite the claims of the church of England respecting its own members, with liberal concessions to those who differ from it. In 1774 he published his "Four Tracts, together with Two Sermons, on Political and Commercial Subjects," in which he unfolded his whole plan for settling the dispute with America, deemed by both the contending parties extrav-
gant; this was "to separate entirely from the North American colonies by declaring them to be a free and inde-
pendent people, over whom we lay no claim; and then by offering to guarantee this freedom and independence against all foreign invaders whatever." But he did not wish to con-
cede the point of right in this controversy, as appeared from his publication in 1775, entitled "The respective Pleas and Arguments of the Mother Country and of the Colonies diff-
tinctly set forth; and the Impossibility of a Compromise of Differences, or a natural Concession of Rights, plainly dem-
onstrated." Mr. Burke treated his scheme with some de-
gree of contempt, and therefore he addressed to him one of three subsequent publications on this subject. The dean became ardent and irritable in the prosecution of this dis-
pute, and allowed himself in the abuse of the colonists, and particularly of Dr. Franklin. In 1781, apparently devi-
ing from the principles which he had avowed in more early life, he attacked Mr. Locke and his followers on the origin, extent, and end of civil institutions, in his "Treatise con-
cerning Civil Government." The advocates of Locke re-
torted upon him with warmth, and perhaps with some de-
gree of ability; but "he might confide himself (as one of his biographers says) by having his work quoted by lord Mansfield in the house of peers, with a fine enologium on the talents of the author, whom he mentioned as a writer of the firft class for ingenuity and knowledge." Indulging his refentment against the Americans, and predicing con-
sequences likely to result from their independence, which have not been verified by fact, he addressed to M. Necker, in 1782, a pamphlet entitled "Cui Bono? or, An Enquiry, what Benefits can arise either to the English or the Americans, the French, Spaniards, or Dutch, from the greatf Victories or Successe in the prefent War." In the "Preface" to this work, he undertakes to refute the opinions of the advocates for equal representation. In his subsequent commercial publications he declares himself adverse to all restrictions upon trade, and decries of leaving it to regulate itself. Having resigned his rectory at Bristol to his curate, he re-
fixed at his deanship in Gloucester, and discharged the various duties of his office with exemplary alacrity. Although he was married, he left no issue. He lived to the advanced age of eighty-eight years, and died in 1799, by a paralytic stroke. Gent. Mag. Month Rev. Gen. Biog.

TUCKER, the Rev. William, one of the gentlemen of king Charles II.'s chapel, and precentor of Westminster Abbey, was a very judicious composer of choral music. Mr. Mafon, in speaking of the full anthem, "O give thanks unto the Lord," by this ingenious dilettante, very truly obser-
ves, that "every syllable in this composition has its just length, and each part of a sentence its proper pause; it ad-
mits no perplexing alterations or unmeaning repetitions, but proceeds in one ful, yet distinct strain, harmoniously, yet intelligibly." So many circumstances must concur in forming a com-
plete musician among the lovers of the art, who have no other view in its cultivation than pure amusement, that however ardent their zeal and sublime their genius, if they have not been early initiated in the mysteries of counterpoint, and purfed its labours with the perseverence of pro-
feffional students, timidity, embarrassment, ignorance, and confusion, will appear in their scores at the first glance of a regular-bred composer. In general, their practice, reading of scores, experience, and application, are inferior to thofe of the meanest organist, or ripieno performer: disdaining to perform under parts, or to study them in the works of great masters, as soon as they know their gamut, their chief practice consists in folos and amusing melodies; so that they remain to the end of their lives unable to count reeks, or keep
TUC

keep time, with professional firmness and accuracy; and either totally neglecting or running away too soon from plain counterpoint to florid, a want of instruction and regular study appear in the bascs they put to the slightest and most natural melodies.

TUCKER'S ISLAND, in Geography, a small island in the Pacific ocean, so called by Capt. Wilfon of the Duff, from one of the crew who left the ship there. N. lat. 7° 22', E. long. 122° 5'.—Allo, a small island near the coast of South Carolina. N. lat. 32° 36'. W. long. 80° 16'.

TUCKERTON, a sea-port of New Jersey, in Little Egg Harbour.—Allo, a town of Burlington county, New Jersey; 201 miles from Washington.

TUCKET, a word used by Shakspeare in "All's well that ends well," act iii. sc. 8. corrupted from tuctata, Itals. a fourrith.

TUCKIN, in Agriculture, the name of the fatchel that is sometimes used in sowing beans in the field.

TUCKING-MILL, in Rural Economy, a name given in some places to a fulling-mill.

TUCKT HAZARA, in Geography, a town of Hindoostan, in Moultan; 10 miles N.W. of Tolumba.

TUCKUM, a town of the duchy of Courland; 33 miles E. of Oldingen.

TUCKUSH, a small island in the Mediterranean, near the coast of Algiers, opposite a town of the same name on the continent; 12 miles E. of the Cape of Iron.

TUCKWAPOUR, a town of Hindoostan, in Oude; 14 miles S. of Bahraich.

TUCKYPARA, a town of Bengal; 24 miles S. of Burdwan.

TUCOPIA, an island in the Pacific ocean, discovered by Quiros in 1606. He could not find any anchoring place, but was near enough to converse with the inhabitants, who offered him a present of nuts, and a piece of cloth made of palm-leaves; and they gave him plantations of fruit-trees.

TUCRI, a town of Naples, in the county of Molife; 13 miles E.S.E. of Molife.

TUCUBI, or Tucumbis, in Ancient Geography, a town of Spain, in Lusitania.

TUCUMAN, or Tacama, now called the Intendency of Salta, in Geography, a province of South America, in the vicerealty of Buenos Ayres, extending from 26° to 33° W. long., and from 22° 30' to 36° S. lat.; bounded on the N. by Chicas and Tarija, on the E. by Chaco and Yaptizlagia, on the S. by Cordova, and on the W. by the Andes, which separate it from Chili. This province is now divided into thiofe of Salta and Cordova. Elñallía says that the province of Tucuman was the largest in America, extending from the corner called La Guardia to the river of Quiaca, 380 leagues; of which 314 are fertile lands with carriage-roads, and the remaining 66 barren country with horse-paths. As far as Jujuy the temperature is benign, inclining to the warm and humid, and travellers find much convenience and abundance of provisions. The territory of Tucuman is rich and well cultivated, especially towards Chili, with some desert cantons upon the Magellanic fide. The soil is sandy, and almost without stones, but very well watered, producing plenty of cotton, wild cochineal, wax, honey, paltel for dyeing, and a variety of fruits, with roots, Indian wheat, &c. They likewise breed here vast numbers of cattle, and have plenty of deer, and other game, with lions and tigers in their woods. The sheep here are very large and strong, but their wool is fine, and the inhabitants use them also for carriage. The natives were formerly naked, but since somewhat civilized by the Spaniards, and covered with their woollen and cotton manu-

factures; they live in small villages very close to one another. Its two principal rivers are the Dolce and Saladó, i.e., the sweet and salt ones, besides innumerable smaller streams. In this province a kind of large crow is hunted, and an animal between a hare and rabbit. Here are said to be twelve kinds of bees, all producing honey of different qualities. The chief drink is called "Aloja," but Elñallía does not mention its ingredients, but it is the chica made of maize. Throughout the province there is, as he says, no perfon so poor that he does not kill a cow or a heifer every day for the support of his family.

In the jurisdiction of San Miguel de Tucuman (see St. Miguel) is found the tree called "Quebrachro," a name derived from its extreme hardwes, which breaks the axe; the outer part being white and the centre red, and the latter, after being steeped in water, becoming hard and heavy like stone. In the fame province are found spiders, which weave a thread of great strength and beauty. About a league to the south of San Miguel is the salt river called Sali. This town is remarkable for the manufacture of a kind of cars, used in transporting articles of commerce. The city of Salta (see Salta) is crowded with merchants in February and March, though in the rainy season the roads are fearfly passable: the surrouding vale of Lerma produces excellent wheat, and abundant patturne, but the poor are tormented with a kind of leprosy. The graziers, who deal in mules, and the merchants, chiefly Gallicians, are robust, and the women are remarkable for their beautiful complexion and flowing hair; yet the fex, after twenty-five years of age, is subject to a swelling in the throat, called "Coto," producing an effect very illogical and ridiculous, and which is carefully concealed with neckclothes, but attended with no disfigure or abbreviation of life. This deformity seems to belong to the goitre, a disorder formerly believed to be restricted to the mountains; but as Salta is situated in a valley, it is probably produced by the water or the fogs.

TUCUMANITA, a town of South America, in the province of Tucuman; 10 miles W. of St. Miguel de Tucuman.

TUCUYO. See Tucuyo.

TUCUYO, or Tucuyo, a river of Venezuela, which runs into the sea, N. lat. 10° 38'. W. long. 69° 22'.

TUDDER, a town of France, in the department of the Reoi; 11 miles S. of Ruremond.

TUDDETON. See Tuddington.

TUDELA, a town of South America, in the kingdom of New Granada.—Allo, a town of Spain, in the province of Leon; 5 miles E. of Valladolid.—Allo, a town of Spain, in Navarre, on the Ebro; taken from the Moors in 1118; 4 miles S. of Pamplona. N. lat. 42° 11'. W. long. 1° 40'.

TUDE, in Ancient Geography, a town of Italy, in Umbria, to the S.W., among the mountains. From being a small place it became a Roman colony.

TUDEGUA, in Geography, a town of Aftic Turkey, in Natoia; 32 miles N.N.E. of Edik-Shehr.

TUDES, in Ancient Geography, a town of Spain, on the route from Bracara to Alfurica, between Limia and Burbilla. Antón, Inn.

TUDWAY, Dr. Thomas, in Biography, an ecclesiastical composer, educated under Dr. Blow, at the same time as Turner and Purcell. He was one of the second set of children of the chapel-royal after the Reformation. Soon after quitting the chapel-royal, he was received into the choir at Windsor as a tenor singer. Tudway, like his fellow-disciples, endeavoured to distinguish himself early as a composer, and has entered into the Collection of Church Music which he transcribed for lord Harley, an anthem of his
his own composition, in 1675, when he was only nineteen, with fix more of his early productions for the church, of which the counterpoint is but ordinary and clumsy. The words are likewise often inaccurately accented: he throws the accent of the word triumph upon the second syllable, like Handel; which, though but slight, is, indeed, the only resemblance between them.

In 1681, at twenty-five years of age, he was admitted to the degree of bachelor of music at Cambridge. And in 1705, upon her majesty queen Anne visiting that university, he composed an anthem, "Thou, O God, hast heard my vows," which he performed as an exercize for a doctor's degree; and, after receiving that academical honour, he was appointed public professor of music in that university.

Dr. Tudway composed an anthem, "Is it true that God will dwell with men upon the earth?" on occasion of queen Anne going to St. George's chapel, at Windsor, for the first time; and for this, and other occasional compositions, was permitted to style himself organist and composer extraordinary to that princess.

In the latter part of his life Dr. Tudway resided much in London, and was patronized by the Oxford family. The valuable scores of English church music, in fix thick volumes quarto, which are now in the British Museum, No. 7357, were transcribed by himself at this time.

It is said that he used to meet Prior, sir James Thornhill, Christin the engraver, Bridgman the gardener, and other eminent artists, at lord Oxford's, once a week; and that sir James drew all their portraits with a pencil, among which is Tudway playing upon the harpsichord. Prior wrote sportive verses under these drawings, which were in the possession of Mr. Weft, the late president of the Royal Society.

Dr. Tudway's picture is in the music-school at Oxford: at Cambridge he was longer remembered as an inveterate punnister, than a great musician.

In the time of the duke of Somerfet's chancellorship at Cambridge, during the discontent of several members of that university at the rigour of his government and paucity of his patronage, Tudway, himfelf a malcontent, and joining in the clamour, said, "the chancellor rides us all, without a bit in our mouths!" Nor did the wicked fin of punning quit him even in sickness; for having been dangerously ill of a quinsey, and unable, for some time, to swallow either food or medicines; the phyfician who attended him, after long debates and difficulties, at length turning to Mrs. Tudway says, "Courage, madam! the doctor will get up May-hill yet, he has been able to swallow some nourishment?" the doctor cries out, "Don't mind him, my dear, one swallow makes no summer!"

In the Annals of Queen Anne's reign, 1706, vol. v. p. 333 the following relation of Tudway's disgrace at Cambridge is unaccountable, and mentioned no where that we know of but in these Annals by Boyer, printed in 1707: "About the latter end of July, the vice-chancellor of the university of Cambridge, having received information that Mr. Tudway had spoken words highly reflecting on her majesty, he convened the heads of houses at the regent's, where Mr. Tudway was cited to appear, which he did, and the words being positively proved upon oath, they all unanimously found him guilty, and proceeded to sentence, which was solemnly pronounced in the presence of the heads, and entered as an act by the public regifter, as follows: 'That Mr. Tudway be suspended of all degrees taken and to be taken; that he be deprived of his organist's place in St. Mary's church, and of his professorship of music in the university.'

"Mr. Tudway being of King's college, the provost deprived him of that place in the college, and the regifter there likewise entered his deprivation; and the butler and pantler took his name off the tables in their offices. The master of Pembroke-hall, where he was also organist, in like manner deprived him of that office, and the regifter there entered it accordingly, so that he was deprived of all he held in the university of Cambridge."

We thought it probable that this sudden paroxysm of disloyalty may have been brought on by the dismissal of his patron Mr. Harley; but that did not happen till a year after. In the account which Tudway gives of himself in his prefaces to the Collection of Choral Music which he made for lord Harley, he speaks with the greatest reverence of the queen, affumes the title of her majesty's composer extraordinary, and speaks of anthems which he composed expressly for her chapels-royal at St. James's and at Windfor. It was perhaps only for the sake of an irresistible pun which offered itself in conversation, that he twifled some sentence or expression into treason, or at least into disrepute; for he recovered all his places, had the degree of doctor in music conferred upon him when queen Anne visited Cambridge, and lived and died music-professor in that university.

TUEK, are cones of call-iron with an aperture to receive the nozzle of smiths' bellows, to prevent the heat of the fire injuring them.

TUECH, in Geography, a town of France, in the department of the Ardèche; 18 miles N.W. of Viviers.

TUEL, among Sportsmen, denotes the fundament of a horfe, or wild beast.

TUEL CAR, in Geography, a town of Hindoostan; 20 miles N.E. of Travancore.

TUEL COS, favages in the southern part of the American continent, or Terra del Fuego, refiding on the Rio Negro or Colachel, N. of the Moluches or Tehuelches. (See Patagonia.) The Tuelcos are a numerous tribe. They are divided into horfe and foot, and are dreaded by the Indians of the Pampas, who amount to five or six thoufand souls, with about one thoufand warriors; and they often join in attacks on the frontier. Their attachment to war is fuch, that in cafe there be no foreign enemy, one aduar or village of tents will make war againft another. Their lances are generally of ftrong wild reeds, and they are fo dangerous on horfback, that the Spanifh fucceflors cannot fometimes f tand the charge. The head is large and makes a terrible wound, by which, as they exprefs it, they may fee through their enemies. In these encounters the Spanifh cavalry prefer the fpear, fabre, and piftoles, the carabine and cartouch-box being of little avail. The bola or bow is of stone or metal, about the fize of thofe used in billiards; this is fixed to a string about a yard long, and at the extremity, by which it is held, there are fome feathers of the American offrich or caffowary. This string is turned round the head like a fling, and with it they can frike with certainty at a fufficient diftance. The bolas or bowels have been adopted by the Spanifh foldiers; being two globes of stone or hard wood flavened at the ends of a string, and ferving not only to enthrall the wild horfes and cattle, but alfo to annoy their enemyes. Poniards, sabres, and cutlaffes are more ufual among thefe favages than the bow or the fling. During war they are all cavalry; and they chufe for their general the moft robust and valiant of their chiefs. They paint their bodies, particularly the face and hands, with black and red, not onl y to inflire terror, but to serve as a mark, that they may not be fingly out by the enemy. The tents or houfes of all the tribes of favages are fimilar, being compofed of hides of horfes, beeves, or other animals, and arranged in streets.
The tent of the cazique is distinguished by painting and superior arrangement. The common food is the offrich and castawary, and a kind of armadillo; but their chief regale is the flesh of the snare or foal. In cafe of urgent thirst, they will drink warm blood, which they draw from their horses. The want of food is supplied with bones, greafe, and dry dung. The use of clay is universal, in making various forts of earthenware. They eat with their meat rosted or boiled, and are no strangers to some preparations of milk. The Serranos or mountaineers make a paste of corn, of which they form their bread in loaves, called pateis. In Tuculca, and in other southern parts, the guanoaco abounds, the fleuth of which, with that of a kind of hare, forms the chief food of the Tehuels or Patagonians. But the fleuth is eaten half raw. The drefs of both sexes is a mantle, extending to the mid-leg, with an opening for the arms, and gilt with a leathern belt. On horfaeeback, the skirts are drawn together so as to form loose breeches. These clothes are sometimes made of wool, but they prefer the skins of the guanoaco, lion, and tiger; and the Patagonians use those of seals. With the feathers of the offrich they make fans, and ornaments for bridles, flaining them of various colours. These articles they exchange for tobacco, brandy, and the tea of Paraguay, which with them are articles of luxury. Hard-ware and also coarse woollen are much esteemed. The brandy they exhaust at once, making no reserve. The herb of Paraguay, after having served once, is dried, again used, and finally eaten. The tobacco is smoked in a wooden pipe. The caziques or captains have several wives, but monogamy generally prevails. Jealousy is little known, and a payment in kind is the usual penalty for adultery. Homicides and duels are frequent, and these latter open conflicts are deemed honourable; but treason and assassination are capital crimes, and the guilty are put to death with lances or wooden clubs, nor are there any churches to protect murderers. Although all are thieves, they will make war on a tribe that protects robbers. In every tented village, there is a priest revered as a forcerer and physician. In the night they have no light but that of fire, which they procure by friction of hard wood. Their conflicts are so violent, that few are seen without marks of deep wounds. The desire of revenge passes from one generation to another. They celebrate their victories with dancing, singing and drinking; painting and adorning themselves for such occasions. Their number has been greatly reduced by the small-pox. They appear to have no religion; but contemplate with reverence the sun, which they call "Antu," and the moon "Quien." The only ceremony that has any aspect of religion is, when they kill a beeve, their sprinkling some of the blood on the ground, with the formulay, "Give me to eat, me, and my people." They think that the moon confers strength and valour; and when the new moon appears, they present their infants, and say "make them strong." They also pray to Quien for courage and strength to avenge injuries, and destroy their enemies. Inefficient attempts have been made by popish missionaries for their conversion. The missionaries were slain and the few Christians dillered. Such is Eftalla's account of these savages.

**TUELLA, La.** A town of France, in the department of the Dora; 16 miles W. of Aosta.

**TVER,** a town of Russia, and capital of a government, at the conflux of the Tvertza and Volga. It is the see of an archbishop, and, according to Buflching, contains seventy churches and convents. Tver, from a small fortress, became a town, and increased in population and wealth to fo great a degree, as to become the metropolis of an independ-
matter in solution, or mechanically suspended. Tufa is also
formed by the concretion of loose volcanic dust or cinders
cemented by water; and also by the consolidation of mud
thrown out of volcanoes. The disintegration and subse-
cquent concretion of basaltic rocks forms a third kind of
tufa, which the German geologists call trope-tufa.

calcareous tufa is formed in large quantities in many
lime-stone districts. The waters which issue from calcareous
rocks rise to the surface impregnated with a considerable
quantity of carbonate of lime. On exposure to the air and
light, they deposit their contents on whatever substance is
presented to them, and in the beds of rivulets form solid
incrustations, sometimes of great extent, and many yards in
thickness. The stone thus deposited is always more or
less porous or vesicular, and contains portions of plants and
fresh-water shells which it has enveloped. This stone
hardens by exposure to the air, and is frequently employed
in architecture. It is not a little remarkable, that St.
Peter's church, and some of the grandest works of ancient
and modern architecture at Rome, are formed of a species of
calcareous tufa, called by the Italians travertino. In
the vicinity of Stroudwater, in Gloucestershire, many of
the springs that issue from the feet of the Cotswold hills make
large depostions of calcareous tufa. At one situation, called
the Rock-mill, a bed of this stone, more than thirty feet in
thickness, has been worked formerly for building, as ap-
ppears from some of the oldest edifices in the neighbourhood,
which proves the hardnefs and durability of this stone.
In Derbyshire, and all the calcareous districts in England, beds
of tufa are formed by similar depofitions. Beds of tufa
are very common among the mountains which terminate the
high valleys of the Alps, and there arc promontories of
calcareous tufa in the valleys of Switzerland. It was generally
supposed that the particles of lime-stone were held in solution
by carbonic acid in the water, and that the evaporation of
this acid, after exposure to the air, occasioned the depofition
of the calcareous particles. Dr. Kidd, of Oxford, has
made some experiments on the solvent power of simple
water on carbonate of lime, which he finds to be much
greater than was generally suppos'd. If, says he, half an
ounce of distilled water be agitated for a short time in con-
tact with pulverized carbonate of lime, it will be found, on
the addition of oxalate of ammonia, that the water will be
rendered turbid. It appears, therefore, that when a spring,
charged with as much calcareous matter as it is capable of
holding in solution, has issued from beneath the earth, the
requisite quantity has been diminished by evaporation, the
particles of calcareous matter are liberated and depofited.
Calcareous tufa forms so rapidly in some situations, as
to entirely close up the passage in canals and aqueducts
through which calcareous waters flow. Many hot springs
deposit tufa in abundance; the heat appears to afford the
solvent power of water, and to accelerate the precipitation of
its contents by a more rapid evaporation from the surface.
The travertine, or travertino, is the moft remarkable of all
the calcareous tufas, as it has been employed for the con-
struction of some of the proudest monuments of architectural
genius in ancient and modern times. Of this stone,
Brickla, an Italian mineralogift, gives the following in-
teresting description.
"The Anio, or Tiverone, which descends from the Apen-
nines of Viècovaro and Subiaco to the east of Rome, crofes
Tivoli before reaching the plain where it unites with the
Tiber. All the land through which the Anio paffes in
Tivoli, whether near the great caftaie or the fmalier ones, is
palfed with mafsies of a calcareous ftone, produced by the de-
position of its waters. Sometimes a piece of rush or reed, or
other vegetable matter, is the firft point to which the calca-
reous earth begins to attach itself. It generally depofes in
concentric layers, and has the hardness and fibrous tiffue of
alabaff. These layers are neverthelefs separated by a
bed of calcareous earth, friable, yellowish, and very fine.
At the foot of the mountain of Tivoli, where the Anio
enters the plain which extends to Rome, are the quarries of
travertine. This calcareous rock is depofed in horizontal
beds: its colour is yellowish-white, its grain earthy, frac-
ture uneven, and its hardness far furpasfes that of thofe cal-
careous mafles produced by the Anio in the neighbourhood
of Tivoli. Cavities, where the calcareous fubfance has
assumed a fparry grain and falaftitic form, are common in
travertine. Sometimes thefe cavities have been finel fince
felled by a calcareous falaftite, whiter, of a finer grain, and harder.
This is the origin of thofe white spots, the regularity of
which has caufed them to be miftaken for marine bodies en-
veloped in its pale. Travertine contains no remains of
marine fubfiances, but fometimes it affords fragments of
vegetables. It is not doubted but travertine owes its
origin to the depofitions of the Anio; depofitions which in
the plain may have formed a more solid and compact rock:
because its current was fefs rapid, and perhaps its waters
more flaguant in feveral places. Not far from the quarry
of travertine is the Solfatara, foon called on account of the
great heat of its waters, which abound in sulphuric hy-
drogen gas, and form a confiderable fediment of calcareous
matter. A cardinal d'Elle caufed the canal to be dug
which conveys the waters of the lake to the Anio. The
calcareous depofitions are there fo abundant, that if every
three years it was not cleaned out, it would be closed up,
notwithstanding its depth and breadth. The water which
runs in the canal, on meeting with the bits of ruflh or other
bodies, covers them with a white calcareous crust, two or
three lines in thicknefs. These incrustations are known by
the name of comfits of Tivoli. Before this paffage was
opened, the overflows to which the lake is subject were
often fo confiderable, that the water fpread over the neigh-
bouring grounds, and formed on their surface a fowy
crust. The waters of the lake fo charged with calcareous
earth, uniting with thofe of the Anio in the floods which
their union muft produce, have themfelves contributed to
the formation of travertine. I do not think that the Anio
alone would have been capable of forming the quantity
which is found in that rock.

"Independent of the immense quarries worked by the
ancients, there are besides others of fuch vast extent, that
they may fupply the demands of many ages. The lake of
Solfatara seems to have greatly afhifted in the formation
of this rock. Its water being charged with gaz, explains the
great number of hollows which travertine prefents. It
proves, that when the rock harden'd, a gaz has at the fame
time escaped in feveral places, which has prevented the ap-
proximation of its parts, which were still fott. As often
as the interior of a mass of rocks prefents cavities without
any indication of foreign fubfiances which might have op-
pofed the union of its parts, I conceive their origin may be
attributed to the ecape of gaz at the moment when the
fubstance was paffing from a state of fottnefs to folidity, by
cooling or drying. From what I have juft fhewn, it follows
that the travertine or rock of Tiber or of Tivoli is a carbonate
of lime, formed by the depofitions of the Anio and the Solfa-
tara of Tivoli. The Roman artists give the name of traver-
tine only to the stone taken from the quarry situated at the
foot of the mountain of Tivoli. The lithologists, less faves
TUFAN, in Geography. See SIFAN.
TUFARA, a town of Naples, in the province of Capitanata; 5 miles W. of Volturara.
TUFECI, a body of the iphsis, or horse, in the service of the grand vizier.
TUFFE, in Geography, a town of France, in the department of the Sarte; 7 miles S.W. of La Ferté Bernard.
TUFFEN, a town of Switzerland, in the canton of Zurich; 13 miles N. of Zurich.
TUFFENBACH, a town of the duchy of Stiria; 9 miles S. of Judenburg.
TUFFO, in Botany, a name given by the people of Guinea to a plant common in that country, and used in decoction to wash fore eyes with. It is of the fun-flowers kind, and is called by Petiver, flōs Guineensis folto sæbrem flore minore. It much resembles some of the American sun-flowers. Phil. Trans. N. 232.
TUFFOA, in Geography, a town on Africa, on the Slave Coast; 40 miles W. of Affom.
TUFFPOONS, in Meteorology. See TONQUIN.
TUFT, in Botany and Vegetable Physiology, technically implies a head of flowers, capitulum, of which each individual is not sepal, but elevated on either a simple or subdivided partial flalk, though all together composing a dense roundish mass. Perhaps tufa would be better retained in English as synonymous to fasciculus, in which sense it is often practised to use, for any small number of flowers, on short aggregate or subdivided flarks, springing from the bosoms of leaves, or the divisions of a panicle or corymb. In like manner this term is applied, with more laxity, to little bundles of leaves, hairs, &c. on different occasions.
TUFTED DUCK, in Ornithology. See Tufted DUCK, or Fuligula under DUCK.
TUFTED VETCH, in Agriculture, a term commonly applied to a perennial fort of this plant, which is highly delving of cultivation by the farmer, for either meadow or pasturage land. It is frequently found mixed with other grasses, in rather moist ground. See VETCH, and VICIA Graeca.
TUFTONBOROUGH, in Geography, a town of New Hampshire, on the north side of Winnipigooke lake; 32 miles N. of Concord.
TUG, BAVIN, in Agriculture, a sort of carriage used in some districts for loading bavins or faggots, and sometimes other kinds of field produce. It is so made as to be capable of carrying a hundred and fifty faggots, each four feet in length, and three feet in girth, without being over top-heavy, so as to be liable to turn over in bad roads. It is much used in the weald of Kent, and some other counties.
TUGGLOO, in Geography, a town of the state of Georgia; 95 miles N.W. of Augusta. N. lat. 34° 30'. W. long. 83° 21'.—Alfo, a river of the state of Georgia, one of the branches of the river Savannah, which joins the Keowee; 28 miles N.W. of Peterburg.
TUGGA, a town of Tunis; 20 miles S.W. of Cairoan.
TUGGALA, or TEGEA, a town of Africa, in Kordofan; 150 miles S.W. of Sennar.
TUGGEN, a town of Switzerland, in the canton of Glarus; 5 miles S.W. of Utznach.
TUGGURT, a town of Africa, in the kingdom of Tunis; 60 miles S.W. of Tunis.—Alfo, a town of Africa, in Nigritia, capital of a district called Wadreg; 360 miles N.E. of Tumbudoo. N. lat. 20° 30'. E. long. 6°.
TUGOURT, or TOGOURT, a town of Algiers. It was formerly under the protection of the Turks, and paid a trifling acknowledgment. The inhabitants being disguised with the conduct of their masters, revolted; but were reduced to obedience, the town taken, and great numbers of them put to the sword; 240 miles S.S.E. of Algiers. N. lat. 32° 40'. E. long. 5° 50'.

TUGIA, in Ancient Geography, a town of Spain, upon the route from Caftulo to Malaca, between Caftulo and Truxinam. Anton. Itin.

TUGMA, a town of India, on the other side of the Ganges and near it, with the title of Metropolis, according to Ptolemy.

TUGPINS, in Artillery, are the iron pins which pafs through the fore-ends of the shafts of the army carts, to fallen the draughts chains for the fore-horses.

TUGUESA, in Geography, a town of South America, in the province of Darien; 20 miles N.E. of St. Maria.

TUGULIAN, a town of Ruffia, near the flrains which separate the continent of Asia from America. N. lat. 65° 54'. E. long. 189° 14'.

TUGUS, in Botany, the name of a sweet aromatic plant, growing up sometimes to eight or nine cubits, much esteemed in the eastern parts of the world, and supposes by father Camelli, who very strictly compared it with the accounts given by Dioscorides and the ancients of their amomum, to be that very plant. The clutered manner of growing of the fruit, together with its oblong shape, and the aromatic taste of the seeds, feed greatly to countenance this opinion.

Each fruit of the tugus contains five or seven seeds; these are of an oblong figure, of a reddith colour, and of an agreeable aromatic taste, but not too acid. They are much fought after by birds, insects, and field-mice.

The natives feed as fond of these as the ancients were of the amomum; and the young women firing them on threads, and wear them as bracelets; sometimes they make the bracelets of the seeds alone; but more usually they firing them alternately with pearls, and pieces of red coral: these bracelets they call carapi, as well as the fruit itself.

They are supposied, when worn by way of necklace, to keep off the effects of a bad air, and to preserve them from the bites of serpents, or the centipes. If not a preservative, they are, however, found, upon experience, to be a very good remedy in the last cafe, the common application for the bite of this animal being some of the seeds of the tugus chewed in the mouth to a fort of paste.

The clutered fruit of the tugus, or true amomum, when newly formed and unripe, somewhat resembles the pseudo-amomum of Garcius; but this likewise wears off as they ripen. For Camelli's accurate description of this plant, illustrated by a figure, see Phil. Trans. No 248. p. 2.

TUGUZAK, in Geography, a river of Ruffia, which runs into the Uvelka, 12 miles E. of Troitz, in the government of Upha.

TUGWELL PLOUGH, in Agriculture, a light, easy-going, well-contrived implement of this kind, invented by a perfon of that name. It performs the work well, but not deeply, consequently is improper for weeding lands. It is sometime termed the Gloucester plough. See Plough.

TUHERE', in Geography, a town of Brazil; 45 miles E. of Paru.

TUHLOIS, a town of Sweden, in Tavalland; 15 miles N.E. of Tavalthus.
TUL

nem gentis conditionerque." Caesar thought that Pluto was
honoured under this appellation. Accordingly he says
(De Bell. Gall. l. 6.) "the Druids report that the Gauls
are come from Dis or Pluto, who after his death was
worshipped by both nations as their father and founder,
by the Gauls under the name of Pluto, and by the Germans under
that of Tuilhon, and both of them erected statues to him in
the woods."

Some have ascribed the origin of the name Tuesday to this
day. See WEEK.

TUTIRICA, in Ornithology, the name of a Brazilian
parroquet, which is a little larger than the common kind;
all over of a fine beautiful green, but deeper on the back
and wings than elsewhere; its beak is very hooked, and of
a pale red; its eyes black, and its feet blue; its tail is but
a little longer than the wings when closed. This is a spe-
cies much esteemed in the Brazil, as it easily learns to talk,
and becomes so tame as to eat out of any one’s mouth. See
Psittacus Tiriæ.

TUK, in Geography, a town of Charâfim; 18 miles N.
of Ursæneg.—Afto, a town of Egypt, on the left bank
of the Nile; 6 miles N. of Nékkadé.

Tuk el Efferâl, a town of Egypt; 5 miles N. of
Girge.

TUKERA, a town of Hindostan, in Oude; 14 miles
N. of Lucknow.

TUKKIKARI, a town on the east side of the gulf
of Bothnia. N. lat. 65° 26’. E. long. 25° 12’.

TUULIKAZAK, an island in the North sea, near the
coast of East Greenland. N. lat. 61°. W. long. 46° 20’.

TUUKO, a town of Abyssinia; 20 miles W. of
Tectarin.

TUKURN, a town of the duchy of Courland; 32
miles E.S.E. of Goldingen.

TUL, a town of Grand Bucharia; 36 miles S.E. of
Anderab.

TULA, a city of Russia, and capital of a government,
on the Upha. According to Balhching, it contains 144
churches and convents. Near it are some iron mines, and
in the city are manufactures of fire-arms, all sorts of cutlery
and other works in polished steel, and leather. The number
of merchants, including shop-keepers, is estimated at 40,000,
few of whom are very rich. The number of inhabitants
is estimated at 50,000; the population is increasing, and be-
fides wooden buildings here are many of stone; 112 miles
S. of Moscow. N. lat. 53° 45’. E. long. 37° 39’.

Alfo, a town of Mexico Proper; 40 miles N. of Mexico.

Alfo, a river of Mexico, which runs into lake Chapala,
near Zamora.

TULACUM, in Natural History, a name given by the
people of the East Indies to a species of the yellow orpi-
ment, of the courer kind, variegated with red. They
prepare this by several calculations, and then give it inter-
ally in fevers, and many other disorders, effecting it a
fort of panacea. They say that gold may be extracted
from it, which is not improbable; for it is well known,
that some of the Roman emperors did actually procure
gold from one of the other kinds of orpiment, which is
now found at Goffslæer in Saxony.

TULAH, in Geography, a town of Hindostan, in
Bengal; 31 miles E. of Dacca.

TULBGIA, in Botany, so named by Linnaeus in
honour of the Dutch governor Tulbagh, long resident at
the Cape of Good Hope, who sent numerous plants from
that country to professor Burmann, and furnished Linnaeus
with several of its insects, particularly a fine species of
Papilio, which is called Tulbaghia, being one of the tribe of

Lamarck Uhufr. t. 243. Gartn. t. 16.—Clais and order,
Hexandra Moumington. Nat. Ord. Spathacæ, Linn. Narciffi,
Juss.

Gen. Ch. corrected from the Linnean MSS. Cal.
Sheath of two oblong membranous valves, containing many
stalked flowers. Cor. of one petal, inferior, falver-shaped;
tube cylindrical; limb in six equal, lanceolate, acute,
spreading segments, shorter than the tube. Nectary of three,
distinct or combined, cloven, acute, equal, fleshy leaves,
crowning the tube. Stam. Filaments fix, very short, three
in the throat of the tube, three lower down; anthers heart-
shaped, acute. Pfl. German superior, ovate: foldy cylin-
derical, much shorter than the tube; stigma turbinated,
decrepited. Peric. Capsule oval, with three angles, three
intermediate furrows, three cells, and three emarginate
valves. Seeds few, oblong, obtuse, triangular, compressed,
corrugated.

Eff. Ch. Corolla falver-shaped; limb in six equal seg-
ments. Nectary of three cloven scales, crowning the tube.
Stamens three in the throat, three within the tube. Cap-
fluence superior, of three cells and three valves. Seeds
compressed.

Mag. t. 806. (T. capenis; Linn. Mant. 2. 223. Jacq.
Hort. Vind. v. 2. 52. t. 115.)—Flowers drooping. Ne-
catory of one leaf, in six segments, as long as the limb of
the corolla. Native of low sandy spots, near the town,
at the Cape of Good Hope, flowering about July, and called by
the Dutch colonists Wilde Knoplook, or Wild Garlick. It is
said to be used for disorders of the breast, flowed in nulks;
but whether internally or externally, is not recorded. This
species was sent to Kew by Mr. Maffon, in 1774. Jacquin
had it a few years earlier. Root tuberous, with numerous
fleshy fibres. Leaves radical, erect, numerous, two-ranked,
linear, blintth, channelled; exuding at the base. Stalk
solitary, about a foot and a half or two feet high, roundish,
simple, bearing a hoof umbel of from ten to fifteen spread-
ning or drooping flowers, whose partial flasks are near an
inch and a half long. Each flower is rather thinner than a
Harebell, oppresively sweet in an evening. Corolla green
or slightly glaucous. Nectary purplish-brown. Seeds black.
The whole plant, when ever to slightly bruised, exhales a
rank smell of garlic, still perceptible in the old dried
specimens of the Linnean herbarium, whenever they are
touched or moved.

2. T. cepaææ. Purple Tulpagia. Linn. Suppl. 194,
excluding the synonyms. Willd. n. 2. Ait. n. 2. Thunb.
Prodr. 60.—Flowers erect. Nectary of three distinct
cloven leaves, half as long as the limb of the corolla.
Native of the Cape of Good Hope, from whence it was
sent by Mr. Maffon to Kew garden in 1795. A smaller
plant than the foregoing, with much narrower leaves.
Umbel, in our only specimen, of seven flowers, whose
coarolla is purple, or crimolin. Of the colour of the ne-
cary we cannot judge, but its length is about half that of
the segments of the petal.

There can scarcely be a greater example of confusion
than the history of these two plants in the Supplementum
of Linneus, nor could it be unravelled without the original
specimens. If in the character and description of the first,
we read folia subefusiformis, instead of fusiformis, it may
be intelligible. The root moreover, in one specimen, seems
bulbous. All the rest answers tolerably well. In the
second
second species, the leaves are perfectly linear; the root by no means fasciculate, except its fibres, being exactly like the former; to which the fynonyms, even of Liananus himself, undoubtedly belong. A figure of T. capitata is much wanted. The plant is laid to flower at Kew in April.

3. T. hypoxidea. Short-crowned Green Tulbagia.—

Flowers drooping. Nectary very short and obtuse. Segments of the limb of the corolla taper-pointed.—This hitherto nondescript species flowered in March 1792, in the border of Meffrs. Lee and Kennedy, of Hamner smith, who received the root from Holland. There can be little doubt of its having been brought to that country from the Cape of Good Hope. The leaves are linear and very narrow, about one-fourth the breadth of T. alliacea. The inflorescence, as well as the peltate and general aspect of the flowers, most resemb that species. The corolla is green, but its segments more taper-pointed, and full as long as the tube; while the nectary is extremely short and blunt, rising but little above the mouth of the tube, and confining, if we mistake not, of three undivided lobes.—Mr. Sowerby made a drawing of this species at the period above-mentioned, which, though now meiliad, may one day probably be given to the public.

Tulbagia, in Gardening, contains plants of the tender, herbaceous, exotic kind, among which the species cultivated are, the alliaceus or garlic tulbagia (T. alliacea); and the cepaccus or onion tulbagia (T. cepaccus).

Method of Culture.—In each of these sorts, the young plants may be increased by fowing the seeds, flippin the branches, and offsets from the roots.

The seeds should be sown while fresh in pots filled with light mould, and be plunged into a tan hot-bed any time in the autumn or spring feasons, when they will soon begin to grow. And the slips and offsets may be planted and managed in the same way. The young plants in all the cafes muft conilantly remain in the fove, and have water occasionally given them.

Both these plants afford an agreeable diversity in fove collections.

TULBING, in Geography, a town of Audfria; 4 miles S.S.E. of Tuln.

TULCA, a town of European Turkey, in Bulgaria, on the south side of the Danube, opposite Ilmait. In the year 1771, this town was taken by the Russians, and again in 1790.

TULCZIN, a town of Russian Poland; 12 miles S.W. of Braclaw.

TULEBRAS, a town of Spain, in Navarre, on the Queios; 7 miles from Tudela.

TULIAN, a town of South America, in the province of Cordova; 110 miles N.W. of Cordova.

Gen. Ch. Cal. none. Cor. bell-shaped, inferior, of six ovate-oblong, concave, erect, deciduous petals. Stam. Filaments fix, awl-shaped, much shorter than the corolla, taper-pointed; anthers oblong, quadrangular, erect, very fatile, ditant. Pifl. Germen superior, large, oblong, bluntly triangular; style none; stigma with three prominent angles, or three divided lobes, permanent. Petal. Capule triangular, somewhat elliptical, of three cells, and three ovate valves fringed towards the edges. Seeds very numerous, flat, semicircular, lying horizontally over each other, in a double row, with scales of the same shape (or barren seeds) between.

1. T. fylusfris. Wild Yellow Tulip. Linn. Sp. Pl. 438. Willk. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 63. Fl. Dan. t. 375. Curt. Mag. t. 1202. Redout. Liliac. t. 165. (T. bononifinis; Ger. Ern. 138.)—Flower solitary, somewhat drooping. Leaves lanceolate. Stigma triangular, abrupt, slightly three-eflet. Stamens hairy at the base. Petals acute, hairy at the tip.—Native of Sweden, England, Bohemia, Germany, Switzerland, and France, flowering in April. Root an ovate bulb, flatish at one fide, prominent at the other. Stem quite simple, erect, round, smooth, twelve or eighteen inches high; leafy in the middle; tapering at the base. Leaves about three, alternate, lanceolate, acute, keeled, entire, smooth, somewhat glaucous; the uppermost linear and much the narrowest. Flower drooping, till it is fully expanded, of a fine golden yellow, sweet-scented; the three outermost petals greenish at the back; all of them elliptical, acute at each end, and tipped with a little white wool at the summit; three innermost fringed with similar wool at the base. Stamens yellow; their filaments densefily woolly at the bottom; anthers linear-oblong, Gerden pale yellow or greenish, crowned with a triangular, abrupt, not dilated stigma, gradually splitting into three small notches, slightly downy at the top. The Early Yellow Tulip of the gardens, which is figured in the plates of Redouté and Curt. Mag. cited above, can hardly be distinguished from our wild kind, except being larger, with a rather more decidedly three-lobed woolly stigma. Our Bohemian wild specimencs are intermediate between the two.

2. T. Celfana. Small Yellow Tulip. Redout. Liliac. t. 38. Ait. Epit. 375. Curt. Mag. t. 717, erroneously named there Melanathum uniforum. (T. biflora; Donn. Cant. ed. 5. 75? T. pericca minima; Rubb. Elyl. v. 2. 112 f. 8.)—Flower mostly solitary, erect. Leaves lanceolate. Stigma triangular, with three short, rounded, downy lobes. Stamens slightly hairy above their base. Petals smooth at the tip.—Native of the south of Europe, and of the banks of the Wolga. We have known this species for above twenty-five years in Chelsea garden, where it was cultivated by the late Mr. Fairbairn, in pots, amongst alpine plants, protected by a frame in winter, and flowered about May. So little was it understood, that the able writer on this tribe of plants in Curtis's Magazine originally misfliok this Tulip for Melanathum uniforum; an error corrected at t. 1135 of the same work. It is very nearly allied to the fylusfris, but not half so large, and the flower is tinged with red externally. The three innermost petals are slightly fringed at the lower part, but all fix are quite smooth at the extremity. The stamens are smooth at the base, though they bear a tuft of hairs a little way above it. Anthers shorter, and more elliptical, than in T. fylusfris. Stigma more decidedly three-lobed, rounded, and downy. Capule elliptical. Very rarely there are two flowers on a stem. They have no scent. Each petal has sometimes, not always, a green keel.

3. T.
TULIP.

3. T. biflora. Two-flowered Yellow Tulip. Pallas It. v. 3. 727. t. D. f. 3. Linn. Suppl. 136. Willd. n. 4.—Stem two or three-flowered, with two spreading lanceolate leaves. Stigma triangular, abrupt, downy, fearfully notched. Petals widely spreading, hairy, like the stamens, above their base; smooth at the tip. Native of desert deserts about the river Wolga, in a stiff clay soil, along with the, but flowering a few days earlier, and of much shorter duration. This is fearfully half the size of T. Celsiana, of which a two-flowered spémen has sometimes been taken for it. The more simple stigma, more elliptical and expanded petals, green at the back, and more oblong authors, are abundantly different from that species. From the *flevirif* the present is still more unlike, as to size, smoothness of the tips of its petals, and their flat spreading position, to say nothing of an orange spot at their base. The *flevirif* too is said by Pallas to be more glaucous and succulent. The flowers vary rarely to one or three, and are fragrant.

4. T. Sibthorpiana. Yellow Greek Tulip. Sm. Prodr. Fl. Græc. Sibith. v. 1. 229. Fl. Græc. t. 330. unpubl.—Stem single-flowered, smooth. Flower drooping. Petals obtuse. Stigma club-shaped. Filaments hairy all over.—First observed by the late professor Sibthorp, near the ancient Cretea, now Porto Cavaliere, in Asia Minor; and afterwards, as Mr. Hawkins informs us, on a small rocky eminence near Naouarin, in the Peloponnesus. The root is a white, roundish, downy bulb, scarcely an inch in diameter, surrounded by numerous lateral offsets. Stem a span high, bearing two alternate erect smooth leaves, of which the lowest is largest and most ovate. Flower entirely yellow, pendulous, an inch long. Petals apparently smooth in every part. Stemena whitish as well as the perianth. Anthers linear, beaked, nearly as long as the filaments, which are clothed from top to bottom with short dense prominent hairs. Germin short, obtutely triangular, smooth. Stigma twice or thrice the length of the germin, triangular-club-shaped, obtuse, slightly three-lobed, almost as hairy in every part as the filaments. This is a very different species.

5. T. Clyftana. Red and White Italian Tulip. Redout. Liliait. t. 37. Ait. Epit. 375. Curt. Mag. t. 1390. Sm. Prodr. Fl. Græc. Sibith. v. 1. 229. Fl. Græc. t. 329. unpubl. (T. pericosa proco; Cluf. Cur. Polt. 9, with a figure. T. pericosa, flore rubro, oris albidis, elegans; Ger. Em. 142. T. pericosa; Park. Parad. 52. t. 53. f. 6. T. variegata pericosa; Redout. Elyf. v. 2. 111. f. 7.)—Stem single-flowered, smooth. Flower erect. Petals acute, smooth. Leaves linear-lanceolate.—Native of Italy, Sicily, and Persia, flowering in March. About the size of *T. fylvestris*, but the stem bears four or five leaves, gradually smaller and narrower upwards, most glaucous beneath, smooth, somewhat undulated, at least the lower one; all taper-pointed. The three inner petals are white on both sides, sometimes blunted; three outer rather larger, acute, white or blushed-coloured within, crimson at the back, with white edges, and a green tip; all of them marked at the base internally with a dark-violet spot, and all quite smooth in every part, as are the violet-coloured filaments, and green perianth. The stigmas consists of three rounded, compressed lobes, each marked with a downy furrow, like the Garden Tulip hereafter described.

Commonly cultivated in Holland, by the name of *Due Van Thol*, from whence the heft roots are brought to us. They flower in the open ground in March or April, but in a room, whether in water, sand, or earth, about January. The whole plant is of a dwarf stature, and glaucous hue. Flower broad-bell-shaped, sweet-scented. Petals: scarlet, edged with yellow, more or less acute. Stigma like the bell, but rather larger.

7. T. Oculo folis. Agen Tulip. "St. Amans Rec. Soc. d’Agr. d’Agen, v. 1. 75." Redout. Liliait. t. 219. Ker in Edw. Bot. Regist. t. 204. (T. boloniensis, fives bombsycia, flore rubro, major; Park. Parad. 51. t. 52. f. 1.)—Stem single-flowered, smooth, as well as the petals and filaments. Flower erect. Leaves ovato-lanceolate, finely fringed.—Found about Agen, in France, and several places in the southern part of that kingdom, flowering in April, and lately imported into England, by Messrs. Whiteley and Co. of Fulham. This differs from the last in the particulars contained in our specific character, and more nearly approaches the following. The coat of the bulb is said to be internally woolly. Leaves broad, slightly glaucous. Flower large, bell-shaped, of a fine scarlet red, each petal marked with a broad, a black, yellow-eroded spot at its base. Stigma like the following.

8. T. Gefneriana. Common Garden Tulip. Linn. Sp. Pl. 438. Willd. n. 3. Ait. n. 3. Curt. Mag. t. 1135. "Sowerb. Fl. Luxur. t. 5. 6. 11. 117." (Tulipa; Redout. Elyf. v. 2. 102—108.)—Stem single-flowered, smooth, as well as the petals and filaments. Flower erect. Leaves ovato-lanceolate, glaucous, smooth. Lobes of the stigma decurrent, deeply divided.—Native of the country bordering on mount Caucasus, where it flowers in April, and from whence Dr. Fisher has sent us a wild specimen. Conrad Gfener reports, that it was brought from Cappadocia into the European gardens, in 1559. Nothing is now more common or more famous, particularly the many varieties in form and colour, which florists, especially in Holland, have so much cultivated, and in some cases so highly prized. The old botanical writers, in their wooden cuts, represent many of these, and almost all the supposed species in Bawinn’s *Pinax*, are really, as Linnæus indicates, mere varieties. In a wild state, the petals are crimson, yellowish at the base, about an inch and a half long; by cultivation they increase in size, become streaked in colour, and sometimes assume a jagged and spurred appearance, with every variety of scarlet, yellow, purple, and even green, in their colouring. This we first called the Parrot Tulip, a name now generally adopted. It is Rudbeck’s *T. flore luteo rubro variegato, petalis lanestatis*, Camp. Elyf. v. 2. 108. A plain yellow tulip, the blunt points of whose petals are somewhat recurved, and whose whole flower is of a handsome ovate figure, seems to us possibly a distinct species; but this must be decided by cultivation from seed.

TULIPA, in Gardening, furnishes plants of the bulbose rooted, flowery, perennial kind, among which the species cultivated are the Gesner, Turkey, Cappadocia or common garden tulip (T. Gesneriana); and the wild or yellow tulip (T. fylvestris).

The flower is distinguished from the other fort, according to Martyn, by its pubescent sepal, spreading sweet-smelling corolla, the carlinets of its flowering, and the smallness of its faze.

And in respect to the varieties, the editor of Miller’s Dictionary observes, that the old authors divided tulips into *procoes* or early-blowers, and *feronia* or late-blowers, with an intermediate division of *dubia medius*, doubtful or middle blowers, which flowered between the two others, and for the
the most part rather belonged to the late-blowers. Modern florists, he affirms, have almost neglected the early-blowers. The first sort, according to him, are not near so fair, nor do they rise half so high as the late ones; they are chiefly valued for appearing early in the spring; some of them will flower the middle of March, in mild seasons, if planted in a warm border near a wall or other shelter, and others will succeed them, so that they will keep flowering until the general season for these flowers is come, which is towards the end of April.

It is said that the several varieties of these early-blowing tulips rise to different heights in their stems, and scarcely any two of them are equal. The Duke Van Tull, which is one of the first that appears in the spring, is generally very short-stalked, and the others, in proportion to their earliness, are shorter than those which succeed them; and the late-blowers are all considerably longer in their stems than any of the early-blowers.

The late-blowing tulips producing much finer flowers than the early ones, have engrossed almost the whole attention of the florists. It would be to little purpose to enumerate all the varieties, since there is scarcely any end of their numbers; and what some value at a considerable rate, others reject; and as there are annually many new flowers obtained from breeders, those which are old, if they have not very good properties to recommend them, are thrown out and despised.

It is observed further, that modern florists in Holland and Flanders, and our English florists from them, boast a prodigious variety of late-blowing tulips. And that Mr. Maddock of Walworth, in his catalogue of flowers for the year 1792, has no less than about five hundred and sixty-five of these admired beauties, all ranged under their proper families and colours, with their names and prices: besides the early sorts, double tulips, parrot-tulips, French tulips, and breeders. And moreover that the late-blowers are distributed into five families: 1. Primo Baguets, very tall; fine cups, with white bottoms, well broken with fine brown, and all from the same breeder. 2. Baguets Rigauts; not quite so tall, but with strong stems, and very large well-formed cups with white bottoms, well broken with fine brown, and all from the same breeder. 3. Incomparable Verports, a particular kind of Bybloemens; with midst perfect cups, very fine white bottoms, well broken with shining brown, and all from the same breeder: some of these are from two to five guineas a root. 4. Bybloemens; with bottoms white, or nearly so, from different breeders, and broken with a variety of colours: those of the Verports are cherry and rosy. 5. Bizarres; ground yellow, from different breeders, and broken with a variety of colours. These barbarous terms, used by the Dutch florists, are, it is said, a mixture of Dutch and French. Baguet is from the French baguette, a rod or wand, so named from its tall flender stem. Bizarre is also French, and the tulips of that family have the name from the variety and irregularity of their colours. Rigauts are probably from the name of some eminent florist, as Rigaud. The other terms are Dutch. Breeders are of one colour, and when broken produce new varieties.

It may be more particularly noticed in regard to each of the principal varieties of these tulips, that they, in every instance, comprehend a great number of intermediate ones, in so far as respects the colours and variegation, which takes place in the flower, notwithstanding each has been originally all of one and the same colour, particularly the feeding-raised bulbs, which after they have arrived to the flowering state, each separate flower is either wholly red, purple, violet, grey, brown, black, yellow, or some other individual colour, without any sort of variegation or stripe whatever, confounding simply of one-coloured flowers, with white bottoms, with yellow bottoms, and some with blue bottoms, with purple bottoms, and with blackish bottoms; all of which, while they retain this original sameness in the colour, are, in the peculiar language of the florist, termed whole-blowers or breeders, as each flower is wholly of one and the same colour. But on the bulbs or roots being planted out for one or two years, in properly prepared soils, in order to breed, or disperse them to gradually produce flowers, that break or run from the original single colour into variegations and stripes, in many different modes and forms, they are denominated breeders or variegated tulips, each different variegation constituting a separate and distinct variety, which mostly consists of flowers with white bottoms broken, with brown stripes, with blue stripes, with violet stripes, with rose stripes, with red stripes, and with some other kinds, separated by streaks of white, and other colours disposed in various ways; with yellow bottoms, broken with different reds, crimsons, and golden-yellow flakes, and also a variety of other colours; and some with blackish-purple, and other bottoms broken with stripes of dark colours, yellow, and tints of red; so that, particularly in these sorts of breeders or variegated tulips, which have white and yellow bottoms, there are, moreover, white and red striped flowers, white and purple striped, white and violet striped, white and rose striped, white and brown striped, violet and white flaked, red and white flaked, red and yellow flaked; and a great number of other intermediate variegations and stripes, disposed in an almost endless diversity of modes or manners.

The principal of these diversities or varieties are usually distinguished, in the language of the florist, by the names or titles of some great perfonage, eminent admirers or cultivators of flowers, places where first grown, or some other great mark of distinction; but there is such a multitude of new varieties raised annually from seed and seedling plants in different places, which are designated by new titles, without any relation to the old ones, and the fame sort of flower so often characterised by a different name, that it would be utterly impossible to give any satisfactory lift of the names of such a vast number of continually changing varieties, as has been suggested above.

It is said that the properties of a fine variegate late tulip, according to the best modern florists, are these: 1. They should be strong, upright, and tall; about thirty inches high. 2. The flower should be large, composed of six petals, proceeding a little horizontally at first, and then turning upwards, so as to form an almost perfect cup, with a round bottom, rather wider at top. 3. The three outer petals should be rather larger than the three inner ones, and broader at their base: all the petals should have the edges perfectly entire; the top of each should be broad and well rounded; the ground colour at the bottom of the cup should be clear white or yellow, and the various rich stripes, which are the principal ornament of a fine flower, should be regular, bold, and distinct on the margin, and terminate in fine broken points, elegantly feathered or pencilled. 4. The centre of each petal should contain one or more bold blotches or stripes, intermixed with small portions of the original colour, abruptly broken into many irregular obtuse points. Some florists, it is said, are of opinion that the central stripes or blotches do not contribute to the beauty of the tulip, unless they are confined to a narrow stripe exactly down the centre; and that they should be perfectly free from any remains of the original colour: it is certain that such flowers appear very beautiful and delicate, especially when they have a regular narrow feathering
feathering at the edge; but it is unanimously agreed, that the tulip should abound in rich colouring, distributed in a distinct and regular manner throughout the flower, except in the bottom of the cup, which should indubitably be of a clear bright white or yellow, free from fawn or tinge, in order to constitute a perfect flower.

The colours which are generally held in the greatest estimation in the variegated or striped sorts of tulips, are the blacks, the golden yells, the purple violets, the rose, and the vermillion, each of which being varied in different ways; but such as are striped with three different colours, in a distinct and unmixcd manner, with frong regular streaks, with but little or no tinge at all of the breeder, are supposed the most perfect. However, though it is extremely difficult to meet with such as posses all these efficacious properties of good flowers of this fort, yet many are found which have sufficient perfection to become of high value as fine flowers.

The double and parrot tulips, are it is said, held in no fort of esteem among florists. Among the flirli fort, however, there are many distinct varieties, in so far as regards the colouring of the flowers; as the yellow-flowered, the yellow and red-flowered, the white and red-striped, the white and blufh-coloured, besides a great number of intermediate variations. And in the latter, those with long hooked petals of flowers, confilling of yellow-flowered, red-flowered, red-striped, and other kinds.

The second species has the bulb ovate, and gibbous in the shape; the stem is quite simple, nearly upright, round, smooth, leafy in the middle, and attenuated at the base, with the flower always yellow in its colour, but a little greenish on the outside.

And it is further noticed, that it has most of these characters in common with the garden species; but the circumstances that abundantly distinguish this fort are, the narrow leaves, the nodding flower, the hairless at the base of the flarns and on the tips of the petals, and especially the simple obfute form of the fligma, which is totally different from that of the garden tulip: the flower too is fragrant; the pollen yellow, not black; and the anthers remarkably long. But in the Flora Danica they are represented as short and round.

As this sort of tulip is of much inferior beauty to that of the other and its several varieties, it is of course not nearly so much known and cultivated in flower-gardens, though it was formerly held in considerable estimation by some, before the Turkey kind became so very general; and it is still to be found in some of the older gardens of this nature, and is not underserving of a place in that of the modern ones, among the other sorts of tulips and spring flowers, for the purpose of its early blooming and increasing the variety.

Method of Culture.—All the different sorts of tulips may be increased by offsets from the roots, and by fowing seeds to produce new varieties. The offsets should be separated from the old roots every year in June, especially for the fine sorts, on taking them up when the flowering is over, planting them in nurfery-beds, in rows six inches apart, and to the depth of three, four, or five in the beginning of autumn, to remain for one or two years, until they attain the flowering state, and are proper for being set out regularly. They may also, in the old root, be planted in beds, or in the borders or other parts where they are to remain and blow, in patches of four or five, placed regularly; and to have a succession, they may be planted at different times; they are usually planted with a blunt dibble: the new roots should always be planted by themselves.

In this way the most approved sorts are propagated and continued always the fame, and the stocks of any good varieties multiplied and increased as may be necessary and convenient to the growers of them.

The early and late sorts should likewise be each put in, in places by themselves; and it is advised that the roots of the early blooming kinds should be planted the beginning of September, in a warm border, near a wall, paling, or hedge; as, when they are put into an open spot of ground, their buds are in danger of suffering by morning frosts in the spring. The soil for these should be renewed every year, or it is intended to have them fair. The best soil for this purpose is that which is taken from a light sandy patur, with the turf rolled amongst it, and to this should be added a fourth part of fen-land. This mixture may be laid about ten inches deep, which will be sufficient for these roots, as they need not be planted more than four or five inches deep at the root.

The offsets should not be planted among the blooming roots, but in a border by themselves, where they may be set pretty close together, especially when they are small; but these should be taken up when their leaves decay, in the same manner as the blooming roots, otherwise they would rot if the scion should prove very wet, as they are not so hardy as the late blowers, nor do they increase half so fast, so that more care is requisite to preserve the offsets of them.

When these sorts come up in the spring, the earth upon the surface of the beds or borders should be gently tilled and cleared from weeds; and as the buds appear, if the scion should prove very severe, it will be of great service to cover them with mats, for want of which many times they are blighted, and their flowers decay before they blow, which is often injurious to the roots, as is also the cropping of the flowers soon after they are blown; as their roots, which are formed new every year, are not at that time arrived to their full magnitude, and are of course deprived of proper nourishment or support.

When these flowers are blown, if the scion should prove very warm, it will be proper to shade them with mats, &c. in the heat of the day; and when the nights are frosty, they should be covered in the same manner, by which means they may be preserved a long time in beauty; but beauty: but when their flowers are decayed, and their feeding vellsy begin to wither, they should be broken off just at the top of the stalks, as when they are permitted to feed it injures the roots greatly.

In these sorts, when the leaves are decayed, which is usually before the late blowers are out of flower, their roots should be taken up, and spread upon mats in a shady place to dry; after which they should be cleared from filth, and put in a dry place where vermin cannot come to them, until the scion for planting them again, being very careful to preserve every sort separate; that it may be known how to dispose of them at the time of planting.

For this purpose, it is a good method to have large flat boxes made, which are divided into several parts by small partitions, each of which is numbered the same as the divisions of the beds; so that when a catalogue of the roots is made, and the number, fixed to each sort in the beds, nothing more is necessary in taking the roots, but to put every kind into the division marked with the same number in the bed. This saves a great deal of trouble in making fresh marks every time the roots are taken up, and effectually answers the purpose of preferring the kinds separate and distinct.

In raising these plants from seed, it is, from the time of sowing, seven or eight years before they produce flowers; and after all, they at first appear only single-coloured, often requiring two, three, or more years longer before they break into
TULIPA.

...into different colours or variegations; so that the teudion ... raifing feeding tulips, to a flowering state often deters from the undertaking. It is, however, the method by which all the fine varieties were first obtained, and by which new varieties are still annually gained; as many persons sow the same every year, in expectation that another will fix or seven years a new show of flowers will be produced, out of which many new varieties may annually discover themselves in each parcel. It is by this process the Dutch are so famous for furnishing such an infinity of fine varieties, supplying almost all other countries.

In effecting this business, great care should be used in the choice of the seed; the best is that which is faved from breeders which have all the good properties before related, for the seeds of flirled flowers seldom produce any thing that is valuable; and the best method to obtain it is to make choice of a parcel of such breeding tulip roots as are wished to be fed from, and place them in a separate bed from the breeders, in a place where they may be fully exposed to the sun, planting them at least nine inches deep, as when they are planted too shallow their stems are apt to decay before their feed is perfectly ripened: the flowers should be always exposed to the weather, as when they are shaded with mats, or any other covering, it prevents their perfecting the feed. About the middle of July, according to the season, the feeds will be fit to gather, as shown by the dryness of their stalks and the opening of the seed-veffels, at which time they may be cut off, and the seeds be preserved in the pods till the season for fowing, being careful to put them up in a dry place, otherwise they will be subject to mould and be rendered useless. The beginning of September is the proper season for fowing the seed; for which there should be provided a parcel of shallow feed-pan, or boxes, which should have holes in their bottoms to let the moisture pass off; these should be filled with fresh sandy earth, laying the surface very even, upon which the feeds should be fown thinly as regularly as possible; some of the same light sandy earth being grated over them, about half an inch thick. These boxes or pans should be placed where they may have the morning sun till eleven o’clock, in which situation they may remain till October, at which time they should be removed into a more open situation, where they may enjoy the benefit of the sun all the day, and be sheltered from the north winds, where they should remain during the winter season; but in the spring, when the plants appear with gravy leaves, they should be again removed to their first situation; and if the feed be dry, they must be refreshed with water while the plants remain green; but as soon as their tops begin to decay, no more should be given. The boxes should be placed in a shady situation during the summer season, but not under the drip of trees. The weeds and mofls should be kept constantly cleared off from the surface of the earth in the boxes, and a little fresh earth be fowder over them soon after their leaves decay; and at Michaelmas they should be fresh earthed again, and as the winter comes on, be again removed into the sun as before, and treated in the same manner, until the leaves decay in the spring, when the bulbs should be carefully taken up, and planted in beds of fresh sandy earth, which should have tiles laid under them, to prevent their roots from shooting downward, which they often do when there is nothing to stop them, and are destroyed. The earth of these beds may be about five inches thick upon the tiles, which will be sufficient for nourishing the roots while young. The distance of planting them need not be more than two inches, nor should they be planted above two inches deep. Toward the end of October it will be proper to cover the beds over with a little fresh earth about an inch deep, which will prevent the roots from the frost, and prevent mofls or weeds from growing over them; and when the winter is very severe, it may be proper to cover the bed either with mats or peat-haulm, to prevent the frost from entering the ground, as these roots are much tenderer while young, than after they have acquired strength. In the next spring the surface of the ground should be again gently stirred to make it clean, before the plants come up; and when the spring proves dry, they must be frequently refreshed with water in small portions during the time of their growth; and when the leaves are decayed, the weeds should be taken off, and the beds covered with fresh earth, as before, which should also be repeated again in the autumn. When the bulbs have been managed in this way two years, they should in the summer following, when their leaves decay, the roots being by that time considerably improved in growth, be again taken up, and planted in a fresh prepared bed, in drills three or four inches asunder, in which to remain two years longer; then, at the decay of the leaf, be again planted out into fresh beds, in rows as before, where they should be let remain to blow, being afterwards ordered as the flowering bulbs. When they are in full flower, they should be examined, in order to mark such of them as discover the best properties, that they may be separated from the others at the proper lifting season, and be replanted in beds by themselves for breeders; removing them annually at the proper season into different beds of opposite or contrary soils, as one year in poor hungry earth, the next in a much richer mould; continuing them till they break into variegations and stripes of different colours, which are the only modes by which it can be asfifted. When the leaves and flower-stems are decayed and withered, and the roots have ceased growing and drawing nourishment from the earth, it is the proper period for lifting or taking the old roots out of the earth, to reserve them till autumn for planting, being preferred in the manner which is directed for them above.

It may be noticed in addition, that all the ferts and varieties of tulips will grow pretty well and succeed tolerably in any foil where the earth or mould is moderately light and dry in the winter season, but that they delight most in such as are of a sandy vegetable earthy nature, and in an open sunny exposure. They are most injured by such as are of a retentive and wet damp quality, in which it is constantly necessary to have the beds in which they are put railed four or five inches above the common level of the rest of the ground. It is customary, however, with florists to have the beds for this purpose composed of and prepared with different kinds of materials of the sea sandy and earthy coorts, particularly for their finest kinds. But such trouble and expense are often quite unnecessary, as they succeed well enough without it; only care must always be taken not to plant them more than one or two years together, especially the fine sorts, in the same earth or bed, without changing the quality of the soil, in some measure, either altogether or in a partial manner, by some removal of the old and addition of new fresh portions of light mould, garden earth, or compost, or by a complete clearing away of the former earthy matter and the suppling of wholly new; thus rendering the blow of the tulips more strong as well as fairer. But as this is only practised for the particularly fine sorts in beds, those which are to be planted in the open border may be placed any where in the common foil, without any fear of their not flowering well.

In preparing the beds, or other parts, for the more choice sorts, the ground is to be well dug to the depth of one or two feet, and they are to be formed three or four feet in width, having alleys or intervals of one or two feet width
TULIPA.

width between them: the top or surface of each bed being raked quite even and smooth, in order for the bulbs or roots being put into it.

When they are in this state of readiness for being planted, a dry day is to be selected for setting out or planting the bulbs or roots, which is to be done in rows, either in the bedding method, drilling in rows, or that of dibble-planting, a blunt-edged instrument being employed in the last, by way of making the holes for the bulbs as sufficiently wide below as above, and perfectly clean quite to the bottom, making out the lines lengthways of the beds at eight or nine inches distance from each other, the roots being then set in finely to the depth of three or four inches, and at the distance of fix from each other in the lines. The work of planting being thus finished, the upper parts of the beds are to be raked even and smooth, which completes the whole.

The tulips intended for the open borders may either be planted in a regular line at a foot or eighteen inches distant from the edge, irregularly along it, or be disposed in separate small patches and clumps of three or four roots together in each, occupying spaces of about eight inches, some of which being placed more forwards, and others backwards, in order to afford greater diversity and variety.

When the old roots or bulbs have been thus planted out in the autumn, as they bear the winter well, nothing farther is required in their culture until the vernal and summer months, when they should be preferred in quite a clean state of growth, and in some cases the buds of the more choice sorts in the beds be sheltered and guarded from cold and severe weather in the nights, and at some other times by mats, supported archways on hoops, or other convenient means, though this is seldom absolutely necessary; or when the bedded sorts come into flower, to prefer their beauty and duration, to shade and screen them from the excessive noontide fun, heavy rains, and stormy winds, by an awning of canvas or mats raised across the beds, and, in some instances, formed in a tent-like manner, in order to walk under and view the flowers at pleasure; but the flowers will blow in great perfection without these coverings and trouble, only by means of them these fine sorts will blow and continue for a longer time in full beauty than would be the case if they were openly exposed. However, as soon as ever the flowers begin to fade, all such coverings should be carefully removed, in order to permit a free circulation of air, and have the full influence of rains, dews, &c. for the nourishment and support of the root-bulbs.

But when the flowering is quite past, and the flowers begin to die away, it is necessary and proper to cut off the heads or feed-vessels, especially of the fine sorts and varieties, that the roots may not be deprived of the proper quantity of nutriment for their full and perfect growth.

And in the middle of summer, when they are at rest, or have ceased growing, and the flower-items and other parts are quite decayed, it is time to lift or take up the old bulbs or roots, which should be done for the most part every year for the fine sorts, and every other year for the other kinds, not only for the purpose of separating the fuckers or young bulbs, but also for preferring both them and the old ones without any fort of growth out of the ground until the autumn, which is the time of planting them again in fresh or newly prepared beds for the future year's bloom. At this period, therefore, when the weather is dry, the work of lifting or taking them up should be begun, which should be done with a garden-trawl, as being the best and safest method, digging them up finely in a perfect and careful manner; and afterwards spreading them out in a shady, dry, airy place, where they may remain for a few weeks, without being acted upon by the sun or wet, and then become gradually dry and hardened; when the fuckers or young bulbs, the adhering earth, and the outer decayed skins or bulks, should be taken away and removed from them, after which both the old and the young offset bulbs should be again exposed to further drying, and more effectual hardening, in the same or other more proper situation, and be ultimately put safely into some dry receptacle separately, to be kept until the proper season of planting them out again takes place. Each sort of bulbs should be planted out in a separate manner, as already noticed. See Bulb and Root.

It may be remarked, that although the tulip may be said to be a plant of the perennial kind, yet that after the bulb of it has arrived at the flowering state or stage, the fame individual old root or bulb does not always remain and continue to flower anew, but gradually wears or wastes away, as is evident by its remains at the lifting season; but previously to its dissolution it affords from its sides a new supply of fuckers or young bulbs, which perpetuate the kind, one of which, being large and similar to the parent bulb, is capable of flowering equally strong for the succeeding year; so that at the end of many years, that which is often supposed to be the fame individual bulb, is in reality in every way another, or new one. In common, it is, however, termed the old bulb or root, by those who are unacquainted with the nature of such roots.

All the sorts and varieties of the tulip have flowers, which are succeeded by plenty of coarse seed in the latter summer months, that is contained in the cells of an oblong capsule, the different seeds being placed on each other in double rows.

In order to raise good seed, some heads of the best and stoutest plants of each sort should be selected and left in a proper situation to stand until they become in a perfectly ripe state, which is easily known by the items taking on a fine hard dry appearance, and the parts containing the seeds opening themselves, when they should be cut away, and the seed be taken out, and wrapped up carefully, or left to remain in them until the time of its being sown, preferring it in either way quite dry and free from any thing of a moudly nature.

In order to promote the acquisition of the vast and wonderful diversity of colouring which often takes place in tulips, and which, in many instances, is effected in a great measure by nature alone, the natural process is sometimes greatly assisted and expedited by means of proper culture and management. Thus, in the first place, when the young feeding bulbs of the whole blower or breeder have reached the full size, and have flowered once, by transplanting or removing them into beds of any sort of weak, poor, unfruitful earths, which, by their want of nutrient properties, may check and restrain the natural luxuriant tendency of the plants, and induce a weak enfeebled general growth, a change may be gradually produced in their general state, whereby they may break out into new variations in the first, second, or third years. And accordingly, as this happens, they should be planted out into beds of good earth, as has been directed above.

Another means of assisting nature in accomplishing this object is, that of making as great a change in the quality of the soil as possible, as if they were this year planted in a weak poor sort of earth, they should in the following be set out in a highly rich garden mould, and afterwards in a compot of several sorts of earth: or they may be removed and transplanted from one part of a garden to another; and
into different gardens; or in any other familiar methods. All these various ways contribute in a great degree to afford in, and promote the production of, this desirable diversity of colours and variegations.

The roots of all the sorts and varieties of the tulip are kept for sale in large collections by the nursery and seedmen, who have them every year in great quantities from Holland and other places, each variety of which is distinguished by some appropriate name, as has been already noticed, and arranged in regular catalogues, the prices being charged in proportion to the estimation in which they are held, which were formerly very extravagant, but are now more moderate, on account of their abundance, as from seven or twelve shillings, to as many pounds the hundred, and not unfrequently considerably more for scarce, curious, and capital sorts. The most eligible and proper season for buying or laying in a collection is in the early part of the autumn, as from August to November.

For the main collection of flowers to blow in the spring and early summer, the most proper time of planting the roots or bulbs is in the autumn, from the end of September to December; but to have a later bloom in succession, some may be planted out about the close of the year, and in the two beginning months of the new one. These last, however, will seldom grow so strong as those of the autumn planting.

The roots of the late sorts of tulips may be planted in any common beds, or in the borders, as they are not much liable to be injured by bad weather. But those of the fine or more valuable sorts of the early, as well as the late kinds, are in general, for the most part, dispersed together, as has been seen, in beds by themselves, in order to exhibit a grand blow, and be defended in the manner which has been explained.

However, some of the inferior common sorts, and even any of the capital varieties, may occasionally be distributed about the ordinary borders, in affinage with other spring flowers of the bulbous-rooted and other kinds, in the ways which have already been directed, where they have often a fine effect when in their blowing state.

The double variety of the common tulip is very beautiful, though not held in such estimation by the florist as the common single variegated sorts, from their not polluting that profusion of variegations in their colours, or such a regularity of stripes. They, however, exhibit an elegant ornamental appearance in their upright, tallish, firm stems, and the crowns of large double flowers at the tops, formed somewhat as in those of the double peony, but far more beautiful in their diversity of colours, variegations, and stripes of white and red, or yellow and red, &c. On these accounts they certainly deserve to be cultivated either alone in beds, at a little distance from the other sorts, for the sake of increasing the variety; or in patches about the borders, in affinage with the common large variegated tulips, as blowing nearly about the same time in the later spring months.

The early dwarf sorts are the most proper for forcing for early blowing, and also for being placed in glasses, in rooms, &c. These sorts are sometimes rendered more early in their blowing than would otherwise be the case, by planting the roots or bulbs in pots or boxes in the autumn or winter season, and placing them in the house, or a hot-bed of tanner’s bark, thereby bringing them into blossom in the month of January, or sooner, and continuing succussions of them, until the natural ground blossoms are ready. A quantity of bulbs is also sometimes placed upon phial-glasses containing water, a single bulb in each, during the same season, which are then put into a warm light room in the house, near the windows, or into a greenhouse or flowe, in which way they often flower very agreeably in the winter and early spring, as they are well suited to such modes of cultivation.

These sorts of roots or bulbs are likewise kept by the nursery and seedmen for the purpose of sale in pretty large collections of the different kinds, under titles which are chiefly French or Dutch, as may be seen by the catalogues of those flowers which they exhibit.

Roots of these sorts may be planted out in any good, light, rich, earthy soil, where the situation is warm at the season, and in the manner stated above, in speaking of the general culture of tulips, when they will rise soon in the vernal months, and reach the blowing state about March, continuing until the late tulips come into flower. They, however, succeed best when allowed a sheltered sunny situation, as they rise and flower so soon in the spring while the weather is often cold and pinching. Some of them look extremely well in the fronts of warm borders, in small patches, in affinage with anemones, ranunculuses, and other similar kinds.

The second species may be managed in the same manner as those of the common sort, in so far as its culture is concerned, in much the same way, having nearly the same treatment in every respect.

They are all highly ornamental flowers, from their much varied and most beautiful colours; but those of the common garden sort, and its numberless varieties, are the most generally introduced, being admirable ornaments for beautifying the various flower borders and other parts of gardens and pleasure-grounds during some weeks in the spring and summer seasons.

TULIPIFERA, in Botany, the Tulip; see Liriopodenbreon; see also Magnolia, of whose sorts are called Tulip-trees.

TULISCHANA, in Geography, a river of Russia, which runs into the Podkamenka Tunguska, N. lat. 61°. E. long. 97°. 35'.

TULISKOWO, a town of the duchy of Warsaw; 16 miles N.N.E. of Kalisz.

TULL, Jethro, in Biography, a distinguished agriculturist, was a descendant of a respectable family in Yorkshire, educated at one of the universities, and admitted a barrister of the Temple towards the commencement of the 18th century. Returning from the tour of Europe, in which his attention was particularly directed to agricultural subjects, he married, and settled upon a paternal farm in Oxfordshire, which gave him an opportunity of prosecuting a variety of experiments in husbandry. Upon his return from France and Italy, which he was under a necessity of visiting on account of his impaired health, and with a fortune also impaired, he took a farm near Hungerford, in Berkshire, where he purposed his plans for improved cultivation. His grand principle was, that labour and arrangement would supply the place of manure and following, and raise more grain at a less expense. (See Horne, Husbandry, and Drif-Husbandry.) Tul, in 1731, printed "A Specimen" of his system; and in 1733, "An Essay on Horne-hoeing Husbandry," fol. which was translated into French by Du Hamel. He purposed his system till his death, which happened in Jan. 1740.

TULLA, in Geography, a town of Arabia, in the province of Yemen; 25 miles W.N.W. of Sana.

TULLAGH, a small poll-town of the county of Clare, Ireland; 102 miles W.S.W. from Dublin.

TULLAGHAN, a bay of the county of Mayo, Ireland into
TULLAMORE, a post-town of the King's county, Ireland, so called from the river Tullamore, which divides it into two nearly equal parts. This is a neat thriving town, owing partly to the well-directed exertions of the proprietor, Lord Charleville, whose benevolence extends to the suburbs, and partly to the advantage of the Grand Canal palling close to it. Here are a barrack and market-house; and, what is of still greater importance, the linen manufactury has been introduced with a prospect of success. Tullamore is 46 miles W. by S. from Dublin.

TULLE, a city of France, and capital of the department of the Corrèze; before the revolution the capital of Lower Limousin, and see of a bishoprufffragant of Bourges; 58 miles S. of Paris. N. lat. 45° 16'. E. long. 1° 51'.

TULLEN. See Toolen.

TULLINS, a town of France, in the department of the Ière; 12 miles N.N.E. of St. Marcellin.

TULLIS CREEK, a river of Virginia, which runs into the Potomack, N. lat. 39° 33'. W. long. 78° 2'.

TULLN, a town of Austria, on a river of the same name; the see of a bishop, suffragan of Paffau; 13 miles W.N.W. of Vienna. N. lat. 48° 18'. E. long. 16° 3'.

TULLO, a river of Austria, which runs into the Danube, at the town of Tulln.

TULLOARGAUM, a town of Hindoostan, in Vihapour. In 1779, when general-majour Egerton was marching towards Poonah, this town was burned by the Mahrattas themselves; 12 miles N.W. of Poonah.

TULLOCHARD, a mountain of Scotland, in the south-west part of Ross-shire. In frequent times, by burning pitch on this mountain, all the tenants and valets of Seaforth assembled at the castle of St. Donan in twenty-four hours.

TULLONG. See Pullo-Tullong.

TULLOON, a town of Hindoostan, in the circear of Sirhind; 35 miles W. of Sirhind.

TULLOW, a post-town of Ireland, in the county of Carlow, pleasantly situated on the river Slaney, over which it has a bridge of six arches. The castle, which was deemed formidable, and which was reduced by Cromwell, has been converted into a barrack. Here are a neat church and a good market-house; and near the bridge the ruins of an old abbey, which, with all its poffessions, was granted by queen Elizabeth to Thomas, earl of Ormond, in 1557. Tullow is 38 miles S.S.W. from Dublin.

TULLUM, TouH, in Ancient Geography, a town of Gaul.

TULLUS HOSTILIUS, in Biography, was elected king of Rome, after the death of Numa, in the year B.C. 672.

He began his reign with rendering himself popular, by dividing a portion of the regal lands among those who had no such property; but deviating from the course pursued by his paffion predecessor, he contrived by a stratagem to engage the Romans in a war with the Alans. The Alans declining a combat, Tullus propofed an union between Rome and Alba, and for the accomplishment of this object, that the principal Alban families should settle at Rome. To this proposal the Alans objected, but it was agreed that the superiority of either city should be decided by a combat between three perions of each city. (See Curiathi and Horati.) The superiority of Rome having been thus determined, Tullus proceeded to punish the Fidenates for their alleged mifconduct in the Alban war; and having summoned Mettius Fufettius, the Alban dictator, to join him with the troops of his nation, the dictator apparently complied, but in an engagement that ensued proved treacherous. The Romans, however, obtained a complete victory. Tullus and Mettius practiced the same kind of dissimulation: whilst the former courteously received the congratulations of the latter, he sent a body of troops to demolish the city of Alba in the absence of its soldiers, and at the same time ordered the Roman and Alban troops to attend him in his camp unarmed, but he privately instructed the Romans to provide themselves with swords under their garments. Charging Mettius with perfidy, he ordered him to be feized, and to be fastened between two chariots, and thus to be torn asunder, as an emblem of his attempt to diffuse the union of the two states; the first and least example, says Livy, of a punishment in which little regard was paid to human laws! His accomplices were also put to the sword; the rest of the Alans were conveyed to Rome, and henceforth formed one people with the Romans. Alba, with the exception of its temples, was razed; and for the accommodation of these new inhabitants, mount Caesium was taken into the confines of Rome.

Having subdued the Fidenates, Tullus made war against the Sabines and conquered them, and then summoned the Latin towns dependent upon Alba to acknowledge the supremacy of Rome, whose country, on their refusal, he invaded. In his old age, however, he exchanged his military prowess for the weaknesses of superstition; and terrified by prodigies and apprehended tokens of the displeasure of the gods, he had recourse to a variety of expiatory rites. The manner in which his life terminated has been differently represented. Some fay that his palace was struck by lightning, which destroyed him and his family; whilst others have charged his murder on Ancus MARTIUS, his successor, who is also suspected of having let fire to his palace. He died, however, after a reign of thirty-three years, during which he enlarged the size and population of Rome, with little addition to its territories. Livy. Dionyf. Hal. Gen. Biog.

TULLY, in Geography, a town of Hindoostan, in the circear of Ellichpaur; 20 miles E.S.E. of Ellichpaur.

TULLY, a township of New York, on the S. line of Onondaga county, 14 miles S. of Onondaga; bounded N. by Otisco, E. by Fabius, S. by Cortlandt county, W. by Spafford, which was erected from the W. half of Tully in 1811. It is now formed of the N.E. quarter of the military township of Tully, the S. half being Preble, in Cortlandt county. Its waters are small, being head-dreams of Onondaga creek, and also of Tioquhino creek, of Che- nango, of the Susquehanna, &c. The whole is well watered by springs and brooks. Like Spafford, this town has ridges of hills on the E. and W. boundaries, but its valleys are extensive, rich and productive. Tully flats are much admired. The settlements commenced about 1796, and the lands are held by right of soil, principally by farmers from the eastern states. In 1810, the population was 1292, and the senatorial electors 67; but these aggregates are now diminished nearly one-half by the erection of the town of Spafford from the W. part in 1811. Tully is now about five miles square.

TULLYCLEA, a small river of Ireland, rising in the southern part of the county of Tyrone, and discharging itself into lough Erne, a little to the north of Devenish island.

TUMERO, a town of South America, in the province of Venezuela, situated in the vale of Aragen, two leagues from Maracay. This town is modern, well built, and the residence of a number of planters; but it is peculiar the abode of all the officers, factors, and persons employed in the administration of the tobacco cultivated in its viciniry,
vicinity, on account of the king. Here are a handsome church, a vicar for the religious department, and a tenant of justice for the civil. Its population consists of 8000 persons.

TULOMA, a river of Russia, which runs into the Ladoga lake, 32 miles N.W. of Olonetz.

TULON, a town of Tibet; 45 miles E. of Tankia.

TULONIUM, in Ancient Geography, a town of the interior of Spain, belonging to the Varduli, according to Ptolemy. In the Itinerary of Antonine, this place is on the route from Affuria to Burdigala, between Suffatium and Alba.

TULOS, a word used by some medical writers to express a callus.

TULOSTOMA, in Botany, so named by Peroon, from tulos, a wart, or other protrusion from the skin, or fistula, and stom, the mouth; which is exactly descriptive of the little orifice, by which the powdery seeds of this fungus are discharged.—Perf. Syn. Fung. 139. (Lycoperdon; Tourn. t. 331. f. E. F. Lamarck Illust. t. 887. f. 3.)—Clas and order, Cryptogamia Fungi. Nat. Ord. Fungi.

Eff. Ch. Receptacle coriaceous, globular, stalked, discharging the powdery seeds, intermixed with hairs, by a cylindrical cartilaginous mouth.

1. T. brunnea. Common Stalked-Puff-ball. Perf. n. 1. (Lycoperdon pedunculatum; Linn. Sp. Pl. 1654. Hudf. 643. With. v. 4. 379. Sowerb. Fung. t. 206. Dickf. Dr. Pl. n. 100. Bulliard Fung. v. 1. 161. t. 294.)—Stalk nearly smooth, solid. Orifice flatish. Found on the mossy tops of walls about Paris and London, in the winter or spring. It may easily be overlooked for some common unexpanded Agaric. The stalk is an inch and a half high, cylindrical, not quite straight, of a light brown, or tawny-colour, fixed by fibrous annual roots. Head globose, smooth, half an inch or more in diameter, with a small, regular, orbicular orifice at the top, whose edges are flat and cartilaginous.

2. T. squamosum. Scaly Stalked-Puff-ball. Perf. n. 2. (T. brunnea; ibid. Lycoperdon pedunculatum; Sowerb. Fung. t. 206, the dissected figure, and some near it. L. pedunculatum axiferum; Bulliard Fung. v. 1. 161. t. 471. f. 2. L. album mammosum, pediculo longo et velutii squamo- mofo, ac fultulo, donatum; Mich. Gen. 218. f. 97. f. 7.)—Stalk scaly, hollow, with a central thread. Orifice prominent, tubular. Found by Micheli, on banks near Florence. Mr. Sowerby received his specimens from Norfolk, by favour of the Rev. Dr. Sutton. Bulliard seems to have gathered his in France. We presume this must be a distinct species, well marked by the above characters.

3. T. giganteum. Great Stalked-Puff-ball.—Stalk woody, clothed with upright scales.—Gathered at Owbyhee, by Mr. Archibald Menzies. Mr. Sowerby says this is "a gigantic representation, as it were," of the common kind, the stalk being twice as long, and four times as thick, more woody, and sometimes truly squamoso, the squamae pointing upwards. The size of the head is in proportion. We know this fungus only from Mr. Sowerby's incidental account, but have no doubt of its being a distinct species, in which more particular investigation might discover more decisive characters; and on this account we record it here.

TULOUR, or TANNA LABU, in Geography, an island in the East Indian sea, about 90 miles in circumference. N. lat. 4° 45'. E. long. 124°.

TULP, Nicholas, in Biography, an eminent physician, was the son of an opulent merchant, and born at Amsterdam in 1593. Having studied and graduated at Leyden, he settled in his native city, and rose to a high rank, not only in his profession, but as a citizen. Under the latter denomination he was distinguished by the high parts which he occupied, and by the services which he rendered to his country. As burgomaster, to which station he was advanced in 1652, he refuted the invasion of Holland by Lewis XIV. in 1672, and thus faved his country; on which occasion a medal was struck to his honour with this motto, from the Æneid, "Vires ultra sortemque feneçte." Having completed his 80th year, he died in 1674. Tulp's "Observationum Medicinarum Libri tres," 1642, 12mo. have been several times reprinted, and contain many valuable physiological remarks. He is said to have been among the first who observed the leafy vesicles. Hallay. Elyo.

TULPEHOCKEN, in Geography, a township of Pennsylvania, in the county of Berks, which, together with Bern and Bethel, contains 5800 inhabitants.

TULPEHOCKEN Creek, a river of Pennsylvania, which runs into the Alleghany, N. lat. 40° 22'. E. long. 76° 58'.

TULSK, a poït-town of Ireland, in the county of Roscommon. The promiscuous and indiscriminate ruins of castles and churches, bear ample testimony to its former importance, but it is now a wretched village. Tulkf was represented in the Irish parliament, but lost its privilege at the Union. It is 75¼ miles W. N.W. from Dublin.

TULSKOE, a government of Russia, bounded on the north by Moskovkaia, on the east by Riazankoe and Tambovkoe, on the south by Orovskoe, and on the west by Kabzikoe; 120 miles long, and from 40 to 100 broad. Tula is the capital. N. lat. 53° to 55°. E. long. 36° to 38°.

TULUM, a town of Peria, in the province of Ghilian; 10 miles S. of Refid.

TULUN, a town of Russia, in the government of Irkutsk, on the Ija; 44 miles E. of Niznii Udink.

TUMAGURRA, a town of Bengal; 18 miles N. of Toree.

TUMANSKOI, an island of Russia, in the Frozen Ocean, of a triangular form, lying north of the Isle of Kirlach, from which it is divided by a narrow channel; about 360 miles in circumference. N. lat. 71° 50' to 73° 15'. E. long. 119° to 126°.

TUMANUNA, in Ancient Geography, a municipal town of Africa, in Mauritania Cæsariensis, according to the Table of Peutinger.

TUMARRA, a town of Africa, in Mauritania Cæsariensis. Ptolemy.

TUMB, or TOMBO, or PETOMBO, or CATOMBO, or SLENGE, or Great Tomb, in Geography, an island in the Persian gulf, about three miles in length from east to west, and much frequented by tnankees from the Arabian shore, which refise here a week or ten days for the benefit of fishing. A sandy bay on the east side feoms a good landing-place. N. lat. 26° 24'. E. long. 55° 38'.

TUMB NAMIU, or Little Tumb, a small island in the Persian gulf; 10 miles S.W. of Tumb.

TUMBABA, a word used by chemists to express sulphur vivum, or crude sulphur.

TUMBACH, in Geography, a town of Bavaria; 17 miles N.N.W. of Amberg.

TUMBADO, a small island among the Bahamas. N. lat. 26° 24'. W. long. 79° 30'.

TUMBALA, a word used by some authors, to express the sqamae, or scales, of any metal.

TUMBALI, in Geography, a town of Hindoostan, on the coast of Malabar; 25 miles S. of Cochin.

TUMBELAN, TUMBELAN, TUMBERIDIPAL, a town of Hindoostan, in Myf ore; 22 miles N. of Darapuram.

TUMBEZ,
TUMBEZ, a town of Peru, in the jurisdiction of Piura, near a river of the same name, which discharges itself into the bay of Guayaquil, almost opposite to the illand of St. Clare. Barks, boats, balzas, and canoes, may go up and down this river, being three fathoms deep, and twenty-five broad; but it is dangerous going up it in the winter season, the impetuosity of its current being then increased by torrents from the mountains. At a little distance from the Cordillera, on one side of the banks of the river, stands the town of Tumbuz, in a very Randy plain, interposed with some small eminences. The town consists only of seventy houses, built of cane, and thatched, scattered up and down, without any order or symmetry. In these houses are about 150 families of Mefitos, Indians, Mulattoes, and a few Spaniards. There are, besides these, other families living along the banks of the river, who having the convenience of watering their grounds, continually employ themselves in rural occupations. The heat is excessive; nor have they here any rain, for several years successively; but when it begins to fall, it continues during the winter. The whole country, from the town of Tumbuz to Lima, contained between the foot of the Cordillera and the sea, is known by the name of Valles. Tumbuz was the place where, in 1526, the Spaniards first landed in these parts of South America, under the command of Don Francisco Pizarro, and where he entered into several friendly conferences with the princes of the country, but was slain by the Incas. If the Indians were surprised at the flight of the Spaniards, the latter were equally so at the prodigious riches which they everywhere saw, and the largeness of the palaces, castles, and temples, of all which, though built of stone, no vestiges are now remaining. 280 miles N. of Truxillo. S. lat. 3° 13'. W. long. 80° 6'.

TUMBLER, a name given to a particular species of pigeon, called by Moore the * columba revolutionis*. See *Pigeon*.

It has its name from its peculiar property of tumbling when it is in the air, which they are very fond of doing; and effect exactly in the same manner as our posture-matters do it; by throwing themselves over backward. It is a very small pigeon, and is always short-bodied, full-breasted, thin-necked, narrow-beaked, and has a small short head; the iris of the eye in this species is usually of a bright pearl-colour.

The English tumbler is usually of one plain colour; black, blue, or white: the Dutch is much of the same make, but has different colours, and is sometimes feathered on the legs; it has also a larger head, and thin skin round the eye. Some of the finest pigeons of this sort are bred from a mixture of the Dutch and English kinds. These pigeons are remarkable for the height to which they fly; they never ramble far from home, but will rise almost perpendicularly, till they appear no larger than a sparrow, or become quite out of sight; they will often keep at this height five or six hours, and then come gradually down again: they never tumble when they are at any great height, but only as they ascend or come down again. There are particular times also, at which these birds will take much higher flights than at others; but they ought to be kept by themselves, and practiced to it by the company of one of their own species; for if they mix while young with other pigeons, they will learn to fly as they do; a flight of a dozen of these birds sent out together, will keep so close, as to be all in a compas that might be covered with a handkerchief; but they should never be turned out in foggy weather, or in high winds; in the first cafe, they lose sight of their home, and perhaps never find it again; and in the other, they are blown away; and if they return, it is not till another day; in the mean time lying out, they are in danger of cats, and other accidents.

Lastly, the hen should never be turned out with egg, for she is then sick, and not fit for flying; and beside often drops her eggs, and the breed is lost by it. Moore's *Colurnariam*. p. 30.

TUMBLER is also a fort of dog, called in Latin *vertagus*, from his quality of tumbling and winding his body about, before he attacks and falls on the prey. See *Dog*.

This species took its prey by mere subtlety, depending neither on the sagacity of its nose, nor its swiftness; if it came into a warren, it neither backed nor ran on the rabbits; but by a seeming negligence of them, or attention to something else, deceived the object till it got within reach, so as to take it by a sudden spring.

These dogs are often less than hounds; being lanker, leaner, and somewhat prick-eared; and by the form of their bodies, they might be called mungrel greyhounds, if they were a little bigger. They seem to answer to our modern lurchers.

TUMBLING-BAY, in a Canal, is the same with overfall or weir; which fee.

TUMBLING DAM, in Geography, a place on the river Delaware; 20 miles above Trenton.

TUMBLING-HOME, the inclination of the top-fides of ships from a perpendicular towards the centre or middle line of the ship. The top-fides of three-decked ships have the greatest tumbling-home, not only from their being lofier, but for the purpose of clearing the upper works from the smoke and fire of the lower guns. The advantages and disadvantages of tumbling-home fides will be found discussed in *Ship-building*; which fee.

TUMBREL, TUMBRELUM, a ducking or cucking-fool, an engine of punishment, which ought to be in every liberty, that has a view of frank-pledge, for the correction and cooling of scolds, and unquiet women.

TUMBREL, in Artillery, is a kind of carriage with two wheels, used to carry the tools of the pioneers and miners, and sometimes likewise the money of the army.

TUMBREL is also a common name for a dung-cart.

TUMBRIAL, SHEEP, a contrivance of the balsket kind for the purpose of keeping different sorts of food for the use of them. It consists of a fort of circular cage or balsket made of osiers, willows, or any other plants of the bruswood kind. It is about ten feet in circumference in the whole, and closely wattled to the height of about one foot, above which it is left open for the space of eighteen inches; it is then wattled again to the height of eight or ten inches more, and an opening, about eighteen inches in breadth, is left at the top, for putting in the hay, roots, or other sorts of food, whether green or dry. The flaves which form the skeleton of it are put ten inches asunder, so that twelve sheep may feed at it at the same time.

Considerable advantage may be derived from this simple contrivance in the feeding of these animals, as it not only effects a material reduction in the consumption and expense of the provender, which is by this means prevented from being trodden under foot, or foiled by the dung; but in this state of separation the stronger sheep cannot drive away the weaker, as each is secured by the head. And as the construction of such tumbrils is attended with no difficulty, they may be easily provided and conveyed to any part of a farm, and with due care be kept in constant use for eight or ten years, or even much longer.

TUMBUK, in Geography, a town of Africa, in Kordofan; 180 miles S.W. of Sennar.
TUMEFACION, the act of swelling, or rising into a tumour.

Inflammations and tumefactions of the testes frequently happen in the gonorrhoea; either from the weaknesses of the vesicles, violent motion, unseasonable use of astringents, a neglect of purging, or the like.

TUMMARAH, in Geography, a town of Africa, in Sahara.

TUMMEL, a large river in Perthshire, Scotland, rises on the confines of Argyleshire. Near its source it forms a broad lake, called Loch Rannock, at the termination of which the river assumes the name of the Tummel. In its progress it forms another lake, called Loch Tummel, in which is a small island, with an old fortress or castle, formerly the residence of the chief of the clan of the Robertsons. The whole course of the Tummel is rapid and furious, and in several places forms very romantic and picturesque cascades. One of its falls, near its junction with the Garry, is particularly grand, as its whole water is precipitating over the broken rocks with astonishing violence. After its union with the Garry, the character of the Tummel feems entirely changed: before, it was an impetuous torrent; it now becomes a quiet and placid stream. The banks below the junction are extremely rich, and the river meanders through a fine valley; now dividing its stream, and forming small islands, now running in a broad sheet. Though the Tummel is smaller than the Garry, it gives the name to the river formed by their union, because it can trace its origin farther back than the Garry, which is composed of the waters of the neighbouring hills, while the source of the Tummel is a considerate lake, in its course from which several distant streams contribute to its importance. The Tummel pours its waters into the river Tay at Logierait.—Garnet's Tour through the Highlands, 4to. 1800. Beauties of Scotland, vol. iv. Perthshire, 1806.

TUMNEROO, a town of Meckley; 25 miles S.E. of Munnypour.

TUMMOO, a town of Meckley; 45 miles S. of Munnypour.

TUMOURS. The meaning of the word tumour, in Surgery, is exceedingly comprehensive; for it applies generally to the growth of all distinct superfluous parts, or substances, which did not make any portion of the original structure of the body, as well as to every morbid increase in the bulk of other parts, which naturally and always existed in the human frame. Within this definition will come the greater number of diseases; as effeite or droppy, broncheocele, adenoma, fungus hematudes, hydrocele, ganglions, inflammations of various organs, mobile swellings, aneurisms, abscebes, hemorrhoids or piles, exsudates, exerstences, polypi, hernie or ruptures, stfribus, sturts, &c. &c. (See these words.)

Had it, therefore, entered into our arrangement to consider, in the present article, all the diseases which may be classed as tumours, we should have had a very tedious and laborious task indeed, namely, that of writing out and prenaming to the reader, in this part of the Cyclopaedia, a description of the nature and treatment of at least two-thirds of all the diseases usually considered as surgical. Our plan, however, has been different; and for the sake of avoiding all occasion for so long a production, we have treated of numerous kinds of tumours in separate articles, which are alphabetically distributed in this Dictionary.

In the present article, we propose to offer a few general remarks on the formation of tumours; to describe particularly those of the cystified and sarcomatous kinds; and to give some account of the manner of removing tumours in general.

It is difficult to give altogether an unobjectionable account of the formation of tumours, the secrets of which proceeds will perhaps never be disclosed. We know that parts become thickened and enlarged by inflammation; but the causes of the origin and growth of all such swellings as conflit of some new production, which made no part of the original composition of the body, may be said to be totally unknown. In Mr. Abernethy's surgical works will be found some remarks upon this subject, which are more rational and interesting than those generally advanced.

"The incipient state of tumours," he observes, "will naturally first engage our attention; and those which perhaps form the best example and illustration of the subject, are such as hang into cavities from the membranous surfaces, which form their boundaries. The cause of tumours having a pendulous attachment attracted the attention of Mr. Hunter, who made the following remarks on the formation of one on the inner surface of the peritoneum, as is related by Sir E. Home, in the Transactions of a Society for the Improvement of Medical and Chirurgical Knowledge, vol. i. p. 231. 'The cavity of the abdomen being opened, there appeared lying upon the peritoneum a small portion of red blood recently coagulated; this, upon examination, was found connected to the surface, upon which it had been deposited, by an attachment half an inch long; and this neck had been formed before the coagulum had lost its red colour.'

Now had vessels that this slender neck, and organized the clot of blood, as this would then have become a living part, it might have grown to an indefinite magnitude, and its nature and progress would probably have depended on the organization which it had assumed. I have," says Mr. Abernethy, "in my poiffeion a tumour, doublets formed in the manner Mr. Hunter has described, which hung pendulous from the front of the peritoneum, and in which the organization and consequent actions have been so far completed, that the body of the tumour has become a lump of fat, whilst the neck is merely of a fibrous and vascular texture. There can be little doubt, but that tumours form every where in the same manner. The coagulable part of the blood, being either accidentally effused, or deposited in confequence of disafe, becomes afterwards an organized and living part, by the growth of the adjacent vesseis and nerves into it. When the deposited subflance has its attachment by a single thread, all its vascular supply must proceed through that part; but, in other cases, the vessels shott into it irregularly at various parts of its surface. Thus, an unorganized concrete becomes a living tumour, which has at first no perceptible peculiarity as to its nature: though it derives a supply of nourishment from the surrounding parts, it seems to live and grow by its own independent powers; and the future structure, which it may acquire, seems to depend on the operation of its own vessels. When the organization of a gland becomes changed into that unnatuural structure, which is observable in tumours, it may be thought in some degree to contradict those observations; but, in this case, the subflance of the gland is the matrix, in which the tumour is formed.

"The structure of a tumour is sometimes like that of the parts near which it grows. Those which are pendulous into joints
TUMOURS.

Joints are of a cartilaginous or osseous fabric; fatty tumours frequently form in the midst of adipose substance; and I have seen some tumours growing from the palate, and having a slender attachment, which in structure resembled the palate. Sometimes, however, they do not resemble in structure the parts from which they grow. The incidence, just mentioned, of the pruniform portion of fat growing from the perilunum, will serve as a proof: the vessels, which had first into it, made the tumour into fat, whilst the neck was a fibrous and vascular structure. I have seen osseous tumours unconnected with bone, or periosteum; and, in general, the structure of a tumour is unlike that of the part in which it is produced. Therefore, we fear warranted in concluding, that, in many cases, the nature of the tumour depends on its own actions and organization; and that, like the embryo, it merely receives nourishment from the surrounding parts.

"If, then, the coagulable part of the blood be from any cause effused, if the adjacent absorbents do not remove it, and the surrounding vessels grow into it, the origin of a tumour may be thus formed. It may be right," says Mr. Abernethy, "to reflect a little on the causes which may occasion a deposition and consequent organization of the coagulable part of the blood; as such reflections throw light on the nature and growth of tumours, and lead to the establishment of principles, which are applicable to tumours in general. The deposition of the coagulable part of the blood may be the effect of accident, or of a common inflammatory process; or it may be the consequence of some diseased action of the surrounding vessels, which may influence the organization and growth of the tumours.

"In the former cases, the parts surrounding the tumour may be considered simply as the sources from which it derives its nutriment, whilst it grows apparently by its own inherent powers, and its organization depends upon actions begun and existing in itself. If such a tumour be removed, the surrounding parts, being found, soon heal, and a complete cure ensues. But if a tumour be removed, whose existence depended on the disease of the surrounding parts, which are still left, and this disease be not altered by the stimulus of the operation, no benefit is obtained: these parts again produce a diseased substance, which has generally the appearance of fungus; and, in consequence of being irritated by the injury of the operation, the disease is in general increased by the means which were designed for its cure. It appears, therefore, that, in some cases of tumours, the newly formed part alone requires removal; whilst, in others, the surrounding substance must be taken away, or a radical cure cannot be effected."

"There is yet another circumstance deserving attention," says Mr. Abernethy, "before I proceed to the particular consideration of the subject; which is, that a tumour, once formed, seems to be a sufficient cause of its own continuance and increase. The irritation which it causes in the contiguous parts, is likely to keep up that increased action of the vessels, which is necessary to its supply; and the larger it becomes, the more does it stimulate, and of course contribute to its own increase."

"Suppose then a tumour to have formed and increased; it will continue to grow, and to consume the surrounding cellular substance, and thus acquire for itself a kind of capsule. Tumours are more closely or loosely connected to the surrounding parts; which circumstance seems to depend upon the degree of stimulus which they occasion, and the inflammation which they thus excite. This irritation perhaps may be the cause why some tumours, which are in their first increase, grow rapidly after they have acquired a certain size." See the Surgical Works of John Abernethy, F.R.S., &c. vol. ii. p. 7, et seq.

We regard the preceding account of the formation of tumours as the most rational and probable which has hitherto been offered.

All tumours, which are such as may be termed new-formed parts, and did not enter into the original structure of the body, appear to be ended with inferior powers of life, and are much sooner destroyed by inflammation than other parts, which always naturally existed in the animal frame. The knowledge of this fact has led to the method of curing several kinds of tumours, by the application of stimulating substances to them; but it is not a plan of treatment which will invariably answer. Some tumours are so large, that the constitutional illness, which would arise from the inflammation and sloughing of the whole of their mass, would in all probability be fatal. Some swellings are of a malignant, irritable character, so that applying stimulants to them is more likely to exasperate than cure the disease. Hence, it is generally deemed improper to apply caustics to cancerous affections; because unless every particle of such diseases, and a good deal of the surrounding sub stance, be destroyed by the action of these violent remedies, the case will not be benefited, but rendered ten times worse. Indeed, we may lay it down as a general maxim, that the plan of attacking tumours with stimulants and caustics is a bad one, unless it be certain that every particle of the disease can be in this manner easily and quickly destroyed, without too much local and constitutional irritation being produced.

Encysted Tumours.—In the midst of the subcutaneous cellular substance, of that which separates the muscles, or even of that which enters into the texture of different organs, tumours are observed to form, whose circumference presents a particular structure, and whose cavity is filled with usual kinds of matter. The parietes of these tumours are composed of a fragment of membrane, named a cyst, and are connected with the surrounding parts by means of the neighbouring cellular substance. This latter circumstance appears to have attracted the attention of a great many writers, who have conceived the formation of cysts, by supposing that a cavity of the cellular membrane, in consequence of disease, may have all its communications with the other cavities of the cellular membrane destroyed; that it may acquire the property of secreting matter entirely different from that which it secretes in the natural order of things; and that the accumulation of the deposed substance may produce a progressive dilatation of the small cavity. The layers of the cellular substance, in which the tumour develops itself, are afterwards supposed to undergo a kind of condensation; and by such theories, it is attempted to explain the considerable thickenings of some cysts, the extraordinary appearances of their organization, and the possibility of resolving them into cellular substance by maceration, inflammation, suppuration, &c. It is difficult, observes M. Delpech, to adopt this opinion, and reconcile it to the following observations.

1. There are some thin transparent cysts, which have been termed froze, whose inner surface is villous, and whose cavity is filled with a sero-mucous secretion, resembling synovia. In the same cavity, hairs are frequently observed, which are of different lengths, and always curved; the roots being implanted into the sides of the cyst.

2. There are other cysts, which are generally of a thin, but much more compact, texture than cellular membrane, being, as it were, almost horny and half opaque. Their inner surface is pulpy, and sometimes irregular. Their cavity

Vol. XXXVI.
cavity is filled with a fluid, that has more or less consistence, is pultaceous, and of a white or yellowish colour, being compared sometimes to sap, sometimes to liquid honey, and in other instances to fuel imperfectly melted. Hence, the names of *atheroma, meliteris,* and *fleatoma,* by which they are commonly distinguished. The contents of these encysted swellings have different proportions of fat; and hairs are also frequently found in the cyst, their insertions into it plainly admitting of demonstration, notwithstanding the difficulty arising from the tenacity of the contained matter.

3. We observe some cysts formed of albumen converted into a fibrous texture, and whose organization is more or less imperfect. Particular cysts of this latter kind are composed of several concentric layers, which are only slightly adherent together, and the organization of which is unequally advanced. In such a case, M. Delpech has found the external layers made up of a perfectly fibrous texture; while the vorticels of an organized structure were much less evident in the subjacent layers, and altogether wanting in those most deeply situated, which were purely albuminous. The contained matter is of an albuminous or gelatinous quality.

4. Other cysts are what Delpech calls fibro-cellular; their sides are very thick, extremely compact, and sometimes even offished in certain parts. The contents are almost like serum, occasionally tinged with blood.

5. Excepting this last sort of cyst, which is closely connected with the surrounding cellular membrane, and almost identical with it, there is, of every kind of cyst, a portion of the surface which scarcely has any adhesion to the circumjacent parts. In extirpating such tumours, if the surgeon makes a perpendicular cut through the parts, covering their external surface, he can afterwards completely detach them with the utmost facility. In short, they can be separated with a spatula, or any other blunt instrument, without any difficulty.

6. Sometimes inflammation attacks the cellular membrane around the cyst, and terminates in suppurition. One or more spontaneous openings serve at first for the discharge of the abscess; but these are at length joined together by the effect of ulceration, and the whole mortified cyst sloughs away. The same thing is occasionally seen, when caustic has been applied to the skin covering the most prominent part of the swelling. The application not only produces an eschar of the integuments, it causes also an acute inflammation of all the cellular substance around the tumour, and mortification of the whole cyst, which comes away in a mafs. Likewise, when the surgeon has been fearful of cutting out every portion of a cyst, and only opened it, or removed a part of it, with the design of completing the destruction of the rest by local applications, it has often happened that the remainder of the cyst has spontaneously sloughed away, while the surrounding cellular membrane was in a state of acute inflammation.

7. Lastly, an encysted tumour, treated in the preceding manner, has often presented phenomena resembling those of cellular substance, and admitted of being cured in the way which was described. Healthy suppuration has been established; granulations have arisen; the cavity has been gradually lessened; and a solid cicatrix has at length been formed. But it has much more frequently happened, that the cavity has not been obliterated; but become filled with painful, bleeding, fungous excrecences, which have caused an apprehension of cancer, and a necessity for no longer deferring the extirpation of the disease.

These reflections appear to M. Delpech to justify the conclusion, that encysted tumours do not proceed from an accidental or mechanical modification of the cellular membrane; but that they are so many new-formed organs, which are not cured either with the same degree or the same mode of vitality as the surrounding parts.

The causes of the formation of encysted tumours are entirely unknown: it is observed, however, that a strongly marked propensity to be afflicted with many such swellings exists in particular individuals, which is a fact that would lead one to suspect the operation of constitutional causes. For instance, it is common for those firm cysts, which contain a pappy matter, and which have received the appellations of *atheroma, meliteris,* and *fleatoma,* to be very numerous in the scalp, or other particular situations. It is well known also that the fibro-cellular cysts, usually named dropily of the ovary, are sometimes prodigiously numerous, either in one or both of these organs together. It is superfluous to remark, that external violence, to which encysted tumours have been often ascribed, has in reality no concern with the disease. Besides the evident disproportion between this species of caufe and so great an organic change, it may be observed, that if a blow can sometimes be cited, as having preceded the formation of an encysted tumour, the same cause cannot be specified in other cases, where twenty or more of these swellings originate in succession.

An encysted tumour, at its commencement, is always exceedingly small, and of a perfectly indolent nature. It is not known whether, in this early state, the cavity of the cyst already exists. The swelling usually grows with remarkable rapidity: indeed, it is often many years before it attains a considerable size. It even frequently happens, that after the tumour has become large enough to be manifest, the cyst remains stationary for years, until some irritation occurs, which renders the disease painful, and accelerates its progress. It appears that, in these circumstances, the latter enlargement of the tumour does not depend upon a briner secretion of the kind of matter originally contained in it, but rather upon suppuration of the cyst. In fact, the infide of the fac is then found to be inflamed or ulcerated, and a certain quantity of pus blended with the pappy matter, with which the swelling had no doubt been previously filled. This change, however, seldom happens, unless the tumour be, by its situation, exposed to repeated external violence.

An encysted swelling is ordinarily of a spherical shape, except when this form is altered by the disposition of the surrounding parts. The tumour is moveable in a degree proportioned to the mass of cellular substance around it; and its surface is in general smooth and regular. Sometimes, however, bands of aponeurotic fibres prefixed upon certain portions of it, as it enlarges; and thus is it rendered irregular. The same alteration may be produced by great inequality in the thickness and consistence of the sides of the cyst, or by their being weakened by internal ulceration. It is not uncommon in the beginning, and even sometimes in an advanced stage, for the swelling to have a very firm feel, either because the cyst is still of considerable thickness, and the contained matter not copious; or else because the cyst is exceedingly tense, not having yielded to the dilatation of the matter within it. In this circumstance, the swelling is not compressible; and if, at the same time, its surface should chance to be irregular and tuberculated, and especially if the disease should also be painful, the surgeon may easily make a mistake, and imagine the case to be cancer. The resemblance, indeed, is very great; and M. Delpech affures us, that he has seen practitioners of the highest merit deceived by it. But it more usually happens, that an encysted tumour presents, from the first, a soft, fluctuating,
fluctuating, doughy feel. The fluctuation is obvious enough, when the cyst is thin, and the contained matter almost all liquid. This symptom, however, is absent, when the fides of the swelling are very thick and firm, and its cavity is occupied by a pappy sort of matter; but in this last kind of cæfa, the shape of the mass may be altered by compresion, and the tumour will retain every impression made in it. If to these circumstances we add, that the tumour is everywhere soft and compressible, we have all the proper symptoms of this class of swellings; symptoms by which they may be most frequently distinguished from every other disease that has any resemblance to them.

The stationary condition of an encysted tumour may last during life, if the disease be not exposed to external violence, and it be free from every complication. But, as we have already explained, an accidental irritation may cause an inflammation, and suppuration, and ulceration, of the cyst. The consequence may also be inflammation and ulceration of the integuments. In both cases, the cyst may spontaneoufly burst, the contents escape, the cyst flough away, and the ulcer heal; or else soft, painful, fungous granulations may shoot from the inner surface of the cyst, and render cicatrisation impracticable. With regard to complications, a cancerous affection, which is sometimes joined with the organization of an encysted swelling, is the most afflicting: in this case, when ulceration occurs, the carcinomatous symptoms immediately make rapid and dangerous progres.

Encysted tumours, like aneurisms, may destroy the parts of bones, upon which they make considerable preasure. Delpech, Précis Élémentaire des Maladies Chirurgicales, tom. iii. fect. 8.

A curious appearance is sometimes the consequence of an encysted tumour being filled with a fluid resembling horn in consistency; for, when the cyst bursts, the indurated contents gradually protrude, and sometimes form an appendage very much like horn. Some years ago, we saw a complete horn removed from the cranium, by Sir J. Earle, in St. Bartholomew's Hospital. It had begun as a tumour, which, after bursting, emitted from its inside the horny excrecence. The preparation is now in Mr. Abernethy's museum.

In the British Museum is preserved a curious specimen of a horn, which grew from a woman's head, and, in all probability, was formed by a process similar to that which we have mentioned. In Mr. A. Cooper's plate it is a still more remarkable specimen, which was given to him by Dr. Roots of Kingstown, and which in shape and size bears a close resemblance to a ram's horn. It also grew from the head, and had been preceded by another horny excrecence, similarly situated and shaped, which had like wise been removed. We have subsequently been informed, that the patient, who was a gardener, had afterwards a third horn, which grew in the same identical place. In this case, we must suppose that a portion of the cyst had not been extirpated in the previous operations, and that it retained the power of secreting the horny matter. Firil Lines of Surgery, p. 142. edit. 3. See also Hornv Excrerences, in this Cyclopaedia; and Sir E. Home on the same subject, in the Philosophical Transactions.

We have already noticed the curious fact of many cysts containing hairs: we have now to mention the more surprising circumstance of teeth having been sometimes found in the cavities of encysted tumours. A remarkable example was lately published by Mr. S. Barnes, surgeon at Exeter. The cæfa was a double encysted swelling in the orbit; in the extirpation of which disease, a sharp bony process was discovered, and removed, together with the remains of the fac which adhered to it.

On examination, it was found to be in structure a tooth, and much resembling in form and size the supernumerary teeth sometimes found in the palate. The part which projected into the fac was conical, and covered by smooth, shining, white enamel; the fac firmly adherent round a contracted portion at the base of the cone, resembling the neck of a tooth; and on the outside of the fac, the appearance of a root, truncated obliquely, with a paffage in the centre, evidently containing blood-vessels. It was by this part that it was connected with the floor of the orbit. See Medico-Chirurgical Transactions, vol. iv. p. 316, et seq.

Practitioners are not acquainted with any effectual means of stopping the growth of encysted tumours; nor are the endeavours to promote the dispersion of the cyst and its contents by general or topical treatment, attended with any success. It has been alleged, that, in cases of what have been called fero-mucous cysts, the removal of these cysts and their contents might be brought about, by exciting the action of the absorbents with strong diffusive topical applications; and infusions of this mode of cure have been cited in relation to such swellings formed upon the patella, or at the extremity of the anclerosom. But Delpech remarks, that, in these cases, the nature of the disease is mistaken, because, in the situations specified, there constantly exists a synovial membrane, a bursa mucosa, forming a kind of joint between the bony prominence and the integuments. The synovia may accumulate and lodge in the cavity of the membranous fac; and if the membrane be not thoroughly diseased, as to render the absorption of the synovial fluid impossible, the natural functions of the part may be re-established, and the swelling admit of being slowly dispersed. This is what is sometimes accomplished by different local remedies, particularly those of the difcutant class. But if the synovial membrane is more completely diseased, its properties may be so altered, that the secretion from it is altogether of a different nature, and absorption is totally obstructed. This is what sometimes occurs in persons who are in the habit of kneading a great deal; in them the synovial membrane is often considerably thickened; sometimes it is partly ossified; and Delpech mentions, that he has even found loose fibrous cysts in its cavity. Here we see, that in the first instance, an immediate cure is possible, since the disease is not an organic alteration. But in the second example, which more resembles the state of encysted tumours, although it be only the change of a pre-existing organ, the affection cannot be cured without destroying the dis-tempered part. Delpech, with a view of opposing evident facts to such as are wrongly interpreted, or doubtful, adverts particularly to those fero-mucous cysts which so often form in the fibrous of the eye-lids. The apprehension of a fear upon the face, says he, constantly leads to a trial of topical resolvents, before extirpation is attempted. Surgeons know, however, that the tumours are not removed by absorption; and that, if the local applications sometimes accomplish the cure of the disease, it is by producing an irritation of the skin, which irritation extends itself to the cyst, where inflammation, suppuration, ulceration, and floughing, are the consequences. But, generally speaking, these effects are not excited, and when they are, a cure of the disease is not uniformly the result. The inflammation, carried to the requisite pitch to produce ulceration of the cyst, may only affect some points of it, and perhaps merely that portion which is next to the integuments. Every where else the inflammation may be very flight, and quite insufficient to cause ulceration and floughing of the deeper part.
TUMOURS.

part of the cyst. Then, external ulceration taking place, the
tumour empties itself; and the part either heals up, with the
exception of a fistulous opening; or things are brought into
their original state by the formation of a perfect cicatrix, so
that the encysted tumour makes its appearance again.

Some practitioners have thought that encysted tumours
might be cured by the employment of irritating injections,
like those successfully used in the treatment of hydrocele.
The experiments which have been made with them, how-
ever, have not generally answered; and, if we reflect upon
the comparative state of things, it will appear that, in these
cases, the object aimed at would not be the same. In the ex-
ample of hydrocele, it is unnecessary to destroy the tunica
vaginalis, and the obliteration of its cavity is all that is
needed. Experience also proves, that, in consequence of a
very mild degree of inflammation, the cavity of the tunica
vaginalis is filled with lymph, which becomes organized, and
connected with the adjacent membranous surfaces. This
suffices to render all exhalation for the future impossible.
But encysted swellings have a peculiar organization, differ-
ent from that of any originally formed parts. We have no
reason for supposing, that any slight inflammation will make
them pour out coagulating lymph that is capable of becom-
ing vascular. They seem so indifferently to be thus
affected, that nothing at all resembling it happens, unless
the cause of the inflammation is kept up with considerable
permanence. The inflammation also, when it is excited,
more readily produces mortification of the cyst, than the
other kind of alteration. In fact, it is observed, that while
some portions of the inflamed cyst become covered with
fungus granulations, others mortify and separate in the
form of sloughs. The whole of a cyst has not always the
same structure, and offlided parts of it, for instance, are not
likely to admit of that process, by which a hydrocele is
usually cured. The hairs often growing in the cavity of an
encysted tumour, must generally have their attachments
destroyed by the inflammation following the use of an irri-
tating injection, and they would then probably operate as
extraneous substances.

These circumstances tend to shew, that the practice of
making an incision into the swelling must be at all events
preferable to that of employing irritating injections. By an
incision, all the contents may be dischaged, the whole
cavity of the cyst exposed, and such applications constantly
made as are calculated to keep up the requisite degree of
inflammation. This method, also, gives the surgeon an
opportunity of destroying particular portions of the cyst
with caustic, if necessary. In this way, he is sometimes
obliged to destroy the large fungi, which frequently origi-
nate from the thickest parts of the cyst, after it has been
opened and cauterized, or merely irritated by the dressings.
Too often, however, the superficial use of caustic is insuf-
ficient to leffon the size of these fungous growths, and not
adequate even to retrain their daily increase; while deep
cauterizations produce acute long-continued pain, fever, los-
of rest, and great irritation of the whole extent of the dif-
case. The train of symptoms, indeed, which the repeated
free use of caustic may occasion, must seem still more alarm-
ing, when it is recollected that the cyst of the tumour some-
times becomes the seat of cancer; and that all the ravages of
the latter disease in the ulcerated state may be the con-
sequence. In this circumstance, the practitioner is obliged to
have recourse to the extirpation of the swelling, and this
sometimes a long while after the cyst has been opened, and not
before the patient has suffered a long series of other painful,
unavailing measures. Nor can these dangerous effects be
avoided by opening the tumour with caustic instead of with

a cutting instrument. The more certain inflammation of the
cyst thus aimed at, is by no means sure of ensuing; and it
will never follow, unless the caustic act strongly on the cyst.

Besides, the action of caustic is too variable to justify the
calculation, that its effects will reach to a precise depth, and
always effectually destroy the cyst. See Delpech, Précis
Elémentaire des Maladies Chir. tom. iii.

The inconveniences of opening an encysted tumour ought
to make us give a decided preference to extirpating or am-
pulating the whole of the swelling, whatever may be the
nature of the cyst. Indeed, this method of treatment is
superior to all others. The art of doing the operation skil-
fully, consists in detaching the tumour from the surrounding
parts without wounding the cyst. If the latter accident oc-
cur, the contents frequently flow out, the cyst collapses, and
the continuance of the dilatation is attended with more dif-
culty. It is a great point to remove every particle of the

cyst; and hence it is satisfactory to take it out entire, that
is, without wounding it. When any portion remains be-
hind, the wound will frequently not heal, in consequence of
fungous granulations arising from the diseased part. Unles-

The swelling be large, a single incision through the skin is
sufficient; but in other instances, it is advantageous to
make two semicircular cuts in this manner, \( \text{\ldots} \); first, be-
cause it facilitates the removal of the tumour; and secondly,
because it prevents a redundancy of skin, which would take
place if none were removed, and which would have the ef-
fect of seriously retarding the cicatrization of the wound.

After the operation, the edges of the wound are to be
brought together with sticking-plaster, and a compress and
bandage applied.

The excision of encysted tumours, superficially situated,
is most very easy, as the cyst is only slightly connected
with the surrounding cellular membrane. But there may
be more difficulty when the swellings have been in a previous
state of inflammation; when they are very large, or when a
portion of the cyst is deeply situated, or closely adherent
to other parts. First Lines of Surgery, p. 144, edit. 3.

We must not quit the subject of encysted tumours, with-
out making a few remarks on those of the scalp.

The encysted tumours met with in this part, are situated
between the integuments and the aponeurosis of the occi-
dito-frontalis muscle. Their cysts are most of a hard,
hornyness consistence, and filled with a pulpyaceous matter,
being what are termed cases of atheroma. It is very common
for such swellings to grow in great numbers. The intimate
union between the aponeurosis and the skin causes the latter
to be considerably stretched by the growth of tumours un-
derneath it; but notwithstanding this effect, and that the
integuments are also sometimes rendered very thin from the
same cause, they are seldom altered in appearance, excepting
occasionally their exhibiting a livid colour, which is a sign of
their being about to ulcerate. When encysted tumours of
the scalp have slowly attained an immense size, the skin
covering them is diffused in such a degree, that it is either
quite bald, or at most only has a very few hairs upon it, so
widely separated are the bulbs. It rarely happens that the
preature of the swelling produces an abscess of the part
of the skull underneath the diseased; but examples of this
kind have sometimes been observed.

Encysted tumours on the top of the head, even when they
have acquired a considerable size, may be easily concealed
by a hat, cap, or the head-drefs; and, unless in a painful,
inflamed, or ulcerated state, cause but little inconvenience.

But when they are situated at the sides of the cranium, they
render the wearing of hats, or any kind of head-dress, less
TUMOURS.

ficultations for these swellings. But their occurrence is so frequent, that there are few surgeons who have not had many opportunities of seeing them in almost every region of the body. We once saw an adipose tumour which grew on the thigh, and after it had been removed by Mr. Cline, in St. Thomas's hospital, was found to weigh between fourteen and fifteen pounds. Sometimes adipose tumours are formed in parts where there is naturally but a small quantity of fat: thus Delpecch has seen a fatty swelling formed in the labia pudendii, the structure of which is very different from fat. Sometimes adipose swellings are formed between the peritoneum and the parietes of the abdomen, in which circumstances the tumours make their way outwards under the integuments, drawing along with them the part of the peritoneum to which they are attached. Such cases have been improperly named by the French surgeons "hernies graisseuses."

The causes of the growth of adipose tumours are not known: the disease has been sometimes ascribed to blows, and other kinds of external violence; but we agree with M. Delpecch in believing, that this doctrine is altogether incorrect and unfounded.

The shape and slow growth of adipose tumours might suffice to indicate their nature; but they present other characters, amongst which the confidence of the mass of the swelling deferves particular notice. These tumours are not elastic, but of a peculiar soft feel, resembling what is perceived on handling a bag filled with cotton. Their surface is unequal, but the irregularities which are distinguishable through the thin integuments have no firmness, and are obliterated by compression. These circumstances, however, are only strongly marked in those adipose tumours as have not yet acquired an immense size, and which remain free from every complication. When the swelling has become exceedingly large, its weight, its magnitude, its pressure on the surrounding vessels and integuments, materially obstruct the circulation; and an oedema then takes place between the skin and adipose substance, the confidence of the latter part may appear to be increased. A manual examination, however, made by a surgeon of experience, will still detect the kind of softness which is peculiar to all fatty tumours, and discriminate it from the firmer feel of the cellular membrane immediately under the skin. Any previous attacks of inflammation may produce the same effect, and this even in a more remarkable degree. Such attacks are very common in those adipose swellings whose situation particularly exposes them to frequent causes of irritation. Thus, M. Delpecch once saw a large lipoma growing in one of the labia pudendii, the incessant motion of which swelling, together with the friction of the thighs against it, and the irritation of the urine, had frequently made the skin inflame, and caused deep ulcerations in the sides of the tumour. The swelling was heavy and indurated; the irregularities of its surface were much firmer than usual; but in handling the mass attentively, the peculiar confidence of lipoma could be distinguished in the deeper part of the tumour, and be discriminated from the hardness of the integuments and cellular substance. Such induration is accidental; it seldom affects the whole of an adipose tumour; when it occurs, it is always confined to the layers of cellular membrane in which the adipose substance is lodged; it originates from repeated external irritation; and it should always be well discriminated from the hardness arising from a cancerous disease.

Adipose tumours, for the most part, grow in a regular, slow, and progressive manner; and their vessels are generally neither large nor numerous. Hence the removal of these swellings is attended with little danger of any serious degree
of hemorrhage, and they are very easily separated from the surrounding parts. The detachment of the tumour, however, may be more difficult when there have been previous attacks of inflammation in the part. An adipose tumour, even when large, may continue for many years without producing any material inconvenience, provided no complication attend the disease. The swelling may grow with more or less rapidity, or remain stationary; but it has never been observed to disappear spontaneously; and every means which has been hitherto tried with a view of dispersing it, has proved ineffectual. The only method of cure consists in cutting away every part of such a swelling, which ought to be done before the diseased mass is of very large size.

Of some other Kinds of Sarcomatous Tumours.—It is extremely difficult to name and describe, clearly and unobjectionably, all the different varieties of sarcoma. Mr. Abernethy has proposed naming them according to their anatomical structure, or their supposed resemblance in texture to particular organs. Thus he adopts the terms common vascular, or organized sarcoma; adipose sarcoma, which we have already described; pancreatic sarcoma; cystic sarcoma; mafloid or mammary sarcoma; tuberculated sarcoma; medullary sarcoma, &c.

Under the title of common vascular, or organized sarcoma, Mr. Abernethy comprehends all tumours which appear to be composed of the gelatinous part of the blood, rendered more or less vascular by the growth of vessels through it, without having any distinguishing peculiarity of structure. Mr. Abernethy conceives that this kind of organization in tumours is the most simple, and, perhaps, may always precede other descriptions of structure. Vascular sarcoma not only makes its appearance as a tumour, which is altogether extraneous in regard to the original conformation of the body, it also enlarges natural parts, especially the testis, mamma, and absorvent glands.

When this sort of swelling has attained a considerable size, the superficial veins become quite varicose. If left to itself, the tumour generally grows till the skin is so distended, that it ulcerates and exposes the new-formed substance, which floughs and falls out.

In this manner the disease might be got rid of; but such are the constitutionally irritating attending it, and the fever and frightful appearance of the part, that the surgeon generally waits no longer, but removes the whole mass of the diseased with his knife.

Pancreatic sarcoma is the name which Mr. Abernethy applies to those fleshly tumours which resemble the pancreas in structure. The substance of which they consist is composed of irregularly-shaped mafses, connected together by a fibrinous kind of texture. This species of sarcoma is sometimes formed distinctly in the cellular substance; but most commonly occurs in the female breast, perhaps originating in the lymphatic glands. The tumour increases slowly, and generally has little tendency to inflame and suppurate. The morbid structure in question frequently takes place in the breast, a little above, and on that side of the nipple which is next to the arm. In general the disease is chronic, and does not involve the neighbouring absorvent glands. But, in a few instances, this species of sarcoma, when situated in the breast, deviates from its ordinary indolent nature, and occasions severe, lancinating pain, an inflammatory state of the integuments, and an adhesion of them to the tumour, the axillary glands also becoming enlarged. Pancreatic sarcoma is sometimes so irritable a disease, that Mr. Abernethy thinks it may frequently be considered as bad as cancer. When the glands in the axilla become affected, one generally first swells, and is extremely tender and painful; afterwards the pain abates, and it remains indurated; another then becomes affected, and runs through the same course.

Those farcomatous tumours which contain cysts or cells, Mr. Abernethy distinguishes by the term cystic. The disease sometimes occurs as a distinct swelling; but it is more commonly observed in the testicle and ovary. The cysts are very vascular, so that they admit of being made quite red with an anatomical injection. They generally contain a ferial fluid; but sometimes a caseous substance. Mr. Abernethy believes that this species of sarcoma is peculiarly intractable when situated in the testicle.

The mafloid or mammary sarcoma is so named from its resemblance to the mammary gland in structure. Mr. Abernethy has not frequently seen this kind of tumour, and his attention was called to the nature of the disease by a case, in which a swelling, partaking of the above structure, and about as large as an orange, was removed from the front of the thigh. The wound seemed at first dispersed to heal; but it afterwards degenerated into a malignant ulcer, which in about two months proved fatal. As this sort of tumour is gradually lost in the surrounding parts, which probably remain a disposition to assume a similar morbid alteration, Mr. Abernethy very judiciously recommends a more extensive removal of them than was practised in the foregoing example.

Tuberculated sarcoma is the name proposed by Mr. Abernethy for those fleshly swellings which consist of an aggregation of small, roundish tumours, of various sizes and colours, connected together by a kind of cellular substance. This gentleman has principally seen the disease in the lymphatic glands of the neck. The tumours ulcerated, became painful, and ultimately destroyed the patients. Mr. Abernethy regards the tuberculated sarcoma as an incurable and fatal disease; though, fortunately, its occurrence is unfrequent.

Medullary sarcoma is the term applied by Mr. Abernethy to a malignant and dangerous kind of tumour, which resembles in its structure and appearance the medullary substance of the brain. It is often seized affecting the teftis, and has been termed the softest of that part. Many surgeons consider this affection and the fungus hematodes as the same; we do not therefore deem it necessary to offer here any remarks in addition to those already delivered on the latter disease in another article. See Fungus.

Treatment of Tumours.—Surgeons not only remain ignorant of those particular causes which produce the commencement of the growth of the various descriptions of fatty, fleshly, indolent tumours; they also know no effectual means by which the progress of the disease can be checked, and the patient freed from the inconveniences of continually bearing about with him a mass of redundant matter, which, in a chronic state, is both a deformity and an oppression; and in an inflamed or ulcerated state, is a source of severe pain, and even of fatal mischief. It has been conjectured that topical bleaching and cold applications would check the growth of indolent tumours; but experience teaches us to place no dependence upon the plan. Mercurial frictions, electricity, blisters, and local stimulants, have also been repeatedly tried, with a view of exciting the action of the absorvent glands, and dispersing the swelling. These methods, however, are not recommended by many examples of success; and they are attended with some risk of irritating the tumour, without lessening it, in which case the disease sometimes changes from an indolent quiet form to an irritable state, in which it inflames, enlarges, ulcerates, emits fungi, and assumes a character as dangerous and intractable as that of cancer itself. Whenever a swelling is suspected of being either a mammary, tuber-
TUMOURS.

Of the Operation of removing a diseased Breast, and Tumours in general.—The operation of cutting away a diseased breast, is done nearly in the same manner as the removal of tumours in general, and is indicated whenever the part is affected with an incurable disease, which admits, however, of being entirely removed with the knife. When the breast is affected with growths, ulcerated, or medullary sarcoma, it is particularly necessary to abstain from doing any thing which may irritate the part.

The surgeon, indeed, would be inexcusable, were he to neglect to take away such portion of the integuments covering the growths, as is evidently affected, appearing to be fo discoloured, pucked, and closely attached to the diseased lump beneath. No surgical instrument is ever left behind. There is no doubt that there is no absence of operations for cancers with different, so much as the neglect to make a free removal of the skin and parts surrounding every slide of the tumour. Hence the diseased has frequently appeared to recur, when, in fact, it had never been thoroughly extirpated; the diseased, though entirely a local affection, has been deemed a constitutional one; and the operation frequently rejected as ineffectual and useless.

But, strongly as we have urged the prudence, the necessity of making a free removal of the skin covering, and of the parts surrounding every cancerous or malignant tumour, the cure can only be regarded as unscientific, in most operations for the removal of simple, fatty, or spongy tumours. However, even in the latter cases, when the swelling is very large, it is better to take away a portion of skin; for otherwise, after the excision of the tumour, there would be a redundancy of integuments, the cavity of which would only serve for the lodgment of matter. The loose superficial skin, also, would lie in folds, and not apply itself evenly to the parts beneath, so as to unite favourably by the first intention; nor could the line of cicatrices itself be arranged with such nice evenness as it might be, were a part of the redundant skin taken away at the time of operating.

The best method of removing a diseased breast is as follows: The patient is usually placed in a sitting posture, well supported by pillows and cushions, but the operator would find it equally convenient, if not more so, to remove the tumour with his patient in a recumbent position; and it certainly is better whenever the operation is likely to be long, or much blood to be lost, which circumstances are very apt to bring on fainting. We remember that Mr. Abernethy, in his lectures, used to recommend the latter plan; which, however, without the sanction of any great name, or authority, possesses such obvious advantages, as will always entitle it to approbation.

The arms should be confined back, by placing a flick between them and the body, by which means the fibres of the great pectoral muscle will be kept on the stretch, a state most favourable for the dissection of the tumour off its surface. The flick also prevents the patient from moving her arm about, and interrupting the progress of the operation.

When the tumour is not large, and only a simple sarcoma, free from malignancy, it will be quite unnecessary to remove any of the skin, and of course this need only be divided by one incision, of a length proportionate to the tumour. The cut must be made with a common dissecting knife; and, as the division of the parts is chiefly accomplished with the help of the edge towards the point, the instrument will be found to do its office best when the extremity of the edge is made of a convex shape, and this part of the blade is turned a little back, in the way in which dissecting knives are now often constructed. The direction of the incision through the skin should be made according to the greatest diameter of the tumour to be removed, by which means it will be most easily dissected out.
TUMOURS.

The direction of the incision is various with different practitioners; some making it perpendicular, others transverse. In general, the shape of the tumour must determine which is the best. In France, it has been said, that when the incision follows the second direction, it heals more expeditiously, because the skin is more extensible from above downward, than laterally, particularly towards the sternum, and consequently allows the sides of the wound the more readily to be placed in contact; and that the action of the pectoral muscles tend to separate the edges of the wound when it is perpendicular. On the other hand, it is allowed that the wound, made in the latter manner, is the most favourable for the escape of the discharge, if suppuration should occur. See Defaut par Bichat, tom. ii. p. 312.

The cut through the skin should always be somewhat longer than the tumour; and as it is, perhaps, the most painful part of the operation, and one attended with no danger whatever, it should be executed with the utmost celerity. Pain is certainly more or less to be dreaded, according to its duration. The fear, however, of giving pain, has probably led many operators to err, by not making their first incision through the integuments large enough, the consequence of which has often been, that there was not room enough to get at the tumour to as to dissect it out with facility: the patient has been kept nearly an hour in the operating room, instead of five minutes, and the surgeon confounded by the spectators as awkward and tedious. It is clear, also, that, besides the great deal more blood lost from this error than would otherwise happen, the vessels being commonly not tied till the cut is finished, the avoidance of pain, that fear which led to the blunder, is not effected, and the patient suffers much more, and for a much longer time, in consequence of the embarrassment and obstacles in the way of the whole operation.

When the disease is of a fibrous or malignant nature, the skin covering the tumour should at all events be in part removed. All that portion which is discoloured, puckered, tuberculated, or otherwise altered, should be taken away. Some must also be removed, in order to prevent a redundance, in all cases in which the tumour is large. We have said too, that in cases of fibrous and cancer of the breast, the nipple is considered a dangerous part to be left behind. For the purpose of removing the necessary portion of skin, the surgeon must obviously pursue a different mode from that above described; and instead of one straight incision, he is to make two circular ones, one immediately after the other, and which are to meet at their extremities. The size of these wounds must be determined by that of the disfigure to be removed, and by the quantity of skin which it is deemed prudent to take away; for the part which is included in the two circular cuts, is that which is not to be separated from the upper surface of the swelling, but taken away with it. The shape of the two cuts together may approach that either of a circle or oval, as the figure of the tumour itself may indicate as most convenient. The direction of the incisions is to be regulated by the same consideration.

In the above ways, the first division of the integuments is to be made in removing tumours of every description covered with skin. The same principles and practice should prevail in all these operations; and, whether the swelling is the mamma, or any other disfigured mass, whether situated on the chest, the back, the head, or extremities, the same considerations should always guide the operator’s hand.

The incision or incisions in the skin having been made, the next object is to detach every side of the tumour from its connections, and the separation of its base will then be the last and only thing remaining to be done. When the tumour is a fibrous, or other malignant disease, the operator must not dissect close to the swelling, but make his incisions on each side, at a prudent distance from it, so as to be sure to remove with the disfigured mass, every atom of morbid mischief in its vicinity. But when the tumour is only a mere fatty or other masses, perfectly free from malignancy, the cellular bands and vessels forming its connections may be divided close to its circumference. It is astonishing with what ease fatty tumours are removed, after the necessary division is made in the skin; they may almost be turned out with the fingers, without any cutting at all. When they have been inflamed, however, they are then more adherent to the surrounding parts.

Thus we see, that the first stage of the operation of removing a tumour, is the division of the skin; the second, the separation of the swelling from the surrounding parts on every side; the third and last stage is the division of the parts to which its under surface, or base, is attached. The latter object should be accomplished by cutting regularly from above downward, till every part is divided.

It is a common thing to see many operators constantly embarrassed and confused, whenever they have to remove a large tumour, on account of their having no particular method in their proceedings. They first cut a few fibres on one side, then on another; and turning the mass of disease now to this side, now to that, without any fixed design, they both prolong the operation very tediously, and prevent the bystanders a complete specimen of surgical awkwardness. On the contrary, when the practitioner divides the cutting part of the operation into the three methodical stages above recommended, in each of which there is a distinct object to be fulfilled, he proceeds with a confidence of knowing what he is about, and soon effects what is to be done, with equal expedition and adroitness.

Having taken out the tumour, the operator is immediately to tie such large vessels as may be pouring out their blood; indeed, when the removal of the swelling will necessarily occupy more than three or four minutes, it is better to tie all the large arteries as soon as they are divided, and then proceed with their division. This was the celebrated Defaut’s plan, and it is highly deserving of imitation in this country, not only because many subjects cannot afford to lose much blood, but also because the profound effusion of this fluid keeps the operator from seeing what parts he is dividing.

The largest arteries being tied, the surgeon should not be immediately solicitous about tying every bleeding point which may be observed. Instead of this, let him employ a little time in examining every part of the surface of the wound, in order to ascertain that no portion of the swelling, no hardened lump, nor disfigured fibres remain behind. Even if any part of the surface of the pectoral muscle should present a morbid feel or appearance, it must, on every account, be cut away. Also, if any of the axillary glands are disfigured, the operator should now proceed to remove them. After the time spent in such measures, many of the small vessels, which bled just after the excision of the swelling, will now have stopped, the necessity for several ligatures will be done away, and of course the patient saved a great deal of pain, and more of the wound be likely to heal by the first intention.

Some information may be derived, respecting whether any of the tumour is left behind, by examining its surfaces, when taken out, and observing whether any part of them is cut off; for if it is, it may always be found in the corresponding part of the wound.

The
The axillary glands may always be taken out, without the least risk, if the plan pursued by Default in France, and Sir Charles Blicke, and other eminent surgeons in this country, be adopted. The method alluded to is, after dividing the skin covering the gland, and freeing the indurated part from its lateral connections, to tie its root, or base, with which it is connected, with the parts on the side towards the cavity of the axilla. Then the indurated gland itself may be safely cut off just above the ligature. Were the gland cut off in the first instance, the artery which supplies it with blood would be exceedingly difficult to tie, on account of its deep situation; and, by reason of its shortness and vicinity to the heart, it would bleed almost like a wound of the thoracic artery itself. In this way, there is also not the least hazard of injuring the latter vessel. It would be a great improvement in the mode of operating for the removal of these glands, if surgeons were always to make the patient lie down, with the arm placed in such a position as would let the light fall into the axilla. How much the steps of the operation would be facilitated in this way, we need not attempt to explain.

The above directions will enable a surgeon to remove tumours in general. They apply also in a great measure to encysted tumours; but in the latter cases, particular care must be taken not to wound the cyst, as it then collapses, and the dissection of it out is much more difficult. One half of each ligature is always to be cut off before drying the wound. The edges of the incision are to be brought together with strips of adhesive plaster; and, before this can be done with ease, the prick confining the arm back must be removed, and the os brachii brought forward, so as to relax the pectoral muscle and integuments of the breast. No future should ever be employed, as they are useless, painful, and irritating. The wound being closed with sticking plaster, and a pledget of simple cerate, a compress of folded linen, or flannel, may be put over the dressings; these are to be secured with a broad piece of linen, which is to encircle the chief, be fastened with pins or flitches, and kept from slipping down by two tapes, one of which is to go from behind forward, over each shoulder, and be flitted to the upper part of the bandage both in front and behind. The arm on the same side as that on which the operation has been done, should be kept at rest in a sling; every motion of the limb must evidently disturb the wound by putting the great pectoral muscle into action, or rendering its fibres sometimes tenes, sometimes relaxed.

In the article Surgery, we have adverted to the plan of cutting off both ends of the ligatures applied to the arteries, with a view of lessening the quantity of extraneous substance in the wound, and rendering union by the first intension more probable. This method has been tried by Mr. Lawrence after operations on the breast, and also by M. Roux and professor Delphech in France, who all make favourable reports of the practice.

The removal of tumours from the neck is frequently an operation of delicacy and difficulty, especially when the exact attachments and depth of the swellings are not precisely known. The many large arteries in this part of the body, and its being the situation of the carotid artery, and internal jugular vein, are considerations which ought to deter every surgeon who is not an anatomist, from venturing to cut away swellings from the neck, particularly such as have bales extending more or less deeply, and not very moveable. Unfortunately for the man who is deficient in anatomical knowledge, the neck is as common a situation for tumours requiring the ufe of the knife, as any part which can be specified.

One of the boldest operations, for the removal of a tumour from the neck, was that lately performed by Mr. William Goodlad, surgeon at Bury, in Lancashire, and recorded in the seventh volume of the Medico-Chirurgical Transactions, p. 112. In order to do away the danger of hemorrhage from arteries, this gentleman began with tying the trunk of the carotid artery; some conception of the nature of the whole proceeding may be formed from the view which the wound presented after the entire swelling had been removed. "The whole fibrous-mafloid muscle was exposed, and its fibres dissected clean, except about half an inch from its insertion into the clavicle. The wound extended backwards from behind the mafloid procefs to the trachea anteriorly, but became narrowed in the direction of the muscle at the lower part of the neck. The sub-maxillary gland was exposed, and about one-fifth of its substance, not appearing healthy, was removed. The digastric and the greater part of the mylo-hyoidus were exposed, the ramus of the jaw was only covered by perioleum, except where covered by the mafleter muscle, part of which, not appearing healthy, was dissected away. The whole of the condyloid process of that bone was laid bare in the same manner, and behind it the pterygoid muscles were also exposed. The membrane of the cheek was only covered by a cellular substance, which did not appear healthy; but sufficient skin was favored to cover the zygoma. The parotid gland was entirely removed.''

This, which is one of the boldest operations on record, proved successful, the wound having completely healed in ten weeks, and no recurrence of the tumour having followed. See Abernethy's Classification of Tumours. Delphech Précis Élémentaire des Maladies réputées Chirurgicales, tom. iii. Cooper's Dictionary of Practical Surgery. Medico-Chirurgical Tranls. vol. vii. pt. 1, &c.

TUMOUR, among Animals, is a preternatural swelling or enlargement in any part, arising either from an external injury, or an internal cause. Tumours in them are of several different kinds, according to the nature of the causes.

Where tumours or swellings are caused by external accidents, such as blows, bruises, and other such means, they should at first be treated with restringent applications; such as having the parts bathed frequently with warm vinegar or verjuice; and where they will admit of bandage, a flannel wetted with the same should be rolled or laid on, and fastened by it. When by this method the tumour or swelling does not give way and subside, a poultice made with red-wine lees, strong-beer grounds, and oatmeal, or with vinegar, oil, and oatmeal, should be applied, Especially when on the legs; either of which applications may be used and continued twice a day after bathing the parts in the above manner, until the swelling abates; when, in order to wholly disperse them, the vinegar should be changed for camphorated spirits of wine; to four ounces of which, one of spirit of ful ammoniac may be added; or they may be bathed with a mixture of two ounces of crude ful ammoniac boiled in a quart of chamber-ley, twice a day, and cloths dipped in the same be put on them. Fomentations, too, made by boiling wormwood, bay-leaves, and rosemary, with a proper quantity of spirits, are not unfrequently of use in a high degree.

However, in bruises where there may be extravasated blood, which is not taken up or dispersed by these means, the shortest and most convenient way is to open the skin, and to let out the grumous blood.

The critical tumours or swellings in horses or other animals, which terminate fevers, or other difeases, should by no means be dispersed, except when in the horse, they fall upo-
upon the pattern or coffin-joist, so as to endanger them; in which cases the discontinue fomentation may be applied three or four times a day, and a cloth or flannel frequently wrung out of the same may be bound on the parts.

But when the swellings fix themselves under the jaws, behind the ears, on the poll, the withers, or in the groin, shieth, or other parts of the horse, or any other animal, they should be encouraged and brought forward by ripeening poultices, wherever they can be applied: oatmeal boiled soft with milk, to which a proper quantity of oil and lard is added, may answer this purpose; or the poultice composed of linseed-meal, as used in other cases: these should be applied twice a day, until the matter is perceived to fluctuate, by the feel, under the finger, when it should be let out; for which purpose a knife or strong lancet should be used, making an opening the whole length of the tumour, where it can be safely done, as nothing contributes so much to a kind healing of the parts, as the matter having a free discharge, and the opening being sufficiently large to dresst it to the very bottom.

After this, pledges of lint or tow, spread thinly with black or yellow balsam, or the wound ointment, and dipped in the same, melted down with a fifth part of oil of turpentine, should be laid to the bottom of the fore, and the whole filled up in a very light manner with the same, without any sort of ruffling. It may be dressed in this way once or twice a day, if the discharge be great, until a proper digitation be brought on, when it should be changed for pledges spread with the ointment with red precipitante, used in the same manner. If the fore should not digest kindly, but look pale, and discharge a thin watery fluid, it should be fomented as often as it is dressed with the above fomentation, and the strong beer poultice be applied over the dressing, continuing the same until the matter grows thick, and the fore has a florid appearance.

There are other indolent tumours sometimes occurring in animals, but which are noticed under their proper heads.

Tumours, Moor, in Agriculture, a term applied to the small hilly spots or swells of boggy plots which are formed on the banks of hanging slopes, or diffused over flatter surfaces, in particular cafes and situations. They may be formed in various ways, as, in the manner of quickfords, by the waters which fall in their immediate vicinities, but which, to produce certain defects of the wet kind in the lands, find a receptacle sufficient to give the affected tumours parts a constant supply of moisture, or what is enough for giving the bog plants that take root upon them strength and support. Thus, such rising grounds as are formed of open, porous, or freely conducting materials, having the lower borders of them imperfectly covered with an impermeable soil, are peculiarly liable to be affected with this sort of tumour defect. They are likewise capable of being caused by mists of impenetrable matters, which are lodged on the sides of the declivities, or at the feet of them; also by internal wetness, descending through the kind in partial channels that lead it to the surface; and by the fame sort of wetness when confined beneath an impermeable soil, but which is defective, and by reason of the weight thereof above it, admits of the confined moister rising through veins of the sandy kind, or other conducting substanfes and passages to the surface where these sorts of tumours are produced.

Wherever lands are troubled with these kinds of tumours, which is not unfrequently the case, they are to be removed by drawing away the wetness in proper methods, and the suitable manuring, flocking, and managing of the ground, by which means they may often be converted into good sound land. See Moor and Waste-Land.
At the pipes regular and 10 fold £343, £a alfo Livonia, is Paris ankers, A a Spanifti viz. loaden 25 tonnes Englifti ancertain arrobas, answering gens noftels. this Copenhagen 224 tonnes, pipe 2 of Elfmeur, Brunfwick, of Liftjon, of A fafs only gallons: tun corn mingels. At last, of Englifti of bon wine that of 80 herrings; a laft of herrings, Luneburgh salt, honey, pitch, tar, ahes, &c. contains 12 tonnes or barrels; and a laft of French, Scotch, or Spanish salt, when lying together, contains 18 tonnes, and when in sepa-
rate tonnes, only 16.

At Elifieur, in Deamark, the tonneau of French wine is reckoned for 4 hogheads, or 24 ankers; the pipe of Spanifti and Portugal wine for 2 hogheads, or 12 ankers; 30 Spanifti arrobas, or 25 Portuguese almdus of wine, for 1 regular pipe; the pipe of French brandy for 6 ankers; the poinçon ditto for 9 ankers; the tierçon ditto for 4 ankers.

At Embden, corn is fold in tonnes of 4 verps, 8 fcheffels, or 144 kruefen; 15 tonnes, or 60 verps, make 1 laft, anfwer-
ing to 10 English quarters.

In France, by the old fytum, a tonneau of Orleans contains 2 muids of Paris, the mud of wine at Paris being = 174 English gallons; a tonneau of Bourdeaux = 4 barriques, each of 216 pintes of Paris, or 53 3/4 English gallons.

In moft parts of Germany, a laft of lime, tar, pitch, train oil, butter, &c. is 12 tonnes or casks; a laft of herrings is 12 tonnes, each tonne containing about 850. See Tonneau.

At Hamburgh, a tonne of butter, small measure, is 224 lbs.; ditto, great measure, 280 lbs.; a pipe of oil is 820 lbs.; and a small tone of green soap is 60 lbs.: a tone of beer contains 48 flubgens; a small ditto, 32 flubgen; a quartel of train oil contains 2 tonnes or 64 flubgen, and is reckoned at 224 lbs. net weight.

In Hanover, a tone or barrel of honey contains 256 flubgens, and weighs 300 lbs.

In Holstein, the meafure for corn is the fame as that of Copenhagen: viz. the tone of 8 fcheffels, or 32 verps, 100 of which tonnes yield about 49 English quarters. A tone of beer contains 128 quarters, or 25 English beer-gallons.

For the value of the tonne at Königberg in Pruffia, see Tonneau.

At Libon, 13 3/4 quintals make a tun; and each quintal contains 4 arrobas; the arroba 32 lbs., the pound of Libon weighing 70842 grains English Troy weight; so that 83 lbs. of Libon are equal to 84 lbs. of avoidupois weight. The standard gauge, at the Collum-house of London, of a pipe of Libon, is (as above-mentioned) 140 gallons, and this pipe is reckoned at 31 almdus, and the almdus at 4 1/2 English gallons nearly.

At Nantes, in France, a tonneau of wine contains 2 pipes; a pipe, 2 barriques or hogheads, or 240 pots; the pot containing 2 Paris pinte, and the barrique containing 596 English gallons, and a poinçon of wine about 54 1/2 ditto.

At Narva, in Livonia, a laft of corn contains 24 tonnes, and a tone 4 verps, or 32 kapps: 26 tonnes of Narva = 15 English quarters nearly: the laft of French and Spanish salt is reckoned at 18 tonnes, each of 34 kapps. The ahm of wine contains 4 ankers, and a pipe of Spanish wine is reckoned at 10 ankers; of Alicant and Portuguese wine at 13 ankers, Hamburgh meafure: a fass of beer or brandy contains 128 foles, and 44 foles answer to about 15 English gallons.

At Oporto, the ton is = 2 pipes = 50 almdus = 2 potes = 12 canadas = 24 quartillos = 8 meios. At Libon, both wine and oil are fold by the pipe of 26 almdus; but the pipe of Libon wine lent to England contains about 31 almdus, and its standard gauge is 140 gallons: and therefore the Libon almdus is reckoned at 4 1/2 English gallons. At Oporto, the pipe is divided into 21 almdus, but this almdu and its subdivisions are 49 1/4 per cent. greater than those of Libon. Thus the standard gauge of a pipe of port, at the Cutfom-house of London, is 138 gallons, which gives the almdu of Oporto equal to 6 English gallons and 5 pints nearly. Ships are measured by the ton, being a cylinder 6 feet high and 3 3/4 feet in diameter, which gives the contents 573 cubic feet nearly. The proportion between the almdue of Libon and that of Oporto is variously given by different authors; some make it 30 per cent., others 25, and others from 25 to 40; but the real proportion, says Dr. Kelly, is 49 1/4 per cent.; but in the common course of buineses, 2 almdus of Oporto are reckoned equal to 3 of Libon.

At Pernau, in Livonia, a laft of corn contains 24 tonnes, the laft containing about 863 Winehefter buhles, or 16 lafts = 173 English quarters. But a laft of linseed is reckoned at 12 tonnes, and a laft of salt at 18 tonnes.

At Revel, in Livonia, a laft of corn contains 24 tonnes, and a tone of salt is 4 lofs: 19 tonnes of corn in Revel are = 8 English quarters.

At Riga, a laft of rye contains 22 3/4 tonnes; a laft of wheat or barley, 24 tonnes; a laft of oats, malt, or peafe, 30 tonnes: 24 tonnes being = 48 lofs, and 56 lofs of Riga = 13 English quarters.

At Straulfund, a laft of corn contains 8 dromts = 32 tonnes = 96 fcheffels: 46 fcheffels contain 51 English buhles nearly, or 46 dromts = 76 1/2 English quarters. Kelly's Univ. Cambi. passim.

The great ton or Rhenifh wine-veffel of Heidelberg, made in 1343, contained 672 urnez, of 4 1/4 English gallons each; being in all 2690 English gallons, or about 42 hog-
hheads, or 21 pipes of wine.

Tun is also a certain weight, by which the burden of shps, &c. is effimated.

The tea tun is computed to weigh 2000 lbs., or 20 quins-
tals or hundred weight (amounting to 2440 lbs. avoidupois); so that when we say a vefsel carries 200 tons, we mean it is able to carry 200 times the weight of 2000 lbs., i.e. 400,000 lbs.: it being found by a curious obfervation, that the tea-water, whole room the vefsel fills when full laden, weighs fo much.

To find the burden and capacity of a shp, they measure the hole or place where the load is to be; allowing 42 cubic feet to the tea tun. See Burren, and Tonnage under Shp-building.

The price of freight, or carriage of merchandizes, is ordinarily settled on the foot of the tea tun: and yet, though the tun is regularly 20 cwt., there is some difference made in it, either on account of the cumbermenefes or bulk of the commodities, the space they take up, or the like. See Freight.

Accordingly, at Bourdeaux, 4 barriques of wine, and also
of vinegar, honey, and turpentine, are held a tun; 5 of brandy, 3 of syrup, 20 bushels of chestnuts, and the like of corn, beans, linseed, walnuts, &c.; 5 bales (each of 100 lbs.) of cork, 5 bales (each of 100 lbs.) of feathers and skins, and 8 of paper; 10 cubic feet of marble, 20 quintals of iron in bars, or lead in pigs, 3 bales of hemp (each of 300 lbs.), 20 quintals, or 150 rolls of tobacco.

At Stettin, the freight of ships is generally valued by the Dutch ship laft, 5 of which are equal to 4 lafts of Stettin; and 4000 lbs. of iron, and other heavy goods, 2000 lbs. of lighter goods, such as hemp and flax, 568 sheffes of corn, 13 casks of herrings, 8 hogheads of wine, 5 sheffes (each of 60 pieces) of pipe-flaftes, 7 sheffes of hoghead-flaftes, 9 sheffes of barrel-flaftes, 65 cubic feet of oak-temper, or 70 cubic feet of fir-temper, are reckoned for a Dutch laft.

A tun or load of timber is forty solid feet, if the timber be round; if it be hewed or square, fifty-four.

Tuns, in Natural History, a family of univalves. See SHELLS and CONCHOLOGY.

Tun, Ten, in the ends of words or names of places, signifies a town, village, or dwelling-place: from the Saxons, tun, fetes, vaflum, villa, vicus, oppidum; and this from don, or dan, a hill, where they formerly built towns.

Tun-Greece, a name anciently used for a reeve or bailiff, qui in villis, & que dicimus manerii, domini perfonam suam, cyliqve vicis anna dispersat & moderatam. Spelman.

Tun-Hoef, in Botany. See GLECHOMA.

Tuna, in Botany, slightly altered by Dillenius from the South-American or West-Indian appellation of the same plants, Tunes, Tuna, or Tunas, is retained by him for the tribe of American Figs, named Opuntia by other modern botanists. He contends, with great probability, that Opuntia of the ancients must be something very different. Linnaeus refers Tuna to Cactus; see that article.

Tuna, in Geography, a small island in lake Menzeleh; 8 miles S.E. of Tennis.—Also, a sea-port of Egypt, in the Red Sea. The entrance is between rocks, and within the greater part is filled with shoals and rocks, which make the harbour small. On the north side is a tongue of land, which forms good defence against the north-west wind; 52 miles S.S.E. of Cofier.—Also, a town of Sweden, in Helingland; 3 miles N. of Hudwickwall.—Also, a town of Sweden, in the province of Smaland; 56 miles N. of Calmar.—Also, a town of Norway, on the Glammen; 2 miles N.E. of Frederiksbogladt.—Also, a town of Arabia, in the province of Hedjas; 28 miles E. of Medina.—Also, a small island and village of Egypt, in the Tennis lake; 21 miles W.N.W. of Tinet.—Also, a town of Sweden, in Dalecarlia; 10 miles S. of Falun.

Tunla, a town of Mexico, in New Bifcaf; 74 miles N.N.W. of Durango.

Tunallus, in Ichthyology, a name given by Albertus, and some others, to the grayling, or amber. TUNB, in Geography. See Tunb.

Tunbathe, a town of Brifh, in the government of St. Paul; 65 miles N.N.E. of St. Paul.

Tunbo, a town of Sweden, in Sudermanland; 50 miles W. of Stockholm.

Tunbridge, or Tunbridge, a market-town in the lathe of Aylesford, and county of Kent, England; is situated at the favourite point of the Lowey of Tunbridge, and is distant 13 miles W.S.W. from Maidofone, and 30 miles S.E. from London. The term Lowey is derived from the Norman French, and signifies an exempt jurisdiction round the castle or chief manor to which it appertained. In the Domesday book this dioclet was included under the name of Hallow, but no mention is made of a castle; whence it seems probable it was not erected when that survey was made; though it certainly was very shortly afterwards. It was built by Richard Fitz-Gilbert, afterwards earl of Clare; and under the protection of this fortress the town grew up, and gave its own name to the castle, which name appears to have been derived from the bridges over the different streams of the Medway, which flow on the south side of the town. Of these streams, which have each a bridge, and are five in number, the southernmost was anciently the principal, as the northern now is; though the latter was originally formed to supply the inner moat of the castle. This fortress has been at different periods the scene of war and of festivity. Gilbert Rufus, who possessed it in the reign of Henry III., joining the rebellious barons, was besieged by prince Edward, when the garrison burnt the town to prevent its being useful to that prince, who, however, took the castle: but Gilbert having joined the royal standard, it was restored to him. Here he entertained Edward, then become his sovereign, in a splendid manner for many days, on his return from Palestine. Prince Edward, afterwards Edward II. also made Tunbridge his temporary residence. In the next reign, the castle and manor passed by marriage to Ralph, earl of Stafford, whose descendants were to a rank that eclipsed all other subjects, having five earldoms vested in them, and being at length advanced to ducal honours. In the reign of Henry VIII. the castle became forfeited to the crown by the attainder of Edward, duke of Buckingham. Queen Elizabeth granted the lordship and castle to her cousin Henry Carey, lord Hunsdon, from whom they descended to the Berkleys: having passed through various possessors, they are now the property of the Woodgates of Summerhill. The remains of the castle stand on the south-west side of the town, but are principally confined to an entrance-gateway, flanked by round towers, and tolerably perfect, (probably rebuilt in the 14th century,) and the artificial mound on which the keep stood. The castle was envirioned by three moats, within the outermost of which the ancient town was chiefly confined. At a short distance was a priory of Austin canons, founded by Richard de Clare, first earl of Hertford, about the end of the reign of Henry I. The buildings were all destroyed by fire in 1351; but were soon afterwards rebuilt. This was one of the houses suppressed in 1535, to endow Wolsey's intended colleges at Ipswich and Oxford. From the foundations, yet visible, this priory appears to have been very extensive: but only a few fragments now remain, besides the refectory or hall, which is used as a barn.

The town of Tunbridge principally consists of one long and wide street, kept remarkably clean, and containing many respectable houses. At the entrance from London is a stone caufeway, the gift of John Wilford, citizen of London, in 1528. The principal bridge was erected in 1775, at the expense of 1100l., from a design by Mr. Milne: near it is a wharf for the reception of the timber brought hither from the Weald, and afterwards sent down the Medway. The church, which is a spacious fabric, was new paved and ornamented, with a bequest of 500l. made by the late John Hooper, esq. It contains some good monuments of various families. Weever mentions the portraits of lord Hugh Stafford, kneeling in his coate-armour, and his bow-bearer, "Thomas Bradlaire, by him," as remaining in his time in the north window. Many bequests have been made by different persons for the use of the poor inhabitants of this dioclet; but, the principal charitable foundations are the free grammar-school, a capacious edifice at the north end of the town, which was founded and endowed by Sir Andrew Judde, a native of
of Tunbridge, and lord-mayor of London in the fifth year of Edward VI. He died in 1558; and by his will directed that certain lands, of the annual value of 56l. oz. 4d., and situated in various parishes in London, should be vested in the company of skinner of London, for the perpetual maintenance of this school, for the free education of the boys inhabiting this town and the parts adjacent. Sir Thomas Smith, who married Sir Andrew’s daughter, considerably increased the endowments, and founded fixed Exhibitions to the University; and several others were endowed by different persons. The Skinners’ Company, who are the governors, visit this school every year in May, attended, as the Statutes direct, by some eminent clergyman, who is required to examine into the progress made by the different classes. The examination is conducted with much ceremony; and honorary rewards are distributed to the best scholars. The masters have, in general, been men of eminent abilities. The learned Dr. Vicimins Knox, well known for his literary productions, succeeded his father in this office in 1778. Though the annual income arising from the respective endowments of this school is very great, the number of boys educated on the foundation is very few: which, among other instances, points out the necessity of a parliamentary revision of our ancient charitable Establishments. Immediately opposite the school is the seat of George Children, esq. to whose respectable family a very large and valuable tract of land belongs in this vicinity. The population of Tunbridge, as ascertained by the act of the year 1811, amounted to 9522, the number of houses to 958. Four fairs are held annually, and a market weekly on Friday. The adjacent roads have of late years been much improved, and that leading from the town to the Wells particularly so, by a laborious excavation on Quarry-Hill, by which the former steep ascent over it has been reduced to a very easy draught. It appears, from the “Notitia Parliamentaria,” that two members were returned in the 23d year of Edward I. for the borough of Tinebrig.

About a mile and a half to the south-east of Tunbridge is Summerhill, an ancient and celebrated seat, now the property of William Woodgate, esq. The venerable mansion was erected by Richard de Burgh, earl of St. Albans, at a vast expense, in the reign of James I.; of the style of building in whose days it forms a complete specimen; though its external appearance has, in some respects, been injured by injudicious alterations. It is a very extensive and interesting structure, and stands on a commanding eminence amidst romantic scenery.

On Quarry-Hill, about a mile and a half from Tunbridge, on the road to the Wells, is the seat of James Burton, esq. recently erected with the appropriate materials of the country, as the fragment of a castle, but replete with modern conveniences.

Within a mile, on the same road, is Bounds Park and House, now the property of the earl of Darley. The demesne surrounds the park, and consists of about a thousand acres of well-wooded land.—Hallé’s History of Kent, vol. ii. Beauties of England and Wales, vol. viii. Kent; by E. W. Brayley.

Tunbridge-Wells, a hamlet in the west half hundred of Wadhington, lathe of Aylesford, and county of Kent, England; consists of several villages within five or six miles from the town of Tunbridge, and situated in the three parishes of Tunbridge, Frant, and Speldhurst, at the distance of 18 miles S.W. from Maidstone, and 35 miles S.E. by S. from London. The principal villages are, Mount-Ephraim, Mount-Pleasant, Mount-Sion, and the Wells, properly so called. The springs, to which this neighborhood is wholly indebted for its origin, rise in the parish of Speldhurst, and were accidentally discovered in the reign of James I. (See Tunbridge Waters.) Their falluous quality being soon ascertained, wells were sunk, paved with stone, and inclosed with rails in a triangular form. Hitherto came the afflicted, and returned healthy: but as no accommodations were nearer than the town of Tunbridge, the number was few. Henrietta Maria, queen of Charles I., being much indisposed after the birth of prince Charles, flaid here six weeks; but no house was near, and the her suite remained under tents pitched upon Bishop’s-Down. The splendid court formed a fine contrast to the country, every where rude, and in the unadorned attire of nature. In honour of her majesty, the Wells changed their name from Frank to that of Queen Mary’s Wells, which afterwards gave place to Tunbridge-Wells. During the civil war the Wells were neglected, and almost forgotten; but at the Restoration, recovered their former fame. Their celebrity was greatly increased in 1664, by queen Catherine being recommended to drink the waters after a dangerous illness. She continued here about two months, in great splendour: hence may be dated an assembly-room, bowling-green, and other appropriate places, at Rutfhall; and another bowling-green and a coffee-house at Southborough. The surrounding country was spotted with neat rural habitations; till then, and fome alteration between the lord of the manor and the tenants, varied the scene. Rutfhall was now deserted for Mount-Ephraim, and that for Southborough, which was soon eclipsed by Mount-Sion. At this changeable era, many of the houses were wavelo on sledge from one into another, as the caprice or interest of the owners dictated. The town of Tunbridge was now left to its original quiet; for the Wells became a complete village, with houses sufficient to accommodate all the visitors. A chapel and school were erected by subscription, and the former being found too small for the increasing congregation, was enlarged a few years afterwards. This chapel stands in the three parishes; the pulpit is in Speldhurst, the altar in Tunbridge, and the vestry in Frank. A Presbyterian and also a Methodist meeting-house have been since built. During the last century, the buildings have gradually increased; and many persons of rank and respectability have houses for constant or occasional residence. Trade is carried on similar to that of the Spa in Germany, and consists chiefly in the manufacture of a variety of articles in wood of various kinds: the goods are well known by the name of Tunbridge-ware, as tea-cheats, dressing-boxes, snuff-boxes, punch-ladles, children’s toys, and many other articles. The air of this district is very pure and falluous, and probably aids the efficacy of the waters, which are of the chalybeate kind, and nearly of equal strength to those of the German Spa. They are considered to be of great use in removing complaints arising from febrile occupations, weak digestion, and nervous and chronic disorders. During the last and present reigns, Tunbridge-Wells has been frequently visited by different branches of the royal family. The Wells, properly so called, form the centre of the place; near which are the markets, the medicinal water, chapel, assembly-rooms, and public parades, called the Upper and Lower Walks; the Upper Walk was formerly paved with brick, but in 1793 has a Purbeck stone, at an expense of 71c.l.; the other is unpaved, and used chiefly by country people and servants. On the right of the paved walk, in the way from the Wells, are the assembly-room, library, coffee-house, and post-office, with shops for Tunbridge-ware, millinery, and different kinds of toys. A portico extends the whole length of the parade, supported by Tuscan pillars, where the company occasionally
occasionally walk. On Mount-Sion, Mount-Pleasant, Mount-Ephraim, and Bishop's-Down, are dispersed some neat villas. That of the late celebrated writer, Richard Cumberland, esq., is on Mount-Sion, and was his retreat for many years.

The High Rocks, about a mile and a half south-westward from the Wells, are much celebrated, and certainly form a very romantic and striking picture. This spot is said to have been first brought into notice by James II., who, when duke of York, came hither with his duchesses and his two daughters, afterwards the queens Mary and Anne.—Burr's History of Tunbridge-Wells, 8vo. 1766. Beauties of England and Wales, vol. viii. Kent; by E. W. Brayley.

Tunbridge, a township of Vermont, in the county of Orange, containing 1640 inhabitants; 20 miles N.N.W. of Hanover.

TUNE, the title of a short melody, or series of notes, in some specific measure. If vocal, it is a ballad; if merely instrumental, it is a country-dance, a jig, or a hornpipe. Our parochial psalmody consists of psalm tunes. The music of the "Beggar's Opera" is a medley of tunes selected from the streets of all nations, that are never honoured with the name of airs. See Ballad.

Scotch, Irish, and Welsh fongs and dances, are called national tunes. The tonadillas and fiquedillas of Spain are likewise national tunes; as are the elegant little street-fongs of Venice, called Venetian ballads; and such are the pleasing and popular Provençal and Languedocian melodies, very different from the Vaucluse and ballad tunes of the Pont-neuf and streets of Paris.

Thus far concerns tune as a subjunctive: as a verb, to tune, is a preparation for the performance of music. A found may be sweet, clear, and very perfect in itself, yet agree with one of its relatives on any instrument, or in any key: it is then said to be out of tune. The regulator of all founds in a musical composition is the key-note of a diatonic scale, in which every found must be in tune with all the intervals.

"Tune your harps to cheerful strains," that is, render your harps fit for tune or fong. This belongs to intonation, found, musical tunes. Intonazioni perfide, in Italian, is an expression for false intonation, out of tune, in singing or playing. So in French, intonation vraie, intonation fausse, are musical expressions for true or false intonation. Entoneur, in Romish cathedrals, is to give the tone of an anthem, a hymn, with the organ; and in our cathedrals, of the refpondes.

Our great lexicographer, though no musician himself, has defined the expression, to tune, with true technical accuracy, in saying that it is "to put instruments into such a state, as that the proper founds may be produced." Dr. Holder well defines the word tunable, when he says, "all tunable founds, of which the human voice is one, are made by a regular vibration of the fonsorous body, and undulation of the air, proportional to the acuteness or gravity of the tone."

Causa and Measure of Tone, or that on which a Tone of a Sound depends.—Sonorous bodies, we find, differ in tone:

1. According to the different kinds of matter; thus the found of a piece of gold is much graver, than that of a piece of silver of the same shape and dimensions; in which case, the tones are proportional to the specific gravities.

2. According to the different quantities of the same matter in bodies of the same figure; as a solid sphere of brafs, one foot in diameter, founds acuter than a sphere of brafs two feet in diameter; in which case the tones are proportional to the quantities of matter. See Gravity.

Here then are different tones connected with different specific gravities, and different quantities of matter: yet cannot the different degrees of tone be referred to those quantities, &c. as the immediate cause. In effect, the measures of tone are only to be found in the relations of the motions that are the cause of found, which are no where so discernible as in the vibrations of chords.

Sounds, we know, are produced in chords by their vibratory motions; not, indeed, by those sensible vibrations of the whole chord, but by the sensible ones, which are influenced by the sensible, and, in all probability, are proportional to them. So that founds may be as truly measured in the latter, as they could be in the former, did they fall under our lenses: but even the sensible vibrations are too small and quick to be immediately measured. The only resource we have, is to find what proportion they have with some other thing: which is effected by the different tensions, or thickners, or lengths of chords, which, in all other respects, excepting some of those mentioned, are the same.

Now, in the general, we find that in two chords, all things being equal, excepting the tension, or the thickners, or the length, the tones are different; there must, therefore, be a difference in the vibrations owing to those different tensions, &c. which difference could only be in the velocity of the courfes and recourfes of the chords, through the spaces in which they move to and from again. Now, upon examining the proportion between that velocity, and the things just mentioned, on which it depends, it is found to be a demonstration, that all the vibrations of the same chords are performed in equal times.

Hence, as the tone of a found depends on the nature of those vibrations, whose differences we can conceive no other than as having different velocities; and as the small vibrations of the same chord are all performed in equal time; and as it is found true in the fact, that the found of any body arising from one individual stroke, though it grows gradually weaker, yet continues in the same tone from first to last; it follows that the tone is necessarily connected with a certain quantity of time in making every single vibration; or that a certain number of vibrations, accomplished in a given time, constitutes a certain and determinate tone: for the frequenter those vibrations are, the more acute is the tone; and the flower and fewer they are in the same space of time, by so much the more grave is the tone; so that any given note of a tone is made by one certain measure of velocity or vibration, i.e. such a certain number of courfes and recourfes of a chord or string, in such a certain space of time, constitutes a determinate tone. See Sound.

This theory is strongly supported by our best and laziest writers on music, Dr. Holder, Mr. Malcolm, &c. both from reason and experience. Dr. Wallis, who owns it very reasonable, adds, that it is evident the degrees of acuteness are reciprocally as the lengths of the chords; though, he says, he will not positively affirm, that the degrees of acuteness answer the number of vibrations, as their only true cause: but his difference arises hence, that he doubts whether the thing has been sufficiently confirmed by experiment. Indeed, whether the different number of vibrations in a given time be the true cause, on the part of the object, of our perceiving a difference of tone, is a thing which we conceive does not come within the reach of experiment; it is sufficient the hypothesis is reasonable.

Tune by Water. To. See Lasus, Hyppasus, and Water.

Tuneke, in Geography, a town of Russia, in the government of Irkutsk, on the Ilim; 84 miles N. of Bala-ganskoii.
TUNES, in Ancient Geography, a town of Africa, mostly on a hill, to the W., and on the border of the port named Stagnum by Procopius, situated S.E. of Carthage, and surrounded by lakes and marshes. See TUNIS.

TUNG, in Natural History, the name given by the Indians to a little insect, called by the Spaniards pique, which is very common and very troublesome in some parts of the East and West Indies.

It is of the size of a small flea; its place of laying its eggs is within the skin of the human body, and it diligently searches opportunities of doing this, and often succeeds in the attempt, to the great pain and trouble of the person who suffers it.

The creature, knowing that it shall be soon crushed to death under the skin, generally makes its way either under the nails, or where there is some callus on the surface; there it eats its way along, and, in fine, lays its eggs, which hatch into so many young ones, and spread themselves between the flesh and skin all over the finger and hand, if not prevented by taking out the old one in time.

The person often does not perceive the creature's getting in, it enters so gradually and easily; but he is soon advertised of the place where it is by a violent gnawing pain, the creature really eating its way as it goes along. The only remedy in this case, is to enlarge the orifice at which it entered, and take it out whole; the wound soon heals up, and there is an end of the matter. This may often be done with the point of a needle; but if not, it is much better to submit to the opening it with a lancet than to the ill confquences which otherwise will attend it. Obcrv. fur les Coutumes de l'Afie, p. 184.

TUNGA, in Geography, a town of Africa, in the kingdom of Tunis.

TUNEBADRA, a river of Hindoostan, which runs into the Kilkiah, 7 miles E. of Rachore, in the country of Golconda.

TUNGERSHEIM, a town of the duchy of Wurzburg, on the Maine; 9 miles N. of Wurzburg.

TUNGINSKOI, a town of Ruffia, on the Irkut; 80 miles S.W. of Irkutsk. N. lat. 57° 18'. E. long. 103° 14'.

TUNGONG, a town of Meckley; 16 miles S.E. of Munypour.

TUNGRI, or Tongres, in Ancient Geography, the name of a people who, according to Tacitus, succeeded that of German, by which were designated the first people who from the other side of the Rhine had abandoned their territory to the Gauls. But according to other authors, the Tongres inhabited the country of Ligue for a long time before the entrance of the Romans into the Gauls. Conquerors of the Eburons, they succeeded them, so that they were entirely forgotten. Their conquests were very extensive; and though they were subjugated by the Franks, and Attila, commanding the Huns, completed their extermination, yet their bishops long after retained their title.

TUNGSTEIN, in Mineralogy; Scheelica calcis, Hauy. The name tungsten, denoting heavy stone, was given to this mineral on account of its great specific gravity. Its appearance is not metallic, it has a yellowish or greyish-white colour, and is more or less translucent. The structure is lamellar; it is infusible by the blowpipe, but becomes opaque. When powdered and digested with nitric acid, it communicates to it a yellow colour. These properties distinguish it from carbonates of lead, white tin-flint, and barytes. Tungsten occurs both massive and crystallized; the form of the crystals is most frequently the octahedron. The primitive form of the crystal, according to Hauy, is an acute octahedron, having the angle at the summit 62° 24', and the angle formed by the junction of the planes at the base of each pyramid 113° 36'. The principal planes of the crystals are smooth, the luster pendent. Tungsten yields to the knife, and is brittle; its specific gravity varies from 6.800 to 10.015. This mineral occurs with wolfram, (see Wolfram,) tin-flone, magnetic iron-flone, and brown iron-flone; it sometimes forms large or small granular diffused concretions with streaked and shining surfaces. It is found in the mines of Cornwall, Sweden, Bohemia, and Saxony. Its constituent parts are,

- Acid of tungsten - 75.25
- Lime - - 18.70
- Silex - - 1.60
- Oxyd of iron - - 1.25
- Oxyd of manganese - - 0.75

TUNGSTEN, in Chemistry, is the metal obtained from the ore of the same name above described. By some of the German chemists it is denominated Scheelium, from Scheele, who first pointed out the peculiar nature of one of its oxyds. Tungsten was first obtained in the metallic state by the Meffrs. D'Elhuyart from another of its ores called wolfram. New experiments have been since repeated by Vauquier, Klaper, Meffrs. Allen and Aikin, and others, with various success, and very lately they have been confirmed by Bucholz.

This metal has been obtained by exposing the tungstate of ammonia to a violent heat. It has never been procured in the state of a solid button, or in large panes, but only in small panes as fine as sand, having a strong metallic lustre, a light iron-grey colour, and slightly agglutinated. It is one of the hardest of the metals, and very brittle. Its fp. gr. according to the D'Elhuyarts, is 17.6; according to Meffrs. Allen and Aikin, 17.2; and according to the late experiments of Bucholz, 17.4, which is about the mean of the others, and probably very near the truth. Hence, next to gold and platinum, it is one of the heaviest metals.

This metal requires a heat of at least 170° of Wedgwood (probably much higher) to melt it. It is not attracted by the magnet. Exposed to heat in an open vessel, it gradually absorbs oxygen, and is converted into an oxyd. Two oxyds of this metal were formerly known, viz. the dark brown or black, and the yellow or tungstic acid; but besides these, Bucholz has lately described another of a dark brownish-red or reddish-brown colour, and which he considers to be intermediate to the other two. Of these, the best brown and most important is the yellow oxyd, or tungstic acid. This oxyd is without taste. It is insoluble in water, but remains long suspended in it. It has no active or vegetable colours. It is stated to be composed of

| Tungsten | - | 80 |
| Oxygen | - | 20 |
| Total | - | 100 |

Little is known of the nature and composition of the other oxyds of this metal, so that we cannot with any degree of certainty ascertain the weight of its atom. This metal combines with sulphur and phosphorus, and forms alloys with many of the metals; but these compounds do not appear to be interesting. The yellow oxyd, or tungstic acid, seems capable of forming compounds with all the alkaline, earthy, and metallic bases, though very little is known at present of the nature of these compounds.

TUNGURAGUA, in Geography, a mountain of Peru; 21 miles S. of Riohamba.

Tunguragua. See Maranon.

TUN-
TUNGUSES, a branch or division of the Mandchures, or Mandhu, who originally composed one people with them, as appears not only from their mutual resemblance in features, manners, and customs, but chiefly from their agreement in language. The Tungufes call themselves Ozyes, probably from the usurped founder of their race; or, like most of the Siberian tribes, from the word which in their language signifies men. They are called Tungufes only by the Oltiaks of the YeniSef and the Tartars: By the Mandhu, they are denominated Bolomi, protectors, or Orontfebhen, people with reindeer. The extensive defects in which they now nodizade, reach from W. to E. from the YeniSef across the Lena, as far as the Amoor and the Eastern ocean. From S. to N. they keep between about the 53rd and 65th degree of N. lat., and accordingly touch neither upon the Songarian borders, nor upon the coasts of the Frozen ocean. Being of an accommodating disposition, they have admetted into their seats Oltiaks, Samoyedes, and particularly Yakutans. The districts now mentioned lie mostly in the government of Irkutsk; nevertheless, some few races of the Tungufes are reckoned as belonging to the government of Tobolfs. The first accounts which the Russians obtained of these people were received from the Oltiaks of the YeniSef; and in the year 1697, Cossacks were first sent from Mangafey against the Tungufes, to force them into submision. On occasion of these Russian attacks, the Tungufes displayed a greater degree of courage than the other Siberians; nor were they brought to the imperfect state of submision in which they are now held, till the latter half of the last century. By the enumeration of the year 1766, they consisted of 12,000 males; but besides these, distinct Tungufian flems wandel among the Siberian nations, who together amount to about 1500 yoorts, or families. Although they constitute one of the most numerous nations of Siberia, yet, on account of their roaming mode of life, few flems of them can be actually registered. The Tungufes who nomadise about the coasts of the Eastern ocean, are known under the name of "La mutants." Of these, in the forementioned year, only about 400 men were enrolled to the payment of tribute.

The Tungufes are indefatigable in the chase, and are constantly changing their habitation. In the feasons of fishing and of collecting berries, they remain for some time nearly stationary; and then they remove their tents, leaving their supplies of dried fish and berries in large boxes, constricted on trees or poles, for the benefit of themselves and their tribes, in travelling during the winter. They seem callous to the effects of heat or cold; their tents are covered with samoy, or the inner bark of the birch, which they render as pliable as leather, by rolling it up, and keeping it for some time in the flame of boiling water and smoke. Their winter dress is the skin of the deer, or wild sheep, drested with the hair on it; a breast-piece of the same, which ties round the neck, and reaches down to the waist, widening towards the bottom, and neatly ornamented with embroidery and beads; pantoflions of the same materials, which also furnish them with short fockings, and boots of the legs of reindeer, with the hair outward; a fur cap and gowes. Their summer dress only differs in being simple leather without the hair. They are religious observers of their word, punctual and exact in traffic; some few are chirstianised, but most of them are Demonolatists, have their forreces, and sacrifice chiefly to evil spirits. They commonly hunt with the bow and arrow, but some have rifle-barrelled guns. Instead of burying the dead, they place the body, drested in its belt apparel, in a strong box, and suspend it between two trees. The implements of the chase belonging to the deceased are buried under the box. Except a forrecer is very near, no ceremony is observed; but in his presence they kill a doe, offer a part to the demons, and eat the rest. They allow polygamy, but the first wife is the chief, and is attended by the rest. The ceremony of marriage is a simple purfachne from her father; and the price is from 20 to 100 deer, or the bridel-groom works during a stated time for the benefit of the bride's father. The unmarried are not remarkable for chastity. A man will give his daughter for a time to any friend or traveller to whom he is attached; if he has no daughter, he will give his servent, but not his wives. They are in fine somewhat below the common nature, very active, and have lively inviting countenances, with small eyes; and both sexes are very fond of brandy. The Tungufes wander about the mountains, and seldom visit such plains as are occupied by Yakuts; but frequently resort to the solitary habitations of the Cossacks, appointed to the different flages; as they are there generally supplied with brandy, needles, thread, and such tri tes as are requisite among them and their women, who always accompany them in their wanderings. See MANDSHURES.

TUNGUSKA, a river of Russia, which rises in lake Baikal, and runs into the Enifei, about 20 miles S. of Enifei. In the former part of its course it is called Angara, in the latter Tunguska or YeniSef.

This Upper Tunguska, for there are three rivers of the same name, which bears the name of Angara till it unites with the Ilim, takes up several other rivers, as the Koda, the Tfhaveltech, the Iriki, the Kamenga, the Olenka, and the Tataritkaia, all on the right; and to the left, the Oka, and the Tihana or Uda. This Tunguska has for the most part a bed strewed with rocks, and forms several cataracts, five of which are very confiderable. Although it be navigable, the navigation is toilome and difcult. The Middle or Podkamnenaia Tunguska rises in the government of Irkutsk, among the Baikal mountains, not far from the origin of the Lena; and after a course of about 800 verits, and after having, on the right, taken up the Thiuacha and the Thorna, falls into the YeniSef in 62° N. lat. The Lower or Nimvei Tunguska takes its source in the fame diftrict, but bends its course northward, and after having taken up on the left the rivers Niepa, Svetiaia, with many others, and on the right the Rofmakaia, the Turiga, and the Gorela, and running a course of about 1500 verits, strikes into the YeniSef, not far from Turukansk. In this river are several dangerous whirlpools.

TUNGUSKOI, Ust, a town of Russia, in the government of Tobolfs; 24 miles S. of Enifei, at the conflux of the Enifei and Tunguska.

TUNGUSLI, a town of Russia, in the government of Tobolfs, on the Ob; 56 miles S. of Tara.

TUNIA, or TUNJA, a town of South America, in the vicerealty of New Granada; 60 miles N. of Santa Fe de Bogota. Tunia, founded in 1539, was formerly an opulent town, but has now declined, the inhabitants not exceeding 200. The edifices retain marks of former splendour, and the parish-church might well ferve for a cathedral. Here are three convents, that might answer the purpose of manufactories. N. lat. 5° 5'. W. long. 72° 56'.

Tunic, in Botany and Vegetable Physiology, the E. diff name of the appendage to certain feeds, termed Anillus in Latin; see that article, where, however, the explanation given by our predecessor, Dr. Woodville, refers only to the use of the term Arillus in the genus Carex. The Tunic, or Arillus, is attached to the bafe only of the feed, immediately adjoining to the Scar, Hilm, and envelopes the fett of the feed more or lefs completely and closely. Its fize and texture, as well as colour, are various. In the Spindle-tree,
tree, Euonymus, the part in question is a pulpy, wrinkled, orange-coloured wrapper; in Ascleia a beautiful, firm, close, fearect cup, embracing great part of the lower half of the black hard seed; in Hippophae a double membraneous, but tough, coat, within the pulp of the berry; in Myristica, the Nutmeg, a jagged, brittle, highly aromatic, complex integument, well known by the name of Mace. Narthecium, and great part of the Orchis, have each of their minute seeds clothed in a lax membraneous Tunic, extending beyond them at each end, and probably designed to give them buoyancy, like a sort of wing. Oxalis has an elastic pouch-like Tunic, serving to project its polisher feeds to a distance, like the hard rigid bivalve Tunic of Dictamnus, Boronia, and their allies. (See Rutaceae.) That curious genus named by M. König, in Ann. of Bot. v. 2. 360, Bignonia, the Ake of Guinea in the West Indies, has each seed supported by a large, fleathy, lobed Tunic, for which alone, as a delicate article of food, the tree is cultivated. Some difficulty occasionally arises in differentiating between a real Arillus and the Tela of certain seeds, or at least the outer coat of the latter. (See Testa.) This difficulty occurs in the order of Alserio-folia; witness Cynoglossum; while the real capsules of Gramium, Pelargonium, Malva, etc., have, on the other hand, been sometimes called Arilli.

TUNIC, a kind of waistcoat, or under garment, worn by the ancients, both at Rome and in the East.

The common people ordinarily wore only a tunic; but those of better fashion wore a toga or gown over it. The philosophers wore a gown without a tunic, as professing to go half naked.

The tunica was peculiar to the men; the under garment of the women not being called tunicas, but flosa.

The senators wore their tunicae enriched with several little pieces of purple, cut in form of large nails; whence it was called laticlavia: the knights had less nails on their tunica, which was hence called angusticlavia: the common people wore their tunicae without any clavi at all. And it was by these three different sorts of tunicae, that the three different orders of the Roman people were distinguished in habit.

It has been a common opinion, that the angusticlavia distinguished the knights from the common people, in the same manner as the laticlavia did the senators from those of the equestrian rank. But Rubenius avers that there was no manner of difference between the tunics of the knights and those of the commons. As to the persons who had the honour of wearing the laticlavia, it may be maintained, says Kennet (Ant. of Rome, p. 308.), that the sons of those senators who were patricians had the privilege of using this vest in their childhood, together with the praetexta. But the sons of such senators as were not patricians, did not put on the laticlavia till they applied themselves to the service of the commonwealth, and to hearing offices. Yet Augustus changed this custom, and gave the sons of any senators leave to assume the laticlavia presently after the time of their putting on the toga virilis, though they were not yet capable of honours. And by the particular favour of the emperors, the same privilege was allowed to the more splendid families of the knights.

In the declension of the empire, the tunics did not only reach down to the ankles, whence they were called talares, but had sleeves too coming down to the hands, whence they were called chromoteta. And now it was counted as scandalous to appear without sleeves, as it had been hitherto to be seen in them; and, therefore, in the writers of that age, we commonly find the accursed perfons at a trial habited in a tunic without sleeves, as a mark of disgrace and infamy.

Besides the different sorts of tunicae above-mentioned, there was also the tunica palmata, worn by generals in a triumph, and perhaps always under the toga picta. It hath its name either from the great breadth of the clavi, equal to the palm of the hand, or else from the figures of palms embroidered on it.

Among religious, the woollen shirts, or under garments, are styled tunices, or tuniques.

TUNICA, in Anatomy, a technical name applied to the membranes which compose various organs; thus the serous and mucous membranes, and the muscular ftratum of the stomach or intestines, are called their tunicae: in the same way we have the tunics or coats of the eye, the blood-vessels, the telces, &c. &c.

TUNICA, in Botany, a name adopted by Dillenius, as he himself avows, from the apothecaries, and perhaps originally corrupted by them from Petonica, or Betonica, its synonyms. These names all belong to the Floe Caryophyllus, Clove-flower, Carnation, or Pink; and Dillenius was led to the above choice, for the purpose of removing the ambiguity arising from Caryophyllus; (see that article,) as properly belonging to the valuable spice called Cloves. Limnæus, not satisfied with either appellation, invented a new one, which has been generally approved. See Dranthis.

TUNICATED ROOTS, among Botanists, such as are formed of a multitude of coats surrounding one another. See Root.

TUNIOK, in Geography, a town of Hungary, on the river Samos; 6 miles E. of Etef.

TUNIS, a city of Africa, and capital of the country so called, situated on a rising ground, on the west bank of a lake, or rather a shallow in form of a lake, communicating with the gulf by a narrow channel. The situation of Tunis, probably first chosen by some fishermen, to whom that of almost all the maritime cities is to be ascribed, appeared to the inhabitants to be preferable to that of Carthage; as soon as, enriched by rapine, they dared openly to attack the trade of every nation. The eminence on which the ruins of Carthage, N.E. of Tunis, that ancient rival of Rome, advances into the middle of the gulf, and on that account would have exposed the Tunifiants to be taken by surprize. This city was called, by Diodorus Siculus, "Léuckon Tunéta," that is, White Tunis; perhaps from the chalky cliffs which it round, when viewed from the sea; and was founded about 1250 or 1300 years B.C., as appears from Herodotus and the Parian chronicle. It is surrounded by lakes and marshes, which, however, do not render it unhealthy, which is, by Dr. Shaw, attributed to the number of myrtaceous and myrtle trees, roemaries, and other gymnos and aromatic plants, with which they heat their ovens and their baths; the water is obtained a mile distant, for the general use of the inhabitants. The infected atmosphere of Tunis is attributed by baron de Tott to the putrid emanations of a channel, which conveys all the filth of the city to a neighbouring lake; which lake likewise produces exhalations that appear no less dangerous; and the sultrubt of Tunis, he says, can only be attributed to the depth of the valley, which comes down to the gulf, and which, by attracting the vapours of the channel and the lake, does not allow them to acquire that degree of corruption which would render them hurtful to the constitution of the inhabitants. The Tunifiants are the most civilized nation of Barbary, with little of the insolent haughtiness of the Algerines; and affairs with the government are transacted with ease: the English, French; Dutch, and several European states, having confids here, who are treated with civility and respect. Including the suburbs, Tunis is, by Dr. Shaw, supposed

Vol. XXXVI.
TUNIS.

Tunis, the central region of Northern Africa, usually dignified with the title of kingdom; bounded on the north and east by the Mediterranean, on the south by Tripoli, and on the west by Algiers. This is the western part of the proper Africa of antiquity, and was formerly the chief seat of Carthaginian power; and in the middle ages, Tripoli was subject to Tunis, which was seized by Barbarossa in 1533.

It is now about 200 miles from north to south, and 120 from east to west. According to Desfontaines, this kingdom begins in the east at the isle of Garbi, and terminates in the west at the river Zaine, called also Tufca or Suftca. After the decline of the Roman empire, this country came under the power of the Vandals and Goths; and after them, under the Saracens, when they were governed by viceroyts, called emirs. It afterwards became subject to the emperor of Morocco. For a space of time it was an independent and powerful kingdom. In the year 1538, it was over-run by Barbarossa; and notwithstanding the endeavours of Charles V. and his successors, the kingdom was made a province of the Ottoman empire, under the dominion of Selim II., by Sinan, bahawf of the Levant. At present the whole kingdom is divided into two circuits, the summer and the winter, which the bey makes in perfon through his dominions at those two seafons. The summer circuit, or northern district, is by far the most pleasant, fertile, and populous, and has the greatest number of cities, villages, and downs, and carries the fairest appearance of plenty, prosperity, and cheerfulness of the two; advantages owing to the mildness of its government, and its being free from tyranny and oppression than that of Algiers. The Tunifians, in general, are like the Algerines; a mixture of Turks, Moors, Kabibs or indigenous inhabitants of the mountains, Arabs, Jews, and Chrifitian merchants, and slaves; with this difference, that they are here polite and civilized. They are much more kind and humane to their slaves, in general; though they treat the knights of Malta with greater severity. In other repects, the Tunifians are courteous to strangers; and all affairs, with the regency are transacted in a very friendly manner: the confines that reft here are treated with greater affability and condescension, justice, and dispatch, than in any other court on the African coasts: in a word, this nation hath, for many years, been more intent upon trade, and the improvement of their manufactures, than upon plundering and cruising; upon which account, it hath cultivated the alliance of many Chrifitian powers. The dress of the Tunifians, of both sexes, is much of the fame fashion with that of the Algerines. The women are handsomely neat, and more familiar: they go, indeed, veiled out of doors, but are allowed to be seen and converse with strangers, their husbands not being tainted with such jealousy as reigns among other Africans. The religion is the same as that of the Algerines. This kingdom, as well as Algiers, and others along the Barbary coast, are very subject to earthquakes, which commonly happen after heavy rains, at the end of the summer, or in autumn, and are often felt at a great distance from land, where the depth of water hath been above 200 fathoms; in other respects, the country is, for the most part, as healthy and fertile as any under the same climate. The northern parts, which are the best cultivated, enjoy a wholesome temperature. The southern part is sandy, barren, and parched by a burning fun; that near the sea is rich in olive-trees, and presents a great number of cities and populous villages. But the western part abounds with mountains and hills, and is watered by numerous rivulets; its environs being extremely fertile, and producing the finest and most abundant crops. The soil is in general impregnated with marine salt and nitre, and springs of fresh water are more rare than salt. The chief river is the Mejerda, or ancient Bagrada, which in summer is not navigable. The chain of Atlas feems here to terminate in Cape Bon, being called the mountains of Megala, Uzelette, &c. The winds are mostly from the sea, confequently refreshing; but those that blow from the southern sandy deserts are quite suffocating, especially as they prevail mostly in July and Auguft: if they continue five or six days incessively, the inhabitants are obliged to keep themselves cool by sprinkling their floors with water. The sea-winds, that blow west-north-west and north, bring dry weather in summer, and rain in winter; but the easterly, as well as the footherly, are for the most part dry, though attended with a thick cloudgy atmosphere in most fefons. Their first rains commonly fall in September, and sometimes in October; about three weeks after which, the Arabs break the ground, sow their corn, and plant their beans, barley, lentils, and garvances; their harvest usually begins in May, or the beginning of June, according to the quality of the preceding fefon. The Tunifians are much more addicted to agriculture than their neighbours, the Algerines, and are for making the most of every inch of their ground. Mines of metal and minerals they disregarde; though Dr. Shaw oberved, among the mineral productions of Tunis, alabaster, cryftal, boles, plumbage, iron, and lead. The cattle are small and slender, and the hofes have degenerated. Here are lions, panthers, hyenas, chakals, and other ferous animals. The manufactures are velvets, tilks, linen, and red caps worn by the common people. The government of Tunis is perfect, like that of Algiers, is altogether despotic; but with this difference, that there it is elective, and here not only hereditary, but the bey hath power to name which of his sons he pleafes for his fucceffor, without regard to elderfhip; or, in cafe he doth not think him worthy, he may appoint a brother, or a nephew, to the fucceffion; in all other cafes, likewife, they are equally abfolute and independent, either on the Porte, or the Douwan or Divan. They were once, indeed, under the protection of the former; and the rapacious extortion and tyranny of its bahawfs had, in some measure, obliged them to shake off their yoke, and form a government of their own, which they settled in such a manner, that their days, as they were then called, could do nothing without the advice and consent of the Douwan or Divan; but they have found means, in time, to rid themselves of this uneasy efg alo, though
they still retain a kind of form or shadow of both. The
Porte hath a balhaw refiding here, but in power and influence
he is a mere cypher, and serves only to remind the Tunisians,
that they were once subject to the Turkish sultans. The
Dowwan, being chiefly composed of friends and creatures
of the boys, is rather assembled to give a forced approbation
to their revolutions, than to consult them about the justice
or expediency of them. At the first fetting of this new
form of government, the deyship was the supreme dignity,
as it is still at Algiers; as that of bey was the next in rank,
but wholly subordinate to it. However, having since built
their power upon the ruins of the deys, they have, by de-
grees, raised the beyship to be despotic and independent;
and by making it hereditary, have prevented, in a great
measure, those frequent depilations, rebellions, and mas-
facres, which are the almost constant concomitants of the
regal authority, wherever it is made elective. Yet far from
preventing jealousies, cabals, and rebellions, in spite of all
their precautions, the dignity oftener falls to the share of
that son who has been able, by his address, to form the
strongest party, than to him who has been appointed to it
by the father. Hence it is, that whenever the throne be-
comes vacant, whether in the course of nature, or by open
treason and rebellion, it is seldom filled up again without
a great deal of bloodshed, rapine, and violence, in proportion
to the number of competitors. In the summer the bay of
Tunis resides in the northern part, and in the winter retire
s to the south, where is a lake of considerable extent, the
"Palus Tritonis" of antiquity. The authority of the bay
extends over a large tract of country, of which he receives the
tribute, with a small army, which marches out annually for
that purpose. Tunis, which had formerly a considerable
commerce with France, exports thither corn, oil, beans,
linens, wax, wool, hides, and Morocco skins; and receives,
in exchange, Spanish wool, Languedoc cloths, vermilion,
fugar, pepper, cloves, wine, brandy, paper, hardware,
iron, and steel. The Italian trade is wholly carried on by
the Jews, who send the same commodities to France, and
import from thence Spanish cloths, damasks, several parts
of silk and woollen stuffs, gold and silver tissued. The
French pay 3 per cent. for all the goods they bring from
France, and the Jews 10 per cent. on their imports from
Italy. The Turks and Moors export to the Levant
woollen stuffs, lead, gold-dust, and chequins, and a vast
number of bales of caps; and bring, in return, silks, calicoes,
iron, alum, and vermilion. They send much of the same
kind of commodities into Egypt; but the oil that is
considered thither must be put up in jars, and not in caisso,
because the greatest part of it is designed for the lamps of
Megaza and Medina; and the Arabians would think it pol-
luted, as the vessels might formerly have contained wine.
They import, in exchange, from thence, linen, cotton, rice,
flax, and coffee. The number of French ships freighted
at Tunis, by Turks, Moors, and Jews, has amounted yearly
to one hundred and fifty to the Levant, and fifty for France
and Italy; as for those of the English, their number is un-
certain. All public conventions and instruments are written
in the Arabic tongue, but the public commerce is com-
monly carried on by the medium of the Lingua Franca.
Gadames, or Galama (which see), had formerly a flourishing
commerce; but it has ceased since the caravans passing
from Tripoli to Tombuctoo do not stop there, but at
Agadez. The caravans of Tombuctoo bring slaves, ostrich
feathers, ivory, and amber; those of Sallies, gold, as well
as those of Gadames, which also bring Negro slaves. Ruins
of ancient monuments are found near Zowan, Spitola,
Caffa, Pharahfa, Hammamet, and Chafpa. Desfontaines
mentioned in particular with admiration a large and beau-
tiful amphitheatre near Elgen. Some vestiges are also
found here and there of an ancient Carthagian aqueduct,
which served to draw water from the springs of mount
Zowan; but there fearfully exist any other remains of Car-
thage. Near the river Mejesta are still seen some ruins of
Utica, which are, at present, at the distance of about
4,000 fathoms from the shore; though this city was for-
merly a sea-port.

At Tunis, accounts are kept in piastres of 52 apers, each
after being divided into 12 burbes. The coins consist
of gold tunisians, valued at 100 apers; of silver nantras (a
square or shapeless coin), valued at 52 apers; and of
doubles, valued at 24 apers. The burbes are a small cop-
per coin. Gold, silver, and pearls, are weighed by the
ounce of 8 termini; and 80 ounces of Tunis = 81 ounces
English troy. The cantaro, which is a weight for mer-
chandise, contains 100 rotoli, weighing about 111 pounds
avoirdupois. The caffello, a corn measure, contains 18
weals, or 216 saws; 53 caffelli = 67½ English quarters.
The mattaro, an oil measure, is 32 rotoli, = 35½ pounds
avoirdupois, and is about 5 English gallons. The mattaro,
wine measure, is only half that for oil measure. The pic,
long measure, is for woollen 29½ French lines, or 26½
English inches, for silk 24½ English inches, and for linen
18½ English inches.

TUNKAT. See TOUCAT.
TUNKERSTOWN. See EPIRATA.
TUNKHANOCK, a township of Pennsylvania, in the
county of Luzerne, containing 884 inhabitants.
TUNKHANOCK Creek, a river of Pennsylvania, which
runs into the east branch of the Susquehanna, N. lat. 41° 31'
W. long. 75° 57'.
TUNNA, in Commerce, a measure of grain in Sweden,
equal to four bushels five quarts Winchester measure.
TUNNAGE, or TONnage, a duty or custom due for
merchandise brought or carried in tons, and such like vessels,
from or to other nations: thus called, because rated at so
much per ton.

Tunnage is properly a duty imposed on liquids according
to their measures; as poundage is that imposed on other
commodities according to their weight. See POUNDAGE
and CUSTOMS.

TUNNAGE is also used for a certain duty paid the
mariners, by the merchants, for unloading their ships arrived
in any haven, after the rate of so much per ton.
TUNNEL, or TUNCEL, an instrument through which
any liquor is poured into a vessel.

Part of a draught of a chimney, above the mantle-piece,
is also called by the same name.
TUNNEL is a large subterranean arch, driven through a
summit or hill, for the passage of boats upon a canal con-
tinued through the same: also, smaller drains or culverts
are called tunnels; and the execution of making and driving
them is called tunnelling.

TUNNEL-Pit, a well or shaft sunk to the line of an
intended tunnel, through which the stuff excavated from it is
drawn up to the surface.

TUNNEL-KILN, in Agriculture, a term applied to a lime-
kiln in which coal is burned, in contradistinction to that in
which wood, peat, and other such matters are used, termed
the flame-kiln. See LIME-KILN.

There is much less waft of heat in the former forts than
in those of the latter, and they have much advantage in the
quick dispatch in drawing the lime; as, in the flame-kilns,
after the matters are burnt, much time is lost by waiting
until the lime be cold, and by emptying it at the mouth
part
The nature of these different kinds of kilns, and many useful particulars relating to them, may be seen in detail in the Corrected Report on Agriculture for the County of Suffolk.

Tunnel-Net is a kind of net much used for the catching of partridges; thus called from its form, which is a cone fifteen or eighteen feet long.

This net must be made of three-twisted thread, and must not be too thick; it should be dyed green, that the colour may give no suspicion to the birds, and the meshes should be about two inches and a half broad.

Into the kind meshes, at the larger end, there must be put a smooth wooden rod, about the bigness of a gun-rammer; of this must be made a sort of hoop, both ends being tied together; and at different distances from another, there must be placed many more such, which are to be rounded in the same manner, and are to support the net its whole length in the tunnel form. Two flakes, or strong pegs, must be fastened at the sides of the entrances into the net, and one at the farther end, or narrow part: the two flifts are to keep the mouth of the net sufficiently extended, and the last is to keep it pulled out lengthwise to its full dimensions, the hoop preventing its falling in.

There must be used with this net two others, of that kind which they call ballers. These are long and straight nets, and are to be fastened down to the mouth of the tunnel-net on each side, extending seven or eight fathoms on each side from it, so as to take in fourteen or sixteen fathoms in front, beside the breadth of the mouth of the tunnel-net, and to direct all that shall move forward within that compass into the net.

In order to use this net, a covey of partridges is to be found, and then the net is to be placed at a considerable distance behind them: when this is fixed, the sportsman is to take a compafs, and get before the birds with a flaking horse or flaking ox, and then to move forward, driving them towards the net. This is to be done gently and carefully; they are not to be driven at once strait forwards, but the sportsman is to wind and turn about, and at times to stand still; as if the horse was grazing. If the partridges, in the time of driving, make a stand, and look at the machine, it is a sign they suspect it, and are ready to take wing: in this case the sportsman must stand still, or even go back a little; and when they are become composed again, he is again to advance upon them. If any single bird lies remote from the reft, the sportsman must take a compafs around him, and fetch him in; for if he takes wing the reft will all follow; in this manner, with patience and caution, the whole covey may be driven like a flock of sheep up to the nets. A real horse, trained to the purpofe, is, however, much better than a flaking machine. The ballers, or wings of the tunnel, must not be pitched ftraight, but in a sort of femicircle; and the birds, when they frop their march, will run along them to the middle, where the mouth of the tunnel is open.

When they come to the mouth of the tunnel, the old ones will make a stand, as if to confider what was before them; but on prefling gently on them with the horfe, the young ones will run in, and then all the reft will follow.

The sportsman must then make all the haffe he can to the mouth of the net, to secure them from coming back again.

TUNNING, or TONNING, a part of the process of brewing, or rather an operation which is the sequel of it.

The tunning of beer, &c., is performed various ways; some being of opinion it is best tunned as it cools, or begins to come; while others let it stand longer to become riper.

The most regular method is, to cleanse and tun just as it comes to a due ferment, and gets a good head; for then it has the most strength to clear itself. What works out of the cask is to be supplied with fresh beer of the same brewing.

TUNNING-DISH, a term applied to a large wooden dish, employed in tunning malt liquor.

TUNNUTDIORBIK, in Geography, an island near the coast of East Greenland. N. lat. 60° 45'. W. long. 46° 50'.

TUNNY, in Ichthyology, a name given by us to the Spanish mackerel, a large fish of the focomeber kind, called by authors thytnus and arcytnus, by Salvin limafa, and pelamys by Arifotole, Allan, and the other old writers. See Scorber.

In the lochs on the western coasts of Scotland, as well as in the Mediterranean (see Scorber Thytnus), tunnies are also found in pursuit of herrings, and sold to people, who either carry them fresh to the country markets, or salt and preserve them in large cafsks. The pieces, when fresh, look like raw beef, but when boiled turn pale, and have somewhat the flavour of salmon. One of them has been found to weigh four hundred and sixty pounds.

TUNS, The, in Geography, rocks in St. George's Channel, near the coast of Ireland, and county of Wexford; 3 miles N.E. from the Saltee islands.

TUNSLA, a town of Sweden, in the province of Savolax; 52 miles N. of Nyfiol.

TUNSTALL, JAMES, D.D., in Biography, a learned divine, was born about the year 1710, and educated at St. John's college, Cambridge, of which he was a tutor and fellow. In 1741 he was chosen public orator of the university, and became one of the chaplains to archbishop Potter. It was said of him, that many came to Lambeth humbe, but no one left it so but Dr. Tunfall. He was created D.D. in 1744, and in 1757 took possession, upon an exchange, of the valuable vicarage of Rokstake, in Lancashire; but his life terminated in 1772. He had a controversy with Middleton concerning the letters between Cicero and Brutus, of which he had made great use in his "Life of Cicero," and which Tunfall not only refuted, but proved, in the judgment of Markland, to be suppolitious. He was also the author of some other publications: the principal of which is his "Academia, Part I, containing several Discourses on the Certainty, Difficulties, and Connexion of Natural and Revealed Religion," continued, as it is suppos'd, by Part II. printed after his death, under the title of "Lectures on Natural and Revealed Religion, read in the Chapel of St. John's College, Cambridge." Nichols's Anecdotes.

TUNSTEDE, or TUSTEDE, an English D.D., and a learned musician, who flourished in the fourteenth century. Pits, Bâl, Tanner, and all our biographical writers, speak of him with respect. And among the MSS. at Oxford, we found, in 1780, a Tract on Musick, entitled "Quatuor Principalia Artis Musicæ," by this writer, dated 1351, Bodl. 515, bound up with other tracts.

What this author calls the four principals of music, will not appear from his own manner of dividing the work. In the first part or principal, consisting of nineteen chapters, he treats of music in general, its constituent parts and divisions. Secondly, of its invention, intervals, and proportions; twenty-four chapters. Thirdly, of plain chant and the ecclesiastical modes; fifty-eight chapters. Fourthly, of measured music or time, of difficult, and their several divisions. This last principal is divided into two sections, of which the first contains forty-one chapters, and the second forty.
forty-nine. The whole treatise fills a hundred and twenty-four folio pages: the diagrams, which are very numerous, are beautifully written, and illuminated with different coloured inks; and it seems to be in all respects the most ample and complete work of the kind which the fourteenth century can boast.

TUNUB, in Geography, a town of Egypt, on the west branch of the Nile; 6 miles N.N.W. of Amrus.

TUNUPOLOH, in Zoology, the name of an East Indian species of viper, found principally in the islands of Ceylon; it is of a small size, and of a fine fattin-like glows, beautifully variegated with shades of brown. Ray.

TUONI Ecclesiastici, Ital., in Musici, tones of the church. (See Canto Fermo and Moni.) The modi authentic are the odd numbers 1, 3, 5, 7; and the modi plagali, the even numbers 2, 4, 6, 8.

TUONO, Ital., a musical tone or sound. (See Tone.) "Tuono," says the Cruica, "apprezzo a' mulcic, sono i gradi, per cui paffano succesivamente le voci e li fuoni nel falire verfo l'acuto, et nello fendere verfo il grave colla regolata interpofizione de' femitoni a' loro luoghi per riempire gli'intervalli maggiori confonanti, e diifonanti."—"Tones among musicians are those degrees or gradations by which voices and instruments ascend and descend successively from the grave to the acute, and descend from the acute to the grave, with the interpofition of the necessary femitones to fill the greater confonant and diifonant intervals." Varchi. In this arrangement of the scale, all the simple and perfect confonances are found, that is, the key-note, the fourth, the fifth, and the diapason or octave.

TUP, in Rural Economy, a term often applied to a ram in different districts.

TUPELO Tree, in Botany. See Nissa.

TUERSDORF, in Geography, a town of Saxony, in the Vogtland; 4 miles N.E. of Oelnitz.

TUPE, a town of Bohemia, in the circle of Chrudim; 8 miles N.W. of Chrudim.

TUPICA, a town of Peru; 50 miles S.E. of Lipes.

TUPINAMBAS, a nation of South American Indians, who inhabited near Rio Janeiro; but after the settlement of the Portuguese, removed towards the river of the Amazons, where the Tapayos are now their descendants.

TUPISTA, in Botany, an unexplained name, used by Mr. Ker, in Curt. Mag. t. 1655.—The plant which bears it, T. squillata, was imported by Mehrs. Lodiges from Amboyna, in whose flow it flowered, for the first time, in April 1814. The learned author did not examine the specimen in a perfect state, fo that his ideas, like our's, must be chiefly derived from Mr. Edward's figures, the accuracy of which there is no reason to doubt, and from which the close affinity of this plant to Orontium japonicum is apparent. No botanist however is as yet sufficiently acquainted with the parts of fructification in either to determine their generic character, or to distinguish them generically from O. aquatica. See Orontium.

T. squillata has a perennial tuberous root, with thick fibres. Stem none. Leaves few, erect, equitant, lanceolate-oblong, entire, coriaceous, smooth, about two feet long. Stalk solidary, erect, not a sparsely fimple, cylindrical, smooth, firm, purplish, bearing a dense spike of numerous scented flowers, of a pale dingy, or brownish lead-colour, quite seiffulle, with a bractea at the base of each. Calyx none. Corolla of one petal, bell-shaped; the limb in fix or more spreading segments, each bearing on its disk a seiffulle, two-lobed, but seemingly imperfect, anther. A cylindrical body, four-lobed at the top, in the centre, looks like a germen and stigma.

TUPMAN, in Rural Economy, a term frequently applied to a breeder and dealer in rams, in some districts, as those of the midland parts of the kingdom. See Ram.

TUPPA, a name given to Tibet children, who at the age of eight or nine years are admitted into the monastery at Teophoo-Loomboo, and who are occupied in receiving the instruction suited to their age, and the duties for which they are designed. See Tohba.

TUPPING, in Rural Economy, a term applied to the impregnating of ewes by the rams or rams.

TUPPING-TIME, the period or season of putting rams or rams to the ewes. It should be done neither too early nor too late, as in the former case the lambs are dropped too much in the cold weather, while in the latter they are liable to be of inferior size for the markets. It is consequently best done according to the nature of the circumstances. See Sheep.

TUQUILIGASTA, in Geography, a town of South America, in the province of Tucuman, on the Salado; 4 miles S. of St. Yago del Eletro.

TUR RABAH, a town of Asiatic Turkey, in the government of Morah; 10 miles E. of Nifabun.

TURA, a river of Russia, which rises about 40 miles W. of Verechotra, in the province of Ekaterinburg, and runs into the Tobol, opposite Turchatkoi, in the government of Tobolok. See Tobol.—Alfo, an island in the Grecian Archipelago. N. lat. 39° 34'. E. long. 24° 15'.—Alfo, a town of Hungary; 24 miles W. of Topolzian. —Alfo, a town of the county of Tyrol; 24 miles S.W. of Trent.

TURA Bamba, a spacious plain, in which flands the city of Quito.

TURALINZES, one of the first colonies which was founded for themselves permanent habitations, when the Tartars subjegated Siberia in the 13th century; hence their name (from Tura, signifying in the Tartar language a town), which signifies the name of Tartars with settlers. Ever since their arrival, they have inhabited the region on both sides of the river, which from them is denominated the Tura, between the Tavda and the Ifer, in the Ekaterinenburg and Tobolok districts of the governments of Perme and Tobolik. Their oldest fixed seat was the city of Tishinghiden; but when Yermak made the conquest of these parts, the khan Yeiapania raised higher up the Tura in a city, which after their restoration by the Russians was called Turenik, and bears this name at present, though it is also called by the Tartars Yaratichina.

TURAMIANA, in Ancient Geography, a town of Spain, in the eastern part of Buttice, S.W. of Urfi. According to the Itinerary of Antonine, it was on the route from Caflulo to Malacca, between Urfi and Murgi.

TURAN, in Geography. See Taraz.

TURANCOURCHY, a town of Hindoostan, in Madura; 12 miles N. of Nattam.

TURANNO, a town of Hindoostan, in Malwa; 18 miles N.E. of Ougain.

TURANO, a town of Naples, in Calabria Citera; 3 miles W. of Bibignano.

TURAPIIUM, Shih-Ellah, in Ancient Geography, a town of Africa, in Mauritania Carierniens, situated in the mountains of the interior, S. of Icofium.

TURATTE, in Geography, a town of the island of Celebes, and capital ef a powerful kingdom; 180 miles N. of Macallar.

TURBA, in Ancient Geography, a town of Novempopulani, belonging to the Aquitains, in Gaul.

TURBAN, TURBANT, the head-drefs of most of the Eastern
Eastern and Mahometan nations; consisting of two parts, viz. a cap, and a fahn of fine linen or taffety, artfully wound in divers plaits about the cap.

The word is formed from the Arabic َخَرَدْ, or َدْرَع, or َخَرَدْ, or َدْرَع, which signifies to encompass, and َمَنَدَد, or َمَلَد, which signifies fasth, or fcarf, or band; so that durband, or turbant, or turbant, only signifies a fcarf, or fasth, tied round; it being the fahn that gives the denomination to the whole turban.

The cap is red or green, without any brim, pretty flat, though roundish at top, and quilted with cotton, but does not cover the ears. About this is wrapped a round piece of fine thin linen or cotton, in several wreaths variously disposed.

There is a good deal of art in giving turbans the fine air; and the making of them up constitutes a particular trade, as the making of hats does among us.

The emirs, who pretend to be descended of the race of Mahomet, wear their turbans green: these of the other Turks are ordinarily red, with a white fahn. The gentel people have frequent changes of turbans. M. de Tournesfort observes, that the turban, all things considered, is a very commodious dress; and that he even found it more easy to him than his French habit.

The grand vizir's turban is as big as a bufhel, and is so exceedingly respected by the Turks, that they dare scarce touch it. It is adorned with three plumes of feathers enriched with diamonds and precious frones; he has a minister on purpose to look to it, called fullmeniocli. See Crown.

That of the grand vizir has two plumes; so have those of divers other officers, only smaller one than another; others have only one, and others none at all. The turban of the officers of the divan is of a peculiar form, and called mogenezek.

The fahn of the Turks' turban, we have observed, is white linen; that of the Perfians is red woollen. Thefe are the distinguishing marks of their different religions; Sophi, king of Perfia, who was of the fect of Ah, being the first who assumed that colour, to distinguifh himfelf from the Turks, who are of the fect of Omar, and whom the Perfians esteem heretics.

Turban, or Claviceo, in Conchology, denotes the aggregate, or whole fect of the whirls of a fhell, and forms its lower part. The flat, or helix turban, is one fo slightly prominent, as to be nearly on a level. There are also the short turban, the produced turban, and the long turban.

Turban-Top, in Botany. See Helvella.

Turban-Shell, Cidaris, in Natural History, the name of a genus of the echnodermata, which are of a hemispheric or fphericoid figure, and have their name from the Latin cidaris, a Perfian turban, as in some degree resembing that head-dres.

Of this there are several genera, and fubordinate species. This class of the echnodermata is made out by the affilance of the foffil, as well as the recent animals; many of the kinds being now unknown on any fhores. Klein's Echinod. p. 17. See Echinodera.

Turba, in Ancient Geography, a fountain of Palestine, at the foot of mount Gilbon, according to William of Tyre.

Turbaria, Turbartia, a right to dig turf in another man's ground; from turba, an old Latin word for a turf.

Turbaria, Common of, is a liberty which fome tenants have by prescription to dig on the lord's waife. See Common.

Turbaria is sometimes also taken for the ground where turfs are digged.

Turbaria Bruria, more particularly denotes flaw-turf, or heath-turf; mentioned in the charter of Hamon de Massy.

Turbed, in Geography, a town of Perfia, in the province of Chorasan; 90 miles S.S.W. of Melfcid.

Turbelia, in Ancient Geography, a town of Hither Spain, situated towards the south, and supposed to be the fame with that which Livy calls Turba.

Turbet, in Geography, a town of Pennsylvania, in the county of Northumberland, containing 2917 inhabitants.

Turbiço, or Turbigo, a town of Italy, in the department of the Olona; 18 miles W. of Milan.

Turbinata Ossa, in Anatomy, turbinated bones; certain bony plates belonging to the nose. See Nose and Cranium.

Turbinated, is a term applied by naturalifts to fshells which are spiral or wreathed, conically, from a larger bif to a kind of apex.

Turbinas, in Natural History. See Turbo.

Turbinis, or Turbinitae, foffil fshells of the turbo kind, or frones found in those fshells.

Turbit, in Ichthyology, the fame with turbot.

Turbit Pigeon, a particular species of pigeon, remarkable for its short beak, and called by the Dutch cort bek, that is, short beak. Moore calls it in Latin columba simbricata; and its English name feems no other than a bad pronunciation of its Dutch one. It is a small and short-bodied pigeon, and has a beak no longer than that of a partridge; the shorter this is, the more the pigeon is esteemed. It has a short round head, and the feathers upon the breast open, and reflect both ways, standing out like the frill of the bofon of a flirt. This is called by many the purle, and the more the bird has of it, the more it is esteemed; the tail and back are generally of one colour, as blue, black, red, yellow, or dun, and sometimes chequered; the flight-feathers, and thofe of all the rest of the body, are white; they are a light nimble pigeon, and, if trained to it, will take very high flights, in the manner of the tumblers.

Turbitth, Turpeth, or Turpethum, a medicinal root, brought from the East Indies, particularly from Cambay, Surat, and Goa; though others will have it, that the true turbitth comes chiefly from Ceylon.

It is the cortical part of the root of a fpecies of convulvalus, vide. the convulvalus turpethum of Linnaeus.

The turbitth of the moderns bears fo little reſemblance to that of the ancients, that it is difficult to fuppofe them the fame. That fold by our druggifts is a longifh root, about the thicknefs of the finger, refinous, heavy, and of a brownifh hue without, and white within. It is brought to us cloven in the middle, lengthwife, and the heart or woody matter taken out. The bark is ponderous, not wrinkled, easy to break, and discoveres to the eye a large quantity of refinous matter.

This root, on the organs of taste, makes at first an impreffion of sweetneſs; but when chewed for some time, betrays a naufeous acrimony. It is accounted a moderate strong cathartic, but does not appear to be of the fakeft or molt certain kind; the refinous matter, in which its virtue refides, being very unequally diffributed; infomuch that, as it is said, fome pieces taken from a fernule to a drachm purge violently, whilft others in larger doses have very little effect. Lewis.

It is commonly fuppofed to take its name turbit from turbar, on account of the violence of its operation, as difturbi;g
turbid the whole economy; and has accordingly been
used in the droopy, palpy, and apoplexy.

It yields a deal of resinous matter in a spirituous
 menstrum, which Quinsey observes does not affect the larger
 passages much; but is very active in the smaller vessels, and
 glandular contortions, which it wonderfully clears of all
 viscid adhesions.

Some apothecaries, either through ignorance or parsi-
mony, substitute white thapia, which they call grey turbit,
or turbit glandularum, for the true turbit; though both as to
 taste, colour, and qualities, they are very different.

_Turbit_ Mineral, _Tartaricum Minerales_, is a name
which the chemists give to a yellow precipitate of mercury,
now called yellow sub-fulminate of mercury.

For the method of preparing it, see HYDROGYPHY Sub-
sulphur flavus.

Turbit mineral may also be made by precipitating mer-
cy from its solution in nitrous acid by means of vitriolic
acid, or of some vitriolic salt. For this purpose the nitrous
acids must be well saturated with mercury.

We may observe that turbit mineral becomes yellow
only by being deprived of the adhering vitriolic acid, and
that it remains white till it has been washed with a large
quantity of water; and, in general, the more perfectly it is
deprived of acid, the deeper yellow colour it acquires.

Some chemists have supposed, that a portion of vitriolic
acid remaining united with the turbit, though not enough to
render it soluble in water: M. Beaume affirms, that when
sufficiently washed it contains no acid; but the latter
experiments of M. Bayen prove the contrary.

This powder is called mineral turbit, from the re-
semblance it bears to the vegetable turbit of the Arabians,
in strongly purging the most internal receisses of the body;
for though it be impudent upon the tongue, yet it is beneficial
of very considerable virtues. Being boiled with water, it
loses more of its salts, and thereby grows milder, and more
safe; so it does also by being dephlegmated twice or thrice,
or distilled with spirit of wine.

The powder, prepared in the manner above described,
proves, though not corrosive, strongly emetic; operating,
in this intention, the most effectually of all the mercurials
that can be given with safety. It is used chiefly in virulent
gonorrhoeas, and other venereal cafes accompanied with a
great flux of humours to the parts: it is said likewise to
have been employed with success in robust constitutions,
against leprous disorders, and oblitrate glandular obstruc-
tions.

The dose, as an emetic, is from two grains to fix
or eight; though some constitutions, habituated to mercurials,
can bear larger quantities. It may be given in smaller
doses, as half a grain or a grain, as an alternative, after
the same manner as the red calc of mercury; and even
when intended as an evacuant, it may perhaps, as Malouin
observes, be more advisable to give only a small quantity at
a time, as one grain, and repeat the dose every hour till the

Art. Turbit mineral.

Turbit mineral appears to have been the grand secret of
Paracelsus, which, in his scarce German book of hospital
medicines, he praises so extravagantly for the venereal and
all chronic diseases. Sydenham also commends it in
venereal cafes, given in the quantity of fix or eight grains,
in strong habits of body, as to prove emetic; but when
imprudently used, it is apt to bring on a dysentery.

Turbit mineral has been used as a fermentary, and is
said to have made wonderful cures in distempers of the eyes.
Mr. Boyle relates a cure of this sort, performed by the
famous empiric Adrian Glass-maker on Mr. Vatteville, a
Swiss officer of distinction in the French service, and totally
blind. This gentleman was ordered to suck about a grain
of turbit up each nostril, which immediately operated in a
violent manner, by vomit, rood, sweat, salivation, and the
lacrymal glands, for twelve hours together; and also caused
his head to swell greatly; but within three or four days
after this single dose had done working, he recovered his
sight. Boyle's Works, Abr. vol. i. p. 103.

We read of this preparation being given to the quantity
of ten grains, with the fame quantity of camphor, and in-
fections of the whole body, of the pilul. ex duo. to remove the swelling of
the testicles. This medicine, which in the beginning vom-
ited and purged, at last operated chiefly as an alterative.
It is said to be successful in oblitrate venereal and febrile

Turbit mineral is an efficacious bright true yellow, of
a great body like vermillon; will stand equally well, and
work with oil or water much in the fame manner. The
qualities (says the author of the Handmaid to the Arts,
vol. i. p. 105.) render it very valuable for many purporses;
as it is much brighter than any other yellow used in oil, ex-
cept king's yellow, and is free from its nauseous smell, and
cooler. Mixed with Prussian blue it yields a much finer
green than from the king's yellow without ultramarine. As
it is now procured, it requires levigation in water before it
be used.

_Turbo_, in the Linnean System of Zoology, is a genus of the
Tetacea order of worms. Its characters are: that its
animal is a flag; the shell univalve, spiral, and solid; and
the aperture straightened, orbiculated, and entire. Gmelin,
in his edition of Linnaeus, enumerates one hundred and
seventeen species, besides several varieties. See _Turbo_ under the
article Conchology.

In Da Colta's system, the turbo is a genus of shells, with a
lengthened clavicle or turban; which have generally a per-
fet round mouth; the columella, or inner lip, not much
faced outwards, and the body spher very belled, so that the
turban is suddenly, and not inensiblement, produced from it. See
_Shells_.

The most remarkable species of the turbo, or screw-shell,
is that called _practice_ by Rumphius, from its spires running
up hollow, or with a space between them. This is a very
scarce and valuable shell when large, but is often found small
in the Adriatic.

Aldrovand, and many others of the old authors, make
no difference between the turbinates and screw-shells, though
the distinction of the genera is very obvious; the screw-
shells having a long, large, and dentated mouth, which ter-
minates towards the base in a narrower aperture than else-
where; and the shell itself always runs to a very sharp point
at the end: whereas the turbinates terminate in a less sharp
point, and have thicker bodies, and always much wider
mouths. The screw-shells are indeed very easily confounded
with the Buccinum; and it requires more accuracy to dinstin-
guish them, than has fallen to the share of the generality
of writers on these subjects an age or two ago. Aldrovand
and Rondellet have confounded these genera, and have
brought in a third among them, by the epithet _muricatum_,
which, when applied to the Buccinum, is generally observed
to bring into that family a shell of the murex clas, and
which might have been very properly called by that short
name.

For the sake of distinguishing these, it may be observed,
that the screw-shell is of a very long and slender shape, ter-
minating in a very sharp point, with its spires running an
imperceptibly, without any great cavity, and the base small
and flat, as well as the mouth.

_Turbo_
Turbo Cochlea, in Natural History, a name by which some authors have called the Perian shell, a species of concha globosa, or dolium.

Many have been puzzled with this shell, not knowing in what clafs to rank it; and Aldrovand has placed it at the end of his work, saying, that it would seem to belong to the turbinated kinds, but that it wants the turbo.

TURBOT, in Ichthyology, a name given to the fish which, in the sytems of Artedi and Linneaus, is a species of pleuronectes, being the pleuronectes of the former, with the eyes on the left side, and a rough body, and the pleuronectes maximus of the latter, and the rhombus maximus after non fquamofus of Ray. See Pleuronectes Maximus.

Turbots grow to a large size, some of them weighing from twenty-three to thirty pounds. They are taken chiefly off the north coast of England, and others off the Dutch coast. The large turbots (as well as several other kinds of flat fish) are taken by the hook and line, for they lie in deep water; the method of taking them in weirs, or flaked nets, being very precarious. When the fishermen go out to fish, each person is provided with three lines, which are coiled on a flat oblong piece of wicker-work; the hooks being baited, and placed regularly in the centre of the coil. Each line is furnished with fourteen fores of hooks, at the distance of fix feet two inches from each other. The hooks are fastened to the lines upon flews of twisted horse-hair, twenty-seven inches in length. When fishing, there are always three men in each coble, and consequently nine of these lines are fastened together, and used as one line, extending in length near three miles, and furnished with 2520 hooks. An anchor and a buoy are fixed at the first end of the line, and one more of each at the end of each man's lines; in all four anchors, which are common perforated flones, and four buoys made of leather or cork. This line is always laid across the current. The tides of flood and ebb continue an equal time upon our coast, and, when undisturbed by winds, run each way about fix hours; they are so rapid that the fishermen can only shoot and haul their lines at the turn of tide, and therefore the lines always remain upon the ground about fix hours; during which time the myxine glutinosa of Linneaus will frequently penetrate the fish that are on the hooks, and entirely devour them, leaving only the skin and bones. The fame rapidity of tides prevents their using hand-lines; and therefore two of the people commonly wrap themselves in the sail, and sleet while the other keeps a strict look-out, for fear of being run down by flips, and to observe the weather. For ftons often rife fo suddenly, that it is with extreme difficulty they can sometimes escape to the shore, leaving their lines behind. Besides the coble, the fishermen have also a five-men coble, which is forty feet long, and fifteen broad, and of twenty-five tons burthen; it is fo called, though navigated by fix men and a boy, because one of the men is commonly hired to cook, &c. and does not share in the profits with the other five.

This boat is decked at each end, but open in the middle, and has two large lug-fails.

All our able fishermen go in these boats to the herring-fifhery at Yarmouth, in the latter end of September, and return about the middle of November. The boats are then laid up till the beginning of Lent, at which time they go off in them to the edge of the Dogger, and other places, to fish for turbot, cod, ling, skates, &c. They always take two cobsles on board, and when they come upon the ground, anchor the boat, throw out the cobsles, and fish in the fame manner as those who go from the shore in a coble; with this difference only, that here each man is provided with double the quantity of lines, and instead of waiting the return of the tide in the coble, return to their boat and bait their other lines; thus hawling one set, and fishing another every turn of tide. They commonly run into harbour twice a week to deliver their fish.

The best bait for all kinds of fish is fresh herring cut in pieces of a proper size; the five-men boats are always furnished with nets for taking them. Next to herrings are the lefter lamprey. The next baits in esteem are small haddocks cut in pieces, sand-worms, and limpets, here called flidders, and when none of these can be had, they use bullock's liver. The hooks are two inches and a half long in the shank, and near an inch wide between the shank and the point. The line is made of small cording, and is always tanned before it is used.

Turbots, and all the rays, are extremely delicate in their choice of baits; for if a piece of herring or haddock has been twelve hours out of the sea, and then used as bait, they will not touch it. Pennant's Brit. Zool. vol. iii. p. 234, &c.

TURBOWKA, in Geography, a town of Russia, in Poland; 32 miles S.E. of Zytomiers. TURBUNNY, a town of Napaal; 60 miles S.W. of Catamandu.

TURCAE, in Ancient Geography, the name of a people who inhabited the environs of the Palus Gothfeldes, according to Pomponius Mela. See Turk.

TURCHANS, or ROOHANS, in Zoology, a kind of wild horses in the great desert about Azof. They are higher than the tarfants, (which fee,) mofs-grey in colour, with long upright standing ears, their manes and tails thinner and shorter than the common breed, their coats long and thick. They feed by thousands together in one taboon. The Khirges Rhaiflaks shoot them with guns, and eat them.

TURCICA SELLA. See SELLA.

TURCICA Terra, Turkey Earth, in the Materia Medica, a very fine bole or medicinal earth, dug in great plenty in the neighbourhood of Adrianople, and used by the Turks as a sudorific and astringent, and famous among them in pellential diseases. It is sometimes brought over to us also made up into flattish orbicular maffes, of two or three drachmes weight, and sealed with some Turkifh characteres. The earth is of a somewhat lax and friable texture, yet considerably heavy, of a greyish-red colour, but always redder on the surface than within; extremely soft, and naturally of a smooth surface. It breaks easily between the fingers, and melts freely in the mouth, with a considerably strong astringent taffe. It adheres but slightly to the tongue, raifes no effervescence with acids, and burns to a dually yellow colour. Hill.

Many authors who have written of the materia medica, and of foftils in general, have indiscriminately called the various kinds of Lennian earth by this name; but the true terra turcica, defcribed by Schroder, Wormius, &c. is a different substance, though not sufficiendy characterised by those authors to distinguish it from all the other earths.

TURCKHEIM, in Geography, a town of Germany, in the lordship of Mindelheim; 6 miles E. of Mindelheim. —Alfo, a town of France, in the department of the Upper Rhine, formerly imperial; 3 miles W. of Colmar.

TURCKHEIM Rhein, a town of France, in the department of Mont Tonnerre; 4 miles N. of Worms.

TURCO, a town of Peru, in the diocefe of La Plata; 60 miles E.N.E. of Atacama. S. lat. 20° 30'. W. long. 68° 20'.

TURCOCORIA, a town of Europea Turkey, in Livadia; 14 miles N. of Livadia.

TURCOIN,
TURCOIN, a town of France, in the department of the North, and chief place of a canton, in the district of Lille. The unfortunate conflict between the French and the duke of York, who commanded the allies, may be said to have decided the fate of the Netherlands; 6 miles N.E. of Lille.

TURCOIS, or Turquois, in Natural History and Mineralogy, a substance found in Persia and other parts of Asia, and formerly classed with stones. It has a beautiful light-green colour, and is susceptible of a high polish. The surface is smooth and polished; it has also a smooth shining fracture, and is so hard as to scratch glass slightly; the specific gravity is 3.127. It has for a long time been considered as the tooth of an unknown animal impregnated with copper; but by a series of analytical experiments, La Grange has proved that it does not contain a particle of copper, but is in reality bone coloured by phosphate of iron. The constituent parts are as under:

- Phosphate of lime - 80
- Carbonate of lime - 8
- Phosphate of iron - 2
- Phosphate of magnesia - 2
- Alumina - 1
- Water - 6

Guyton Morveau suspected that the turcois contained felsile, but this is supposed by others to have been accidental. This celebrated chemist made some experiments on fossil bones, and found that they assume in the fire the colour of turcois; and when digested in a weak solution of potash, they turn blue, varying from a greenish to deep blue. Mellan, Fourcroy and Vauquelin have also observed that bones strongly calcined often assume a blueish tinge, which they considered to be caused by a small portion of phosphate of iron.

Turcois is employed in jewellery. See Gems.

The Greeks and Latins seem to have known it under the name callais; and it appears to have had a place in the rationale of the high-priest of the Jews.

Some writers mention turcoises both oriental and occidental, of the new rock and of the old. The oriental partakes more of the blue tincture than the green; and the occidental, more of the green than the blue. Those of the old rock are of a finer blue, and those of the new rock are often whitish, and do not keep their colour.

The oriental ones come from Persia, the Indies, and some parts of Turkey; and some even Suppose, that it is hence they derive their modern name turcois. The occidental are found in various parts of Europe, particularly in Germany, Bohemia, Silezia, Spain, and France.

Turcoises are found of a round or oval figure; they cut easily, and besides teeth, which are frequently engraved on them, some are formed into crucifixes, or other figures, near two inches high; though De Boedt mistookly affirms, that none have been known to exceed the bigness of a walnut; for the specimen exhibited by Mr. Mortimer to the Royal Society was twelve inches long, five inches broad, and in some places near two inches thick.

The turcois is easily counterfeited; and that often is done so perfectly, that it is impossible to discover the deceit, without taking it out of the collet.

In the Memoirs of the Academy of Sciences for the year 1715, we have a very curious account of the formation of the turcois, and the manner of managing its naturally irregular colour, by M. Reaumur. The turcois, he observes, is one of the most durable of precious stones, its hardnefs usually not coming up to that of a crystal, or a transparent pebble; though some are much harder than others; and still the harder, ceteris paribus, the more valuable, by reason of the vivacity of the polish, which is always proportionable to the hardnefs.

Reaumur, a jeweller, and the author of a scarce treatise, called Mercure Indien, cultivating the several precious stones, sets a hard turcois, whose blue is neither bright nor deep, on the foot of the most perfect emeralds, that is, nearly on a level with a diamond; but such are rarely ever met with. Those with any defect, he only values at a French crown the carat.

Tavernier affirms, but erroneously, that there are but two mines of turcoises known in all the earth, and those are both in Persia; the one called the old rock, near a town called Nisabour, three days' journey to the north-east of Meshed; the other, called the new rock, is five days' journey from it. The stones from the latter, he adds, are but little valued; and the king of Persia hath for many years prohibited the digging in the former for any but himself. M. Reaumur takes the old rock to be now exhausted; in effect, the common division of turcoises into the old rock or oriental, and new rock or occidental, is very arbitrary and precarious. All the best, and most perfect, wherever they occur, in India or Europe, are reckoned among the former, and the rest among the latter. Near Simore, in the Lower Languedoc, there are several considerables mines of turcoises; but that fine blue colour, admired in the turcois, is not natural to those of these rocks; the prevailing colour being sometimes white, and sometimes much like that of tripoli of Venice. Other precious stones are dug out of the mine with all their colour, to the force of which nothing can be added, though it may frequently be diminished, as we see fire bring down the too deep colour of the sapphire, and quite take away that of a pale sapphire: these turcoises, on the contrary, are naturally whitish or yellowish, of a colour as ordinary as that of a free-stone; and by opposing them for some time to the action of the fire they assume a blue colour.

It seems a paradox, and yet M. Reaumur has attempted to prove, that turcoises are originally the bones of animals. In the mines in France, pieces have several times been found in the figure of teeth, bones of the legs, &c. And turcoises which are yet imperfect, or half-formed, are apparently composed of laminæ, or leaves, like those of bones, between which some petrifying juice, iniminating itself, binds them close together; and still, the softer, the more imperfect the stones are, the more distinguishable are the different directions of the fibres and laminæ, with their interlacements, and the great resemblance they bear to fractured bones, and the laths to any kind of stones known.

To give them a blue colour, they dry them awhile in the air, then heat them gradually in a furnace made after a particular manner. If they are heated too hastily, the humidity between the laminæ wanting time to evaporate, the whole will separate into scales or flaws. Some of the stones require a greater degree of heat to bring them to their colour than others; and even in large pieces, the several parts ordinarily require several degrees of heat.

On this account a great deal of care is to be taken in the heating of them; for the fire, which gives them their blue by degrees, if they be exposed beyond a certain degree, takes it away again.

M. Reaumur accounts for their taking a blue colour by heat very well; when fresh cut out of the rock, it seems their substance is found sprinkled and streaked all over with spots, veins, little circles, &c. of a dark blue colour; these he takes to be sources of a deep blueish matter, which the fire rarefying,
rarefying, spreads and diffuses throughout the whole substance of the stone. This matter, again, he concludes to have been either originally the juice contained in the bones, since mixed and coagulated with the petriflying juice, or some other mineral matter insinuated into the pores of the stone.

According to M. Reaumur's Mem. Par. 1715, nitrous acid will not disolve that of Persia, though it will that of France, which shews a difference between them.

Dr. Woodward maintains, that the turcois, or callais of Pliny, is nothing else but fossil ivory tinged with copper; but Mr. Mortimer, who produced a specimen of the turcois to the Royal Society, is of opinion, that those which authors call stones of the old rock, and in which the colour is permanent, are real mineral stones; the form and size of the sample which he produced evincing this; for its shape shews that it could not be part of any animal bone, but its botryoid form seems to prove, that it is the product of fire, which has once melted this substance, and that when it cooled, its surface was formed into blisters and bubbles, in the same manner as the hematites botryoids, or blood-stone, whose surface consists of knobs, resembling a bunch of grapes. He apprehends the elphias spectus, or ebull sulphure of Theophrastus, to be what Dr. Woodward calls the turcois, and suspects that it is what De Boole calls the new rock. He thinks that, for distinction sake, all these stones of ivory origin should be called pseudo-turcois, or bastard turcois. By a chemical analysis he concluded, that his stone was a rich copper ore; some of it powdered and dissolved in spirit of hartthorn gave a deep blue; in aqua fortis, a fine green; and an iron wire put into it was in an hour's time incrusted with copper; some of it, being calcined without any flux in a crucible, ran to a slag of half-vitrified substance; whereas the same heat, if it had been ivory or bone, would have reduced it to a white ash, like bone-ashes, for it was exposed to a fire that vitrified the tile which covered it. Its hardness and confidence to an engraver's tool seemed to be the same as that of common white marble; its colour was not improved by heat, and it became brittle when red-hot.

Sir Hans Sloane had several specimens of these oriental turcoises, which are all botryoid, and seem to be copper ores; and in his museum there are also samples of turcoises from Spain and the south of France, which are small, and seem to be pieces of ivory tinged with copper. Phil. Trans. vol. xliv. art. 17.

The great defect of turcoises in general, is, that in time they lose their blue colour, and become green; and then cease to be of any value.

The pale blue of the natural turcois gem, is a very favourite colour in the glais-trade, and is given to glais in the following manner. First calcine common sea-felt, and beat it into fine powder; then make a pot of the sea-green glas, of a fair and full colour; to this, when in fusion, throw in at times the powder of salt, till the mass has lost all its tranparency, and is become paler and opaque; then add, by very small quantities at a time, more and more salt, till the colour is exactly that of the turcois gem; and when it is so, work it immediately, for the salt is soon burnt off, and the glas becomes transparent, and of its green colour. If it become transparent while working, more salt must be thrown in, and that will reduce it to the same opacity again. Neri's Art of Glais, p. 57. See Glass.

For making a paste resembling the turcois, see Paste.

TURCOMANIA, in Geography, that part of Armenia which belongs to the Turks.

TURCOMANS. See Turkomans.
brown; quill-feathers and tail black; chin and throat white, frizzled with brown; breast cinereous; abdomen white. The Jamaica thrush of Latham.

G U I A N E N S I S. Above greenish-brown, underneath ochre-coloured, with black longitudinal flake. The Guiana thrush of Latham.

M U S I C U S. With quill-feathers at the inner base ferruginous. The Mavis thrush or song-thrush of Ray, Willughby, Pennant, and Latham. Found in the woods of Europe, imitating in the mornings the song of the nightingale, and continuing it for almost nine months. Of this there are three varieties.

O L I V A C E U S. Brownish; beneath yellow. Found at the Cape of Good Hope.

I N D I C U S. Olive-coloured; bill and legs blackish; quills brown on the inner side. The Indian thrush of Latham; so called because it is found in India.

C I N E R E U S. Ash-coloured, with the two intermediate tail-feathers cinereous; the next on both sides black at the margin, and cinereous at the apex; the ruff black. The ash-coloured thrush of Latham. Found in India.

M I G R A T O R I U S. Grey; abdomen red; eye-lids white; the external tail-feather white at its interior apex. The American fieldfare of Forster, and red-breasted thrush of Latham. Found in North America, from Hudson’s Bay as far as the bay of Natka and Carolina.

T R I C H I A S. Olive-coloured; the body beneath yellow; the ocular band black. The Maryland yellow-throat of Edwards, and the yellow-breasted warbler of Pennant and Latham. Found in summer in the most low lands of Carolina, Maryland, and Pennsylvania.

C A N O R U S. Brown; beneath ferruginous; with a white line on the sides of the head, and a rounded tail. The crying thrush of Latham. Found in Bengal and China.

R U F U S. Red; beneath spotted whitish, with quill-feathers of the same colour; the tail rounded and red. The ferruginous thrush of Pennant and Latham. Found in America, from Newfoundland to Carolina.

P O L Y G L O T T U S. Obfuscely ash-coloured; beneath paler ash-coloured, with the greater quill-feathers white on the exterior half. The singing-bird, mocking-bird or nightingale of Sloane, the mock-bird of Catesby and Kalm, and the mimic thrush of Pennant and Latham. Found in Jamaica, and the mossy woods of America, practising in the way which its name imports.

O R P H E U S. With brown back; breast and lateral wing-feathers whitish; eye-brows white. The polyglott bird of Willughby, the lesser mocking-bird of Edwards, and the mocking-thrush of Latham. Found in Jamaica, and the warmer parts of America. It has two varieties.

S A N D W I C H I E N S I S. Above and abdomen brownish; beneath and front cinereous-white. The Sandwich thrush of Latham. Found in the Sandwich islands.

P A C I F I C U S. Above cinereous; beneath brownish-white; the lori black; the tail black, with a white tip. The Pacific thrush of Latham. Found in the Friendly islands.

S U R A T E N S I S. With the head somewhat crested; the neck, tail, and greater quill-feathers and legs black; the body above amber-coloured; beneath dirty-grey; the wing-coverts and second quills green. The Surat thrush of Latham: named from its habitat.

P H I L I P P E N S I S. Above olive; neck and breast red, spotted with white; abdomen and vent ochre-coloured. The Philippine thrush of Latham; so called from the islands which it inhabits.

S H A N B U. With chin, throat, and the ocular area black, with a large white streak at the ears; the rest of the head, neck, breast, and abdomen grey; the back and wings greenish-brown. The black-faced thrush of Latham. Found in the woods of China.

N O V E H O L L A N D I E. Blueish lead-coloured; the anterior part of the head, the bill, chin, throat, and legs black; the quill and wing-feathers black, with lead-coloured margin; the intermediate white at the apex. The New-Holland thrush of Latham.

P L U M B E I S. Black, with yellow axilles, and cuneated tail. The red-legged thrush of Pennant and Latham. Found in North and South America, and in the Bahamas islands.

C R A S S I N O R I S. Above from red, and beneath from black, with the quill-feathers acuminated; the two intermediate obscure. The thick-billed thrush of Latham. Found in New Zealand.

U L I E T E N S I S. From red to brown; quill-feathers black at the margin, and roundish tail black. The bay thrush of Latham. Found in Ulitea.

P A L L I D U S. From yellowish to ash-coloured; beneath whitish; tail-feathers from cinereous to brown; the side ones white at the apex. Pale thrush of Latham. Found in Siberia, beyond the lake Baikal.

S I B I R I C U S. Black, with yellow mouth; eye-brows and space under the wings white. White-browed thrush of Latham. Rare in the alpine and more northern woods of Siberia.

R U F I C O L L I S. Above brown, below snow; neck and equal tail-feathers red; the two intermediate cinereous. Red-necked thrush of Latham.

P H E N I C U L U S. Above olive, with white eye-brows; ocular band black; tail-feathers and two intermediate quills fimbriate; sides with throat and breast red. The red-tailed thrush of Latham. Found at the Cape of Good Hope.

R U F I C A U D U S. Above olivaceous; beneath purplish and white; tail-feathers and quills black; sides for the most part red. The rufous-tailed thrush of Latham. At the Cape of Good Hope.

M A L A R A R I C U S. Ash-grey; beneath red-brown; bill and tail-feathers black; legs yellow. The Malabar thrush of Latham. Found in Malabar.

P A G O D A R U M. Black; back and rump grey; vent white; head crested. The pagoda thrush of Latham. Found in Malabar and Coromandel.

C A Y E N N E N S I S. Cinereous; beneath whitish; vent white; greater wing-feathers and tail-feathers black; throat, bill, and legs black. The Cayenne thrush of Latham.

S T R I A T U S. Varied with yellow and grey; a longitudinal streak of the back yellow. Yellow-backed thrush of Latham. Found in Surinam.

M U S T E L I N U S. Beneath white, spotted with black; cheeks brown, spotted with white; rump and greater quills acuminated, and tail-feathers brown. The tawny thrush of Latham. In New York.

C A N T S C H A T E N S I S. Brownish; beneath from brownish to white; eye-brows pale; chin and throat carpyllous-coloured. Kantschata thrush of Pennant and Latham. Found in Kantschata.
NAEVUS. With head and pectoral band black; break from the eyes to the hind part of the head ferruginous; body above cinereous; beneath ferruginous. The varied thrush of Pennant, and spotted thrush of Latham.

HUDSONICUS. From blueish to cinereous; bill and legs black; feathers of the crown, nape, wing-covers and primary quills pale at the margin, red. The Hudsonian thrush of Pennant. Found in Hudson’s Bay.

NOVEDRACENSIS. With head, neck, and breast varied from black, and dilutely ferruginous; feathers of the back ferruginous at the margin; with double band above and below the eye, wings, and roundish tail shining-green, and legs black. The New York thrush of Pennant. Found in North America.

CURACUS. Shining-black; bill sub-friated, and tail cuneated. Found in Chili.

NITENS. Green; spot on the wing-covers violet. Shining thrush of Latham. Of this there is a variety, the green merula; beneath violet, throat and rump blueish. Found in Angola, and at the Cape of Good Hope.

ÆNEUS. Shining-green; beneath brassy; head blackish to shining-gold; rump and intermediate tail-feathers purplish; tail wedge-formed. Gloppy thrush of Latham. Found in Senegal.

AURATUS. Violet; back and wings green-gold; band of the wings at the internal margin and tail, with the superior wing-covers, blue. The gilded thrush of Latham. Found at Whidah, in Africa.

LEUCOGASTER. Violet; with white belly; blackish quills; bill and legs cinereous. The Whidah thrush of Latham.

ROEUS. Subincarnate; head, wings and tail black; occiput crested. Merula rosea of Aldrovand, Ray, and Biffon; rose or carnation-coloured ouzel of Pennant, Williamsby, and Edwards; the rose-coloured thrush of Latham. Found in various parts of Europe, Siberia, and Syria, migrating in flocks, and feeding chiefly on locusts.

LEUCURUS. Black; rump and tail white; tail-feathers black at the apex. White-tailed thrush of Latham. Found about Gibraltar.

CAFER. Blackish; somewhat crested; rump and belly white; vent red. Cape thrush of Latham. Of this there is a variety, the merula above brownish to cinereous; striated brownish; beneath hoary. Found in China, and at the Cape of Good Hope.

MACROURUS. From purplish to shining-black; beneath from ferruginous to yellow; rump and three tail-feathers on both sides exteriorly white. The long-tailed thrush of Latham. Of this there is a variety with the two intermediate tail-feathers black; the rest half white. Found in Pulo Condore and Malabar.

AMOENIS. Spadiceous; beneath yellow; secondary quill-feathers yellowish from the base to the middle; tail euniform; beneath yellow. The Amboine thrush of Latham.

BORONICUS. From cinereous to olive; black crown; abdomen and vent from olive to yellow; tail brown, with two obsolete bands towards the apex. The Bourbon thrush of Latham. Found in the island of Bourbon.

OCHIOCEPHALUS. With the larger quill-feathers, tail, and legs green; vertex and cheeks yellowish; collars black; abdomen and breast cinereous; the latter varied with agitated spots. The yellow-crowned thrush of Latham. Found in Ceylon and Java.

ORIENTALIS. Black; beneath white; rump cinereous; ocular band black; three tail-feathers on both sides externally white. Ash-rumped thrush of Latham. In India.

NIGERRIMUS. Wholly black; feathers yellow at the margin; cheeks and throat holosericous. The black-cheeked thrush of Latham. Found in Madagascar.

HISPANIOLENSIS. Olive-coloured; beneath varied from olive to grey; brown tail-feathers, whitish at the interior margin, olive at the exterior; with the intermediate altogether olive. The Hispaniola thrush of Latham.

ALBIFRONS. From black to lead-coloured; beneath yellowish; with the spot on the front white; and brown legs. The white-fronted thrush of Latham. There is a variety black; beneath white, tail beneath cinereous. Found in New Zealand.

CAPENSIS. Brown; abdomen yellowish; vent yellow. A variety has the head and tail black. Found at the Cape of Good Hope.

ATRICAPILLUS. Brown; black head; abdomen and rump red; spot on the wing white. Found at the Cape of Good Hope.

MAURITIANUS. From greenish to deep blue; the feathers of the head and neck narrow and long; bill cinereous; and legs lead-coloured. The Mauritian thrush of Latham.

MINDANAENSIS. Steel-coloured; beneath white; the longitudinal band of the wings white; tail subcuneated. The Mindanao thrush of Latham.

MADAGASCARIENSIS. Brown; abdomen and vent white; tail subfuscated; two intermediate tail-feathers wholly, and the rump at the external margin green-gold; the exterior margin of the outmost on both sides white. The Madagascar thrush of Latham.

SENECALENSIS. From grey to brown; abdomen whitish; bill, tail-feathers, tail and legs brown. The Senegal thrush of Latham.

LONGOSTRIS. From olivaceous to pale-brown; beneath pale sulphureous; rump and eye-brows yellowish; tail round and yellow; intermediate tail-feathers brownish. The long-billed thrush of Latham. Found in the islands of Eimeo and York.

GREIUS. Grey; crown and neck whitish; breast, abdomen and vent from very pale red to grey. The grey thrush of Latham. Found in Coromandel.

PALMARUM. Green-olivaceous; beneath sub-cinereous; black head, with three white spots on each side. The palm thrush of Latham. There is a variety, viz. merula palmarum atricapilla; found among the palms of Cayenne.

MONACHA. Above yellow, with brown; beneath yellowish; black head; terminating with black on the breast acetly. The nun thrush of Latham. Found in the woods of Abyssinia.

ÆTHIOPICUS. Black; beneath white; with a transverse white band on the wings; tail round, tail-feathers quadrated at the apex. The Ethiopian thrush of Latham. Found in the thick woods of Abyssinia.

ABYSSINICUS. Brown; beneath yellow; brownish throat, and black legs. The Abyssinian thrush of Latham.

COCHINCHINENSIS. Green; with blue spots on both sides at the base of the bill; face, chin, and throat black; the latter encompalTed with a yellow arc. Found in Cochinchina.

CINAMOMEUS. Beneath more diluted cinnamon; throat, legs, temples, checks, chin, covers of the wings, and breast black; with white nebulous wreath. The black-breasted thrush of Latham. Found in Cayenne.

RUPIFRONS. Brown beneath, and the front and temples red; vent white; tail and legs cinereous. The rufous thrush of Latham. Found in Cayenne.

CANTANS. From red to brown, varied with transverse black or blackish streaks; beneath whitish; chin, checks, and
and throat from red to orange; with black area, spotted with white on both fides of the neck. Mu[cion thrufh of Latham. In the recesses of the for[eets of Cayenne.

Coraya. Red-brown; beneath more diluted; vertex and fides of the head and neck black; tail grey, varied with blackish lines. The barred-tailed thrufh of Latham.

Fuscipiers. Cinereous; beneath red; vertex black; legs and tail-feathers brown; tail sub-cuteneate. The buff-winged thrufh of Latham; fupposed to be found in Cayenne.

Alapi. From olive to brown; throat and breast black; abdomen cinereous; tail wedge-formed, blackish. The white-backed thrufh of Latham. In Guiana.

Cirrihatus. Cinereous, with wedge-formed tail, white at the margin and apex; cremated crown; throat varied with white and black; breast black. The black-crested thrufh of Latham. Found in Cayenne.

Tintinnabulatus. Vertex and temples white, spotted with black; eye-brows black; chin white; incarnated breast spotted with black; back, wings and tail brown; rump, abdomen and vent from red to orange. The chinning thrufh of Latham. Found in Cayenne and Guiana.

Bambula. Spotted; above from red to brown; beneath cinereous; wings black; with a white tranfive band. The black-winged thrufh of Latham. Found in Cayenne.

Auritus. Varied from red and olive-coloured; beneath white; vertex and wreath from red to brown; chin and throat black; feathers near the eyes, and at the fides of the neck, fshing-white; elongated and more wide. The white-earred thrufh of Latham. Found in Cayenne.

Colma. From red to brown; beneath cinereous; chin and throat white, spotted with black; breast from grey to brown. The rufous-napped thrufh of Latham. It has a variety from black to brown; the occiput and neck red. Found in Cayenne.

Tinniens. Above brown; beneath white; breast spotted with black; equal tail. The alarum thrufh of Latham. Found in Cayenne.

Lineatus. From olive to brown; chin, throat and breast white; the latter spotted with brown; the fides of the neck marked with white lines. The speckled thrufh of Latham. Found in Cayenne.

Formicivorus. Above from red to brown; beneath cinereous; chin, throat, and breast black; band varied with white and black. The ant thrufh of Latham. Found as the former.

Cyannus. Spadiceous; beneath varied with blue and yellow tranfive alternate freaks; vertex at the nape to the quill-feathers and ocular band black; another orange; pectoral band and wedge-formed tail blue. The blue-tailed thrufh of Latham. In Guiana.

Rex. From red to brown; beneath more dilute; oc[ciput lead-coloured; front varied from white to brown. The king thrufh of Latham. Found in South America, particularly Guiana and Brasil.

Sinensis. Reddish; head brown ftriated; white eye-[brows; tail-feathers marked with obscure brown freaks, and legs yellow. The Chinese thrufh of Latham. Found in China.

Arcuatus. Above spadiceous; with eye-brows, col[lars, chin and vent white; cheeks and bow of the throat white; tail rounded, black towards the apex; apex white. The cresent thrufh of Latham. Found in China.

Melanopis. Grey; back and wings from green to brown; orbits, chin, and throat black; spot on the ears white. The black-faced thrufh of Latham. In the woods of China.

Violaceus. From violet to blue; feathers of the head, neck, breast, and covers of the wings fteel-faciated at the apex; bill and legs black. Found in China.

Leucocephalus. Grey; black quill-feathers; the fifer with the covers of the wings and tail green-brayly and fshing-violet. The white-headed thrufh of Latham. In China.

Nigriceps. Brown; head, chin and nape white; ocular band and breast yellowish; neck, back and tail-feathers black; tail wedge-formed, lead-coloured. The black-necked thrufh of Latham. Found in China.

Bulul. Of the colour of terra umbra; longitudinal band near the eyes black. The chanting thrufh of Latham. Found in the southern part of China.

Perspicillatus. With head and neck cinereous; front and ftrake under the eyes on both fides black; body above from greenish to brown; beneath ochreous. The spectacle thrufh of Latham. In China.

Flavus. Yellow; white orbits; band from upper mandible produced near the eye black; bill and legs red. The yellow thrufh of Latham. In China.

Viridis. Green; with eye-brows, spot below the eye, abdomen and vent white; throat grey, spotted with white; breast reddish. The green thrufh of Latham. In China.

Atra. From grey to brown; beneath from greenish to yellow, spotted with black; bill, legs, front, face, chin, and throat black; the latter with a red margin. The black-throated thrufh of Latham. In the island of St. Domingo.

Dominicus. Brownish; beneath white; with the principal tail-feathers white at the base; the three outer tail-feathers white. The St. Domingo thrufh of Latham. Found in St. Domingo and Jamaica.

Brasiliensis. Black; beneath from ferruginous to yellowish; rump ferruginous; tail sub-cuteneate; outermost tail-feathers wholly, the rest at the apex, white. The yellow-bellied thrufh of Latham. Found in Brazil.

Merula. Black; with bill and eye-bids yellow. The blackbird of Pennant, Ray, Willughby, and Latham. Of this there are the varieties of merula leucocephala of Buffon, merula varia of the fame, or pied blackbird of Albinus, and merula alba of Baffon. Found in the woods of the temperate parts of Europe.

Aurantius. From blackish to brown; throat and abdom[en whiti; bill and legs orange-coloured. The thrufh of Sloane and Ray; the white-chinned thrufh of Latham. The varieties are, merula gula fusca, merula nigra, and merula americana. Found in the woody mountains of Jamaica, in New Caledonia, in Surinam, and the warmer parts of America.

Labradorus. Shining-black; with a blue and green tint; bill and legs black. The Labrador thrufh of Pennant and Latham.

Torquatus. Blackish, with a white wreath, and bill yellowish. The ring-onzel or amulet of Pennant, Ray, Willughby, Albinus, and Latham. The varieties are, merula torquata alba, merula torquata albo-maculata, merula albo-maculata, non torquata. Found in Europe, Asia, and Africa.

Saxatilis. Brown; beneath ffordly orange, undulated with brown and white; rump ferruginous; chin white; throat and intermediate tail-feathers brown, the latter in the margin; fde ones wholly orange. The greater red-bird of Willughby, and rock thrufh of Latham. Found in Italy and Spain.

Eremita. With whitish orbits; olivaceous vertex; the upper feathers of the occiput brown, near the whitish apex black-banded, and the lower ones from red to white; brown at the margin; and cinereous rump. The hermit thrufh of Latham. Found in the Philippine isles.
Turdus Manillensis. From cinereous to blue; blue-rump; tail-feathers and tail red at the margin, blackish; throat and breast spotted with yellow; abdomen orange-coloured, undulated with blue and white. The penive thrush of Latham. Found in the Manillas.

Turdus Solitarius. Brown; spotted for the most part with white and blackish tail. The solitary sparrow of Ray and Willoughby, and solitary thrush of Latham. Found in France, Italy, and the islands of the Mediterranean and Archipelago.

Turdus Cyvanus. With feathers cinereous-blue at the margin; mouth and eye-lids yellow. The Indian mock-bird of Ray, the solitary sparrow of Edwards, and blue thrush of Latham. Found in Canda, the Archipelago islands, and the rocks of Italy.

Turdus Arundinaceus. Brown-ferruginous; beneath whitish-tea-faces; with tail-feathers banded and reddish at the apex. The junco of Gersen, Aldrovan, Ray, and Willoughby. The varieties are T. arundinaceus, with red rump and tail; the T. arund., above varied with black darts; and left T. arund., above yellowish to green; with covers of the wings ferruginous. Found among the reeds of Europe.

Turdus Morio. Shining-black, with the greater tail-feathers red, and apex black. The African thrush of Latham. Found at the Cape of Good Hope.

Turdus Bicolor. Brown tinted with green; abdomen and vent white. The white-rumped thrush of Latham. Found as the former.

Turdus Erythropterus. Black, with red wings; wing-covers and lower quill-feathers of the tail, the intermediate excepted, white at the apex; tail wedge-formed. The Rufous-winged thrush of Latham. Found near the Senegal river.

Turdus Chrysogaster. Green tinted with orange; beneath orange; bill and legs brown. The orange-bellied thrush of Latham. A variety is from blue to green; beneath orange. Found near the river Senegal, and at the Cape of Good Hope.

Turdus Urovang. Cinereous; vertex greenish-black; rest of the head, neck, breast, and body above varying to olive-coloured; the abdomen and creast yellowish. The cinereous thrush of Latham. Found in Madagascar.

Turdus Surinamus. Shining-black; vertex, rump, and lateral spot on the breast yellow. The Surinam thrush of Latham.

Turdus Columbinus. Green, reflecting different farts of colours; the rump and vent sometimes white. The pigeon thrush of Latham. Found in the Philippine isles.

Turdus Dominicanus. Above brown; here and there tinted with violet and steel; beneath from brownish to white; tail steel-coloured at the base, greenish towards the apex. The Dominican thrush of Latham. Found in the Philippine isles.

Turdus Cantor. From greenish to black, shining-blue and violet; with tail-feathers and tail black. The song thrush of Latham. Found as the former.

Turdus Malabaricus. Shining-green; yellow front; throat, bill and legs black; covers of the wings and strike on the lower mandible blue. The yellow-fronted thrush of Latham. Found in Malabar.

Turdus Seleucia. With bill and legs yellowish; abdomen and back incarnate; tail, wings, and thighs brown. Found in Smyrna.

Turdus Zeylonus. Green; beneath yellow; ocular line on both sides extended as far as the black breast. The Ceylon thrush of Latham. Found at Ceylon and the Cape of Good Hope.

Turdus Aquaticus of Brissom. See Tringa Macularia.

Turdus Chiapae, the name of a bird of the west Indies, called also paffar heter.

Turdus in Ichthyology, the name of a genus of fishes, according to Mr. Ray, of the class of those which have only one back-fin, the anterior rays of which are prickly; the hinder ones soft and smooth.

If these fish there are several species, which may properly be divided into two orders; the first, of those which are smaller and broad; the second, of those which are larger and oblong.

Of the first order are the tinea marina, or secrwaff (see Labrus Tinea); the merula, or turdus niger (see Labrus Merula); the leprous, and pita picta; and the turdus viridis, or verdone. Ray's Ichthyogr. p. 320.

Of the second order are the pavo, or peacock-fish (see Chletoon Pavo); and the turdus viridis major, and turdus sphenus maculosus.

The turdus viridis major, or great green wraase, is of a fine green on its back and sides, even to the side-lines; and the lower part of the sides and belly are of a pale whitish yellow, variegated with greyish and pale blue spots; its body is long, and not much unlike that of the pike in figure; its back-fin is long, and has thirty-two ribs, the anterior nineteen of which are rigid and prickly, the hinder twelve soft, flexible, and ramose; the scales are large, the eyes small, and the teeth very large and strong.

The turdus sphenus maculosus, or brown spotted wraase, fearlessly at all differs from the others, except in colour. It is of a dusky hue on the back and sides, variegated with blue spots; and on the belly blue, with lines and spots of red. All the fins, except those of the gills, are of a red colour, spotted with blue; the tail also is of this colour, and the gill-fins are yellow. Ray's Ichthyogr. p. 332.

Turdus Ocelo Radiato of Catelby. See Sparus Radiatus.

Turdus Primoris Branchialeus of Carsen. See Labrus Griseus.

Turdus Flavus. See Labrus Rufus.

Turdus Turecuato, in Geography, a town of Mexico, in the province of Mechoacan; 60 miles W. of Mechoacan.

TUREE, a town of Bengal; 40 miles S.S.E. of Curruckdeah. N. lat. 24° 30'. E. long. 86° 57'.

Turenberg, a town of Prussia, in Samland; 16 miles W.N.W. of Königsberg.

Turenne, Henri de la Tour, Fifteenth of, in Biography, a famous general, was the son of Henry de la Tour d'Auvergne, Duke of Bouillon, by Elizabeth, daughter of William I. prince of Orange, and born at Sedan in 1611. Defined from his childhood to the military profession, his education and habits were conducted and formed with this view. Having acquired the necessary qualifications, he was placed, in 1634, at the head of a French regiment, in which post he acquitted himself with honour; and having pursued a career of distinguished services, cardinal Richelieu, in 1639, offered him one of his nieces in marriage; but his attachment to the reformed religion led him to decline the proposal. After he had served 17 years in Italy and elsewhere with fingular reputation, he obtained, in 1644, the staff of marshal of France, and was entrusted with the command of the army in Germany, the wants of which he supplied out of his own purse. When the war of the Frond broke out in 1649, he withdrew to Holland, but afterwards returned and engaged with the party opposed to the court. In this connection he was defeated near Rhetel in 1650; and when asked how he had lost this battle, he replied, "By my own fault; but when a man commits no faults in war, it is because he has not been long engaged in it." In 1651 his difference with the French
French court was accommodated, and he was appointed general of the royal army. In 1653 he married the daughter of the marshal duke de la Force, a Protestant, but, constantly making the Conde, in the service of Spain, Turenne in 1657, having gained the battle of Dunes, captured Dunkirk from the Spaniards, and the greatest part of Flanders; so that Magazine was enabled to make the peace of the Pyrénées. Upon a renewal of the war with Spain in 1667, Lewis XIV. made choice of Turenne, now marshal-general of the French armies, as his tutor in war; and the result of the first campaign was the conquest of the greatest part of Flanders, and afterwards of Franche Comté. In the following year, Turenne, from motives not satisfactorily ascertained, but not redounding much to his honour, abjured Calvinism, and was reconciled to the church of Rome. In the year 1672, it was determined by Lewis to conquer Holland, and the command of the army was assigned to Turenne; to whose arms reliance was in the course of the campaign intellectual. The elector of Brandenburgh, proposing to relieve the Dutch, was pursued to the gates of Berlin, and obliged to sue for peace. When at this time it was proposed to the marshal to gain 400,000 livres without the knowledge of the court, he thanked the general officer who made the proposal, and told him, that as he had often declined such advantages, he did not intend to alter his conduct at his age. On another occasion, a considerable city offered him 100,000 crowns for not passing through its territory; and his reply to the deputies was, "As your city is not in my proposed line of march, I cannot in confidence take your money." We should exceed our limits, if we detailed his various successful movements during the following campaign. The soldiers repented confidence in their commander, and to this confidence he owed the proper success of various expeditions. The glory of his conquests, however, was tarnished by his cruel devastation of the Palatinate, which Voltaire has justly reproved; observing at the close of his account, that "he rather chose to be called the father of the soldiers that were entrusted to him, than of the people, who, according to the laws of war, are always made the sacrifice." The imperial court, determined to make every possible effort to check the progress of Turenne, called forth Montecuccoli, his best general, to oppose him. As these two masters of war were preparing for an engagement, Turenne, whilst he was reconnoitering a fit place to fix a battery, on July 27, 1675, was struck by a cannon ball, which killed him on the spot, in the 64th year of his age; and with him terminated the good fortune of the French in that campaign. His remains were interred with the highest funeral honours at St. Denis. The greatness of Turenne's soul was disguised by a rude and vulgar appearance. His temper was cool, and his manners modest and unassuming. He was not always successful in war, and committed faults, which he had the magnanimity to acknowledge; but, as Voltaire says, "(Age of Lewis XIV.)" "by always repairing them, and doing much with small means, he passed for the ablest general in Europe, at a time when the art of war was more fluid than ever before. Though he was reproached for his defection in the war of the Fronde; though at the age of near fifty, love caused him to reveal a state-secret; though he exercised cruelties in the Palatinate, which seemed unnecessary; he preferred the reputation of a man of worth, wise and moderate, because his virtues and great talents, which were his own, covered weaknesses and faults which were common to him with so many other men." Ramfay, in his "Life of Turenne," mentions the following anecdote, as an instance of his strict performance of a promise. Being attacked one night by robbers near Paris, and stripped of his money, watch, and rings, he engaged to give them 100 louis d'ors, if they would return him a ring, of no great worth, but which he highly valued. The highwaymen complied; and one of them had the boldness to go to his house the succeeding day, and in the midst of a large company to demand, in a whisper, the performance of his promise. The vicount gave orders for the money to be paid, and suffered the villain to escape, before he related the adventure.

Turenne, in Geography, a town of France, in the department of the Corrèze; before the revolution, the capital of a vicounty; 9 miles S. of Brive.

Turevskoi, a town of Russia, in the province of Ufling, on the Vim; 65 miles N.E. of Yarenk.

Turf, in Agriculture, a term often used to signify the green sward or surface of grass-land. It is of great use and importance to the farmer to have the turf of such land close, firm, and well set, as where this is not the case, it soon declines, grows thin, and becomes of little value either for the purpose of mowing or pasturage. It has been noticed, in the "Georgical Effays" of Dr. Hunter, in speaking of the improvement of the turf of poor pasture land, that, on such, it constantly gets worse a few years after having been laid down for that purpose: the cause of which is plainly this. There are a few fairy grasses, natural to moist poor lands, which are denominated natural grases; while those from the seeds of clover, and others of similar kinds, which are introduced, are in general termed artificial. The roots of these latter are not very durable, especially on poor land; and as the cattle as well as other forts of live-flock are greedy of such fown grases, they constantly crop them, and prevent their going into seed, by which the land is deprived of fresh supplies of young plants; whereas the former fort, or the natural grases, being, in general, much inferior to the other in quality, are refuted by fuch flock, and the land, consequently, soon becomes plentifully focked and provided with them.

It is suggested too, that the general method of practice for improving land, when the turf gets thin and bad, is to bring it under a course of tillage. But when that is not proper or convenient, or when the occupier of such land is not inclined to introduce this mode, it may be greatly improved by having fresh seeds of the grass fort fown upon it; the best seefon for which is in the beginning of the first spring month. The ground should fift be well wrought over with a heavy harrow of the buff kind, which will bruft up and rafe the foil, and prepare it well for the fiking of the seeds in it. Compost earth should then be used as a dressing, and the seeds fown therfon; after which the ground may be lightly brufted over again, and well rolled. When the fefon proves moist and kind, the seeds will be found to thrive to admiration, and to wonderefly improve both the turf and verdure. And where the turf of land has been greatly cut up by carriages, or much trod up by cattle, it is also capable of being improved in this way, without the dressing of compost earth. Even in paddocks where the turf of the land has been cut up to an extreme degree by rude and wanton horses, a new and verdant turf has been seen to arise, even to amazement, in a few weeks after fowing the seeds. It is, however, necessary that cattle should be prevented from coming upon the land until the turf get well set, and in a firm state.

The turf, in all forts of land, may be greatly benefitted by
by the proper use of manure upon it, and at the same time properly feeding it down with suitable kinds of live-flock. See Grass, Grass-Land, and Grazing.

Turf is likewise a term applied to a blackish fibrous vegetable earthy substance, which is used in many parts of the country as fuel. It varies considerably in its nature and composition in different places, being, in some cases, hard and of a dark or black colour, while in others it is soft and very spongy, and of a brownish colour. It is cut and formed into turves for the purpose of fuel, by means of a particular fort of instrument, employed in a certain manner. See Turfing Spade.

It is a substance which is not only very useful in this way, but for burning calcareous flones into lime, and many other purposes in agriculture.

Turf or peat-earth is capable of extensive use as a manure, but it mostly requires some preparation to properly fit it for this sort of application; as it is found that it is a substance which is held together partly by the intertexture of its fibres, and partly by its natural viscidity; and that when it is allowed to dry steadily in that state, it becomes almost incorruptible; and that it does not yield food to growing vegetables, unless its natural conformation be destroyed, and its parts separated by the intervention of other substances. This strongly shews that its structure or texture should be somehow broken down and reduced, and the water which it originally contains be forcibly discharged from it, as soon as possible after it is taken from its native bed, in order to prepare it for manure. There are different methods of effecting this. It has been suggested, that as this sort of fibrous matter will not ferment unless some substances are mixed with it, which act the same part as the mucilage, sugar, and extractive or albuminous matters, with which it is usually associated in herbaceous and succulent vegetables; a mixture of common yard-dung has been lately properly recommended for the purpose of bringing turf or peat-earth into fermentation; any putrefiable or fermentable substance will, however, answer the end; and the more a substance heats, and the more readily it ferments, the better it will be fitted for the purpose. In forming this mixture, it is flated, that one part of dung is sufficient to bring three or four parts of the turf or peat into a state in which it is fitted to be laid upon land; but that, of course, the quantity must vary with the nature of the turf and the dung. In circumstances where some living vegetables are mixed with the turf or peat, the fermentation will be more readily accomplished.

Turf or peat of this sort, after being reduced in its parts, may also be prepared for this use by being soaked in the urine of cattle, in putrid water, and other such liquids; likewise by the action of lime, and by being ridged up and mixed in the manner below.

This material, both in mixture with dung and lime, has been used with great success and advantage in Cheshire. The method of preparing it there, in the practice of some, is, before the winter sets in, to trench and throw it up into narrow ridges, that it may be dried and reduced into a powdery state by the action of the atmosphere. After some time it is turned over and laid flat, being then usually found much lighter than when first dug up. It is now covered over with dung, in the proportion of a fourth or fifth part of the weight, and left so for about three weeks, when it is turned over, mixed perfectly with the dung, and thrown into heaps. A fermentation commonly soon takes place, that varies in its duration in proportion to the moisture in the turf. When it has subsided, the mixture is turned over again, as before, and the turf or peat at the same time broken very small, that it may mix the more intimately with the dung. This often produces another fermentation, more powerful than the first. The mixture is mostly ready for use in the beginning of the spring, if lime be used, the quantity is very much less than that of the dung, but the proceeds otherwise much the same.

If, for this purpose, the turf or peat were thrown up in long narrow ridges, and a little quicklime dusted between the different layers, it would, it is supposed by some, expedite its separation, and dispose it sooner to incorporate with putrid matters.

This substance has likewise been used with great benefit in both of these mixtures, as well as in its simple reduced slate in different instances, in Lancashire, by Mr. Pateron and others. See a paper in the third volume of the Transactions of the Highland Society of Scotland, and Lord Meadowbank's Directions.

Turf, in Gardening, the green surface or sward cut from pastures, &c. for the purpose of laying down grass-grounds; as lawns, plats, bowling-greens, banks of pieces of water in pleasare-grounds, &c.

It is flayed off with the turfing-iron, in regular lengths of two or three feet, and a foot wide; and being properly laid down close and regular in the places intended, it immediately forms an even swarded floor, which quickly strikes root in the ground, in proper growth and verdure. This sort of work may be performed any time in autumn, winter, and spring, in open weather, or occasionally in summer, in a moist season; but the autumn is the best season. The belt turf is mostly procured from fine cloe-feet pastures, commons, or downs, &c. where the sward is close and even; or that of any sward-field of similar close, firm sward, where the grass is not rank and coarse, nor abounding in weeds, or much over-run with the common wild daily, dandelion, or other similar plants.

In the operation of cutting the turf, a line should be drawn tight lengthways of the grass-ground, and then the cutting-racer be strucken into the surface of the sward, close to the line, pulling it along so as to cut or score the sward in a straight cut the length of the line, about an inch and half deep; and having thus raced out one length, the line should be moved a foot and a half further to face out another length as before, proceeding in the same manner to a third, and so on to as many lengths of the line, in foot widths, as may be necessary; then, by the same means, the sward is to be raced crof-sways in yard distances, and thus the proper lengths and widths are formed. After the sward has been thus raced out, it should be flayed, or cut up with the turfing-iron, beginning at one side, cutting evenly longways the whole length of each raced line, about an inch or inch and half thick; a person following immediately after to roll them up separately in yard lengths, grass-side inward, as close and tight as possible; having thus cut up one range, proceed with another in the same manner, and so continue with the whole. As the turfs are rolled up, they should be piled close and regular together, ready for carrying away. When cut by the hundred, as is often the case where large quantities are required, they are commonly piled up in tens; four below, three next, then two, and one at top, for the more ready reckoning of the number wanted.

In performing this sort of work, it is constantly necessary to keep a steady hand, in order that the turf may be cut all of an even regular thickness without any sort of lumps, or roughness; which renders it less difficult and troublesome to lay down, as such lumps cause many inequalities that can-
not be easily made level, but require so much beating as often to greatly injure and defray the turf, as well as to be productive of a great waste of time and labour, thereby causing a great deal of unnecessary expense. Besides, such work under these circumstances can never be done so well as where the contrary is the case.

**Turf-Ashes**, in Agriculture, those formed from any sort of turfy or peaty matters. Turf-ashes have been used as a manure on poor thin soils, in some districts, with great effect and advantage; and for potato crops; but they are probably, in general, the best when employed as top-dressings for grasses and certain kinds of crops. See Top-Dressing.

The ashes formed from turf or peat in Berkshire have lately increased greatly in value, in consequence of their general application as a top-dressing to clover and other sorts of artificial grasses, as well as to tares, turnips, and occasionally wheat in the young state of its growth. The usual time of applying them is the very early spring. They are there commonly taken in carts, and fown by the hand over the ground, either before or after the feed for the crop is fown. But when used only as a top-dressing, they are merely sown on the surface of the land evenly by the hand. The quantity made of is mostly from twelve to fifteen flatulate bushels to the acre, as the soil and crops may be. It is believed, that too large quantities would be hurtful. Some do not hold them in much estimation for grain crops, or those of the pea kind; but they are preferred to all other manures, especially for all sorts of artificial grasses. In turnip crops, they are said to afford much in preventing the ravages of the fly; and in those from the seeds of grass, the farmers suppose, that on an acre which is manured with them, the produce in hay will be nearly a ton more than what it would have afforded without them.

On meadow-land too, in some cases, from fifteen to twenty bushels of these ashes may be laid with great improvement to the grasses. The effect of them is supposed to be of longer duration than two years.

Several acres may be gone over with the sowing of the ashes in the course of a day, by one person and a two-horse cart. See Ashes and Sulphate.

**Turf-Dressing**, a term applied to that sort which is formed in turfy situations, and filled with turves or peats; and which is done in an useful, neat, and successful manner in many districts, especially in Lancashire, as may be seen in the corrected agricultural report of that county. It also signifies a sod-drain. See Surface-Drain.

An improved mode of turf or sod-draining may likewise be met with in the report on agriculture for Cheshire.

**Turf-Hedges**, that fort of fence which is formed by means of fods, or the dug-up turf, and plants of different kinds. For turf-hedges that are to be fix feet high when finished, fix-feet bales are allowed in some places, as in Cornwall; and as they lettle a good deal, half the height is only built at a time, with the filling well ridged up in the middle to throw off the wet. This remains to lettle perfectly, when the other half is laid, and the proper plants or cuttings put in. This is thought to be an improvement in the forming of this sort of fence. See Fence.

**Turf-Houses**, in Rural Economy, that fort which is formed of the turf cut from land, and which is common in the northern parts of the island.

**Turf-Mats**, or Bog, a term applied to a tract or extent of turfy, mossy, or boggy land, from which turf is cut, or which stands in need of being reclaimed and brought into order by suitable draining, and the proper application of weighty earthly substances of different kinds. See Bog, Moor, and Moss.

**Turf-Spade**, a tool of this kind, which is used in cutting turf for fuel. It is about four feet in length with the handle, and four inches in breadth, being made sharp in the mouth-part, and having an ear or sharp iron on one side of it, which is bent or turned up to a right angle, that serves to cut and separate one side of the turf from the bed of turfy matter, as the back and mouth of the implement do the other.

The work of cutting the turves for burning by means of this spade, is performed somewhat in this manner: the ground being first marked out on the surface in a straight line, of a length at pleasure, and between three and four feet in width, is then dug level on the surface with a common spade, the whole of the bad and imperfect turfy parts being removed. The turf is then cut by a person standing in the pit or ditch, with the narrow spade described above, which is laid at the lower end with iron, as has been said, in a sharp manner. By this means every turf is cut and formed into a long fort of square, which is then taken from the workman, and spread on the ground in a close manner, until dry, when they are set up on end, three or four together, and afterwards put up into windrows and small flacks, till ready to be led or carried home for use.

The spade which is made use of in cutting the turf or peat for being reduced into ashes in Berkshire, is somewhat of this form too, but it has a considerably greater length of the mouth-part. The turf or peat, when dug by it, is carried from the spot in little wheel-barrows, to a short distance, where it is spread on the ground, and after lying some days, the pieces are turned, which after being several times repeated, a heap is made of it, in the middle of which dry turf is put, which is set fire to, and the whole slowly burnt, additional quantities of turf or peat being occasionally supplied, so that the burning may be slow and smothering. The heap is mostly of a circular form, and rather flat at top, being small at first, but ultimately sometimes two or three yards in depth, and fix or seven in diameter.

The remaining materials, when passed through a riddle, are taken away, in a covered manner, to great distances.

**Turf-Sweating**, an Indian method of curing deficiencies, which has been found to succeed very happily on many trials.

Paul Dudley, esq. gives an account of a man of seventy-four years old in New England, who drinking cold water when very hot, had a painsettled in one side and arm, which baffled all art to remove; till after nine weeks' confinement to his bed, when he was given over by every body, it was proposed to try this method of cure upon him.

An oven full of turf was ordered to be cut; the turves were of about eighteen inches square each, and were of the nature of the English turf used in gardens.

The Indian doctor, before the turf was put into the oven, rubbed over their grassy side with some sort of oil or spirit, and then putting the two grafs sides together, placed them in the oven. When they had been two hours there, and were well baked, he took them out, and made a bed upon the floor, the place for the head being a little raised; the old man was then taken out of bed without his shirt, but wrapped in a sheet, and being laid on the turf-bed, such another parcell of the hot turf was laid over him. The turf was laid thickest on that side where the pain was, but none of it was put on his breast or head.

He was then covered with a blanket to keep in the heat; and while he was in this warm bath, he was continually supplied with warm cordials to keep him from fainting, of which he was in great danger. After he had lain in this bath about three quarters of an hour, which was as long as he
he could bear it, he was put into a bed very well warmed, without his shirt, where he soon fell asleep, and sweated to that degree, that it ran through the pillow and bed on the floor. After about two hours' sweat, they rubbed and dried him, and put on his clothes, and the old gentleman found himself much eated and refreshed. The operation was performed in the morning, and before night he walked about the house comfortably, his pain being almost all gone. The cordials were, after this, repeated, and, on the fourth day, the sweating was performed again; the day after which, the old gentleman was well enough to go about his business. He lived eleven years afterwards in perfect health, and free from pain.

Great care is to be taken in this operation that the patient do not lie too long in the turf: in many cafes, a quarter of an hour is found to be long enough; and the general rule is, that as soon as the patient begins to hitch his breath short or faint, he must be put to bed immediately, and the cordials must by no means be omitted, for the life of the patient is endangered without them. Phil. Trans. № 384, p. 129.

TURFAN, in Geography. See Taurfan Hutan.

TURFING, in Gardening, the operation of laying down turf. In preparing the ground for this purpose, it should, where loose, be well trodden, or occasionally rolled and rammed; then be properly levelled on the surface with the fpade, and afterwards raked smooth; when it will be ready for laying. In laying the turfs, they should be unrolled regularly on the ground, each in its place, making them close edge to edge, so as to form at once a close even fward; beating the whole down close and even afterwards with a heavy wooden beater, to settle the roots of the grafs close to the earth, as well as to form the surface equally close, firm, even, and smooth; the turf thus soon strikes root below, and grows above, without any further care in this part of the business, except occasionally beating down any swelling inequalities, and sometimes rolling it with a heavy iron roller. Sometimes, when turf is laid in the summer, or in the early part of autumn, in dry hot weather, it will shrink and open considerably at the joints, and assume a decayed-like appearance. In this case, a few good waterings would be serviceable; but should this be omitted, the first heavy rain will mostly recover the whole effectually, and swell the fward, so as to close all the chafms, and revive the verdure of the grafs plants, when a heavy rolling should be given, to settle the whole firm and even, and to give the surface a neat appearance. The principal circumstance to be regarded in this sort of work, is to have the surface of the ground well levelled before the turfs are laid down, for where this is neglected, it is utterly impossible to do the business so as to look well.

In respect to the after-culture of ground formed with turf, it is chiefly to give occasional mowings, from the spring through the summer till October, and occasionally rolling and rolling the surface to keep it even and level. The mowings in these cafes should constantly be performed before the grafs gets to too high a growth, so as to injure the surface appearance by rendering it tender and of a bad colour.

TURFING-Iron, an implement made use of for flaying or cutting up grafs, turf, or fward from land for the purpose of turfing; it is formed with an iron plate for the cutter, from 6 to 10 feet or eight inches wide, a little rounding forward at the edge, which is thin and sharp for cutting, but thickening gradually behind to the upper part, where it is forged to a long bent iron handle, the bending of which formed as to admit of the plate or cutter rolling flat with its back on the ground, in the proper position for readily cutting or flaying the turf or sward evenly off, of a regular depth or thicknigh; the handle at top being either formed of iron, with an opening like the top of a fpade, or a socket in which to fix a short wooden handle of that kind. In using it in cutting the turf or sward, the workman takes hold with one hand in the top handle, the other below, with the latter guiding the tool in the proper position, while the upper hand is placed against his knee, &c. which affists him in thrusting it forward into the ground evenly under the sward; and thus he proceeds along in a regular manner, moving the tool gradually along at each stroke, level and even, at an equal depth. Thus, as one range of turf or sward is pared off, another is begun with until the whole work is done.

It is necessary that the edges of the cutting iron should be well fleeced, and ground perfectly sharp, as the labour by such means is rendered much less, and the work far better performed.

TURFING-Spade, in Agriculture, the name of an implement used to under-cut the turf, after it is marked out with the plough, in the old practice of paring and burning the turfy surface of land.

TURGA, in Geography, a town of Bengal; 40 miles S. of Dofea. N. lat. 22° 22'. E. long. 85° 5'.

TURGANA, in Ancient Geography, an island on the coast of Arabia Felix, in which was a very magnificent temple dedicated to Serapis, according to Ammianus Marcellinus.

TURGESENCE, Turgescency, a swelling or growing bloated.

TURCHE, in Geography, a river of Wales, which runs into the Cothby, in Caermarthenshire.

TURGOT, ANNE-ROBERT JACQUES, in Biography, an enlightened and patriotic minister of state, was born at Paris in the year 1727, and studied theology at the Sorbonne, where, in his 22d year, he delivered two Latin discourses, "On the Advantages derived to Mankind from the Christian Religion," and "On the Progress of the Human Understanding." At the age of 24 he translated Virgil's Georgics, and thus a change took place with regard to the direction of his studies; so that he became attached to the principles of Quesnay, and of the sect called Economists. Having quitted the Sorbonne, he was appointed intendant of Limoges; and in the course of twelve years, during which he occupied this office, his conduct in distributing alms and providing a supply of food in a time of scarcity, and in introducing various improvements in the province, ennobled his character, and commanded for him great respect. With him, it is said, first originated the institution of charitable work-shops. As comptroller-general of the finances, he adopted various regulations, which, without injuring the revenue, encouraged industry, promoted agriculture and commerce, and lightened the burdens of the lower classes. Although many of his beneficial plans of reform were treated with contempt and ridicule, he succeeded to a considerible degree in ameliorating the state of the country. His resolution, diligence, and activity, overcame many obstacles and difficulties, infomuch that the benevolently disposed Lewis once said, on leaving the council-chamber, "No one loves the people but M. Turgot and I;" nevertheless, the cabals against him prevailed, and he was dismissed from the important office which he occupied with so much advantage to the people. As an incitement to his industry, he alleged, that in his family life was not protracted beyond the age of 50; and, therefore, having but a few years before him, he determined to leave nothing unfinished. Accordingly he died in 1781, at the age of 49. Of the pieces which
which he published, Condorcet has given an account in a "Memoir on his Life and Writings," 1782, 8vo. La Harpe has given us the following sketch of his character. He was a man of a strong mind, whom nothing could divert from justice, even at court, and in the highest places; of an unalterable equanimity, even in the midst of the oppressions and dignities of his ministry; of a laborious activity, which difeased could not slacken. He had only two passions, that of science, and that of the public good. During the few years in which he occupied the post of minister of finance, he bent all his views to the relief of the people. Attached to the doctrines of the Economists, he developed them in edicts which tended to the encouragement and improvement of agriculture. He was the first among us who changed acts of the sovereign authority into works of reasoning and persuasion; and it is perhaps a question whether this method may be useful or dangerous. His suppositions and reforms in the finance raised him many enemies; but among all who complained against him and reproached him, not one attacked his integrity. No one disputed the purity of his motives, but fault was found with his measures. Perhaps there was something unyielding in his character, which impeded the good which he wished to effect. Further, the courtiers could not pardon a minister who encircled himself with men of letters and philosophers. His innovations in favour of the people created a prejudice against him, on the ground of his being one of the promoters of the French revolution. Nouv. Dict. Hist. Gen. Biog.

TURGUT, in Geography. See DURGUT.

TURHUSSEY, a town of Bengal; 17 miles N.N.E. of Palamov.

TURIA, in Botany, an Arabic name, retained by Forckall, Fl. Egypt.-Arab. 161, and cited by Jussieu, Gen. 395, under Anguria. The above name, if wanted, might not be inadmissible; at least, if any such, of barbarous origin, are allowed to remain. But whether the five, partly doubtful, species on which Forckall has founded his genus be really entitled to stand alone, or whether they may be referrible, as Jussieu hints, to Anguria, or to any other genus of the Cucumber tribe, no one, concurring with Forckall's works, will, surely, venture to determine. He attributes a pentapetalous corolla to these plants, which is unexampled in their natural order, and which, by other parts of his account, appears to be an error. The villous cylindrical fruit, tapering at each end, and marked with ten furrows, will scarcely afford a generic character.—Forckall's first species, Turia of the Arabs, to which he has given no specific name, is cultivated in Yemen, but we are not told for what purpose. Some of the others are called, in that country, Lela or Lua, Giffij, and Mogabid.

TURIAMO, Bay of, in Geography, a bay of Caraccas, three leagues to the windward of Porto Cabello, which extends one league from north to south. Having no shelter from the north wind, and the country round it affording no commodities sufficient for inducing merchants to encounter its inconveniences, scarcely any ships resort to it. The cafe is the fame with regard to Patanemo, Baborura, and Sianega. The whole population of these bays consists of not more than a small party of soldiers, stationed there to prevent smuggling.

TURIN, a river of Sicily, which runs into the sea, 10 miles N.E. of Mirtettra.

TURIS, the Guadalquivir, in Ancient Geography, a river of Hither Spain, on the banks of which was built the town of Valencia.—Alfo, a river or torrent of Italy, mentioned by Silius Italicus (l. xiii. v. 5.), and thought to be the fame with that mentioned by Livy, and placed six miles from Rome. But the orthography is much controverted.

TURJA So, TARACOA, or Tarasoa, a town of the interior of Hither Spain, towards the south-west. Pliny speaks with high commendation of its iron. It was municipal. It was situated eaf of Numantium, and south-west of Calaguris.

TURICUM. See ZURICH.

TURIGA, a town of Spain, in Baetica.

TURIGA, in Geography, a river of Russia, which runs into the Nizni Tunguska, N. lat. 66° 12'. E. long. 98° 44'.

TURIN, a city of France, capital of the department of the Po, during the revolution, before and finance capital of Piedmont, situated at the conflux of the Po and the Grand Doria, about seven miles from the foot of the Cottian Alps, in the road from France to Italy, by the way of Mount Cenis. According to Pliny, the inhabitants derive their origin from the Ligurians, and were anciently called "Taurini." Hamilcar, the Carthagian general, when he invaded Italy, took and destroyed the town, because the inhabitants would not take part with him; which frightened the other people who inhabited the banks of the Po. It was erected into a Roman colony by Julius Caesar, who gave to it the name of "Julia," and it was called "Augusta Taurinorum" by his successor Augustus. It was successively subjected to the Goths, Huns, Eruli, and Burgundians, who ruined and destroyed it; but it was soon rebuilt, though not so large as before. When the Lombards became masters of the country, it became the capital of one of their principal duchies. Some of the dukes became kings of Italy. After Charlemagne had abolished the kingdom of the Lombards, Turin became subject to the marquis of Sufa, who had the charge of guarding the passages of the Alps, and continued in that family to the death of Ulric Manfred, the last marquis of Sufa, in 1502; whose daughter, Adelaide, married Odo, comte of Maurienne and Savoy. Turin submitted to him and to his descendants, who possessed it with little interruption till its union with France; before which Turin was the see of an archbishop, and was paid to contain 150 churches or chapels, several hospitals, and about 80,000 inhabitants. The approach to it is magnificent, and the environs beautiful, though thick fogs from the two rivers are frequent in autumn and winter; so that the air of Turin is then very thick and moist. The four gates are highly ornamental: the streets in the New Town are wide, straight, clean, having plenty of water running through them, well built, in a good taste, chiefly of brick succedee, and generally terminating in some agreeable object. No inhabitant could rebuild or repair his house but on an uniform plan, laid down by government, for the improvement of the city. The fortifications of Turin were regular, and kept in excellent repair. The citadel is a regular pentagon, confiding of five strong bastions, and is reputed one of the strongest in Europe. At the end next the new gate is the arsenal, which, besides the armories found in such places, contains a cabinet of minerals, a good chemical laboratory, a library of books in mineralogy and metallurgy, and furnaces for casting cannon; here, also, are mathematical, mechanical, and other matters, for the instruction of engineers, miners, &c.

The garrison of Turin was changed at the end of two years, and then there was a general review. The university was founded first in 1405; by Amadeo, duke of Savoy, and consists of schools, wherein the 24 professors read lectures, from the 3d of November to the 24th of June; the royal library, in which are about 50,000 volumes of printed books, besides manuscripts, is open every day,
day, except holidays, both morning and afternoon. The
royal museum has a good cabinet of medals, and a collection
of antiquities, found chiefly in Piedmont or Sardinia, and
elegantly arranged: also of natural history, as shells, and
English minerals, polished marbles, and hard stones, petrifi-
cations, corals, zoophytes, and fome minerals, collected by
Donati in the Adriatic; also, fome chefs of natural cu-
ricities, which Donati during his travels in Egypt and
Arabia, fent from Gea. In the military academy, young
gentlemen, both natives and ftrangers, might be instructed
in the exercises at a moderate expence, the king defraying
a part of the charge attending this institution. The palace
is in a fimple and noble style of architecture. The apart-
ments are handsomely fitted up and furnished; the ceilings
painted by Daniele di Sanfierre and others. They con-
tained a great collection of pictures, among which were
many good ones. The king's theatre, or great opera-houfe,
is reckoned one of the fnefl in Europe. The buildings
which are most effecfuen in point of architecture, are the
palace of the duke of Savory, called Castello Reale, by Fi-
lippo Giuvara; the Carignano palace, by Guarini; the
buildings of the university, and the town-houfe. There is
a literary society at Turin, which has published memoirs,
under the title of "Miscellanea Philofophico-Mathematica."
The chief trade of this city and country is in thrown flilk,
which is sent to England and Lyons; they manufacture,
however, fome of it into excellent flockings, and good flilk
for furniture. In the year 1736, Turin was taken by the
French, and again in the year 1849, after a long fiege.
In the year 1796, the fame enemy made another attempt; but
after besieging it upwards of three months, under the con-
duct of the duke of Orleans, they were driven away with
great lofs, by the duke of Savory and prince Eugene. In
December 1797, the French took this city, and levied on
the king of Sardini a contribution of 2,000,000 livres.
In May 1799, it was taken by the Autfrians and Ruffians,
and the citadel furrendered foon after. It was afterwards
furrendered, with the whole of the principality of Piedmont,
to the French republic, but restored after the revolution and
re-eftablifhment of the French government. N. lat. 45° 3'.
E. long. 7° 40'.
At Turin, accounts are kept in lire, foldi, and denari,
Piemonte fcurrency: 12 denari = 1 foldo, and 20 foldi
= 1 lira: accounts are also kept in francs and centimes, as
in France. The gold coins now in circulation are carlini,
of 5 doppie or piibolos, with half carlini in proportion,
and doppie, with halves and quarters in proportion: the
carlini paffes for 100 lire, and the doppia for 24 lire,
Piemonte fcurrency. The silver coins are fcuo of 6 lire,
with halves, quarters, and eighths in proportion. Here
are also base fliver coins of 3½ and 2½ foldi; and copper coins
of 1 foldo; also pieces of 3 denari, called quattrini. The
doppia contains 172½ troy grains of fine gold, or 139! grains
of English standard gold, and is worth 17 l. 2s. 6d.
In English gold coin: the fcuo contains 492 troy grains of
fine fliver, or 532 of English standard, and is worth 5s.
8d. in fterling fliver coin: thus the lira Piemonte fcurrency
may be valued at 114d. fterling. The rubbo, com-
mercial weight, is 25 lbs., each pound containing 1½ mark,
or 12 oz. of the gold and fliver weight: fo that 70 lbs. of
Turin = 57 lbs. avoirdupois. The facco, corn meafure,
contains 3 flaga, 6 mine, or 48 coppelli; and 22 facchi =
9 English quarters nearly: the brenta, wine meafure,
contains 6 rubbi, or 36 pinte; the rubbo weighs 25 lbs.
of Turin, and holds about 24 English gallons. Oil is sold
by the rubbo of the fame weight, or 20½ lbs. avoirdupois:
the rafo or ell is = 2½ Genofe palmi = 23½ English inches;
the foot = 143½ French lines = 3¾ English inches: fo
that 180 Piemonte rafi = 119 Eflgh yards, and 53
Piemonte feet = 35 English feet.
Turin exchanges with, and gives Amflerdam, 38 foldi,
more or lefs, for 1 florin banco; Augsburg, 46 foldi for
1 florin current; Geneva, 86 foldi for 1 ecu of 3 livres cur-
rent; Genoa, 190 foldi for 1 fequin; Leghorn, 82 foldi
for 1 pezza of 8 reali; London, 409 foldi for 1 fterling;
Lyons and Paris, 50 foldi for 3 livres Tournois; Milan,
38 foldi for 1 filippo of 7½ lire current; Rome, 90 foldi
for 1 fcuo of 10 paoli; Venice, 54 foldi for 1 ducat
piccoli.
The ufance for bills drawn from London is three months
after date, from Holland two months, and from France one
month. The holder of a bill payable after date, may
either demand payment when it becomes due, or wait
till the fifth day; but bills at fight must be paid when
presented. Kelly.
Turin, a large poft-town of New York, in the S.W.
corner of Lewis county, 143 miles N.W. of Albany. It
comprises seven townships, viz. Pomona and Lucretia, adjoin-
ing Black river, and on which are the fettlements; Flora,
Xenophon, Rurebbela, Hybla, and Penelope, unfettled.
The fettled part is about nine miles along Black river and
seven back. The inhabitants are emigrants from the easter
flates, farmers of plain domestic habits. Here are nine
school-houfes, in which are also held the meetings for
worship. The whole population in 1810 was 856, and
theffenial electors were 111; in 1812, 170. The Black
river road from Johnstown leads through this fettlement,
which has an excellent foil, and in which are two grain-
mills, fix saw-mills, a carding machine, and two distilleries
of grain and fruit spirits.
Turing, a town of Sweden, in the province of
Blekingen; 7 miles N. of Carfferona.
Turinge, a town of Sweden, in Sudermanland; 24
miles W.S.W. of Stockholm.
Turini, Francesco, in Biography, an eminent Ita-
lian compofeer of the feventeenth century, who gained great
reputation by the compofition of canons. He was organ-
iff of the Duomo at Brefcia, and publifhed many learned
compofitions for the church and chamber; but particularly
a mas in 1643, for four voices, in canon.
In this work there is a perpetual fugue, upon the sub-
ject of which Handel has compofed one of his fnefl instru-
mental fugues; but, according to his ufual practice, when-
ever he adopted another's thought, he has elivened and
embellifhed Turini's theme, like a man of true genius, with
a counter fubject; and fhewn that he faw farther into the
latent fertility of the fame feries of notes, than the original
inventor, whose theme was the following.

\[
\begin{align*}
&\text{The firft fonatas for two violins and a bafe, which our} \\
&\text{musical enquiries have been able to discover, were} \\
&\text{publifhed by Turini, with a fet of "Madrigali a una, due, tre} \\

\]
the solution of harmonical problems, which require such intense application as to leave him not a single idea to bellow on anything else.

TURINSK, in Geography, a town of Russia, in the government of Tobolik, containing a wooded fort, seven churches, and about 350 houses; 144 miles W. of Tobolik. N. lat. 58°. E. long. 63° 44'.

TURINSK is a town of Russia, in the government of Tobolik, on the Niznica Tunguska; 132 miles E. of Turunchan.

TURIN, in Geography, an appellation of a very ancient origin and of very comprehensive extent. It is said to be derived from the name of one of the sons of Japheth, the eldest son of Noah, who is generally allowed to be the progenitor of the Moguls and Tartars. This opinion has been adopted by those who have been most conversant with Oriental literature, and the Tartars themselves have expressed their persuasion of its truth. Accordingly it is said, that the progeny of Magog, Meshech, and Tubal, subverted both the Scythias, and consequently the country of the ancient Moguls and Tartars. If it be admitted that the Turks and Tartars were originally the same people, whatever is advanced concerning the first progenitors and early antiquities of the one, must, with the strictest propriety, be applicable to those of the other. It has been alleged as highly probable, that both the present Turks and Tartars are descended from the Scythians of Arisaces Proconneus, and the Scythian Nomades of Herodotus (lib. iv.). Upon this supposition, the ancient Turks or Tartars cannot be considered as one of the earliest nations of antiquity, nor as occupying a tract for many ages of very considerable extent. For they fearfully made any figure at all before the reign of Cyrus, king of the Medes, or the time of Ogres Khan, about 637 years B.C., when they drove the Cimmerians from their territories bordering upon the Palus Maeotis into the Upper Asia. Nor could their primitive seat, upon the eastern bank of the Volga or Araxes, have been at that time very extensive; since it is well known that they were then a people of little note, and in the vicinity of some nations who were contending for unlimited empire. In the time of Herodotus, Scythia lay only between the 45th and 57th degrees of latitude, and the 45th and 55th degrees of N. latitude, so that the Scythians at that period cannot be regarded as a very formidable power. The first Scythian king, according to this historian, did not live above 1000 years before Darius Hystxes invaded Scythia, in the year B.C. 514: or by reducing the calculation of the Greeks and other ancient nations, as far Isaac Newton has done, it may reasonably be supposed that the first Scythian prince could not have preceded Darius Hystxes above 800 years. At this early period, therefore, or 1300 years before the commencement of the Christian era, the countries bordering upon the Palus Maeotis, as well as the Euxine and Caffian seas, must have been very thinly peopled. The Tartars, however, though they derive their name from Tatar Khan, pretend that this was not their primitive appellation, but that they are the descendants of Turk, as we have already said, the eldest son of Japheth, whom they call Japhis; and accordingly they maintain that they were originally denominated Turks; which name they seem to have retained till the time of Genghis Khan. But when that prince reduced all the tribes bearing the name of Turks under his obedience, they, with regard to their neighbours, gradually lost it, and were by them afterwards called Tartars. Nevertheless, though this was the case with respect to their neighbours, most of them have always denominated themselves Turks; nor do they allow, that any other nation has the least title to that denomination. The name of Tatars was at first probably applied to one particular tribe or horde of the Turkish nation, confiding of persons more considerable, warlike, and better known to the Aliates, on account of their military exploits than the rest, till the time of Genghis Khan. This was succeeded by that of Moguls, which prevailed as long as the dominion of the people lo called lallted over the southern provinces of Asia; when that expired, the former appellation was resumed. It is observable, that Sirerh al Edrili, commonly called the Nubian geographer, makes no mention either of Moguls or Tartars; but intimates that the whole country bearing now the denomination of Oriental and Western Tartary, was peopled by different cantons of Turks. This is the more remarkable, as that author wrote but a little before the reign of Genghis Khan, about the year of Christ 1170.

Turk, it is said, was appointed by his father Japhet to bear the chief rule in his family after his death; and being a man of superior genius, he invented many of the conveniences of life, made tents, and governed his family and subjects with great justice, prudence, and moderation. He also formed a body of salutary laws for his descendants. Turk is said by the Arabs to have had four sons; and from him the country in which he settled was called Turks in the Arabian language, and his subjects were denominated Turks. From Tatar Khan, the Tatars or Tartars derived their name, as the Moguls did theirs from Mogul or Mung' Khan. These two branches of Turks, being rendered independent of one another, formed two considerable empires, which flourished for several generations. See Mongols and Tartars.

The name Turk, says Volney, originally, was not peculiar to the nation to which it is now applied; it denoted, in general, all the hordes dispersed to the east and to the north of the Caspian sea, as far as beyond lake Aral, over those vast countries which have taken from them the denomination of Tartary. These are the same people, who were known to the ancient Greeks by the names of Parthians, Maflageites, and even of Scythians, for which we have substituted that of Tatars. These formed a nation of shepherds, continually wandering like the Bedouin Arabs; and in every age exhibiting themselves as brave and formidable warriors. Neither Cyrus nor Alexander was able to subdue them. The Arabs, however, about 80 years after Mahomet, by order of the caliph Waled IV. invaded the country of the Turks, subdued them, and imposed upon them their religion; and obliged them to pay tribute. But the power of the caliphs was reftored and vanquished. Like the Bedouins, the Turks were divided into tribes or camps, called "ordou," of which has been formed the term horde; and these tribes, allied or at variance, according to their several interests, were perpetually engaged in wars. Hence we see, in their history, several nations, all equally called Turks, alternately attacking, destroying, and expelling each other. Volney, in order to avoid this confusion, has confined the name of Turks to those of Constantinople, and given that of Turkomans to their predecessors. (See Turkomans.) For a further account of the Turks, see Turkish and Turkey.
Turk's Cap, in Botany, a name given to a species of lily. See Lilium.

Turk's Head, a name sometimes given to the melon thistle.

Turk's Turban, a name given to a species of ranunculus.

Turk Islands, or Turk's Islands, in Geography, a cluster of small islands among the Bahamas, the largest situated N. lat. 21° 20'. W. long. 74°.

TURKAL, a town of Asiatic Turkey, in the province of Sivas; 25 miles S.E. of Amarcin.

TURKAREL, a town of Candahar; 30 miles W. of Cabul.

TURKEIM. See TURKHEIM.

TURKESTAN. See TURAZ.

Turkestain, (formed of Turk and ostan, a Persian word signifying country,) or Turan, a country of Asia, bounded on the N. by deserts, which separate it from the dominions of Russia, on the E. by a part of Tartary, belonging to the Kalmucks, on the S. by Buharia, and on the W. by Kharafm or Kharafm, near 300 miles in length, and not much less in breadth. It is at present divided between two Tartar khan's or chiefs; one of them, residing at Tashkund, possesses the eastern part; the other, who possesses the western part, resides at Turkistan or Taraz. The latter is generally called the khan of the Karakalpaks. Turkistan, taken in a larger sense, is understood to include all the country between Russia to the N. and Buharia to the S., and between the Caspian sea to the W. and Chinife Tartary on the E., not less than 700 miles from E. to W. and 350 from N. to S.

In ancient periods, Western Turkistan and the N. of the Cappadocia were the seats of the Mafflaget; to the S. of whom were the Scythians, on this side of the Imaus or Belur-Tagh. In the sixth century, the Turks, having migrated from their habitations near the mountains of Bogdo, adjoining to those of Altai, or the mountains of gold, and having impared to the country the name of Turkistan, and forming a grand branch of the Tartars, or Huns, spread themselves to the Cappadocia. They soon after subdued the people of Sogdiana, and the Nephthalites of Great Buharia, called in that ignorant age White Huns. As the Turks founded their first western settlements in the regions now held by the Kirgises, they thence received the name of Turkistan, the capital city being denominated Otrar, and sometimes Taraz, also called Turkistan. From the centre of their power flourished those Turkheim armies, which have changed the names of to many nations. Little Buharia was called Eastern Turkistan from a similar cause; but appears to have been first subdued by the Turks of Cathay, on the N.W. of China. The Turks and Huns may be considered as one and the same Tartar race, totally unknown to Europeans till the appearance of the latter, who first passed the steppes, deserts and mountains which had concealed them from observation till the fourth century. The Huns, who appeared about A.D. 375, feem to the writers of the period as a new and unknown race, having passed in a course of uniform depredation from Asia to Europe; while the Gothic and Slavonic nations had left many of their settlements vacant, in their progress into the Roman empire. But the Turks, though originally the same people, perhaps alarmed by the fate of their brethren, made a slow and gradual progress, and appear to have been blended by marriages and conquests with the Slavonic and Gothic tribes on the N. and E. of the Cappadocia. Such was the origin of the name of Turkistan, from which the Turks spread defoliation over the most beautiful countries of the East, and even threatened the liberties of Europe. Pinkerton's Geog. vol. ii. See BUCHARIA and INDEPENDENT TARTARY.

TURKEY, an extensive empire, comprehending a great number of countries on the continents of Europe, Asia, and Africa, and several adjacent islands. Turkey in Europe extends, according to the statement of Pinkerton, about 870 miles in length, from the northern boundary of Moldavia to Cape Matapan in the Morea; and its breadth, from the river Unna to Conflantinople, is about 650 British miles. It is computed to contain 182,560 square miles. Its eastern and southern boundaries are formed by the Euxine or Black sea, the sea of Marmora, the Archipelago, and the Mediterranean. Its utmost northern limit is now the river Drisfer, and the western confines of an arbitrary line, sometimes supplied by rivers or mountains. In its whole extent it comprehends many ancient kingdoms and republics, which, since the subjugation of its greater part in the 15th century, after the fall of Conflantinople and of the Byzantine empire, afford only the records of clasical names and events. Moldavia, the most northern province, was part of ancient Dacia; and Jaffy or Yaffi, the capital, was the "Jailfiorum Municipium" of the Romans. Budzak, or Bejaria, was the country of the Cete and Pucicini. Walacliya was also a province of the ancient Dacians; and Bulgaria, on the S. of the Danube, embraces nearly the two provinces of Macia. Romelia, a spacious territory, contains ancient Thracie, Pazonia, Macedonja, and the northern part of the clasical country of Greece; and the Morea is equivalent with the ancient Peloponneseus. Dalmatia retains its ancient apellation; while Servia and Bohemia represent ancient Pannonia. Turkish Croatia, the most western province of the empire, forms a portion of ancient Pannonia, with probably a small district of Noricum; but the Turkish part of Croatia is a diminutive province, about 40 miles in length by 20 in breadth, bounded by the river Save on the N., and partly by the river Unna on the W. In modern times Turkey, sinking before the power of Russia, has lost the provinces of the Crim and New Servia, which, with several Aftatic districts, have surrendered to Russia; and on the W., Transylvania, Schavonia, with the Buckovin part of Moldavia, and a great part of Croatia, have been subjugated by Austria. Of the original population of the Turkish empire, we have already given some account under the article TURK; and it appears to have been derived from the ancient Scythians on the Euxine, the progenitors of the Dacians, Thracians, &c. and even of the Greeks. These were originally blended northward with many Sarmatic or Slavonic tribes; which on the fall of the Roman empire migrated towards the S., so that about one-half of the population may now be regarded as Slavonic. Walacliya, however, is supposed to contain many descendants of the ancient Roman letter in Dacia. This original population, in consequence of the extent of the Turkish empire, has been blended with various Aftatic tribes, among whom the Turks constitute a part. Of that branch called Ottomans, and the commencement of their appellation of Ottoman empire, we have already given a brief account under the articles OTHMAN and OTTOMAN; and for the more remote antiquity of the name and power of the Turks, we refer to TURK. Those Turks, or Turkomans, descending, about the middle of the sixth century, from the Altaina mountains, spread as far as the lake Magoni; but their progress was restricted to the region near the river Oxus; from the Oxus and Samarcand they afterwards spread to the E. of Peria, where Mahmoud of Gazna established a powerful kingdom, subdued by the Turks of Bochara, who in the 11th century
century founded the dynasty of the Seljuks. The sultans of this race gradually extended their power towards the W. and took possession of Armenia and Georgia, their first acquisitions in the Byzantine empire; and it is remarkable that they should have continued, when it is considered, that the Turks had subdued almost the whole of Asia Minor before the beginning of the 12th century. Nevertheless the extension of their dominion was restrained by the progress of the Crusades, which obliged them by the capture of Nice to remove the seat of power to Iconium. About the middle of the 14th century the Turks first passed into Europe, and soon after seized the greatest part of Thrace. In the 15th century their sultan, Bajazet, extended his conquests even to the Danube, and the provinces of Thrace and Macedonia fell under the Turkish sceptre, while Adrianople became the seat of their government.

Although the Turks, as we have above intimated, formed a part of the people denominated "the Scyths beyond the Imaus," and originally proceeded from the Altsian mountains, they were intermixed by their settlement on the Oxus with Sogdian and Bactrian tribes, and after their subversion of the Byzantine empire, in which they were assisted by European troops, many different nations joined their standard, and various circumstances, beside their intermarriages with Circassian women, contributed to render them a very mixed race. When the Roman arms had subdued many of those countries and cities which were comprehended under the widely extended Turkish empire, they became in the fifth century an important part of the Byzantine empire; and we shall follow Mr. Pinkerton in tracing their principal historical epochs. Accordingly he observes, that the first dawn of Turkish history preceding the reign of Othman, occurs A.D. 1290. In the reign of his successor, Orkan, the Turks took Gallipoli, and penetrated into Thrace, so that Adriano-ple was taken A.D. 1360; two years after which period, Amurath established the military bands called Janizaries. The Turkish power was for some time restrained after the famous battle near Ancyra, A.D. 1402, between Bajazet and Timur; nevertheless the dominion of the Turks increased in Europe, though they received several checks from the Hungarians under Huniades, and from the Albanians under the command of George Cafriot, called by the Turks Scanderberg. On the 20th of May, A.D. 1453, Constantinople was taken by the Turks. Crimea and the Morea were subjugated A.D. 1458; and in 1480, Otranto in Italy was captured by the Turks. The conquest of Egypt in 1517 made a considerable accession to the Turkish power; Rhodes submitted in 1522; and soon after the battle of Mohazzat, in 1526, the sultan Soliman took Buda. In 1552 the Turks seized the bannat of Temesvar, and they took Cyprus from the Venetians in 1571. Although after the famous naval engagement of Lepanto, in this year, their power at sea ceased to be formidable, they invaded Hungary with various successes, yet Europe obtained an interval of security by their wars with Perza; however, in 1642, the sultan Ibrahim took Azof from the Cuffacks, and about the middle of this century the Turks took possession of some Greek isles. Hungary became the scene of repeated Turkish and Austriam conquests until the year 1699, when, by the peace of Carlowitz, the Turks surrendered Transylvania to the Austrians, the Morea to the Venetians, and Azof to the Ruffians. By the peace of 1739 the Turks renounced Belgrade and Orlova, with parts of Servia and Walachia, formerly ceded to Austria, and Ruffia was constrained to abandon Azof. The last epoch of Turkish history would lead to a detail of the Ruffian wars against the Turks, and the decline of the Ottoman empire. We may here observe in general, that the Turkish dominion, wherever it has prevailed, has been detrimental in a very high degree to the best interests of humanity, and to every improvement, mental or moral, ecclesiastical or civil.

The religion of the Turks is the Mahometan; although in this European division of the empire, it is supposed that two-thirds of the inhabitants are Greek Christians. The Turkish sultan has for some centuries been the principal leader and support of that attachment to the religion of the Koran, which has been the flag and guard of the Mahometan faith. The Mahometan pontiff, or mufti, prelates at Constantinople. The next in rank to him are the moulahs, and from these are selected the inferior muftis, or judges, through the empire, and the candlefellers or chief justices. The next class of divines consists of the imams or parish priests, who perform the service of the mosques, or places of worship, while the cadis are judges annually appointed to administer justice in the towns and villages. The Turks have also their monks, denominated derviches, of four orders, dedicated to religious offices, public prayer and preaching. Of these, the Kadiri constitute a singular order, appearing almost naked, and displaying their devotion by frantic and extravagant dances. The Greeks retain their priests, bishops, archbishops, and patriarchs; but their church is in the lowest state of degradation, and its dignities are openly sold by the Turks.

As to the government of Turkey, the sultan is a despotic sovereign, but no restricted by the laws of the Koran, to which he is bound to submit, that many Christlian sovereigns are reckoned more arbitrary. The despotism of the monarch is balanced by a religious ariarchy; and many circumstances have lately occurred, such as the infractions of the Janizaries, and the power usurped by the pashas over their own provinces, which indicate the decline and approaching perdition of the empire. The Turkish laws are contained in the Koran, and in the comments of approved and renowned doctors, which have acquired the force of laws. The Turkish empire is chiefly guided by those of Abou-Hanife.

The number of inhabitants in Turkey in Europe has been estimated at 8,000,000, or about 43 to each square mile; but as the countries which it comprehends are intersected by many mountains and barren tracts, this estimate is supposed to exceed the truth. The navy is rated at about 30 ships of the line, and the army at 150,000 of ill-disciplined soldiers. The revenues of the whole Turkish empire are computed at about 7,000,000l. sterling, and the usual expense as not exceeding 5,000,000l. Their revenue is partly derived from a capitation tax on unbelievers, and from the "zeechat," or cullums, but principally from a tax on land of about 6s. an acre, called the "jizie." Upon the whole, the Turkish empire may be regarded as in a declining state, notwithstanding all its endeavours to secure the friendship of various European powers.

Of the manners and customs of the Turks, our limits will not admit of a minute detail. Marriage is a civil contract, managed by female mediation, and liable to dissolution at the pleasure of either party. Circumcision is performed at the age of 12 or 14. The dead are perfumed with incense, and buried in a kind of shroud, open at both ends, that the deceased may be able to fit up and reply to the interrogatories of the angels of death. The burial grounds are near the highways, and as one grave does not intrude upon another, they are very extensive. With regard to diet the Turks are moderate, and their favourite food is rice, of which they prepare their pilau, boiling it with
with mutton or fowl, their lappa, which is merely boiled rice, and the tcherebe, a kind of broth made of the same vegetable. The fish of the Archipelago is very good, and the beef tolerable; the hares, partridges, and other game are excellent. The meat is usually spread on a low wooden table, over which the master of the house pronounces a short prayer. The frugal repast is followed by fruits and cold water, and these are succeded by hot coffee and pipes with tobacco. The houses are expensive, and the most costly part of the furniture is the carpet that covers the floor. Their dres consists of a calico shirt, and the loose robe is fastened by a girdle, in which is stuck a dagger; while the tobacco-box, pocket-book, &c. are worn in the bosom. The robe is commonly made of English broad cloth, trimmed with fur. The shoes are light slippers. The dres of the women resembles that of the men, differing only in that of the head, which is a sort of bonnet, formed of pafteboard covered with cloth of gold, or other elegant materials, with a veil reaching to the eyes, and a fine handkerchief concealing the lower part of the face. In their perfons the Turks are very cleanly; the females, however, flain their nails with a red tincture. Their amusements are principally such as favour indolence, hunting and military exercises excepted. They are fond of reclining on an elegant carpet, or in a hot season by the side of a stream, and smoking the delicate tobacco of Syria. With opium they procure what they call "rief," or a placid intoxication, but a stronger dose produces irritation and fercity. Chefs and draughts are favourite games; whereas those of chance are regarded as immoral. Their coffee-houses and baths afford other means of amusement; and the beimar, or festival succeeding their long lent, is a feaon of universal dilipation.

The Turkifh language is far inferior to the Persian or Arabic, and is formed by a mixture of several dialects. Literature is not wholly neglected, but they have some schools and libraries. In the 18th century a printing-office was set up at Constantinople by Ibrahim Effendi, which was at first much oppofed, but afterwards allowed to print all kinds of books, thofe on religion excepted. Their market for books contains many thop well supplied with Oriental MSS.; and they have their ancient poets, hiiftorians, and divines, though of little estimation compared with thofe of Persia or Arabia. Education, however, is little encouraged; fo that ignorance forms the diftinguifhing character of the nation. Law, connected with their theology, is the chief fubject of their study; but they have no infitution that merits the appellation of a college or university.

The chief city of European Turkey, and of the whole Turkifh empire, is Constantinople; next to this in dignity and extent is Adrianople, two miles in circuit, and poffeffing several fpendid works, and a confiderable share of commerce; Philippopolis is a city of confiderable importance; Sofia, though meanly built, contains about 70,000 inhabitants, and has confiderable trade; Silifria in Bulgaria, on the Danube, contains about 60,000 fouls; and Buccharof, the chief city of Walachia, is faid to have the fame number; while thofe of Jaffy or Yaffy, the principal town of Moldavia, and Bender of Baffarabia, are each confiuated only at 10,000 or 14,000. Bragd, the capital of Servia, is fuppofed to contain about 25,000 inhabitants; and thofe of Banjaluca, which is a confiderable town in Bofnia, are confiuated at 18,000. In the southern provinces we may first mention Salonica, containing 60,000 inhabitants, and diftinguifhed by a confiderable commerce; Lariffa, 80 British miles to the S., an inland town, containing 25,000 fouls; and Atini, the ancient Athens, of small population. See each article.

If we except the ferglios and royal palaces, the chief edifices in Turkey are the mosques and caravanferas.

The manufactures and commerce of Turkey in Europe are chiefly conducted by foreigners. The Levant trade almost entirely centres in Smyrna and the Asiatic shore.

The manufactures principally exported from European Turkey are inconsiderable, being chiefly carpets and some few other articles; but the products are currants, figs, faftron, flutuari marble from Pafos, filk, and drugs.

The climate and feasons vary with the different regions comprehended within the limits of European Turkey; and to these we refer for an account of them. The general appearance of Turkey in Europe is magnificent, here and there interpersed with delicious plains and vales; enriched by the Danube, which interfets its provinces, and the numerous gulfes of the Archipelago and Mediterranean. The foil is generally fertile, the northern parts producing wheat and rich paffure, the middle and southern abundance of rice; but agriculture, as well as almost every other art and science, is neglected by the Turks. The principal rivers of Turkey are the Danube, already mentioned, the Marits or ancient Hebrus, the Vardari or ancient Axios, the Efsir or ancient Oesius; the Morava or ancient Margus, and the Drin, rising in N. of Albania, and falling into the Save. Budzak and Walachia, as well as Albania and the southern provinces, contain confiderable lakes. The chains of mountains in Turkey are numerous and extensive. Here we might mention, if they were not elsewhere noticed, the Carpathian chain, anciently called the Baltaic Alps; the grand range of the Harom with its branches; and mount Athos of ancient celebrity. European Turkey also abounds with forests. Of its zoology we shall merely notice the jackal, the camel, and foarfe, and also its cattle and sheep, which are numerous and of different kinds. Its mineralogy has been little investigated. The gold mines of Philippi, about eighty miles E. of Salonica, produced in the time of Philip of Macedon annually about 1000 talents, or 2,880,000 florin; and silver mines were found in Attica, and other quarters.

The chief islands belonging to Turkey in Europe are those of the Archipelago; for an account of them we refer to their names, fuch as Crete or Candia, Negroport, the Cyclades, Sporades, Lemnos, &c. &c.

Turkey in Asia extends from the shores of the Aegean sea or Archipelago, to the confines of Persia, through a space of about 1050 British miles. The boundaries towards Persia are the mountains of Ararat and Elwend. Towards the N. the Turkish territories are divided from the Russian by the river Cuban and the chain of Caucasus; in the S. they extend to the junction of the Tigris and the Euphrates, which last river separates, for a confiderable interval, the Turkish possessions from those of the Arabs. The diftance from the Cuban to the junction of the Tigris and Euphrates may be efimated at about 1100 British miles. This extensive empire is divided into nine or ten provinces, viz. Natolia W., Karaman S., and Roum N.E. of Armenia are Guria or Guriel, Mingrelia, and the Akbas of Caucasus, the ancient Circassias. To the S. of Armenia, also denominated Turcomania, are Curdlan and Irak-Arabi, part of ancient Persia, round the celebrated capital Bagdad. The ancient Mefopotamia, between the Tigris and the Euphrates, now partly corresponds with the province of Algezira; and Syria, or Soria, comprehends the celebrated countries along the easterm extremities of the Mediterranean. These provinces are subdivided into governments, arbitrarily admiinistered by pashas. The original population of these regions consisted chiefly of Scythians blended
TURKEY.

blended with some few Assyrians from the south. See *TURK*, and *Turkey in Europe*, supra.

The prevalent language is the Turkick, to which we may add the modern Greek, together with the Arabic, Syrian, Periian, and Armenian, with the various dialects used by the tribes on the Black sea, and indicating the diversity of population. To the account already given of the historical epochs of Turkey, we may here subjoin the following from Pinkerton. Armenia and Georgia were subdued by the Turks in the eleventh century, and the whole of Asia Minor soon followed. Their kingdom of Roum extended from the Euphrates to Conflantinople, and from the Black sea to the confines of Syria. Successive war-like princes acquired additional territory from the Manemukes of Egypt and the Periians. Syria, formerly an appendix of Egypt, was conquered by Selim II. in 1516; Tauris and Diarbekir, the last of which had formerly belonged to Peria, were subjugated by the same monarch; and in 1589 Abbas, the great sovereign of Peria, was obliged to yield three provinces to the Ottomans, though he extended his conquests to the eait and Bagdad, with the surrounding province of Irak-Arabi, became subject to the Turks in 1638. The present limits seem to have been fixed by the treaty between the Porte and Peria in 1736, since which period the Turks have been chiefly employed in defending themselves against the Ruffians; but such had been their ascendency over Peria, that in 1727 they had acquired the territory from Erivan to Tauris or Tebriz, and thence to Hamadan, a boundary which seems to be more precisely marked by nature than the pencil.

The antiquities of Asiatic Turkey are those of Balbec and Palmyra or Tadmor in the desert, and those that have been discovered in the seite and plain of Troy; for which see these articles.

The Turkick empire in Asia is estimated at 470,400 square miles, and the population at 10,000,000; which, allowing 3,000,000 for the European part, will render the total 18,000,000. The reader will find a sketch of the manners and customs of the inhabitants of Asiatic Turkey under this article, which we shall now proceed to mention. The Curds or Kurds pass in summer from Moufoul to the sources of the Euphrates, and they are never punished either for robbery or murder. They are a pastoral people, who conduct their herds from one country to another, and extending sometimes as far west as Tocato; where Tournefort, in his time, found other hordes called Turkomans. The Armenians, though Eutychian Christians by profession, and of course irreconcilable enemies of the Greeks, are distinguished by many singular manners and customs. They are reprented as a sensible and polite people; and by their frugality and enterprise, are admirably qualified for conducting the Levant trade, which is chiefly their province. For an account of the Druses and Maronites, see these appellations. In the northern extremities of Asiatic Turkey, there are many tribes which have adopted singular practices. Six or seven languages are said to be spoken in the country between the Euxine and the Caspian. The Abkhas, called by the Circassians " Kuth-Haipp," a people beyond the mountains, retain some traces of Chrisitianity. The territory of the Tcherkausses, or Circassians, is extensive: part of it is subject to Ruflia, but their manners are invariable. The princes cannot pledge lands, and their nobles are chosen by the princes from the vaflals, or third clafs. Public measures are proposed by the prince, and debated by the nobles and deputies of the people, on a spot defined for this purpose, near the royal residence. The agriculture of these people is barely sufficient for their own consumption; but they export sheep and horses, and slaves taken in their predatory excursions. The beauty of their women has been much extolled. Having received a suitable education, and formed from their youth according to their own standard of beauty, they are sold from 20l. to 100l., and sometimes at a much higher price. Soon after the birth of a girl, a belt is fewed round her wailt, and when this furth, it is replaced by a second; so that their waists become very small, and their shoulders broad, which is a defect little regarded, on account of the beauty of their breasts. On the wedding-night the belt is cut by the husband with a dagger, an operation which is sometimes accidentally fatal. The bride-groom pays for his bride a present, or " kelym," consisting of arms, or a coat of mail; but he must not then, nor on any future occasion, see her, or cohabit with her, without the greatest mystery. The young men recommend themselves by their activity and address in military exercises; and those who are most alert have the privilege of choosing the most beautiful partners. Their musical instruments are a long flute, with only three stops, a species of mandoline, and a tambourine. Their dances are in the Asiatic style, with little gaiety or expression. The women pride themselves on the courage of their husbands, and liberally recompense them when they are defeated. It is their business to polich and take care of the armour of the men. The habitation of a Circassian consists of two huts, because the wife and husband are not supposed to live together. At meals the whole family is assembled. Their food consists only of a little meal, pulse made of millet, and a kind of fermented beer, prepared from the same grain. The Manemukes of Egypt are slaves regularly imported from Circassia and Georgia. In Imeritia, Mingrelia, and Guriel, as well as in Georgia, which forms a Periian province, the barons have power of life and death over their vaflals, and form a very powerful aristocracy, very formidable to the prince, who resides at Kutais. The religion of all these provinces is the Greek; but they can scarcely be regarded as subject to Turkey. It may be observed in general, after this brief detail, that the most striking feature of manners and customs in the Turkish empire, is that half the people may be considered as somewhat civilized, while the other half may be regarded as pastoral wanderers ranging over extensive wilds. Next to the capital of the Turkish empire, the next city of Asiatic Turkey in dignity and importance is Aleppo, containing about 250,000 inhabitants, where the manufactures of silk and cotton are flourishing, and whither large caravans frequently return from Bagdad and Baffora, with the products of Peria and India. Damascus is supposed to contain 180,000 souls: Smyrna may be regarded as the third city in Asiatic Turkey, and contains about 120,000 souls: Prucha is a beautiful city at the northern bottom of mount Olympus, and its number of inhabitants is estimated at about 60,000: Magnifici, or Magnesia, is also a city of some repute in this quarter of the empire; and Kircahatch has risen to importance by the cultivation of cotton, being situated about 40 miles N.E. in Angora contains of Magniffi, on the route to Prucha: Angora contains 50,000 inhabitants, and trades chiefly in yarn for shawls, and in Angora furfs of its own manufacture from the hair of a breed of goats: Tokat is flourishing, and its inhabitants are about 60,000; its manufactures are filk and leather, and chiefly copper utensils: Bafra, or Baffora, contains on the estuary of the Euphrates and Tigris, contains about 50,000 inhabitants, and is a place of great consequence; as the various products of Europe and India are here exchanged for those of Peria; and opium caravans
caravans proceed from this most central port of the Oriental trade to the chief cities of Asiatic Turkey:—Bagdad, the seat of the caliphs, and scene of many Eastern fictions, is now reduced to a town of about 40,000 inhabitants:—the ancient and celebrated city of Jerusalem is now a mean town, chiefly depending on the piety of pilgrims; and towards the frontiers of Peria frequent wars have spread defoliation; nevertheless Erzeron, the capital of Armenia, has still about 25,000 inhabitants; but Kars, the extreme town upon the frontiers of Peria, though tolerably fortified, is an unconsiderable place. The chief articles of commerce in Asiatic Turkey are carpets, rhubarb, and several other drugs. The Levant or Turkey trade was formerly of great consequence to Great Britain; but from the middle of last century it has been more advantageous to France. The state of the Levant trade chiefly carried on at Smyrna appears from the following documents:

France sends coffee, sugar, indigo, clothes, and cochineal.

England, shalloons, muslins, iron, tin, spices, refined fuggars.

Holland, muslins, India goods, clothes, spices.

Austria, from Trieste, cloths, glafs, hard-ware, linen, wood, amber.

Raffia, iron, corn, caviare, dried fish, furs.

Italy, filks and velvets, wax and paper.

European Turkey, wines, filks, tobacco.

Natolia and Syria, woolens, cottons, filks, drugs.

Egypt, coffee of Yemen, rice.

Barbary, dates, woolen caps from Tunis, butter, wax.

The port of Marseilles, which carries on the French trade with Smyrna, draws the wool and cochineal from Spain; but this country has lately begun to conduct her own commerce. Venice, under the Aulonian power, might become the chief port of the Levant busines. Of the French commerce, the chief staple is coffee: but this cannot be re-formed with much vigour till France shall acquire a greater naval power.

Upon the whole, says Pinkerton, if the commerce of Smyrna be at present valued at fifty millions of francs, the English trade for thirty millions, the Dutch for ten, while France shares the remaining ten millions with the emperor, Italy, and other states above-mentioned.

The climate of Asin Minor has been always considered as excellent. The heat of the summer is tempered by numerous chains of high mountains, some of which are covered constantly with snow. The aspect of Asiatic Turkey is mountainous, intermingled with spacious and beautiful plains, which afford pasturage to the numerous flocks and herds of the Turkomans. The soil is various; but the chief agricultural products are wheat, barley, and durra. It abounds also with grapes, olives, and dates. In Syria the agriculture is deplorable, and the peasant is in a wretched condition, being fold, as in Poland, with the soil, and their constant fare being barley bread, onions, and water.

The principal river of Asiatic Turkey is the Euphrates, the course of which may be estimated at about 1400 British miles: next in importance is the Tigris, whose course is about 800 miles; and both these rivers are navigable to a considerable distance from the sea. The third river is called by the Turks Kizil Irnak, the celebrated Halys of antiquity, rising in mount Taurus, and discharging itself into the Euxine sea on the W. of the Gulf of Sanfom: the river Sacaria, or ancient Sangarius, rises about fifty miles S. of Angora, and joins the Euxine about seventy miles E. of Constantinople: next in rank is the Mxander, rising N. of Apannea, and winding its course about 250 British miles: the Sarabat is the ancient Herusma, famous for its golden sands. The chief river of Syria is the Orontes, now called Oron or Afs, which runs into the Mediterranean.

The lakes of Asiatic Turkey are numerous. The most remarkable are the Van and Urmiannah: others are the Dead sea in Syria, fifty miles long, and twelve or thirteen in breadth: that of Raekama, S. of Hilla and the ancient Babylon, about thirty miles long, and flowing into the Euphrates; the Tatta, or Palus Salfa of D'Anville, a saline lake about seventy miles long, and one or two in breadth towards the centre of Asin Minor, being the modern Toulla or salt lake: that of Ulabad in Natolia, widely denominated the lake of Apollonia, twenty-five miles in circumference, and in some places seven or eight miles wide, sprinkled with several inlets and peninsulas, and the grand receptacle of the waters from mount Olympus: the largest of these isles is called Abouillona, probably from the ancient name of the city which stood upon it: and about fifty miles to the N.E. was the lake anciently called Acanus, now Innik.

The mountains of Asiatic Turkey are of ancient celebrity: such are the Taurian chain; the Caucaian mountains, ranging from the mouth of the river Cuban in the N.W. to the place where the Kur enters the Caspian in the S.E., and furnishing various chains, such as the Antitaurus of antiquity, and others branching out into Peria; mount Taurus, terminating at the Euphrates and desarts of Algezira: the chain of Taurus is now called Kurnun, and extends about 600 miles E. and W. from the Euphrates to the vicinity of the shores of the Archipelago. These and other mountains of Asiatic Turkey are conjectured to be calcareous; while the Caucasus alone aspires to the rank of a granitic or primitive chain. Towards the E. of Armenia is Ararat, properly belonging to Persia; and beyond Ararat are branches of the Caucaian chain, to which probably belongs the mountains of Elwend, or Niphates of antiquity. In Syria, the most celebrated mountains are Lebanon or Lebanon, and Anti Lebanon. On the eastern side of the Archipelago was Olympus (now Ketifik Dag); and 140 miles W. of Olympus is mount Ida, the branch of which was called by the ancients Garganos, which gave source to the Granicus, the Simos, and other streams, most of which directed their course to the N., and extended in western prominences to the Hellepont, amidst which was situated the celebrated city of Troy. Other remarkable mountains on this classical shore, as it has been denominated, were those of Rhea, Pedapus, &c. &c. S. of the Mxander, the Taurus detaches a chain called Cadmus and Grins, bending towards the isles of Cos and the Cyclades. The numerous mountains of Asiatic Turkey are frequently clothed with immense forests of pines, oaks, beeches, elms, and other trees; and the southern shores of the Black sea present many gloomy forests of great extent. The inhabitants are licenced to supply with abundance of fuel, in defect of pit-coal, which has not been explored in any part of Asiatic Turkey. Sudden conflagrations arise from the heathful wafle of the caravans, which, instead of cutting off a few branches, set fire to a standing tree. The extensive provinces of Natolia, Syria, and Melpontainia, have been little accessible to European curiosity, since their reduction under the Turkish yoke. In Pinkerton's Geography we have a catalogue of those plants and trees that have been found wild in the Asiatic part of the Ottoman territory. Several dyeing drugs and articles of the materia medica are imported from the Levant, among which are madder, and a variety called alizar, which grows about Smyrna, and affords a much finer red dye than the European kind; jalap, fummony, sebeften, the ricinus, yielding
TURKEY.

yielding by expression castor oil, squirting cucumber, colocynthita, opium poppy; and spikenard. The best horsefles in Asiatic Turkey are of Arabian extract; but mules and asles are more generally used. The bee is scarce and bad, the mutton superior, and the kid a favourite repast. Other animals are the bear, tiger, hyena, wild boar, jackal, and dogs in great abundance. On the summits of Caucaus is found the ibex, or rock-goat; at Angora, tangerine goats and cats; the gazel, and deer and hares in great abundance are found in Afia Minor. The partridges are generally of the red-legged kind, larger than the European; fih is plentiful and excellent. The mineralogy of these extensive provinces has not been yet sufficiently explored. The most noted mineral waters are those of Prufa, at the bottom of Mount Olympus: the baths are splendid, and paved with marble. Walachia furnishes many other hot-springs.

The chief islands belonging to Asiatic Turkey, situated in the Archipelago, are Mitylen, Scio, Samos, Cos, and Rhodes. Along the southern shores of Afia Minor are some small islands, such as that of Caflil Rosso, S.E. of Patira; but these are of no moment compared with Cyprus, about 160 miles long and nearly 70 at its greatest breadth; the chief cities of which are Nicofa and Famaguta.

Some geographers, in opposition to the testimony of travellers, have considered Egypt as a Turkish province; whereas it was only occasionally tributary, and subject to the military aristocracy of the beys. Some of the maritime Mahometan powers have likewise afflicted the Porte with ships in time of war; but they cannot be regarded as subject to the Ottoman sceptre.

TURKEY. Coinage, &c. As the Turks, though aspiring to a very ancient derivation, comprehending Tartars and Moguls, (fee Türk,) are merely a mixture of Sarmaate or Slav, Arabs and Greeks, which began to form a nation in the fourteenth century, they seem to have issued no coins till they feizied Constantinople in 1453; and their coins resemble those of Peria and Arabia, having merely inscriptions on both sides. Turkey keeps accounts in piastres, commonly called grouch by the Turks, and by the English dollars. Each piastre is divided into 40 paras, and each para into 3 aspers. Sometimes, instead of these real coins, the piastre is divided into 80 or 100 imaginary parts, called aspers, or minus. Jux or juck is a sum of 100,000 real aspers; a chife or parwe is 500 ditto. The gold coins of Turkey are the sequin or chequen (fee Séquin,): the silver coins are the two-dollar piece of 80 paras; the almiticelle of 60 paras; the dollar or piastre of 40 paras; the zolotta or izolotta of 30 paras; the roup of 10 paras; the bellick of 5 paras; the para of 3 aspers; and the asper. The Turkish coins, notwithstanding the regulations of 1780, when a single piastre weighed 5½ drachms, or 277 English grains, have been gradually deteriorated; so that a piastre of the latest coinage, weighed and assayed by the king's alay-mater of the Mint, was reported to be as follows: weight 8 dwts. 6 grs., fineness 5 oz. 6 dwts. worse than the English stand; hence its fineness was 47 car. 2 grs. Turkish, and its value in sterling 13½d.

The Turkish chequen or pound, with which gold, silver, diamonds and precious stones are weighed, is divided into 100 drachms, and the drachm into 16 kiltots or carats, or 64 grains. A chequen weighs 10 oz. 5 dwts. 3 grs. Troy weight, and a drachm 494 grs. disto; so that 48 chequens = 41 lbs. Troy very nearly.

The cantaro, quintal or kintel contains 44 okes, or 100 rottoli; the oke, 4 yufrdomes or chequens, or 400 drachms; the rottolo, 176 drachms. A metical is 3½ drachms. The kintel of cotton-yarn is 45 okes.

The cantaro weighs about 125 lb. avoirdupois; the oke, 21 lbs. 13 oz.; the rottolo, 19½ ounces; the chequen, 11½ ounces avoirdupois.

Silks from Peria are weighed by the batom of 6 okes, or 2400 Turkish drachms, or 16 lbs. 14 oz. avoirdupois; silks from Brufa are weighed by the taffee of 610 Turkish drachms, or 4 lbs. 4 oz. 10 drs. avoirdupois.

The chequen of goats' wool is 800 Turkish drachms, or 5 lbs. 10 oz. avoirdupois; the chequen of opium 250 Turkish drachms, or 27 oz. 10 ds. avoirdupois.

Corn is measured by the quilet or kille, weighing, in wheat, about 22 okes, or 60 lbs. avoirdupois; 4 killos make 1 fortin: 8½ killos answer nearly to 1 English quarter. A killo of rice is 10 okes.

Oil and other liquids are sold by the meter, or almad: the meter weighs 8 okes, or 22½ lbs. avoirdupois; and 8 almadas equal 11 English gallons.

The pic or pike is of two forts: the longest, called halebi or archim, with which silks and woollens are measured, is 314 French lines, or 27½ English inches long; the other, called endafl, with which cotton goods and carpets are measured, is 3 per 100 shorter. But, in the general course of European trade, the pike is reckoned at 2½ths of an English yard.

The exchanges of Constantinople with the principal commercial places in Europe are as follow: Constantinople gives:

Amsterdam 60 paras, or more, for 1 florin current.
Genoa 23 paras, or more, for 1 lira fuori banco.
Hamburgh 1 piastre, for 24 grotes Fleming banco, more or less.
Leghorn 145 paras, or more, for 1 pezza of 8 reali.
London 18 piastres, or more, for 1/. sterling.
Marcellas 1 piastre for 1 franc 45 centimes, or more.
Naples 120 paras, or more, for 1 ducat regia.
Paris 210 piastres, or more, for 100 ecus of 3 livres, or 300 francs.
Venice 360 paras, or more, for 1 sequin of 2 lire piccoli.
Vienna and Trieste 50 paras, or more, for 1 florin current.

The exchanges between Constantinople and other trading places, where Turkish money is used, are done at a premium of 10 per cent. more or less, in favour of Constantinople.

Bills between Constantinople and the principal trading places of Europe are commonly drawn at 31 days' sight; but from one place, in Turkey, on another, at 11 days' sight. Some European merchants pay their bills on the very day on which they become due; and others take as many days grace as are allowed in their respective countries.

Trieste keeps accounts in florins or florins of 60 cruzenters; also in lire of 20 foldi; the cruzenter being subdivided into 4 pfnings, and the foldo into 12 denari. These monies of account are valued in Austrian currency, in Trieste currency, and in Valuta di Piazza: the first is chiefly used in foreign exchanges, the second in wholesale trade, and the third in retail business. A florin Austrian currency is worth 5½ lire of Trieste currency, or 5½ of lire di piazza. For the coins, &c., see VIENNA.

Tripoli keeps accounts in piastres of 13 grimellini, or 52 apfers: the grimellini is valued at 6 sous Tournois, which makes the piastre of Tripoli worth 3½ 36½ stersling. The weight for gold and silver is called Metael (which fee); the weight for gold and silver is called Metael (which fee); the weight for gold and silver is called Metael (which fee); the weight for gold and silver is called Metael (which fee); the weight for gold and silver is called Metael (which fee).
answer to 158 lbs. peo fottle of Venice, or about 112 lbs. avoirdupois. The corn meafure, called cafino, contains 20 tiber, and is equal to 4 flla of Venice: so that 13 caf-
fisi = 15 English quarters. The oil meafure, called mrfaro, weights 42 rotti, or about 47 lbs. avoirdupois. The pic, or elf, is equal to 28 of Genofe palm, or 215 English inches.
Kelly's Universal Cambiff.
Turky, a town of the state of New Jersey; 13 miles N.N.W. of Ambloy.
Turky Creek, a river of South Carolina, which runs into the Cangaree, N. lat. 34° 50'. W. long. 81° 35'.—
Alfo, a river of America, which runs into the Ohio, N. lat. 38° 22'. W. long. 83° 12'.
Turky Foot, a township of Pennsylvania, in Somerft countv, containing 975 inhabitants.
Turky Hill, a township of Illinois territory, in the county of St. Clair, containing 1151 inhabitants.

Turky, Meleagris, in Ornithology, a diftinct genus of birds, of the order of the Galliue. For the diftinguifhing
characters and fpecies, fee MELEAGRIS.
Wild turkeys prefer a famesens of colouring; the tame varying; but the black approaching neareft to the original
flock. Of late a beautiful kind has been introduced into England of a snowy whitenefs, finely conftraining with its
red head. The ufual weight of the wild turky is about 30 lbs.
The paflions of the males are strongly exprifed by the change of colours in the fhefly fubstance of head and neck,
which alters to red, white, blue, and yellowish, as they are diftinctly affected. One cock ferves many hens, who retire
to an obfcurc place in order to fit, the cock being apt to break the eggs. The females are very affectionate to their
young, and though the eggs addle, will almoft perifh with hunger, unlefs they are removed, before they will quit the
net.
Turkeys delight much in the feeds of nettleis, but thofe of
the purple fox-glove are fatal to them. They are fupid,
quarrelfome, and cowardly birds; they are elft runners,
but indifferent flyers; they love to perch on trees, and in a
wild iftate, get fo high as to be beyond the reach of the
mufter.
In the iftate of nature they go in flocks, even of five hund-
dred, and feed much on the fmall red acorns, frequenting
the fmpafs of their native country, where they rooff, but at
fun-rising repair to the dry woods in fearch of acorns and
berries. The fhefly of the wild turky is faid to be preferable
to that of the tame, but redder.
Wild turkeys are now very rare in the inhabited parts of
America, but are found in numbers in the dilant and moft
unfrequented fots.
The Indians make a very elegant clothing of the feathers,
twifling the inner webs into a firm double thread of hemp, or inner bark of the mulberry-tree, and working it like matting; it appears rich and glossy, and as fine as a filk
flag. They awl make fans of the tail, and the French of
Louisiana were wont to make umbrellas by the junction of
dof the tails.
Turkeys are natives of America, or the New World,
and of course unknown to the ancients: this is a point which
Mr. Peffant has eftablifhed by an elaborate induction of
various particulars in the history of these birds; evincing
that they are natives neither of Europe, Asia, nor Africa.
The first precise defcription of them is given by Ovidio, in
1525; they are also mentioned as natives of the main land
of the warmer parts of America, by Fernandez, phyfician to
Philip II., who wrote between the years 1555 and 1568: they
were also frequently feen, both in their wild and tame iftate,
by Dampier, in the province of Yucatan, now a part of
Mexico.
In North America they were obferved by the firft difco-
erers. They were firft introduced into Europe from Mexico
or Yucatan, and imported into England, probably from Spain,
as early as the year 1524. Since that period they have been
foeefifully cultivated in this kingdom, fo that in the year
1585 they made a dish even in our rural feafts. But in
France they were fo rare, that the fift which was eaten in
that kingdom appeared at the nuptial feast of Charles IX.

Turky Leather. (See Morroco Leather.) The pro-
ccefs for dyeing leather red and yellow, as practifed in Tur-
key, with the directions for preparing and tanning the skins,
as communicated by Mr. Philippo, a native of Armenia, who
obtained 100l. and a gold medal from the Society for the
Encouragement of Arts, as a reward for the discovery,
are as follow.
1. Firft Preparation of the Skins, both for Red and Yellow
Leather, by drenching them in Lime.—Let the skins, dried
with the hair on, be firft laid to soak in clean water for three
days; let them then be broken over the fleece-fide, put into fresh
water for two days longer, and afterwards hung up to drain
half an hour. Let them now be broken on the fleece-fide,
limed in cold lime on the fame fide, and doubled together
with the grain-fide outward. In this fiate they muft be
hung up within-doors over a frame for five or fix days, till
the hair be leafe; which muft then be taken off, and the
skins returned into the lime-pit for about three weeks. Take
them out, and let them be well worked fheft and grain, every
fixth or feventh day during that time; after which, let them
be wafted ten times in clear water, changing the water at
each wafting. They are next to be prepared in drench, as
below mentioned.
2. Second Preparation of the Skins for both the Red and Yel-
low Dyes by drenching.—After squeezing the water out of the
skins, put them into a mixture of bran and water, warm as
new milk, in the following proportions; viz., about three
pounds of bran for five skins, and water fufficient to make
the mixture moderately fluid, which will be about a gallon
to each pound of bran. In this drench let the skins lie three
days; at the end of which time they muft be well worked,
and afterwards returned into the drench two days longer.
They muft then be taken out and rubbed between the hands;
the water fqueezed from them, and the bran scraped off clear
from both fides of the skins. After this they muft be again
wafted ten times in clear water, and the water fqueezed out of
them.
Thus far the preparatory proces of all the skins, whether
intended to be dyed red or yellow, is the fame; but after-
wards thofe which are to be dyed red, muft be treated as
follows.
3. Preparation in Honey and Bran of the Skins that are to
be dyed Red.—Mix one pound of honey with three pints of
lukewarm water, and flir them together till the honey is
diffolved.
4. Preparation in Salt of the Skins to be dyed Red.—After the skins have been fermented in the honey and bran, as above mentioned, let them be taken out of that mixture on the eighth or ninth day, and well rubbed with dry common sea-salt, in the proportion of about half a pound to each skin; the salt must be well rubbed and worked with them. This will make them contract again, and part with a further considerable quantity of moisture; which must be squeezed out by drawing each skin separately through the hands. They must next be feraped clean on both sides from the bran, superfluous salt, and moisture that may adhere to them. After which dry salt must be stirred over the grain-side, and well rubbed in with the hand. They are then to be doubled, with the flesh-side outwards, lengthwise from neck to tail, and a little more dry salt must be thinly stirred over the flesh-side, and rubbed in; for the last operations, about a pound and a half of salt will be sufficient for each skin. They must then be put, thus folded on each other, between two clean boards, placed flopping, breadthwise; and a heavy weight laid on the upper board, in order gradually to press out what moisture they will thus part with. In this state of pressure, they must be continued two days or longer, till it is convenient to dye them, for which they will then be duly prepared.

5. Preparation of the Red Dye, in a proper Proportion for four Skins.—Put eight gallons of water into a copper, with seven ounces of fennel tied up in a linen bag. [Shenam is a drug much used by dyers in the East; and may easily be procured at any of the ports of Syria and Africa, in the Levant. It is the Eastern jointed kali, called by botanists Salicornia; and grows in great plenty in those and other parts of the East.] Light a fire under a copper; and when the water has boiled about a quarter of an hour, take out the bag of fennel, and put into the boiling fluid or lixivium, 1 lb. two drachms of alum; 2 1/2, two drachms pomegranate bark; 3 gills, three quarters of an ounce of turmeric; 3 gills, three ounces of cochineal; 5 gills, two ounces of loaf-fugar. Let the whole mixture boil about six minutes, then cover the fire, and take out a quart of liquor, putting it into a flat earthen pan; and when it is as cold as new milk, take one skin, folded lengthwise, the grain-side outwards, and dip it in the liquor, rubbing it gently with the hands. Then taking out the skin, hang it up to drain, and throw away the superfluous dye. Proceed in the same manner with the remaining three skins; repeating the operation of each skin separately, eight times, squeezing the skins by drawing them through the hands before each fresh dipping. Lay them now on one side of a large pan, let flopping, to drain off as much of the moisture as will run from them without pressure, for about two hours, or till they are cold; then tan them as below directed.

6. Tanning the Red Skins.—Powder four ounces of the belt white galls in a marble mortar, mixing it through a fine sieve. Mix the powder with about three quarters of water, and work the skins well in this mixture for half an hour or more, folding up the skins fourfold. Let them lie in this tan for 24 hours; when they must be worked again as before; then taken out, scraped clean on both sides from the first galls, and put into a like quantity of fresh galls and water. In this fresh mixture they must be again well worked for three quarters of an hour; then folded up as before, and left in the fresh tan for three days. On the fourth day they must be taken out, washed clean from the galls in seven or eight fresh quantities of water, and then hung up to dry.

7. Manner of dressing the Skins after they are tanned.—When the skins have been treated as above, and are very near dry, they should be scraped with the proper instrument or serrate on the flesh-side, to reduce them to a proper degree of thickness. They are then to be laid on a smooth board, and glazed by rubbing them with a smooth glass. After which they must be oiled, by rubbing them with olive-oil, by means of a linen rag, in the proportion of one ounce and a half of oil for four skins; they are then to be grained on a graining-board, lengthwise, breadthwise, and cornerwise, or from corner to corner.

8. Preparations with Galls, for the Skins to be dyed Yellow.—After the four skins are taken out of the drench or bran, and clean washed as before directed in the second article, they must be very well worked, half an hour or more, in a mixture of a pound and a half of the belt white galls, finely powdered, with two quarts of clean water. The skins are then to be separately doubled lengthwise, rolled up with the flesh-side outwards, laid in the mixture, and close pressed down on each other, in which state they must continue two whole days. On the third day let them be again worked in the tan; and afterwards scraped clean from the galls, with an ivory or brass instrument (for no iron must touch them). They must then be put into a fresh tan, made of two pounds of galls finely powdered, with about three quarts of water, and well worked therein fifteen times. After this they must be doubled, rolled up as before, and laid in the second tan for three days. On the third day, a quarter of a pound of white sea-salt must be worked into each skin; and the skins doubled as before, and returned into the tan, till the day following, when they are to be taken out, and well washed five times in cold water, and four times in water lukewarm. The water must be then well squeezed out, by laying the skins under press, for about an hour, between two boards, with a weight of about 200 or 300 pounds laid upon the uppermost board, when they will be ready for the dye.

9. Preparation of the Yellow Dye, in the proper Proportion for four Skins.—Mix six ounces of caffia or ghebra, or the berries of the Eastern rubus, with the same quantity of alum; and pound them together till they be fine, in a marble or brass mortar, with a brass pestle. [The ciafia is the berries of the Eastern rubus, or buckthorn-tree; and may be had at Aleppo, and other parts of the Levant, at a small price. The common Avignon or yellow berries may be substituted, but not with so good an effect; the ciafia being a stronger and brighter yellow dye, both for this use and also that of colouring paper-handings, &c.] Then dividing the materials, thus powdered, into each equal part of four ounces each, put one of those parts into about a pint and half of water, in a china or earthen vessel, and stir the mixture together. Let the fluid stand to cool, till it will not scald the hand. Then spreading one of the skins flat on a table, in a warm room, with the grain-side uppermost, and the flesh-side downwards, rub it well with a smooth glass; let it continue for about three hours, then hang it up to dry.
side uppermost, pour a fourth part of the tinging liquor, prepared as above directed, over the upper or grain-side, spreading it equally over the skin, with the hand, and rubbing it well in. Afterwards do the like with the other three skins, for which the mixture first made will be sufficient.

This operation must be repeated twice more on each skin separately, with the remaining eight ounces of the powder of the barries and alum, with the above-mentioned dye proportions of hot water, put to them as before directed.

The skins, when dyed, are to be hung up on a wooden frame, without being folded, with the grain-side outwards, about three quarters of an hour to drain; when they must be carried to a river or stream of running water, and well washed therein six times or more. After this they must be put under pressure for about an hour, till the water be well squeezed out; afterwards the skins must be hung up dry in a warm room.

This being done, the skins are to be dressed and grained as before directed for those dyed red; except the oiling, which must be omitted.

The processes for dressing and preparing the skins of lambs, sheep, goats, and other thin hides are various, according to the nature of the article. This branch of the manufacture supplies the large demand of white and dyed leather for gloves, the leather called morocco of different colours and qualities, used for coach-linings, book-binding, pocket-books, &c. This leather is applicable to a variety of other purposes. The white leather is not tanned, but finished by the mere procés of tawing; but the coloured leather receives a tanning, generally by sumach, independent of the other materials. The previous preparation of each, or that in which the skin is thoroughly cleaned and reduced to the state of simple membrane, in which it is called pelt, is essentially the same, whether for tawing or dyeing.

It is thus performed at the best manufactories at Bermondsey, near London, a place long celebrated for all branches of the leather busines.

By far the greater number of the skins are imported: if lambs, they are thus prepared; the skins are first soaked for a time in water, to cleanse them from any loose dirt and blood, and put upon the beam commonly used for the purpose, which is a half cylinder of wood covered with strong leather, and scraped on the flesh-side with the semicircular blunt knife with two handles, used in this operation. They are then hung up in considerable numbers in a small close room heated by flues, where they remain to putrefy for a given time. During this process a thick, dirty slime works up to the surface of the skin, by which the regularity of the process is judged; and the wool is loosened, so that it readily comes off with a slight pull. Each skin is then returned to the beam, the wool taken off and preferred, and all the slime worked off with the knife, and the rough edges pared away. The skin is then put into a pit filled with lime-water, and kept there from two to six weeks, according to the nature of the skin, which has the effect of checking the further putrefaction, and produces a very remarkable hardening and thickening of its substance, and probably also it detaches a further portion of the slime. The skin is again well worked upon the beam, and much of its substance pared down, and all inequalities smoothed with the knife. Much pains and judgment are required in these operations, on one hand not to endanger the substance of the skin by the putrefaction (which if carried on too long would soon reduce it to an incohesive pulp), and on the other hand to work out every particle of the slime, of which the leaf, if retained, will prevent the skin from drefling well in the subsequent processes, and from taking the dye uni-

formly and well. The skin is then again softened and freed from the lime by being thrown into a vat of bran and water, and kept there for some weeks in a state of gentle fermentation, being occasionally returned to the beam. All the thickening produced by the lime is thus removed, and the skin is now highly purified, and is a thin extensible white membrane, called in this state a pelt, and is fit for any subsequent operation of tawing or dyeing, or oil dressing, or shomoying.

The method of bringing kid and goat's skins to the state of pelt is nearly the same as for lambs, except that the liming is used before the hair is taken off, the hair being of but little importance, and only to the plaiters; but the lamb's wool, which is more valuable, would be injured by the lime. Kids' skins will take a longer time in tanning than lambs.'

If the pelt excepted, they are put into a solution of alum and salt in warm water, in the proportion of three pounds of alum and four pounds of salt to every 120 middle-sized skins, and worked about therein till they have absorbed a sufficient quantity. This again gives the skin a remarkable degree of thickness and toughness.

The skins are then taken out and washed in water, and then again put into a vat of bran and water and allowed to ferment for a time, till much of the alum and salt are got out, and the unusual thickening produced by it is for the most part reduced. They are then taken to a lofty room with a flue in the middle, and stretched on hooks and kept there till fully dried. The skins are then converted into a tough, flexible, and quite white leather; but to give them a glossy finish, and to take off the harshness of feel till remaining, they are again soaked in water to extract more of the salt, and put into a large pail containing the yolks of eggs beat up with water. Here the skins are trodden for a long time, by which they go completely imbibed the substance of the eggs, that the liquor above them is rendered almost perfectly limpid, after which they are hung up in a loft to dry, and finished by glowing with a warm iron. There are other smaller manipulations, which need not be here mentioned.

The essential difference therefore between tanning and tawing is, that in the former case the pelt is combined with tan and other vegetable matter, and in the latter with something that it imbibes from the alum and salt (possibly alum), and which is never again extracted by the subsequent washing and brauning.

The morocco leather prepared chiefly from sheep's skins and used for coach-linings, the best kind of book-binding, &c. is prepared by the following process. The skin, cleaned and worked in the way already described, is taken from the lime-water, and the thickening thereby occasioned is brought down, not by bran liquor as in tawing, but by a bath of dogs' or pigeons' dung diffused in water, where it remains till sufficiently supplied, and till the lime is quite got out, and it becomes a perfectly white clean pelt. If intended to be dyed red, it is then fewed up very tight in the form of a sack, with the grain side outwards (the dye only being required on this side), and is immered in a cochinial bath of a warmth just equal to what the hand can support, and is worked about for a sufficient time till it is uniformly dyed, a process that demands much skill and experience. The sack is then put into a large vat containing sumach infused in warm water, and kept for some hours till it is sufficiently tanned.

The skins intended to be blacked are merely sumached without any previous dyeing. After some further preparation, the colour of the fine red skins being finished with a weak
weak bath of saffron, the skins when dry are grained and polished in the following way. They are stretched very tight upon a smooth inclined board, and rubbed over with a little oil to supple them. Those intended for black leather are previously rubbed over with an iron liquor, by means of a stiff brush, which unites with the gallic acid of the liquor, instantly strikes a deep and uniform black. They are then rubbed by hand with a ball of glass cut into a polygonal surface, with much manual labour, which polishes them and makes them very firm and compact. Lastly, the graining or ribbed surface by which this kind of leather is distinguished, is given by rubbing the leather very strongly with a ball of box-wood, round the centre of which a number of small equi-distant parallel grooves are cut, forming an equal number of narrow ridges, the friction of which gives the leather the desired inequality of surface.

The proceeds for the real morocco leather, as prepared from goat-skins at Fez and Tetuan, is thus described by M. Broussonet. The skins are first cleaned, the hair taken off, limed and reduced with bran, nearly in the way already described for the English morocco leather. After coming from the bran they are thrown into a second bath made of white figs, mixed with water, which is thereby rendered slimy and fermentable. In this bath the skins remain four or five days, when they are thoroughly salted with sal-gem (or rock-salt) alone (and not with salt and alum), after which they are fit to receive the dye, which for the red is cochineal and alum, and for the yellow, pomegranate bark and alum. The skins are then tanned, dressed, suppled with a little oil, and dried.

Much excellent leather of every kind is prepared in different parts of the Russian empire. The preparation of the fine Russian leather, so well known for its quality and for its peculiar smell, is described in large in Mr. Tooke's "View of the Russian Empire," to which we must refer the reader for the minuter particulars. In general it may be stated that the hides are first put into a weak alkaline ley to loosen the hair, and then scraped on a beam, then (if calves) are reduced by dogs' dung, and a four oatmeal drench, then tanned with great care and frequent banding. The bark used here is feldom oak, but, where it can be got, the bark of the black willow, or if this cannot be had, birch-bark. They are then dyed either red or black, these being the two colours the most esteemed. For the red, the hide is first soaked in alum, and then dyed with Brazil wood. The black is given as usual with an iron liquor. The leather is then aired with birch-tar, which gives the peculiar smell so much prized (and which, when used for book-binding, has the valuable property of protecting the book from worms), and is finished by various other manipulations. The trenched or barred surface is given to the leather by a very heavy steel cylinder wound round with wires. See Vults.

A valuable saffian or dyed maroon leather, almost equal to that of Turkey, is prepared largely at Aitracah and other parts of Asiatic Russia. Only bucks' and goats' skins are used for this purpose. The favourite colours are red and yellow. The general method of preparing the pelts is the same as in this country for the dyed morocco leather, that is by lime, dogs' dung, and bran. Honey is also used after the branning. The honey is dissolved in warm water, and some of this liquor is poured on each skin spread out on wooden trays till it has imbied the whole of the honey, after which it is let to ferment for about three days, and then salted in a strong brine and hung up to dry. The skin is then ready to receive the dye, which for red is made with cochineal and the falsola erioides, an alkaline plant growing plentifully on the Tartarian salt deserts, and the colour is finished with alum. When dyed, the skins are tanned with sumach. To the very finest reds, a quantity of tannin is used with the cochinal bath, and the subsequent tanning is given with galls instead of sumach, which renders the colour as durable as the leather itself. The roughness always observed on the surface of the skin, is given by a heavy kind of iron rake with blunt points. The yellow saffians are dyed with the berries of a species of rhambus (the Avignon berry would answer the same purpose, and is used in other countries), or with the flowers of the wild camomile. For other kinds of leather, see Shagreen and Shamos.

Turkey-Pod, in Agriculture, a troublesome weed in dry sandy pastures, but which is only an annual.

Turki, in Geography, a town of Hindoostan, in Basar; 31 miles W.N.W. of Durbangah. N. lat. 26° 18'. E. long. 86° 33'.—Also, a town of Grand Bucharia; 30 miles N. of Termid.

Turkina, a town of Russia, in the government of Caucasus, on the Caphian sea; 140 miles S. of Affrachan. N. lat. 44° 15'. E. long. 42° 14'.

Turkish Coins, Measures, and Trees, see the Sublacis, and Turkey.

Turkomans, Turcomans, or Turkmans, in Geography, a denomination distinguishing some of the Tartar hordes, who, on the great revolutions of the empire of the caliph, emigrated from the eastward of the Caphian sea, and spread themselves over the vast plains of Armenia and Asia Minor. After having been introduced into the Arabian empire, they proceeded to give law to those who called them in, either as mercenaries or allies. This was signally experienced by the caliphs themselves. In 934, Motaizam, brother and successor of Almam, having taken a body of Turkmans for his guards, was compelled to quit Bagdad on account of their disorder, and, after his time, their power and influence increased to such a degree, that they became the dispensers of the throne and life of their princes, and murdered three of them in less than thirty years. The caliphs, when freed from this bondage, did not profit by their experience; for about the year 935, Radi Begalah, having again renounced his authority to a Turkman, his succedors were entangled in their former chains, and guarded by the Emis-el-0mara, possessed only the shadow of power. Amidst the disorders of this anarchy, a multitude of Turkman hordes penetrated into the empire, and founded different independent states, in the Kerman and the Khorasan; at Iconium, Aleppo, Damascus, and in Egypt. Until this time the Turks, called "Ogouzians," had remained to the E. of the Caphian and toward the Dijboun; but, about the beginning of the 13th century, Chengis Khan, having united all the tribes of Upper Tartary against the princes of Balk and Samarcand, the Ogouzians did not think proper to wait for the Moguls, but marched under their chief Soliman, and driving their herds before them, encamped (in 1214) in the Azerbeidjan, to the number of 50,000 herdmen. The Moguls followed them, and pushed them still farther to the west, into Armenia. Soliman, bearing a gold chain, ordered, on his own authority, the cememn (in 1220) in endeavouring to pass the Euphrates on horseback, Ergotruj, his son, took the command of the hordes, and advanced into the plains of Asia Minor, where he was relieved by the abundant pasture which they afforded for his cattle. The good conduct of this chief procured him in these countries, a power and respect which made his alliance sought after by other princes. Among
Among these was the Turkman Ala-el-din, sultan of Iconium. Ala-el-din, advanced in life and harried by the Tartars of Genghis Khan, granted lands to the Turks under Ertogrul, and even made their chief general of all his troops. Ertogrul proved himself deserving the confidence of the sultan, vanquished the Moguls, acquired still greater power and reputation, and transmitted his honours to his son Olman, who received from Ala-el-din, successor of the former of that name, the Kofetan, drum, and horse-tails, which are symbols of command among all the Tartars. This Olman, to distinguish the Turks, his followers, from the others, gave them the name of "Olmanes," from which we have made Ottomans; which new name soon became formidable to the Greeks of Constaninople, from whom Olman conquered a sufficient extent of territory to found a powerful kingdom. He soon bellowed on it that title, by assuming, in 1350, the dignity of sultan, which signifies absolute sovereign.

No one is ignorant in what manner his successors, the heirs of his ambition and activity, continued to aggrandize themselves at the expense of the Greeks; till, continually depriving them of whole provinces in Europe and Asia, they at length fitted them up within the walls of Constaninople; and Mahomet II. son of Amurath, having taken that city in 1453, annihilated this branch of the Roman empire. The Turks, now finding themselves disengaged from the affairs of Europe, turned their ambitious arms against the southern provinces. Bagdad, subjugated by the Tartars, had been without caliphs for two hundred years, but a new power, established in Perlia, had succeeded to a part of their domains; and another, formed in Egypt, so early as the tenth century, and subduing, at that time, under the name of Mamlouks, had feized on Syria.

The Turks determined to despise those two rivals. Bayazid, the son of Mahomet, executed a part of this plan, by taking Armenia from the Son of Perlia, and Selim his son completed it, by the conquest of the Mamlouks. This sultan having drawn them near to Aleppo, in 1517, under pretext of defiring their allegiance in the war with Perlia, suddenly turned his arms against them, and took from them successively Syria and Egypt, whither he pursued them. From that time the Turks established themselves in that country; but they are not settled much among the villages. We rarely meet with any individuals of that nation, except at Cairo; there they exercise the arts, and occupy the religious and military employments. Formerly they also were advanced to posts under government, but, within the last thirty years, a tacit revolution has taken place, which, without taking from them the title, has deprived them of the reality of power. See Turk and Turkey.

Volney observes, that the language of the Turkmans is the same with that of the Turks, and their mode of life nearly similar to that of the Bedouin Arabs. Like them, they are pious, and consequently obliged to travel over immense tracts of land to procure subsistence for their numerous herds. But there is this difference, that the countries frequented by the Turkmans being rich in pastureage, they can feed more cattle on them, and are therefore less differing than the Arabs of the desert. Each of their "ords" (hence borda), or camps, acknowledges a chief, whose power is not determined by fixed laws, but governed by custom and circumstances. It is rarely abused, because the society is compact, and the nature of their situation maintains sufficient equality among its members. Everyone able to bear arms is anxious to carry them, since on his individual force depend both his personal safety, and the respect paid him by his companions. All their property consists in cattle, that is camels, buffaloes, goats, and especially sheep. They live on milk, butter, and meat, which are in great abundance among them, and the surplus of which they sell in the towns and the neighbouring country, for they are almost able alone to supply the butcheries. In return, they take arms, clothes, money, and corn. Their women spin wool, and make carpets, the use of which is immemorial in these countries, and consequently indicates their manner of living to have been always the same. As for the men, their whole occupation consists in smoking, and looking after their flocks. Perpetually on horseback, with their lances on their shoulders, their crooked fabrics by their sides, and their pillows in their belts, they are expert horsemen and indefatigable folders. They have frequent differences with the Turks, who dread them; but as they are divided among themselves, and form separate camps, they do not assume that superiority which their combined forces would ensure them. The pachalics of Aleppo and Damascus, which are the only parts of Syria they frequent, may be computed to contain about 30,000 wandering Turkmans. A great number of these tribes pass, in summer, into Armenia and Caramania, where they find grass in greater abundance, and return to their former quarters in the winter. The Turkmans are reputed Muffulmen, and generally bear the distinguishing mark, circumcision. But they trouble themselves very little about religion, and they have neither the ceremonies, nor the fanaticism of sedentary nations. As for their manners, to describe them accurately, it would be necessary to have lived among them. They have, however, the reputation of not being robbers, like the Arabs, though they are neither less generous, nor less hospitable than they; and when we consider that they live in plenty, without being rich, and are inclined to war, and hardened by fatigue and danger, we may presume they are equally removed from the ignorance and servility of the peasants, and the corruption and selfishness of the inhabitants of the towns. See Truchimianes.

Turlach-More, i.e. the Great Turlach, in the county of Galway, Ireland, a kind of lake, formed by the expansion of the rivers Clare and Moyne, which is upwards of six miles in length, and two in breadth; but which in summer, from the water being carried off by subterraneous passages, becomes a beautiful and found sheep-walk.

Turlach, a town of Hindoostan, in the circuit of Ciscolle; 25 miles E. of Kimedy.

Turlah, a town of Hindoostan, in the circuit of Ciscolle; 25 miles E. of Kimedy.

Turlos, a small island in the gulf of Engia, near the N.E. point of the island of Engia.

Turlupnade, a term used chiefly among the French for a low leaf or witticism. The occasion of the name is said to be derived from a famous comedian at Paris, called Turlupin; whose talent confided chiefly in raising a laugh by miserable puns and quibbles.

Turlupins, Turlupini, a denomination given to the brethren of the free spirit; whole external aspect and manners carried a very shocking air of lunacy and distraction.

They called their sect the fraternity of the poor, and spread themselves over England and France. They are said by some to have had their name turlupines, quod ea tantum habenter loca, que lupis expedita erant.

They attempted to settle themselves at Paris in 1372, but were a great part of them burnt, with their books; as is related by Gaguin and Du Tillet, in the life of Charles V.

Turmeric, Curcuma, in the Materia Medica, a medicin-
nal root, being the root of the Curcuma longa of Linnaeus, used likewise by the dyers, to give a yellow colour.

It is externally greyish, and internally of a deep lively yellow or saffron colour, very hard, and not unlike, either in figure or fize, to ginger.

It is brought chiefly from the East Indies, but it is common in the gardens of the Chinese, who use it as a mordant, and grows abundantly in Malacca, Java, and Batica. In England it was first cultivated by Mr. P. Miller in 1759. It has been long officially known. That should be choen which is big, new, refined, hard to break, and heavy.

Some people have mistaken it for Indian saffron, and their error was owing to this, that the yellow root, as it grows old, turns brown; and when pulverized, is reddish. It is much used by the grovers, &c. to dye their gloves. The Indians use it to dye their rice, and other foods, of a yellow colour: whence some call it Indian saffron.

Our dyers do not find that it gives so readily a yellow as the luteoia, or weld; nor can any of the mordants give it a sufficient degree of durability; common salt and ammoniacal muriate fix its colour fast, at the same time rendering it deeper; but it is admirable to brighten and heighten the red colours dyed with cochineal and vermillion; as scarlets, &c.

Turmeric has a slight aromatic, and not very agreeable smell; and a bitterish, slightly acid, and somewhat warm taste. It readily gives out its active matter, both to aqueous and spirituous menstrua; communicating to the former its own deep yellow, and to the latter a fine yellowish-red tincture. Diluted with water, it yields a small quantity of a gold-coloured essential oil, of a moderately strong smell, and pungent taste: the remaining decoction, infipid, leaves a bitterish, considerably saline taste. The infipid extract from rectified spirit is moderately warm and bitter, and not a little nauseous. In the Eastern countries, this root, besides its use in colouring and seasoning their food, is much recommended as a medicine; being accounted one of the most effectual remedies in obstructions of the visera and mfenfery, which are there frequent; in uterine disorders, difficulties of urine, and affections of the kidneys. Among us it has also been employed by way of decoction, infusion, and powder, as a debulgruent, in hypochondria, leuko-plagmatic, and cachectical constitutions; and esteem'd by some as a specific in the jaundice: the dose in infusibn is from a scruple to a drachm; in decoction or infusion twice as much. It tinges the urine of a deep yellow colour. Lewis.

Although the ufe of this root has been highly commended, it is now very rarely employed. A platter of turmeric, well bruised, top and roots, is thought to be good against the bite of the rattle-snake. See Phil. Trans. No. 479. p. 144.

Turmeric-Wash, is the gum of the turmeric-root dissolved in water.

The qualities and uses of it are much the same as those of the yellow-berry wash for water-painting; but it is a brighter and cooler yellow; for which purpose it should be dissolved in spirit of wine instead of water, by putting two ounces of proof-spirit, and one ounce of water, in a phial, with two drachms of powdered turmeric-root, shaking them well together, and letting them stand, with a repetition of the shaking, for three or four days.

TURMERO, in Geography, a town of South America, in the government of Caraccas; 40 miles S.W. of Leon de Caraccas.

TURN, a town of Wallachia, at the confluence of the Alaut and the Danube; 24 miles S. of Brancovani.

Vol. XXXVI.

TURN is used for a circular motion; in which sense it coincides with revolution.

TURN, in a Clock or Watch-work, particularly denotes the revolution of a wheel or pinion.

In calculation, the number of turns which the pinion hath is obtained by common arithmetic; thus 5\frac{60}{12}, where the pinion 5, playing in a wheel of 60, moves round 12 times in one turn of the wheel. Now, by knowing the number of turns which any pinion hath in one turn of the wheel it works in, you may also find how many turns a wheel or pinion has at a greater distance; as the contrate-wheel, crown-wheel, &c. by multiplying together the quotients, and the number produced is the number of turns, as \(5\frac{55}{11}\) in this example:

The first of these three numbers has 11 turns, the next 9, and the last 8. If you multiply 11 by 9, that is, in one turn of the wheel 55, there are 99 turns of the second pinion 5, or the wheel 40, which runs concentrical or on the same arbor with the second pinion 5; if you multiply 99 by the last quotient 8, it produces 792, which is the number of turns the third pinion 5 hath. See Clock-Work and Pinion.

TURN, in Mining, is a pit funk in some part of a drift. If the mine be deep, there are many of these turns one below another.

TURN-House. When a drift is driven across the country N. and S. to cut a lode, the miners make a right angle from their drift, and work on the lode itself; which, as it is in a contrary direction to their past drift, they call turning-house, in order to work on the course of the lode.

TURN, in the Manoeuvres, is an arm commonly used in directing to change hands. See Change and Enter.

TURN, in the Sea Language. See LAND TURN, TACK, and TURNING.

TURN, or TOURN, is also used for the sheriff's court, kept twice a year in every hundred within his county, viz. a month after Easter, and within a month after Michaelmas.

From this court none are exempted but archbishops, bishops, earls, barons, religious men and women, and all such as have hundreds of their own to be kept.

It is a court of record in all things that pertain to it, and is also the king's feet through all the county, of which the sheriff is judge; this court being incident to his office. The attendance on it is called festa regalis, or fait-royal.

It is called the sheriff's turn, because he takes a turn or circuit for this purpose through the shire, holding the same in several places.

TURN in the Head, in Rural Economy, a disease in calves and young cattle, in which external objects would appear to turn round. The affection in this case seems to arise from some diseased state of the brain, or parts about it.

In the cured, bleeding is advised, in proportion to the size and strength of the animal; after which a powder, composed of camphor, valerian, nitre, and birthwort, in the quantity of a drachm of the first to an ounce of each of the other ingredients, should be well powdered and mixed together, and then given at once in a pint of rosemerry tea, repeating it as occasion may require.

By this means much advantage has been gained, it is said, in some instances of this disease.

TURNADO. See TORNADO.

TURNAGAIN ARMS, in Geography, a branch of the north part of Cook's inlet, extending east from Point Pofleffion.
The term "Turnament," or "Tournament," refers to a form of medieval sport which featured the display of skill in jousting and combat. The first tournaments were held in France, with the Turnament of 1347 under Richard II being renowned. These contests were not just about winning but also about displaying skill and bravely. The arms used in these tournaments included swords, lances, and shields, and the participants were often knights and nobles. The tournaments were often held with the approval of the local authorities and were part of the cultural and social life of the time. They were also opportunities for noblewomen to observe and participate in the activities of their menfolk. The tournaments were not only entertainments but also served as a means of introducing and disseminating new forms of literature and art, as evidenced by the translations and commentaries written about them. The tournaments were a part of the larger body of literature that included works in Latin, such as those by Varro and Cicero, which were translated into vernaculars like French, to reach a wider audience. The tournaments were not only a form of entertainment but also a way to propagate learning and knowledge.

TURNELL ISLAND, in Geography, an island in the bay of Honduras, about 20 miles long, and 10 broad, abundant in cocoa-nut trees, and much frequented by fisher men. N. lat. 17° 16', W. long. 88° 20'.

TURNEP, in Botany, &c. See BRASSICA and TURNIP.

TURNER, WILLIAM, in Biography, one of the fathers of English botany as well as of the English Protestant church, was born at Morpeth in Northumberland, probably about the year 1520. He was educated at Pembroke college, Cambridge, under the patronage of Sir Thomas Wentworth, and about the year 1538 had already distinguished himself for science and learning, being jutified with the little real information he could obtain from those about him. Natural philosophy, medicine, and botany, chiefly engaged his attention at this time, but the great questions involving the vital interests of religious truth and liberty, having been stirred up, he devoted himself also to their examination, and incurred the danger and obloquy incident to men or laws, in every age and country, to the honest prosecution of such enquiries. Turner, like many others in England, at this period, united the characters of a physician and a divine. He became an itinerant preacher, for zealously a character that the infamous bishop Gardiner threw him into prison; from whence he was, after a long time, released, we are not informed by what means, and became a voluntary exile from his native land. He resided on the continent with many other English refugees, principally at Cologne, and Bals, till the death of Henry VIII. During this interval, Turner travelled into Switzerland and Italy, where he contracted a friendship with many distinguished botanists and physicians, especially the great Conrad Gesner of Zurich, and professor Ghini of Bologna, the founder of the phyc-garden, and of the botanical chair, in that university, and the predecessor of Cefalpinus and Anguillara. At Ferrara Turner received the degree of doctor of physic, which was confirmed to him at Oxford, when he returned to England on the accession of Edward VI. He was made physician to the Protector Somerset, and his ecclesiastical merits were still more amply rewarded, by a prebend of York, a canonry of Windsor, and the deanship of Wells. He had deferred this preferment by several publications in defence of Protestantism, which very caule, however, obliged him to fly from the perfecutions of the bloody Mary, during whose reign Dr. Turner remained abroad. The accession of Elizabeth restored him to his liberty and native soil, as well as to all his ecclesiastical benefits. The rest of his life was devoted to his clerical duties, and his botanical amusements; two pursuits which in many honest and good men have gone very lovingly together, to their mutual advantage and honour. He had a botanical garden at Wells, and another at Kew, and appears to have divided his time between his deanship, and his residence in Crotch Friars, London. Dr. Pulteney thinks, from Turner's frequent mention of the plants of Purbeck, and Portland, that he had some intimate connections in Dorsetshire. This worthy man died July 7, 1568, apparently at no very advanced age, leaving several children. His son Peter was educated to physic, travelled, and took degrees abroad; was incorporated doctor at Cambridge, and at Oxford, and died, aged 72, in 1614, but does not seem to have inherited his father's turn for botany.

Turner's earliest botanical work is said to have been printed at Cologne in 1544, in octavo, under the title of Historia de naturis herbarum, schedis et notis valutaria. But this is mentioned by Bumaldus, or rather Ovidius Montanaus, only, in his Bibliotheca Botanica, Seguier's edition, p. 18, without notice of any other publication of our author; nor does it appear to be known to English collectors, any more than the following. "Names of Herbes in Greek, Latin, English, Dutch, and French," printed at London, 1548, in 12mo., by the same writer.

The chief publication of Dr. Turner is his well-known Herbal, in small folio, black letter, with wooden cuts, of which the first part was originally printed at London in 1551, and is now, on account of its rarity, much valued by collectors. The second part appeared at Cologne in 1562, accompanied by a reimpresison of the first. In 1568 the first and second parts were reprinted at the same place, with a new title page, a dedication to Queen Elizabeth, from which many of the above particulars of the author's life are taken, and the addition of a third part of the same work. To the whole are subjoined "A booke of the natures and properties as well of the bathes in England as of other bathes in Germanye and Italye, very necessarye for all sycke perforce that can not be healed without the helpe of natural bathes"; and "A most excellent and perfecte homih apostlcarie or homely phystick booke, for all the greves and dyesales of the bodye, translated out of the Almane speche into English, by Jhon Hollybusch." For this last lament production Turner is, perhaps, not responsible. The Herbal is arranged alphabetically, and is more original and practical, than the more popular and celebrated publications of Lyte, Gerard, or even Parkinson. The object of the author was to determine the plants of the ancients, and to record their reputed virtues. This is accomplished with more caution and discretion than are common to most of his contemporaries, and with very few dogmatical confidences than Fabius Columba subsequently affirmed. The third part, dedicated to the company of surgeons, professes more especially to treat of medical plants not known to the ancients. The author apologizes in these terms for its imperfections. "For surely bying so much vexed with sicknes, and occupied with preaching and the study of divinity and exercise of discipline, I have had but small leasure to write Herballes." This dedication is dated "at Welles 1564." The wooden cuts of all the three parts of Turner's Herbal are taken from those of Fuchsius, and at first sight appear to be the very same blocks as those used in the octavo edition of the latter author, printed at Lyons, in 1595. A careful inspection however will easily detect minute differences; and we especially observe slight damages in Turner's figures, not occurring in this later impression, which decisively prove it to have been printed from more recent cuts. Haller gives us the author credit for having first figured the true Medicago, and the Rhus Cotinus; see part 2d, 52 and 115. Under the former he describes various species of Medicago, distinguishing their different seed-vessels; and of the latter exhibits a sufficiently expressive delineation, with a correct, though brief, history.

Turner ranks more amongst our earliest British zoologists. He published at Cologne, in 1544, an octavo of ten pages, entitled Aevin praecipuorum, quarnus apud Plinium et Aristotelis mentio of, historia. Conrad Gesner, to whose museum he repeatedly contributed, after his settlement in England, speaks of him as eminently deserving of praise in the department of ornithology; and Merret in his Pinax mentions the above little book, as great in authority, though small in bulk. Gesner has prefixed to the third volume of his own ponderous Historia Animalium, a letter of Dr. Turner's, dated Wissenburg, Nov. 1557, in which the various
kinds of Fishes known in England, amounting to more than fifty, are briefly distinguished, with their Latin and English names. At the conclusion of the dedication of his Herbal to the queen he promises a book of the names and natures of fishes that are within her majesty's dominions, if he might have reft and quietness in his old age, and defence from his enemies, "whiche," says he, "have more then these eight yeares continually troubled me very much, and holden me from my booke." He speaks here also of sickness, as an impediment to his labours. His work upon baths is marked with the fame originality of thought, and practical observation, as his botanical and zoological writings. Turner wrote also on the "Wines commonly used in England," and on the "Nature and Virtue of Tuscple." His numerous treatises on controversial divinity, published and unpublished, were chiefly in defence of the Reformation; but his most valuable undertaking of this kind we preface to have been his collation of the translation of the Bible, with Hebrew, Greek, and Latin copies, in consequence of which he found occasion to correct it in many places. How far his corrections were turned to advantage by the translators in James I.'s time, we are not informed.

Dr. Pulteney observes, that "he procured to be printed at Antwerp, a new and corrected edition of the Historia Genii noflrar. f. Anglia, written by William of Newburgh, from a manuscript he found in the library of Wells;" but he complains of the printer, for omitting his preface as well as other communications. Turner translated several works from the Latin, particularly "The Comparison of the old Learning and the new?" written by Urbanus Regius; printed at Southwark in 1537, in 8vo.; and again in 1538 and 1548. We regret having never met with this book, as the subject promises much; and in the hands of Turner, or any man like him, who dared to think for himself; and whose judgment was regulated by prudence and learning, it could not but be valuable and instructive. — Turner's Herbal. Haller's Bibl. Bot. Pulteney's Sketches of the Progress of Botany. Dryand. Bibl. Banks. S.

TURNER, WILLIAM, a fellow student with Purcell and Dr. Tudway, among the second set of chapel-children under Dr. Blow, was sworn in gentleman of the royal chapel in 1669, as a counter-tenor usher, his voice fretting to that pitch; a circumstance which fo seldom happens, naturally, that if it be cultivated, the possessor is sure of employment: and, in consequence of its utility, soon after his reception into the chapel royal, he was appointed vicar-choral in the cathedral of St. Paul's; and a lay-vicar of the collegiate church of St. Peter, Westminister. In 1696, he was admitted to the degree of doctor in music at Cambridge.

Dr. Turner arrived at the great age of eighty-eight, and dying in 1746, was buried in the cloister of Westminister Abbey, in the same grave with his wife; who, being nearly of the same age, died but four days before him, after living together with great harmony of disposition, and felicity, near seventy years.

In many of our cathedral books there is an anthem, "I will alwaye give thanks," which is called the *club-anthem*, on account of its having been composed by three masters in conjunction; but not, as has been said, by Dr. Boyce and others, "as a memorial of the strict friendship that subsisted between them?" for, according to Dr. Tudway, who remembered the transaction, and records it with the anthem in the Mus. Collec. vol. iii. "the anthem was composed by order of Charles II. at a very short notice, on account of a victory at sea over the Dutch, the news of which arrived on Saturday, and the king willing to have the anthem performed the next day, and none of the masters
Flowers sessile on the footstalks. Leaves ovato-lanceolate, acute, coarsely serrated, with two glands at the base. Outer calyx ovato-lanceolate, notched.—Native of the red hills, and other places, in Jamaica; cultivated by Miller, and frequently seen in our flowers, especially the narrow-leaved variety, B, flowering from June to November. The stem is shrubby, but soft, or partly herbaceous, halving a few years only, several feet high, with roundish, wavy, downy branches, leafy at the ends. Leaves ovate, or lanceolate, varying in length from two to three inches, and in breadth from half an inch to above an inch, unequally and bluntly serrated, strongly ribbed and veined, soft and downy on both sides, felifid when bruised. Footstalks half an inch or an inch long, bearing two peltate glands near the top. Flowers large, bright yellow, short-lived, solitary, on the footstalks of several of the upper leaves, close to the leaf itself. Outer calyx of two ovato-lanceolate, strongly notched or serrated, permanent leaves, resembling the proper foliage; inner tubular, silky, yellowish, in five lanceolate, entire, deciduous segments, shorter than the corolla. We can scarcely think there is any specific difference between the broad and the narrow-leaved varieties. Willdenow’s β and γ are precisely the same plant. He, like Linnaeus, erroneously refers Sloane’s synonym to the broad-leaved variety, though Martyn had previously, like Miller, considered it as belonging to our β. His figure, in fact, represents that intermediate form of leaf which most usually occurs.

2. T. subulata. Awl-shaped Turnera.—Flowers sessile on the footstalks. Leaves ovate, acute, coarsely serrated, with two glands at the base. Outer calyx awl-shaped, entire.—Gathered in New Granada by Mutis, whose specific name was very inappropriately referred by Linnaeus to T. ulmifolia. The leaves are ovate, not much above an inch in length, very downy and hairy, like the flalks and branches. Flowers like- width smaller than those of ulmifolia; their petals, in the dried specimen at least, nearly white, with purple radiating spots on the disk. Calyx clothed with dense silky bristles; the leaves of the outer one very narrow, awl-shaped, channelled, and quite entire, affording a decisive specific character. Capsule the size of a pea, clothed with long silky bristles. The peltate glands, on the edge of the leaf itself, are very large and conspicuous in this species.

3. T. obtusifolia. Blunt-leafed Turnera.—Flowers sessile on the footstalks. Leaves obovate, obtuse, coarsely crenate, with two glands at the base. Outer calyx linear-lanceolate, flat, entire.—Native of Brazil. Communicated to the younger Linnaeus by Thouin, probably from Commerson’s collection. This is very clearly distinguishable from the two former by its broad obtuse leaves, fearly an inch and a half long, and one inch in breadth; wedge-shaped at the base; broadly and bluntly crenate. The leaves of the outer calyx are broader, flatter, and rather shorter, than in the leaf, measuring about half an inch. Capsule twice as large as in that species, coriaceous, densely covered with rigid bristles. Seeds club-shaped, beautifully reticulated, with intermediate depressions; their tunic nearly of their own length.

4. T. Pumila. Nettle-leafed Dwarf Turnera. Linn. Sp. Pl. 387. Am. Acad. v. 5. 395. Wild. n. 2. Ait. n. 2. Swartz Obs. 116. (Pumilea n. 1; Browne Jam. 188. Chamomilla urticae folio, folio luteo; Sloane Jam. v. i. 202. t. 127. f. 6.) — Flowers sessile on the footstalks. Leaves lanceolate, deeply serrated, without glands. Outer calyx linear, minute, hairy.—Native of dry sandy fields in Jamaica, flowering late in the year. Swartz. Root annual, fibrous. Stem herbaceous, from one to three inches, or more, in height, simple or branched, erect or decumbent, round, hairy, leafy. Leaves about an inch long, so deeply serrated as to be almost pinnatifid, clothed with long scattered hairs, but destitute of glands at the base. Flowers small, yellow, seldom expanded, solitary, sessile at the base of each upper leaf, on its hairy footstalk. Outer calyx of two small, linear, upright leaves; inner in five linear hairy segments, preflf close to the corolla. Petals convolute, with long orange-coloured claws. Seeds roundish, compressed, corrugated. Swartz. The Linnaeaceae specimen, from Browne, has no flowers, nor is it easy to fay whence Linnaeus took his account of the inflorescence, which, nevertheless, is confirmed by Swartz.

5. T. fideoides. Soda-leaved Turnera. Linn. Mant. 48. Wildl. n. 4.—Flower-flalks axillary. Outer calyx linear. Leaves nearly sessile, obovate-wedge-shaped, sharply serrated, downy and hoary on both sides, without glands.—Gathered in Brazil by Father Panegai, whose specimen was sent by Arduinio to Linnaeus. The stem is shrubby at the base, or four or five inches high, erect, simple, round, leafy, clothed with hoary down, and long, soft, tawny hairs. Leaves rather more than an inch long, covered on both sides with dense, entangled, somewhat hairy, soft, hoary pubescence; strongly and acutely serrated upwards; entire at the base, and tapering down into a very short hairy footstalk. Flowers axillary, nearly sessile, tawny, their flalks and calyx downy, and clothed with long, yellow, shining hairs. The specific character of Linnaeus, pedunculis bifitis, seems to allude to the two linear or awl-shaped leaves of the outer calyx.

6. T. jetoia. Brittle Turnera.—Flower-flalks axillary, partly combined with the footstalk. Outer calyx linear. Leaves obovate-wedge-shaped, deeply serrated or pinnatifid, very hairy on both sides, without glands.—Gathered by Commerson at Monte Video and Buenos Ayres. The fize of the leaf. Stem shrubby at the base, throwing up a few simple, wavy, nearly upright, hairy, leafy branches, from three to five inches high. Leaves more flalked, and much more deeply cut, than in T. fideoides, being sometimes sharply pinnatifid; they are fearly at all hoary or downy, but covered with long, silky, yellow hairs, such as are extremely copious on the branches, flalks, calyx, and capsule. The flowers are faid to be of a tawny red. Their outer calyx is very long and linear. Their flalks, as far as we can judge, are connected, for about half their length, with the adjoining footstalks. This species is certainly near in the leaf, and the segments of its leaves are evidently variable. We cannot, without spoiling our only specimen of T. fideoides, determine whether its flow-flalk be really separate from the footstalk or not. What Linnaeus in the Monitro terms bractae, are what we have all along called, after his own example in the Systena Vegetabilium, an outer calyx; nor is this part perhaps, as professor Swartz fays, entirely wanting in the next species, though we must allow it to be there still more like bractae.

7. T. eifideoides. Betony-leaved Turnera. Linn. Sp. Pl. 387. Wildl. n. 7. Ait. n. 3. Swartz Obs. 117. (Pumilea n. 2; Browne Jam. 189. Helianthemum betonicæ folio, caule bifuto; Plum. Lc. 141. t. 150. f. 1. Chamomilla caule bifuro, folio oblongo angulato filato, folio luteo, pediculo infundato; Sloane Jam. v. i. 202. t. 127. f. 7.)—Flower-flalks axillary, many times longer than the footstalks. Outer calyx obfolete. Leaves linear-oblong, obtuse, with shallow ferrated.—Native of dry barren ground
TURNERA.

ground in Jamaica. Sent by M. Richard, in 1774, to Kew garden, where it flowered in the fove, from June to October. The root is annual, long and simple. Stem one or more, subdivide, erect, from six to twelve inches high, round, leafy, hairy. Leaves on short stalks, spreading, bluntly toothed or serrate, about an inch and half long, clothed on both sides with minute hary hairs; paler beneath. Flowers small, yellow, on long slender hairy stalks, swelling upwards, bent or jointed about the middle, where are sometimes to be seen two feem to be two minute bracteas, hardly to be deemed an outer calyx. The proper calyx is hairy, in five lanceolate acute segments. Capsule somewhat hairy, pale. Seeds buff-coloured, curved, elegantly impressed with numerous rows of minute dots.

8. T. racemosa. Clutter-flowered Turnera. Jacq. Hort. Vind. v. 3. 49. t. 94. Wildl. n. 8. Ait. n. 4.—Flower-stalks in a terminal cluster; the lower ones axillary, many times longer than the footstalks. Outer calyx wanting. Leaves ovate, bluntly serrate, downy. —The native country of this species is not known, but we have little doubt of its West Indian origin. Jacquin received its seeds with the name of T. ciliolata, under which a specimen lies in the Linnean herbarium. M. Thouin sent seeds to Kew in 1789, and we have what seems a garden specimen from him. The root is annual. Herb much larger than T. ciliolata, with a very hairy, slightly branched, flat. Leaves broad-ovate, two or more in length, unequally serrate, clothed with extremely soft, hary, depressed hairs. Footstalks bristle, almost an inch in length. Flowers small, dull or yellow, on very long and slender hairy stalks. Calyx hairy. Capsule slightly hairy, each of its valves splitting into two. Seeds pale, rough with minute points between the depressed dots.—The calyx in this and the last species does not answer well to the idea of the genus, the tube, though present and permanent, being very short, nor are there any traces of the two outer leaves. Perhaps the latter had been omitted in the generic character, which is sufficiently marked without them.

9. T. guianensis. Slender Guiana Turnera. Aubl. Guian. 291. t. 114. Wildl. n. 9.—Flower-stalks in a terminal cluster, smooth. Outer calyx linear, entire, naked. Leaves linear, smooth, slightly serrate, with two glands at the base.—Gathered by Aublet in the marshy meadows of Timoutou in Guiana, flowering in April. Root fibrous, probably annual. Herb slender, smooth, with a rushy, angular, slightly branched, flat, two feet high. Leaves nearly sessile, two inches long, much less distinctly serrate in Aublet's specimens than in his figure. Flowers small, yellow, on short smooth partial stalks, collected, very few together, into a cluster. Outer calyx permanent, glabrous, at the bottom, rather longer than the inner, whose segments are, as in all the species we have hitherto described, deciduous, the permanent base being shorter, like that of T. racemosa. Capsule very smooth, of three undivided valves.

10. T. rupestris. Rock Turnera. Aubl. Guian. 289. t. 113. f. 1. Wildl. n. 3.—Flower-stalks axillary, very short. Outer calyx linear-lanceolate, toothed, somewhat bristly. Leaves nearly linear, toothed, very smooth, almost sessile. —Found by Aublet, in the moity mossy clefts of rocks about the great water-falls of Sinemari in Guiana, flowering in November. A rigid, slender, branched shrub, about a yard high, whose flowers are more or less covered with Jasminum. Leaves crowded about the ends of the branches, nearly sessile, an inch and a half long, very narrow, tapering at each end, slightly revolute, furnished with disfigured teeth, and by no means serrate, as in Aublet's plate, from which Willowen took his specific definition. Flowers small, yellow, nearly sessile, solitary in the bosoms of the two or three of the uppermost leaves. Outer calyx toothed, or rather serrate, longer than the inner, whose segments are lanceolate and entire; both are slightly clothed with close, silky, white hairs. Petals oblong, jugged at the end.

11. T. fruticans. Shrubby River Turnera. Aubl. Guian. 290. t. 113. f. 2. Wildl. n. 5.—Flower-stalks axillary, very short. Outer calyx linear-lanceolate, toothed, somewhat bristly. Leaves lanceolate, serrate, very smooth, alomost sessile. —Observed by Aublet, on the rocky banks of the Sinemari river, above the great fall, flowering in December. The natives call this shrub, as well as the former, Nupogonea. The present appears to us a variety of the last, differing only in its more luxuriant growth, being seven or eight feet high, with larger and more dilated leaves, whose length is two or three inches, their breadth above half an inch, their veins far more numerous, and their margins rather serrate than toothed. These differences may arise from a more favourable situation, or more fertile soil. In the flowers or inflorescence there seems no difference whatever.

12. T. rugosa. Wrinkled Turnera. Wildl. n. 6. (Piri- queta villosa; Aubl. Guian. 298. t. 117. Burcardia; Schreb. Gen. 206, adopted from Scopoli; expunged at p. 827, and referred to Turnera.)—Flower-stalks axillary, many times longer than the footstalks. Outer calyx wanting. Leaves ovate, unequally crenate, wrinkled, downy. Styles five.—Native of the sandy sea-flows of Cayenne and Guiana, flowering and bearing seed almost all the year round. The root is annual. Stem erect, about two feet high, branched, leafy, villous. Leaves on short stalks, bluntest, two or three inches long, rather elliptical, veiny, rugose, clothed with reddish hairs. Flowers small, yellow, on long, slender, hairy stalks. Capsule very like that of T. racemosa, n. 8, which this species so nearly resembles in many respects, that, were it not for the five styles, and the more crenate and rugged leaves, we should be disposed to unite them. We place this at the end, for future examination, not having seen a specimen to determine the question.

Turnera, in Gardening, comprises a plant of the woody, flowering, exotic kind, for the flower, the species of which cultivated is the elm-leaved Turnera (T. ulmifolia), which has a shrubby stem, rising eight or ten feet in height, and a bright yellow flower. It is found in the West Indies.

There is a variety with narrow leaves, which also rives with a shrubby stalk to the height of eight or ten feet, with branches less slender and stiff than in the broad-leaved form: the leaves narrow-lanceolate, hairy, near three inches long, and about three quarters of an inch broad, terminating in acute points, obtusely serrate on their edges, and flaring upon very short footstalks; when rubbed they emit a disagreeable odour: the flowers are of a pale yellow: the petals large and oval, with the tails or claws twisted, and joining: they are not so large or half so bright a yellow as in the true elm-leaved form. This is a native of Jamaica.

Culture.—Both these plants are easily raised from seed, which should be sown in the spring, in pots, and plunged in the bark-bed, or any other hot-bed, under glass; and when the plants are come up two or three inches in height, they should be planted separately in small pots, plunging them in the bark-bed of the flower, to forward them a little in growth: they may afterwards be placed in any part of the flower, and be managed as other flower exotic plants. They are also capable of being increased by cuttings, planted in pots, and forwarded in the above manner.

They afford a good variety among flower-plants, but they are seldom of long duration, as they mostly go off in the course
course of two or three years, being therefore rather of a biennial nature.

TURNOSE, or Turnsole, in Botany. See Heliotropium, and Crotum Tinctorium.

Some have translated turnsole by the English word sunflower, which has led many to suppose that the great yellow sun-flower, which we keep in gardens, was the plant that afforded the turnsole colour: but this is a mistake; and it is to be observed, that the true turnsole plant, or heliotropium tricocorum, is very common in the fields of France, especially about Montpellier, and in Germany, but does not grow wild with us in England.

The juice of the berries of the turnsole, rubbed upon paper or cloth, at first appears of a fresh lovely green, but presently changes into a kind of bluish purple. It is said that the common blue paper receives its colour from this juice. The same colour, afterwards wet in water, and wrung out, will turn the water into a clear colour; and it is to be observed, that the rags of cloth tinctured by this juice, and turned red by acids, are usually called turnsole in the druggists' shops, and employed for colouring wines and other liquors. M. Nifole, of the French Academy of Sciences, says, that the colouring juice is obtained, not from the berries, but from the tops of the plant, gathered in August, ground in mills, and then comminuted to the prefs. The juice is exposed to the fun about an hour; the rags dip in it, dried in the fun moistened by the vapoour which arises during the flowering of quicklime with urine, then dried again in the fun, and dipt again in the juice. The Dutch and others are faiid to prepare these rags and turnsole in the mafs from other ingredients, of which archil is a principal one. Boyle's Works abr. vol. ii. p. 19.

Neumann's Chem. by Lewis, p. 433.

The Dutch process for making the blue called turnsole is as follows: Lichen, archil, or in cafe this last cannot be obtained, the greater moss of the oak, is dried, cleaned, and pulverized in a mill, refembling the oil-mill, and then fifted through a brafs wire fieve, the interlaces of which do not exceed one millimetre in width (\(\pi\text{m}\) of an inch). The fifted powder is then thrown into a trough, and mixed with an alkali called vedas, which is nothing else but the cendres gravelces in powder. The proportion is one part by weight of the alkali, to two parts of the pulverized vegetable. This mixture is moistened with a small quantity of human urine; the urine of other animals does not contain a sufficient quantity of ammoniac. The mixture ferments, and is kept moist by successive additions of urine. As soon as the materials have become red, they are transferred into another trough, where they are again moistened with urine, and flurred to renew the fermentation. Some days afterwards, the paife acquires a blue colour, in which state it is carefully mixed with one-third of excellcnt potatoes well powderd; and with this new mixture certain trays are fifted, which are one metre (39\(\frac{1}{2}\) inches) deep, and eight decimetres (31\(\frac{1}{2}\) inches) wide. When the fennentation which takes place for the third time has given the paife a considerably deep blue colour, chalk or powdered marble is added, and the whole is well and perfectly mixed. This last addition is made, not to improve the quality of the blue, but to add weight. It is merely an affair of profit. The blue thus prepared is put into iron moulds 32 centimetres long and 22 square at the end (14 inch by \(\pi\text{ths}\) of an inch). The moulded pieces are then placed upon deal planks, in well-aired lofts, to dry; after which they are packed in cases for sale.

The Hollanders made a fecret of this process: and in order to mislead, they have published, that the blue was made with rags coloured by the plant turnsole; whence it has obtained its appellation. The English writers have used this denomination: but the dry-fellers, or dealers in drugs, dilligently these paftills by the name of litmus. We may derive much profit by carrying this discovery into practice.

The principal use of this plant is in dyeing: in order to which, the juice is infipidized and prepared with calx and urine, into blue cakes; which are used also with flarch, instead of flalt.

The lievium of this plant in lime-water and urine, or in the volatile spirit of wine, turns marble blue. See Colouring of Marble.

TURNESS, in Geography, a cape on the east coast of the island of Hoy. N. lat. 58° 41'. W. long. 3° 10'.

TURNETUM, in our old Law Books, a duty paid to the sheriff for holding his turn, or county-court.

TURNHOUT, in Geography, a town of France, in the department of the Two Nethes, built in the year 1212, by Henry IV. duke of Brabant. In the year 1455, the emperor Charles V. gave it to his sister Mary, queen of Hungary, to enjoy during her life. In the year 1648, after the peace of Munster, Philip IV. gave it to princes Amelia, widow of Frederick Henry of Nassau, from whom it came to the house of Orange. The quarter of Turnhout comprehends fifteen villages; 25 miles S.S.W. of Bois-le-Duc.

TURING, in the Mechanical Arts, is the operation of shaping wood, metal, or other hard substances, into a round or oval figure, by the aid of a machine called a lathe; which see.

In turning, the work or substance to be operated upon is placed in the lathe, and made to revolve with a circular motion about a fixed right line as an axis of motion; and the exterior surface is worked to its intended figure by means of some kind of edged tool, which is presented to it and held fast down upon a fixed reft. The protuberant parts of the work, by its rotatory motion, are carried against the cutting edge, and cut off, so as to reduce every part of the outside surface, to an equal distance from the axis of motion, and of course it will be of a circular figure.

The articles which admit of being turned to give them their figure, are all such as combine the three following properties: 1. That they may be suppo'ded to have an ima-ginary right line or axis passing centrically through the whole length of the piece; 2. That all the sections which can be made by planes perpendicular to such axis shall be circular; and 3. That the centre of all such circles shall coincide with the axis or centre line.

It should be observed, that a piece of work may have two or more centre lines in different parts or in different directions; but it must in that case be formed or turned at two or more successive operations, because what can be done at once fixing in the lathe, must come within the above definition.

The work may be turned hollow, so as to make a cavity within: or work may be turned on the outside, to give form to the external surface; and frequently work is turned both without and within; but in either case, the above definitions will apply.

Diodorus Siculus says, the inventor of the art of turning was a nephew of Daedalus, named Talus; and that the reputation which he acquired by this invention excited the jealousy of Daedalus, and induced him to put Talus secretly to death. Pliny ascribes it to Theodore of Samos, and mentions one Thericles, who rendered himself very famous by his dexterity in managing the lathe. With this instrum,
ment, it is said, the ancients turned all sorts and kinds of vases, many of which they enriched with figures and ornaments in baffle relief. Thus Virgil says:

"Lenta quibus torno facili superaddita vitis."

The Greek and Latin authors make frequent mention of the lathe, and Cicero calls the workmen who used it, *vulcani*. It was a proverb among the ancients, to say a thing was formed in the lathe, to express its delicacy and justness.

The art of turning is of considerable importance, as it contributes essentially to the perfection of many other arts. The architect uses it for many ornaments, both within and without highly finished houses. The mathematician, the astronomer, and the natural philosopher, have recourse to it, not only to embellish their instruments, but also to give them the necessary dimensions and precision; in short, it is an art absolutely necessary to the mechanist, the goldsmith, the watchmaker, the joiner, the smith, and others.

As the operation of turning is to be performed by the aid of the lathe, the structure of that machine is the first thing to be considered. In our article Lathe, we have given a description of the most perfect kind of lathe, made in iron, with a triangular bar; and in the article Ross-Engine, we have described a curious lathe for ornamental turning; but it is to be observed, that a much more simple machine will answer all the common purposes of turning.

The essential properties of a lathe for outside work are, first, that it shall have two points which will firmly sustain the work at each end, by penetrating into the ends of the work, and, at the same time, allow it to turn freely round upon the points: there must be a reft or support to hold the tool upon, and also some means of turning the work round upon the points. A lathe to turn hollow or *infinite* work will not admit of a point of support at each end of the piece, and therefore the work is firmly fixed to the extremity of a spindle, which is called a *mandrel*; when the mandrel is turned round, the work revolves with it, and the tool can be applied at the end of the work, to excavate or turn it hollow within, or to turn it on the outside, as required.

Lathes are made in a great variety of forms, and put in motion by different means: they are called *centre lathes*, where the work is supported at both ends; and *mandrel*, *spindle*, or *chuck lathes*, when the work is fixed at the projecting extremity of a spindle.

From the different methods of putting them in motion, they are called *pole lathes*, and *band-wheel lathes*, or *foot-wheel lathes*. For very powerful works, lathes are turned by horses, steam-engines, or water-wheels.

The lathes used by wood-turners are generally made of wood, in a simple form, and are called *bed lathes*; the fame kind will serve for the common turning of iron or steel, but the best work in metal is always done in iron lathes, which are sometimes made with a triangular bar, and are called *bar lathes*. (Such an one is described in the article Lathe; small ones, for the use of watch-makers, are called *turn-benches*, and *turns*; but there is, in fact, no proper distinction between these and the centre lathes, except in regard to size, and that they are made of iron and brass instead of wood.

The *centre lathe* is the most simple of all others. Two beams of wood are fixed horizontally upon legs, like a bench, and form what is called the bed. The two beams are fixed together, parallel to each other, and at a small distance affunder, so as to leave a space or narrow groove between them, nearly the whole length of the bed. This groove is to receive the tenons at the lower ends of the *puppets*, which are short posts rising perpendicularly from the bed, and firmly fixed thereto by means of crofs wedges, put through the tenons beneath the bed; for the tenons are of sufficient length to descend quite through the groove in the bed, and project beneath sufficiently to receive the crofs wedges, which being driven in, draw the bases of the puppets or posts to firmly down upon the surface of the bed, that they will stand firmly erect upon it; or by withdrawing the wedges, the puppets become loose, and can be fixed in another part of the bed, in order that the distance between the two puppets may be made to correspond with the length of the piece of work to be turned. One of the puppets has a pin or *pikes* of iron fixed into it, and the other has at the same level the centre *screw*, working through a nut fastened in the puppet: both the screw and pike have sharp points made of steel, hardened and tempered, that they may not wear away. They must be exactly opposite, and in a line with each other. The piece of work, supposing for instance it is a roller of wood, is supported by its ends between the points of the pike and the screw, that it may turn round freely. The *reel* for the support of the tool is a rail or bar, extending from one puppet to the other; it lies in hooks, projecting from the faces of the puppets.

The work is put in motion by means of the *treadle*, which is worked by the turner's foot; a *screw* or *catgut* is fastened to the treadle, and passing two or three turns round the work, it is fastened to the end of an *elastic pole*, fixed to the ceiling over the turner's head.

The workman stands before his lathe, having one of his feet on the treadle to give it motion; he places a sharp *gouge* or *chisel* on the reel, and approaches the edge of it gently to the piece of work; then pressing the treadle down by his foot, the screw turns the work round, and the chisel or gouge being held firm upon the reel, and so to touch the wood, it will cut it to a circular form. When he has brought the treadle to the ground, he releases the weight of his foot, and the elasticity of the pole draws up the treadle, turning the work back again; during which retrograde motion, he withdraws the chisel from the work, as it would not cut in this direction, though it might impede the motion of the wood, and would injure the edge of the tool. He must perform his work gradually, without leaving ridges; and when he meets with a knot in the wood, he must go on still more gently, otherwise he would be in danger both of splitting his work and breaking the edge of his tool. For turning light work, a bow, itch as is used for shooting arrows, is suspended by its middle over the lathe; the *firing* is then tied to the middle of the bow-firing, in lieu of the pole, and acts in the same manner.

The common centre lathe is a very imperfect machine, when worked in this manner; yet its simplicity is a great recommendation, especially among country workmen, who use it to make various sorts of common articles of household furniture in soft wood, as stool and table legs, *flair-cafe rails*, &c.

In centre lathes, the work is sometimes put in motion by means of a large wheel, turned by one or two more labourers; the wheel should be heavy, that its momentum may be sufficient to overcome any moderate obstacle in the work; and the frame in which it is mounted must be of sufficient weight to stand steady, and not be liable to move, by the exertions of the man turning it. An endless line is used, to communicate the motion of the wheel to the work; it passes round a groove in the circumference of the wheel, and after crossing, like a figure of 8, goes round a small pulley, fixed upon the work. By this means, when the great wheel is turned, it gives a rapid rotatory motion to the matter to be turned, and with a much greater power than can be obtained from the treadle, with the additional advantage of the work turning always
the same way round, so that the turner has no need to take
his tool off the work.

The centre lathe will turn any kind of work which will
admit of being supported at both ends; and it is used by
millwrights and iron-founders, for turning mill-shafts, axles, rollers,
and other iron-work. For such purposes, the lathe must be made exceedingly strong, and with nuts and
screws to fasten the puppets down upon the bed, instead of
wedges; the rest must be made in iron, with the requisite
adjustments for placing it close to the work, at that part
where it is required to be turned. To put the work in motion,
the centre pin or point in one of the puppets is made to
project considerably, and has a pulley fitted upon it, so that
it can turn freely round upon the pin by means of an endless
band or strap, which communicates the motion from a great
wheel. In these large lathes for iron-work, the wheel is
commonly turned by horses, or by a water-mill or steam-engine.

From the pulley a pin projects in a direction parallel to the
centre pin, and a piece of iron, called a driver, is screwed
or clamped fast upon the end of the piece of work, so as to
project from it sufficiently to be intercepted by the pin
which is fastened into the pulley; by this means, the motion of
the pulley is communicated to the work. The tools
employed for turning iron and other metals are different from
those used for wood, as we shall afterwards describe.

The spindle or mandrel lathe will turn hollow or internal
work, and is equally well adapted to turn centre work as
the centre lathe. In Plate Turning, fig. 1, we have given a
representation of one of these, which is on a very good
construction, made by Meirs, Holtzapfel and Deyerlen: it
is put in motion by the foot, so that the turner has both his
hands at liberty to direct the tools. A A are upright legs,
to support the bed B, which consists of two pieces of
bars of cast-iron, put together, and leaving a small crack
between them; C D is a cast-iron frame, which is fastened
down upon the bed B, and supports the spindle or mandrel
a b: E is the back puppet, which is used to support one end
of a piece of work, as is shown in the figure at G, when
the other end is fixed to the end of the mandrel, and turned
round by it: the back puppet, E, has a cylindrical pin
accurately fitted into it at the upper part, and the end of
the pin is formed to a sharp conical point, proper to penetrate
and support the end of the work: this point is called the
back centre. A screw is tapped into the puppet, so as to
press on the opposite end of the pin, and force it towards
the work; and there is likewise a clamp screw, E, at the top,
to bind or loosen the pin into its socket. The back puppet
is fastened down upon the bed, by means of a tenon
entering into the groove, through the bed B, and a screw
defends from the tenon quite through the bed, and
projects beneath it: upon this screw a nut g is tapped, and, by
turning it, the shoulder of the puppet E is drawn down
firmly upon the bed; but when the nut is loosed, the
puppet can be slipped along the bed to place it at any
required distance from the end of the spindle, according
to the length of the piece of work G. It is necessary that
the point of the back centre should in all cases be precisely
in the collars, which collars should be also made of steel,
and hardened, so as to have little friction. The neck of a
mandrel must be very accurately fitted into the collar, so as
to have no shake or looseness, at the same time that it can
turn round quite freely.

The neck at one end projects beyond the collar, and the
projecting part is formed to a screw, for the purpose of fix-
ing the work to it. A variety of pieces, called chucks, are
fitted upon this screw, and each chuck is adapted to hold
a different piece of work: the chucks screw up against a
shoulder on the end of the mandrel, and by the motion of
turning round in the direction in which the lathe works, the
chuck screws itself fast on against the shoulder; but if the
lathe is flopped, and the chuck is turned in the opposite
direction, it will unscrew and come off, and a different chuck
may be put on. In some lathes, the neck of the mandrel
is perforated, and cut within and out, with a female screw adapted
to receive a male screw on the chuck: the effect is just the
same as the above described. The opposite end of the
mandrel to that on which the chucks are ferrewed, must
be supported either by a point or in a collar. In general,
the mandrel is made with a point at one end; and the other end,
which has the screw to fix the work to it, is formed with a
neck, proper to run in the collar, and with a shoulder on the
neck, to stop the neck from going through the collar.

The mandrel represented in the drawing has a neck and collar
at each end, for a purpose which will be explained. When
the mandrel is made with a pointed end, the point must be
received in the end of a screw tapped through the part D
of the frame of the mandrel, just in the place of the end a
of the mandrel. By turning this screw, the mandrel can
be adjusted to run very correctly in length; and to pre-
vent the screw from turning back when the lathe is in
motion, a nut is placed on the screw, beyond the part
d: this causes such a prelance upon the threads of the
screw, that it is in no danger of turning back, as it would
otherwise do with rough work. The mandrel, by this
means, runs very readily and accurately in its bearings,
it is plain that any piece of work, which is firmly attached
to the end of it by means of the screw before mentioned,
may be turned by a tool held over the reel, in the same manner
as if it were mounted between centres, but with the advantage
that it be turned at the end, to make hollow work when
required.

The mandrel is turned round by a band of catgut passing
round the pulley b, and also round the large foot-wheel H,
which is made of cast-iron, and fixed on the end of the axis I.
This axis is bent in the middle, as in the figure, to form a
crank, which crank is united, by an iron link K, to the tread-
le L, on which workman presses his foot. This tread-
le is affixed by three rails to an axis M, on which the treadle
moves. The wheel H is of considerable weight in the rim,
and being fixed fast on the axis I, turns round with it: the
momentum acquired by the wheel is the power that con-
tinues to turn the work while the crank and treadle are rising,
and consequently while the workman exerts no power upon
them.

When the crank has passed the vertical position, and be-
gins to descend, the workman presses his foot upon the treadle,
to give the wheel a sufficient impetus to continue its motion
until it arrives at the same position again. The length of the
iron link K, which connects the crank with the treadle, must
be such, that when the crank is at the lowest position, the
board L of the treadle, to which the link is hooked, should
hang about two or three inches from the floor. To put the
lathe in motion, the turner gives the wheel a small
turn with his hands, till the crank rise to the highest,
and

Vol. XXXVI.
passes a little beyond it; then by a quick tread he brings the crank down again, putting the wheel in motion with a velocity that will carry it several revolutions: he must observe to begin his next tread just when the crank passes the highest point, and then it will continue running the same way with a tolerable regular motion, if he is punctual in the periods of his treads. The foot-wheel, by means of the band, cauves the mandrel to revolve very rapidly, so that it will perform its work very quick, and the workman must acquire a habit of standing steadily before his work, that he may not give his whole body a motion when his foot treads and falls with the treadle.

The reft N of this lathe is fixed on the bed of the lathe by its foot, which is divided in the manner of a fork, to receive a ferrwell-bolt: this bolt passes down through the lathe-bed, and fastens the reft at any place along the bed, by a nut & beneath. The groove in the foot is for the purpose of allowing the reft to be moved to and from the centre of the work, to adfult it to the diameter of the work which is turning. The height of the reft is a matter of some importance in turning, and in some work it should be fixed higher than others; therefore the piece upon which the tool is laid, is made with a Shank of the form of the letter T. This Shank is a round pin, and is received into a socket in the foot of the reft, and can be held at any height by a clamp-ferrwell. As the focket and Shank are cylinrical, the edge of the T of the reft can be placed inclined to the axis of the work when turning cones, or other similar work, though the fame purpofe may be accomphlihed by the ferrwell, which holds the foot of the reft down to the bed of the lathe, admitting the fork to f tand in an oblique direction across the bed.

The wood-turner employs gouges of all sizes, and chiffels of different forms; the gouges are used in the firft instance to rough out and form the wood, as they cut very rapidly, because they can take a very ftrong chip, and the angles will not flick in, as would be the cafe with the chiffels. The latter are used to smooth the work, and to reduce it exactly to shape and figure.

The blade of the turning-gouge is formed nearly half round to an edge, and the two extreme ends of this edge are a little flopped off, in the manner of an apple-foon, that the middle part of the edge may cut away the prominences of the work; and it has no corners, which would catch and get faft in the rough wood. The hollow part is whetted upon a piece of Turkey-foon, made with a convex edge, for the purpofe; the outifde is whetted upon a common flat Turkey-foon, taking care to turn the gouge round, that all parts of the convex edge may fucceffively be sharpened. In turning, the blade of the gouge muft be held confiderably inclined, by depriving the handle (fee fig. 42.), fo that the bevel, or outifide of the edge of the gouge, may come very nearly in the tangent to the circumference of the work, and the cutting edge be above the level of the centre. The turner holds the tool down firmy upon the reft, keeping it fealy, by placing the long handle under his arm.

The turner’s chiffels are mostly ground with a bevel on both the flat fides, fo that either fide may be indifferently applied to the work: they are ground up and sharpened on the oil-foon to a keen edge. In fome chiffels, the line of the edge is inclined to the direction of the blade, inftead of being perpendicularly across it, as in the chiffels used by carpenters; in others, the edge is rounded to a femicircle, inftead of being a ftraight line; and others are made with angular points, like fpears. It is difficult to decribe the proper ufe of each particular tool, as the turner muft employ one or other, according to the particular part of the work which is to be executed. In using the chiffel, the reft is railed confiderably above the centre of the work, fo as to be nearly on a level with the top of it (fee fig. 41.), and the line of the cutting edge muft fland oblique to the axis of the cylinder, fo as to prevent either angle of the chiffel from running into the work. It is neceffary to traverfe the chiffel gradually along the work, but not too faft, otherwife it will leave a roughnefs on the Surface.

The turning-tools fhould be fixed in long handles, and the turner holds them firmly down upon the reft, fteadying them by placing the end of the handle under his arm.

The turner fhould be provided with a grindentone, and an oil or Turkey-foon to fharp en his tools; and he muft have callipers and gauges to afcertain the dimensions of his work. In order to fix the work in the lathe, he muft have a great afcouragement of chucks. The chucks for wood-turning are blocks of wood, each having a ferrwell, by which it can be attached to the mandrel. The end of the chuck being turned true, and the fhouder of the ferrwell upon the mandrel being also turned true, the chuck fixes fo tight to the fpindle, that it becomes as it were one piece with it. Most of the wood chucks are bored out like a box, and the work is jammed into the cavity. There are other chucks, which are only flat round boards, and the work is cemented or fereved againft them; but the generality of chucks are cylinrical blocks, with a cylinrical or conical hole turned in the end, like a box, into which the piece of wood to be turned is driven faft, fo as to be turned round with the mandrel. The chucks are generally hooped with iron, to prevent them from splitting. When centre-work is to be turned in a mandrel lathe, a chuck muft be fereved on the end of the mandrel, which terminates in a sharp conical point.

The lathe fhould be fixed in a place very well lighted; it fhould be immovable, and neither too high nor too low.

The puppets fhould neither be so low as to oblige the workman to floop in order to fee his work properly, nor so high, that the little chips, which he is continually cutting off, fhould come into his eyes.

The piece of wood to be turned fhould be rounded, before it is put in the lathe, either with a small hatchet made for the purpofe, or with a plane or rafe, fixing it in a vice, and having it down till it is every where almost of an equal thicknefs, leaving it a little bigger than it is intended to be when finifhed off. Before putting it in the lathe, it is also neceffary to find the true centres of its two end furface, fo that they fhall be exadly oppofite to each other, in order that, when the centre points of the puppets are applied to them, and the piece is put in motion, no one fide may project out more from the centre line than another. To find these two centres, lay the piece of wood to be turned upon a plank, open a pair of compaffes to almost half the thicknefs of the piece, lay one of the legs on the plank, and let the point of the other mark on one of the ends of the piece when laid flat on the plane with the plank, like a roller, from which plank the point of the compaffes stands up at a given height above the plane on which the piece lies. Describe four marks or arcs on that end at equal distances from each other round the circumference of the end, by laying the piece fucceffively on four different fides, which arcs interfecving one another, the point within the interfec tions will be the centre of the end. In the fame manner, the centre of the other end muft be found.

After finding the two centres, make a small hole at each of them, into which infert the centre points of the back centre and the mandrel, and fereve up the back centre, to fix the
the piece so firmly as not to be shaken out, and yet loose enough to turn round without difficulty.

This is the manner of fixing the work when it is to be turned between centres; but if it is required to be hollowed out, the back puppet is removed, and the work must be fixed in a chuck at the extremity of the mandrel. For this purpose, a chuck is selected which has a hole in it nearly the size of the piece of wood, the diameter of which being taken in the callipers (fig. 35.), the chuck is screwed to the mandrel: the reft is fixed in a convenient position, and the hole in the chuck turned out by a proper tool to the size measured by the callipers: the hole should be rather conical, and the wood, being rabbed to the same figure, is driven in falt by a hammer. By turning the mandrel slowly round, it will be seen if the wood is fixed ftrait in a line with the mandrel, and if not, a blow or two of the hammer, properly directed, will rectify it.

If the piece of wood is not very long, the chuck will be sufficiently to hold it firm while it is turned; but if it is not, then a small centre hole must be made in the extreme end, and into this the point of the back centre screw must be inserted to fteady the work, until the rough part of the turning is done, and then it may be removed; but it is much more convenient to turn without the back centre, and therefore the turner fits the chuck to the wood with care, so that it will fix falt in the fuch.

The work being thus chucked, or fixed in the lathe, the reft is fet, so that its edge is close to that part of the work which is required to be turned, and the top of the reft being raised considerably above the level of the centre of the work, it is there screwed falt.

The turner now puts the lathe in motion by treading with his foot, and takes a gouge, of a proper size, in his right-hand, and holds it by the handle a little inclined, keeping the back of the hand lowermost: he grasps the blade of the tool with his left-hand, the back of which is to be turned upwards, and he holds it as near the end as possible on the front fide of the reft; then leaning the gouge on the reft, he is to present the edge of it a little higher than the horizontal diameter of the piece, so as to form a kind of tangent to its circumference: see fig. 42. This is the beat position for cutting, and the tool must be held very firmly, to prevent the edge being depressed by the motion of the work, for if it does, it will take hold too deep, and tear the wood. The gouge is applied first to one end of the work, and gradually advanced to the other, turning the work true all the way, and reducing it till the callipers (fig. 36.) determine it to be near the intended diameter.

The chiffel is next employed to smooth the cylinder: its handle is held in the right-hand, whiff the left grasps the blade, and keeps it feady upon the reft, holding the edge a little inclined over the work, as in fig. 41.; so that one fide of the flat part of the blade lies on the reft, and the other fide is elevated, that the plane of the blade, and consequently the line of the edge, is not horizontal, but inclined thereto, so that one corner of the edge of the chiffel is elevated above the work: then the bottom of the edge of the chiffel, or near the bottom, cuts away a shaving from the work, and this is the only way in which it will cut; for if the edge of the chiffel is held parallel to the axis of the cylinder, it acts parallel to the length of the grain of the wood, feraping away the fibres, one by one, without cutting, and leaves a very rough surface. In the fame manner, the narrow chiffsels, formers, and other instriments, are to be used according to the work which is to be done, taking care that the wood be cut equally, and that the instriment be not pushed sud- denly forwards, or sometimes more strongly than at others; and taking care also that the instrument does not follow the work, but that it be kept firm on the reft, without yielding. The gouge and chaffe are the instruments by far the molt frequently used, and the molt necessary in this art. Soft woods are almost entirely turned by them.

To make the end of the work exactly flat, the thin fide of the chiffel is laid upon the reft, so that the plane of the edge may ftand exactly upright. The hand is depressed, that the lower corner of the edge may rise against the work, and cut a deep circle into it, near the end, and being steadily advanced, cut to the centre, separating a thin round chip, and leaving the end quite flat. The cutting corner of the chiffel must be directed exactly perpendicular to the length of the work, in advancing it, otherwise the end will be either concave or convex, and care must be taken to keep the plane of the edge truly upright, and hold it very firm, for there is danger of the work drawing the chiffel into the end of it, with a deep spiral cut, like a fcrew, and tearing the work out of the chuck.

A cylinder of wood being formed by the process we have just defcribed, if it is required to turn it hollow withinfide, the reft is fixed opposite the end of it, with the edge of the reft perpendicular to the length: then a fharf-pointed tool is used, to bore such a hollow in the end as will form the required cavity, using the inside callipers (fig. 35.) to determine the size of it. The fide-tool, which is made with a cutting edge on the fide, like a knife, may be used, if it is required to make the bottom of the cavity fquare; or a hooked tool, with the cutting edge at the end of the hook, may be employed to enlarge the inside to the proper fize: the gauge (fig. 34.) is used to determine the depth to which it is to be turned.

This is the procefs for turning foft woods, which are generally of a fibrous texture; but hard woods, ivory, and bone, are turned with different tools. The points or cutting edges of fome fuch tools are represented in figs. 23. and 24.; they are bevelled only on one fide, and the angle of the edges is obtuse. The round-pointed tool, and the fharf angular-pointed tool, are thole employed for firk roughing out the work, and by them a number of contiguous grooves are cut in the wood, until its grain is broken and divided, and the irregularities reduced; then an edged tool can remove the remainder: but as the edged tools will only cut or frape off thin shavings, they are not used when the work is to be reduced to fize, but only to finish it. The manner of applying the tools to the work is fhown in fig. 39. and is nearly the fame as for turning fbras, or other foft metal: the upper face of the tool is directed to the centre of the work, the intention being to fcare away shavings in hard wood, and in foft to cut chips, as at fig. 41. and 42. The graver (fig. 40.) is a veufeful tool for hard wood: the manner of using it, as well as other tools, will be defcribed when we come to speak of turning in metal.

After the work is completely turned, it is next to be polished, and this cannot be done with the instruments hitherto mentioned. Soft woods, as pear-tree, hazel, maple, &c. ought to be polished with fharf-fkin, or Dutch rubes. There are different species of sharks, some of which have a greyish, others a reddifh skin. Shark's skin is always better when it has been used; at firl, it is too rough for fine polishing.

The Dutch rub is the equifetum hyemale; it grows in moif places, among mountains, and is a native of Scotland. The oldest plants are the best. Before using them, they should be moistened a little, otherwise they break in pieces almost directly, and render it exceedingly difficult to polifh with them: they are particularly proper for smoothing the
hard woods, as box, lignum vitæ, ebony, &c. After having polished the piece well by such means, it should be rubbed gently either with wax or olive-oil, then wiped clean, and rubbed with its own turnings or shavings, or with a cloth a little warm. Ivory or horn is polished with pumice-flone or chalk, finely pounded and put upon leather, or a linen cloth a little moistened with this; the piece is rubbed as it turns round in the lathe; and to prevent any dirt from adhering to any part of it, every now and then it is rubbed gently with a small brush dipt in water. To polish metals very finely, the workmen make use of a particular kind of earth called tripoli, and afterwards of putty, or calx of tin. Iron and steel are polished with very fine powder of emery; this is mixed with oil, and put between two pieces of tin or pewter, and then the iron is rubbed with it. Tin and silver are polished with a burnisher, and that kind of red flone called blood-flone. Iron and steel may also be polished with putty, putting it dry into flarnoy-flcin.

All kinds of articles in wood are turned in the above manner; but many contrivances are necessary to mount different things in the lathe.

The small figures in the plate represent various chucks, which are occasionally employed, and which are adapted for turning different kinds of work.

Figs. 2 and 3. exhibit a small wood chuck, which is adapted to be screwed to the mandrel at a, a hole being perforated in the centre of it, at b, into which a small piece of wood or ivory is to be inserted, in order to turn it. To hold the work fast in this chuck, it is divided at the end b by two faw-kerfs, at right angles to each other, as shewn in fig. 3. so as to separate the end into four segments, which admit of expanding or closing: a hoop or ferril is fitted on the outside of the chuck, which part is made tapering, so that forcing the ferril farther on, will close the four segments together, and bind fast upon the work, which is introduced into the cavity b. This is a very convenient chuck for holding small pieces of ivory, and particularly for the purpose of polishing.

Figs. 12 and 13. exhibit a similar chuck, made in brafs, for more delicate work; it is only divided into two segments.

Fig. 4. is a brafs box, to screw to the mandrel, and hold a wood chuck, such as we have before explained. Wood chucks are usually made to screw on the mandrel by means of a hole in the chuck, which is cut with a female ferril within. The objection to this mode is, that the threads of the ferril on the wood wear away by constant use. In fig. 4. a brafs female screw, a, is cut to fit the ferril of the mandrel, and at the other end, b, is a box, also cut with a ferril within, into which the wood block or chuck is screwed, as shewn by the dotted lines, so as not to come out without great force: by this means, the fitting of the chucks to the mandrel is not with a wooden screw, as in general, but with a brafs one, which will not be liable to get out of the truth, but will always screw up to the same shoulder. The lathe should have at least two dozen of these wood chucks, with cavities of different sizes, and some of them hooped with iron at the outer end, to prevent them splitting. The brafs box is a great security against splitting.

Fig. 5. is a very useful arbor for turning wheels, collets, or any other flat piece of work that will admit of having a small hole in the centre of it. A brafs fcrew-chuck, a, is fitted to the mandrel, and a steel pin, b, is fixed into it, and projects an inch or more: the pin is turned true, and the work is fitted fast upon it, either by turning the pin to the size, or by broaching the hole in the work; and to prevent the work from slipping round upon the pin, it is pinched fast up against the flat surface of the chuck, as shewn by the dotted lines, by a nut d, which is screwed on the end of the steel pin b: by this means, the work will be held fast, and will be carried round by the chuck, so as to be turned by the application of proper tools upon the reed. These kinds of arbors should be of all sizes, to fit the holes in different wheels, &c.

Fig. 10. is a brafs chuck, which is very useful for holding small pieces of brafs work; it screws to the mandrel at the end a: the hollow part, b b, has six fcrews tapped through it, and pointing to the centre, as shewn in fig. 11. By screwing in these fcrews, their points will pinch upon any piece of work which is put into the chuck, as shewn at d, and will hold it firm. The fcrews being regulated, admit of adjusting the work d to a true centre with the line of the mandrel.

Figs. 16 and 17, are views of chucks having similar properties to the preceding: a (fig. 16.) is the end which is screwed to the mandrel; b b is a circle of brafs, having a mortice or opening across the centre of it, as in fig. 17; into this opening two steel dies are fitted, and fcrews d, d, are placed behind them, to approach them together: the fcrews come through the outside of the chuck, and have square heads, which are to be turned by means of a key. The adjacent surfaces of the two dies are hollowed, so that they will embrace a piece of wire or other similar substance which is put between them, and the dies may be cut like a file, to hold it fast. By means of the two opposite fcrews d, d, the work may be adjusted to the centre line of the mandrel.

Figs. 20 and 21, are a table-chuck, proper for holding wheels or flat plates by the circumference, whilst the centre parts are turned: a is the fcrew to fix it to the mandrel; b b, a large circular plate, turned perfectly flat on the front surface. In this plate are grooves, pointing from the centre to the circumference, as shewn in fig. 21: the grooves are adapted to receive clamp-pieces, d d, by means of which the wheel or other work is bound fast against the flat surface of the chuck. The grooves admit the clamps d, d, to be placed at any distance from the centre, according to the size of the work, and to place them at those parts where it will be most convenient to apply them.

The form of these clamps is shewn more particularly in fig. 22: f are fiders of metal, which are fitted to the grooves in the chuck; and the grooves are dove-tailed, so that these fiders can be put into the grooves at the back of the chuck, but will not draw through the grooves into the front. Screws are tapped into the fiders, and draw the clamps, b, against the face of the chuck, and hold fast the work, which is placed beneath their claws. The clamps, b, have shanks projecting from them at right angles, which pass through the grooves, and keep the clamp from turning round to one side.

Figs. 35 and 36, represent the calipers used by turners to take the measure of their work: they are made of two curved pieces of steel-plate, united together by a joint. When they are opened, as in fig. 35, the dimensions of a round piece of work may be conveniently taken between their points, as shewn by the dotted circle; but if the points are closed together, as in fig. 35, so that they pass each other, then the calipers are adapted for measuring the diameter of internal cavities, by the distances of their points from each other.

Several other kinds of calipers are used by turners, but these are the most convenient, as they serve equally well for inside and outside dimensions. Some calipers are made double, like a pair of scissors; and the points at one end are for inside measures, whilst the others are for outside measures; and the distances of all the points from the joint being exactly the same, the inside measure of any hollow being
being taken by one end of the callipers, the opposite end will be readily opened to the requisite dimensions for a solid to fill such hollow.

Fig. 34. is a gauge for measuring the depth of hollow work. A is a ruler, through which is a socket to receive another ruler B; and a clamp-screw is fitted through the side of the socket, to hold the ruler, B, fast in the socket. The edge of the ruler, A, is applied to the end of the work, and the other ruler is then slid through its socket, until the end of B touches the bottom of the cavity; and in this state, the clamp-screw being fastened, the gauge may be applied to the piece of work in the lathe, to ascertain if the cavity is turned out to the required depth.

Fig. 6. is a chuck for turning wood when it is a long piece, which will admit of being supported at both ends, or between centres, as it is called. The chuck has a screw within the part a, to fix to the mandrel, and the other end is of steel, with a pin b in the centre; and on each side of the pin is a sharp edge c, like a chisel, the line of the edge pointing to the centre of the pin. When a piece of wood is mounted between the points of this centre pin and of the back centre, as we have before described, if the back centre screw is turned, it will force the piece of work against the mandrel and the pin b, and the edges c will penetrate into the opposite end of the wood; in this case, the motion of the mandrel and chuck a will be communicated to the wood, to turn it round. The centre pin b is made to project beyond the edges c, and by this means the work may be removed from the lathe, and put in again if required, because the centre pin will enter again into the same hole in the end of the work, and restore the work to its original position.

Fig. 7. is a chuck for the same purpose, but it is made with a flat circle of brass, and three pins, c, are fixed in it instead of the edges c. This kind of chuck is shown in use in fig. 1, to turn a pillar for a halberd.

When a piece of metal work is to be turned between centres, the edges or points of the lathe chucks cannot be made to penetrate the end of the piece, and therefore a small chuck, (figs. 14. and 15.) is screwed to the mandrel: in the end of this chuck, at b, is a hole, which is made square with the centre, and the work has a square filed at one end to fit the hole. The other end of the work is supported by the back centre, a small hole being made in the end to receive its point; or if the end of the work is sharp-pointed, the back centre pin is drawn out of its socket, and turned end for end: the end of the pin opposite to the point has a small centre hole for the reception of such pointed work. Iron and steel work may be turned very conveniently by means of a square, but not very accurately; and after the work has been taken out of the lathe, and the square cut off, if it be required to turn the work again in the lathe, it is very difficult to find the true centre.

All works requiring great accuracy, as arbors, screws, axes, spindles, &c. are turned between centre points, thus: a chuck (fig. 8.) is screwed to the mandrel by the screw in the part a, a steel centre point b being formed at the end of it. The point is turned very truly, to be exactly in the centre line of the mandrel. The work is mounted between this point and the point of the back centre; and to communicate the motion of the mandrel to the work, a driver (fig. 9.) is screwed fast on that end of the work nearest the chuck. The driver is an iron ring, with a screw d tapped through one side of it, to pinch the work so fast as to prevent the driver slipping round upon the work; and on the side opposite to the ring is a projecting tail f.

The chuck (fig. 8.) has a steel claw k e fitted through it, and fastened by a screw: the end of the claw is bent at e parallel to the direction of the mandrel, so that the end of it will catch the tail f of the driver, and turn it round, together with the work on which the driver is fixed.

The fret k of the claw slides in and out of the socket, through the chuck, in order to remove the claw e to a greater or less distance from the centre point b, and adapt the chuck to operate upon different sized drivers, for delicate or large work. This is the most accurate method of turning iron work in a mandrel lathe, because the centre points at the ends of the piece are preferred. When one end of the work is finished, the driver may be shifted to the other end. Such work may at any time be mounted again upon its original centre points, in any kind of lathe, to turn wheels, collets, &c. which may be fitted upon it.

The form of the driver is shown in fig. 30. In order to make it fit different sizes, the side of the ring opposite to the screw d is made angular, and the point of the screw forces the work into the angular part.

This driver may be fixed on either end of the work, whilst the other end is turning; but when it is necessary to fix the driver on that part of the work which is finished, the end of the screw d is apt to pinch and bruise it; it is therefore proper to interpose a piece of iron between the point of the screw and the work. But it is better to use the driver shown in fig. 31: it is composed of two bars of iron, united by two screws passing through one bar and tapped into the other; both bars are somewhat hollowed out in the middle, that they may encompass the work. If this should be found to injure the work, a piece of sheet-lead wrapped round it before the driver is put on will prevent it from damaging the work; and if the screws of the driver are drawn very tight, it will carry the work about with sufficient force to bear turning.

When a piece of iron or steel work is to be turned, the centre points at the ends must be found with great precision before it is turned, because it is difficult to cut away great protuberances in metal. The centres are first found by the compasses, and marks are slightly punched in the ends by a conical-pointed punch. The workman now places the work in the lathe, between the points of the mandrel and that of the back centre, but without fixing any driver on the work; he then screws up the centres, so as to hold the work just tight enough to prevent its falling down. In this state, by turning it round with one hand, while he holds a piece of chalk against it with the other, he ascertains whether it is pitched nearly concentric on the points; and if it varies much at any one point, he turns back the screw to take out the work, and punches new centre points, or alters the old ones, taking care to move them nearer to that side which appeared to project farthest in revolving, and was of course marked by the chalk.

When he has, by repeated trials, found the true centre, he screws up the centre point so hard, that it may effectually mark the end of the work, by forcing the points to the bottom of the marks punched; then taking the work out of the lathe, he drills holes in the ends, at the places where the centre points have marked, and to such a depth, that the points of the lathe will not reach the bottom. When the work is again returned into the lathe, it will run very nearly concentric, and the driver being screwed fast on either end of the work, as is most convenient, the work will be turned round by the clutch projecting from the chuck.

The work is now ready for turning, which is done by different tools, and applied in a very different manner from the chisels and gouges for turning wood. Fig. 37. to 42. are different examples of the manner of turning metals: a tool applied in the manner of fig. 39. operates very well upon
upon brafs and bell-metal. The cutting edge should be
ground nearly to the angle which is there represented,
and the upper side should be directed nearly to the centre of the
piece; the edge will then scrape away shavings from
the metal. The tool has some tendency to retreat backwards
from the work, and must be held firmly thereto. The edges
of tools, applied as shewn in fig. 39, may be formed to
any of the shapes shewn in figs. 23. and 24. the angle of the
cutting edge being in all cases nearly the same.

The graver (fig. 40.) is an extremely useful tool, and fit
for turning any metal or hard wood: it is a square bar of steel,
cut off obliquely, and the greatest obliquity of the cutting
plane is in the direction from one angle of the square to the
opposite angle. This produces a prominent point on one of
the angles, which point is applied to the work in the manner
shewn in fig. 40. and cuts off continuous shavings instead of
scrapings: this is owing to the direction of its edge, which
is disposed obliquely to the motion with which the work
meets the edge in its rotation. The turner should be pro-
vided with gravers of all dimensions.

Fig. 37. is the action of what is called a heel tool for
turning wrought iron or copper: the edge of this is applied
nearly in a tangent to the work, on the same principle as the
chiffel is applied to cut wood. The heel of the tool is placed
upon the reft, and being just opposite to the edge on which
the prejudice or drift of the work lies, the tool cannot
escape from its work, although the prejudice upon it is very
great, so much so, that it would be impossible to keep the
tool to its work, if it were held upon the reft, as in the case of
the wood chiffel, merely by the lateral friction on the reft.
The handle of the heel tool is long, and is held inclined up-
wards, so that the workman can reft the end of it on his
shoulder, whilst he holds it very firmly down on his shoulder
and on the reft with both hands. This firm position is
very necessary, because the heel tool is liable to draw
deep into the work, and take away too large a chip.
This tool will cut away thicker chips than any other, being
what the workmen term a greedy tool. The requisite height
of the reft, to make the edge of the tool a tangent to the
proper point, is a matter of importance, and requires the at-
tention of the workman, who can only learn the manage-
ment of this tool by experience. It is not well adapted
for finishing work with accuracy, but is very expedient in
roughing out wrought iron; it generates so much heat in
working, that it is necessary to keep it constantly wet; and
in large lathes, a conflant stream of water is made to fall on
the edge at the place where it is cutting. The graver and
all other tools work wrought iron and steel to the greatest
advantage when wetted.

Fig. 39. is the tool used for turning cast-iron; this sub-
fstance must be scraped away, and it is plain from the figure,
that the cutting edge is presented very nearly in the fame
manner, with respect to the work, as in fig. 39; but from the
hardness of cast-iron, it requires a very considerable force to
press the edge against the work, and it would be impracti-
cable to hold it up effectually on the plan of fig. 39; hence
the tool in fig. 38. is bent at the end, and is lodged over the
edge of the reft, in the manner of a lever; the handle is pre-
ed down at the extremity, and lifts up the edge against the
work with very great force. The workman must bear on the han-
dle of this tool with the requisite prejudice; and in large work,
such as cannon and mill-shafts, he usually lets himself upon
the end of the tool, which is made very long in the handle.

Different substances require different velocities of motion
to cut with the greatest advantage. Wood can scarcely be
made to move too quick; and it is always preferable to take
a very thin chip, and move as quick as possible, than to move
slowly, and compensate for the loss of time by cutting deep.
Brass and bell-metal may be moved very quick,
but not with half the velocity of wood. Wrought iron
and copper must be turned more slowly, and the tool must be
kept wet. Steel should go rather slower than wrought iron,
for it is liable to have hard veins in it, which the workmen
call pins: these will be cut through if the work moves
slowly, but with a quick motion they will destroy the edge of
the tool: this makes some workmen think that the pins
are actually formed, or that they become hard during the
operation of turning, if too great a velocity is used. Cast-
iron must move very slowly, indeed it can scarcely turn too
slowly, and the tool applied as at fig. 38. will cut a thick
chip.

To obtain these different degrees of velocity, the foot-
wheel of the lathe fig. 1. is made with several grooves of dif-
f erent diameters, and the mandrel pulley b has also different
izes. A band can be applied upon any of these grooves at
pleasure, and the workman finds by experience what velo-
city is best for different kinds of work.

The most experienced workmen prefer a centre lathe to a
mandrel lathe, when they have to turn accurate iron-work,
which will admit of being poised between centres; and it is
obvious, that the revolving motion of the centre point at the
end of the mandrel is of no use; and if the point should be the
leaf out of the centre line, or if the mandrel has any shake
in its collar, the work would not be turned truly. But in a
centre lathe, where both points are fixed immovably, or,
as the workmen say, with dead centres, this cannot happen;
and if the work is screwed up tight between the centres, so
that there is no shake, the centre points at the ends of the
work must be precisely in the centre line of the work.

The manner of giving motion to a piece of work in the
centre lathe is, as we have before described, by a loose pulley
fitted on the centre pin, and from this pulley a pin project-
s in a direction parallel to the centre line, so that it comes
effectually in the place of the claw s (fig. 8.), and turns the driver
round when the pulley is put in motion by the band, either
from a foot-wheel or hand-wheel.

When the mandrel lathe is used for centre work, the
centre of the chuck must be turned very exactly, so that
it does not vary in the least from the same position when it
turns round; and in all cases, the mandrel must be fitted with
the most scrupulous accuracy into its collar, so that there
will be no shake; for unless this is the case, the lathe will
not turn chuck-work with any accuracy.

Mefirs. Holtzapfel and Derien make very excellent lathes on the plan represented in fig. 1. The bed and the
puppets are made of cast-iron, and very correctly fitted,
such lathes posses great strength: some of them are fitted
up, as in the figure, with a pattern ferew at the end a of the
mandrel, for the convenience of cutting ferews on work.

For this purpose, the mandrel is fitted in a collar at each end,
and the necks are cylindrical, so as to admit of the mandrel
moving endways at the same time that it turns round.
On the extreme end of the mandrel, beyond the collar D, a pattern
ferew is fixed, which has the diface of its threads corre-
sponding with the ferew that is defined to be cut upon the
work, which is fixed in the lathe by a chuck: a piece of
brass, n, is provided, which is cut with threads adapted to the
pattern ferew, and which can, by turning a ferew, be drawn
up against the pattern ferew, so as to work in its threads;
and in this state the mandrel, at the same time that it turns
round, will move endways in its collars with a screwing mo-
tion; and in consequence, a pointed tool being preferred to
the work, and held fast on the reft, will cut a spiral groove or
ferew upon its circumference. This contrivance is more
fully
fully explained in the article Rose-Engine. It is the most convenient method of all others for cutting screws, and very accurate, if the pattern screws which are fixed on the mandrel are correctly cut. For all purposes of wood turning, it is undoubtedly the best method, and far preferable to the common one of cutting screws flying, as it is called, that is, by means of the tools 32 and 33, which are applied to the work, and moved along endways at the same time that the work turns round, so that they cut a spiral. (See Rose-Engine.) The rapidity and accuracy with which some workmen cut screws in this way exceed belief; but it is only by long experience that this habit can be acquired, and for those who have not had such experience, some mechanical help is necessary. The objections made by accurate workmen to the flying or screw mandrel are, that as the necks must be cylindrical, it cannot be kept so perfectly fitted in its collar as the common mandrels, which have a point at the extremity, and the neck at the other end is made slightly conical, so that it can always be screwed up to fit in the collar. Mr. Holtzapfl's mandrels are made of hardened steel at the necks, and the collars are also hard; they are accurately fitted, and have no shake when new. From the hardness of the materials, they will wear a long time before they get any looseness.

Mr. Maudslay has the most complete set of tools for all kinds of mechanical works at his manufacture, and is particularly well provided with turning apparatus. All his lathes are made with triangular bars, such as is described in our article Lathe, and the mandrels are all formed with conical necks and collars. The bar lathes are very accurate, particularly when the slide-rest is applied to them, as there described. The bed lathe may also have a slide-rest applied, as is shown under Rose-Engine.

If a piece of metal, after being properly turned, is to be bored hollow within, like a gun-barrel, the back puppet is to be removed from the bed of the lathe, and another substituted in its place, having a hole or collar through it, into which the neck or end of the iron is to be correctly fitted, the other end of the iron being supported and turned round by being fitted into a chuck at the end of the mandrel, or else by means of the centre point at the end of the mandrel, and with a driver, as in fig. 8 and 9. The rest is to be set opposite the end of the piece where it comes through the collar, and drills or borers are to be applied, similar to those used by locksmiths in boring keys, beginning with a small one and afterwards using larger ones, until the hole is made as wide and deep as necessary. The borers must be held very firm on the rest, otherwise there is danger of not boring the hole straight. The borers should be withdrawn from time to time, to oil it and clean the hole. As it is difficult to make a hole quite round or concentric with the outside by means of borers alone, it is necessary to have also a turning tool considerably smaller than the hole, one of the fides of which is sharp, very well tempered, and a little hollow in the middle. This instrument being fixed in a long handle, is to be introduced into the hollow, and applied with a feed in to the inner surface of the hole, and it will entirely remove every inequality that may have been there before its application.

The collar puppet is only refitted to, when the piece which is to be bored is of considerable length; for if it is short, it will be held sufficiently fast in the chuck, without the necessity of supporting the extreme end.

A collar puppet is sometimes necessary in turning centre work when the work is long, and so slender, that it bends or springs by the strains of the tools: the collar is then applied to support the work at the part where it is weakest and bends most.

Turning of elliptical or oval Works, such as Picture-frames, Snuff-boxes, &c.—This is performed in the same lathe, and with the same tools, as the circular work; but the lathe is provided with a chuck, which causes the work to traverse in a very curious manner, by a motion given to it in a direction to and from the centre of the mandrel as it revolves; so that a tool held up against the work will cut an elliptical figure instead of a circle. Elliptical work has a very singular appearance when in motion; for after the work has been turned truly elliptical, every part of the circumference, except the exact point where the tool was applied, appears to vibrate, or be eccentric in a great degree, but that one point of the circumference runs perfectly true and regular, the fame as the whole circumference of a piece of circular work does. The mode of action of this ingenious apparatus is rather difficult to describe, and it is first necessary to understand the principle of its action. This is the same as the trammel or elliptic compasses; see fig. 29. An octagonal or square board A A, B B, has two grooves cut in its surface, which intersect each other at right angles; this board is held down upon the surface where the ellipse is to be described, with the centre lines of the grooves coincident with the two diameters of the intended ellipse, and of course their intersection will be the centre. The curve D D is traced beyond the circumference of the board, by means of a pen or pencil, which is fixed at F, to a radial bar or beam F G H; this bar carries two other points or pins, G and H, which are attached to sliders, inserted into the grooves of the board, as shewn in the figure: the sliders are fitted in truly, so that each of them will have a motion in its respective grooves: thus the slider of the pin H will move along A A; and the slider of G, along the groove B B. By turning about the beam F G H, the sliders go backwards and forwards in their grooves with a simultaneous motion; so that when the beam has gone one-fourth way about, one of the sliders will have moved from the circumference of the board A B, to the common centre of the grooves; and when the beam has gone half round, the same slider will have proceeded the whole length of the grooves, and arrived at the opposite side of the circumference. The same applies to the other slider, and when one slider is at the centre, the other will always be at the circumference.

The pins F and G H can be fixed at any part of the beam at pleasure, (though this is not so frequently in the drawings,) for the purpose of setting the trammel to draw any particular ellipse: thus, place the beam in the direction of the line A A, then the pin G will be in the centre of the grooves; now fix F at such a distance from the centre, as is equal to half the small diameter of the ellipse; and let H be so far distant from G, as the difference of the two diameters; consequently, F from G will be equal to half the longest diameter. Now, in turning the beam round from the direction A A, till it comes to the direction B B, the point G will depart from the centre along B B, and H will approach it along A A, till it gets to the centre. Then will the pencil F be so much farther from the centre, as G is distant from H, and the pin has in its circuit traced one-fourth of an ellipse. The beam being turned quite round, will complete the whole curve.

This apparatus may be applied to turning by some modification. Suppose the two grooves made in a round board, as large again as that represented in the figure; then, if the whole apparatus be inverted, and the beam F G held fast in a vice, or otherwise, the board with the grooves may be traversed round upon the fixed sliders, in the same manner as the beam could be traversed round upon the fixed board. Suppose a tracing point is held to the back of the board, exactly
exactly opposite to the place where the tracing point F is fixed to the beam, and held fast; it is evident that its point will trace the face ellipse on the back of the board, that was described on the surface which the board lay upon in the former instance: or a chisel being held fast in the fame spot, will cut the board elliptical when it is turned round; and the chisel being successively applied at different points along the line of the beam, a series of concentric ellipses may be turned in the board, to make mouldings for picture-frames or other ornaments. If the distance of the two fixed pins G and H, and the chisel F, is altered, it will vary the proportion between the two diameters of the ellipse, in the same manner as before described of the trammel.

The oval chuck is constructed in a different manner from this, though it prefers the same movements. It consists of three parts, the chuck, the slider, and the eccentric circle. The chuck c e f (fig. 27.) is attached to the mandrel by a screw-socket, cut in a piece f, which projects from the centre of it; and hence the chuck turns round with the mandrel with a circular motion.

The chuck has a dove-tailed groove, formed in it at the front side, for the reception of a slider g h, (fig. 26.) which travels freely in the groove: the groove is formed, as the figure shews, by pieces i, i, screwed to the chuck on each side. In the centre of the slider, in front, is a screw h; see also the plan, fig. 25. The screw h projects from the slider, and by means of it, a wooden chuck may be screwed against the slider, and any work can be fixed in the chuck in the usual manner. The work so fixed, at the same time that it turns round by the motion of the chuck, has a sliding motion across the centre, which motion being given according to a certain law, produces an elliptic motion. The sliding motion is given by the eccentric circle (fig. 28.); this is a ring of brass, attached fast to the puppet of the lathe, close to the collar, in which the neck of the mandrel runs. The mandrel passes through the aperture l; the ring has a flat plate, m, to strengthen it, and forming two bends at the ends m, m, which bends have screws tapped through them, and pointing exactly to each other: these screws are sharp at the points, and are inserted into small holes in each side of the puppet, as is shewn in the plan, fig. 25. At C, the back of the plate m of the circle lying flat against the front of the puppet C; by this means the circle is fixed fast; the two screws are horizontal, and both point to the centre of the mandrel b; therefore, by screwing one screw in, and the other out, the whole circle may be moved sideways horizontally, so as to give it any required degree of eccentricity from the centre line of the mandrel, and it will be held stationary wherever it is placed.

Fig. 27. is a back view of the chuck, and shews two grooves made through it in the direction of the length of the slider; these admit the shanks of two pieces of steel n, n, to pass through the chuck, and they are firmly attached to the slider g, by a screw for each in front of the slider, as shewn in fig. 26. The two inside edges of the pieces n, n, are exactly parallel to each other, and the distance between them is exactly equal to the diameter of the outside of the ring 28, which ring is included between them, when the chuck is screwed to the mandrel b, and the circle fixed to the puppet C, as shewn in fig. 25.

Suppose then the circle is set concentric with the mandrel; if the mandrel is turned round, it will cause the chuck a, and slider g, together with the work attached to the slider by the screw h, to revolve. The work will now run in a circle, and turn circular work as usual, because the slider is guided by means of its claws n, n, which embrace the circle; and will keep the same position in its groove in the chuck during all the parts of a revolution, because the circle is concentric with the mandrel.

To set the chuck for an ellipse, place the point of a tool opposite the work, at such a distance from the centre of the work, that it will describe a circle of a diameter equal to the breadth or smallest diameter of the ellipse intended to be turned. This is best done by fixing the tool in the slide-reel. Now turn about the mandrel, till the slider g comes horizontal, and let the circle 28 eccentric from the mandrel by its screws m, m; it will of course move the slider g in the groove of the chuck, and also the work will move with it to a greater distance from the centre, because the two steel pieces n, n, at the back of the slider include the circle between them. The quantity of eccentricity given to the ring, must be equal to the difference between the two diameters of the required ellipse, so that the work shall move, or throw out a sufficient distance, to bring the point of the tool as much beyond the circle first described, as the length of the ellipse exceeds the breadth. The point of the tool will now be at one end of the longest diameter, and here we will commence to trace the curve all round. In turning the mandrel round till the slider comes vertical, it must return in its groove to the place it first occupied, viz. the centre; because the eccentric circle which guides the slider is not eccentric in a vertical direction, though it is in the horizontal. In this motion, the point of the tool has cut or described one quadrant of an ellipse, because it gradually approached the centre a quantity equal to the eccentricity of the circle. By continuing to turn the mandrel round farther, the circle will cause the slider to move out the other way from the centre in its groove until it comes again horizontal, when it will be at the greatest throw out, as the turners term eccentricity, and the point of the tool will be at the other end of the longest diameter, having described one half the curve; continuing to move forwards till the slider becomes vertical, it will become concentric again, and the tool will be at the breadth of the ellipse, having finished three quarters of the ellipse; and in turning the next or fourth quarter, the slider throws out till it comes horizontal, and brings the work to the position where we first set out, viz. at its greatest eccentricity: and with the tool at the end of the longest diameter of the ellipse.

The simple trammel (fig. 29.) is not easily recognized in this complicated chuck, although it has all the same movements. Thus, let us return to our first idea of a board with two crofs grooves in the back of it, turning round on two fixed pins, which enter the sliders in those grooves. Suppose that one of the pins is extended to a large ring, and the groove proportionally widened to receive it, this will have the same effect. Such a groove is formed by the two pieces of steel n, n, which have straight edges made truly parallel to each other, and perpendicular to the length of the slider which carries them. The other fixed pin is represented by the mandrel; and the slider being always confined in a right line across it, has the same effect as a pin entering a straight groove.

This ingenious apparatus was invented early in the last century by the celebrated mathematician Abraham Sharp. Before his time, oval-work was always turned in a rote-engine, which had an elliptical pattern.

In turning oval work, the tools must be delicately used, because the circumference moves with an unequal velocity at different parts of its revolution.

Method of ornamenting turned Articles by an Excentric Chuck.
—This produces a similar effect to the rote-engine: but as a chuck of this description can be applied to any lathe which has a mandrel and slide-reel, it has been referred for the present article.

Figs. 18. and 19. are two views of an excentric chuck: a
is a socket, which is screw'd to the mandrel; and the chuck, which is formed in the same piece with the socket; a dovetailed groove is formed in the front of the chuck, by means of two pieces, which are screw'd to the chuck, and into this groove a slider, is fitted: to this slider a centre pin is fixed very firmly, and upon the centre pin a circle, \( f_i \), is fitted, so as to turn round freely; in the front of the centre a screw, \( g \), projects, for the purpose of fixing the chuck to the circle. The slider is applied to the chuck, just the same as in the oval chuck, but is not turned into the chuck, to slide into the grooves for a screw, \( k \), is applied, which will move the slider gradually in the groove, but always holds it fast where it is placed. By means of this screw, the centre pin of the circle, \( f_i \), can be made either to coincide with the line of the mandrel, or it can be set with any required degree of eccentricity from the mandrel, as is shewn in fig. 15, by the difference between the line of the screw \( g \), and that of the socket \( a \).

The circle is divided round the edge with notches or teeth, cut at equal distances; and a tooth or catch, \( b \), is fitted on the slider by a centre screw, and has a tooth which can be inserted into any of the teeth at pleasure, and will hold the circle fast from turning round upon its own centre pin. In this case, any piece of work, which is fixed to the screw \( g \), will turn round with the mandrel, just as though it was fixed immediately thereto. The manner of using this tool is as follows: when the eccentric chuck is screw'd to the mandrel at \( a \), the screw, \( k \), is turned, until the screw, \( g \), is brought exactly into the line of the mandrel. A wood chuck is now screw'd on at \( g \), and a piece of work fitted into it; which work is turned to its required figure, just as though the wood chuck was screw'd to the mandrel itself, without the intervention of the eccentric chuck, which hitherto has been passive. The work being turned, it can be beautifully ornamented on the flat surface, by tracing a number of circles upon it. To do this, turn the screw \( k \), until the centre of the circle, \( f_i \), is removed to a given distance from the line of the mandrel; now apply a tool to the end or flat surface of the work, by means of the slide-red, and turn the mandrel round, until the tool has cut a fine circular line in the surface of the work. Now it is evident that this circle will not be in the centre of the work, but removed from the centre thereof a distance equal to the degree of eccentricity given to the slider. Having thus described one circle, stop the lathe, and release the catch \( b \), and then turn the circle, \( f_i \), round one tooth or notch.

Put the lathe again in motion, and describe another circle by the point of the tool, held exactly in the same spot as before; but the circle so described will fall on a different part of the work to that which was before made, although its centre will be at the same distance from the centre of the piece of work. The lathe is stopped, and the circle, \( f_i \), turned round another tooth: a third circle is then described; and when as many circles are described as the whole number of teeth in the circle \( f_i \), the ornamenting is finished. It will consist of as many circles as there are divisions in the circle \( f_i \), all of an equal size, and their centres arranged at equal distances, around the circumference of a small circle, which is concentric with the work. The whole produces a rosette or engraved figure upon the surface of the work, and the numerous intersections of the eccentric circles have a very pleasing effect to the eye.

This kind of work is seen on the cases of many watches; and when well executed, is much esteemed.

**TURNING**

**Horizontal Hand-Mill, in Rural Economy,** an useful contrivance of the hand corn-mill kind. It was invented by Mr. Wright, and consists of a sort of tub or box; the frame of the mill-part of which is three feet square, and three and a half in height. The mill-stones are eighteen inches in diameter, and indented in the tub or box, supported by two cross-bearers, under which is a lever, having an iron pin or pivot, which runs through the centre of the bed stone into a socket in the bridge of the upper stone or runner, to which is attached the shaft and spindle, running through the eye of the runner and hopper, and supporting the fly-wheel and crank. A piece of wood of a round form, fastened on the shaft, serves as a feeder; and above is a screw to regulate the feed according as the mill is turned. On the side of the tub or box is a thumb-screw, fixed to the lever underneath, which regulates the stones, according as they are turned. The shaft runs through the crown-tree or cross-bar at the top of the frame, on which is the horizontal fly-wheel and crank; to which are attached one or two handles, by means of which the mill is put in motion. Under the stones is a drawer; in which are placed three drawers of different finesses; one for taking away the bran, another for the coarser pollard, and the third for stopping the fine pollard, and letting the flour pass into the drawer, which is effected by a fort of iron fork running through a hole in front of the drawer, and fixing on one of the hoes.

Small hand-mills of this nature are extremely convenient and useful in many cases.

**Turning Palisades.** See **Palisade.**

**Turning-Evil, in Cattle,** a disease that causes them frequently to turn round in the same place. It is also called the **flurdy,** which see. See **Turn in the Head.**

The common remedy, recommended by Mr. Markham, is to throw the beast down, and bind him; then to open his skull, and take out a little bladder, filled with water and blood, which usually lies near the membrane of the brain, and then gradually heal the wound. Boyle's Works, abr. vol. i. p. 87.

**Turning to Red, in Agriculture,** a term used in tillage to signify stripping, ribbling, baulkining, and combing, according to the manner in which it is performed. It is the leaving of a narrow strip of ground whole, on which the furrow-fluice is turned. It is much used in Devonshire, Cornwall, and some other districts.

**Turning to Windward,** in Sea Language, denotes that operation in falling, in which a ship endeavours to make a progress against the direction of the wind, by a compound course, inclined to the place of her destination. This method of navigation is otherwise called **plying.** See **Tacking.**

**TURNIP, or Turpen,** in Agriculture, a most useful and nutritious root-rooted plant, of which there are many different sorts in cultivation by the farmer. It has been long known in this country, but only more lately introduced as a field-crop, probably from Holland, or the Low Countries. It is from a more general introduction of this root into field-husbandry, that much improvement and advantage have been produced, not only in the management of arable land, but in the general system of feeding and supporting different kinds of live-stock. The culture of this root has, indeed, contributed much towards exploding the expensive and wasteful practice of naked fallowing, as well as to cleanse and ameliorate the soil, and render it more abundantly productive.

The turnip belongs to the genus **brassica,** and is well-known by its having a round, or rather long, fleshy, eatable root, that varies considerably in these respects, as well as size and colour, in different sorts, under the state of cultivation. The leaves proceeding from the top of the root in
the middle part are large, and mostly of a full green colour, being ragged on the edges. The stem arises from the midst of thefe in the second season of the growth of the plant, to the height of four feet, or more, producing a yellow flower, with cylindrical pods of some length, filled with small purple, or reddish-brown coloured seeds. See Brassica.

All the different sorts of this excellent plant are, for the most part, distinguished by the form or shape of the bulb or root, which appears in some measure to depend upon the diversity of soil, and the nature of the culture of the plant. But the sorts that have been laid at the disposal of as field-crops, with the greatest success and benefit in different parts of the country, are principally those two kinds; those having a round or flattened-formed root, that rests much on the surface of the land, and those in which the root is of the more long tap-rooted form, penetrating deeper into the mould with the lower part of the root, and standing higher above it with the upper portion of the bulb.

In the first, or round flat-rooted sort, there is likewise much variety in the appearances of the tops as well as the roots, though the latter are mostly a little round and flattish. They are commonly distinguished in field-culture into the red-round or purple-topped, the green-topped, the white-topped, the yellow-rooted, the black or red-rooted, the hard or flone, and the Dutch turnip.

In the latter, too, or long tap-rooted sort, there is some degree of variety in their roots. They are usually known and discriminated by the farm-cultivator under the titles of the tankard, the tap-rooted, the pudding, the oghl, the long, round, and the hardy or Russian turnip.

It may be noticed, that the different varieties of the former of these kinds of turnips, in consequence of the roots of them being formed more on the ground close to the surface, than in those of the latter kind, which often stand high, naked, and much exposed in their upper parts, above it, are better suited to the purposes of general field-culture, in fields where there is much risk of their being hurt by the effects of frosts in the more severe winter months; but that in other crops, as where they are to afford an early feed, as for suckling ewes, and in the fattening of forward sheep at an early period, the latter kind may be had recourse to as the most proper and beneficial. This is said to be the practice of some districts in the vicinity of the metropolis, where it is of importance to have forward lambs.

In different districts where this root is largely cultivated, different sorts of this plant are employed; and it is not improbable that some sorts may be more proper for some qualities of land than others, though little has yet been done in the view of deciding this point. Nor is it unadvisable to suppose, that among the many varieties of this highly valuable plant, there may not be some which, in addition to their superior hardiness, possess a greater proportion of the nutrient principle than others. It has, indeed, been stated that, in a great northern turnip district, the green-topped and white-topped are generally esteemed as more sweet and nourishing than the red-topped sort, which possesses a degree of bitterness, and is disposed soon to become flabby and bad as food: that the white-topped sort, on the better kinds of land, is probably the most proper and beneficial, as while it has the property of being hardy, it grows to a large size; and that this and one of the other or small hard sort, are the most commonly grown, and held in the greatest estimation in some of the best turnip districts still more towards the north. The latter of these sorts is, indeed, by some farmers in those districts, supposed to stand the severities of the winter season much better than most of the other sorts; but then the produce on the acre is commonly much less. And by others in more southern districts, it is thought to bulb quicker, to have a greater solidity, a finer grain, a thinner skin, and to be smoother in the crown of the bulb; consequently to be less liable to injury from wetweather and severe frosts. And that although it may not grow so quick, or so large a slice, the latter of these defects may be obviated by leaving the plants a little thicker on the ground at the time of thinning and setting them out. Indeed, both the white and green-topped sorts are also much grown and approved in all those districts, and by some highly extolled on account of the qualities just noticed, as well as their being of a large growth, and continuing longer in a state fit for use, especially the latter. The yellow-rooted or straw-coloured turnip, too, is found to be a firm-flushed and sweet-flavoured nourishing sort, but it has not yet been much cultivated, so that its properties are but imperfectly known. The red sort, which was formerly much esteemed, has now mostly given way to other sorts. And the black-rooted sort is very rarely cultivated in any district of the kingdom; nor even those of the Dutch sort, though the early kind of them might answer well for forward crops. Much might probably be done in getting good sorts, by collecting seed from such as are the most hardy, and which grow to a large size, and fowing it in continuance.

In some northern and other districts turnips are grown much in mixture, which is a bad plan, as they have different growths, and of course rife unequally. And in the southern ones, the white globe prevails much in some instances; and the green round sort is found to stand well, and be larger as well as more certain in the produce.

The turnip is a sort of crop which is grown after many other different kinds, as thofe of a wheat flubbe, a pea ley, a tare, potatoe, or any other similar kind of crop, as well as after the process of paring and burning the layers of old grass-lands. It is the practice too, in some districts of this sort, to have two turnip crops in succession, as the means of cleaning the land more effectually, which has been found to answer greatly in the barley or other crops that may be grown after them.

The foils which are the most proper for the growth of this sort of crop, are all those of the more light, friable, loamy, medium sandy, and other kinds, which have a sufficient depth; but it may often be raised with success and advantage on many other sorts, which have the surface-mouldy parts sufficiently fine, without there being too much moisture below, as those of the thin gravelly, loofe chalky, and many other sorts and qualities; even on the loamy clays, in some fields, when properly managed in their tillage preparations, and other ways.

A late practical writer has well remarked, that from the successe of the culture of this useful crop, on lands that differ greatly in their nature and qualities, it is plain that the plant admits of more latitude in respect to soil than many other sorts; though an opinion appears to have been too general among the cultivators of it, that it is only capable of being had recourse to with advantage, on such as are of a light, mellow, and open texture and quality. It is suggested too, that this has probably had considerable influence in preventing the culture of the turnip from becoming so general as, from its great utility and importance, it ought at present to have been. But though the turnip may be grown with success and benefit on soils that vary considerably in their natural friabilities and compositions, it is consistently necessary, to the perfect growth of such crops, that at least the more superficial parts of the soil, or the beds of earth in which they grow, should be in as fine a reduced powdery condition as possible, as more is found to depend
TURNIP.

depend on this, than even on the nature or qualities of the soil.

In the view of bringing land into a state of suitable preparation for this fort of crop, much breaking down and reduction of its parts are, of course, requisite. This fort of breaking and pulverization is supposed to be necessary and beneficial in many different ways, as by rendering the land more penetrable to the roots of the plants, by promoting the growth of the small weeds more fully on the surface, and thereby making them capable of being more perfectly eradicated, and the young turnip plants, of course, be less endangered by them; while, at the same time, a more fine and mellow bed of mouldly earth is provided for the reception of the turnip-feed, and its vegetation and growth rendered more quick and strong in consequence of the more equal diffusion of moisture that must take place among the parts of the soil. Without such a state of mould in the soil being produced, it is found to be in vain to expect good crops of this fort. In order to provide this state of preparation in the soil, it is the practice in some of those districts where turnip husbandry is carried on in the most complete and successful manner, when the seed is to be put in on a fallow, to have recourse to three, four, and frequently five ploughings or firrings of the land, having the cloddy parts of it well broken down, between the times, by harrowing in different directions, and the occasional use of the roller or other such means, as by these modes almost every particle of the soil becomes divided, and exposed completely to the influence and action of the atmosphere, and perfectly aerated and faturated with moisture. In these cases, some advise that the first operation should be performed towards the close of the year in a shallow manner; so merely to take off the rough surface; the land may then remain in this situation until just before the beginning of the spring, when it should be well broken and reduced by harrowing, and then cross-ploughed to the full depth. When the land is weedy, it should be again broken down by the harrow in the course of a little time; but when clean, it is better to remain in its rough state. In this condition it may then be left until the spring be a little advanced, when it should have another ploughing to the full depth, and where the season is dry, and the soil of the more heavy or stiff kind, be immediately after harrowed, but where it is light, this may be deferred for a week or two. By repeating these operations sufficiently, the soil is most soon brought into a fine clean state of preparation for the crop.

Others, however, think the first ploughing should be deep, and the after ones and harrowings be continued to a later period, but at the same time, suggest that they must, in general, be much regulated by the nature of the soil, the circumstances of the season, and the convenience of the cultivator.

In preparing fallows, as well as other lands for turnip crops, some, in different places, besides these means, make great use of scoriators and scabol tors, and find them particularly beneficial in foul slates of them.

Where the seed of this fort of crop is, however, to be put in after corn, early pea, tares, or other such crops, the preparation of the land is seldom carried to such an extent of ploughings and other operations. Much fewer are commonly thought sufficient for the purpose, as two, or three at most.

In preparing for this crop, after the surfaces of coarse pasture or other grass-lands that have been long in that state, old fallow lands, or downs, have been taken off and reduced by means of paring and burning them, the practice is to have recourse to once ploughing over the lands in a light manner, the ashes having been previously spread out equally on the surface. In this way the most advantage is afforded to the turnip crops, and they have been well produced by it.

There are some other local practices of preparing for turnip crops, but they need not be noticed in this place, as being only in little use in certain cafes.

In the application of manure in the preparing of land for this crop, in the first of these ways, and where it is of the calcareous kind, such as lime, marl, or other similar forts, it may be the best mode to make use of it after the second or third ploughing, especially in the former of these kinds, in the proportion of from one and a half to about three chaldrons, or thirty-two bushels; and in that of the latter, from eight to ten or fifteen ordinary cart-loads to the acre, as the circumstances and nature of the land may be; as in this manner such matters may become the most perfectly blended and incorporated with the mould of the soil. Each of these sorts of sublimates has been found highly useful, in this way, in several different districts of the kingdom.

It is, however, clear, from the success of different cultivators of this fort of crop, that sublimates of the dung-kinds, where they can be fully supplied, and used in the preparation of the land, or other ways, are the most suited to the growth of the root. And that for such soils as possess a proper degree of lightness, and are in a fine mellow state of mould, those which are in the more reduced, or rotten short condition, may be the most suitable, as they are capable of being the most intimately mixed and incorporated with them; but that where they are more close and heavy, the longer and less reduced kinds may be more proper and beneficial, as they will not only tend to preserve these soils in a more open and loose state, but by their more gradual decay in them, render the earth more friable and mellow. Some, however, think them best applied in the medium state between these extremes. This fort of manure, when used in preparing land in this intention, should vary, in some measure, not only as the nature of the soil may be, but according to the manner in which the crop may be cultivated in general, however, it should be put into the soil as nearly as possible to the period at which the seed is sown; as, in this case, in consequence of the new fermentation that necessarily takes place in the soil, the crop receives the most benefit from it. When, therefore, the crop is to be put in, in the broad-cast manner, the dung may be spread out equally over the land, and be turned in with the seed-furrow; though some advise it to be lightly turned in by the ploughing that precedes the seed-earth, and to be well intermixed with the mould of the soil, by harrowing immediately before that earth be given. The former would appear, however, to be the better practice, especially when the manure is in a sufficiently reduced state, as the plants will have the more full advantage of it. The quantity must necessarily depend in a great measure upon the different circumstances of the soil, and the richness of the dumpy material; but less than from ten to twelve good three-horse cart-loads can seldom be made use of with advantage on the acre.

Where earthy and other matters, in mixture with dung, are had recourse to in this way, after being well prepared, as is sometimes the case, the proportion should mostly be considerably larger.

In cafes where the crops are put in, in the ridge or drill manner, as the manure is wholly confined to the middle parts of the ridged-up earth, and does not occupy all the superficial portions of the land, a somewhat less quantity of it may answer the purpose; though a full and rather liberal
allowance should always be made, as the safety and success of the crops depend much upon the rapidity and strength with which the young plants are at first pushed forward by such means.

In whatever way this sort of manure is made use of in this preparation, it should constantly be applied in an even manner, and be turned into the soil as soon as possible afterwards; as where this is not the case, great loss must often be sustained by the dissipation of the more liquid parts of it.

There are many different practices, in the preparation and application of this kind of manure, recurric to in different districts, in using it for the purpose of raising turnip crops, as may be seen by consulting the Corrected Agricultural Report of the County of Norfolk; and different kinds of it are sometimes preferred by cultivators, as that from fattening beasts, hogs, and the sheep-fold. But good clean dung of any sort is capable of anwering the purpose.

The dungs of rabbits, poultry, and pigeons are occasionally used with success in the raising of crops of this sort, after being rendered dry, and dispersed over the surface of the land in an equal manner. They are mostly used for this purpose in the quantities of from about twenty to thirty bushels to the acre, just before the time of sowing the seed. And as they require to be put into the soil to only a foot depth, harrowing may, in many cases, be sufficient for the purpose, or a very light and shallow ploughing. Rape-cake has long been employed as a manure in some districts, in preparing for turnips, as that of Norfolk, by having it turned over the land in a coarsely reduced state, five or six weeks before the time at which the seed is to be put into the soil, in the quantity of about a ton to three or four acres, and leaving it so, or turning it in very lightly at the period of sowing. But it is considered a great improvement by some, and practised to much extent by Mr. Coke, of the above district, to have it ground by proper mills into a perfect state of powder; and applied at the same time with the seed over it, in the drills or small openings in the land made for the purpose. It is effected by a contrivance of the drill kind, that contains alternate divisions, with small and large cups for delivering the seed as well as the cake into the same drills. The stream of powdered cake is thus rendered constant and regular, the proper cups and funnels being capable of ready application. In this way, it is not necessary to have the cake applied before hand, and a ton is sufficient for five acres, by which there is a considerable saving in labour as well as the material. It is said to answer perfectly in the practice, though some dislike it.

Different other sorts of manures that can be reduced into a powdery state may likewise be employed in this manner, in the growth of this crop, with great economy and advantage in many cases. Malt-duft or combs too, might be made use of in the same way with advantage, though it is commonly applied over the surface in the proportion of about twenty sacks, of three bushels each, to the acre.

Sheep-folding, in some districts, is used as a means of providing manure for the growth of turnips, from the time of first ploughing up the land, to that at which the feed-earth is given. From the treading and comminuting of the soil so much in these cases, it may however be believed only to fold during dry weather, and always to plough over the land in a light manner as soon after the sheep are removed as possible.

The quantity of seed which is necessary must be different in different cases, as a great deal must constantly depend on the nature and quality of the soil, the period of sowing, and the manner and circumstances under which it is put into the ground. In some good foiled districts in the southern parts of the country, where the turnip culture in the broad-cast method is carried on to a considerable extent, the quantity made use of is commonly from about one pound to one pound and an half; but on those of a more light, and those of the sandy kinds, a pound is mostly found quite sufficient; while on some more heavy turnip soils, nearly two pounds are employed. On the calcareous and loamy chalky soils too, a large quantity of seed is mostly necessary. It is indeed, in common, a good practice in fowing for turnips, not to be too sparing of seed, as the unnecessary plants are readily capable of being removed by the first hoeings and thinnings of the crops.

In the culture of the crops in the ridge or drill method, as is commonly practised in some northern districts, in consequence of the feed being deposited in a more regular and exact manner, and the whole of the land not being occupied by plants, a somewhat less quantity of seed may be sufficient.

As the success in the growth of turnip crops has been found to depend greatly on the quick early sprotting of the feed, and the young plants being expeditiously pulled into broad leaf, it may be useful to have the feed deeped a little in water, or some other liquid, before it is put into the ground, especially in dry seasons; but it must become externally dry before it be fown in all cases.

Soaking the seed in strong-scented oils, and drying it by means of brimstone, have likewise been practised in the view of preventing the destruction of the crops, but probably with but little success.

The time which is most proper for sowing crops of this sort, must be principally regulated by the intentions of the farmer in respect to the dispoal and use of them; but for the general more early consumption of them, the most proper season for putting them in may be about the beginning of the month of June; but where it is intended that the crops should ferve as food for stock in the more early spring months, or at late periods, the fowing should take place proportionately sooner or later. Indeed, where the root is grown on a large scale, it may often be of great utility and advantage, as well as very convenient, to have the times of sowing still more conveniently varied; as the crops by such means not only come more suitably in fucception to the hoe, but are likewise ready for the purpose of consumption by different sorts of live-flock, at the different periods when they may be most wanted.

In cafes where the practice of lamb-fuckling is had recourse to for getting them ready soon, it is essential to have crops of turnips as early as possible, in which intention the seed is to be put into the soil often a month sooner than the above period; such land being set aside for the purpose as is well enriched with manure, in a fine state of tilth, and perfectly free from weeds.

In common, however, early sown crops of turnips are not only less sweet and nutritious for stock, but more exposed to injury from mildew and other caufes of the same kind, than those which are sown later in the season; though this may be the case, the sowings in no circumstances should be deferred for long as that the plants cannot have time to fix themselves fully in the soil, and cover it well before their growth is checked and restrained by the coldness of the approaching autumn and winter seasons, as in such cases the crops never answer well for the farmer.

In regard to the methods of fowing or putting this sort of crop into the ground, they vary in different districts, but are chiefly of two different kinds, the broad-cast, and the ridge
ridge or drill. In the great turnip district of Norfolk, and
most of the southern parts of the country, it is the most
prevailing practice to sow this sort of crop in the broad-cast
manner on the level surface: while in the large turnip
districts of Northumberland and Berwickshire, where this kind
of husbandry has undergone considerable improvement, and
in most of the more northern parts of the isle, it is more
common to have recourse to the drill mode, depositing the
seed in rows, either in hollows or ridges mostly raked by
one hand of the plough, or in drills on the level surface; at
the distances of from twenty-four to thirty inches in the
former cafe, as the circumstances of the land and the inte-
tentions of the cultivator may be, and from ten to twelve
or thirteen inches in the latter.

Thefe different general methods may each of them pro-
ably have recourse to with propriety, success, and benefi-
cient under different circumstances and qualities of the foil. As
on the light, mellow earthy, deep sandy, gravelly, and other
similar forts of land, which are apt to part with their
moiſture too quickly, and consequently liable to become too
dry and parched for the healthy perfect growth of the
turnip, it may be the beet and most successful practice to
sow in the broad-cast or drill mode on the plain or level sur-
face, as by such means, the moiſture which is neceffary for
the crop, may be more effectually preferred in the land for
the supply of the plants. And on the contrary, where the
lands are of a somewhat more heavy quality, and not fo much
dispersed to part with their moiſture, but to retain it in a
fort of firm flat, the ridged-up drill method may be the
most suitable and advantageous, as by the mellowness and
fiinenefs of mould which it affords, and its tendency to keep
it dry and preserve the plants from being hurt by the reten-
tion of too much wetness about their roots, the growth and
feverity of the crops will be much promoted. It has a
superiority too in fome cafes in other ways; as on foils
which are rather thin in the staple, this plant, in confequence
of its long tap-root standing in need of a good depth of
mould, can seldom be grown in a perfect or beneficial man-
er, by ridging up the land considerable advantage may be
gained in providing a more suitable depth of cultivated foil
for the plants to grow in, and a better bed for putting in
the seed, as the operation has been found to more than
double the common depth of mould in fome fuch cafes.
The plants in this way grow more strongly, and befeides, by
the manure being confined to the ridges on which they
grow, are lefs exposed to the atmosphere, and not demanded
in fo large a quantity, in confequence of which more land
may be employed in raising this fort of crop; while by its
concentrated, and the feed being placed more immediately
upon it, the nourishment and means of support to the plants
may be more fully and effectually supplied, and a larger
produce, of course, be afforded. This mode of sowing may
be beneficial too in affording the means of more easily and
readily getting up the crops, as food for flock in particu-
larly levere feafons, when eaten off very early in the winter
months. It is of importance also in feveral other cir-
cumstances, as the hoeing, working, and cleaning of the land
between the rows of the plants can be easier, better, and
more perfectly executed, lefs expert perfons can be em-
ployed in much of the work, and from the earth or mould
being laid up to the plants by the ufe of the plough or
fome tool of that kind, the roots of the crops are better
protected and preferved from the effects of severe frosts and
other caufes of injury. They can be railed in this way like-
wise on land that has been lefs prepared and is lefs dry, as the
tops of the ridges are preferred by it in a proper flate, and
the crops are mostly more abundant in this manner of sowing.

Different objections have, however, been made by fome
to the ridged or railed drill method of putting in the feed;
but the principal of thofe that appear to have any fort of
weight or importance are, that in confequence of the roots
of the crops, in fuch cafes, being more elevated or flanding
higher, they are, on account of being too much expofed, lefs
capable of flanding the severity of the winter feaion; and
that larger spaces or distances are allowed than are neceffary
for the roots to attain a proper size in, confequently that
the quantity of produce on the acre will not be fo great.
Notwithstanding the latter fuppoftion, it is probable, how-
ever, that from the nourifhment or food of the plants being
fo greatly inereafed, and the growth of the crops thereby
rendered fo much more healthy and ftrong, the amount of
the produce must be inereafed rather than diminished.
Diftinguifh and calculations would indeed foom to
defcribe this to be the cafe, and that even a greater weight of
turnip is railed on wide intervaleed ridges than thofe that
are narrow within certain limits.

It has been contended too, in oppofition to the railed
mode of fowing, that there is difficulty in refotting the land
to the level flate again, and that the ground in the intervals
becomes unproductive in confequence of the want of
manure; but by forming the ridges in a fuitable and proper
manner, according as the nature of the foil may be, all
these inconveniences may readily be removed. In this
intention, it has been advised to form the ridges in diagonal
and other directions over the fields, keeping the lands dry.

It is further objected to the railed practice of fowing,
that in lands of the more heavy turnip kinds, which have
little intergrality of surface for taking away moifure when
in excess, though larger crops of this root may often be
produced, the grounds are fo much injured by being poached
in getting them off, that the crops of grain or other kinds
which succeed them, are leffened in a far larger proportion
than is compensated by the greater value of the turnips.
In fuch cafes and circumstances, it is advised, as more ben-
eficial, to form the land into large ridges, fo convex as to
throw the wetness quickly into the furrows, as about fifteen
feet in width, that a cart may be eafily paffed along them
without prefling the earth in and obstructing the furrows
on the sides, the feed, where the land is difpofed to throw
up weeds of the annual kind, being fown in the drill man-
er on the surfaces without being railed, as by that means
the work of hoeing may be rendered more eafy and convenient;
but where this is not the cafe, and where the feed is put in
at a late period, or the land much infetted with the grub, it
may be preferable to have recourse to the broad-cast mode
of fowing, as being more certain, from the plants being left fo
much clofer to each other at the firft fowings, as to admit of
thinning out and removing the bad and unhealthy ones in
the succeeding operations of the fame fort. Befeides, they are
advice to have the advantage of growing more strongly,
from the fielter being more complete, and from the ground
being lefs furred about them in their early growth, before
their tap-roots are sufficiently fixed in the foil to support
them perfectly.

It would, however, appear from the fuccefs which has
attended the fowing and raling this fort of crop in the
ridged-up or other drill mode in different districts, and from
the greater facility and cheapnefs of performing the neceffary
after-culture, that it is, in many infances, the moft ben-
eficial manner of fowing; but that the nature of the ridges
or drills, and the distance of the rows, muft often require to
be varied according to the quality of the foil, and many
other circumstances. See a paper in the fend volune of
"Communications to the Board of Agriculture," for the
com-
comparative benefits of the drill and broad-caft methods of
fowing, as ascertained by experiment.

In explaining the practices which are mostly made use of
in putting in turnip crops in the above two different
methods, it may be observed, that where the former or
broad-caft manner of fowing is in use, which may be proper
and advantageous in some cases, as has been just shewn, it is
of much consequence to their success, that the more super-
fi ci al parts of the land be brought into as moidly and fine
even condition as possible previously to the putting in of the
feed, and that in fowing, the feed be befed over the sur-
face of it in as perfectly even and exact a manner as may be,
as soon as it can be done after the ground has been made
ready, as upon these circumstances being well attended to,
the goodness and abundance of the crops in a great measure
depend. An expert feedman is required for performing
this sort of work, but as it can seldom be done by the hand
in a suitable manner by persons who have not been long in
the habit of putting in small feeds in this way, a fort of box
or trough has been invented and constructed for the pur-
pofe, which is in frequent use; and when proper care is taken
to prevent the perforations of it from becoming obstructed by
two or more feeds being fastened in them, it is of great utility
dispersing the feed in an uniform and regular manner over
the surface of the land. After this has been properly
effect ed, the feed is mostly covered in, in a shallow manner,
by means of harrowing, a light short-tined harrow being
u ed for the purpose, as from the turnip plant forming its
bulb in some measure above the surface of the ground, it
should not probably be put in to too great a depth in the
foil. Some advice the pafling of the tool twice over the
land only in the fame direction, in the ffirst going slowly,
and in the latter more quickly, in order to give a neat
finish and finer furface; the ridges having been laid out to
the breadth of from four to ten yards, as the land may be
inclined to be more moist or dry. This is the Norfolk
practice in some meafeure, and found to be extremely benefi-
cial in many cafes of broad-caft fowing for this crop.

In the drill method of fowing turnips, the land, after
being prepared in the manner already defcribed, is either
formed into little ridges by the plough, and the feed put in,
in drills upon them, or there are ftruck in the level surface
as noticed above; but the firft is by far the moft common.
In the great turnip-drilled district of Berwickshire, the
little ridges or drills, in cafes where the ground is not well
reduced, but remains in rather a rough and cloddy flate,
are, it is faid, formed with the common fwing plough, drawn
by two horses, which lays together three or four small
rinds or furrow-slaces for one fuch ridge or drill. But
that the moft common and expeditious method of laying up
these ridges or drills is by a double mould-boarded plough,
which has the boards hung on the fheat with hinges, and
which can be fet wider or narrower, as may be necessary.
This too is drawn by two horses abreast, and forms two
fides of the little ridges or drills at the fame time; the
width of fuch ridges or drills being commonly, as has been
feen, from twenty-feven to thirty inches. In cafes where
the large ridges or lands are not much rounded, the little ridges
or drills for fowing on are not laid in exactly the furface of
them, which is mostly parallel to one or other of the fides of
the fields, but are angled a little, for the purpose of
having the manure better mixed with the foil, when it
comes to be ploughed up into ordinary fixed ridges or lands
for other crops, after the turnips have been caff or taken
off the ground, as already fuggesfed.

But in another district, where this mode of fowing turnips
is largely practiced, in the extensive cultivation of the root
by fome, the manner of performing the work is, after the
land has been prepared and made very fine, as directed
above, for the ploughman to set up three ficks or poles in
a right line where it is thought most proper to begin, and
by having the horses yoked double, and driven by himself
with cords, these poles are feen between the horses, and by
keeping the plough to bear always upon the poles, the
firt furrow is drawn as ftraight as possible. In returning,
the far-fide horse is kept in the new-mad furrow, and the
plough at fuch a distance as to form a one-bout ridge or
drill in a complete manner, which has somewhat this ap-
pearance Δ: by proceeding in this manner over the whole
the land, when finifhed, displays the forms of alternate
little ridges and furrows in this way ΔΔΔ Δ; the difiances
of which are mostly as flated above, as smaller ones do not
admit of ploughing between the little ridges or drills.
However, in the practice of the former of these diftricts,
the land when ridged up or formed into narrow raifed divi-
sions, the ridges have a fels sharp form: thus ΔΔΔ ΔΔΔ ΔΔΔ.

In the latter of these diftricts, or that of Northumber-
land, the next proceedes are thofe of applying and turning
in the dun or other manure into the little ridges or drills,
which is effected in this way: a cart goes down every third
interval between the small ridges or drills, and lays fuch
matters in small heaps in it; when labourers, as women and
children, are ready, and with small three-pronged forks
place them out even and fmall in the bottom of the three furrows of
the ridges or drills; that is, in the one where the matters are
dropped, and in thofe on each fide of it. This being done,
the ploughman fplits the one-bout ridges, and covers up the
manure exactly in the middles of new-formed ridges of the
fame fort: but before the fowing can take place, the tops
of the ridges require to be flattened, which is done by means of
a small roller, four feet eight inches in length, and nine
inches in diameter, which flattens two ridges at once. On
the tops, and exactly in the middles of these flattened
ridges, the feed is deposited in small openings, made by one
or more drill-fowing implements tied to the roller by a rope
of fix or seven feet in length, at which distance the roller is
followed, the fowing-drill or tools being guided by a man, the
work when finifhed appearing in this form Δ Δ Δ Δ Δ Δ Δ Δ Δ Δ Δ;
the letter s shewing the place of the feed, and of that of the
fubfiance ued as manure. The ridging-up the land, and
covering in the manure, are done in the fame way as in the
first diftrict, by ploughs of the fame kind.

And in the mode of this diftrict, or Berwickshire, the
work of manuring and covering it in go hand in hand, and
fucced each other as fhort as poifible; the matters thus ued
being laid in heaps in the furrows of the different ridges or
drills, from the third to the sixth, at the distance of from
eight to ten feet, and immediately put carefuilly in along
the furrows of them, when a few being completed from end
to end, the double mould-boarded plough is ued, as before,
to split the ridges or raided drills, and cover in the manure,
which it does at one bout, leaving the ridge-tops immediately
above the manure put in, rather high. These are sometimes
here, in some cafes and circumftances, a little levelled down
before fowing, in a fort of sharp convex manner, by a light
harrow run once or twice over them. But the moft usual
mode of flattening them is by the light wooden roller, as
above, to which the drill or fowing-plough is attached,
in the manner already feen. Sometimes, however, instead
of the roller, a kind of flcd, made of wood or iron, is had
recourse to in some places, for flattening the tops of one or
more
more bow ridge; but the light rolling mode is much the neatest, most convenient, and ready manner of executing the work.

There are different other modes and practices of performing the business of putting in the feed, in the ridged-up and drill manners made use of in different places; but as they are not common, or of much practical importance, they need not be mentioned here.

In putting in the feed of turnip crops in this way, a great number of different kinds of drill-sowing implements and contrivances are made use of; but tho' wrought by horses, and which are so formed and attached in their different parts, as to perform all or most of the several operations of the process at the same time, are, in general, the most proper and convenient for the purpose. Whatever contrivance of this nature is, however, employed, it is constantly necessary to take care that the feed be regularly delivered and put into the soil; as from the smallness of the perforations in the revolving cylinders of most of them, the feeds are liable to be obstructed in passing, and the regularity of the delivery and sowing thereby prevented.

Every district has mostly its favourite drill-sowing implement for this purpose. In the frit of the above, they, for the most part, make use of a tool of this fort for sowing turnips, which has a cylinder or small barrel of white iron or copper, and that is mounted upon an axle with two wheels. The barrel is perforated with holes at equal distances, and as it turns round with the wheels, the feed falls equally out, and exactly in a straight line. This cylinder and wheels are fixed to a light frame-work, which has two flits, and is kept on the top of the ride or drill by them, by a man or boy, who walks behind, as in managing a common plough. Before the cylinder there is fastened to the frame-work a fort of coulter, which makes a kind of small rut-like opening for the feed, and behind is fixed a rake with two or three teeth, which mixes the feed that is dropped with the mould of the soil, and covers it; and as the horse and implement return by the next furrow or interval to the right or left, the opposite end of the roller rolls the ridge down, and compresses or flattens the top of that on which the sowing implement follows. When it is necessary to do much work at a time, two sowing tools are had recourse to, which follow the same roller, and two ridges at once, and the feed is rolled in by a second roller.

An improved tool of this kind has been invented, which flattens two ridges or drills, forms the little ruts or openings on their tops, puts in the feed, and covers it in all at the same time, by which much saving in tools and labour is made. It is a very complete implement for sowing in the raised drill or ridge method. It is made and much used in Berkshire.

Sometimes the roller used for the feed in these cases is a kind of low broad wheel, which is attached to the sowing tool, and rolls only on the track or rut where the feed is put in, which may answer where the work is on a small scale.

On fine land, fully prepared with reduced dungy matter, and on which it is considered unnecessary to horse-hoe, a sowing implement of this fort is sometimes used, which is attached to the common sowing-plough; and one tool following the other, the feed is sown in rows, at a regulated distance and depth. This tool and mode of sowing answer well in such cafes, and are much employed in some parts of Yorkshire.

In cafes where powdery substanies of the rape-cake, or other such kinds, are to be put in as manure with the turnip-feed, in this way, a sowing implement of this fort has lately been contrived and had recourse to in some of the southern turnip districts, with much utility and benefit. It sows the feed and dust in regular lines and quantities, on two ridges at the same time, the horse passing in the furrow or interval between them. This is effected by having proper cups and funnels for depositing the cake in addition to the other parts, as seen above. It is a very complete and useful tool for the purpose.

Where, however, the feed is to be sown in the drill manner on the level surface, without its being raised in ridges, as is the practice in some districts, especially when formed at narrow distances, as not more than twelve or thirteen inches apart, the larger contrivances of this fort, which sow a number of rows or drills at the same time, may be the most proper and advantageous, as being more quick in the work. There are many other implements of the same kind, which are useful, and suited to different cafes of sowing in this way. See Turnip-Drill.

In whatever manner turnip-feed is put into the ground, experience has shewn that it is of much consequence to have it done in such a way, and under such circumstances, as that the germination and early growth of it may be in as ready a manner as possible, as upon this a great deal in the goodnes of the crops depends, as has been already seen. It has been supposed by some that the seed, in order to secure these effects in the most certain manner, should be put into the soil to the depth of three or more inches; and that the uniformity of the drill method of sowing partly arises from the feed being placed to a greater depth, and growing more rapidly, on account of having more moisture, so as to have the plants become sooner out of danger from insects, or other such causes of destruction; while others think, from these circumstances, that it should be covered in only in a light manner.

A late able practical writer, however, suggests, that as air is necessary as well as moisture to the vegetation of seeds when placed in the ground, it would seem probable that the quick sprouting and growth of such crops may be the belt and most efficiently secured, by only putting them into a middling depth, and according to the particular nature of the land, and state of the feafon may be, as from an inch and a half to about two inches, as the soil or seafon may be inclined to be wet or the contrary. In this way, it is believed, the inconveniences arising from the feed being too much parched and dried by its being exposed near the surface, and from the want of the action of the air on account of its too great depth, may be equally avoided. As crops of this fort are, for the most part, put into the earth during the hotter months, there is another circumstance that may be of equal consequence, it is supposed, in promoting the quick sprouting and growth of the young plants; which is, that the seed, especially in such hot seafons, be well imbued with moisture by soaking it, and consequently with the oxygen principle of the air, as already suggested, before it is committed to the ground; as by such means, there will be less required to be drawn from the mould of the soil which surrounds the feed, and the process of vegetation almost immediately takes place. Sir George Staunton, in his account of the "Embassy to China," as well as Mr. Gillet, in the "Bath Papers," have likewise ascribed the preservation of turnip-crops in that country as well as this chiefly to this practice; and by it good crops of this fort may often be produced, where they would otherwise almoit wholly fail. And the correctness of the practice and principles on which it depends, is further supported by the lucceles of the general custom of putting these crops on the moist, new or fresh turned-up mould. Some interesting and useful observations and experiments on the sprouting and growth of turnip-feed, may be...
be seen in a pamphlet "On the Failure of Turnip-Crops," by the Rev. H. B. Stacey, but which we have not room to introduce here.

After-culture of the Crop.—It is of much consequence in the production of good crops of this fort, to have this part of the culture of them well performed, and at such times as are most suited for promoting the growth of the young plants, as well as preventing those of the weed kind from rising and injuring them by the shade and obstruction which they produce; as without considerable attention in these respects, the labour and expense employed in preparing the land, and putting in the crops, must, in a great measure, be thrown away, from the want of a sufficiently adequate return being afforded. This culture is constantly to be accomplished by means of the hoe, in some way or other. Where the crop has been put into the soil in the broad-cast manner, the hand-hoe only can be made use of for the purpose; but where the seed has been sown in rows by the drill, or in other ways, and a sufficient space of interval allowed, those of the horse kind may be employed, either alone, or in addition, after the plants have been properly set out in the hand manner, to suitable distances.

It is the common practice, when the plants have produced four or five leaves, or when they cover a circle of three or four inches in diameter, which most aptly happens, in favourable seasons, in the course of about a month or six weeks from the time of the seed being put in, to begin the different operations in this sort of work. In the first of which, such plants as stand too close are to be struck out, to leave the others at a suitable distance, according as the circumstances of the season, the nature of the soil, the period of sowing, and the use to which the crop is to be applied, may be. When the season is hot and dry, the striking out of the plants in the first hoeings should not, however, be such as to leave them at too great a distance; as by keeping the remaining plants pretty close together, the moisture may be better preserved in the land, and the crop rendered more secure; but in rich soils, when early sown, and when intended to be consumed by flock at an early period, a greater striking out of plants at first may be advantageous. In the practice of some, the most usual custom is to leave the plants in the first hoeings at the distance of from six to eight inches from each other, but others prefer a still greater distance. In the second hoeing, which should be performed in the course of about a fortnight, or three weeks, from the first, according as there may be a necessity, the plants that are to remain for a crop may be left at the distances of from eight or nine to twelve or more inches in the broad-cast practice, and at those of from nine or ten to fifteen, or a greater number, in the rows where the drill method is employed.

In these second hoeings, the mould between the plants should always be well stirred, in order that it may be rendered perfectly mellow and well aerated, and any weeds that may have arisen be effectually destroyed. The future hoeings that may be necessary in crops of this sort are to be regulated by the particular circumstances of the season; but the mould should never be allowed to become too stiff and compact about the roots of the plants, or any weeds be suffered to interfere with them.

It is the practice in some places, especially with the broad-cast crops, to pass a light harrow over the land once in a place, as soon as the plants are sufficiently strong, in order to render the first hoeing more effectual; and even in particular cases, where they push forward rapidly, it is made use of a second time in the contrary direction. In performing the work, however, great care is necessary, particularly when the plants are thin upon the ground, as otherwise too many of them may be dragged up, and the crop be much injured from the want of a sufficient plant.

In the ridged crops in the latter of the above drilled turnip districts, it is the practice, when the plants have got four leaves, to begin to hoe, leaving the plants at only eight or nine inches distance in the rows; and as they have so much room sideways, or from row to row, the hoers go in that manner and pull out the surplus plants, weeds, and other matters into the furrow or hollow space between ridge and ridge, and the turnip plants are left as regular as if they had been planted out with the greatest care and exactness, the work being performed by women and children at but a trifling expense. After this, when the plants left have perfectly recovered and established themselves again in the soil, as is mostly the case in about eight or ten days, the earth is taken from the rows where the turnip plants stand, by a light plough contrived for the purpose, and turned upon the pulled and struck-out plants and weeds left by the hand-hoers, in the furrows or intervals of the ridges. And when they have once more recovered themselves from this part of the work, and are become again in a vigorous state, or when other circumstances render it necessary; the mould, which was in the former process turned from the turnip rows, is now divided and laid out equally to the different rows by the same tool, or a similar one with a double mould-board. By these means, where the land is clean and free from weeds, the work is completed; but when the contrary is the case, additional hoeings and ploughings are given, according as the state and other circumstances of the land may be.

But in the former of these districts, where the horse as well as the hand methods are had recourse to, they proceed in a different manner. In the former or horse mode, when the turnip plants are from one to three or four inches high, or when weeds begin to appear, a small light common plough of the swinging kind, drawn by one horse, goes along one side of the ridge or drill, and turns off the earth from the young plants, and returns on the other side, doing the same, leaving the plants standing on sharp ridges. But sometimes, instead of this plough, the work of turning the earth off from the different sides of the plants on the ridges is done by a tool of the same nature, mounted with two sharp coulters, which cut or pare from both sides at once, and which on smooth fine land performs the work equally well and much more expeditiously. It is indeed an excellent tool for the purpose, when properly formed and made use of in the work.

In the latter or hand method of hoeing, which is had recourse to when two or three days after the earth is turned off from the plants, the hoers go to work, making use of a hoe of from five to eight inches in breadth, and at one stroke across the ridge, cut out the weeds and unnecessary turnip plants, and leave the crops sufficiently thinned and set out.

When the crop has been hoed and hand hoed in this manner, the field is left in that state for ten or fifteen days, and if weeds grow fast, the same work is repeated. In ordinary circumstances, the whole work of horse and hand hoeing only costs about 7s. the acre.

The turnips are now to be furrowed, or earthed up, which is done after they have been clean hoed, and are beginning to button, by having the earth lying between the rows, which was turned off as above, from both sides of the plants, again laid up to them by means of a double mould-boarded plough with one horse. The whole work is now finished, except only removing any weeds that may afterwards arise.
TURNIP.

It has been suggested by a large cultivator of this sort of crop, that these advantages may be equally well attained, and with more success and less danger and inconvenience, by means of paring one side of a ridge at a time, leaving the other to be performed some time afterwards. It is thought too, that this practice of paring one side only at a time with a fling plough, and leaving the other untouched for several days, has many important uses and some superiority. The tool, in this manner, is capable of going nearer to the plants; the drought has not so much imprefion on their growth; and the land has more benefit from the atmosphere by being flird at different times, than when the mould is directly thrown into its first bed, as in the common manner.

In this mode of proceeding, the work is reversed at times in an alternate manner, and continued as long as a passage is allowed to the plough by the firms of the turnips; and they are never set up at all.

Much advantage in the hoeing of turnip crops may often be gained by having the feed put in at different times, as by this means six labourers have been found capable of performing the work twice over more than one hundred acres, while in the contrary circumstances, a much larger number is always necessary for the purpose. See Hoeing.

In the hoeing culture of turnips, many different tools of different sorts are in use; but in the horsemethod, the work can be well and correctly performed by any light small plough. In this work, some use one which is about five inches in width at the bottom behind, and eleven at the top, which answers well for working the intervals of the drills or ridges. But in setting or earthing up the rows, one of the double mould-boarded plough is probably better, as being more expeditious and convenient. Improved tools of this sort have been contrived, with coulers that are moveable, for cleaning these crops, which by their capability of being readily set to different distances, so as to suit the different widths of the rows, not only perform the work of paring of and removing the earth from the different sides of rows at one operation, but which, by having their earth-boards so attached, as to be set differently as to width, effect the work of moulding up the plants. In managing the buffetings by this tool, there is evidently not only an advantage in double the quantity of work being performed, but in the different operations and processes of it being effected in a more correct manner, such as to stirm the mould in the intervals of the ridges or drills, and the application of it to the slims of the young plants on or in them. For these purposes, the tool of this sort, which has lately been invented by Mr. Waitall, may also be found very useful in different cafes. See Turnip-Hoe.

In whatever way the work may be performed, or whatever tool may be employed for the purpose, it will always be of great utility to have the earth and mould well loofened near to the roots of the plants, when they are in life in any way, and to have all weeds well cleared out from about them.

Dangers to which exposed.—Turnip crops are liable to danger from different causes during the more early stages of the growth of the plants, but the principal of them are those of the attacks of the fly, the flug, and the black caterpillar.

The fly chiefly preys upon the sweet tender feed-leaves of the young plants, and its presence is rendered sufficiently evident by its leaving many little brown spots on them, and by its eating away their flincy green parts down to the fibres of the leaves. It is said to increase in size, and the number to become larger, until the plants be wholly destroyed. It is supposed by some, that from these insect enemies, being extremely numerous on such leaves of turnip plants, and not eating, but, as it were, fucking their sap or juice through long proboscis or organs, that serve to attach them to the leaves in somewhat the manner of leeches, they may, in some measure, be the cause of the very slow progress that is sometimes made in such plants to put in rough leaf.

The ravages of the flug are readily ascertained by looking to the edges of the leaves, as it begins first to feed upon them, gradually afterwards proceeding from one part of them to another, until each is more or less consumed, sometimes exhibiting in the whole of the crop a partially eaten state. In many cases, almost the whole of the plants is destroyed.

The depredations of the black caterpillar mostly take place after the crops are in a more advanced state of growth, and the plants have formed considerable tops, and are in what is usually termed rough leaf; the green parts of the leaves in such cates being eaten through and destroyed, consequently the growth of the plants greatly retarded.

A great many different practices have been proposed and had recourse to at different times, for guarding against the destruction produced in these ways, but hitherto probably without any great success in effectually preventing it. In this intention, the blending of new and old turnip-feed together, or such as has been moistened, and such as is dry, and using them as feed for raising the crops, has been advised by some, as by this means the plants, as crops, coming up at different times, may be less in danger of being wholly destroyed, or may escape in sufficient quantity for the purpose, especially as such insects are well known to frequently make their attacks suddenly in large numbers, destroying the plants as they rise, and as suddenly disappearing again, leaving those that come a few days afterwards untouched.

On the supposition that other sorts of plants are more desirable and liable to be fed upon by this destructive insect than that of the turnip, the old practice of mixing and throwing other kinds of feeds with turnip-feed, as those of the radish and some other sorts, has lately been revived, and much extolled by different persons, but probably the method is extremely uncertain, as it cannot be successful, except when the different kinds of plants rise pretty exactly at the same time, which, from the great difference in the vegetative powers of different feeds, will rarely be the case. Any use that can be gained in this way, must probably be by employing the seeds of such preferred plants, as are rather more quick in their sprouting and growth than those of the turnip, as, where this is not the case, the turnip plants may often be destroyed before the others are in a state to be fed upon. The deftroying of the leaves of turnip crops over with caustic lime in the state of fine powder has been tried, and found useful in saving them in some cases. The same substance, as well as those of vegetable ashes and foot in their reduced states, when used by being thrown over the crops by the hand in pretty large quantities, have likewise occasionally been used with benefit against this insect as well as the flug. The sprinkling of tobacco-water, either finely, or in mixture with soap-fuds and urine by proper means upon the plants and land, has been found to destroy the flugs in a ready manner and to prevent their increase. Heavy night-rolling has long been practiced with supposed successes against both the fly and the flug. And the practice of treading with sheep, by keeping them in constant motion on lands cropped with turnips, as well as that of sowing barley-chaff over them, has often been thought
thought useful against the latter. This last too, as well as
the tobacco mixture, has been tried with benefit against the
black caterpillar, a bulb-harrow being previously passed
over the crop to dislodge the insects. The barley-chaff is
to be applied over the crop on their first appearance.

A great variety of other means has been proposed in
these intentions, but probably with no very great success.
See Black-Ganker, Slug, and Turnip-Fly, Prevention of.

In turnip crops, the roots of the plants are liable to
have a large fort of excrescence formed below the small
apples or bulbs, which, after becoming in a state of some-
thing like maturity, takes on the putrid procens, and tends
forth a most offensive smell. Plants in this condition are
mostly plentiful in their growth, and the crops indifferent.
It is said to depend on soil, and that the soils of some turn-
ip districts are subject to it until they have been clayed or
marled, which is almost a certain remedy for it. This is
the case with Norfolk; the soil is perhaps too light. The
knobs often contain a small worm in the centres of them,
which may be the cause. Taking out the affected plants
and furring the earth about the others may be useful. See
Anbury.

On some thin light soils, especially in dry seasons,
these crops are sometimes liable to be affected with a fort of
white mouldy state, which injures and checks the growth of
the young plants greatly; the chief means of removing
which, is that of proper thinning and furring the mould
about the roots of the plants. When it occurs in deeper
soils, benefit may be derived from rendering them more dry
by deeper furrowing between the ridges. See Mildew.

Turnip-plants often send off numerous stringy roots
with knobby lumps at the ends of them, which are liable
to decay and come to nothing, or what farmers term
fingers and toes, instead of bottling or forming bulbs.
This mostly happens in new or fresh land, and no mode
of preventing it has probably yet been discovered. Uti-
ility in such cases may, however, be derived from better
tillage and preparation.

Where these crops have been destroyed by the fly, or in
other ways, the same lands should not be re-own without a
flight ploughing, as is too often the practice, as there must
always be a great danger of the crops of the second fowings
in such cases. It is better either to leave the land wholly
for wheat, or to give a shallow ploughing or scuffing before
the turnip-feed is again put in. Transplanting is said to
have been employed with benefit in such crops, as the young
turnip plant is found to succeed in this way.

The seasons most favourable to crops of this fort, are
those in which the weather is warm and showery, without
much continued rain. In the autumn and winter periods,
when the changes from frosts to thaws are frequent with
rain, the roots are liable to much injury, by becoming de-
cayed and rotten; and where they fland well in them, seldom
afford the quantity of nourishment and support for flock
that may be fed on them that is usual under other circum-
stances. They are liable too to be much hurt in the winter
season by the wounds and punctures made in them by dif-
ferent forts of birds, as wood-pigeons, rooks, and fome
others; against which they should be guarded as much as
possible.

The expeuces of raising crops of this fort must necessarily
vary considerably according to the nature of the soil, the
crops which they succeed, the methods of putting them
into the ground, the situation, and many other circumstan-
ces of different kinds; but in the ridge or drill practice, they
may in many cases stand in this way.

5 10 4

In the broad-cast practice, the expenses may mostly per-
haps be a little lower than in the above estimate.

It is in most cases the practice to sow barley after turnip
crops, but in some northern districts, wheat, and other crops
with feeds, are occasionally put in after them, when fed off
with sheep, and cleared early on one ploughing.

The quantity of produce or food for flock which is
afforded by crops of this fort, must, of course, differ much
according to the differences of season, the nature of the
soil, and the mode of culture that is pursued; but a medi-
cum crop, where the land is good and suited to the purpose,
may afford fifteen tons or more on the acre; in many cases,
however, it will be much less. The value of such crops
must depend upon many different circumstances, as their
quality and abundance, the manner in which they can be
consumed, as on the land, or in crebs and stalls, in feeding
or rearing live-flock of different sorts, and on the price of
the market for the sale of such flock; but in common, it
may be from about three or four to six or seven pounds the
acre, and in some cases considerably more, as ten and up-
wards. An acre of good turnips will fattcn a beast of
forty stone and more, or about eight sheep.

Seeding Crops.—In raising crops for feed, which is
the produce of the second year's growth of the plant, con-
derable attention is necessary in the view of producing such as
is good; as when it is collected from fuch crops as have
been fown three or four years in succession, without trans-
planting, the roots are liable to be numerous and long, and
the necks, or parts between the bulbs and leaves, coarse and
thick; and when taken from such as have been transplanted
every year, these parts are apt to become too fine, with too
great a diminution of the tap-roots. The best and most
certain way is, therefore, to take feed from turnip plants
that have been transplanted one year, and sown the next;
or transplanting once in three years is supposed by some
sufficient for preserving it good. The most suitable manner
of performing this is to select such turnips as are the hardiest,
the best of their kinds, and that have the most perfect forms,
from the common crops; and after cutting their tops off, to
transplant or remove them, in the latter end of the autumn,
to ground that has been well prepared for them, where
birds can be kept off. The feed will become ready for
gathering towards the close of the ensuing summer. Some
prefer that the feeds taken from a few roots, transplanted in
this manner, should be preferred and sown in the drill me-
thod, for the purpose of providing plants for affording feed
for the general crops, taking out all such as are weak and
improper, leaving only those that are strong, and which
have the best growth; and that when these have applied, or
formed bulbs, to again take out such as do not appear
good and perfect; as, by this means, turnip-feed may be
procured,
procured, which is not only of a more vigorous quality, but which is capable of vegetating with less moisture, and which produces stronger and more healthy plants, and, of course, better crops. The custom of transplanting the whole of the turnips in this intention is said to be too expensive, as well as injurious in some respects.

In either of these modes very good turnip-feed is capable of being raised and provided. When the feed, in these cases, is become fully ripe, the crops are mostly reaped by cutting part of the stems with the feed-pods upon them, afterwards tying them up into wads or sheaves, which, when properly dry, are carried and put into long narrow flacks, to be kept through the winter, and threshed out near the time when wanted in the spring. As in this way, however, much feed is liable to be lost and lost, on account of its readiness to escape from the pods in which it is contained, it is probably a much better practice to have it immediately threshed out, either upon a cloth in the place where it grew, or in some other more convenient spot, being then put into proper bags, and placed in a situation which is perfectly dry.

As crops of the feed kind are subject to injury and loss in many different ways, the quantity of produce must be different under different circumstances; but it may be said in common to be about twenty or twenty-four bushels on the acre. And as the price of turnip-feed is seldom less than seven or eight shillings the bushel, from the great demand for it, the culture may seem at first to be very beneficial; but from the exhausting nature of the crop, the loss in that of the grain, and the quantity of manure afterwards necessary, it is probable that turnips can only be fed to advantage in particular circumstances of soil and situation. As often as possible, however, the farmer should raise his own, as that of the flaps is in general left to be depended upon.

Application and Use of the Crop.—The turnip is a plant or root that is capable of being made use of in different intents, but the principal are those of feeding, supporting, and fattening different sorts of live-foot, in which there are great differences in the practices of different districts of the kingdom; but the most economical and beneficial modes of applying and confining it, under different circumstances of soils, situations, and animals, have probably not yet been sufficiently investigated and ascertained by those engaged in the cultivation of the root. It is stated by a practical writer, that though few trials have been made to determine the particular rate or condition in which these roots afford the greatest and most suitable proportion of nourishment for different animals that are fed on them, it would seem, from their containing a much larger quantity of rich nutritious matter in their fresh state, before being taken from the ground, than afterwards when removed and packed up, as shown by the shrinking and lots of weight that takes place, to be a more saving and useful practice, particularly where the nature and situation of the land and feaven will admit of it, as on dry lands in most of the southern parts of the country, to confume them under the former rather than the latter circumstances; but in more cold and exposed situations, as in many places in the northern districts of the kingdom, and wherever the lands are inclined to moisture or heaviness, as the roots may be greatly injured by frosts and other causes, and the animals receive much harm from the coldness of such places, while feeding on them, as well as the lands be much damaged by their treading, it may be better to eat them under the latter conditions. There are likewise other situations and circumstances, it is supposed, in which it may be particularly necessary, as well as beneficial, to make use of turnips after being drawn, removed, and slurred up, as those where it is difficult or inconvenient to raise and provide other sorts of green food for the winter and spring use of flocks.

Wherever crops of this sort are, however, taken from the land, to be consumed by animals in other places, as from their nature and large growth they must exhaust and deprive it of its fertility greatly, it will constantly be proper and necessary to return an equivalent in manure, otherwise the harm done in this way may more than equal the benefits of the crop. And in all such cases, the tap-roots and other waste parts should always be removed and left on the land, that neither soil nor manure may be taken away, by adhering to them.

In cases where the lands are properly dry, in a high state of fertility, and under good management, it may often too be an advantageous and economical practice to have a partial recourse to both the methods, by having one part of the crop drawn, removed, and eaten off the land, in some adjoining convenient place for the purpose, and the other fed off on the field where they grow; as, by such means, a much larger quantity of land may be benefited and improved, without injury to the crops that may afterwards be grown on the turnip land.

In this mode of improving lands, a great deal more is yet probably capable of being done than has hitherto been the case, when its vast utility and powers in different ways are fully considered.

Some difference in the use and manner of confining this crop likewise takes place, from the kind of flock to which it is applied; as when used in the rearing, keeping, and fattening neats-cattle flock, it is, for the most part, pulled up and eaten, either after having been removed to some proper dry field or spot of ground of the grass or husk kind, or to some field or other building near the straw-yard or feeding-house; in the latter case, being given the flock in bins, troughs, or cribs, or placed before the heads of the cattle in stalls, when tied up, that are contrived for the purpose. The latter of these two modes of eating the root is suppos’d the better, though less frequently made use of, as there is the least possible waste, while, at the same time, the dung and urine of the cattle are the most extensively and effectually prepared. In the former of these methods, the usual practice is first to admit the fattening flock, and then to allow the lean to follow them, and eat up what may remain. In this way there is the least loss.

The cattle are mostly confined wholly upon the roots, except when prevented by the state of the feaven, when they are conformed in other places, or as above. In some cases, the lands to which the roots are removed, in this method of feeding, are those intended to be used for other crops in the ensuing year, by which the different fields, of course, in their turn, have the benefit of being improved in this way most conveniently; and the practice is found more useful than feeding them on the land where they grow. The roots, in these cases and modes of confining them, should not be scattered over the ground in too thick a manner; as, where that is the case, much loss must necessarily be sustained by their being crushed and bruised by the feet of the flock, while upon them.

These several different practices are much had recourse to in some southern turnip districts, where great numbers of different sorts of this kind of flock are every year fattened on turnips.

In cases where milk is a principal object with the farmer, this plant and root are also capable of great use as a proper juicy food for cows, care being taken that the decayed leaves
leaves and other parts be not given, as they are apt to communicate a disagreeable flavour to it. The offal produced in such cases may be given to the dry flock, by which little or no lofs will be sustained in the consumption of the root. This tafe in milk is said to be completely removed by the use of a very weak solution of nitre in water.

These roots, too, have been usefully applied in feeding the flock of work-horses, as by their means the usual quantity of corn may, it is said, be lefened nearly one-half, and the horses never strike in at the same time, as well as perform their labour equally well, and be more free from bowel complaints than in the common manner of feeding them. When used in this way, they should, however, be chopped, and have dry feed of some sort joined with them in proper quantity.

The most extensive use and application of this crop is, however, in its consumption by sheep, particularly where the more suitable improved sorts prevail, in which the most general practice, where the lands are properly light and dry for the purpose, is that of confining them upon a suitable proportion of the crop by hurdles, or other means, and removing them to fresh parts, portions, or breaks, as they are sometimes called, every eight or ten days, or oftener, according to circumstances, or as the spaces may be eaten and cleared by the flock. Where the crop is used as the food of ewes and lambs, the former are sometimes confined in this way, and the latter left at liberty, as feeding more readily in this manner. But where the foils are of a more deep and heavy retentive quality, it is more usual, and a better and more beneficial method, to have the roots drawn and removed, as wanted, to some adjoining field to be confumed by the sheep, somewhat in the way noticed for cattle; as, in this manner, there is not only less injury and waste by foiling and trenching the turnsips into the ground, but the sheep get a more certain and regular supply of fresh roots, by which they do better, and the sheff, by being left clean, are more fully and completely eaten up by the flore cattle that are afterwards put upon them for the purpose. In some cases, the stalks of the land too, in the former mode, it is the practice to have the crop partly eaten off on the land on which the turnsips grow by sheep, and partly drawn and removed, to be confumed in other places. In such cases, the method is usually to turn the sheep upon them, as they stand in the field; but, except the bulbs be much exposed above the foil of the land, it is probably a better practice to have the roots pulled up on the part, before the sheep are turned in and confined on it, as in this way they are not only less apt to break and foil the turnsips, but feed and fatten much better upon them. This practice is much in use in some southern districts.

In some situations, the hilly parts have the turnsips fed off in this manner by sheep, with a certain quantity of hay allowed for every acre thus eaten off, beginning with a break or portion from the lowest part of the field, and allowing a new portion or hitch every day, till gradually rising, clearing the whole off in time for preparing the land for the following crop. The crops on the more flat and heavy parts of the lands are drawn and removed, to be eaten with hay or other dry food in proper places.

It has been suggested, that much lofs is often sustained in these modes of feeding off turnsips by foiling sheep upon them, particularly where the crops are raised in the broad- cast manner, and it is the custom to give the sheep large folds or breaks at a time, in consequence of fruit or snow taking place. In such cases, it is supposed the ridge or drill method is far preferable, as it is easy to have the pens or trays made and fixed in such a manner as to constitute a sort of moveable crib or trough, the bars being let near the sides of the rows, and the boards from ten to twelve inches in breadth, having stakes of suitable lengths, as the depths of the foils may be, nailed to them, and secured on the sides from which the sheep feed. The narrower the spaces the turnsips are included in, the better. As it may be imagined that the animals may get in among the turnsips when fenced off, it is said that, supposing the roots may occupy a regular space of about twelve inches, the troughs may be made little more than a foot in width at the bottom, having a sloping direction upwards. The bars may likewise have an inclination towards the sheep, and hang over the troughs or the parts in which the turnsips are included, and thus prevent them from getting in. It is supposed that in this way the sheep will have their food quite clean, and that by setting off only at a time the quantity necessary for a day, they may eat it with more avidity, and without the danger of spoiling so much by their discharges, as is mostly the case in the common circumstances of feeding upon the root.

On examination, it is contended that this mode, when even largely employed, will be found to be better in many respects, as well as a great deal cheaper, as, on the most moderate calculation, three sheep may be kept in this way to two by the common old method, or perhaps even double the number, and they will fatten much sooner. And on the principle that animals do not feed so well when a redundancy of food is before them, it is thought that if the sheep, in such cases, were driven into the straw-yards for the night, and even to eat from the morning, they would retain the turnsips longer, and fatten quicker; while, in the mean time, the persons employed in looking after them might move the hurdles a row further, and thus little time be loft. If both fattening and store sheep should be kept in this manner, it would be proper to give the feeding flock rather more roots than are sufficient for the day, and to turn in the store sheep the succeeding day to consume what may be left. In this mode, the length of turnsips that may be necessary, without waste being committed, may soon be discovered. It would seem, however, that from the constant trouble, difficulty, and expense of the plan, in providing hurdles, and fixing them for the lands, they would render it incapable of being put in execution, except in cases of a small number of sheep, where it may be an improvement, and a more economical manner of feeding off turnip crops by such forts of flocks.

In the practice of hurdles for this purpose, great attention is necessary to see that the hurdles are at first well set into the ground, and secured by stakes of sufficient length, with proper withs for tying them together, as after frosts and thaws, or snows, they are very apt to be thrown down by the wind, and other causes. The best fort of hurdles for this use is that of the flattened kind; and a material of the netting kind is sometimes employed, which is called fooling, but it is more expensive. See Hurdle.

In whatever manner the feeding off turnsips by sheep is done, the hurdles should always be set in such directions and forms, as that labour and expense may be saved as much as possible.

In some districts, the practice of feeding off these crops in a partial manner, or that of pull and throw, has given way to that of consuming them wholly upon the land, from the full conviction of its greater utility and profit; while in others, the mixed method of eating the root is still had recourse to, as being preferable for the purpose, and affording more benefit.

As it is found, in the fattening of sheep on this crop, that they make the greatest progress just before the turnsips begin to run and form their feed-items, which is supposed to
to depend partly on their containing the greatest proportion of rich nourishing matter at that time, and partly on the weather becoming more dry, warm, and settled; the shoots are sometimes mown off in the spring, and by the lateral sprouts and leaves, a more copious supply of green food is not only afforded, but the roots are preserved longer in a condition fit for use in this application. The feeding or fattening qualities of these roots are, however, much disputed by some, except when some sort of dry food is made use of with them.

In the feeding of these crops off by all sorts of flocks, regard is to be had on first turning upon them, that they do not continue too long, as otherwise injury may be sustained by the difference that is sometimes occasioned by their eating too freely of them, or their being beaten or blown.

Where these crops are drawn for winter and spring ufe, it is sometimes necessary to have them preferved in some way or other. See Turnips, Preferving of.

Great attention in many ways is necessary to turnip crops, as being the foundation of several of the most beneficial practices of the farmer.

Stealing or otherwise defoying turnips, when growing, is by statute punishable criminally, by whipping, small fines, imprisonment, and satisfaction to the party wronged, according to the nature of the offence. By 13 Geo. III. c. 32, the offender shall, on conviction before one justice, by confession on oath of one witness, forfeit such sum, not exceeding one guinea over and above the value of the goods stolen, as to the justice shall seem meet; and in default of payment, be committed to hard labour, for a time not exceeding one month.

No person shall be prosecuted for any such offence, unless the prosecution be begun within twenty days after the offence committed. The provisions of this act have been extended by statute 42 Geo. III. c. 67, in three particulars; viz. in the description of the offence, inferring injuring barns and orchards; in the penalty, making the sum not exceeding 20l.; and in the term of imprisonment, which is made two months.

Turnips, with regard to diet and medicine, are accounted a salutary food; demulcent, detergent, somewhat laxative and diuretic, but liable in weak stomachs to produce flatulencies, and prove difficult of digestion; the liquor, pressed out from them after boiling, is sometimes used medicinally, in coughs and disorders of the breast. The feeds have been accounted alexipharmic or diaphoretic; they have no smell, but discover to the taste a mild acrimony, seemingly of the same nature with that of mustard-feed, though far weaker.

Turnips, Preferving of, in Agriculture, the means of guarding and securing them against the effects of severe frosts and other such causes, by which they are not unfrequently much injured and rendered improper as the food of flocks. In cases where they are designed for the feeding or supporting of neat cattle or other kinds of stock, during the winter and very early spring seafons, as they are then extremely liable to become hurt and destroyed in this way, on account of the sudden alternations of frost and thaw that take place in the former period, this becomes particularly useful and necessary. For want of this attention, the roots often become quite rotten and wholly unfit for ufe, as well as difficult to be got up when wanted.

In the intention of preferving them, many different methods and practices have been attempted and had recourse to at different times, but hitherto probably without any of them having been attended with complete success, and at the same time so cheap as to answer the farmer's purpose.

The only perfectly secure mode would be that, probably, of having them drawn, topped, and piled up with layers of dry straw in hounes properly formed and constructed for the purpose, and conveniently situated for the feeds and other feeding places; but it would be liable to objection, except on a small scale, as being both troublesome and expensive.

A method of preferving this root, which is much in use, very effectual, little expensive, and attended with no great trouble, is that of drawing and piling the turnips up in different portions on the field where they are raised, with layers of dry straw put between each of thefe of the turnips. In this mode, which is much practifed in some southern counties, a load of straw is used to about thirty or forty tons of the turnips. The manner of effecting the work is said to be this: the turnips, on being drawn in a dry time, and the tops and taproots removed, a layer of straw is spread out on a dry part of the ground, and a layer of turnips placed upon it to the thickness of eighteen inches or two feet; after this another layer of straw, and then a layer of turnips; proceeding on, alternately in the same manner, until the pile or heap be brought to a sort of ridge or point; when the edges of the different layers of straw are turned up and fattened, which serves to prevent the roots from falling out, and at the same time affords a sort of external covering to the heap or pile, which is completed by being well thatched over the top with long straw.

It is supposed, too, by some, that the difficulty of getting them out of the ground, and the dangers they are exposed to in severe frothy seafons, as well as the inconveniences the flock experience in feeding upon them from their coldness, and the hazard of their injuring the land by remaining too long, may all be avoided by piling them up in a similar manner, in small heaps in the stack form, the tops outwards, near to the places in which they are to be consumed, covering them over with wattles or hurdles lined with straw.

In some cases, turnips have been attempted to be preferved by being formed, without straw, after the tops and small roots have been taken off, and the former used green, into a fhort of heaps termed pies, in the manner in which potatoes are sometimes kept, being well thatched over on the outfides by straw or some other more cheap material.

They have also been attempted to be preferved in the field by covering them by deep ploughing in different manners, when perfectly dry.

A great many other modes of preferving these roots have likewise been fuggled and practifed by farmers and others, but they need not be noticed here, as they mostly appear les useful than the above.

In all cases of preferving these roots in the heap manner, care must be taken not to have them made too large, or too closely packed up together, as the danger of their heating and being spoiled, may thereby be, in a great measure, avoided.

By some means of these forts, turnips may fublly be preferved, kept ready, and fit for ufe as food for live-flock, even in situations and feafons which are the moft exposed and severe, which under different circumstances are often matters of much conquence to farmers. See Turnip, supra.

Turnip, Sweefifh. See Ruta Baga.

Turnips, Stubble, the crops raised on lands after grain as wheep-feed, which on good dry soils often answer well. See Stubble-Turnips.

Turnip-Cutter, or Slicer and Chopper, contrivances of the cutting kind, which are made ufe of in preparing this fort of root for being eaten by different kinds of live-flock. Implements of this nature are formed and constructed on very different
different principles, but those which have the greatest simplicity are almost always to be preferred, as performing the work in the most easy and ready manner. There is a very useful tool for this purpose, in which the roots are cut by means of a knife fixed upon a fly-wheel, the turnsip being forced upon it through an inclined hopper or port of trough. Some turnip-slicers are so effective as to cut a bushel of the root in a minute.

The chopper is made by a fort of sharp small spade, either fixed or loose, working in a box, into which the roots are thrown for being cut or chopped. The work is readily executed in this way by those who are in the habit of performing it in this manner.

**Turnip-Drill.** That fort of drilling implement which is employed in the sowing of turnip-feed in the row manner.

An improved tool of this fort for one-bout ridges is in use in some districts, which obviates the defects of sowing too many or too little feed. It consists of a solid cylinder, made of iron or brass, about two inches in diameter, and one inch broad, on the surface of which are formed fifteen or sixteen cavities, resembling the shape of a semi-egg when cut longitudinally, and as deep as to hold four or five feeds each. On the back of the cylinder, a little from the top, is placed a hind part of the hopper, to which is fixed a piece of iron or brass, one inch long and half an inch broad, hollowed on the inside in the form of a Gothic arch, the sides of which meeting the sides of the cavities in an oblique angle, prevent the feed from being bruised; at the lower end of this piece of iron or copper, or gatherer, there is a slit, three-tenths of an inch long and one-tenth wide; and at the back of it, a thin flat piece of iron moves up and down by means of a screw at the top of the hopper, which enlarges or lessens the orifice directly above the cavities, and increases or diminishes the quantity of feed delivered, as the workman may think proper. This slip of iron, or regulator, is let into a groove made in the board, which forms the back-part of the hopper. The cylinder is fixed, before the cavities are made, on an iron axle one inch square, turned very true, as well as those parts of the axle which turn in the collars fixed in the handles. To the ends of the axle are fixed two wheels, twenty-six inches in diameter, which turn the axle and cylinder round, and which, in passing through the hopper containing the feed, bring forward in each cavity a number of seeds and drop them into the spout, by which means they are conveyed to the couler, which forms a rut or channel on the top of the one-bout ridge in order to receive them. If the cavities in this sowing implement be made to hold five feeds, when the regulator is screwed close down, and there be fifteen of them, it will deposit eighty feeds each revolution; and from the diameter of the wheels being twenty-six, and the circumference eighty-one inches and a half, eighty feeds will be sown in eighty-one and a half inches, or nearly twelve feet. This being the minimum quantity, by screwing up the regulator, the number may be increased gradually to fifty or sixty in a foot, which is far more than is necessary in almost any cafe.

There are various other improved implements of this nature, which suit different purposes of this fort of culture made use of in different circumstances and places. See **Drill and Turnip.**

**Turnip-Hoe.** A hoe employed in the culture of turnips, which is of the hand as well as the horke kind: the latter is the most ready and effectual, but both are frequently made use of in raising the crops.

A turnip-hoe chopper has lately been contrived, which is both useful in this way and for cutting the roots in feeding stock on the land. It has in the first part the make of the common nine-inch hand-hoe, but forming an oblong square, with an eye to receive the handle from the centre of the first part or hoe, another crosses it at right angles, but this second is not made solid, as in the first common one, but, like the Dutch-hoe, the centre part is open the whole length of it. In working, the turnip being pulled out of the ground by the angles of the hoe, is immediately struck with it about the centre, which divides it into four pieces, and if that be not small enough, the stroke is repeated upon each of the pieces until they be sufficiently fo. It is imagined capable of much improvement, by having two floutish prongs on the back or reverse part of the hoe, proceeding from the neck of the eye; these prongs would pull up the turnips with a great deal more expedition, it is supposed, and the increased weight of the hoe would rather be in its favour, by lessening the force necessary to split the roots. The whole is simple and the expense trifling, which renders it more valuable.

It is said that by means of this tool the turnips may each readily be sliced into as many parts, according to their sizes, as that each piece may be small enough for wether lambs, or, which is of more consequence, for being eaten by the crones, or old toothless ewes, which may fatten in this way with nearly equal facility as the young sheep, as they are capable of picking them up, and by a slight toss of the head, to place them so as to be properly consumed. They can thus feed on the root, when they would otherwise find it difficult to supply themselves with a sufficient quantity of food in the usual manner of nibbling the turnip, either while in the ground, or when picked up without being cut. It is the invention of Mr. Malcolm, and is in much use in the county of Surrey, but may be beneficial in many other districts, where the practice of feeding off the crops on the land by flock is a material object to the farmer.

Hand-hoes of from four to twelve inches in width are in use, in this kind of culture, for fetting out the plants and other purposes, as the nature of the crops may be. See Hoe and Turnip.

**Turnip-Rack.** A contrivance of the rack kind, for sheep eating this and some other forts of food out of with less waste than in some other ways. It is usually made about eight and a half feet long, and on one side two feet high, and on the other two feet three inches, without the feet, which are about three inches long. In the top, the middle part folds back on the rack, and on the lower part of it there is a bend, which serves as a gutter for preventing the rain-water falling from it on the sheep's back. The bottom opens the other way and leans against the top, for the convenience of carrying it. It is sometimes placed on low wheels. It is very useful and convenient in many cases of feeding and fattening sheep.

**Turnip Sowing Trough.** A contrivance of this kind for the purpose of sowing turnip-feed with regularity in the broad-call manner, where it cannot be done by the hand. It is somewhat in the box form, and so contrived as to deliver such small seeds with great exactness over the land. See **Turnip.**

**Turnip-Tray.** A long narrow shallow box of trough or box contrived and made use of for the purpose of sheeps eating turnips out of in confining them upon the land, in order to prevent waste in such modes of feeding.

**Turnip-Cabbage.** See **Cabbage and Kohlrabi.**

**Turnip-Rooted Cabbage.** See **Cabbage.**

**Turnip-Rooted Celery**, a root of that fort of the turnip form. See **Apium.**

**Turnip-Fallow**, in Agriculture, a term applied to that fort of preparation for the crop which is made by repeatedly working
working over the land in some way or other. The most improved practice is that of not having the autumn broken-up lands flitted again, until the surface-working in the early spring has well loosened the mould, to favour the growth of weeds, which is best performed by means of tools that operate the more superficially, as by this tillage keeping the upper parts fine and unburied that have been broken and reduced by the fruits, it is more suited to the rifing of such plants than that of turning it down in a deep manner, and the work is done with greater expedition, which is a material object at such a season. This is a most excellent method; but much must constantly depend on the nature and state of the land in such sorts of work. See FALLOWING and TURNIP.

TURNIP-Fly. Prevention of, the means of guarding and protecting young feeding turnip-plants against its attacks and ravages. Though many different means of this nature have been proposed, few have been attended with much success in preventing the crops. The substances which appear to be the most promising in this intention, are those of foot and quick-lime, and urine and quick-lime, in a state of mixture proper for being thrown over the plants on the land, in a watering manner, by some sort of contrivance for the purpose, or for being put in with the feed. It is supposed that the volatile alkali, which is given off by these mixtures, may be offensive to the insects; while at the same time they afford nourishment and ready growth to the plants. In a trial with lime flaked in urine, in mixture with three parts of foot, applied by means of a small barrel, perforated all round with little gimblet holes, so as to let the quantity of about four bushels to the acre pass out, and fall into the drills with the turnip-seed, the adjoining rows were found to be eaten away, while those to which the composition was applied were fearfully touched at all. The mixture of sulphur with lime has been used, but on a full trial found wholly inefficient. Ammoniacal fumes are said to be successful by some, but further trials are wanting, and they are not very well suited for the farmer's purpose. See SEED, STEEPING, and TURNIP.

TURNITZ, or TWARONICE, in Geography, a town of Moravia, in the circle of Brunn; 30 miles S.S.E. of Brunn.

TURNO VECECOMITUM, in Law, a writ that lies for those that are called to the sheriff's turn, out of their own hundred.

TURNPIKE, a gate set up across a road, watched by an officer for the purpose, in order to stop travellers, wagons, coaches, &c. to take toll of them, or money towards repairing or keeping the roads in repair. See ROAD.

There are several statutes, which have established regulations relating to turnpike-roads, the principal of which, besides those recited under HIGHWAY, are as follow. No person shall be capable of acting as a trustee in superintending turnpike-roads, who is not possessed of lands, &c. of the clear yearly value of 40s., or personal estate to the value of 80l.; to which purpose he makes oath before two trustees, or their apparent of a person possessed of an estate in land of the clear yearly value of 80l. No alehouse-keeper, nor persons retailing liquors of any kind, are capable of acting as trustees, or holding any place under them, or collecting the toll; but they are not precluded from farming the tolls, provided some other person collects them. No gate-keeper, or person renting the tolls, and residing in the toll-house, shall gain a parcel settlement, nor shall the toll, or toll-house, be allied to the poor-rate, or any other public or parochial levy. Any gate-keeper, permitting a violation of the orders pertaining to carriages and horses, and not proceeding with

in one week for the recovery of forfeitures, shall forfeit 40s.; and both he and the surveyor shall render upon oath, when required by written notice from the trustees, an account of all money received, on pain of 5l.; and all officers shall deliver up their books, &c. relating to the execution of their offices, within ten days after written notice, on pain of 20l.; and all persons concerned in the execution of acts relating to turnpike-roads, neglecting their duty, shall forfeit 10l. The trustees, whose meetings are assembled by ten days' notice affixed on the toll-gates, or other conspicuous places, and adjourned for no longer time than three calendar months, or any five of them, may cause weighing-engines to be erected at the toll-gates, order the weighing of carriages and their loads, and take an additional toll for every hundred weight, over and above the following weights: viz. for every four-wheeled carriage, having the fellow of the wheels fifteen inches broad, eight tons in summer, and seven in winter; for every waggon and wain, with axles of different lengths, having the distance of the nearer pair of wheels on the ground not more than four feet two inches, and the distance of the other pair such, that the fore and hind wheels shall roll only a single surface fifteen inches wide, at the leaf, on each side of the carriage, and the fellow nine inches from side to side, six tons ten hundred in summer, and six tons in winter: for every four-wheeled carriage, having the bottom of the fellows of the wheels nine inches broad, six tons in summer, and five tons ten hundred in winter: for every cart, having fellows of nine inches, three tons in summer, and two tons fifteen hundred in winter: for every waggon, having the fellows of the wheels five inches broad, four tons five hundred in summer, and three tons fifteen hundred in winter: for every waggon, rolling a surface of eleven inches, five tons ten hundred in summer, and five tons in winter: for every cart of the same dimensions, two tons twelve hundred in summer, and two tons seven hundred in winter: for every waggon, having the bottom of the fellows of the wheels of less breadth than six inches, three tons ten hundred in summer, and three tons in winter: and for every cart of the same dimensions, one ton ten hundred in summer, and one ton seven hundred in winter. The trustees, however, of the several turnpike-roads within ten miles of London, Welwyn, and Southwark, are allowed to lower these additional tolls at pleasure. (14 Geo. III. c. 82.) The toll-taker offending against these regulations, incurs a forfeiture of 5l.; but the preceding regulations of weight do not extend to any carriage employed in husbandry, and carrying manure for land, hay, straw, fodder, or corn unthreshed; excepting hay or straw carried for sale; nor shall any toll be taken for horses belonging to officers or soldiers upon their march, or upon duty, or for any horses, cattle, or carriages, employed in carrying their arms or baggage, &c. It is required that a table of the several tolls be put up at every toll-gate. (18 Geo. III. c. 63.) For the encouragement of broad wheels, the trustees are empowered to reduce the toll of carriages, having wheels six inches broad, so that it may not be greater than that which is taken for four-wheeled carriages drawn by four horses; and for carts, having the fellows of their wheels six inches broad, no more than for carts drawn by
by three horses; but for every carriage, having the fellies of the wheels of lefs breadth than fix inches at the bottom, and for the horfes, &c. one-half more than the tolls payable for the fame respectively, except carriages carrying corn in the straw, hay, straw, fodder, dung, lime for the improvement of land, or other manure, and implements of husbandry. The fellies of the wheels of carriages entitled to the above exceptions, and the tire upon them, are required to be so flat, as not to deviate more than one inch from a flat surface. And all carriages, moving upon rollers sixteen inches broad on each fide, with flat surfaces, fhall pay only fo much toll as fhall not exceed half of the full toll payable for carriages having the fellies of the wheels fix inches broad, and not rolling a surface of sixteen inches on each fide; and half-toll fhall be paid for waggons having the fellies of the wheels nine inches broad, and rolling a surface of sixteen inches on each fide. These regulations do not extend to any chaffe-marine, coach, landau, berlin, chariot, chaise, chair, calah, or hearfe; nor to the carriage of ammunition or artillery for his majesty's service; nor to any carriage drawn by one horfe, or two oxen; nor to any carriage having the fellies of the wheels nine inches broad, and laden with one block of flone or marble, one cable-rope, and one piece of metal or timber; and no toll fhall be paid at any turnpike-gate for carriages employed in carrying materials for the repair of any turnpike-road, or public highway. No four-wheeled carriage, having the fellies of the wheels of lefs breadth than fix inches, fhall pafs on any turnpike-road with more than four horfes. Two oxen or neat cattle fhall be confidered as one horfe. For other regulations relating to the number of horfes, fee HIGHWAY. Any carriage may be drawn with any number of horfes upon a turnpike-road, where a weighing-engine fhall be erected, provided the carriage be weighed at fuch engine; and the truftees may allow for hills, the rife of which fhall be more than four inches in a yard, fuch number of horfes as they fhall think neceffary, not exceeding ten for waggons with nine-inch wheels, nor fix for carts with nine-inch wheels; and not exceeding feven for waggons with fix-inch wheels; nor five for carts with fix-inch wheels; and not exceeding five for waggons with wheels of lefs breadth than fix inches, nor four for carts of fuch dimensions. There is also an exception in favour of carriages that are drawn in deep snow or ice. No carriages, with the fellies of the wheels of lefs breadth than nine inches, fhall be allowed to pafs upon any turnpike-road, if the fame fhall be drawn by horfes in pairs; except fuch, having the breadth of the fellies fix inches, authorized by fevent or more truftees, and carriages drawn by two horfes only. The penalty, on conviction, by feinement or oath of one witness, is a forfeit not exceeding 5s. nor lefs than 10s. The penalty of evading the tolls, by unloading goods, is 5s.; by turning out of the road, for the owner, any fum not exceeding 5s. nor lefs than 20s.: but for the driver, if he be not the owner, any fum not exceeding 50s. nor lefs than 10s.; or by taking out horfes, 5s.; or by taking the benefit of any exceptions fraudulently, a fum not exceeding 5s. nor lefs than 40s. Exemptions in favour of cattle going to or from water, or pasturage, fhall extend only to fuch as fhall be driven from one parifh to the next adjoining, or that fhall not pafs upon the turnpike-road more than the space of two miles. Turnpike-roads are kept in repair by the flate-duty, required by the ferval acts, or if this be insufficient, by contracting for labour, &c. The surveyor of any turnpike-road, who fhall cofWER to remain in any part, within ten feet on either fide of the middle of it, for four days, any heap of ftones, rubbifh, &c. obftrueting the paffage of it, fhall forfeit 40s.; and any perfon encroaching on it by a ditch, fence, &c. fhall forfeit 40s.; and the truftees may direct prosecution by indictment for any nuissance, at the expense of the tolls. See HIGHWAY and ROAD.

If any perfon shall willfully or maliciously deftroy any turnpike-gate, poft, rail, wall, chain, bar, or other fence, set up to prevent passengers from paffing without paying toll, or any house erected for the use of fuch gate, or any weighing-engine, or refuce any perfon in custody for fuch offences, he fhall be found guilty of felony, and transported for feven years, or committed to prifon for any time not exceeding three years. The indictment for fuch offences may be inquired of, heard, and determined in any adjacent county; and the hundred fhall answer damages, as in cafes of robery. If the truftees erect a gate where they have no power, the juflices upon complaint may order the sheriff to remove it. As for direction-stones, &c. fee HIGHWAY.

The truftees are empowered to let the tolls to farm, in confequence of public notice, to the beft bidder; and if the farmer of the tolls fhall take a greater or lefs toll than he ought to do, he fhall forfeit 5l. and the contract; and every other gate-keeper, offending in the fame way, fhall forfeit 40s. The truftees may alfo leffen the tolls during fuch time as they fhall think proper, provided that the perfons entitled to five-thifts of the money remaining due upon fuch tolls confent. The penalty for obftrueting the execution of any turnpike-act is a forfeit of a fUM not exceeding 10l. nor lefs than 40s. to be paid to the Surveyor for the use of the road, or commitment to the common gaol, or house of correction, for any time not exceeding three months, unless the money be sooner paid. Perfons aggrieved by proceedings in the execution of turnpike acts may appeal, with previous notice, to the general quarter-fellions, when the juflices fhall determine the appeal, and award costs, &c.

But all actions are limited to thirty-three calendar months after the fact committed, and to the county where the defendant resides, or the fact was done; and the defendant may plead the general issue, and if he prevails in the action, have treble costs. 13 Geo. III. c. 84. 14 Geo. III. c. 82. 16 Geo. III. c. 39. 17 Geo. III. c. 16. 18 Geo. III. c. 28. c. 63. Burn's Justice, art. HIGHWAYS.

The fix turnpike-road erected by law was A.D. 1663. 16 Car. II. c. 1.

TURNPIKE is alfo ufed, in the Military Art, for a beam fluck full of spikes, to be placed in a gap, a breach, or at the entrance of a camp, to keep off an enemy. See CHEVAL de frise.

TURNSOLE. See TURNESOLE.

TURNSPIT, VERSATOR, in Zoology, a variety of the dog (which fee), which belonged, in the arrangement of Dr. Caius, to the clafs of degeneres, curs, or mongrels. This breed is much on the decline in England; though still ufed in some other countries.

TURNSTONE, in Ornithology, the English name of a bird, the tringa morinellus of Linneaus, called by authors morinella marina, or sea-dotted. It is a little larger than the blackbird; its head moderately thick, and its body of a longish shape; its beak a finger's breadth long, thick and whitish at the base, and sharp and black at the point; and its head, neck, shoulders, wings, and the upper part of its breast, are of a brownish colour; its throat and forehead are ah-coloured; the back and rump are white; the middle of its back is marked with a very large triangular black spot; the tail confines of twelve feathers, the lower half white, the upper black, and the tips white; the quill-feathers are dusky, but from the third or fourth the bottoms are white, increasing to about the nineteenth, when the
the feathers are entirely of that colour. Its legs are short, and of a reddish-yellow or orange-colour. These birds take their name from their method of searching for food, by turning up small stones with their strong bills, to get at the insects that lurk under them. Ray and Pennant.

Mr. Pennant mentions another species, which is the turnstone from Hudson's Bay, and the _irima interprets_ of Linnaeus; often shot in the north of Scotland and its islands, and also in North America. This bird is of the size of a thrush; the forehead, throat, and belly are white; the breast black; the neck surrounded with a black collar, whence another bounds the sides of the neck, and puffs over the forehead; the head and lower part of the neck behind white; the first streaked with dusky lines; the back ferruginous, mixed with black; the coverts of the tail white, crossed with a black bar; the tail black, tipped with white; and legs rather short, and of a full orange.

**TURN-UP COMPASSES.** See COMPASSES.

**TURNWRIST PLough.** See PLough.

TURO, in Geography, a town of Naples, in the province of Bar; 22 miles S.S.W. of Converano.

TUROE, a small island of Denmark, in the Little Belt; 12 miles S.W. of Affens, in the island of Funen.

TUROK, a mountain of Persia, in Khorassan; 15 miles S. of Mechfud.

TURON, a sea-port town of Cochinchina, in a bay to which it gives name, and which is deeply indented, so as to afford shelter in some or other of its inlets from every blast of wind; the bottom is mud, and the anchorage safe, with a smooth water throughout. N. lat. 16° 9'. E. long. 158° 6'.

As this harbour affords a safe retreat for ships of any burden, during the most tempestuous seasons of the year, Mr. Barrow undertook to draw a plan of it agreeably to geometrical admeasurement. The particulars of the operation and its result are detailed in Macartney's Embassies to China, and minutely illustrated by means of a chart. This chart exhibits an irregular mountainous peninsula, inaccessible on every part of the coast, except that adjacent to the harbour, and at two small sandy bays in the entrance. This peninsula was named New Gibraltar, on account of the local natural advantages which it possesses, and which renders it capable of being made, like our Gibraltar, impregnable. The natives call this peninsula Tien-tcha. United to this peninsula is a level ill-mus, from three-quarters of a mile to a mile in width, containing several small villages and patches of ground, under cultivation, chiefly of rice, tobacco, pufle, and sugar-canes. The chart presents also to view the principal town in the vicinity of the harbour, at which the market is held: the adjoining land is well cultivated; and the name given to the place by the natives, as well as to the harbour, is Han-fan. Connected with the peninsula by a reef of rocks, unnoticed at low water, is the northern point of a small island clothed with trees and thick brush-wood: and as the depth of water is three fathoms within a ship's length of the southern extremity of the island, a convenient place might be prepared, at a small expense, for keeping down and repairing ships. The rocks might be the foundation of a pier or caueway, and thus an excellent dock might be constructed between the island and this peninsula. Such a place would be well adapted for a repository of naval stores, magazines, or warehouses. Other appendages to this harbour are described and represented in the chart; and particularly a valley with a small village, and about forty or fifty acres of land under tillage, mostly bearing rice; a large village on the banks of a considerable river, meandering through an extensive and apparently fertile and populous valley, a cove with plenty of water for ships of any burden, good anchoring ground, well sheltered, especially from the north-east monsoon, and having at its head an extensive plain, with two villages separated by a small running stream, with forty or fifty acres employed in the culture of rice; and a group of curious marble rocks, extending across the ill-mus, one end being washed by the sea, and the other over-hanging the river. The adjacent country is supposed to be, in general, healthy, the violent heat of the summer months being tempered by regular breezes from the sea. September, October, and November, are the season of rains; which are also frequent in December, January, and February, attended at this time by cold northerly winds. The inundations, which take place, generally, once a fortnight, and last two or three days at a time, have an effect similar to that of the periodical overflows of the Nile, in rendering the country one of the most fruitful of the globe. In many places, the land produced three crops of grain in the year. Its most valuable produce, besides the precious metals, consigned in pepper, cinnamon, sugar, silk, and cotton, which the natives give in exchange for a variety of European manufactures. Not far from the harbour of Turon is the town of Fai-fou, a place of some note, and about eight miles E. of the mouth of a considerable river on the coast of Cochinchina, on the banks of which lies Fai-fou; and opposite to the said mouth of the river is Callao, or, as the Europeans call it, Campello, the bearing of its highest peak from the harbour of Turon being about S.E., and the distance from it thirty miles. Staunton's Emb. to China, vol. i. See CALLAO.

**TURONES, or TURONI, in Ancient Geography, a people of Gaul, described by Lucan (i. i. v. 437.) under the epithet of unfitable.**

"Inhabitabes Turones circumcrita causa coercent." According to Ptolemy, they had a town, which he calls "Cefarodunum," and he names the people "Turupii." Their city was situated in the midst of the Loire, and they inhabited the territory that lay to the N.W. of it, and belonged to the third Lyonnae, of which their city became the metropolis. They had the character of not being fond of war: Tacitus calls them "Turones imbelles," and Sidonius Apollinaris says of them, "bella timentes defendit Turones." When the Roman empire was destroyed in Gaul, the Vifgoths became masters of this city under the reign of Eueric, and it belonged to them under that of Alaric in the year 506. But Clovis, having vanquished and killed this prince in 507, took possession of the whole territory from the Loire to the Pyrenees, and also of the city of Turones, the name of which has been since changed to that of Tours; which see.

**TURONILLA, in Ichthyology, a name given by some authors to the common little prickly fish called the fickle-back, or barbiflicate.**

**TUROOT, in Geography, a town of Hindooftan, in Lahore; 25 miles S.E. of Jummo.**

**TUROWLA, in Geography, a town of Poland; 20 miles S.E. of Ploczko.**

**TURPE, a town of Weffphalia, in the bishopric of Paderborn; 3 miles S.E. of Salzktotten.**

**TURPENTINE, Terebinthina; a transparent fort of renous juice, flowing either naturally, or by incision, from several uncious and renous trees: as the terebinthus, larch, pine, fir, &c. Medical writers distinguish four kinds of turpentine; as that
that of Chio or Cyprus, that of Venice, that of Strafburg, and the common turpentine.

The turpentine of Chio, or Cyprus, which is the finest genuine kind, and that which gives the denomination to all the rest, is generally about the consistence of thick honey, very tenacious, clear, and almost transparent, of a white colour, with a cast of yellow, and frequently of blue, of a warm, pungent, bitterish taste, and a fragrant smell, more agreeable than that of any of the other turpentines.

This is the produce of the common terebinth, or pistacia terebinthus of Linnaeus (see Pistacia), an evergreen bacciferous tree or shrub, growing spontaneously in the Eastern countries, and in some of the southern parts of Europe. The turpentine brought to us is extracted in the islands whose name it bears, by wounding the trunk and branches a little after the buds have come forth; the juice isfues thin and clear as water, and by degrees thicken into the consistence in which we meet with it. A like juice, exuding from this tree in the East, inspissated by a flow fire, is said by Kempfer to be used as a masticatory by the Turkish women, for preferring the teeth, sweetening the breath, and promoting the appetite.

The turpentine of Venice is usually thinner than any of the other sorts, of a clear whitish or pale yellowish colour, a hot, pungent, bitterish, disagreeable taste, and a strong smell, without the aromatic flavour of the Chian kind. The true Venice turpentine is said to be obtained from the larch-tree, or pinus laris of Linnaeus (see Pinus), growing in great abundance on the Alps and Pyrenees, and not uncommon in the English gardens. For this purpose, incisions are made at about two or three feet from the ground into the trunk of the trees, and into these they fix narrow troughs, about twenty inches long. The end of these troughs is hallowed, like a ladle; and in the middle is a small hole bored, through which the turpentine runs into a receiver placed below it. The people who gather it visit the trees morning and evening, from the end of May to September, to collect the turpentine out of the receivers. When it flows out of the tree, it is clear, like water, and of a yellowish-white; but as it grows older, it thickens, and becomes of a citron colour. No trees under twelve inches in diameter are tapped; but vigorous trees will yield annually seven or eight pounds for forty or fifty successive years, or during the term of their life. They are of a more graceful kind than that of the trunk; distilled while fresh, they are said to yield a fine essential oil, called by the Germans carpathicum oleum, much superior to that of the turpentines.

The oil of turpentine is obtained by distilling the resin with water in a common still, when the oil is found in the receiver swimming on the water, from which it is easily separated: the average proportion is 60 lbs. of oil from 250 lbs. of good turpentine. This procès is carried on both abroad and at home; but the oil drawn in this country is always preferred.

The Canada turpentine (see Balsam) is obtained from a tree which is a native of North America, that flowers in May, and is brought to this country in casks, each of which contains about one hundred weight. It has a strong not disagreeable odour, and a bitterish taste; it is transparent, whitish, and has the consistence of Copaiba balsam.

Although Linnaeus, and several other writers on the Matteria Medica, refer the common turpentine to the pinus sylvestris, and the terebinthina argentinotarsis, or Strafburg turpentine, to the silver fir-tree; yet upon the authority of Murray, who follows Du Hamel and Haller, Woodville has ascribed the terebinthina vulgaris to the pinus picea, which pours out the turpentine so freely, that it is seldom necessary to make incisions through the bark for the purpose.

All these juices dissolve totally in rectified spirit, but give out little to watery menstrua: they become miscible with water
water into a milky liquor, by the mediation of the yolk or white of an egg, and more effectually by mucilages. Distilled with water, they yield a considerable quantity of a subtile, penetrating, effiential oil, vulgarly called spirit. Neumann says, that sixteen ounces of Venice turpentine, being distilled with water, yielded four ounces and three drachms of effiential oil; and the fame quantity, distilled without water, yielded with the heat of a water-bath, two ounces only. The effiential oil cannot without great difficulty be diffolved in spirit of wine: one part of the oil may be diffolved in seven parts of rectified spirit of wine; but on standing a while, the greatest part of the oil separates, and falls to the bottom. After distillation of turpentine with water, a yellow or blackish resin remains in the still, which is the common resin of the shops. See Rosin and Burgundy Pitch.

The effiential oil, re-distilled by itself in a retort, with a very gentle heat, becomes more subtile, and in this state is called ethereal oil; a thick matter remaining behind, called balsam of turpentine. A like balsam is also obtained by distilling with a stronger fire, the common resin; from which there arises, first, a thin yellow oil, and afterwards the thicker dark reddish balsam, a blackish resin, called colophony, remaining in the retort.

All the turpentines are hot stimulating corroborants and detergents. They are given, where inflammatory symptoms do not forbid the use of them, from half a scruple to half a drachm and upwards, for cleansing the urinary passages, and internal ulcerations in general, and in laxes of the seminal and uterine vesicles. They seem to act in a peculiar manner on the urinary organs, impregnating the water with a violet smell, even when applied externally, particularly the Venice oil. This last is accounted the most powerful as a diuretic and detergent, and the Chio and Strauburg as corroborants. They all loosen the belly, but the Venice most; and on this account they are suppos'd by Riverius and others to be less hurtful than such irritating diuretics, as are not accompanied with that advantage. Dr. Cullen remarks, that terbinthylane glyters, in obtinate coltivines, are much preferable to saline, as being more certain and durable. When turpentine is carried into the blood-vessels, it stimulates the whole system; and hence its use in chronic rheumatifs and paralyzis.

Turpentine readily passes off by urine, which it imbues with a peculiar odour; also by perspiration, and probably by exhalation from the lungs; and to these respective effects are to be ascribed the virtues it may possess in gravelly complaints, febrity, and pulmonic disorders. In all these diseases, however, and especially the last, this medicine, as well as some of the gums and balsams of the terbinthinate kind, by acting as stimulants, are often productive of miscarriage, as was first observed by Boerhaave, and since by Fothergill.

Turpentine has been much used in gleet and fluor albus; its efficacy in the former of these disorders is ascribed by Dr. Cullen to its inducing some degree of inflammation of the urethra: in proof of which he says; "I have had some instances, both of turpentine and balsam of copaiba producing a manifest inflammation in the urethra, to the degree of occasioning a suppreffion of urine; but when these effects went off, the gleet which had subsisted for some time before, was entirely cured." Of these turpentines which we have described, the Venice and Canada turpentines are more generally employed for internal purposes, the Chian not being so easily procured; and the common turpentine is offensive to most stomachs, so that its principal use is in some external applications, among the farriers, and for the distillation of the oil.

The oil is a most potent, stimulating, detergent diuretic. It is sometimes given, in doses of a few drops, in rheuma-
tifs and fixed pains of the joints; and some have ventured on much larger quantities. Cheyne recommends (Eff. on the Gout, p. 199, ed. 10.), as a perfect cure for sciatics, though of many years standing, from one to four drachms of the ethereal oil, to be taken with twice its quantity of honey, in a morning fafting, with large draughts of fack- whye after it, and an opiate at bed-time: this medicine is to be repeated, with the occasional intermiffion of a day, if daily repetitions cannot be borne, for four or five days, or eight at farthest. It appears, however, says Dr. Lewis, highly imprudent to venture on such large doses at once, of a medicine so very hot and stimulating. Boerhaave, after recounting, not without some exaggeration, its fypitic, anodyne, healing, antifeptic, and diluent virtues, when applied hot externally, and its aperient, warming, fudorific, and diuretic qualities, when taken internally, adds, that it must be used with great caution; that when taken too freely, it affects the head, excites heat and pain therein, and, violently urging a diabetes, brings on a flux of the femen and of the liquor of the proflates; and that in venereal runnings, in which it has by some been commended, it tends to inflame the parts, and increafe the disorder.

The oil of turpentine, taken in too large a dose, hath very often bad consequences; such as a frangury, bloody urine, and its total suppreffion, or a fever, violent thrift, and vomiting.

In the Medic. Eff. Edinb. vol. ii. art. 5, we have an account of such symptoms produced by the taking of two drachms of this oil in warm ale. The patient was cured by a warm bath, and drinking plentifully of Fuller's emuljio Arabica.

The oil has lately been given with beneficial effect in unusually large doses for the expulsion of the tape-worm. It differs in its action from the other remedies which have been employed against tape-worms, by killing the worm before it throws it out, and hence it promises to be more permanently useful. The oil is useful when dropped into the ear in deafnesses occasioned by defect of wax. As a diluent, it is applied to indolent tumours, and is an useful primary application to burns.

Turpentines are usually given in doses of grs. x to 3; either made into pills with powder'd liquorice-root, or diffused in water by means of almonds, mucilage, or yolk of egg. The dose of the oil may be m to 5, to produce its diuretic effect: but for the expulsion of tenia, it is necessary to give from 3 to 5, repeated every eight hours till the worm is thrown out. In these large doses, it is more easily taken when exhibited uncombined. The officinal preparations of turpentine are, the "oleum terbinthine;" the "empplastrum Galbani comp.;" the "unguentum elemi comp.;" and of the oil, "hinumentum terbinthine."

This oil is generally used as a drier, to mix with the other oils; for which purpose it has greatly the advantage of drying-oil, with regard to colour, as it is perfectly transparent and white. It is used without any other preparation than mixing it, either alone or together, with drying-oil, with the other oils and colours. Turpentine is sometimes used with other bodies, to render spirit of wine a fit vehicle for colours. The balsam and the inspiflated resins are used chiefly externally: the balsam is less pungent than the oil, and the resins much less so than the turpentines in sublimate. The common yellow resin, in taste considerably bitter, is sometimes given as an internal corroboration, in preference to the turpentines themselves, as being divell'd of the stimulating oil. Turpentine, formerly much used as a digestive application,
cation, is, in modern surgery, almost wholly exploded. Lewis. Woodville. Thomson.

Turpentine may be of use to preserve the bodies of insects. Mr. Boyle took clear Venice turpentine, and evaporating to two-thirds, obtained a reddish transparent gum, clear of bubbles, easily soluble by heat, and as easily rendered brittle by cold. Having first pulverized it, he melted it for use, with a gentle heat, and dipped the body to be preserved several times in it, till it acquired a case of due thickness.

**Turpentine, Balsam, Oil, and Spirit of.** See _Turpentine_, supra.

**Turpentine-Tree.** See _Pistacia_.

This tree, besides its proper fruit, which succeeds the flowers in the usual way, is remarkable for producing what authors of little curiosity have named another fruit, called its horn. This horn is a membranous production, of the length and thickness of a man's finger; and what surprised those authors who esteemed it a sort of pod, was to find that it produced, not seeds, but living animals, which they called flies. The true history of this horn is, that it grows from the surface of the leaves, not from the flalks, in the manner of fruit, and is no natural production of the tree, but a mere accidental thing,occasioned by the wound of an insect on the leaf.

A certain species of animals called pucerons, is peculiarly fond of the juices of the turpentine-tree, and always takes its abode upon its leaves; and these horns are produced in the same manner with the galls of other plants. See _Pucerons_.

**TURPETH.** See _Turbith_.

**TURPIN, F. H.,** in _Biography_, an historical and biographical writer, was born at Caeo in 1709, where he became a professor, but afterwards removed to Paris, and employed himself as a copious writer. As he avowed few principles of government, he was under a necessity of quitting France for some time; but he died at Paris in a state of indigence, betraying neither impatience nor regret, at the advanced age of 90 years. _Nov. Diet. Hist._

**TURPINIA, in Botany, according to De Théis, is a new genus, dedicated by Humboldt and Bonpland, in their 5th fasciculus, to the honour of M. Turpin, an able botanical draughtsman, as well as a distinguished naturalist, the author of several articles in the _Annales du Musé d'Histoire Naturelle_. Respecting the characters, clafs, or order of this genus, we have no information; but the abilities of the person whose name it bears are conspicuous in the _Flora Parisiensis_, published by M. Poiteau and himself, in folio, with splendid plates, printed in colours, a work which unfortunately remains imperfect, for want of encouragement._

**TURPNI, in Geography, a mountain of Silefia, in the principality of Tefchen; 4 miles E. of Jablankau.**

**TURPO, a town of Peru, in the diocese of Guamanga; 36 miles W.N.W. of Guanca Velica.**

**TURQUOIS.** See _Turcois_.

**TURREA, in Botany, received that name from Linnaeus; but whether he designed to commemorate George a Turre, superintendent of the botanic garden at Padua, in the latter part of the 17th century, or Anthony Turra, a botanist of his own time, remains uncertain. The former published at Padua, in 1685, a folio history of plants, without figures, entitled _Dryadum, Amandryadum, Cloridique Triumphus_, which Linnaeus, when he wrote his _Bibliotheca Botanica_, had never been able to meet with, and which, when he afterwards acquired it, certainly could contribute little to his information, being a mere compilation of obsolete opinions. Anthony Turra, who lived at Vicenza, printed in 1765, a 410. dissertation on the _Farsiis_, a genus now established by Mr. Brown in _Att. Hort. Kew._ v. 3. 96. He also published, in 1782, a _Flora Italica Prodromus_, and is the author of an Italian dissertation on the _fritillariae_fruit virtues of Horae-ehufn bark. We cannot but regret that so distinct a genus, remarkable for its elegance as well as rarity, should not be more decidedly or satisfactorily apprised. _Linn. Mant._ 2. 150. _Sm. Plant._ Ic. f. 1. 150. Schrey. Gen. 285. _Willd. Sp._ Pl. v. 525. Mart. Mill. Diet. v. 4. _Cav. Dian._ 7. 362. _Juss._ 264. _Lamarck_ Ill. fl. 1. 351. Clafs and order, _Decandria Monogyna_, Nat. Ord. Tribul., 87. 1. _Linn. Melic. Juff._

**TURZIA, Gen. Ch. Cal. Perianthus inferior, of one leaf, bell-shaped, five-toothed, small, permanent. Cor. Petals five, linear, moderately spreading, very long, slightly dilated upward. Nectary a cylindrical tube, as long as the petal, or longer; its margin in ten acute spreading segments, sometimes divided. Stam. Filaments ten, very short, inserted between the teeth of the nectary; anthers erect, nearly ovate, emarginate. Fil. Germen superior, roundish, style thread-shaped, about the length of the nectary; stigma rather obtuse, corrugated. Peric. Capsule roundish, depressed, five-lobed, five-celled, with ten valves, bulblent lengthwise. Seeds kidney-shaped, two in each cell._

**Eff. Ch. Calyx with five teeth. Petals five. Nectary cylindrical, bearing the anthers between its segments. Capsule superior, five-lobed, five-celled. Seeds in pairs. Linnaeus knew but one species of _Turzia_, sent him by Koenig. The writer of the present article has delineated that, with two new species, in his _Plantarium Icones_, and has now an opportunity of adding a fourth; making, with one described by Cavanilles, and another by Helleniæs, six species in all. The whole are of a shrubby habit, with alternate, flaked, entire, simple, maily undivided, leaves, without _Ripas_, and flaked, lateral flowers, remarkable for their great length._

1. _T. virens._ Evergreen _Turzia_. _Linn. Nat._ 237. Wildl. n. 1. _Sm. Plant._ Ic. fac. 1. t. 16. _Cav._ Dian. 361. n. 524. _Leaves elliptic-lanceolate, emarginate, very smooth. Calyx and fruit silky._—Gathered by Koenig among the lava of extinct volcanoes in the East Indies. This is an evergreen tree, or shrub, with scattered, divaricated, round, brown, leafy branches, slightly silky in their youngest state only. _Leaves_ about three inches long, on short thick flaks, smooth and shining on both sides, terminating in a short, broad, notched point; furnished with a strong midrib, and innumerable finely reticulated veins; their under side much the palest. _Flowers_ in little, short, axillary tufts, on angular partial flaks, and accompanied by a few small leaves, as well as many linear silky _bracteas_. Calyx very small, silky, with five angles, and five small teeth. _Petals_ and _nectary_ smooth, slender and delicate, above an inch long; we shou'd suppose them to be white, or pale flesh-coloured; _Linnaeus_ thought the former, at least, were yellow. _Calyx_ a quarter of an inch in diameter, clothed with silky prominent hairs.

2. _T. pubescens._ Downy-leaved _Turzia_. "Helleniæs in Stockh. Trans. for 1788. p. 296. t. 10. f. 3._—_Wildl._ n. 2. _Leaves ovate, undivided or emarginate; downy beneath. Flowers aggregate. Calyx villous._—Native of the island of Hainan. The _fruit_ of this species has not been observed. We have never seen a specimen, nor are we possessed of any particular volume of the Stockholm Transactions, in which alone it is described and figured. Having formerly however examined that work, in order to contral this with the other species, we have no doubt of its being well defined.

3. _T. maculata._ Spotted-leaved _Turzia_. _Sm. Plant._ Ic.
II. Making T. f.peak marked and 205. Nectary the be and Joseph green fome Flowers 1588, a is teeth. Car-

This appears to be a tree, with deciduous leaves, which are perfectly smooth, of a broad, elliptical figure, bluntly pointed, 5 inches or more in length; marked with pale blotches on the under side, especially near the ribs. Footflaks channelled, half an inch long. Flowers two or three together, on smooth simple flanks, hardly an inch long, erect. Calyx quite smooth, except its silky edges; the teeth blunt. Petals three inches long, yellow in the dried specimen, a little downy externally at the upper part. Nectary, about the same length, slightly dilated, or funnel-shaped, at the top, with undivided segments. 4. T. sericea. Silky-leaved Turrea. Sm. Pl. 1c. t. 12. Willd. n. 4. (T. tomentosa; Cavan. Diff. 361. n. 522. t. 205. f. 2.)—Leaves elliptical; villous on both sides. Calyx and foot-flarks downy. Segments of the nectary divided.—Gathered by Commeron in Madagascar. The leaves are densely clothed, especially when young, on both sides, with short, haggy, silky hairs, and stand on downy footflaks. Some of them, in our specimen, betray symptoms of being occasionally angular, or very slightly lobed. The flowers are even larger than the last, their petals and nectary measuring each five inches. Their colour appears to be reddish, and both are externally downy. The segments of the nectary, an inch long, are divided half way down, into two almost capillary points. The fruit of this, as well as the preceding, is unknown. 5. T. lanceolata. Pink and Green Turrea. Cavan. Diff. 361. n. 523. t. 205. f. 1. Willd. n. 5.—Leaves elliptic-lanceolate, somewhat wavy, smooth. Teeth of the calyx downy, twice the length of its tube. Nectary longer than the petals, its segments bearing the anthers.—Gathered likewise in Madagascar, by Commeron. The leaves are quite smooth, rounded at each end, about two inches long, rather coriaceous; some of them wavy at the edge. Foot-

flarks rather short and flout. Flower-flaks solitary or in pairs, erect, angular, smooth, far more longer than the calyx with its teeth. Petals linear, an inch and half long; rofe-coloured in their lower half; yellow above; green and externally hairy, at the extremity; they cohere in our specimen, forming a tube, so as to resemble some of the tubular-flowered Erica, whose ilanoms moreover are imitated by the pale, prominent, ribbed nectary, bearing the feilie anthers, about the middle of its taper-pointed segments. This peculiar inflorence of the anthers, the apparently monopetalous corolla, and our ignorance of the fruit, have always prevented our publishing this beautiful plant as a Turrea; but Cavanilles seems to have found the petals distinct, and we follow his example in admitting it here, though still with great trepidation, on account of the anthers. 6. T. heterophyla. Various-leaved Turrea. Leaves ovate, undivided or three-lobed, with downy veins. Calyx downy, with short teeth. Petals somewhat flatulate, longer than the nectary.—Gathered on the Cape Coalt of Africa, by Mr. William Bras, and communicated to us by the right honourable Sir Joseph Banks, in 1795. This has slender, downy, leafy branches. Leaves two, or two and a half, inches long, on shortish, downy flaks; some of them ovate, pointed, quite undivided; others, rather the large, wedge-shaped at the base, dilated beyond the middle, into two, more or less distinct, blunt, lateral lobes; all thin, copiously veined, paler beneath; their principal veins downy on both sides. Flowers red, smaller than any of the foregoing, on downy flaks not an inch long, standing in pairs on one shorter, more downy, axillary common-flak, accompanied by a few small bracteas. Calyx angular, with broad, short, pointed teeth. Petals scarcely an inch in length, much dilated upwards, palest on the inside. Nectary two-thirds as long as the petals, exactly cylindrical, smooth. Feem to have almost capillary marginal teeth, between which are feated the large tumid anthers; but our specimen is not in sufficiently good order to allow us to speak positively to this point. The stigma is club-shaped, large and prominent. Fruit wanting. 7. TURREBA, the Earth-Apple, in Natural History, a name given by the people of Guinea, and some other parts of Africa, to a very fine kind of truffle, which they find in great plenty in their barren deferts, four or five inches under the sand. TURREFF, in Geography, a market-town in the district of the same name, and ilure of Aberdeen, Scotland; is situated on the banks of the Deveron, 43 miles N. by W. distant from Aberdeen, and 153 N. by E. from Edinburgh. It is a free burgh of barony, by charter of James IV. granted in 1511, whereby it was entitled to hold a weekly market and two annual fairs: the market is well supplied; and the number of fairs has been increased to seven. The principal manufactures are thole of linen-yarn, thread, and brown linen, and here is a considerable bleach-field. The church was rebuilt in 1794. Here was formerly an hospital belonging to the knights Templars; and also one for twelve old men, founded in 1272 by Cumyn, earl of Buchan, and richly endowed in the succeeding century by king Robert Bruce. The parish of Turrel extends round the town about 44 miles in every direction, except to the N.W. where it is bounded by the Deveron. Agricultural improvements have been lately introduced; and here are several considerable plantations. In the population return of the year 1811, the inhabitants of the parish are stated to be 2227; the number of houses 502.—Beauties of Scotland, vol. iv. Aberdeenshire, 1826. Car-

liltie's Topographical Dictionary of Scotland, 1815. TURRETS, Moveable, in the Roman Art of War, were of two forts, the left and the greater: those of the lefter fort were about 60 cubits high, with square fides, 17 cubits broad; they had five or six, and sometimtes ten stories or divisions, each of which was open on all fides. The greater turrets were 120 cubits high, and 23 cubits square, containing sometimtes fifteen, sometimtes twenty divisions. They were of great use in making approaches to the walls, the divions being able to carry folders, with engines, ladders, calling-bridges, and other necessaries. The wheels on which they moved were contrived to be within the planks, to defend them from the enemy, and the men who were to drive them forwards ffood behind, where they were moft fecure; the folders within were protected by raw hides thrown over the turrets, and guarding those parts that were moft exposed. See Tower. TURRET Island, in Geography, a small island in the Mergui Archipelago, N. lat. 10° 24'. TURRETINI, Benedict, in Biography, an eminent Protestant divine, was the defendant of an eminent family of Lueca, and born at Zurich in 1588, being the fon of a re-
fugee from his country on account of his attachment to the principles of the Reformation; and in 1612 became a parlor and proctor of theology at Geneva. He was employed in several successful missions, by the conduct of which he gained distinguished reputation; and died in 1631, with the charac-
ter of an eminent theologian, and a man of prudence and moderation. His works were, "A Defence of the Fidelity of the German Version of the Bible," written in French, and comprised in 3 vol. 4to. 1618—20, with a sequel in 1626; a variety of theological disputation in Latin, on the Calvinside System of divinity; and sermons in Italian and French. Moreri.
His son, Francis Turretini, was born at Geneva in 1623, and received his education under several eminent German professors, also at Leyden, and afterwards at Paris, where he attended the lectures of Gaffendi. Returning to Geneva, he was admitted to the exercise of his ministry. Having for some time officiated as pastor of the Calvinist church at Lyons, he became, on his return to Geneva in 1653, professor of theology, in which station he continued through life. He was employed in various departments of public business, and died in 1687. Among other theological writings, didactic and controversial, he published "Institutionum Theologicarum Elenchi et Partes tres," 1679—1685, exhibiting a fair and candid view of the points that were controverted between the different communions.

Moreni.

A son of the preceding, John Alphonso Turretini, and the most celebrated of the name, was born at Geneva in 1671, and having, in consequence of disdaining talents and application, the tuition of able masters, access to a well-flowered library, and an ample patrimony, laid the foundation of learning at home, he commenced, in his 20th year, his travels, and at Leyden studied ecclesiastical history under Spanheim. During his residence here he published, in 1692, his "Pyrrhonismus Pontificus, sive Theologico-Historicae de Variationibus Pontificiorum, circa Ecclesiae Infallibilitatem," designed to counteract the influence of Bosquet's book "Les Variations des Eglises Protestant," by shewing that the Roman Catholic church had been equally fluctuating in its opinions. At this time he visited England, and being introduced to Burnet, Tillotson, and Wake, he laboured to cancel the false notions that were entertained by some English divines concerning the Genevan church. Upon his visit to Paris, he is said to have astonished the doctors of the Sorbonne, in a public disputation, by the purity of his Latin, the depth of his reasoning, and his polite manner of arguing. When he returned to Geneva, he commenced the exercise of his ministry in 1694, and was much admired as a preacher. The magistrates established for him, in 1699, a professorship of ecclesiastical history, the duties of which he discharged without any salary. These lectures were introduced with an oration, "De Sacrarum Antiquitatum usu et Praelectione," and the substance of these lectures comprised a body of ecclesiastical history, divided into more than 300 dissertations. In 1701 he was chosen rector of the academy of Geneva; and in this station, which he occupied for ten years, he delivered ten annual discourses, displaying eloquence united with erudition and excellent moral sentiments. Upon being appointed to the office of professor of theology in 1705, he delivered an inaugural speech, "De Theologo Veritatis et Pacis studio." In his course of divinity lectures, he discussed the most important topics of divinity, without the formality of system; such as natural religion, the excellence and evidences of the Christian revelation, the perfections of the Deity, the interpretation of Scripture, and similar subjects. It was very much the object of his wish to unite all Protestants; and with this view he took part with those German ministers who, in 1706, obtained a dispensation from the necessity of signing the formulary, intituled "Confession," introduced during the violent disputes that had occurred concerning Grace and Predestination. Some other public offices were devolved upon him, which engaged his attention, and occupied much of his time and labour. His arduous exertions, together with the uneasiness that was occasioned by the perturbed state of Geneva, are thought to have shortened his life, which terminated in May 1737, at the age of nearly 66 years. His works in 3 vols. 4to, were published in 1737; and after his death appeared his Commentaries on the Epistles to the Romans and The Philalmonians. Moreni. Gen. Biog.

Gen. Ch. Cal. Perianth inferior, of four ovate-oblong, erect leaves, converging in a parallel manner, deciduous. Cor. crumiform, of four ovate-oblong, obtuse, erect, undissected petals, with erect claws. Stam. Filaments six, awl-shaped, erect, the length of the claws, two of them shorter; anthers simple. Pist. German the length of the flower, rounded, slightly compressed; style none; stigma obtuse. Peric. Pod remarkably long, straight, quadrangular, but with two opposite angles obsolete and flattened, of two cells, and two keeled ribbed valves, scarcely equal in length to the partition. Seeds very numerous, roundish, emarginate; their cotyledons accumbent.

Eff. Ch. Pod very long and straight, linear, two-edged; its valves ribbed and keeled. Calyx closed, erect. Corolla erect.

All botanists, who have examined into the subject, have found great difficulty in distinguishing this genus from Arabis (see that article); the character of the four prominent scales, or nectariferous glands, in the latter, being very uncertain. The style attempt at discriminating these genera that has ever perhaps been made, is Mr. Brown's, in the Hortus Kewensis, which is founded on the seeds of Arabis being ranged in a simple row in each cell, while those of Turritis compose a double one; for this is, in fact, the only real difference in our learned friend's characters. By his rule, Turritis hirsuta and alpina are removed to Arabis; while Brassica arvensis and Sisymbrium Loefelli, with probably some others, become species of Turritis. In the latter cafe, great violence is offered to natural affinity, but perhaps the character itself is not clear in S. Loefelli, and its merit is therefore not invalidated by this species, whose close relationship to S. Iris we have noticed in the proper place. (See Symbium.) We are almost perfudcd of the merit of the above distinction, in sending away to Arabis all the species of Turritis which have a simple row of seeds, and some of which have always been ambiguous. They meet in that genus with their natural allies. Nevertheless, as we have not yet treated of these species, we shall retain them here, for the present at least, indicating under each Mr. Brown's alterations, for the guidance of those who may wish to judge of his sentiments, or hereafter to conform to them. On subjects connected herewith, the reader will find some remarks under Tetradynea.
the numerous spreading radial leaves are very rough with partly forked hairs, toothed, or pinnatifid. Flowers cream-coloured, corymbose, very numerous, their common stalk greatly elongated, after flowering, into a dense cluster of long, slender, smooth, erect, flaked pods, each two inches long, and full of numerous small seeds, imbricated in two rows, as we have already mentioned, and not alternately crossing each other, so as to form a simple row. These seeds were formerly an article of the Materia Medica, being esteemed hot and dry, stimulating to the generative faculty, preserving against apoplexy, &c. virtues scarcely intelligible, or confidential.

2. T. levigata. American Smooth Tower-mustard. Wildl. n. 2. Mühlern. Cat. 61. Pursh n. 1.—Leaves all smooth, glaucous; radical ones obovate, flaked, forked, the root linear-lanceolate, entire, clasping the stem.—Sent from Pennsylvania by the Rev. Dr. Muhlenberg. On rocks from Pennsylvania to Virginia; rare; flowering in May and June. Very smooth and glaucous, about a foot high. Pursh. Root biennial. Stem quite simple. Radical leaves oblong, finely serrated; those of the stem arrow-shaped, the lowermost an inch long, lanceolate, obtuse, forked at the extremity; the rest smaller, narrower, entire. Flowers like the first species, but rather less. Pods erect. Willdenow.

3. T. frigida. Slender Tower-mustard. Allioni. Auct. 18. Wildl. n. 3.—Leaves all smooth and shining; radical ones ovate, somewhat flaked, slightly toothed; the root lanceolate, strongly toothed, sessile.—In meadows, and rather moist pastures, in several parts of Piedmont. Root white, woody. Stem two feet high, erect, quite simple, round, smooth, firm, clothed from top to bottom with alternate, close-prefixed leaves, which are tapering, not arrow-shaped, at the base. Flowers small, white. Pods linear, flat, acute, erect, above an inch long, thin at the margin; the lower ones on longish stalks, and leaf crowded. This species is akin to T. bisnuta. Allioni.

4. T. bisnuta. Hairy Tower-mustard. Linn. Sp. Pl. 360. Wildl. n. 4. Fl. Brit. n. 2. Engl. Bot. t. 587. Jacq. 1c. Rar. t. 126. Fl. Dan. t. 1040. Ehrh. Herb. 159. (T. n. 456; Hall. Hist. v. 1. 198. Arbosis bisnuta; Scop. Carn. v. 2. 30. Brown in Ait. n. 11. Erysimos similis hisnuta alba; Bauh. Prodr. 42. Barbarea muralis; Bauh. Hist. v. 2. 869.)—Leaves all rough, toothed in the middle. Stem hairy; the hairs simple and spreading. Branches straight, erect. Pod slightly quadrangular.—Native of dry open pastures, and old walls, in most parts of Europe; not very common in England; flowering in May. The root is strong, woody, and, as we believe, perennial. Stem generally several, one of which is much stronger than the rest, erect, a foot or eighteen inches high, leafy; branched, round, clothed with thick-felt, prominent, simple hairs, the flowering part only being smooth. Leaves toothed, chiefly about the middle, bluntish, all more or less hairy; the radical ones obovate, slender at the base, but not flaked; those on the stem sessile, or partly embracing it, rarely dilated at each side into a small auricle. Flowers numerous, small, white, not coloured. Pods forming a very long, close, erect clatter, all narrow, compressed, but the valves are more or less strongly keeled, so as to render the pod quadrangular; its surface is smooth and shining, beaded, in a manner, with the projecting seeds, which though inception of, of course, alternately, in two rows, range in one simple seris. When ripe the pods drop a little. Linnaeus originally confounded with this his T. alpina, whose leaves are all smooth on both surfaces; and also the following.

5. T. pracna. Early Tower-mustard. (T. n. 2; Ge-

nard Galoprov. 367.)—Leaves all rough, obutate, toothed in the middle. Stem hairy; the hairs forked and depressed, like those on the leaves. Branches straight, erect. Pods erect.—Native of Provence and Switzerland. Nearly out of flower when the hisnuta first expands, being full a month earlier than that species, from which, though very like in general habit, it differs in having larger flowers, tinged with purple in both calyx and petals; pods nearly flat, their valves with scarcely any sign of a rib or keel; and the hairs of the stem forked, or branched, depressed and entangled, as are all those on the leaves. The late Mr. Davall of Orbe in Switzerland first distinguished this plant from the foregoing.

6. T. patula. Spreading Tower-mustard. Ehrh. Beitr. v. 7. 159. Pl. Scelct. n. 28. Wildl. n. 5. (Tourrette cotoneuse; Rey. Mem. de la Suisse v. i. 169. Arabis spumalis; Allioni. Ped. v. 1. 268.)—Leaves all rough with spreading forked hairs, ovate, toothed, clasping the stem. Branches spreading.—Native of rocks in Switzerland, in a southern exposure. Favrod. Root annual, tapering. Stem one, or more, erect, about a foot high, round, leafy, clothed with forked or flary hairs, intermixed with longer simple ones. Branches axillary, alternate, slender, loosely spreading. Leaves hardly an inch long, clasping the stem with their heart-shaped base, hoary with minute, brisly, divided hairs, and ordered with tooth-like serrations; radical ones contracted at their base, disappearing early. Flowers corymbose, very small, white. Calyx not always, as Ehrhart describes it, quite smooth; we find it sometimes tipped with fine hairs. Pods spreading, very slender, an inch and a half long, their valves without any ridge or keel. The general habit of this species, except the pods, is more like Draba murullus than any other Tourrita. Allioni’s synonym, hinted by Reymer, is confirmed by a Piedmontese specimen from Dr. Moleners.

7. T. pubescens. Downy Tower-mustard. Desfont. Atlant. v. 2. 92. t. 163. Wildl. n. 6.—Leaves all rough with prominent hairs, coarsely toothed; those of the stem sessile. Branches spreading. Pods erect, downy.—Native of hills about Algiers, flowering early in the spring. This resembles T. bisnuta, but is less flaky, rather larger, with more spreading branches, and downy, leaf crowded, pods. The leaves are all more deeply serrated or toothed.

8. T. ovata. American Hairy Tower-mustard. Pursh n. 2. (T. bisnuta; Mühlern. Cat. 61.)—Radical leaves flaked, ovate, toothed, obtuse, rough on both sides with hairy hairs; those of the stem oblong, somewhat arrow-shaped, serrated, smooth above. Hairs on the stem depressed. Pods flat, smooth, scarcely keeled. On rocks from Pennsylvania to Virginia, flowering in May and June. Biehnial. Pursh. This also resembles T. bisnuta, to which we have formerly been disposed, like Dr. Muhlenberg, to refer it. The close-prefixed hairs of the stem, less prominent keels of the pods, and the flossy roughness of the upper surface of the stem-leaves, appear sufficient marks of distinction.

9. T. alpina. Alpine Tower-mustard. Linn. Syt. Veg. ed. 13. 502. Wildl. n. 8. Sm. Compend. ed. 2. 101. Engl. Bot. t. 1746. T. ciliata, Wildl. n. 7. Schleich. Catal. 59. Tourrette ciliata; Rey. Mem. de la Suisse, v. i. 171. Arbosis alpina; Brown in Ait. n. 10.)—Seeds somewhat toothed, smooth, distantly fringed and bearded; the radical ones obovate, the root elliptical, half embracing the stem.—Native of Gothland, Austria, Switzerland, and the west of Ireland, flowering about July or August. It was first observed in the latter country by Mr. J. T. Mackay, who gathered this plant by the sea-side at Rinvale, Cummamara, in 1806. Linnaeus originally confounded his own Gothland specimens as a mere variety of bisnuta.
hirsuta (see Fl. Succ. 236.), but afterwards corrected that error. The root is apparently biennial. Stem one, or more, from two to twelve inches high, simple, erect, leafy, round, mostly smooth. Leaves all smooth on both sides, fringed with simple or forked, scattered, spreading hairs, a few of which are often clustered into a little tuft at the tips; the radical ones are frequently tinged with red. The more evidently the leaves are toothed, the less they seem to be fringed, as observed in Engl. Bot. Flowers white, larger than in T. hirsuta, forming a simple corymb, soon becoming a long cluster of narrow smooth pods, whose valves are very perceptibly keeled. Reynier’s original specimen from Favrod proves his plant, and consequendy that of Schleicher and Willdenow, to be the Linnean T. alpina.

The T. ceravola of Allioni, Fl. Pedem. v. 1. 270. 1. 42. f. 2, being considered as an Arabis by Wulfen, who followed by Willdenow, Sph. Pl. v. 3. 557, as well as by Mr. Brown in Ait. Hort. Kew. v. 4. 104, we shall leave it there. However naturally allied this plant may seem to be to our last-described T. ritrita, it is at least as much akin to A. alpina, bellidifolia, and others of that genus.

TURRORAH, in Geography, a town of Hindooftan, in Goownda; 30 miles S.W. of Coomtah.

TURROW, a town of Hindooftan, in Bahar; 26 miles S.W. of Arrah.

TURRONG, a river of Asia, which empties itself into a lake, 18 miles S. of Candahr.

TURSHISH, sometimes written Terciz and Terffia, a town and district of Peria, in the province of Khorrân, 63 furfungs W.N.W. of Herat, lately taken possession of by the troops of his Perian majesty. The old city, called Saltanabad, is small; but to this a new one has been added, where the governor and his principal officers reside. They both together contain about 20,000 people, amongst which are 100 Hindoo families. The trade of this place arises principally from the importation of indigo, and other drugs, from the westward; wool and cloths, and rice, from Herat; and the chief export is iron, wrought in thick plates. The trifling quantity of European goods required is brought from Mazanderan. Between this city and Herat the country is in general mountainous, wild, and uncultivated. Kinneir’s Mem. of the Perian Empire.

TURSI, a town of Naples, in the Baficiana, the see of a bishop, suffragan of Mataria; 24 miles S. of Mataria. N. lat. 12° 17’. E. long. 16° 30’.

TURSIO, in Ichthyology, a name by which Bollanous, Scalliger, and several others, have called the phoca, or porpessif, distinffively from the dolphin, with which it is confounded by the vulgar. See Porspess.

TURSOSKA, in Geography, a town of Hungary; 16 miles N. of Bolefto.

TURSAL, a town of Sweden, in Weft Bothnia; 45 miles N. of Torne.

TURSEREDES, a town of Hungary; 14 miles N.E. of Zatmar.

TURTLE, in Ornithology. See Columbia.

Turtle, in Ichthyology, the name by which we commonly call the great sea-tortoise. See Tortoise.

Turtle-Shell. See Tortoise and Tortoise-Shell.

Turtle Bay, in Geography, a bay on the west coast of Africa. S. lat. 14° 56’.—Allo, a bay on the south coast of New Ireland, so called by captain Carteret. Dampier before called it “St. George’s Bay,” and from Bougainville it obtained the name of “Profin Bay.”

Turtle Creek, a branch of the Moongahela river. At the head of this creek general Braddock was killed in 1755.—Allo, a township of Ohio, in the county of Warren, containing 3442 inhabitants.

TURTLE INLET, a channel between two small islands, on the coast of New Jersey. N. lat. 39° 21’. W. long. 74° 47’. “

TURTLE ISLAND, a small island in the East Indian sea. S. lat. 6° 35’. E. long. 132° 51’.—Allo, a small island in the South Pacific ocean, surrounded by a reef of coral rocks.

S. lat. 19° 50’. W. long. 177° 57’.

TURTLE LAKE, a small lake of Canada. N. lat. 48° 34’. W. long. 71° 31’.

TURTLE POINT, a cape on the south coast of Java. S. lat. 7° 42’. E. long. 109° 58’.—Allo, a cape on the coast of West Florida, in the gulf of Mexico. N. lat. 29° 54’. W. long. 89° 4’.

TURTLE RIVER, a river of the state of Georgia, which runs into the sea, N. lat. 31° 12’. W. long. 81° 42’.

TURTON, a township of England, in Lancashire, with 1782 inhabitants; more than half employed in trade and manufactures; 6 miles S. of Blackburn.

TURUCAI, a town of European Turkey, in Bulgaria, on the Danube. In 1773, it was taken and burned by the Russians; 34 miles S.W. of Drifta.

TURTUR, in Ornithology. See Columbia.

TURUB, in Ichthyology, a name given by Paulus Jovius, and some other writers, to the fish called the paffinaca marina.

Turtle, the Turtle-shell, in Natural History, the name given by the collectors of shells to a very beautiful species of murex, common in the cabinets, but not found anywhere on the shores. This is owing to its having greatly altered its appearance in polishing; for it is not other than the white and brown-mouthed murex, which is common in its rough state, with its outer coat taken off.

TURTURA, in Geography, a town of Naples, in Baficiana; 40 miles S. of Potenza.

TURURANO, a town of Naples, in the province of Otranto; 5 miles S. of Brindifi.

TURUCHAN, a river of Russia, which rises from a lake, N. lat. 6° 42’. E. long. 84° 14’, and runs into the Enifei, a little south of Turunchak.

TURUCHANSK, a town of Russia, in the government of Tobolaki, on the Enifei, formerly called “Mangafea.” According to an old tradition delivered down from father to son, a colony from Archangel built the old otfrog of Mangafea, before any other Russian town existed in Siberia. It derives its name from a Samoiedean tribe, who inhabited this country, calling themselves Mangafea; who, by promising to pay tribute to the Russians, occasioned the building of the town. Old Mangafea, which stood on the river Taz, gradually fell to decay; in 1668, the present town was built, and the inhabitants of the old otfrog were removed hither. This new otfrog was also called “Mangafea;” but as it lies at the mouth of the river Turukan, it had also the name of Turukankh, which it retains to this day. As this otfrog proved the means of several nations becoming tributary to the Russians, it was probably on that account afterwards endowed with the privileges of a town. The houses in this town are not contiguous, and at most do not exceed one hundred. The greatest part of it is included within a small wooden fortification, with four pieces of cannon; and in this stands the house of the governor or prefect, and the principal church; and without it are two other churches. Most of the inhabitants have always been Cossacks; who were placed here, in order to subdue, or at least to check, the Pagan nations of this country, particularly the Tungufians and Samoiedes; 724 miles N.E. of Tobolki. N. lat. 65° 40’. E. long. 88° 44’.

TURUNDA, a tent, so called in Surgery, is usually composed of a bit of lint rolled up, or else of a piece of common sponge, or prepared sponge. Its general use is to keep an
an opening from healing up too soon, in cases of abscesses, diseased bone, &c. Sometimes, also, it is used for dilating the aperture, by which means extraneous substances can be removed, without employing the knife. Tents have even been used for dilating the meatus urinarius, and thus enabling the surgeon to extract stones of considerable size from the bladders of female subjects.

TURUNGA, in Geography, a town of Hindoostan, in the circular of Rutnupour; 24 miles N. of Raypour.

TURZA, or TURCETA, in Ancient Geography, Boufia, a town of Africa, 6 leagues S.W. of Tunis, now a heap of ruins.

TURZEC, in Geography, a town of Lithuania, in the palatinate of Novogrodek; 24 miles E. of Novogrodek.

TURZO, TRUZE, in Ancient Geography, a town of Africa, mentioned by Ptolemy, situated eight leagues W. of Vicus Auguli.

'TURZONZA, a town of Mexico, in the province of Mexicoan, on the side of a lake; 25 miles W. of Mexicoan.

TUS. See Meschid.

TUSA, a town on the north coast of Sicily; 8 miles S.E. of Cefalu.

TUSANTLU, a town of Mexico, in the province of Mexicoan.

TUSBY, a town of Sweden, in Nyland; 15 miles N. of Helingfors.

TUSICA, the Zaine, in Ancient Geography, a river of Africa, which separated Africa Propria from Numidia. Pliny.

TUSCAN, in Architecture, the first, simplest, and most massive of the five orders.

The Tuscan order takes its name from the ancient people of Lydia, who, coming out of Asia to people Tuscany, first erected it in some temples, which they built in their new plantations.

Vitruvius calls the Tuscan the rustic order; with whom agrees M. de Cambray, who, in his Parallel, says, it ought never to be used but in country-houses and palaces. M. le Clerc adds, that in the manner Vitruvius, Palladio, and some others, have ordered it, it does not deserve to be used at all. But in Vignola's manner of composition, he allows it a beauty, even in its simplicity; and such as makes it proper not only for private houses, but even for public buildings, as in the piazzas of squares and market, in the magazines and granaries of cities, and even in the offices and lower apartments of palaces.

The Tuscan has its character and proportions, as well as the other orders; but we have no ancient monuments to give us any regular Tuscan pillar for a standard.

M. Perrault observes, that the characters of the Tuscan are nearly the same with those of the Doric; and adds, that the Tuscan is, in effect, no other than the Doric, made somewhat stronger, by shortening the shaft of the column, and simpler, by the small number, and largerness of the mouldings.

Vitruvius makes the whole height of the order 14 modules, in which he is followed by Vignola. M. le Clerc, &c. Serlio only makes it 12. Palladio gives us one Tuscan profile, much the same as that of Vitruvius; and another too rich; on which side Scamozzi is likewise faulty. Hence it is, that it is of Vignola, who has made the order very regular, is most followed by the modern architects. See Column.

Of all the orders, the Tuscan is the most easily executed, as having neither triglyphs nor dentils, nor modillions to cramp its intercolumns. On this account, the columns of this order may be ranged in any of the five manners of Vitruvius, viz. the pycnotyle, styliile, eufild, diafyle, or aracotyle. For the parts and members of the Tuscan order, their proportions, &c. see Capital, Base, Pedestal, Freeze, &c.

TUSCANY, in Geography, now called Etruria (which see), a grand duchy or kingdom, long celebrated for the arts; the capital of which is Florence, which see. Pinkerton states its length at about 160 British miles, and its breadth at 90; and its area of 7000 square miles as containing about 1,750,000 persons. The revenue is computed at about half a million sterling; but the forces do not exceed 5000 or 8000. Tuscany is one of the most beautiful and fertile regions of Italy, with a temperate and healthy climate. It abounds in corn and cattle, and produces excellent wines and fruit. The mountains in the Siene, or southern part of Tuscany, contain valuable ores of antimony, copper which is wrought at Mafia, and other metals, with slate and yellow marble. The herpetine of Impurcata, 7 miles S. from Florence, presents beautiful varieties used in ornamental architecture. Borax has been found in the lakes of Tuscany, near Sienna and Volterra. The Florentine marble is remarkable for picturesque representations of ruins, &c. caused by the infiltration of iron between the laminae. The river Arno receives many small streams; and the Ombrone is a considerable river which pervades the Siene.
in the evening, on account of the wild beasts. In this vale no single habitation is visible for near 15 or 20 miles. Jack-son's Journey from India, p. 120.

TUSULAN, in Matters of Literature, is a term which frequently occurs in the phrase Tusulan Questions. Cicero's "Tusulan Questions" are disputations on several topics in moral philosophy, which that great author took occasion to denominate, from Tusulum, the name of a country, seat, or villa, where they were composed, and where he lays the scene of the dispute.

They are comprised in five books; the first on the con-
tempt of death; the second of enduring pain; the third on afflicting grief; the fourth on the other perturbations of the mind; and the last, to shew, that virtue is sufficient to a happy life.

TUSULUM, in Ancient Geography, a town of Latium, at a small distance from Rome, towards the S.E. Its ori-
gin was referred to the time of Ulysses, whose son Teleagonus, by Circe, is said to have been its founder. Its inhabitants were distinguished for their courage, and placed themselves at the head of the allies in the war of the Latin people. It was afterwards subdued by Rome and became municipal. Its situation on a mountain and between the hills induced the rich inhabitants of Rome to select it as the site of their country-houses. It had a citadel of no less importance with regard to this city than the Capitol with regard to Rome. It had also an amphitheatre and aqueducts. It was afterwards denominated Priscati or Priscati, which fee.

TUSUM, or Thusum Mare, the name of a part of the Mediterranean sea, which washed the coasts of Etruria, as far as the coasts of Sicily.

TUSGEL, in Geography, a town of Asiatic Turkey, in Caramania; 42 miles N.W. of Cogni.

TUSHES, in the Mange, are the fore-teeth of a horse, seated beyond the corner teeth, upon the bars, where they shoot forth on each side of the jaws, two above, and two below, about the age of three, three and a half, and sometimes four; and no milk or real-teeth ever come up in the place where they grow. See Teeth.

TUSHETI, in Geography, a town of Asia, in Daghestan; 80 miles S. of Telif.

TUSIAGATH, in Ancient Geography, a town of Africa, in the interior of Mauritania Cafarimanda, according to Pto-
lemy.

TUSIS, in Geography, a town of the Helvetian republic, in the Grifons, on the Rhine. In 1759, it was taken by the French; 15 miles S. of Coire. N. lat. 46° 32'. E. long. 9° 30'.

TUSK, in Carpenterv, a bevel-shouder, made to streighten the iron of the joint, which is let into the girder.

Tusk, in Zoology, is used to denote the long tooth of a fighting animal; and in the name fenne with tuliphe, as applied to other animals besides horses.

TUSKAR, in Geography, a small island, or rather rock, off the coast of the county of Wexford, Ireland, forming a conspicuous object for mariners. N. lat. 52° 13'. W. long. 6° 10'.

TUSKAU, a town of Bohemia, in the circle of Pilfen; 6 miles N.W. of Tetsitz.

TUSKAWARA, a township of Mukiqum county, in the district of Ohio, containing 1151 inhabitants.

TUSO, in Ancient Geography, a river of India, on this side of the Ganges, into which it runs.

TUSPA, in Geography, a town of Mexico, in the province of Mechoaca; 25 miles N.W. of Colima.—Alfo, a town of Mexico, in the province of Tlascala, at the mouth of a river so called; 140 miles N.W. of Puebla of los Angeles.—Alfo, a river of Mexico, which runs into the gulf of Mexico, N. lat. 21° 28'. W. long. 98°.

TUSSER, John, in Biography. In Henry VIIIth's time, when music was more cultivated in England than it had ever been before, an arbitrary and oppressive power was given to the deans of cathedrals and collegiate churches, to imprefs children poiffessed of good voices, in order to supply their several choirs with chorillers. And John Tussler, the subject of this article, and the unfortunate author of the "Five Hundred Points of Good Husbandry," one of the most pleafant and instructive poems of the time, tells us, that he was imprefled from Wallingford college, in Berk-
shire, into the King's chapel. Soon after, by the interief of his friends, he was restored to St. Paul's, where he received instructions in music from John Redford, an excellent con-
trapuntift, and organift of that cathedral. There feems, howe'er, to have been care taken of the general education of boys so impreffed, as we find that Tussler was sent from St. Paul's to Eton school, and thence to Cambridge. He afterwards tried his fortune in London about the court, under the auspices of his patron lord Paget, who re-
mained ten years; then he retired into the country, and embraced the occupation of a farmer, in the several counties of Suffex, Suffolk, and Essex; but not prospering, he procured a finging-man's place in the cathedral of Nor-
wich; where he does not feem to have remained long before he returned to London. But being driven thence by the plague, he retired to Trinity college, Cambridge; return-
ing afterwards, however, to the capital, he there ended his reiiefs life in 1580; not, as has been faid, very aged, if he was born about 1523.

TUSEY, in Geography, the name of mountains of Penn-
svllyania; 10 miles N. of Huntingdon.

TUSSELAGO, in Botany, an ancient name, composed of tussis, a cough, and ago, to act upon, or cure; in alli-
ion to the reputed virtues of this herb, as a remedy for coughs and other pectoral diseases.—Linn. Gen. 423.

Gen. Ch. Common Calyx cylindrical, tumid at the bottom, of from fifteen to twenty linear-lanceolate, equal, somewhat membranous scales, the length of the dikk. Cor-
compound, various. Florets in fone all perfect, tubular, funnel-shaped, with an acute, four or five-cleft, reflexed limb, longer than the calyx; in others such florets are found in the dikk only. Female florets when prefent either ligu-
late, very narrow, undivided, longer than the calyx; or tubular, and rather longer than the perfect florets. Stam-
in the perfect florets, Filaments five, capillary, very short; anthers more or less united into a cylindrical tube. Pip-
Germen in the perfect florets, short; stye thread-shaped, longer than the stamens; stigma thickift, emarginate; in the female ones, Germen short; stye thread-shaped, the length of the former; stigma deeply divided, acute. Peric-
one, except the scarcely altered calyx. Seeds solitary, ob-
long, compressed, generally abortive in the florets of the dikk, or centre thereof. Down capillary, sometimes stalked. Recept. naked, dotted.

Eff. Ch. Receptacle naked. Seed-down simple. Calyx simple,
fades; according to Swartz's description it answers to the characters of this genus. Sed-down shining, with a reddish, or pink, hue.

3. T. punila. Dwarf Jamaica Colt's-foot. Swartz Ind. Occ. 1350. Willd. n. 6.—Stalk single-flowered, naked, downy. Flower radiated, erect. Leaves ovate, with reverted teeth; finated at the base; downy beneath.—Found on the lofty calcareous mountains of the fourth part of Jamaica, near Cold-spring, flowering in summer. Smaller than the last, to which it seems nearly allied; but the leaves, only an inch or two in length, are pinnatifid in a lyrate manner. Stalk mostly solitary, from three to six inches high, roundish, cottony; purplish in the lower part. Flower small, white; erect according to Willdenow, and the specific character of Swartz, though the latter calls it drooping in his description. Its structure is that of a Tussilago.

4. T. natans. Drooping Jamaica Colt's-foot. Linn. Sp. Pl. 1213. Am. Acad. v. 5. 406. Willd. n. 7. Ait. n. 1. Swartz Off. 305. (Leontodon n. 1; Browne Jam. 410. Dens leonis, folio fubitus incano, flore purpureo; Sloane Jam. v. 1. 255. t. 150. f. 2. After primula veris folio, flore singulari purpureo; Plum. Ic. 29. t. 41. f. 1.)—Stalk single-flowered, naked, cottony. Flower radiated, pendulous. Leaves falked, oblong-heart-shaped, wavy, toothed; cottony beneath; finated at the base.—Native of cultivated and grassy places in Jamaica. Swartz describes it as annual. Mr. Aiton marks it biennial, flowering in the fow and July. The much larger leaves, near a span long, pinnatifid in a lyrate manner, and the falks twelve or fifteen inches high, distinguish this species from all the preceding. The flower is pendulous, with a white disk and radius, but the slender points of the calyx-scales being tipped with purple, have, as it appears to us, been mistaken for a purple radius by Sloane, and even by the more learned professor Swartz. When in f pitched, the falk becomes erect. The down is rather tawny, or reddish.

5. T. trifurcatum. Three-forked Colt's-foot. G. Forster, Pl. Magell. 28. Willd. n. 8.—Stalk fingle-flowered, fally. Flower radiated, erect. Leaves fpatulate, with three or more oblong segments, fmooy.—Native of dry filty situations about the fronds of Magellan. Root perennial, somewhat tuberous. Leaves radical, tufted, an inch long, divided into three, four, or five, oblong, erect, finger-like segments, spreading, quite smooth and naked. Stalk from one to three inches high, round, clothed with awl-shaped fally branches. Flower white, with all the characters of its genus. Inner scales of the calyx large, with spreading horizontal points.

6. T. alpina. Alpine Colt's-foot. Linn. Sp. Pl. 1213. Willd. n. 9. Ait. n. 2. Jacq. Auctr. t. 246. Curt. Mag. t. 84. (T. alpina secundua; Cluf. Hift. v. 2. 113; A. Matthioli; Ger. Em. 836.)—Stalk fingle-flowered, with oblong scattered branches. Flower without leaves. Leaves kidney-shaped, toothed, smooth on both fides.—Native of the Alps of Switzerland, &c. flowering in June and July. The root is perennial, tuberous, and creeping, brown, with many long fibres. Leaves few, radical, falked, from one to two inches broad, bluntly toothed; quite smooth, and of a fining green, reticulated with depressed branching veins above; paler beneath, but equally smooth, except some hairs on the ribs or veins. Stalk solitary, a foot or more in height, erect, purplish, hairy, bearing a few fiant, variously faprated, conve, upright branches. Flower erect, half an inch broad. Calyx purple, smooth. Flores white, sometimes purplish, all regular and five-eflet, with purple anteras and fignum.

Tussilago.

247. Willd. n. 10. Ait. n. 3. (T. alpina 8; Linn. Sp. Pl. 1214. T. alpina prim; Chuf. Hift. v. 2. 112. T. alpina; Ger. Em. 812.) — Stalk single-flowered, nearly naked. Flower without rays. Leaves kidney-shaped, toothed, downy and white beneath. — Native of the Alps of Austria, Carniola, &c., growing along with the lad, and flowering at the same season. This is rather smaller than the preceding, usually with fewer bracteas. The under side of the leaves is clothed with dense white cottony down, which affords the most distinguishing mark of the plant, and is allowed by recent authors to prove it specifically distinct. Linnaeus thought it but a variety.

8. T. floeriras. Lobed Alpine Colt's-foot. Scop. Carn. v. 2. 157. Jacq. Auct. v. 5. Append. 33. t. 12. Willd. n. 11. — Stalk mostly single-flowered, with dilated scabrous bracteas. Flower without rays. Leaves smooth, kidney-shaped, many-lobed and toothed. — Native of mountainous, chiefly beech, woods of Styria, Carinthia, Carniola, &c., flowering in May. Allied to T. alpina, with which its synonyms have been confounded by Scopoli, Haller, and even Jacquin; but the leaf has the merit of subtilely distinguishing this very well-marked species. It is larger than alpina, and the flum sometimes bears two or three flowers, fearfully differing from those of alpina or discolor. The bracteas however are broader, often terminating in a leafy appendage, particularly the lower ones. The radical leaves are very different, being cut into about seven rather shallow lobes, of which the middle ones more especially have about three pointed teeth. The upper surface is green, sometimes roughish to the touch, thinly marked with veins; the under paler, peculiarly smooth and even, a little shining. We have not heard of this plant in any British garden, nor had Linnaeus a specimen.

9. T. Farfara. Common Colt's-foot. Linn. Sp. Pl. 1214. Willd. n. 12. Fl. Brit. n. 1. Engl. Bot. t. 429. Curt. Lond. falc. 2. t. 60. Woodv. Med. Bot. t. 13. Bulliard Herb. de la Fr. t. 329. Fl. Dan. t. 195. (Tussilago; Ger. Em. 811. Math. Valgr. v. 2. 198. Camer. Epit. 590, 591.)— Stalk single-flowered, fealy. Flower radiated. Leaves heart-shaped, angular, toothed; downy beneath. — Native of moist chalky shady situations, throughout Europe, flowering in March or April, before the leaves appear. Dr. Sibthorp met with it about rolls and inundated places in Greece, nor can there be any doubt of our Colt's-foot being the 2x, of Dioecoides, of which Farfara, see that article, is an ancient synonym. The roots of this species are perennial, creeping to a great extent. Stalks five or six inches high, erect, simple, downy, clothed with numerous, alternate, ovate, erect, purplish, nearly smooth scales, three-quarters of an inch long. Flower drooping before it expands, then erect, yellow, an inch broad; the radius of very numerous, long, narrow, spreading, ligulate flores, which Dr. Stokes has observed to be the only ones that ever perfect their seed. Indeed the plant increases so much by root that fearfully any seeds are ever ripened. The flores come forth on erect footstalks, after the flowers and their flakks have withered, and are from three to fix inches wide, sharpen toothed; very smooth, and rather glaous, above covered beneath with dense, white, cottony down. They are mucilaginous and astrangent, slightly bitter, and are recommended either in infusion, or smothered like tobacco, as a curst for coughs. The latter mode of application is advised by Dioecoides in difficulty of breathing, dry cough, &c. and he prefers these leaves bruised, with honey, as an external remedy for erysipelas, and other inflammations of the skin. The cottony web of this herb serves extremely well for tinder, and to staunch the blood of flight wounds. — Willdenow says there is a variety with perfectly smooth leaves.

10. T. japonica. Japan Colt's-foot. Linn. Mant. 113. Willd. n. 15. Thunb. Jap. 313. Banks fc. Kämpf. t. 27, 28. (Arnica tussilaginis; Burm. Ind. 182. Doro- nium tussilaginis folio, &c.; Phil. Amath. 71. t. 390. f. 6. Tiza; Kämpf. Am. Exot. 827.) — Stalk with several radiated flowers, corymbose, bracteated. Leaves roundish-heart-shaped, toothed; slightly downy beneath. — Native of Japan, flowering in October. Root perennial, tuberous. Stalks twelve or fifteen inches high, angular, furrowed, reddish, downy in the upper part, bearing a few scattered fealy bracteas, and terminating in from five to eight large yellow radiated flowers, on downy alternate partial flakks. Rays wedge-shaped. The feed-down is fensitive, like the last. Leaves coming after the flowers, on long upright foot-stalks; their breadth three or four inches; length much less. But their side paler, but scarcely downy. The root, according to Thunberg, is bitter, and esteemed a counter-poiion by the Japanese. Kaprefays the flakks are used as a pot-herb.

11. T. frigida. Lapland Colt's-foot. Linn. Sp. Pl. 1214. Fl. Lapp. ed. 2. 246. Willd. n. 14. Ait. n. 5. Purii n. 1. Fl. Dan. t. 61. (T. n. 128; Gmel. Sib. v. 2. 150. t. 70.) — Stalk with many radiated flowers, corymbose, bracteated. Leaves triangular-heart-shaped, with deep triangular teeth; downy beneath. — Found by Linnaeus plentifully in woods and pastures among the Lapland Alps, flowering towards the end of May, and featurering its seeds about a month afterwards. It occurs likewise in Norway and Siberia, as well as, according to Mr. Purii, in Canada, and on the highest peaks of the Vermont and New Hampshire mountains, at the same season. The root is somewhat tuerous and creeping, though less flaky than the last, with copious long fibres. Leaves and flowers appearing nearly together, on stalks about equal in height, from ten to fifteen inches; the former remarkable for their very large angular teeth. The flower-stalk bears several alternate, large, true, smooth bracteas, sometimes ending in a small leaf. Flowers white; the floret's of the dill tinged with pale purple, especially their large, club-shaped, hairy, prominent, but we believe unleafy, ficnmat. Sed-down fensitive, above an inch long, flaky.

12. T. fragrant. Sweet-scented Colt's-foot. Villars Actes de la Soc, d'Hift. Nat. de Paris, v. 1. 72. t. 12. Willd. n. 15. Ait. n. 6. Curt. Mag. t. 1388.—Stalk panicked, level-topped, somewhat leafy. Flowers radiated. Leaves roundish-heart-shaped, obtuse, equally and finely toothed; rather hairy beneath. — Native of the neighborhood of Naples, and of Sicily near Palermo; introduced into England by Mellers. Lee and Kennedy in 1806. It flowers in the winter, or early spring. The leaves, which are green on both sides, rounded, obtuse, not at all lobed or cut, appear with the flowers. The latter are large, fragrant like Heliotropium peruvianum, with broad light-purple rays, and a white dish, the timid stigma of whole floret is dark-purple. The panicule is compound, rather dense; its stalk taller than the foliage, clothed with very large inflated bracteas having leafy terminations.

13. T. levigata. Smooth Straw-coloured Colt's-foot. Willd. n. 16. (T. cepa imbricato, floribus epicaulis radiatis, folis utrinque glaberrimis; Gmel. Sib. v. 2. 148. n. 126.) — Stalk panicked, level-topped. Flowers radiated. Leaves heart-shaped, acute, slightly angular, toothed, smooth on both sides. — Abundant about the banks and sloughs of rivers in Siberia, flowering in spring, at which time all but the flowers is generally under water. Gmelin. * Root flaky, purplish,
pulviform, creeping to the extent of many feet, with many long, thick, simple fibres. Leaves about two inches broad at the flowering period, but when fully grown, eighteen inches in diameter; bright green and smooth on both sides, pulviform at the edges, fleshy; copiously veined beneath; their margin irregularly and sharply toothed, sometimes angular. Footstalks smooth, a foot or more in length. Flower-flats taller than the leaves, thick, succulent, reddish, fluted, slightly cottony, bearing many large, inflated, sheathing bracteas; and terminating in a more or less compound, level-topped, or corymbose, panice, whose downy flats are furnished with many smooth, linear-lanceolate, flat, much smaller bracteas. Flowers from eight to twenty, scarcely half an inch broad, straw-coloured, with shortish rays. Wildenow's opinion of this being a very distinct species, is confirmed by Gmelin's own figments in the Linnaean herbarium; which also, unless we are greatly mistaken, flew n. 127. t. 69. D, E, of the same author, to be the very same plant, totally different from the common T. petasites, with which he compares it, in many other points besides the colour of the flowers.

14. T. alba. White Col's-foot, or Double-toothed Butter-burr. Linn. Sp. Pl. 1214. Willd. n. 17. Ait. n. 7. Fl. Dan. t. 524. Petasites flore albo; Camer. Epit. 593. P. n. 119; Hall. Hist. v. 1. 61.—Panicle dense, level-topped. Flowers without rays. Leaves roundish-heart-shaped, doubly and sharply toothed; white and shaggy beneath.—In mountainous woods, and about the banks of rivers, in the alpine parts of Europe, not rare in Switzerland, but unknown as a native of Britain. It appears to have been cultivated at Edinburgh in the time of Sutherland, 1683, and we obtained a specimen from the botanic garden there 100 years after, under the erroneous name of T. hybrid. This is a large species, distinguished from all the rest, of those which bear many flowers on a stalk, by its strongly, doubly, and acutely-toothed leaves; quite smooth above; very veiny and cottony beneath, when young, but afterwards the pubescence of that side becomes more grey, shaggy, and loose. The tall downy flower-flats bear a great number of broad, concave, rather cottony bracteas, and terminate in a branched many-flowered corymbose panice. The flowers are rather small, snow-white, without rays. Down felise. Wildenow and other botanists have observed, that some individual plants have but very few, and others many, female florices, in comparison to those furnished with both flowers and pistils; but the author just named has been missed by Villars to cite, as the female plant of this species, Gmelins's t. 69. f. D, E, which has yellow flowers; see our n. 13.

15. T. nivea. Snowy Col's-foot, or White-leaved Butter-burr. Villars Actes de la Soc. d'Hill. Nat. de Paris, v. 1. 73. t. 12. f. 2. Willd. n. 18. Ait. n. 8. (T. frigida; Villars Dauph. v. 3. 175. T. paradoxo; Retz. Obl. f. 2. 24. t. 3. Petasites n. 141; Hall. Hist. v. 1. 62. P. minor, tutfallaginis folio; Moris. f. 7. t. 10. f. 4.)—Panicle dense, rather obtone. Flowers without rays. Leaves triangular-heart-shaped, finely toothed, with spreading, angular, cottony lobes; densely downy beneath.—Native of the mountains of Switzerland, Germany, Dauphiny, &c. flowering in April. Differs from the last in the snowy whiteness, and dense pubescence, of the under side of the leaves, as well as in their triangular form, and their simple series of marginal teeth. Flowers pale flesh-coloured. Common flat clothed with similar large bracteas. Seed-down near an inch long. The female plant, termed paradoxo, as a distinct species, by Retzius, has but about three apparently perfect florices in each calyx, and of these the anthers are unconnected. In a remark on the faxes of this tribe of plants, at p. 431 of Engl. Bot. T. alba is inadvertently mentioned for nivea.

T. hybrid; Linn. Sp. Pl. 1214. Fl. Brit. n. 2. Engl. Bot. t. 430. (Petasites major, floribus pedunculis longis infundibulis; Willd. Etr. 509. t. 230. P. n. 140; Hall. Hist. v. 1. 61.)—Panicle dense, ovate-oblong. Flowers without rays. Leaves roundish-heart-shaped, unequally toothed, slightly angular, with rounded converging lobes; paler and somewhat shaggy beneath.—Native of moister, boggly, shady meadows, the borders of rivers, pools, &c. throughout Europe. Dr. Sibthorp found it in Greece, but not common, except in rather mountainous, as well as watery situations. There can, however, be little doubt of this plant being, as all botanists have thought, the Petaetis floribus pedunculis longis, infundibulis, of Diederich. Our B grows with the common kind, though far less frequently. Both flower in April, before the leaves expand, and, are, of course, perennial. The root is thick and fleshy, creeping very far, and hard to be extinguished. Stalk a span high, thick, downy, clothed with oblong roundish bracteas, partly leafy at their extremity, and terminating in a dense ovate panice, of pale dully flesh-coloured flowers. The florices are all tubular, furnished with united red anthers and a thick cleft stigma. The younger Linnaeus, and Haller, have detected a few female ones, laid to afford good food; but many botanists have remarked that the Common Butter-burr never perfects seed, nor does even its seed-down make a very conspicuous appearance. T. hybrid, which we have marked as a variety, because its leaves are rather smaller, and the panicle rather longer, with smaller flowers, is allowed to be the female plant, or at least an individual in which that sex prevails. In this mode the florets are female, with a slender calix, and a taper, acute, efficient stigma. One or two of the central ones only are male, having separate anthers, and a thick ulefs stigma. The panicule when in seed is much elongated, and becomes cylindrical, conspicuous for its copious, brilliant, though short, seed-down, forming an elegant silvery plume, a foot or more in length. The leaves of the common T. Petasites are the largest of any British plant, being often three feet broad. They are grey or hoary beneath, far less white than those of T. nivea, as well as more rounded, and with their lobes approaching each other.

17. T. spuria. Cloven-lobed Butter-burr, or Col's-foot. Retz. Obl. f. 2. 29. t. 2. Willd. n. 20. (T. tomen-tosa; Ehrh. Beitr. v. 3. 65.)—Panicle corymbose. Flowers without rays. Leaves triangular-heart-shaped, finely and acutely-toothed, with spreading, angular, cottony lobes; densely downy beneath.—Native of Lapland, Scania, and Germany, about the banks of rivers. The general outline of the leaves, with their spreading acute lateral lobes, is most like nivea, n. 15, but those lobes are remarkable for being always divided, or double. The marginal teeth of the whole leaf are also more numerous, crowded, regular, and smaller, as well as more obtuse, than in nivea; the soft, cottony, very white downieaves of the under side nearly accord with those species; the upper is green, and quite smooth, except when young. Flowers corymbose, rather than panicled, cream-coloured, with linear bracteas. Authors have distinguished two varieties; one with a more short dense inflorescence, and only three female florices, all deficiente.
destitute of a corolla, which is Ehrhart's tementosa; the other with a more elongated corystb, and numerous female florets, each with an oblique tubular corolla, but whose fligma nevertheless is said to be small and barren; this is the original Paradossa. We presume the idea of the barren fligma may be a miftake of Retzius; that part, when imperfect, being, in this tribe of plants, always thickened; but we have had no opportunity of examining living specimens of T. spuria, which is a stranger to the gardens of England.

19. T. palmata. Cut-leaved Colt's-foot. Ait. n. 10. ed. 1. v. 3. 180, t. 11. Wild. n. 21. — Flowers corymbbose, level-topped, radiated. Leaves seven-lobed, palmate, cut; downy beneath. — Native of Newfoundland and Labrador. Introduced into England by Dr. Fothergill, in 1777. Perennial, flowering in April. The flalk and inflorescence resemble the leaf. The flowers are light flesh-coloured, or purplish, with short obtuse rays. The leaves, which with Wildenow's account vary in the depth of their lobes, afford a clear specific difference from all the other species.

Tussilago, in Gardening, comprehends plants of the low, hardy, herbaceous, creeping-rooted perennial kinds; among which, the species most commonly cultivated in gardens for different purposes are, the common tussilago or colt's-foot (T. farfara); the mountain colt's-foot (T. alpina); the Sibcrian colt's-foot (T. anandra); the pectafltes, tussilago major, or common butter-bur (T. pectafltes); the hybridan German tussilago, greater colt's-foot, or long-flalked butter-bur (T. hybridus); and the white alpine tussilago, or smaller butter-bur (T. alba).

The first fort has a creeping perennial root, short, thickish flalk, with fine roundish hoary leaves; which are produced after the item and flower; hence it is denominated one of the flus ante patriat, or on before the father, tribe or clafs of plants, or thofe in which the flowers rise before the leaves.

It is not much cultivated in the garden manner, except in herbaceous collections as a medicinal herb for making decoctions and other mild balsamic drinks, and for the use of its leaves as a principal ingredient in the preparation of the Britifh herb tobacco, and other similar compositions. Sometimes, however, it is employed for variety in patches in the borders and other parts of ornamented grounds.

In the second kind, there is a variety which has round hoary leaves.

The fourth fort is also sometimes cultivated and employed as a medicinal plant in different intentions.

Method of Culture. — They are all capable of being raised and increafed by fowing the seeds of them in any proper and fuitable foil and situation in the early spring fefon, but not to too great a depth, when they will freely raise and become good plants. But the belt and moft expedifion method is that of parling the roots and planting them, which may be done either in the autumnal or spring fefon, when the smallfle flip will readily take root and grow, multiplying in a very quick manner.

Most of the farts poifef the fingular property of producing and fending up their flowers and flalks before the leaves are formed and seen.

The plants mostly affect rather moist soils and situations, but they will grow and succeed almost any where, and may be employed for affording greater variety and ornament, as well as some of them for the purpofes and intentions which have been fuggetted above.

Tussis. See Cough.

Tusslen, in Geography, a town of Bavaria; 4 miles W.S.W. of New Oeting.

Tut, in Armoury, &c. an imperial enflign of a golden globe, with a crofs on it.

Tut Bargain, among the Miners, denotes a bargain by the lump; as when they undertake to perform a piece of work at a fixed price, however it may prove.

Tutcorin, or Tuttocorn, in Geography, a town of Hindooftan, in the Carnic, where the Dutch have a factory; 25 miles E. of Palamcotta.

Tutary, a town of Sweden, in the province of Smal land; 24 miles W. of Wexio.

Tutbury, or Stutesbury, a market-town in the hundred of Offlow, and county of Stafford, England; is situated on the western bank of the river Dove, at the distance of 4 miles N.W. by N. from Burton-upon-Trent, and 134 miles in the same bearing from London. It was erected a free borough at an early period, and the burgesses and other inhabitants were invested with a variety of privileges and immunities; but never had the right of sending members to parliament, though the town still retains the appellation of a borough. The parish-church is an ancient and spacious edifice, with a square embattled tower surmounted by four small pinnacles; its principal entrance is decorated with fine specimens of Saxon sculpture. A free school was founded and endowed by Richard Wakefield in the year 1750; it was rebuilt in 1789. Here is also a meeting-house for Diffenters. According to the population return of the year 1811, the parish of Tutbury contained 242 houses, occupied by 1235 persons. Wool-combing constitutes the principal businefs of the inhabitants; and a cotton manufacture, recently established, gives employment to a considerable number. Three fairs are held annually, and a market weekly, on Tuesdays. On the north side of the town are the remains of the castle of Tutbury, which was erected soon after the Conquest, by Henry de Ferrars, a noble Norman, to whom the Conqueror gave large eftates in this county. In the family of Ferrars it continued till the reign of Henry III., when, being forfeited by the attaintor of Robert de Ferrars, earl of Derby, the king granted it to his second son Edmund, earl of Lancaster. It again reverted to the crown, in conseqienee of the rebellion of Thomas, earl of Lancaster, who fortified it against Edward II., but was obliged to surrender. Having sustained considerable damage during this contest, and being afterwards fuffered to fall into decay, John of Gaunt rebuilt the greater part of it upon the ancient feite in 1350. This castle, being the principal seat of the dukes of Lancaster, was long distinguished as the scene of much feditious and splendour. So great was the number of miniftrles retiring to it, that it was found necefary to adopt special regulations for the prefevation of order. Accordingly, one of their body was invested with the title of king of the miniftrles, with officers under him for the due execution of the laws. A charter for that purpofe was granted by John of Gaunt in 1381: and a court was eftabflihed for determining all controversy connected with miniftrelly. At this court, which was annually held with great formality, the king and his officers were appointed for the year ensuing; and the business of the day concluded with a bull-running and baiting. This barbarous custom was abolished, by commutation, about the middle of the last century; but the court still continues to be held. Tutbury castle was twice the residence, or rather prinif, of Mary queen
queen of Scots; in 1568, and again in 1585. At the commencement of the civil war in the reign of Charles I. it was garrisoned by Lord Loughborough, a zealous supporter of the royal cause; but was besieged and taken by Sir William Breton, one of the parliamentary commanders. The damage sustained by the castle on this occasion was very great; but it was not doomed to total destruction till 1646, when, by order of the parliament, it was reduced nearly to its present ruinous condition. What still remains, sufficiently declares its former extent and grandeur; the ancient gateway is tolerably entire; and towers, staircases, divisions of rooms, and fire-places, can yet be discovered in different parts of the walls, which appear to have been of immense strength and thickness: the whole was surrounded by a broad and deep ditch, over which, Dr. Plott informs us, there was in his time an extraordinary timber-bridge, composed of distinct pieces of wood, none of them above a yard long, yet unsupported by any arch-work, pillars, or other prop. Coeval with the castle, and founded by the same person, was a Benedictine priory, largely endowed by King William Rufus. The site was granted by Edward VI. to Sir William Cavendish. Scarcely a vestige of the ancient building is now left, and we know little more of its structure, than that it was of large extent, and contained a splendid monument to the memory of the founder. A portion of the old priory church constitutes a part of the present parish-church.—Description of the Castle and Priory of Tutbury, 8vo. 1786. Beauties of England and Wales, vol. xiii. Staffordshire, 1814.

TUTELA, in Ancient Geography, a town of Spain, in Celtiberia, according to Martial.

TUTELA, in Mythology, a goddess worshipped at Bourdeaux, of which city she was patroness, and where she had a magnificent temple. She is supposed by learned antiquaries to have been a divinity peculiar to sailors and merchants, who trafficked upon the rivers, as it was a common practice to put upon their ships the figures of certain gods, who gave names to them, and were called by the ancients "Tutela Navis," the tutelar divinity of the ship.

TUTELARY, Tutelar, one who has taken something into his patronage and protection.

It is an ancient opinion, that there are tutelary angels of kingdoms and cities, and even of particular persons, called guardian angels.

The ancient Romans, it is certain, had their tutelary gods, whom they called Paterae; which see. And the Romish church to this day, hold an opinion not much unlike it; they believe that every person, at least every one of the faithful, has, from the time of his birth, one of those tutelary angels attached to his person, to defend him from all temptations; and it is on this, principally, that their practice of invoking angels is founded.

F. Antony Macedo, a Portuguese Jesuit of Coimbra, has published a large work in folio on the tutelary saints of all the kingdoms, provinces, and great cities of the Christian world; "Divi Tutelarum Orbis Christiani," at Lisbon, 1678.

TUTELINA, or Tutilina, in Mythology, the goddesses of corn, who had the care of it when deposited in the granary. She had a chapel on the Aventine mount, and a statue in the Circus.

TUTENAG, a name given in India to the semi-metal zinc. It is also sometimes applied to denote a white metallic compound, brought from China, called also Chinefs, or white copper, the art of making which is not known in Europe. It is the best imitation of silver which has been made: it is very tough, strong, malleable, may be easily cast, ham-mered, and polished; and the better kinds of it, when well manufactured, are very white, and not more disposed to tarnish than silver is.

Three ingredients of this composition may be discovered by analysis, viz. copper, zinc, and iron. See Alleys of Copper.

TUTESERAI, in Geography, a town of Hindoostan, in Lahore; 14 miles E.S.E. of Sultanpur.

TUTIA, or Tuttia, in Ancient Geography, a town of Hither Spain.

TUTICUM, a town of Italy, in Samnium, called in the Itinerary of Antonine, "Equus Tuticus."

TUTLING, in Geography, a town of Bavaria; 10 miles N. of Paffau.

TUTOR, in the Civil Law, is one chosen to look to the person and estate of children left by their fathers and mothers in their minority. See Guardian. By the custom of Normandy, the father is the natural tutor of his children. A person nominated tutor, either by testament, or by the relations of the minor, is to decline that office if he have five children alive; if he have any other considerable tutorage; if he be under twenty-five years of age; if he be a priest, or a regent in an universit; or if he have any law-fuit with the minors, &c.

The marriage of a pupil, without the consent of his tutor, is invalid. Tutors may do any thing for their pupils, but nothing against them; and the same laws which put them under a necessity of preferring the interest of the minors, put them under an incapacity of hurting them. See Parent.

TUTOR, Honorary. See Honourary.

Tut is also used in our universities for a member of some college or hall, who takes on him the instruction of young students in the arts and faculties.

TUTORAGE, Tutela, in the Civil Law, a term equivalent to guardianship in common law, signifying an office imposed on any one, to take care of the person and effects of one or more minors. See Guardian.

By the Roman law there are three kinds of tutorage. Tectoritary, which is appointed by the father's testament. Legal, which is given by the law to the nearest relation. And dative, which is appointed by the magistrate.

But in all customary provinces, as France, &c. all tutorages are dative and elective; and though the father have by testament nominated the next relation to his pupil, yet is not that nomination of any force, unless the choice be confirmed by that of the magistrate, &c.

By the Roman law, tutorage expires at fourteen years of age; but in France, not till twenty-five years. A minor quits his tutorage, and becomes free by marriage; in which case a curator is given him.

TUTOVA, in Geography, a river of Moldavia, which runs into the Birlat, 4 miles S. of Birlat, in the province of Moldavia.

TUTSAN, in Botany. See Hypericum.

TUTTI, in the Italian Music, is used to signify that all the parts are to play together, or to make a full concert.

In this sense, tutti stands opposed to falso or falso. It is often found expressed by omnes, ripieno, chorus, &c.

Tutti, in Geography, a town of Bengal; 13 miles N.N.E. of Burwa.

TUTTLINGEN. See Duttlingen.

TUTTUM, a town of Hindoostan, in Bundelcund; 20 miles N.E. of Chatterpour.

TUTTY, Tutia Alexandrina, or Lapis Tutia, an argil-laceous ore of zinc, found in Persia, formed on cylindrical moulds into tabulous pieces, like the bark of a tree, and baked
baked to a moderate hardmess. This account of its original is supported by the authority of Teixeira and Douglas, and by its chemical properties. That the common opinion of its being a sublimable produced in the European foundries, where zinc is melted with other metals, is erroneous, appears from hence, that tatty is not found, upon strict enquiry, to be known at those foundries; and by its confounding, in a great part, of an earth not capable of rising in sublimation. This, however, is probably, that sublimates, or the common ores of zinc, are often mixed with argillaceous earths, and baked hard, in imitation of the genuine oriental tatty.

Bonitus, in his animadversions upon Garcia ab Ord, informs us, that it is made of a glutinous or argillaceous earth, like clay, found in great quantities in a province of Perâa, called Kirmann, which the Indians, who gather it, put into earthen pots made on purpose, and, adding water to it, flit it with a stick: these pots are then placed in furnaces till the water is evaporated; afterwards removing the dregs which remain at the bottom, they pick off from the sides of the pots the calcined earth or tatty, which they carefully preserve for sale. He adds, that it is used in India as a cosmetic for destroying hair, more especially by the women, when they bathe.

Tatty is generally of a brownish colour, and full of small protuberances on the outside, smooth and yellowish within, sometimes whitish, and sometimes with a blueish tuff. Like other argillaceous bodies, it becomes harder in a strong fire; and after the zinc has been revived and digested by inflammable additions, or extracted by acids, the remaining earthy matter affords with oil of vitriol, an albumous salt.

Tatty, levediated into an impalpable powder, is, like the laps calaminaris and calcines of zinc, an useful ophthalmic, and frequently used as such in ointments and collyria.

Ointments for this intention are prepared in the shops, by mixing the levediated tatty with so much viper's fat as is sufficient to reduce it to due consistence, or, by adding one part to five parts of a simple limiment made of oil and wax. See Zine.

TUTUCAC, in Geography, a town of Mexico, in the province of Hiaqui; 100 miles E. of Riochico.

TUTULUS, among the Romans, a manner of dressing the hair, by gathering it up on the forehead into the form of a tower.

TUTUS likewise signifies a woollen cap with a high top.

TUTURA, in Geography, a town of Russia, in the government of Irkutsk, on the Lena; 160 miles N. of Irkutsk. N. lat. 54° 40'. E. long. 105° 44'.

TUTUS, in Ancient Geography, a town of Egypt, between Talmas and Piescis. Anton. Itin.

TUVE, in Geography, a lake of Norway, about 20 miles in circumference; 52 miles from Christiansand.

TUXAL, a town of Hindoostan, in the circar of Sirkind; 60 miles N.E. of Sirkind.

TUXFORD, a small market-town in South Clay division of the wapentake of Baffetlaw, in the county of Nottingham, England; is situated 24 miles N.E. by N. from the county-town, and 138 miles N. by W. from London. It was destroyed by fire September 8, 1702; consequently its appearance is more modern than that of many other towns in the country. Great part of it consists of farm-houses; agriculture being the chief employment of the inhabitants. Scarcely any trade is carried on here, except in hops, of which a considerable quantity is raised in this and the adjacent parishes. A fair for this article is annually held in September; and another in May for cattle, sheep, pigs, and poultry.

A weekly market on Mondays is well supplied in proportion to the population of the parish; which, in the return to parliament in the year 1811, is rated to be 841, occupying 157 houses. The church is an ancient structure, and consists of a nave, side-aisles, and chancel; with a spire. It contains the mutilated remains of monuments and other sculpture of a remote period. A rude representation of St. Laurence on a gridiron is still entire; one man is employed in blowing the fire, another is turning the faint with tongues, and a third appears to be a preacher, or director. A free grammar-school, still in high repute, was founded, and liberally endowed, by the will of Mr. Charles Read, dated the 30th of July, 1699. A manuscript copy of the regulations, as contained in the will, is preserved in the British Museum.—History of Nottinghamshire, by J. Thropey. 3 vols. 4to. 1797. Beauties of England and Wales, vol. xii. Nottinghamshire.

TUXIUM, in Ancient Geography, a town of Italy, and capital of Samnium. When Fabius Fabricianus pillaged this city, he removed the statue of the victorious Venus, worshipped here, to Rome. Plutarch.

TUY, in Geography, a town of Spain, in Galicia, situated on a mountain, near the north side of the Minho, opposite Valencia, in Portugal; the seat of a bishop, suffragan of Compostella. In a war between Spain and Portugal, this is one of the places of rendezvous for the Spanish troops; 50 miles S. of Compostella. N. lat. 42° 3'. W. long. 8° 37'.

Tuy, a navigable river of Caraccas, which discharges itself into the ocean, 30 leagues E. of the port of Guayra. It rises in the mountains of San Pedro, 10 leagues from Caraccas, and being joined by the Guayra, becomes navigable, and serves for the transportation of produce, abounding in the valleys of Aragoa, Tucata, Cua, Sabana, Ocupara, St. Lucia, and St. Thertha, through which it paffes, and particularly cacao, which is here of the best quality.

TUYU, a country of South America, in Patagonia, to the south of the vicerey of Buenos Ayres.

TUZ-KURMA, a town of Cashibtan; 50 miles S.S.W. of Sherezur.

TUZLA, a town of Asiatic Turkey, in Caramania, situated at the western extremity of a lake, to which it gives name. The lake is 36 miles in length, and about 4 in breadth; 28 miles N. of Cogni.—Alio, a town of Asiatic Turkey, in Natalia; 24 miles E. of Constantinople.

TWAGGER, a town of Sweden, in the province of Halland; 28 miles N.W. of Halmstad.

WIAITE, in Ichthyology. See Shad.

WIAITE, in our Old Writers, a wood grubbed up and converted into arable land.

TWA-NIGHTS GESTE, in our Ancient Customs. See Third-night awen Hynde.

If the twa-night's gelt did any harm to any, his hoft was not answerable for it, but himself.

TWARDONICE, in Geography. See TURNITZ.

TWASHTA, or TWASHI, in the Mythology of the Hindoos, a name of the fun, or of its regent Surya. The name occurs as of the sun in the article SARASWATI. Other legends make Twasha the parent of Suranath, one of Surya's wives. In some points he corresponds with Vulcan, or Dædalus; being profoudly skilful in the mechanical arts, and hence defined in gratitude for his useful invention. He seems to be the same personage with Vifwakarma; being, like him, called the "chief engineer of the gods." Mr. Wilford's learned Effay on the sacred isles of the Well, in the
TWEEDMOUTH, a sea-port of England, in the county of Durham, separated only by the Tweed from Berwick. In 1811 the number of inhabitants was 3917.

TWEEING, an operation in weaving, which is performed by multiplying and varying the number of leaves in the harnesses; by the use of a back harness, or double harnesses; by increasing the number of threads in each fillet of the reed; by an endless variety of modes in drawing the yarns through the harnesses; and by increasing the number of tredles, and changing the manner of treading them. When the number of tredles requisite to raise all the variety of sheds necessary to produce very extensive patterns would be more than one man could manage, recourse is had to a mode of mounting, or preparing the loom, by the application of cords, &c., to the harnesses; and a second person is necessary to raise the sheds required, by pulling the strings attached to the respective leaves of the back harness, which are func to their first position by means of leaden weights underneath.

VOL. XXXVI.

This is the most comprehensive apparatus used by weavers for fanciful patterns of great extent, and it is called the drawloom. In weaving very fine silk trowsers, such as those of thirteen leaves, the number of threads drawn through each interval of the reed is so great, that, if woven with a single reed, they would obstruct each other in rising and falling, and the shed would not be sufficiently open to allow the shuttle a free passage. To avoid this inconvenience, other reeds are placed behind that which strikes up the weft; and the warp threads are so disposed, that those which pass through the same interval in the first reed are divided in passing through the second, and again in passing through the third. By these means the obstruction, if not entirely removed, is greatly lessened.

In the weaving of plain thick woolen cloths, to prevent obstructions of this kind, arising from the clomenets of the warp, and roughness of the threads, only one-fourth of the warp is sunk and raised by one reed, and a second is prefixed down to complete the shed, between the times when every shot of weft is thrown across. See Weaving.

TWELFTH-FIND, in our Ancient Customs, imports much the same with ibane.

Among the English Saxons, those who were worth 1200s. were called 'twelve-hinds'; and if any injury was done to them, satisfaction was to be made accordingly. See Hinden.

TWELFTH-DAY, or Twelfth-tide, the festival of the Epiphany, on the manifestation of Christ to the Gentiles, so called, as being the twelfth-day, exclusive, from the Nativity, or Christmas-day.

TWELVE MENS, duodecim homines legales, otherwise called jury, or inquisitor, is a number of twelve persons, or upwards, as far as twenty-four; by whole oath, as to matters of fact, all trials pass, both in civil and criminal cases, through all courts of the common law in this realm. See Jury.

TWELVE TABLES, Laws of the. See Table.

TWELVE APOLLOSES, in Geography, a number of small islands at the west extremity of the Straits of Magellan, on the coast of Terra del Fuego, between Cape Pillar and Cape Descaida.

TWELVE ISLES, or Twelve Apolloises, islands on the south side of lake Superior.

TWELVE PINS, The, or Beannabola, a vaft ridge of almost perpendicular rocks in the western part of the county of Galway, Ireland, called Cunnemara. These mountains belong to the primitive formation.

TWELVE-MILE CREEK, a river of South Carolina, which runs into the Saluda, N. lat. 34° 50'. W. long. 81° 16'.

TWELVE-MONTH, the space of a year, according to the calendar months.

TWENTE, in Geography, a district of the flate of Overfijl, of which Oldenzel is the capital.

TWENTY-FOUR MENS, men chosen every half year to redrefs the grievances of the mines and miners; but every man generally ferves his year when chosen.

TWENTY-MILE CREEK, in Geography, a branch of the river Tombighe, in Georgia.

TWICE-LAID CORDAGE, is made of cast rigging, as throids, flays, mooring and other cables, which, if not much worn, will make good ropes, &c. for many purpofes, as small cable-laid ropes for warbing ships, worming and woolding for cables, worming for large flays, netting for ships' sides, &c.; ratings, scaffolding-ropes, spun-yarn for feizes, &c.

To open a cable for making it into small ropes, hang the frand
frond upon three hooks in the tackle-board, stretch it out
tight upon the hooks in the fledge, and heave till they are
untwisted; then draw out the yarn.

When the yarn of this worn fluff is overhauled, a little
thin tar should be poured upon it, which will make it pliable,
and lie better. The yarn unfit for knotting will pick into
oakum for caulking.

TWICKENHAM, in Geography, an extensive and pop-
ulous village in the hundred of Isleworth, and county of
Middlesex, England; is situated on the banks of the river
Thames, at the distance of twelve miles W.S.W. from St.
Paul’s cathedral, London. This parth extends about three
miles and a half in length, one and a half in breadth, and is
nine miles in circumference; it is bounded on the east and
north by Isleworth, on the west by Hanworth, Hampton,
and Teddington, and on the south by the river Thames.
It contains about 1850 acres, of which, according to a sur-
vey taken in the year 1635, about 630 were arable, 490
girth, 40 wood, and 690 common; which does not much
vary from the present proportion, reckoning the fruit gar-
dens, of which there are above 150 acres, among the arable
land. The gardens have long been celebrated for good ma-
agement and abundant produce, and they afford a com-
stant supply to the London market: one gardener, Mr. Wall,
has, in a good season, sent upwards of 40000 gallons of rasp-
berries to a distiller within fifteen days. Twickenham is not
mentioned in the Domesday record, as the whole of this hun-
dred seems to have been included, when that survey was
made, in the manor of Isleworth. In ancient records,
the name is written Twitham, Twittanham, and Twiccan-
ham: and the most popular writers of the early part of the
last century often termed it Twitenham. The manor of
Twickenham appears to have been poiffed, by the religious
long antecedent to the Norman conquest; for the jurisdic-
tion of the lord of Isleworth did not extend to church lands.
This manor appears to have been vested in the crown in the
time of Henry VIII., and by him annexed to the honor of
Hampton-Court. By Charles I. it was settled as part of
the jointure of his queen, on whose death, Charles II. settled
it for life on his comfort, Catherine. A leaf under the
manor house has since been granted to several persons. The
manor house stands opposite to the church, and is traditionally
told to have been the residence of Catherine of Aragon, the
divorced queen of Henry VIII. The parith-church is situated
near the river-side: the old church fell to the ground in the
night of April 9, 1713; the tower, which is composed of fre-
stone, is still remaining; the body was rebuilt, and completed
in the year 1715. This is a brick fabric of the Tuscan order,
with fone coigns and cornices, and was erected after the de-
sign of John James, architect, who likewise built the churches
The interior is fparious, with galleries on the two fides, and
at the west end. The monuments, tablets, and other sepul-
chral memorials, are numerous. A chapel, called Montpelier,
was built about the year 1720, and is the private property
Here is also a meeting-house for Wesleyan Methodists.
A charity-school for boys, and a similar institution for girls,
were established many years back: an extensive and appro-
 priate building has been recently erected by subscription;
and one hundred boys and seventy girls are now educated
according to Dr. Bell’s plan. Thirty of the boys, and
twenty-four girls, are likewise clothed. Here are also
two Sunday schools. Six almshouses were built in 1704,
and fix more in 1721. In the population return of the year
1811, this parish is stated to contain 685 houses, and 3757
inhabitants. The principal manufacture is that of gun-
powder: the powder-mills, formerly the property of Mr.
Hill, but now of Mr. Butts, are seated on the small river
Crane, which, rising in the vicinity of Harrow, is here aug-
mented by an artificial cut from the Colne. Accidents fre-
quently occur in this dangerous business: one cornmill-house
for graining powder was thrice blown up in the year 1795;
in the months of January, July, and November. Seventeen
lives were lost by the three explosions. Five similar casual-
ties have since happened, by which twelve men were killed.
Yet, notwithstanding the frequency of these accidents, and
though the wages of the workmen is but small, employment
in the mills is eagerly sought after: the only apparent reason
is, that the labour is light.

Twickenham Park, Isleworth Park, or the New Park of
Richmond, was, towards the end of the sixteenth century,
the property of the great Sir Francis, afterwards lord, Bacon,
who paffed in this retirement the earlier and more happy part
of his life. He here entertained queen Elizabeth, on which
occasion he presented her with a foonet in praise of her fave-
rite, the earl of Essex. The estate has recently been divided
into lots, and the greater part purchased by Francis Goffing,
efq. The grounds contain some fine cedars: and it is be-
lieved, that the first weeping willow known in this kingdom
was planted in this park in the early part of the last century.
Part of the manifon is in the parth of Isleworth: in the
meadows, between this house and the river, was the original
ftefe of Sion monastery, founded by king Henry V. in
1414.

Twickenham has for a century paft been the retreat of
persons distinguished by their rank or literary fame; and has
been embellished with various manions and villas, to which
a degree of celebrity has attached. We shall briefly notice
the most interesting.

Marble Hill was built by king George II. as a villa for his
miftris, the countess of Suffolk. The purchase of the
estate is said by lord Orford to have cost the king ten or
twelve thousand pounds. The house was erected after a
design of Henry, earl of Pembroke, who superintended the
progress of the structure. Its exterior is of a plain but
well-proportioned character; the interior contains the prin-
cipal attractions, and is finished in a delicate, costly, and
ornamental style. The great hall is entirely composed of mahogany, finely carved; and the flooring of the ong
rooms are of the same wood. This is now the residence
of Charles Augustus Tulis, esq.

Pope’s Villa, as it has long been emphatically called, from
its having been, for nearly thirty years, the residence of our
great poet Alexander Pope, was purchased by him in the year
1715. The improvement of the house and gardens was for
many years his favourite employment; and he was particularly
interested in the construction of a grotto, which he enriched
with many curious spars and gems; from the grotto was a sub-
terraneous passage to the gardens. On the decease of Pope,
which occurred May 30, 1744, the estate was sold to sir
William Stanhope, who added wings to the house and enlarged
the gardens. From him it paffed to his foon-in-law, Welbou
Ellis, afterwards lord Mendip, who guarded every memorial
of the poet as a sacred relic, particularly a fine willow planted
by his own hand. This tree his lordship prapped with affidu-
ous care, but notwithstanding his utmost attention, it perifned
and fell to the ground in 1801, about a year before the death
of its noble owner. The estate was afterwards sold to sir
John Brice, on whose decease it was purchased by baronets Howe
in 1807; under whose direction the house has been taken
down, and a new dwelling erected about a hundred yards
distant from the fite. The grotto has been stripped of its
most curious spars and minerals, by the zeal of those who
wished
TWIN, in Geography, a township of Preble county, in the district of Ohio, containing 719 inhabitants.—Alto, a township of Rofs county, in the same district, containing 1053 inhabitants.

TWIN, North, an island in James's Bay, Hudson's Bay. N. lat. 53° 20'. W. long. 80° 40'.

TWIN, South, an island in James's Bay, Hudson's Bay. N. lat. 53° 10'. W. long. 80° 40'.

TWIN Oat, in Agriculture, a name sometimes applied to an early kind of white oat, which is very productive on deep good land, and which affords full crops on moit fots that are not too poor in quality. It commonly yields somewhat more than the pollard fort. See OAT.

TWINE. Bolt-rope twine, used in fewing fails to their bolt-rove, is made of the long hemp, or from the long rough hemp unbeat. It contains two or three threads, is twitted slack, and wound into half-pound flains containing two hundred yards. Eight threads are spun out of half a pound of hemp, each fifty yards long.

Steal-twine, for feal-nets, is made of twelve threads, two threads first twitted together, then fix of them hardened together, and wound up into half-flains, or eight yards.

Long's Astron. vol. 1. p. 258.
Scanning or fail-maker's twine, for fewing the seams of sails, is made of the best long hemp, beaten, spun fine, and well dressed over a fine clearer: eighteen threads are spun out of half a pound of hemp, every thread being fifty yards in length: two threads are twined together slack, and wound on a reel, in half-pound bobbins containing four hundred and fifty yards: but twine of three threads is used in the navy.

Seam-twine is made from good long hemp, each thread spun fifty-four yards: three threads are laid together. When hardened and stretched, each cord stands fifty yards; nine hundred yards are wound on a reel, and eighteen cords weigh two pounds.

Store-twine, used by fail-makers for old work and on board of ships, is made from good long hemp, well dressed. Fourteen threads are spun from half a pound; two threads are twined together, and wound into half-pound bobbins of three hundred and fifty yards.

Turlha-twine, for turtle-nets, is made of good bar hemp, spun one hundred yards; three threads are laid together, stand ninety yards, and weigh one pound.

Whipping-twine, the fame as bolt-rope twine.

TWILLING IRONS, square bars with an efs-hook at one end, which grafs the porter or the flank of an anchor to turn it over.

TWINKLING OF THE STARS, denotes that tremulous, vibratory, intermitting motion, which is obferved in the light proceeding from the fixed stars: Alhazen, an Arabifh phi/opher of the twelfth century, confiders refraction as the caufe of this phenomenon.

Vitello, in his Optica, published in 1270, p. 449, attributes the twinkling of the flars to the motion of the air in which the light is refracted: and he obferves, in confirmation of this hypothesis, that they twinkle ftronger when they are viewed in water put into motion.

Dr. Hooke (Microgr. p. 231, &c.) very reasonably attributes this phenomenon to the incoherent and unequal refraction of the rays of light occasioned by the trembling motion of the air and interperfed vapours, in confequence of variable degrees of heat and cold in the air, producing correfponding variations in its rarity or density, and also of the action of the wind, which must cause the fuccesive rays to fall upon the eye in different directions, and confequently upon different parts of the retina at different times, and alfo to hit and mif the pupil alternately; and this is also the reafon, he fays, why the limbs of the fun, moon, and planets appear to wave or dance.

These tremors of the air are manifest to the eye by the tremulous motion of shadows call from high towers; and by looking at objects through the fmoke of a chimney, or through drees of hot water, or at objects situated beyond hot fands, especially if the air be moved tranfverely over them. But when fars are feen through telecopefs that have large apertures, they twinkle but little, and at times not at all. For, as Sir Isaac Newton has obferved, (Opt. p. 98.) the rays of light which pass through different parts of the aperture, tremble each of them apart, and by means of their various, and fometime contrary tremors, fall at one and the fame time upon different points in the bottom of the eye, and their trembling motions are too quick and confined to be separately perceived. And all these illuminated points constitute one broad lucid point, compofed of thofe many trembling points coherently and indifferently mixed with one another by very fhort and twift tremors, and thereby caufe the far to appear broader than it is, and without any trombling of the whole.

Dr. Jurin, in his Essay upon Di/fitinent and Indif/itinent Vision, has recourfe to Sir Isaac Newton's hypothesys of fits of easy refraction and reflection for explaining the twinkling of the flars: thus, he fays, if the middle part of the image of a far be changed from light to dark, and the adjacent ring be at the fame time changed from dark to light, as must happen from the least motion of the eye towards or from the far, this will occasion fuch an appearance as twinkling.

Mr. Michell (Phil. Trans. vol. viii. p. 262.) fuppofes that the arrival of fewer or more rays at one time, especially from the smaller or more remote fixed flars, may make fuch an unequal imprefion on the eye, as may, at leaft, have fome share in producing this effect: since it may be fuppofed, that even a fingle particle of light is sufficient to make a fenfible impref-ffion upon the organs of light; fo that a very few particles arriving at the eye in a fecound of time, perhaps not more than three or four, may be fufficient to make an obje/ contemplably visible. See Light.

Hence, he fays, it is not improbable, that the number of the particles of light which enter the eye in a fecound of time, even from Sirius himfelf, may not exceed three or four thoufand, and from flars of the fecound magnitude they may, therefore, probably not exceed a hundred. Now the apparent increafe and diminution of the light, which we obferve in the twinkling of the flars, feem to be repeated at not very unequal intervals, perhaps about four or five times in a fecound. He, therefore, thought it reafonable to fup- pofe, that the inequalities which will naturally arife from the chance of the rays coming fometimes a little ferner, and fometimes a little rarer, in fo small a number of them, as must fall upon the eye in the fourth or fifth part of a fecound, may be fufficient to account for this appearance. An addition of two or three particles of light, or perhaps a fingle one, upon twenty, especially if there should be an equal deficiency, out of the next twenty, would, he fuppofed, be very fenfible, as he thought was probable from the very great difference in the appearance of fars, the light of which does not differ fo much as is commonly imagined. The light of the middlemfll far in the tail of the Great Bear does not, he thinks, exceed the light of the very small far that is next to it, in a greater proportion than that of about 16 or 20 to 1; and M. Bouguer faw, that a difference in the light of objects, of one part in sixty-fix, was sufficiently diftinguifhable.

Since these obfervations were publifhed, Mr. Michell (as we are informed by Dr. Priestley, Hist. of Light, p. 495.) has entertained fome fufpicion, that the unequal definity of light does not contribute to this effect in fo great a degree as he had imagined; espe/ally in confequence of obferving that even Venus does sometimes twinkle. This he once obferved her to do remarkably when she was about fix degrees high, though Jupiter, which was then about fixteen degrees high, and was fenfibly lefs luminous, did not twinkle at all. If, notwithstanding the great number of rays, which, without doubt, come to the eye from fuch a furface as this planet prefents, its appearance be liable to be affected in this manner, it must be owing to fuch undulations in the atmo/phere, as will probably render the effe/ct of every other cause altogether ine/vable.

M. Mulfchenbroeck (Introd. ad Phil. Nat. vol. ii. feft. 1741, p. 7071.) fuppofes, that the twinkling of the flars arises from fome affection of the eye, as well as the flate of the atmo/phere. For, he fays, that in Holland, when the weather is froithy, and the sky very clear, the flars twinkle much manifestly to the naked eye, though not in telecopes; and since he does not fuppofe there is any great exhalation, or dancing of the vapour at that time, he quefitions whether the vivacity of the light, affecting the eye, may not be concerned in the phenomeno.
TWI

But this philosopher might have satisfied himself with respect to this hypothesis, by looking at the stars near the zenith, when the light traverses but a small part of the atmosphere, and therefore might be expected to affect the eye most sensibly. For he would not have perceived them to twinkle near so much as they do near the horizon, when much more of their light is intercepted by the atmosphere.

Some astronomers have lately endeavoured to explain the twinkling of the fixed stars, by the extreme minuteness of their apparent diameter; so that they suppose the light of them is intercepted by every mote that floats in the air.

To this purpose Dr. Long observes (Afron. vol. i. p. 170.) that our air near the earth is so full of various kinds of particles, which are in continual motion, that some one or other of them is perpetually passing between us and any star which we look at, and this makes us every moment alternately see it and lose sight of it; and this twinkling of the stars, he says, is greatest in those which are nearest the horizon, because they are viewed through a great quantity of thick air, while the intervening particles are most numerous; whereas stars that are near the zenith do not twinkle so much, because we do not look at them through so much thick air, and therefore the interfering particles are fewer, come less frequently before them.

With respect to the planets, it is observed, that they, because they are much nearer to us than the stars, have a sensible apparent magnitude, so that they are not covered by the small particles floating in the atmosphere, and therefore do not twinkle, but shine with a steady light. The fallacy of this hypothesis appears from the observation of Mr. Michell, that no object can hide a star from us that is not large enough to exceed the apparent diameter of the star, by the diameter of the pupil of the eye; so that if a star was a mathematical point, the interfering object must still be equal in size to the pupil of the eye: and, indeed, it must be large enough to hide the star from both eyes at the same time.

The principal cause, therefore, of the twinkling of the stars is now acknowledged to be, the unequal refraction of light, in consequence of inequalities and undulations in the atmosphere.

Besides a variation in the quantity of light, it may here be added, that a momentary change of colour has likewise been observed in some of the fixed stars. Mr. Melville (Edinb. Enc. vol. ii. p. 81.) says, that when one looks fixedly at Sirius, or any bright star, not much elevated above the horizon, its colour seems not to be constantly white, but appears tinted, at every twinkling, with red and blue. Mr. Melville could not entirely satisfy himself as to the cause of this phenomenon; observing, that the separation of the colours by the refractive power of the atmosphere is, probably, too small to be perceived. Mr. Michell's hypothesis above-mentioned, though inadequate to the explanation of the twinkling of the stars, may pretty well account for this circumstance. For the red and blue rays being much fewer than those of the intermediate colours, and therefore much more liable to inequalities, from the common effect of chance, a small excess or defect in either of them, will make a very sensible difference in the colour of the stars.

TWINS, two young ones delivered at a birth by an animal which ordinarily brings forth but one.

It has been greatly disputed, which of two twins is to be esteemed the elder? The faculty of Montpellier have given it, that the latter born is to be reputed the elder, because first conceived: but by all the laws which now obtain, the first-born enjoys the privilege of seniority; and the custom is confirmed by the scripture influence of Esau and Jacob.

But if two twins be born so intermixed, that one cannot distinguish which of the two appeared first, it should seem that neither the one nor the other can pretend to the right of primogeniture, which ought to remain in suspense by reason of their mutual concurrence. In such case, some would have the decision left to the father, and others to the chance of a lot.

In cattle, twins are seldom desirable, as they can rarely be well supported, though occasionally cows are capable of suckling two calves; but in sheep, it is often greatly desirable in different breeds or varieties. The frequency of twins in sheep is much influenced both by the condition of the ewes, and the state of vigour in the rams. Such flocks as are well fed, and pasture easily about the Tupping time, usually produce a far larger proportion of twins, than those which have higher walks, or pastures which are of inferior quality. Twins too are the most frequent in the early part of the lambing season: all which shows the propriety of keeping the ewes well supported, and of not letting the rams have too great a number put to them at each season.

Nice attention is necessary to twins at the time of lambing, by the person who has the charge of the flocks, to see that they are in every way properly taken care of.

See SHEEP.

TWINS, in Astronomy. See GEMINI.

TWINS, in Geography, two small islands in the East Indian sea, near the island of Paraguay. N. lat. 9° 18'. E. long. 113° 3'.—Alfo, two small islands in the East Indian sea, near the north coast of the island of Flores. S. lat. 8° 21'. E. long. 122° 33'.

TWIST of a Rope, Cord, &c. See ROPE.

TWIST, again, is used for the inside, or flat part of a man's thigh, upon which a true horseman rests when on horseback.

TWIST a Horse, To, is violently to wring or twist his tendons about, which causes them to dry up, and deprives them of nourishment, and reduces the horse to the state of impotency with a gelding.

TWISTE, in Geography, a river of Germany, which runs into the Erpe, near Valckmaren, in the duchy of Westphalia.

TWISTED COLUMN. See COLUMN.

TWISTED Silk. See SILK.

TWISTED Thumb-Band, in Rural Economy, a term used to signify the band of hay or straw which is formed by means of the thumb and fingers, by twisting it with them, and employed in binding up trusses of these kinds for sale. See TRUSS.

TWITCH, in Agriculture, a name often applied to a very troublesome plant of the weed kind in tillage land, of which there are several sorts, as the black, white, creeping, and some others. See COUCH-GRAF.

TWITCH-Rake, a name sometimes applied to a large tool of this kind, made use of in dragging and collecting the roots of couch together in arable land, by means of a horse. See COUCH and RAKE.

TWITE, in Ornithology. See LINNET.

TWO Brothers, in Geography, two small islands in the Chinefes sea. N. lat. 8° 30'. E. long. 105° 48'.—Alfo, two small islands in the East Indian sea, near the W. coast of Borneo. S. lat. 1° 32'. E. long. 109° 13'.—Alfo, two small islands in the East Indian sea, 27 miles from the E. point of the island of Madura. S. lat. 6° 50'. E. long. 114° 43'.—Alfo, two small islands in the East Indian
the bay front, is the tool the coast the wheel the tool for,

Two-Headed Point, a cape on the S.W. coast of the ifland of Kodiak, in the North Pacific ocean, compofing a small ifland, which terminates to the N.E. by a low flat rocky point. South-westward from Two-headed ifland the coast is low, and appears to be compact; but immediately to the northward of it, the shores defcend abruptly into the sea, appear to be much broken, and form an extensive ifland, of which the flat rocky point may be confidered as its S.W. point of entrance; from this, its N.E. point being low projecting land, lies N. 58° E. at the distance of nine miles. The several branches that appeared to flow into the Sound, feemed to wind toward the bafe of a connected range of high fnowy mountains, which no doubt gave boundaries to their extent. N. lat. 56° 54'. E. long. 209° 5'.

Two Hills, a small ifland among the New Hebrides, in the South Pacific ocean. S. lat. 16° 15'. E. long. 166° 38'.

Two-Hill ifland, a small ifland in the Mergui Archipelago. N. lat. 11° 27'.

Two Keys, two small iflands in the bay of Honduras. N. lat. 17° 30'. W. long. 89° 52'.

Two-Saddle ifland, an ifland in the Mergui Archipelago, about four miles long, and two broad. N. lat. 10° 42'.

Two Sifters, two small iflands in the East Indian sea, covered with wood, and surrounded by a reef of coral-rocks. S. lat. 8°. E. long. 106° 12'. Alfo, two small iflands in the Spanish main, near the Mosquito shore. N. lat. 11° 17'. W. long. 82° 55'.

Two Specks, small iflands in the bay of Honduras, surrounded with rocks. N. lat. 17° 20'. W. long. 88° 30'.

TWOBILL, in Agriculture, the name of a tool commonly employed in cutting up roots in the work of paring and burning in the old mode. It is feen in fig. 7, in the plate on paring ploughs. It has fometimes the title of double-bitted mattock.

TWO-FURROW Plough, a term fometimes applied to that of the double kind. It is often useful for cross-cutting land in different cafes, and in giving the laft earth for turnip-crops.

TWO-FURROWING, a term used to signify double furrows, or the breaking up land by the double plough: it also implies trench-ploughing and sod-burying.

TWO-MEAL Cheese, in Rural Economy, a term applied to that fort which is made from the skimmed milk of the evening, added to the new milk of the meal of the morning; that made from the neat milk being termed one-meal. In fome districts, as that of Gloucefter, two-meal cheeſe is made of one meal or portion of coward or clean milk, and the fame of such as is skimmed; but often two of the latter are used to one of the former. Hence this fort is fometimes called coward-cheeſe.

TWO-MOULD-BOARDED Cleaning and Earthing Hoe for Potatoes, in Agriculture, a tool of somewhat the plough kind, contrived for the purpose of cleaning and earthing up these crops with. It has a wheel before to direct the depth of its working, with handles behind to regulate it. There is a sharp hoe attached to a front of coulter-bar in front, with a mould-board on each fide, capable of being fet to different diftances, by a kind of screw in the middle, by which means the ground is pared and laid to the crops. It is confidered a tool that produces much faving and advantage in the culture of potatoes, and which performs its work very effeetually.

TWOPENCE, Herb, in Botany, a species of Lyμsma-chia; which fee.

TWO-THIRDS SUBSIDY. See Duty and Subsidy.

TWUNT, in Geography, a town of Algiers, on the coast of the Mediterranean, defended by a fort; 30 miles N.W. of Tremeanc. N. lat. 35° 18'. W. long. 1° 2'.

TWAYBLADE, in Botany. See Opiums.

TYACUL, in Geography, a town of Hindooftan, in Myfore; 10 miles S. of Colar.

TYAHTATOOA BAY, a bay on the coast of Owhyhee, one of the Sandwich iflands. N. lat. 19° 37'. W. long. 203° 54'.

TYANA, in Ancient Geography, a town of Cappadocia, in the Tyanitide prefecture; the only one in this prefecture, according to Strabo; but according to Ptolemy, there were three others. It was known as the native country of Apollonius Tyanaeus, the celebrated impostor.

TYANA, in Geography, a town of Asiatic Turkey, in Natalia; 25 miles S.W. of Sis.

TYBEE, an ifland near the coast of Georgia, at the mouth of the Savanna: on it is a light-house. N. lat. 32°. W. long. 81°.

TYBEIN. See DUNO.

TYBER. See TIBERIS and Tyberinus. The Tyber appears on the reverse of a medal of Vefpasian, not only as a divinity, but also as the patron and protector of Rome. When Æneas reifed in Italy, he performed religious ceremonies to this river, gave himself up to his protection, and prayed that he might be propitious to him.

TYBERINUS, a king of Alba, and from this prince having drowned himfelf in the Albuca, that river gained the name of Tyber, which it has ever fince retained.

TYBOINE, in Geography, a township of Pennsylvania; 100 miles W. of Philadelphia.

TYCHE, in Ancient Geography. See Syracucus.

TYPHONIC System, or Hypothefa, is an order or arrangement of the heavenly bodies, of an intermediate nature between the Copernican and Ptolemaic, or participating alike of them both. See System.

TYDAL, in Geography. See Ruden.

TYDH, in Ancient Geography, a people of Asiatic Sarmatica, who inhabited mount Caucasus, according to Phiny.

TYE, Dr. in Biography, the bel English compofitor of church music, anterior to Tallis, that our country can boast; for though his name does not appear in the list of musicians of the chapel royal, or household establishment in the short reign of Edward VI., he was, doubtles, at the head of all eccleifiafal compositors of that period. Neither the state of the church, nor religious principles of its nominal members, were fo fetled as to render it poffible to determine, in these times, who among quiet and obedient subjects were Protentants, and who Catholics; for, during the conflict between the zealots of both religions, the changes were fo violent and rapid, that great flexibility or great
great dissimulation must have been practiced by those who not only escaped persecution, but still continued in offices, either of church or state. The few who seem to have been truly pious and conscientious on both sides, suffered martyrdom in support of their opinions; the rest seem to have been either unprincipled, or fluctuating between the two religions. One of the principal evils which the champions for reformation combatted, was the use of the Latin language in the service of the church; however, the best choral compositions produced by the masters of these times, that are come down to us, are to Latin words. Specimens remain of Dr. Tye's clear and masterly manner of composing for the church in that language, when he was at least a nominal Catholic, either during the reign of Henry VIII. or queen Mary; and the late worthy Dr. Boyce has given an admirable example of his abilities in the anthem for four voices, "I will exalt thee, O Lord," inserted in the second volume of his excellent "Collection of Cathedral Music, by English Masters." There is hardly any influence to be found in the productions of composers for the church during his time, of a piece so constantly and regularly in any one key, as this is in the key of C minor, and its relatives; the harmony is pure and grateful; the time and melody, though not so marked and accented as in those of the best compositions of the last century, are free from pedantry, and the difficulty of complicated measures which this composer had the merit of being one of the first to abandon. That he translated the first fourteen chapters of the Acts of the Apostles into metre, in imitation of Sternhold's Pindar, which were the delight of the court in which he lived, was doubtless an absurd undertaking, and was not rendered less ridiculous by the elaborate music to which he set them, consisting of fugues and canons of the most artificial and complicated kind. Dr. Tye, however, if compared with his contemporaries, was perhaps as good a poet as Sternhold, and as great a musician as Europe could then boast; and it is hardly fair to expect more perfection from him, or to blame an individual for the general defects of the age in which he lived.

Tye, in Geography, a river of Virginia, which runs into James river, N. lat. 37° 30'. W. long. 79° 8'.

Tye, in Mining. See STREAMING.

Tye, in Sea Language, denotes a sort of runner, or thick rope, used to transmit the effort of a tackle to any yard or gaff, which extends the upper part of a sail.

The tye is either passed through a block fixed to the maff-head, and afterwards through another block moveable upon the yard or gaff intended to be hoisted; or the end of it simply fastened to the fall, yard, or gaff, after communicating with the block at the maff-head. See JERS.

TYER, in Geography, a river of South Carolina, which runs into the Cangaree, N. lat. 34° 30'. W. long. 81° 45'.

TYERS, JOHNATHAN, in Biography, the late proprietor, and indeed the creator of Vauxhall gardens, (see VAUXHALL,) deserves a place among our biographical articles on many accounts. His taste, liberality, and spirit in supporting and ornamenting this elegant place of amusement with paintings by Hogarth and Hayman; an excellent band of music; an orchestra in the form of a temple in the open air, with an organ equal in size and workmanship to many of the most noble instruments of that kind in our churches; and a constant succession of ingenious exhibitions; rendered it a public place more attractive, admired, and imitated by foreigners, than any one our country could boast. In every part of Europe a nominal Vauxhall has been established; nor was there a theatre on the continent thirty years ago, with scenery and ballet pantomimes, without an attempt at representing Vauxhall.

The proprietor began with a small band of wind-instruments only, before he erected an orchebra, and furnished it with an organ; but in the summer of 1745, to render it still more attractive, he added, for the first time, vocal to his instrumental performances. Here the talents of many of our national musicians were first displayed and first encouraged; here Collet and Tinto on the violin, Snow on the trumpet, Millar on the bassoon, Worgan on the organ, &c. annually increased in merit and favour. Here Mellet, Arne, Lowe, and the elder Reinholt sung during many years, with great applause, Dr. Arne's ballads, duets, dialogues, and trios, which were soon after circulated throughout the kingdom, to the great improvement of our national taste. During this first summer, his little dialogue of Colm and Phæbe, written by the late Mr. Moore, author of "Fables for the Female Sex," was constantly encored every night for more than three months successively.

But here the good sense, found judgment, and good taste of the spirited proprietor of Vauxhall, derive a record for the veneration and respect which he manifested for Handel; at a time when the health and favour of this great master were on the decline, and opposition had almost ruined him: it was then that Tyers erected, at his sole expense, the marble statue which still adorns the gardens; an honour which has seldom been conferred on a subject and a professional man, during his life-time, in any country, since the flourishing state of the Greeks and Romans. And as this transgression doth honour, not only to the genius of Handel, but to the public spirit of his votary, we shall relate it as recorded in the registers of the times.

April 15th, 1733, in the London Daily Post, a paragraph says: "The effigies of Mr. Handel, the famous composer of music, is going to be erected at Vauxhall gardens, at the expense of Mr. Jonathan Tyers." And on the 19th of the same month, "We are informed, from very good authority, that there is now near finished a statue of the justly celebrated Mr. Handel, exquisitely done by the ingenious Mr. Roubilliac, of St. Martin's-lane, Haymow, out of one entire block of marble, which is to be placed in a grand niche, erected on purpose in the great grove at Vauxhall gardens, at the sole expense of Mr. Tyers, conductor of the entertainments there; who, in consideration of the real merit of that immovable matter, thought it just and propriety that his effigies should prefide in that place, where his harmony has so often charmed even the greatest crowds into the most profound silence and attention. It is believed, that the expense of the statue and niche cannot cost less than 3000; the fair gentleman, likewise, very generously took at Mr. Handel's benefit, fifty of his tickets."

May 2d, we have a farther account of this species of apotheosis, or laudable idolatry, in the following words: "Last night at the opening of the Spring-gardens Vauxhall, the company expressed great satisfaction at the marble statue of Mr. Handel, who is represented in a loose robe, sweeping the lyre, and listening to its sounds; which a little boy sculptured at his feet seems to be writing down on the back of a violoncello. The whole composition is in an elegant taste."

Soon after, the following verses appeared:

"That Orpheus moved a grove, a rock, or stream,  
By music's power, will not a fiction seem;  
For here as great a miracle is shown—  
A Handel breathing, though transform'd to stone."

TYFORD,
TYFORY, in Geography, a small island in the East Indian seas, 45 miles W. of Gilolo. N. lat. 1° 0' E. long. 126° 28'.

TYGARTS VALLEY, a district of Pennsylvania, watered by the Monongahela river.

TYGER, in Zoology. See Tiger.

Tyger, in Geography, a river of South Carolina, which joins the Saluda, 5 miles N. of Columbia; and both together form the Congaree.

Tyger's Point, a cape of Asia, on the south-west coast of Asia, at the mouth of the Perfian. N. lat. 15° 50'. E. long. 94° 45'.

Tyger's Creek, a river of Kentucky, which runs into the Ohio, N. lat. 38° 22'. W. long. 83°.

Tyger's Island, a small island in the Chincoteague, near the coast of Chippa. N. lat. 16° 47'. E. long. 107° 45'.

—Allo, a small island in the Chincoteague, near the coast of the Ohio, N. lat. 16° 51'. E. long. 106° 13'.

Tyger Island, a small island in the Pacific ocean, at the entrance of the bay of Amapalla. N. lat. 13° 10'.

Tyger Islands, a cluster of small islands and shoals in the East Indian seas; 30 miles E. from the island of Saleyer.

TY-GWYN, a village of South Wales, in the county of Caernarthen, where Howel Dha, first monarch of all Wales, had a palace: and in the year 947, a council was held, to form a body of laws. On this spot a Cetirian monastery was founded, called Whetford Abbey; 5 miles W. of St. Clare.

TYING, in Music. See LEGATE-Note and SYNCOPE.

TYKOCZYNS in Geography, a town of Poland, in the palatinate of Bieflk. In 1705, Augustus II. instituted the order of the White Eagle in this town; 28 miles N.N.W. of Bieflk.

TYLAMG, in Ancient Geography, a town of the Peloponnesus, in Triphylia, according to Polybius.

TYLE, or Tile, in Building, a sort of thin, factitious, laminated brick, used on the roofs of houses, or, more properly, a kind of flat clayey earth, kneaded and moulded of a jutthickens, dried and burnt in a kiln, like a brick, and used in the covering and paving of houses.

It is thus called from the French tuile, of the Latin tegula, which signifies the same.

Tiles are made, says Mr. Leyburn, of better earth than brick-earth, and something near akin to the potter's earth.

By 17 Geo. III. c. 42, all combinations for enhancing the price of tiles and bricks, shall be void; and every tyle-maker, or brick-maker, offending, shall forfeit 20l., and every clerk, agent, or servant, to half the poor, and half to him who sues within six months.

By 43 Geo. III. c. 69, schedule (A.) and the 45 Geo. III. c. 30, in lieu of any duties of excise then subjoined, new duties were imposed.

The said duties on bricks and tyles to be paid by the maker or makers thereof respectively.

For the duties on exportation and importation, see the schedules annexed to the said act of 43 Geo. III. c. 69.

Provided always, that tyles made for the sole purpose of draining land, 19½ inches long by 13½ inches broad, and bent into a semi-elliptical form, the inside of the crown of the arch thereof being not less than seven inches perpendicular, from a straight line drawn from the one to the other side thereof after the fame is fo bent, and such lines not being at any part thereof more than five inches distant from each other on the inside, as near of the dimensions, and bent as nearly into the form aforesaid as may be, to be used for the purposes aforesaid, shall not be subject to any of the said duties. 34 Geo. III. c. 15.

And the exemption is extended to tyles made for such purpose not less than nine inches long; such being in every other respect of the same description and dimension as before preferred. 42 Geo. III. c. 93.

And by the 46 Geo. III. c. 138, it is further enacted, that semi-elliptical tyles not exceeding in wide width six inches, and the height of which from the outside of the crown of the arch in a perpendicular line to the edge shall in all cases exceed the width, but with a foot from the bottom of the arch where necessary, not exceeding two inches in breadth, made for draining wet or marly lands, are exempted from the excise duty.

And any person using any such tyle for any other purpose than above-mentioned, incurs the penalty of 6d. each tyle so used.

And every maker of bricks or tyles, before he begins to make, shall leave or give notice in writing at the next excise office of his name and place of abode, and of the sheds, workhouses, or other places where such bricks or tyles are intended to be made; on pain of 100l. 24 Geo. III. c. 24. feft. 2.

All bricks and tyles chargeable with the said duties shall be taken account of and charged by the officer whom they are drying, after being turned out of the moulds, and before removed to the kiln or clamp for burning, for which purpose any officer may enter into the fields, sheds, or other places where making, and shall take an account thereof in writing, and leave a copy (if demanded) with each maker, on pain of 40l.; and if any per son shall obstruct such officer, he shall forfeit 50l.

The officer charging the duty shall allow ten for every hundred when charged in the field before burned, in compensation for all waste, loss, or damages.

And if the maker shall remove any bricks or tyles to the kiln or clamp or other place of burning from out of the field or place where they shall be put or placed to dry before the officer shall have taken an account thereof, he shall forfeit 50l. And all so carried away, and found in the possession of any maker, or trader therein, or per son for his use, shall be forfeited and may be seized, or the value thereof shall be forfeited. 25 Geo. III. c. 66.

Provided, that no such maker shall be subject to the said penalty, if the officer shall fail to take an account, on due notice given him three days before such removal. 24 Geo. III. c. 24. feft. 2.

The maker shall keep the bricks and tyles unsurveyed separate from those that have been surveyed; on pain of forfeiting 50l. 25 Geo. III. c. 66.

And such maker shall, while the same are drying, place them in such manner as the officer may easily and securely take an account thereof; and if he shall place them in an irregular or unusual manner, with intent to make it difficult or unsafe for the officer to take such account, he shall forfeit 50l.

If any maker shall fraudulently conceal or hide any bricks or tyles in any part of the operation of making, with intent to evade the duties, he shall forfeit the same, and also 20l. 24 Geo. III. c. 24. feft. 2.

Every such maker shall once in every six weeks make entry in writing upon his oath, or on the oath of his chief workman, at the next excise office, of all bricks and tyles by him made within that time, on pain of 50l. And shall also, within six weeks after such entry, clear off all the duties then due thereon; on pain of double duty. And if any person shall carry away such bricks or tyles before the duty be cleared off, he shall forfeit double the value thereof. But such
Tyl

fuch maker shall not for making fuch entry be obliged to go
further than the next market-town.

And all tools, implements, and utensils used in making fuch bricks or tyles, in custody of the maker, &c. shall be liable to be fized for any debts or penalties, (arising or incurred under this act,) whether the debtor or offender be the lawful owner thereof or not. 28 Geo. III. c. 37.

Bricks or tyles for which the duties have been paid may be exported, and on security given before the shipping thereof that the fame shall not be relanded, the perfon exporting the fame shall be allowed a drawback of fuch duties; and in cafe fuch bricks or tyles shall be relanded, the fame shall be forfeited to the ufe of his majefly, over and above the penalty of fuch bond. 27 Geo. III. c. 13. fched. (F.)

All penalties and forfeitures are to be fized for, levied, and mitigated as by the laws of excif, or in cafes at Welfminster, and to be distributed half to the king, and half to him that fhall fize. 24 Geo. III. c. 24. eff. 2.

For the method of burning tyles, fee BRICK.

As to the applying of tyles, fome lay them dry, as they come from the kiln, without mortar, or any thing elfe; others lay them in a kind of mortar made of loam and horfe-dung. In fome parts, as in Kent, they lay them in mofts.

There are various kinds of tyles for the various occasions of building; as plain, thack, ridge, roof, creafts, gutter, pan, crooked, Flemifh, corner, hip, dornan or dornam, scallop, aftragal, travefes, paving, and Dutch tyles.

Tyles, Plain or Thack, are thofe in ordinary ufe for the covering of houfes. They are fqueezed flat, while yet foft, in a mould. They are of an oblong figure, and by flat. Edw. IV. c. 4. are to be ten inches and a half long, fix and a quarter broad, and half an inch and half a quarter thick. But these dimensions are not ftrictly observed.

Plain tyles are not laid in mortar, but only pointed in the infide.

Tyles, Ridge, Roof, or Creafes, are thofe ufed to cover the ridges of houfes, being made circular, breadthwife, like a halve cylinder. Thofe are what Pliny calls interculi, and are by flatute to be thirteen inches long, and of the fame thicknefs with the plain tyles.

Tyles, Hip or Corner, are thofe which lie on the hips or corners of roofs. As to form, they are firt made flat, like plain tyles, but of a quadrangular figure, whole two fides are right lines, and two ends arcs of circles; one end being a little concave, and the other convex. The convex end is to be about seven times as broad as the concave end; fo that they would be triangular, but that one corner is taken off; then, before they are burnt, they are bent on a mould, breadthwise, like ridge tyles. They have a hole at their narrow end to nail them on by, and are laid with their narrow end upwards. By flatute, they are to be ten inches and a half long, and of a convenient breadth and thicknefs.

These, as well as the ridge tyles, are to be laid in mortar, because they feldom lie to clofe as not to admit any water to pafs between them.

Tyles, Gutter, are thofe which lie in gutters or valleys in crofs-buildings. They are made like corner tyles, only the corners of the broad end are turned back again with two wings. They have no holes in them, but are laid with the broad end upwards, without any nailing. They are made in the fame mould as corner tyles, and have the fame dimensions on the convex fides. Their wings are each four inches broad, and eight long.

These tyles are feldom ufed where lead is to be had.

Tyles, Pan, Crooked, or Flemifh, are ufed in covering

Vol. XXXVI.

of theds, ftables, out-houfes, and all kinds of flat-roofed buildings. They are in form of an oblong parallelogram, as plain tyles, but are bent breadthwise forwards and backwards, in the form of an S, only one of the arches is at least three times as big as the other, which biggest arch is always laid uppermost, and the left arch of another tyle lies over the edge of the great arch of the former. They have no holes for pins, but hang on the laths by a knot of their own earth. By 17 Geo. III. c. 42. they are to be, when burnt, not less than thirteen inches and a half long, and a half inches wide, and half an inch thick, on pain that the maker fhall forfeit 10s. for every 1000.

Pan-tyles are laid in mortar, because the roof being flat, and many tyles being warped in the burning, they will not cover the roof so well as that no water pafs between them.

Tyles, Dornam or Dorman, confift of a plain tyle, and a triangular piece of a plain one, standing up at right angles to one fide of the plain tyle, and swept with an arc of a circle from the one end, which end terminates in a point. Of thofe tyles there are two kinds; the triangular piece, in fome, standing on the right, in others on the left fide of the plain tyle. And of each of thofe, again, there are two kinds, fome having a whole plain tyle, others but half a plain tyle. But in them all, the plain tyle has two holes for the pins, at that end where the broad end of the triangular piece stands.

Their ufe is to be laid in the gutters, betwixt the roof and the cheeks or fides of the dornars, the plain part lying on the roof, and the triangular part standing perpendicularly by the cheek of the dornar. They are excellent to keep out the wet in thofe places, and yet they are hardly known any where but in Sufex. The dimensions of the plain tyle part are the fame as thofe of a plain tyle, and the triangular part is of the fame length, and its breadth at one end seven inches, and at the other nothing.

Tyles, Scallop or Aftragal, are, in all refpects, like plain tyles, only their lower ends are in form of an aftragal, viz. a femicircle, with a square on each fide. They are ufed in fome places for weather tyling.

Tyles, Travefes, are a kind of irregular plain tyles, having the pin-holes broken out, or one of the lower corners broken off. These are laid with the broken end upwards, upon the rafters, where pinned tiles cannot hang.

Tyles, Flemifh or Dutch, are of two kinds, ancient and modern. The ancient were ufed for chimney foot-paces; they were painted with antique figures, and frequently with fculptures of foldiers, fome with compartments, and fome with moriffeque devices; but they came greatly short, both as to the defign and colours, of the modern ones.

The modern Flemifh tyles are commonly ufed plastered up in the jamb of chimneys, instead of chimney cornerstones. Thofe are better glazed, and fuch as are painted (fome for fome are only white) are much better performed than the ancient ones.

But both kinds feem to be made of the fame whitifh clay as our white-glazed earthen-ware. The ancient ones are five inches and a quarter square, and about three-quarters of an inch thick; the modern ones fix inches and a half square, and three-quarters of an inch thick.

When thofe tyles are fet with good mortar they look beautiful, and caft a greater heat than stone; for, being very smooth and glazed, the rays of heat striking upon them are all reflected into the work, especially when the fides of the chimneys are oblique, or in the form of circular arches. But they are little ufed.

Tyling is measured by a square of 100 square feet; and the number of tyles required for such a square depends on

3 R
the distance of the latter, which, when six inches, requires 800; when six and a half inches, 740; when seven inches, 690; when seven and a half inches, 640; and when eight inches, 600 tyes.

**TYL**

**TYLER.** See Tyle.

**TYLERS, Great.** in Geography, a small island in the Gulf of Guinea. N. lat. 50° 50' E. long. 27° 12'.

**TYLERS, Little.** a small island in the Gulf of Finland. N. lat. 59° 48'. E. long. 26° 54'.

**TYLERY.** See Tulerie.

**TYLIS.** in Ancient Geography, a town of Thrace, on mount Hamus.

The plants of this genus have twining, either herbaceous or shrubby, stems. Leaves opposite, membranous, flat. Umbels standing between the footstalks. Flowers for the most part small. Four of the species are natives of New Holland, chiefly within the tropic, but extending as far as thirty-three degrees of south latitude. As many are found either in the East Indies or the equinoctial parts of Africa, but of these four latter, none of them described in any botanical work, the learned author has favoured us with no account. We can therefore merely give the characters of the New-Holland species, from his Prodromus. It only remains for us to observe, that Tylophora comes very near Hoya, see that article; differing scarcely in any part of the essential character, except the want of a tooth at the inner angle of each leaf of the crown; and with respect to habit, distinguished from one only of the two species of that genus, by having membranous, not flabby, leaves.

1. **T. grandiflora.** Large-flowered Tylophora. Br. n. 1.—Umbels nearly fleshy, simple, of few flowers; their partial stalks smooth. Leaves heart-shaped, ovate, acute, downy as well as the branches.—Native of Port Jackson, New South Wales.

2. **T. barbata.** Bearded Tylophora. Br. n. 2.—Umbels mossily in pairs; their common stalk shorter than the leaves. Corolla bearded. Leaves ovate, acute, very smooth.—Gathered near Port Jackson, by Mr. Brown himself.

3. **T. flexuosa.** Zigzag Tylophora. Br. n. 3.—Umbels alternate, fleshy on a zigzag common stalk. Leaves heart-shaped, oblong, veiny. Corolla bearded.—Found by Mr. Brown, in the tropical part of New Holland.

4. **T. paniculata.** Paniced Tylophora. Br. n. 4.—Panicles forked. Segments of the corolla ligulate upwards. Leaves ovate, pointed, nearly smooth; the lowermost somewhat heart-shaped.—Discovered in the neighbourhood of Port Jackson, by Mr. Ferdinand Bauer, the botanical companion of Mr. Brown, to whose exquisite pencil the duty of perpetuating the acquisitions of their hazardous expedition, undertaken at the national expense, was entrusted. Yet too little has the engagement to the public been fulfilled, that except a small but exquisite falciculus of plates, and the excellent but incomplete publications of Mr. Brown, all the discoveries of these naturalists have as yet remained fruitless: not, certainly, for want of their ability or inclination to complete what they have undertaken, but because, as we presume, the due injuctions, as well as the necessary aids, have been withheld.

**TYLOS, in Orni**thology, a name by which many authors have called the *Sords filius*, or redwing.

**TYLOTICA.** medicines supposed to promote the formation of callus.

**TYLSEN, in Geography, a town of Brandenberg, in the Old Mark, on the Dicke; 5 miles S.W. of Salzwedel.**

**TYLUS, in Ancient Geography, a town of the Peloponnesus, on the coast of the gulf of Messenia, between the isles of Tyrides and the town of Leuctrum, according to Strabo; it is called Otyile by Pausanias, who places it between the port of Melia and Talama.—Alfo, an island of the Persian gulf, at the distance of twenty-four hours' navigation from the mouth of the Euphrates, according to Arrian.—Alfo, Tylus minor, distant 10 miles in the same gulf from the greater Tylus; named Arados by Strabo, and Arathos by Ptolemy.

**TYLWITH, in matters of Heraldry and Defect, is sometimes used for a tribe or family branching out of another, which the modern heralds more usually call the second or third house.**

**TYLWDAN, in Geography, a river on the S. coast of the island of Java, which runs into the sea, S. lat. 7° 38'. E. long. 108° 47'.**

**TYMARE, a town of Hindostan, in Bahar; 25 miles E. of Chuta Nagpour.**

**TYMBALES, Fr. kettle-drums, instruments of percussion, consisting of two mettalic globes covered with parchment; beaten with two drum-sticks, in the form of round hammers or mallets, from eight to nine inches long. The tone is short and dull. They are tuned 4ths to each other. The smallest drum produces the key-note of the composition in which they are employed, and the largest, the 4th below; as in the key of C the tones are these:

```
C E G
```

There are braces, by which the pitch can be raised or lowered at pleasure. See Drum, and Kettle-Drum.

**TYMBERS of Skins.** See Timber.

**TYMBRA, in Ancient Geography, a town of Asia, in Pindia.**

**TYMBRE, Fr. in Music, is a term used to express that quality of tone or sound which renders a voice or instrument rough or smooth, harsh or sweet, coarse or mellow in tone. Sweet-toned instruments seem always feeble, and harsh-toned too loud. A perfect voice or instrument would be that which united force with sweetness. The quality of tone generally determines our idea of its force. The voice of Manzoli, at once extremely powerful and extremely sweet, was miraculous. There are perhaps no instruments that can be at once loud and sweet, except those of the violin family, played with a bow; as the violin, tenor, and violoncello.**

**TYMENIAUM, in Ancient Geography, a mountain of Asia, in the vicinity of Phrygia.**

**TYMES, a town of Africa, in Libya.**

**TYMIUM, a small town of Asia, in Phrygia.**
TYMNISSUS, a town of Asia Minor, in Caria.

TYMNUS, a town of Asia Minor, in Caria, which derived its name from the promontory called by Mela Tymnias.

TYMPAN, or Tympanum, in Architecture, the area of a pediment, being the part which is in a level with the naked of the freeze. Or it is the space included between the three cornices of a triangular pediment, or the two cornices of a circular one.

Sometimes the tympan is cut out, and the part filled with an iron lattice, to give light; and sometimes it is enriched with sculpture, in baffe-relëve, as in the west front of St. Paul's, in the temple of Castor and Pollux at Naples, &c.

Tyman is also used for that part of a pedestal called the trunk or dye.

Tyman, among Joiners, is also applied to the panells of doors.

Tyman of an Arch, is a triangular space or table in the corners or sides of an arch, usually hollowed and enriched, sometimes with branches of laurel, olive-tree, or oak; or with trophies, &c.; sometimes with flying figures, as Fame, &c. or fitting figures, as the cardinal virtues.

Tyman, in Anatomy, Mechanics, &c. See Tymanum.

Tyman, among Printers, is a double frame belonging to the press, covered with parchment, on which the blank sheets are laid in order to be printed off. See Printing-Press.

TYMANA, or Tyman, among the Athenians, a capital punishment, in which the criminal, being affixed to the pole, was punished to death with cudgels. Potter, Archæol. Graec. lib. c. 25. tom. i. p. 134.

TYMANIA, in Ancient Geography, a town of the Peloponnæus, in the interior of the Elide. Ptolemy.

TYMANITES, in Medicine, from τυμπανόν, tympanum, a drum, a flatulent distension of the belly, which, when itruc, emits a sound which has been compared to the noise produced by that instrument. It has been called, in English, the tympany, and windly dropy.

The tympanites is a swelling of the abdomen, in which the integuments appear to be much stretched by some distending power within, and they are equally stretched in every portion of the body. The swelling does not very readily yield to any pressure; and so far as it does, being extremely elastic, it very quickly recovers its former state, when the pressure is removed. Being stuck, it gives an obscurion found, somewhat like that of a drum, or other distended animal membrane. No fluctuation within is to be perceived; and the whole feels less weighty than might be expected from its bulk. The unevenness from the distension is partially relieved by the discharge of wind from the alimentary canal, either upward or downward.

These are the characters, then, by which the tympanites, or flatulent swelling of the belly, may be distinguished from the afeites, or dropy of that cavity, and from physonia, or solid tumours, sometimes occurring there; and many experiments shew that the tympanites always depends upon a preternatural collection of air somewhere within the teguments of the abdomen. But the situation which the air occupies in different infinences is somewhat different; and this produces the different species of the distene which nololoists have deveribed.

One species, and indeed the most common and curable species, is that in which the collected air is confined within the cavity of the alimentary canal, and chiefly in that of the intestines. This species, therefore, has been named the tympanites intestinalis. (See Sauvages Nofol. Method.

Clars. x. (spec. 1.) To this species, indeed, which is the most frequent, the character above given especially belongs.

A second species is, when the air collected is not entirely confined to the cavity of the intestines, but is also present between their coats; and such is that which is named by Sauvages tympanites enterothefodes. (Sauv. spec. 3.) This has certainly been a rare occurrence; and has probably occurred only in connection of the tympanites intestinals, by the air escaping from the cavity of the intestines into the interstices of the coats. It is, however, possible, that an erosion of the internal coat of the intestines may give occasion to the air, so constantly present in their cavity, to escape into the interstices of their coats, though in the whole of their cavity there has been no previous accumulation.

A third species is, when the air is collected in the sac of the peritoneum, or what is commonly called the cavity of the abdomen, that is, the space between the peritoneum and visera; and then the disease is named tympanites abdominalis. (Sauv. p. 2.) The existence of such a tympanites, without any tympanites intestinals, has been disputed; and it certainly has been a rare occurrence; but from several directions, it is unquestionable that such a disease has sometimes truly occurred.

A fourth species of tympanites is, when tympanites intestinals and abdominals are joint together, or take place at the same time. With respect to this, it is probable that the tympanites intestinalis is the primary disease; and the other only a consequence of the air escaping, by an erosion or rupture of the coats of the intestines, from the cavity of the peritoneum, into that of the abdomen. It is indeed possible, that in consequence of erosion or rupture, the air which is so constantly present in the intestinal canal, may escape from thence in such quantity into the cavity of the abdomen, as to give a tympanites abdominals, whilst there was no previous considerable accumulation of air in the intestinal cavity itself; but we have no facts by which to ascertain this matter properly.

A fifth species has also been enumerated. It is when a tympanites abdominals happens to be joined with the afeites, or dropy of the belly; and such a disease is therefore named by Sauvages tympanites asfeticus. (Sauv. spec. 4.)

In most cases of tympanites, indeed, some quantity of serum has, upon distension, been found in the sac of the peritoneum; but that is not enough to constitute the species now mentioned; and when the collection of serum is more considerable, it is commonly where, both from the causes which have preceded, and likewise from the symptoms which attend, the afeties may be considered as the primary disease; and therefore that combination does not exhibit a proper species of the tympanites.

As this last is not a proper species, and as some of the others are not only extremely rare, but even, when occurring, are neither primary nor to be easily distinguished, nor, as considered in themselves, admitting of any cure, it will be unnecessary to take any farther notice of them; we shall therefore confine ourselves, in what follows, to the consideration of the most frequent case and almost the only object of practice, the tympanites intestinalis.

With respect to this, it does not appear that it arises in any peculiar temperament, or depends upon any predisposition, which can be discerned. It occurs in either sex, at every age, and frequently in young persons.

Various remote causes of it have been assigned; but many of these have not commonly the effect of producing this disease; and although some of them have been truly antecedents of it, we can in few instances discover the manner
manner in which they produce the disease, and therefore cannot certainly ascertain them to have been causes of it.

The phenomena of this disease, in its several stages, are the following.

The tumour of the belly sometimes grows very quickly to a considerable degree, and seldom in the flow manner the affections commonly come on. In some cases, however, the tympanites comes on gradually, and is introduced by an unusual flatulency of the stomach and intestines, with frequent borborygmi, and an uncommonly frequent expulsion of air upwards and downwards. This state is also frequently attended with colic pains, especially about the navel, and upon the sides towards the back; but generally, as the disease advances, these pains become less considerable. As the disease proceeds, there is a partly constant desire to discharge air, but it is accomplished with difficulty; and when obtained, although it give some relief from the pain of digestion, this relief is commonly transient and of short duration. While the disease is coming on, some inequality of tension and tension may be perceived in different parts of the belly; but the tension soon becomes equal over the whole, and exhibits the phenomena mentioned in the character. Upon the first coming on of the disease, as well as during its progress, the belly is bound, and the faces discharged are commonly hard and dry. The urine, at the beginning, is usually very little changed in quantity or quality from its natural state; but as the disease continues, it is commonly changed in both respects, and at length sometimes a strangury, and even an itch, comes on. The disease has seldom advanced far, before the appetite is much impaired, and digestion ill performed; and the whole body, except the belly, becomes considerably emaciated. Together with these symptoms, a thrill and uneasy sense of heat at length come on, and a considerable frequency of pulse occurs, which continues throughout the course of the disease. When the tumour of the belly arises to a considerable bulk, the breathing becomes very difficult, with a frequent dry cough. With all these symptoms, the strength of the patient declines; and the febrile symptoms daily increasing, death at length ensues, sometimes probably in consequence of a gangrene coming upon the intestines.

The tympanites is commonly of some duration, and to be reckoned a chronic disease. It is very seldom quickly fatal, except where such an affection suddenly arises in fevers. To this, Sauvages has properly given a different appellation, that of *meteorismus*; and it may perhaps always be considered as a symptomatic affection, entirely distinct from the tympanites which we are now considering.

The tympanites is generally a fatal disease, seldom admitting of cure; but we shall mention what may be attempted in this way, after having endeavoured to explain the proximate cause, which alone can lay the foundation of what may be rationally attempted towards its cure.

To ascertain the proximate cause of tympanites is somewhat difficult. It has been supposed, in many cases, to be merely an uncommon quantity of air present in the alimentary canal, owing to the extrication and detachment of a greater quantity of air than usual from the alimentary matters taken in. Our vegetable aliments probably always undergo some degree of fermentation; and in consequence, a quantity of air is extricated and detached from them in the stomach and intestines; but it appears, that the mixture of the animal fluids which our aliments meet with in the alimentary canal, prevents the same quantity of air from being detached from them that would have been in their fermentation without such mixture; and it is probable that the same mixture contributes also to the re-absorption of the air that had been before in some measure detached. The extrication, therefore, of an unusual quantity of air from the aliments, may, in certain circumstances, be such, perhaps, as to produce a tympanites; so that this disease may depend upon a fault of the digestive fluids, by which they become unfit to prevent the too copious extrication of air, and unfit also to occasion that re-absorption of air, which in sound persons commonly happens. An unusual quantity of air in the alimentary canal, whether owing to the nature of the aliments taken in, or to the fault of the digestive fluid, does certainly sometimes take place; and may possibly have, and in some measure certainly has, a share in producing certain flatulent disorders of the alimentary canal; but cannot be supposed to produce the tympanites, which often occurs when no previous disorder had appeared in the system. Even in those cases of tympanites which are attended at their beginning with flatulent disorders in the whole of the alimentary canal, as we know that a firm tone of the intestines both moderates the extrication of air, and contributes to its re-absorption or ready expulsion, so the flatulent symptoms which happen to appear at the coming on of a tympanites, are probably referred to a less of tone in the muscular fibres of the intestines, rather than to any fault in the digestive fluids.

Thence, and other considerations, lead us to conclude, that the chief part of the proximate cause of tympanites, is a less of tone in the muscular fibres of the intestines. But further, as air of any kind accumulated in the cavity of the intestines should, even by its own elasticity, find its way either upwards or downwards, and should also, by the assistance of inspiration, be entirely thrown out of the body; so when neither the re-absorption nor the expulsion takes place, and the air is accumulated so as to produce tympanites, it is probable that the passage of the air along the course of the intestines is in some places interrupted. This interruption, however, can hardly be supposed to proceed from any other cause than spasmodic constrictions in certain parts of the canal; and we may conclude, therefore, that such constrictions concur as part in the proximate cause of tympanites. Whether these spasmodic constrictions are to be attributed to the remote cause of the disease, or may be considered as the consequence of some degree of atony first arising, cannot with certainty be determined.

**Cure of Tympanites**—Having thus endeavoured to ascertain the proximate cause of tympanites, we proceed to treat of its cure; which indeed has seldom succeeded, and almost never but in a recent case of the disease. It may be proper, however, to state what may be reasonably attempted; what has commonly been attempted; and what attempts have sometimes succeeded in the cure of this disease.

It must be a first indication to evacuate the air accumulated in the intestines: and for this purpose, it is necessary that those constrictions, which had especially occasioned its accumulation, and continue to interrupt its passage along the course of the intestines, should be removed. As these, however, can hardly be removed but by exciting the peristaltic motion in the adjoining portions of the intestines, purgatives have been commonly employed; but it is at the same time agreed, that the more gentle laxatives only ought to be employed, as the more drastic, in the overstrung and tense state of the intestines, are in danger of bringing on inflammation. It is for this reason, also, that glysters have been frequently employed; and they are the more necessary, as the faces collected are generally found to be in a hard and dry state. Not only on account of this state of the faces, but, farther, when glysters produce a considerable evacuation of air, and
and thus shew that they have some effect in relaxing the spasm of the intestines, they ought to be repeated very frequently.

In order to take off the contractions of the intestines, and with some view also to the carminative effects of the medicines, various antispasmodics have been proposed, and commonly employed; but their effects are seldom considerable; and it is alleged that their heating and inflammatory powers have sometimes been hurtful. It is, however, always proper to join some of the milder kinds with both the purgatives and glirres that are employed; and it has been very properly advised to give always the chief of antispasmodics, that is, an opiate, after the operation of purgatives is finished.

In consideration of the overstrung and tense state of the intestines, and especially of the spasmodic contractions that prevail, fomentations and warm bathing have been proposed as a remedy; and are said to have been employed with advantage: but it has been remarked, that very warm baths have not been found so useful as tepid baths long continued.

Upon the supposition that this disease depends especially upon an atony of the alimentary canal, tonic remedies seem to be properly indicated. Accordingly, chalybeates and various bitters have been employed; and, if any tonic, the Peruvian bark might probably be useful. But as no tonic remedy is more powerful than cold applied to the surface of the body, and cold drink thrown into the stomach; so such a remedy has been thought of in this disease. Cold drink has been constantly prescribed, and cold bathing has been employed with advantage; and there have been several instances of the disease being suddenly and entirely cured by the repeated application of ice to the lower belly.

It is hardly necessary to remark, that, in the diet of tyrannical persons, all sorts of food disposed to become flattulent in the stomach are to be avoided; and it is probable, that the mineral acids and neutral salts, as antacids, may be useful.

In obliterative and suppurative cases of tympanitis, the operation of the paracentesia (tapping) has been proposed; but it is a very hazardous remedy, and there is no satisfactory testimony of its having been practised with success. It must be observed, that this operation is a remedy suited especially, and almost exclusively, to the tympanitis abdominalis; the existence of which, separately from the intestinals, is very doubtful, at least not easily ascertained, yet it is not very likely to be cured by this remedy: and how far the operation might be safe in the tympanitis intestinulis, is not yet determined by any proper experience. There would be a danger, indeed, of converting the tympanites intestinals into the tympanitis abdominalis, by allowing the air to escape through the puncture of the intestine into the face of the peritoneum, and thus of converting a less disease into a greater, and, in fact, of producing irreparable mischief.

TYMPANOTRIBA, among the Ancients, a designation given to an effeminate person, who could do nothing but play on the tympanum.

TYMPANUM, in Anatomy. See EAR.

TYMPANUM. Discharges of. The cavity of the drum of the ear is sometimes affected with a puriform ichorous discharge, attended with a loss of hearing, proportionate to the degree of disorganization which this part of the ear has sustained. In general, on blowing the nose, air is expelled at the meatus auditorius externus: and, when this is the case, it is evident that the discharge is connected with an injury, or destruction of the membrana tympani. However, when the Eustachian tube is obstructed with mucus, or matter, or when it is rendered impervious, and permanently closed by inflammation, the membrana tympani may not be perfect, and yet, it is clear, no air can in this state be forced out of the external ear in the above manner. An examination with a blunt probe, or with the eye, while the rays of the sun fall into the passage, should therefore not be omitted. If the membrane have any aperture in it, the probe will pass into the cavity of the tympanum, and the surgeon feel that his instrument is in contact with the osseous.

In this manner the affection may be discriminated from a herpetic ulceration of the meatus auditorius externus. The causes are various: in scarlatina maligna, the membrana tympani occasionally inflames, and though; all the ostioli are discharged, and, if the patient live, he continues quite deaf. An ear-ache, in other words, acute inflammation of the tympanum, is the most common occasion of suppuration in this cavity, in which, and the cells of the mastoid process, a good deal of pus collects. At length, the membrane tympani ulcerates, and a large quantity of matter is discharged; but, as the secretion of pus full goes on, the discharge continues to ooze out of the external ear.

Instead of stimulating applications, inflammation of the tympanum demands the rigorous employment of antiphlogistic means. Unfortunately, it is a too common practice, in this case, to have recourse to acid spirituous remedies. Above all things, the repeated application of leeches to the skin behind the external ear, and over the mastoid process, should never be neglected. As soon as the inflammation ceases, the degree of deafness, occasioned by it, will also disappear. This, however, does not always happen.

When an affection is situated in the cavity of the tympanum, Mr. Saunders seems to think, that the membrana tympani should not be allowed to burst by ulceration, but be opened by a small puncture. Sometimes the disease, of which we are treating, is more insidious in its attack: flight paroxysms of pain occur, and are relieved by flight discharges. The case goes on in this way, until, at last, a continual discharge of matter from the ear takes place. The disorder is destractive in its tendency to the faculty of hearing, and it rarely stops until it has so much disorganized the tympanum and its contents, as to occasion total deafness. Hence Mr. Saunders very properly defends the propriety of making attempts to arrest its progress,—attempts which are free from danger; and he censures the foolish fear of interfering with the complaint, founded on the apprehension, that bad constitutional effects may originate from stopping the discharge.

If the case be neglected, the tympanum is very likely to become carious; before which change, the disease, says Mr. Saunders, is most commonly curable.

Mr. Saunders divides the complaint into three stages: 1. A simple puriform discharge. 2. A puriform discharge complicated with funguses and polypi. 3. A puriform discharge with caries of the tympanum. As the disease is a local one, direct applications to the parts affected are chiefly entitled to confidence. Blisters and fomentations may be advantageously employed in aid of topical applications. Mr. Saunders's practice, in these cases, consists in administering laxative medicines, and fomenting the ear while inflammatory symptoms last, and afterwards injecting a solution of zincum vitriolatum, or cerufa acetata.

In the second stage, when there are funguses, he removes or destroys them with forceps, afterwards touches their roots with the argenteum nitratum, or injects a solution of alum, zincum vitriolatum, or argenteum nitratum.

TYMPANUM, in Architecture. See Tympanum.

TYMPANI, Chorda. See Chorda.

TYMPANUM, Tympan, in Mechanics, is a kind of wheel placed
placed round an axis, or cylindrical beam, on the top of which are two levers, or fixed flaves, for the more easy turning the axis about, in order to raise a weight required. The tympanum is much the same with the peritrochium; but that the cylinder of the axis of the peritrochium is much shorter and less than the cylinder of the tympanum. See Axis in Peritrochio.

TYPANUM of a machine is also used for a hollow wheel, in which one or more people, or rather animals, walk to turn it; such as that of some cranes, calenders, &c.

TYPANUM, Lat. a drum, in Antiquity; but in modern Music, it is equivalent with tymbale, or a pair of kettle-drums; which see. See likewise Timpano, Itat. for a kettle-drum.

TYPHAEI, in Ancient Geography, a people of Thrace, towards the sources of the Peneus. Strabo.

TYNA, a river of India, in the eastern part of the peninsula on this side of the Ganges, according to Ptolemy; marked by D'Anville to the N. of Mallarpha.

TYNAN, in Geography, a small poft-town of the county of Armagh, Ireland; 69 miles N. by W. from Dublin.

TYDRALE, William, (named also Hutchinson,) in Biography, a learned martyr to the Reformation, was born towards the latter part of the fifteenth century, on the borders of Wales, but the precise place of his nativity is not known. He received part of his education at Magdelan-Hall, Oxford, where he imbibed the doctrines of Luther, which caused his being dismissed from Wolley's new college of Christ-church, into which he had been admitted; so that he removed to Cambridge, where he took a degree. From hence he removed to Gloucestershire, to take the charge of Sir John Welch's children; and, during his residence here, he tranlated Erasmus's "Enchinizacion Militis Christiani" into English, for the benefit of the family with which he resided, and he often preached in and about Bristol. By the company which visited Sir John, Tyndale was reproached as a heretic, and articles were preferred against him by the chancellor of the diocese, so that he was under a necessity of removing to London, where he preached at St. Dunstan's in the Well. Dif forums of being admitted one of bishop Tofall's chaplains, he made application for that purpose, but was disappointed. In a retirement near London, he prepared a translation of the New Testament into English, which he accomplished, by unwearied industry, in about half a year; but the times would not admit of its publication. The author therefore withdrew to the continent, and at length took up his abode at Antwerp; and here he completed his work, which was printed in 1526, 8vo., without a name. The number of copies was 1,500, most of which were bought in England, and indifferently circulated. The zealous papists were alarmed, and foreseeing the diffusion of error and heresy, obtained orders from Warham, archbishop of Canterbury, and Tofall, bishop of London, that those who possessed any copies should deliver them up on pain of excommunication. Tofall procured all that were uncollected at Antwerp, and having purchased them, they were brought over and burnt at St. Paul's Cross. This circumstance favoured Tyndale's design, who took occasion to prepare a more correct edition, which was printed in 1534; and cheaper editions increased the circulation. In order to discourage and restrain these measures for differminating the Scriptures, Sir Thomas More ridiculed Tyndale's version in a dialogue in 1529, to which Tyndale replied: and the king, in a court of flar-chamber in 1531, with the concurrence of the prelates, univerities, and clergy, pronounced a severe condemnation of it, together with other heretical books. Tyndale, however, persevered with undaunted resolution, and engaged in a translation of the five books of Moses from the Hebrew. But in a voyage to Hamburg he was shipwrecked, and lost his books, papers and money. At Hamburg, where he at length arrived, he met with Miles Coverdale, and cooperating in their labour, they completed the Pentateuch, and printed it in 1530. Tyndale published a translation of the prophecy of Jonah, with a prologue, in 1531, and thus ended his labour on the Old Testament. At Antwerp he took up his residence in 1534, as a place of safety; but Henry VIII. and his council employed a perfon to betray him under the mask of friendship, and he was conveyed as a prisoner to Vilvorden, where he remained for a year and a half. At length, in 1536, he was brought to trial upon the emperor's decree at Augsburg; and here he was condemned, and strangled at the stake; and his body was reduced to ashes. He expired with uttering this prayer, "Lord, open the king of England's eyes!" It is needful to make any reflection on the conduct of such savage percutors, who thus treated a man of irreproachable manners, and who was pronounced, by the emperor's procurator, who assisted in his condemnation, "Homo doctus, pius, et bonus," for no other crime besides that of enabling Christians to peruse a book which is the only authoritative director of their faith and practice. Tyndale's other works were introductions to, and comments upon, parts of Scripture. Biog. Brit.

TYNDARIDÆ, in Mythology, a name given by the poets to Castor and Pollux, the sons of Jupiter and Leda. Though, according to the fabile, Pollux and Helena proceeded from the egg which Leda had conceived by Jupiter, and were therefore immortal; whereas, out of another egg, which she conceived by Tyndarus, her husband, came Castor and Clytemnestra, who were mortal. See Castor and Pollux.

TYNDARIS, in Ancient Geography, Pandarri, a town of Asia, in the Colchide, on the right bank of the Phasis, E.N.E. of Circeum, and S.W. of Cyta (Cattisii.) Pliny.

—Alla, a town of Sicily, towards the S.W., which was a Roman colony. It is called by Ptolemy Tyndaris.

TYNDIS, DANDA, a port of India, upon the coast of the country denominated Lymryca, according to the Ptolemy of the Erythraean sea.

TYNDIS, Tanaon, a river of India, in the peninsula on this side of the Ganges. Ptolemy.

TYNE, in Geography, a river of Scotland, which rises a few miles S. of Dalketh, crofses the county of Haddington, and runs into the German sea, N. lat. 56° 2'. W. long. 2° 38'.

TYNE. See TINE.

TYNEMOUTH, a townhip in the eait division of Castle-Ward, in the county of Northumberland, England; is situated on the banks of the river Tyne, 9 miles E.N.E. from Newcastle, and 286 miles N. by W. from London. It is a place of remote antiquity; and recent discoveries have proved that the Romans had buildings here. It is chiefly noted for its ancient monaftry, which is reckoned to be one of those founded by Oswald, the first Christian king of Northumberland. Great local facility was soon attributed to it, and several kings and other illustrious personages were buried here. St. Here bald, the companion of St. John of Beverley, was abbot here at the beginning of the eighth century; but before the end of it, the monastery was plundered by the Danes, as it was again in the next century by the forces under Hungar and Hubba, and a third time in the reign of King Athelstan. The old church seems to have lain desolate for a century, till a short time before the Norman conquest, when Tofti, earl of Northumberland, rebuilt and
and endowed it. On the banishment of Totti, the Conqueror gave his possessions to Robert de Mowbray, who then became earl; he refounded Tynemouth priory, and filled it with Black monks from St. Alban's, to which abbey the priory was subordinate. In his conspiracy against William Rufus, he converted the place into a fortress, which, after a siege of two months, was taken by storm. The priory progressively increased in consequence. In 1244, the prior mediated a peace between England and Scotland; and soon after obtained a charter from Henry III., to hold a market in his manor of Bewickc. He also claimed a market for Tynemouth; but in a suit on that account, judgment was given against him. Many privileges and immunities were, however, obtained for the inhabitants. At the surrender of the priory, in 1539, its possessions were very large, having twenty-seven villas with their royalties, besides the impropriations of many churches; its annual income being estimated at 706l. 10s. 8d. The chief remains are those of the church, at the east end of which is a neat little chapel or oratory. Till 1659 the church was parochial, but being decayed and damaged during the civil war, another was erected, and completed in 1668; but the old cemetery is still much used in preference to the new one. The castle, erected by earl Mowbray, appears to have been a place of great strength. It was garrisoned in the reign of queen Elizabeth; and again in that of Charles I., when it was besieged and taken by the parliamentary forces. Little remains of this ancient fortress except a strong gateway, the approach to which has been recently flattened by the town. The village of Tynemouth is much frequented in the bathing season, and commodious warm and cold baths have been erected. Here are some considerable salt-works; and it is estimated that 700,000 chaldrons of coal are annually sent here to London. In the population return of the year 1811, the number of houses in this township is stated to be 930, and of inhabitants, 5834.—Beauties of England, vol. xii. Northumberland, by the Rev. J. Hodgson.

TYNIDRAM, or Thunodronum Colonla, Hydrous, in Ancient Geography, a town of Africa, mentioned by Ptolemy, and placed between two degrees W. of Sicca Veneria.

TYNECZ, or Tynez, in Geography, a town of Austrian Poland, on the Vistula; 4 miles S.W. of Cracow.

TYNNA, in Ancient Geography, a town of Affa, in the Lefter Armenia, and in the prefecture named Catsonna. Ptol.—Alfo, a river of India, on this side of the Ganges, the mouth of which was in the country of the Avari. Ptolemy.

TYNSBOROUGH, in Geography, a town of Massachusetts, in the county of Middlesex, containing 704 inhabitants; 31 miles N. of Boston.

TYNOWSTA, a river of Pennsylvania, which runs into the Alleghany, N. lat. 41° 29'. W. long. 73° 30'.

TYORA, in Ancient Geography, known as Matienza, a town of the Aborigines, on the coast of Latium; distinguished by a very ancient oracle of Mars.

TYP, in Geography, a harbour on the coast of China, at the entrance of the river of Canton, formed by several islands. The anchoring place is N. lat. 22° of E. long. 114° 40'.

TYPÆA MONS, in Ancient Geography, a small mountain of Triphylia, near the banks of the river Alpheus. It was a law of the Eleans, that any female who was surprized in attendance at the Olympic games, should be precipitated from this mountain, the reason of which law is said to have been, that the Athletes were naked in the exercises.

TYPE, Typus, formed from words form, figure, a copy, image or resemblance, of some model. The term type is used in use than its compounds prototype and archetype, which are the originals that are made without models.

Type is also a scholastic term, much used among divines, signifying a symbol, sign, or figure, of something to come.

In this sense the word is commonly used with reference to antitype, antitypes, which is the thing itself, of which the other is a type or figure.

Thus Abraham's sacrifice, the paschal lamb, &c. were types or figures of our redemption; and the brazen serpent was a type of the cross, &c.

Types are not mere conformities, or analogies, which the nature of things holds forth between them; nor arbitrary images arising merely from the casual resemblance of things; but there is farther required a particular institution of God to make a type, and a particular declaration of his that it is so.

Gale divides types into historical and prophetic. The first are those used by the ancient prophets in their agitations and visions: the second, those in which things done, or ceremonies instituted in the Old Testament, prefigure Christ, or things relating to him in the New Testament. Or, they are things which happened and were done in ancient time, and are recorded in the Old Testament, and which are found afterwards to defy or represent something which befell our Lord, and which relates to him and his gospel. E.g. Under the law, a lamb was offered for a sin-offering; and thus an atonement was made for transgressions. John the Baptist calls Christ "the lamb of God that taketh away the sins of the world," and St. Peter tells Christians that they are redeemed "by the blood of Christ, as of a lamb." Hence we infer and conclude that the lamb was a type of Christ; and upon considering it, we find that it has all that can be required to constitute a type; for it is in many respects a very just and lively representation of Christ. The lamb died for no offence of his own, but for the sins of others; so did Christ: the lamb could not commit sin by his nature, nor Christ by his perfection; the lamb was without bodily spot orblemish; Christ was holy and undefiled: a lamb is meek and patient; such was the afflicted and much injured Son of God.

These types are useful to persons who have already received Christlikeness upon other and stronger evidence, as they show the beautiful harmony and correspondence between the Old and New Testament: but they seem not proper proofs to satisfy and convince doubters, who will say perhaps, with the schoolmen, "theologia fymbolica non est argumentativa."

Unless we have the authority of the Scriptures of the New Testament for it, we cannot conclude with certainty that this or that person, or this or that thing mentioned in the Old Testament is a type of Christ, on account of the resemblance which we may perceive between them: but we may admit it as probable.

The ancient fathers, as well as the modern critics, have been greatly divided about the nature and use of the types and typical representations in the Old Testament; and it is this makes one of the great difficulties in understanding the ancient prophecies, and in reconciling the New and Old Testament together.

There is no denying but that there were some types which the divine wisdom instituted to be the shadows and figures of things to come; and yet people run into an excess of those ways; some looking for types in every thing, like Origen, who discovered mysteries in the very cauldrons of the tabernacle. A prudent man should be contented with the more sensible and obvious ones, nor propone any without.
without proving them as much as possible, and shewing that they were really intended for types, in order to justify the
solfidity of the reasoning of the apostles, who argued from them.

An author, in reference to this subject, maintains, that
not the fathers only, but St. Paul himself, was of the opinion,
that Christianity was all contained in the Old Testament,
and was implied in the Jewish history and law; both
which are to be reputed types and shadows of Christianity.

In order to which, he quotes Hebrews, viii. 5. x. 1. and
Coloss. ii. 16, 17. He adds, that the ritual laws of
Moses, being in their own nature no other than types
and shadows of future good things, are to be considered as
having the effect of prophecies. This is likewise the sense
of Mr. Whitton, and others; but the same author even quotes
our Saviour speaking in behalf of this typical reasoning in
that passage, Matth. xi. 13. where he affirms that, "the
law prophesies; and that he came to fulfill the law as well
as the gospel." (Matth. v. 17. Diff. of the Grounds, &c.)

An ingenious divine takes this occasion to observe, that
had the ancients, with the modern retainers to the typical
way, expressly designed to have exposed Christianity, they
could not have done it more effectually than by thus making
everything types and prophecies.

Not that he denies the reality of such things as types. It
is manifest there were many under the Old Testament; such
were Zechariah's staves, beauty, and bands, ch. xi. 7. 10.
14; such was Hosea's adulterous wife, chap. i. 2; and such
were his children, ver. 4. 6. The prophets designed by
these to prefigure future events; but in these infinences the
reader is at once, by the declaration of the prophet, made
to understand, and not left to his own conjectures
about them after the events are over.

In effect, all that is urged from Scripture for the typical
or allegorical interpretations of the Jewish law, history,
ceremonies, &c. it is asserted, may be set aside, without any
violence to the Sacred Text, which may be explained on
more natural and intelligible principles, and more consistantly
with grammar.

The word 

τύπος

we have observed, literally denotes no
more than a copy or impression of any thing; and accordingly,
in our translation, we find it sometimes rendered by

print, sometimes by figure, sometimes by fashion, and sometimes
by form.

Hence also the word is figuratively applied to denote a
moral pattern; in which sense it signifies no more than an
example and similitude.

Again, the word 

αὐτότυπος, antitype,
in Scripture, signifies
any thing formed according to a model or pattern; and thus,
in the Epistle to the Hebrews, the tabernacle, and the
holy of holies, being made according to the pattern shewn
to Moses, are called antitypes, or figures, of the true holy
places. In the like sense, St. Peter, speaking of the
flood and the ark, by which eight persons were saved, calls
baptism an antitype to them; by which he expresses no more
than a similitude of circumstances.

The other words used in Scripture to imply a future
event, prefigured by some foregoing act, are—

τύχωμα, rendered by imitation and example; and 

σώμα, shadow.

Such being the import of all the terms used in the New
Testament writers, seeming to imply any prefiguration of
future events under the Gospel, it is observed,

1. That to argue from types, is only to argue from examples or similitudes; and, consequently, that all inferences
drawn from such reaonings are no farther conclusive than reaonings from similitudes are. The intent of similitudes
is only to help to convey some ideas more clearly or strongly;

so that to deduce consequences from a simile, or infer any
thing from other parts of the simile, than what are plainly
similar, is absurd.

The same author also alleges, 2. That it cannot be
proved, that the ceremonies of the Mosaic law were ever
designed to prefigure any future events in the state of the
Melliah's kingdom. No such declared prefigurations are
mentioned in the writings of the Old Testament, whatever
notions prevailed among the writers who immediately
followed. It is granted, that the apostles argued from the
rites in the Mosaic institution; but this (he says) appears to
have only been by way of illustration and analogy.

There is certainly a general likeness in all the dispensations
of Providence; an analogy of things in the natural as
well as the moral world, from which it is easy arguing by
way of paracy, and it is very just and usual so to do; but that
one of these dispensations was therefore given to prefigurize
another that was future, can never be proved, unlefs it be
expressly declared.

It is in the same way of similitude (he maintains) we are to
understand St. Paul, where he says, "that Christ our pass-
over is sacrificed for us." And thus we are to understand
John the Baptist, when he calls our Saviour the "Lamb of
God." There was this similitude of circumstances, that
Christ was slain on the same day with the paschal lamb;
that he died about the same time of the day when the priests
began their heel; that not a bone of the one or the other
was broken. Add, that as the paschal lamb was without
blemish, so was Christ without sin. From these, and other
circumstances, the apostle applied the term 

πασχαλις

to Christ.

Thus, also, we are to account for what St. Paul calls the
baptism of the children of Israel in the cloud, and in the
sea; and for the comparison between the high-priest entering
the holy place every year, and Christ entering into heaven.

TYPE, τύπος, is also a name given to an edict of the em-
peror Constanl II. published in 648, to impose a general
sentence both on the orthodox and the Monothelites.

It had the name of type, as being a kind of formulary of
faith; or rather a form on which men were to regulate their
conduct.

The type owed its original to Paul, patriarch of Con-
stantinople, who persuaded that emperor to take away the
ephes, compiled and hung up in all the public places by
Heraclius (as occasioning great complaints from the ortho-
dox, by its favouring the Monothelites); and to publish an
edict to impose sentence on both parties.

But such kinds of pacifications are held inexplicable in
matters of religion; accordingly pope Theodore soon pro-
cured the patriarch Paul to be depos'd; the type was ex-
amined in the council of Rome, consisting of a hundred and
five bishops, in 649, and condemned; and an anathema
was pronounced against all such as admitted either the impious
ephes or τύπος.

TYPE, Typhas, is also used to denote the order observed
in the intention and remission of fevers, pulses, &c.

Type, among Letter-founders and Printers, denotes the
name with letter. See Foundery.

TYPHA, in Botany, Cat's-tail, or Reed-mace, τύφος of the
ancient Greeks, from τύφω, a bog or marsh, of which situations
the plants of this genus are among the most conspicuous in-
habitants. They are often vulgarly mistaken for the Bull
rush, a very different plant. (See Scirpus, sect. 2.)

TYPHAE, one of Jullien's natural orders, the eighth of his general series, the second of his second clas. Its name is derived from one of the two genera which constitute this order, (see Typha); the other being Sparganium, which the reader will find in its proper place.

The second of Jullien's classes is formed of monocotyledonous plants, whose stamens are inserted below the germen. Their calyx is either of one or more leaves, or wanting. Corolla (in Jullien's opinion) none. Stamens inferior, mostly definite in number. Germen superior, simple; style either one or more, or wanting; stigma simple or divided. Seed solitary, naked or covered; or the fruit is of one cell, with one or many seeds. Leaves mostly alternate and sheathing. Flowers sometimes distinct in sex, by the failure of one or other of their organs of impregnation.—The orders are four; Aroides, Typhæ, Cyperoides, and Graminae; for the two last, see Calamaris and Gramina. The Aroides consist of Ambrosia, Zeaera, Arum, Colla, Dramantum, Pothos, Houttuinia, Orontium, and Acorus.

The Typhæ are thus characterised. Flowers monoeious; the males aggregate, triandrous, with a three-leaved calyx; females likewise aggregate, with a three-leaved (rather, we would say, many-leaved) calyx; germen superior; style simple; seed solitary. Leaves all alternate and sheathing. Plants herbaceous and aquatic.

Mr. R. Brown makes the Typhæ of Jullien but a section of his Aroidæ. He observes that their seeds are pendulous; those of Sparganium each in a dry drupæ, those of Typhæ in that kind of membranous clove coffyle termed by Gærtner utriculus.
TYPHIUM, a name used by some authors for colt’s-foot. TYPHIUM, in Ancient Geography, a mountain of Greece, in Boeotia.

TYPHLE, or TYPHLINE, a name by which some authors have called the fifth more usually known by the name of the acus.

TYPHLINUS, in Zoology, the name by which the Greeks, and from them others, have called the cecilia, or slow-worm.

TYPHLOSIS, from τυφω, blind; blindness.

TYPHODES, Febris, in Medicine. See Typhus.

TYPHOMANIA, probably from τυφω, smote, and μασσε, phrenesy, but the propriety of which is not very obvious, a term used by the older writers in medicine to denote a state of disease in which lethargy was combined with delirium, or, as some have stated, an apparatus with actual watchfulness: whence the appellation has been deemed synonymous with coma vigilia. A more accurate pathology has diffused these vague distinctions; for every degree of morbid dormolency, from lethargy up to complete apoplexy, appears to be the same in kind, differing only in violence. See Apoplexy, Coma, and Lethargy.

TYPHON, or Typhus, in Mythology, the name of one of the rebel giants.

The fable of Typhon is one of the most mysterious among the ancient mythologists. The Greeks and Latins, depending upon traditions received from the Egyptians, describe him as a horrid monster, produced, as they say, from the Earth by the jealous Juno, in order to avenge herself of Latona, her rival. Hefiod says, that this giant was the son of Tartarus and Terra. Manilius expresses himself to this purpose:—

"----- Merito Typhonis habentur
Horrenda fedes, quern Telus fesva profudit,
Cum bellum Coio peperit."

Apollophanus makes Typhon the most terrible of all monsters; describing him as having a hundred heads, and as being able to devour flames and flames to destroy, that he equally terrified gods and men. His body, whose upper part was covered with feathers, and the extremity entwined with serpents, was so vast, that he touched the skies with his head. His wife, says this author, was Echidna, and his offspring were the Gorgon, Geryon, Cyscerus, the Hydra of Lerna, the Sphinx, and the Eagle which preyed upon the unfortunate Prometheus; in a word, all the monsters that were hatched in the country of fables. Hyginus adds, that Typhon no sooner sprung from the earth, than he resolved to declare war against the gods, and to revenge the overthrow of the giants. A contest took place between Typhon and Jupiter, which, after various dreadful conflicts, terminated in the defeat of Typhon, who, being pursued by Jupiter and assailed with thunderbolts, was at last driven into Sicily, and there buried under mount Etna. The conjectures of modern authors in their attempts for explaining this fable have been very various. Some, among whom is G. Vossius, are of opinion that Typhon was the name of Og, king of Bashan. Bochart supposes that he was the same as Enceladus. Some others think that Typhon was king of Sicily, and others that he was the same as Efu. Huet apprehends that Typhon was the legislator of the Hebrews, become extremely odious to the Egyptians by the destruction of their first-born. Banier supposes, that Typhon and his brother Osiris were much more ancient than Moses; and that the idolatrous worship of the oxen Apis and Mnevis, consecrated to Osiris, was spread through Egypt before the Israelites entered there, since it was upon this model, according to Selden, that Aaron made the golden calf which the Jews worshipped in the wilderness. A dispute arose between Typhon and Osiris, and he was drowned, as it is said, on the authority of Herodotus, in the marshes of the lake Serbonis, or killed in a battle fought with his nephew Orus, whence the Egyptian priests made the people believe, that the gods interred themselves in avenging Osiris, by destroying his persecutor with a thunderbolt. Thus, however, perished the cruel tyrant of Egypt, and the kingdom was left to young Osiris, under the regency of his mother Isis. For further particulars we refer to Banier’s Mythology, vol. i.

TYPHON, or Typho, in Physics. See Whirlwind.

TYPHONIS INSULA, in Ancient Geography, an island of the Mediterranean sea, upon the coast of the Troade.

TYPHUS, Febris Typhos, in Medicine, a term used by Hippocrates to denote a fever of an inflammatory character, probably derived from τυφω, I inflame. The disease, however, not having been very distinctly described by that writer, other authors have applied the term to fevers of a nervous character, and it is now received as the appellation of ordinary low fever, and islands in opposition to inflammatory fever. In short, by the word typhus, we now understand the common contagious fever of this and other northern climates, which has received various appellations, according to the situations in which it has prevailed, or to some of its symptoms, or to the degree of its severity; such as hospital, gazol, and ship fever; petchial, spotted, or purple fever; putrid, malignant, infectious fever; continued fever, &c. This common fever, or typhus, differs essentially from the eruptive fevers, small-pox, morse, chicken-pox, and scarlet fever, which affect any individual but once during life; it differs from the plague of the East, which is accompanied with buboes, and from the yellow fever, the bilious remittent fever of hot climates; and from the remittent and intermittent fevers, the effect of marsh effluvia, in more northern latitudes: but, under all the circumstances and denominations above alluded to, it appears to be of the same nature, and is usually understood by physicians in Europe, when they speak of fever simply. As we have entered at great length into the nature of this disease, and the doctrines of pathologists respecting it, under its proper head, it would be superfluous to enter more largely into the subject here. See Fever.

TYPIC FEVERS, an appellation given by medical writers to those fevers which are regular in their attacks, and in their general period: they are thus called by way of distinction from the erratic, which observe no regular type, or determinate appearance.

TYPOGRAPHY, formed from τυγγω, τυγγω, and χρώμα, writing, the art of printing.

TYPOLITES, or Typolithus, formed of τυγκω, types, and λίθος, stone, in Natural History, names given to stones or fossils, on which are impressed the figures of various animals and vegetables. See Stones, Adventitious Fossils, &c.

TYR, in the Ethiopian Calendar, the name of the fifth month of the Ethiopian year. It commences on the 25th of December of the Julian year.

TYR, in Mythology, a name given to a warrior deity, the protector of champions and brave men, invoked by the ancient northern nations.

The third day of the week was consecrated to Tyr, from whom, it is said, the name given to it in most of the northern languages is derived; it is called in Dan. Tjoflag, or Tiflag; in Sued. Tjoflag; in English, Tirftay; in Low Dutch, Diuglag; and in Latin, Dies Marii: whence it is inferred, that Tyr answered to Mars.

The
The Germans, in High Dutch, call this day Eric-haag, from the word heric or harce, a warrior, which comes to the same thing. 

Tyr must be distinguished from another deity called Thor. 

TYRA, in Ancient Geography, a town of European Sar- 
matica, upon the banks of the river Thrasus; sometimes called Ophiula. 

Tyra, in Geography, a river of Germany, which runs 

into the Belin, one mile W. of Kelbra, in the county of 

Schwartzburg. 

TYRAMBE, in Ancient Geography, a town of Asiatic Sar- 
matica, 660 fladia from the river Rhombites, according to 

Strabo; but Ptolemy places it between Azabites Mitra and 

the mouth of the river Attica. 

TYRAN, or Tyrens, in Geography, a small island in the 

Red Sea. N. lat. 27° 40'. E. long. 34° 48'. 

TYRANNICIDE, formed of tyrannus and cede, i kill, 

denotes the act of killing a tyrant. 

TYRANNIO, in Biography, a Greek grammarian, was 

a native of Amida, in Pontus, and a disciple of Dionysius of 

Thrace at Rhodes. Upon the conquest of the kingdom of 

Mithridates by Lucullus in the year B.C. 70, Tyrannio 

became a captive, but was liberated by Murena, and taken 

to Rome, where he opened a school, in which he gave in- 

struction to the son and nephew of Cicero, and also to 

Strabo. In this situation he acquired considerable wealth, 

and accumulated a library of more than 35,000 volumes. 

Among other valuable works which he possessed, he pre- 

ferred the writings of Aristotle and Theophratus, which 

he obtained from the librarian of Syria, and which he after- 

wards imparted to Andronicus of Rhodes. Tyrannio lived 

to an advanced age; but none of his works are extant. 

Bayle. 

TYRANNUS, in Ornithology, a name given by some to 

the lanius, or butcher-bird, a species of hawk not larger than 

a thrush, but a very fierce and fatal enemy to the small 

birds. See Lanius. 

TYRANNY, in Political Government, is the exer- 

cise of power beyond right, to which nobody can have a right; 

and thus it is distinguished from Ufurpatian (which fee) 

or the exercise of power which another hath a right to: and 

it is the use of power which any one polleth, not for the 

good of those who are subject to it, but for his own private 

separate advantage; when the governor, however, intituled, 

makes not the law, but his will the rule; and his command 

and actions are not directed to the preservation of the 

property of his people, but the satisfaction of his own ambition, 

revenge, covetousness, or any other irregular passion. 

It is a mistake to think this fault peculiar to monarchies; 

other forms of government are liable to it as well as that. 

For wherever the power that is put in any hands for the 

government of the people, and the preservation of their 

property, is applied to other ends, and made use of to im- 

povery, haras, or seduce them to the arbitrary irregular 

commands of those that have it, there it becomes tyranny, 

whether those who thus use it are one or many. 

Accordingly we read of the thirty tyrants at Athens, as 

well as one at Syracuse; and the intolerable dominion of the 

decemviri at Rome was nothing better. Every wan- 

ton and saucy restraints of the will of the subject, whether 

practised by a monarch, a nobility, or popular assembly, is 

degree of tyranny. 

Whenever the constitution of a state veils in any man, 

or body of men, a power of destroying at pleasure, without 

the direction of laws, the lives or members of the subject, or 

of alienating their property, or of depriving them of their 

liberty at pleasure, such constitution is tyrannical. In a 

word, wherever law ends, tyranny begins, if the law be 

transgressed to another's harm. And whoever in author- 

ity exceeds the power given him by the law, and makes 

use of the force he has under his command, to compacts that 

upon the subject which the law allows not, ceases in that to 

be a magistrate, and, acting without authority, may be 

opposed as any other man, who by force invades the right 

of another. The end of government, whatever be its name or 

nature, is the good of mankind: and upon this principle, 

whoever uses force without right, as every one does in 

society who does it without law, puts himself into a state of 

war with those against whom he uses it; and in that state 

all former ties are cancelled, all other rights cease, and every 

one has a right to defend himself, and to redress the aggrieved. 

If it be asked who shall be judge; whether the prince or 

legislative act contrary to their will? The answer is obvious, 

the people shall be judge; for who shall be judge whether 

the trustees or deputy acts well, and according to the 

trust repose in him, but he who deports him, and must, 

by having deputed him, have still a power to dissuade him when 

he fails in his trust? If this be reasonable in particular 

cases of private men, why should it be otherwise in that of 

the greatest moment, where the welfare of millions is con- 

cerned; and also where the evil, if not prevented, is greater, 

and the redress very difficult, dear, and dangerous? Locke, 

of Civil Government, ch. xviii. and xix. in his Works, 

vol. ii. p. 214, &c. 

TYRANT, Tyrannus, among the Ancients, denoted 

simply a king or monarch. 

But the ill use several persons invested with that character 

made of it, it has altered the import of the word, and tyrant 

now carries with it the idea of an unjust and cruel prince, 

who invades the people's liberty, and rules in a more de- 

potic manner than the laws of nature, or the country, do 

allow. 

The term tyrant, we are told, became odious among the 

Greeks, those zealous lovers of liberty, almost as soon as 

introduced; but Donatus affirms us, it was never taken to 

among the Romans till the latter ages of that empire. 

The motto of a tyrant is, Oderint dum metuant. Rowland 

contends, that this word, as well as the correspondent Greek 

and Latin, is derived from tir, Welsh and Erfe, land, and 

rbaner, Welsh, to bear; q. d. tirbaner, a earcer or divider of 

TYRANTS, Thirty, an appellation under which the 

thirty tyrants, established by the Lacedaemonians in Athens, 

in order to enslave and keep it in slavery, are denominated. 

Thrafulus formed the generous design of driving them from 

Athens, and succeeded; upon which event Cornelius Nepos 

has remarked, that many have defied, and few had the 

happiness to rescue their country from a single tyrant! but 

Thrafulus delivered his from thirty. 

One of the means which these tyrants used for carrying 

on their scheme of enslaving the Athenians, was the ordering 

of the suffrages of the Alopeagites to be public, that they 

might manage them as they pleased. See Montefieu's 

TYRAS, in Ancient Geography. See Dniestr. 

TYRAWLEY'S Point, in Geography, the south-west 

extremity of Tresvanion's island, in the South Pacific ocean. 

S. lat. 10° 48'. E. long. 163° 41'. 

TYRBE, thyreus, in Antiquity, a festival celebrated by 

the ancients in honour of Bacchus. 

TYRE, in Ancient Geography, a city of Phoenicia, distant 

23 miles from Sidon, its rival, according to the Itinerary of 

Antoninus. (See Sidon.) This city was anciently de- 

ominated
minated Sor, whence it derived its name (see Sur), and was called the daughter of Sidon. It was situated upon the sea. Tyre has been distinguished, in the order of time, into three cities; as Tyre on the continent, or Pale-Tyre (old Tyre), Tyre on the island, and Tyre on the peninsula, after the island was joined to the main land. There were four different places in Phoenicia which bore the name of Tyre. Tyre, of which we are now speaking, had two havens, one looking towards Sidon, the other towards Egypt. These havens were formed by the isthmus which joined the island to the main land, and were called, the one open, the other close. The former looked towards Egypt, and was the most southern of the two: it was accordingly called the Egyptian port. The Eristi Edrisi says, that one of these ports had an arch over its entrance, through which the shipping passed; and that it was fortified with a chain drawn across it. These bays or ports are still pretty large, and, in part, defended from the ocean by a long ridge, resembling a mole, stretching directly out on both sides from the head of the island; but whether these ridges are walls or rocks is uncertain; they were most probably walls. (See Sur.) Tyre, including Pale-Tyre, was 19,000 paces in circumference, whence it is plain, that Tyre on the island, and old Tyre on the main, were considered as but one city, after the isthmus was thrown up between them; and possibly they might have had buildings contiguous to each other. If Pliny's numbers are right, the old city must have been by much the most extensive part of the whole, and especially as the place appears at this day. According to Pliny, the island was but 700 paces from the continent: whereas Strabo says that it was 30 fadia, or somewhat more than three of our miles from Pale-Tyre; and according to the same geographer, Tyre was wholly an island, like Aradus, excepting the artificial isthmus, which formed it into a peninsula. The city by itself, according to the statement of Pliny, measured only twenty-two furlongs, or not quite three of our miles, and this is too great an allowance, if we may rely on our modern accounts; which reprent Tyre itself as a small city in extent, though it covered the whole island; and the scantiness of the space on which it stood, induced the inhabitants to raise their buildings so high, which plan they would have otherwise avoided, from fear of earthquakes, that threatened them with destruction. At present the island appears to have been, in its natural state, of a circular form, hardly containing forty acres of ground; and the foundations of the wall which surrounded it are still to be seen at the utmost margin of the land. If it be true then, that the whole circuit of the old and new Tyre amounted to 19,000 paces, or 19 Roman miles, and that they were dilant from each other but 33 fadia, or 3½ of the same miles, it is evident that the old city stood upon a much greater space of ground than the new. A considerable part of the island was, what we call, made ground. The buildings were in general spacious and magnificent; and above the reef appeared the temples built by Hiram to Jupiter, Hercules, and Astarte. The walls of Tyre were 150 feet high, proportionably broad, and firmly built of large blocks of stone, bound together with white plaster. For its present reduced and ruinous state, see Sur.

Herodotus ascribes to Tyre situated on the island a very ancient epocha: and its priets, according to his account, reprent that their temple, which was of greater antiquity than the city, subsisted about 450 years before the Christian era. Josephus refers the foundation of this city to 1255 years B.C., whilst the Israelites were under the government of judges. But these dates cannot be applied to insular Tyre, which was more modern than that of continental Tyre, which is said to have been built and known before the Israelites took possession of Canaan. (See Joshua, xix. 29.) The Sidonians, with a view of extending their commerce, sent out a colony to ancient Tyre, which contributed very much to its augmentation; and hence it became powerful, eclipsed the metropolis, and became itself the metropolis of several cities, which it furnished with colonies. The Tyrians were not known in the time of the Trojan war, according to Strabo (ib. xvi.) and Homer, who often speaks of the Phoenicians, mentions only the Sidonians, under which general appellation the Tyrians were probably comprehended.

Josephus and Theophilus Antiochus begin the succession of kings of Tyre with Abibal, upon the authority of Menander the Ephesian, and Dias a Phoenician, authors of credit. Abibal was contemporary with David, and his reign is referred to 1056 B.C. He was succeeded by his son, Hiram (1046 B.C.), who maintained an intimate friendship with David and Solomon: under this prince the kingdom of Tyre was very prosperous and flourishing; the city was enlarged, and by means of a dam, joined to the temple of the Olympian Jupiter, standing in an island. He also built two temples, one to Hercules and another to Astarte, enriching them with donations. Besides erecting a statue to Hercules, he repaired the temples of other gods, and endowed them to a very great value. Titian relates, on the authority of three Phoenician historians, that he gave his daughter in marriage to king Solomon, who, by her influence, was induced to worship Astarte, the goddess of the Sidonians. Hiram, having lived fifty-three years, and reigned thirty-four, was succeeded by his son, and a series of other princes, until Nebuchadnezzar, king of Babylon, laid siege to the city, in the reign of Ithobal II. 585 years B.C. This siege lasted thirteen years (see Ezekiel, xxvi. 8, &c.;) and at last it was taken by Nebuchadnezzar and utterly destroyed. Some Phoenician historians have said, that Ithobal was succeeded by Baal; nor is it improbable, that the inhabitants of Tyre, during the siege, retreated with their effects to an island about half a mile distant from the shore, where they built for themselves a new city; which, after the destruction of the old town, submitted to Nebuchadnezzar, who appointed Baal to be his viceroy; and that, upon Baal's death, in order to render the government more dependent on the Assyrians, he changed the royal dignity into that of temporary magistrates, called suffetes, or judges, 562 years B.C. After Tyre had been thus governed for some years, the royal dignity was restored, and Balator created king, 556 B.C. Both he and his successors were dependent on, and tributary to the Assyrians for seventy years; at the expiration of which they recovered, according to the prophecy of Isaiah (ch. xxxiii. 15, 17), their ancient liberty. In the year 480 B.C., under the reign of Marten, the Tyrians, as well as the other Phoenicians, were tributaries to the Persians, though they had a king of their own, being favoured by the Persian monarchs on account of the services which they rendered to them in their naval expeditions. About this time reigned Strato, whose accession to the throne, in consequence of the insurrection of the slaves, is particularly related by Justin, lib. xviii. cap. 3. He was succeeded by his descendants, among whom was Azelmic, in whose reign happened the memorable siege and reduction of Tyre by Alexander the Great. This siege commenced about the year 333 B.C. which was rigorously carried on, and obstinately reafifted by the Tyrians. At length Alexander, having battered down the walls, took the city by storm, 332 B.C., after seven months siege, and fully executed the sentence which the Tyrians had, by their pride and other
vices, drawn down upon themselves and their country. The city was burnt down to the ground, and the inhabitants, (those whom the Sidonians secretly conveyed away in their ships excepted,) either destroyed or enslaved by the conqueror, who, upon his first entering the city, put 8000 to the sword, caused 2000 of those whom he took prisoners to be crucified, and sold the rest, to the number of 30,000, says Arrian, for slaves. His cruelty towards the 2000 that were crucified was highly unbecoming the character of a generous conqueror, and reflects eternal disgrace upon his fame.

After the city was reduced, king Azelmic took sanctuary in the temple of Hercules, and was not only spurred by the conqueror, but restored to the throne, after Alexander had repeopled the place; for having cleared it of its former inhabitants, he planted it anew with colonies drawn from the neighbouring parts; and henceforth styled himself the founder of Tyre, a city which he had most ungenerously destroyed. From hence, having unchained Apollo, whose statue the Tyrians had fattened, during the siege, with golden chains, to the altar of Hercules, returning him thanks for his intention of coming over to the Macedonians, and offering sacrifice to Hercules, Alexander continued his march into Egypt. This city afterwards regained a considerable degree of power; for in the year 313 B.C. it sustained a siege against Antigonus of fifteen months, before it was compelled to capitulate. It afterwards belonged to several masters, until Antiochus the Great, who took possession of it in the year 218 B.C. It afterwards became subject to the Seleucids. Caius, a Roman governor, sold it to Marion, whose wealthy enabled him to purchase the principality. Tyre, formerly called Tyor (Jos. xix. 29.), renowned for its trade and the numerous colonies which it transplanted into several parts of the world, and the wars in which its inhabitants valiantly engaged, was in all its glory when Alexander took it, about 300 years after its capture by Nebuchadnezzar. Tyre was still in great repute in the time of our Saviour. (See Matth. xii. 21. xxv. 21. Mark, iii. 8. Luke, vi. 17.) It made a considerable figure in the reign of Herod Agrippa, who designed to wage war against it, if it had not secured peace by its deputies. (Acts, xix. 20.) When the apostle Paul travelled through this place, it had some Chiritian inhabitants. (Acts, xxii. 4.) In the second century it was a bishop's see; and St. Jerome tells us, that in his time it was the most famous and most beautiful city of Phoenicia, and a mart for all the nations of the world. This ancient father alleges this circumstance as an objection to the accomplishment of Ezekiel's prophecy (ch. xxvi. 14.), and replies to it, that the prophet's declaration is to be understood as intimating, that Tyre should no longer be the queen of nations, and enjoy the same authority and dominion as it possessed under Hiram, and its other kings, but should be subject to the Chaldeans, Macedonians, Ptolemies, and lastly to the Romans. Others have supposed, that the prophet does not speak of the ruin of Tyre by Nebuchadnezzar, and Alexander the Great, but of its final destruction, of which the latter events were forerunners. And indeed Tyre, as we have said, is now only a poor village, inhabited by fishermen (see Sun.); so that the prophecy is fulfilled, which declared, "that it should be a place for fishermen to dry their nets on." Ezekiel may also be explained by the prophet Isaiah (xxiii. 15.), who limits the destruction of Jerusalem to 70 years. But the prophecy of Ezekiel may be more satisfactorily explained, with Sir J. Marsham, Le Clerc, and other learned authors, who interpret it concerning Old Tyre, i.e. Palætyrus, which flooded a little lower on the continent, and the best materials of which were used by Alexander the Great, in making the isthmus which now joins Tyre to the continent. (See Q. Curtiius, i. iv. c. 2.) This Tyre was destroyed by Nebuchadnezzar, and never rebuilt. The inhabitants, finding themselves upon the brink of destruction, removed, as we have already said, with their wives and children, and most valuable goods, to the island of Tyre, where they built a city of the same name; so that Nebuchadnezzar, according to the prophecy (Ezek. xxix. 18.), was no gainer by his expedition. The Jews at Tyre, as Josephus informs us, suffered much from the Tyrians. This city was formerly the metropolis see of the province of Phoenicia. Tyre was transferred to the Arabsians, with the rest of Syria; and before it was reduced to its present miserable state, it was twice besieged by the Christians in the time of the Crusades, viz. in 1112, and again in 1124. It was unsuccessfully attacked by Saladin in 1192; but in 1291, Kabil, sultan of the Mamelukes, obtained it by capitulation, and razed its forts.

TYRESIO, in Geography, a sea-port town of Sweden, in Sudermanland; 9 miles S.E. of Stockholm.

TYR, a lake of Norway, in the province of Aggerhus; 15 miles N.W. of Christiania.

TYRLÆUM, in Ancient Geography, a considerable town of Afia, in Paphidia, called also Tyrox.

TYRINGHAM, in Geography, a town of Massachusetts, in the county of Berkshire, containing 1689 inhabitants; 140 miles W. of Bolton.

TYRIUM MARMOR, a name given by the ancients to a species of marble of a beautiful white, sometimes free from veins, and sometimes variegated with dusky blackish-grey ones. When pure, it was little inferior to the Parian, and often was used instead of it by the Iturians. See MARBLE.

TYRNAU, in Geography. See TIRNAU.

TYRNAU, a town of Moravia, in the circle of Olmutz; 14 miles N.W. of Olmutz.

TYRNITZ. See DYNITZ.

TYRNSSTEIN. See DIERNSTEIN.

TYRO. See TYRICUM.

TYROCINIUM, TYROCIUS, formed of tyro, a raw beginner, a novicite or apprenticeship in any art or science.

We have several writings under the title of tyricini; tyricium chymicum, tyrocinium chirurgicum, &c., containing the rudiments of those arts, accommodated to the apprehensions of beginners.

TYROL, in Geography, a citadel which gives name to the Tyrolese county; 1 mile N. of Meran. N. lat. 46° 37'. E. long. 11°.

TYROLESE, or Upper Austria, a county, bounded on the north by Bavaria, on the east by Salzburg and Carinthia, on the south by Italy, and on the west by Bavaria and the Grisons; in this circle are included the county of Tyrol Proper, the bishopric of Trent, and the bishopric of Brixen. The bishopric of Trent is situated to the south; the bishopric of Brixen occupies the north-east part; and the county of Tyrol the centre. This county is mountainous, and capable of making a powerful stand against an invading enemy; but the Tyrolian mountains, though covered with snow to the very utmost summits of them, are also fertile; where are found not only the finest woods, abounding in a variety of game, but also large and good corn-fields; or, where these mountains are barren, there are, for the most part, mine works, or excellent marble, of all colours. Corn thrives well in many, nay in most places here; and in some places flax. On the eminences grow also all sorts of fine fruits which Italy yields, and likewise small woods of chestnut trees, together with fine vines. Among the wild beasts here
there are chamois and wild goats. There are, likewise, in this county, several species of precious stones, as granites, rubies, amethysts, and emeralds, a species of diamonds, agates, cornelians, chalcedonies, &c. Hot baths and medicinal springs are found in several places; at Hall are profitable falk-pits. Not far from Schwartz is a mine of silver and copper; and some miles distant from the latter is also a mine work, which yields a very soft and malleable copper. The copper contains in it some silver and gold. Good lead, together with fine mineral colours, alum, vitrilo, and fine silver ore, are also found here. The principal rivers in this county are the In, or Inn, the Adige, the Lech, and the Iser. In this county are twelve towns and ten villages, which have markets. The common people here, exclusive of the sufficiency which the mines and falk-works yield them, have not much to earn; so that a great part of them seek for sufficiency out of the country, either by trade or labour. Tyrol was formerly a part of Rhetia, but, in the fifth century, the greatest part of it defended to the dukes of Bavaria, and this was afterwards reckoned in Noricum; but, over the southern part, the Longobards, at the same time, extended their dominion. The dukes of Bavaria appointed margraves here; but Henry the Lion, duke of Bavaria and Saxony, being, in 1180, put under the ban of the empire, by the emperor Frederic I., this laft dismembered the present province of Tyrol from Bavaria, investing therewith the margrave Berchtold, under the title of duke of Meran. Otto II., grandfons to this Berchtold, dying without male issue, in the year 1248, this county came to count Albrecht III., who resided at the citadel of Tyrol, gave up the title of duke of Meran, and ruled the whole country the county of Tyrol. Tyrol had, afterwards, frequently princes of its own, of the house of Aultria; the laft of whom, named Sigismund Francis, died in 1665, upon which the emperor Leopold received homage on that account, in person, at Inpruck; and by the peace of Preiburg it was ceded to Bavaria. The high sovereign colleges over Tyrol, when subject to the house of Aultria, were seated at Inpruck; and towards the maintenance of the military flate, it contributed yearly 100,000 florins.

TYRONE, a county of Ireland, in the province of Ulter, which is entirely inland, and very irregular in its shape. On the north it has the county of Derry; on the west, Donegal; on the south, Fermanagh and Monaghan; and on the east, Armagh, with Lough-Neagh. Its divisions from these counties are seldom marked by nature, but the river Blackwater bounds it for about 30 miles on the south-east and east, and the rivers Fin and Foyle for about 10 miles on the north-west. The greatest length from east to west is 43 Irish miles, or 544 English; and the greatest breadth 33 Irish, or 42 English. The area measures 457,700 acres, or 724 square miles Irish, which is equal to 751,387 acres, or 1163 square miles English. Dr. Beaufort states the number of houses at 28,704, which, at 4. per house, would give a population of near 185,000, or about 40 to each square Irish mile. As this was the statement in 1792, the increase must have been considerable. The number of parishes is only 35, and these have 38 churches. Most of these are in the diocese of Armagh, but there are some in the dioceses of Derry and Clogher. Tyrone is represented in the imperial parliament by two members for the county, and one for the borough of Dungannon. The northern part of the county is rough and mountainous. The Cairntogher and Manterly mountains occupy a large space; and to the south of these are the high hills called "Belfy Bell" and "Mary Grey." These produce very little, being in general wet and spongy. Where, however, gravel or any porous substance forms the sublustrum, the surface is dry and wholesome, and well calculated for pasture. The other parts of the county contain very good land; and some districts are remarkable for their fertility, especially the neighbourhood of Dungannon, extending eastwards towards the Blackwater, and about Cookstown. The produce of this county, and the flate of manufactures, agree in the leading features with those of the other northern ones. The farms, except in the mountainous districts, are usually small; and the produce in general oats, barley, potatoes, and flax. The linen manufacture is extensively carried on; and it gives a favourable idea of the industry of the inhabitants, to learn from the county survey, that much cultivated ground has been gained from the bogs and mountains. "In all parts of this country," said Dr. Beaufort in 1792, "cultivation is creeping, and that not slowly, up the sides of all the hills and mountains that are capable of improvement." In this county, the culture of the grains called firim was commenced by Dr. Richardson at Clonofede, near May, the excellencies of which have been laid before the public in various publications, and have attracted the attention of many eminent agriculturists. Many parts of Tyrone contain large quarries of lime-stone, though it is not generally used for manure. There are also many quarries of free-stone; and good mill-stones are hewn out of detached rocks. It is probable that iron-ore is abundant; but without greater plenty of fuel, it can be of no use. Clay fit for bricks, and for various kinds of pottery ware, is also found in many places. But that mineral which has engaged most attention is coal. At Coal-Iliffand, in the eastern part of the county, coal-works have been carried on with some success. Five pits were working in the year 1800, with the appearance of industry. There seemed, however, a want of encouragement; and the canal, which had been made from this place to the Blackwater, was choked up with mud and weeds. A similar account may be given of the colliers at Drumgal, near Dungannon; so that though above 140,000l. were expended from the national purse in making canals, independently of private exertions, the object has not been obtained; and the Newry canal, instead of conveying the Tyrone coal to that port, to be shipped for Dublin and other places, supplies the county through which it passes with English and Scotch coal. At the time of making these grants, from 1751 to about 1770, there was a surplus of the revenue, which was spent on various public works, but not always to advantage, and very seldom with economy. In the infancy above mentioned, the object was to save the large sums sent annually out of Ireland for coal, or rather to procure a supply of that article on lower terms than it was usually obtained. But though some advantage has arisen from the Newry canal, so great has been the expense attending it, and so complete the failure of all the other parts of the speculation, except for the supply of the adjoining country, as seems to illustrate the opinion, that the interference of government in such plans seldom succeeds, and that the grants intended to encourage them are too commonly abused and perverted. It has been said, that there are indications of a rich coalmine near the village of Drumquin, in the south-west of the county, and in a district abounding with iron-ore; and as this is only 12 miles distant from Lough Erne, a canal has been recommended; but since the union, and especially since the taxes have been pressed so heavily on all ranks, such speculations are not so readily adopted. The report of Mr. Griffith, the mining engineer of the Dublin Society, on the Ulter coal district, will throw much light on the subject; but his opinion, as expressed in his report on the
Tyr

Leinster district, is not favourable to the extent or value of that in the county of Tyrone. The rivers of this county are very numerous, so that it is well supplied with water for bleaching, &c. The principal river is the Mourne, which falls through the centre of the county from south to north. It rises in the mountains near Clogher, and receives several streams before it comes to Omagh, where it is joined by the Cameron from the south; and a few miles lower, by the Po from the west. At Newtown-Stewart the united streams of the Moyla, and another river from the mountains between Tyron and Derry; and at Ardstraw the Dergh, which flows from Lough Dergh, in the county of Donegal, add their stores. Thence it runs to the town of Strabane, below which it meets the river Fin, from the county of Donegal; and they proceed together, under the name of Foyle, to the sea, being navigable for large vessels. The river Blackwater, which is also navigable for about ten miles of its course, is of great service to the eastern part of the county. The Ballinderry passes by Cookstown, and afterwards becomes the northern boundary, until it flows into Lough Neagh. The other streams are inconsiderable, and there are no lakes which deserve notice. The towns of this county are not large. Omagh is the county-town, probably on account of its central situation; for it is inferior to Dungannon or Strabane. Dungannon was the principal residence of the O'Neils, when chieftains of Ulter. These towns, and Cookstown, May, &c. are mentioned under their respective names. The country and inhabitants near Newtown-Stewart were much improved by the exertions of Lord Mountjoy, who was killed at the battle of Ros in 1798, fighting against the rebels, at the head of his regiment. His useful and benevolent plans have not, however, been neglected. About Fintona good flooring and ridge tiles are made, and a great variety of crockery ware for country use. Near Coal-Iland is a pottery, supposed to be the birth in Ireland for rough crockery ware, fire-bricks, and tiles for malt-kilns, which are of as good a quality as any imported. The fame clay made into small oblong pieces, and dried in the sun, is used for cleaning of leathers, &c. and is sent for this purpose to very distant places.

Having thus given an account of the present state of Tyrone, with respect to its productions and manufactures; it may be added, that when O'Neil, the descendant of the kings of Ulter, was compelled to submit to queen Elizabeth, he was created earl of Tyrone; and when his rebellion, in the reign of James I., occasioned the forfeiture of his possessions, this was one of the counties planted, that is, allotted to settlers, chiefly from Scotland, whose descendants are at present the principal landed proprietors.—Mr. E. Survey of Tyrone. Bean's Memoir of Map of Ireland, &c.

Tyrone, a township of Pennsylvania, in the county of Adams, containing 648 inhabitants.—Also, a township of Pennsylvania, in the county of Cumberland, containing 2604 inhabitants.—Also, a township of Pennsylvania, in Huntingdon county, containing 753 inhabitants.—Also, a township of Pennsylvania, in Fayette county, containing 980 inhabitants.

Tyrroot, a cirear of Hindooftan, in the subah of Bahour, bounded on the north by Morung, on the east by Purnah, on the south by Bogilipour, on the south-west by Haiypour, and on the west by Bettiah. Durbarung is the capital.

Tyrosis, τυροπ, formed of τυρος, chese, in Medicines, a coagulating or curdling of milk in the stomach, after the manner of chese.

Tyrrell, James, in Biography, a political writer and historian, was the son of Sir Timothy Tyrrell, kn., of Shotover, near Oxford, by Elizabeth, the only daughter of archbishop Usher, born at London in 1642, and admitted, in 1657, a gentleman-commoner of Queen's college, Oxford. Devoting himself to the study of the law at the Inner Temple, he was called in 1665 to the bar. But declining the practice of his profession, he retired at Oakley, in Buckinghamshire, and studied the history and constitutions of his country, of which he entertained more liberal sentiments than those with which he commenced his researches. In 1681 he published an answer to Sir Robert Filmer's patriarchal scheme, under the title of "Patriarcha non monachra; or, The Patriarch unmonarched." Having refused to assent to the abolition of the penal laws, and the tell again against popery, he was struck out of the commutation of the peace by James II. As a zealous friend to the Revolution, he vindicated King William's right to the crown in "Fourteen Political Dialogues," printed from 1692 to 1705; which were afterwards collected into one volume folio, with the title of "Bibliotheca Politica, &c." in which all the chief arguments, both for and against the late revolution, are impartially represented and considered. He also composed an abridgment of bishop Cumberland's work "De Legibus Naturarum," 1692, 8vo, of which work a second edition, corrected and enlarged, was printed in 1701. But his principal performance was "The General History of England, both Ecclesiastical and Civil, from the earliest Accounts of Time," concluding with the reign of Richard II., and comprised in 5 vols. fol. 1700—1704. The political purpose of this work seems to have been to confute the leading doctrines of Dr. Brady, who maintained that all the liberties and privileges of the people of England were concessions from the kings, and derived from the crown; and that the representation of the commons, as now existing, was not introduced before the 49th of Henry III. These points are still controverted, and serve to distinguish two parties in the state. Mr. Tyrrell died in 1718, in his 76th year. Biog. Brit.

Tyrrel, in Geography, a maritime county of North Carolina. It contains about 3364 inhabitants.

Tyrrel's Bay, a bay on the south coast of St. Vincent; 2 miles E. of Kingstown.

Tyrrel's Pafs. See Terril's Pafs.

Tyrrhenia, in the same Geography, that part of Italy which is now called Tuscany, but more extensive towards the north and south-east. This country has changed both its name and its inhabitants.

The Umbrians were expelled by the Pelasgi, and these by the Lydians, under the conduct of Tyrhenus, the son of the king of Lydia, whence the name Tyrrhenia. As the Tyrrenians were a religious people, and offered many sacrifices, the Greeks called them Thusi, or Thufi, denoting sacrificers, from θυσις, to sacrifice. See Etruria and Tuscany.

Tyrrhenus Sinus, a gulf of Italy, on the coast of Etruria. According to Dionysius of Halicarnassus, this gulf was denominated "Artemus Sinus."

Tyreteus, in Biography, a Greek poet, is supposed to have been a native of Miletus, and to have refided at Athens, as a poet, musician, and school-master. Somewhat deformed in body, he polished a mainly and elevated soul. In a contest between the Lacone-monians and Melitenians, the former, having experienced some ill success, are said to have consulted the oracle of Delphi, B.C. 623, and to have been directed to seek a general at Athens. The Athenians, as some say in derision, sent Tyreteus, who, by therecital of poems in praise of valor and patriotism, animated the Spartans, so that they became victorious, and reduced the Melitenians to subjection. He is said to have also given them useful
useful advice as a military leader, in consequence of which the Spartans conferred upon him the right of citizenship, and honoured him whilst he resided among them. His war-poems have been celebrated by the ancients, and particularly by Horace, who joins him with Homer in his eulogy:

"—— Poet hos insignis Homerus
Tyrtænique mares animos in martia bella

Besides these poems, he composed, also, "Moral Precepts," and a work "On the Polity of the Lacedaemonians." Some fragments of his "War-Poems" are extant, which are published with the other minor Greek poets, and are said to be characterized by a masculine simplicity. Modern scholars have corrected the "Gen.

TYRWHITT, Thomas, in Biography, a profound scholar and acute critic, was born in 1735, sent to Eton school in 1741, and entered at Queen's college, Oxford, in 1747. In 1755 he was elected fellow of Merton college, and in 1756 acted as under-secretary of war. In 1762 he became clerk to the house of commons, which post he retained till the year 1768. At this time he retired to pursue those studies which were adapted to his genius and taste, and to the acquirements he had already made in the knowledge of ancient and modern languages, and of the old as well as modern writers of his own country. He commenced his publications with compositions in poetry; such were "An Epitaph to Florio," and Latin versions of the "Melliah" and "Splendid Shilling," with an English one of "Pindar's eighth Itholian Ode." In 1766 appeared his "Observations and Conjectures on some Passages of Shakspere," which enabled him to communicate ingenious remarks to Mr. Stevens and Mr. Reed, for their editions of the works of this great dramatist. His "Proceedings and Debates in the House of Commons in 1620 and 1621, from an original MS. in Queen's College, Oxford," appeared in the same year; and in 1768 he published a corrected and enlarged edition of "Ellys's Manner of holding Parliaments in England." His first publication in critical literature was "Fragmenta duo Plutarchi," 1773, from one of the Harvard MSS. This was followed by a very valuable edition of Chaucer's "Canterbury Tales," in 4 vols. 8vo. 1773, which, besides corrections of the original text, contains an introduction and admirable essay on the author's language and verification. In 1776, he further displayed his Latin erudition and critical acumen, by a Latin dissertation on Babirus, one of the writers of the Euporean fables. In 1777 he gave a complete edition of the poems attributed to Rowley, with a preface and glossary. In a subsequent edition, which appeared in 1778, he expresses his full conviction, with the grounds of his opinion, that they were written solely by Chatterton, and he afterwards satisfied all unprejudiced judges with regard to this subject of literary controversy. (See Chatterton.) We shall merely enumerate his remaining works, which were, an edition of a Greek poem, Περὶ Αἴων (on Stones), ascribed to Orpheus, together with a supplement to his dissertation on Babirus, 1781; "Conjectura in Strabonem," 1783; and a newly discovered "Oration of Iesus agains Meneicles," 1785. Mr. Tyrwhitt was a member of the Royal and Antiquarian Societies, and a curator of the British Museum. He died, much lamented, in 1786, in his 56th year; having established a character that was truly estimable. He bequeathed to the British Museum all those of his books which were not before in that repository. Nichols's Lit. Anecd. Gen. Biog.

TYSCA, in Ancient Geography, a country of Africa, in which there were fifty towns. Maffiufa and the Carthaginians disputed the possession of this country, and the dispute was referred to the senate of Rome, according to Appian. TYSERRA, in Geography, a town of Hindooftan, in Bahar; 32 miles S. of Dofta.

TYSHAS, among the Ethiopians, the name of the fourth month of their year, commencing the 27th of November in the Julian year.

TYSNASOE, in Geography, a small island in the North sea, near the coast of Norway. N. lat. 60°.

TYSSSENS, Peter, in Biography, was born at Antwerp in 1625, and practised painting in portraiture and history with very great success. In the latter, however, he acquired the most substantial portion of his fame; and after the death of Rubens, he was made director of the Academy at Antwerp in 1661. His compositions are rich and ingenious, and are conducted in a style more correct and grand than that of most of his countrymen, and his colour is clear and harmonious. Amongst the best of his works are his "Martyrdom of St. Benedict," in the church of the Capuchins at Bruxels; the "Crucifixion," at the Carmelites; and the "Assumption of the Virgin," at the church of St. James at Antwerp. He died in 1692, aged 67, leaving two sons, painters.

TYSTED, in Geography, a town of Denmark, in North Jutland, situated on a river which runs into the Lymford gulf; 40 miles W. of Aalborg. N. lat. 57° 3'. E. long. 8° 45'.

TYTERSAAI, a round island of the Baltic, belonging to Russia: it is pretty high, but not above ten versts in circuit. It lies 18 versts to the S.E. of Hochland. As appendages, on the western side, or in the Sound, between it and Hochland, it has four small isles, quite low, but pretty far aunder: Kleinittert, the two Viri, and Vroutcalla, and on the southern side a flony ground, seven or eight versts in length, to the Narva passage; hence, it is hardly possible to land on this island. A third part of it is rock, another third is moras, and the remaining part an arid and fertile sand-hill. The island has no springs. The feal-fisherry is here considerable: the inhabitants live together in one village.

TYTH, or rather Tüth. See Tethe.

TYTHING, and Tüthing-man. See Tithing, Deeners, Tenementale, Hundred, Wapentake, &c.

TZAGANUSKIOI, in Geography, a town of Russia, in the government of Irkutsk, on the borders of China; 48 miles S.S.W. of Selengink.

TZAGONIA, a district in the south part of the Morea, between Misitra and Cape Malio.

TZAMAMENI, a town of Asiatic Turkey, in the government of Marafch; 40 miles S.E. of Marafch.

TZAMANDUS, in Ancient Geography, a town of Asia, in the vicinity of the Lesser Armenia.

TZANATLI, in Ornithology, the name of an American bird described by Nieremberg, which, he says, has all over very long and beautiful feathers, of a fine green, and of the shining globs of the feathers of the peacock. The upper side
side of the wings is black, but their under part is of a very fine and shaded green; it has a very beautiful crest on its head; its throat and breast are of fine scarlet; the wing-feathers are very long, and very beautifully variegated with several colours. The Indians esteem the feathers of this bird more valuable than gold; they dress up the images of their gods with them. Ray's Ornithol. p. 303.

TZANG, among the Ancients, a kind of Parthian garments, according to some; but others will have them to have been shoes set with precious stones, formed into the figure of eagles, and designed for the emperor's use.

TZANI, in Ancient Geography, a people of Asia, in the vicinity of Armenia. According to Procopius, they were formerly independent, and lived a savage life; worshipping birds and other animals, and inhabiting mountains covered with thick and dark forests. They paid no regard to agriculture, and had neither corn nor pastures, so that the culture of the soil was wholly neglected. They had no restraint on their liberty, till they lost it under Justinian, to whom they voluntarily surrendered themselves. In process of time they embraced Chriltianity, which produced a total change in their manners and habits. They afterwards served in the Roman armies. Justinian contributed, by the regulations which he introduced, to civilize them. But some authors say, that at this day the Tzanius have no kind of religion; that they have neither temples, nor altars, nor priests, nor any worship.

TZANPAU, in Ornithology, the name of an American bird described by Nieremberg, and famous for the modifications of its voice, and is by many esteemed the female of the [polyglossa arviv, or] conjugatoli of the Indians.

TZAVEVAR, in Geography, a town of Ruffia, in the government of Tobolik, on the Tobol; 28 miles S.E. of Okunevki. N. lat. 55° 20'. E. long. 64° 34'.

TZAVEVOKOKHAIISK, a town of Ruffia, in the government of Kazan; 68 miles N.W. of Kazan. N. lat. 54° 50'. E. long. 47° 54'.

TZAVEVOSANGURSK, a town of Ruffia, in the government of Viatka; 100 miles S.W. of Viatka. N. lat. 57° 8'. E. long. 47° 54'.

TZARI, a town of the principality of Georgia, in the province of Kack; 93 miles S.E. of Teflis.

TZARITZIN, a town of Ruffia, in the government of Saratov, on the Volga, defended by a ditch and rampart, with artillery and a considerable garrison; 180 miles S. of Saratov. N. lat. 48° 35'. E. long. 44° 34'.

TZEKINSKOI, a fortrist of Ruffia, in the government of Irkutsk, on the borders of China; 100 miles W.S.W. of Selenginsk.

TZEPETH. See Safad.

TZERIMISH, a horde of tartars, pretty numerous, in the neighbourhood of Kazan.

TZERNA, a river of Ruffia, which runs into the Mariza, near Tzernitz.

TZERNITZ, a town of European Turkey, in Romania, near the Tzerza; 32 miles N.E. of Adriano pole.

TZERVINKA. See Zervinka.

TZETZES, John, in Biography, a Greek poet and grammarian, flourished in the twelfth century, and was distinguished by his talents, natural and acquired, and particularly by a retentive memory, insomuch that he had the whole Scriptures by heart. He was the author of "Allegories on Homer," and of "Miscellaneous Histories," in thirteen chilaidas, written in that lax kind of verse which is called politieal, or popular. The characteristics of this poet, says one of his biographers, appear to be didoulnes and infi-
U.

The twentieth letter in the alphabet, and the fifth vowel.

Besides the vowel u, there is a consonant of the same denomination, wrote v or v.

V consonant and U vowel ought to be considered as two letters, but as they were long confounded while the two u’s were annexed to one form, the old custom still continues to be followed.

U, the vowel, has two sounds; one clear, expressed at other times by eu, as obtuse; the other close, and approaching to the Italian u, or English oo, as obtund.

V, the consonant, has a sound nearly approaching to those of b and f. With b it is by the Spaniards and Galicians always confounded, and in the Runic alphabet is expressed by the same character with f, distinguished only by a diacritical point. The sound found in English is uniform; it is never mute.

V is also a numeral letter, and signifies five; according to the verb,

“V vero quinque dabat tibi, fi recte numerabis.”

When a diphthong was added at top, V, it signified 5000.

V. R. among the Romans, flood for uti rogasi, as you desire, which was the mark of a vote, or suffrage for the palling of a law.

The following abbreviations sometimes occur: viz. V. A. for Veterani assignati; V. B. vero bono; V. B. A. viri boni arbitrati; V. B. F. vir bene fidei; V. C. vir consularis; V. C. C. F. vale, conjug. charifme, feliciter; V. D. F. voto dedicatur; V. G. verbi gratia; V. L. videlicet; V. N. quinto nonarum.

V, on the French coins, denotes those that were struck at Troyes.

V, in Music, besides its numerical import of five, in ancient madrigals implies quintus pars, a fifth part added to the treble, counter tenor, tenor, and base. In instrumental music it stands for violin, as V V do in the plural for violins. V. S. are the initials of vero subito, Lat.; and voli subito, Ital., for turn over quick.

VAAH, East, in Geography, an island in the North sea, 20 miles from the coast of Norway. N. lat. 68° 26’.

VAG, East, an island in the North sea, 30 miles from the coast of Norway. N. lat. 68° 12’.

VAASOE, a small island in the North sea, near the coast of Norway. N. lat. 56° 57’.

VAARSOE, a small island of Denmark, on the E. coast of Jutland, at the mouth of the gulf of Holmsen. N. lat. 55° 53’. E. long. 10° 1’.

VAAS, a town of France, in the department of the Sarte; 21 miles S. of Le Mans.

VAC.

VAAST, St. See St. Vanst.

VABAR, in Ancient Geography, a town of Africa, on the coast of Mauritania Cæfaris. Ptolemy.

VABAR, Aa-h-can-man-kar, a promontory of the eastern part of Mauritania Cæfaris. Ptolemy. The port Salis, mentioned by Strabo, lay S. E. of this promontory.

VABBAS, a town of Africa, in Mauritania Tingitana, formerly sometimes designated Julia Campellenis.

UABE, in Geography. See HILAIU.

VABELIRAKE, an island in the Red sea. N. lat. 25° 38’.

VABRES, a town of France, in the department of the Avignon, at the union of two small rivers, which soon after run into the Tarn. Before the revolution, it was the seat of a bishop, suffragan of Alby; 2 miles S. W. of St. Afrique.—also, a town of France, in the department of the Cantal; 4 miles E. of St. Flour.

VACAN, one of the small Philippine islands, near the N. coast of Samar. N. lat. 12° 47’. E. long. 121° 15’.

VACANCY, in Philosophy. See VACUUM.

VACANCY, in Law, &c. a post or benefice wanting a regular officer, or incumbent.

The canonists hold, that the kind of vacancy is to be expressed in the imprention of a benefice.

A future vacancy, or voidance of a spiritual living, some writers call vacaturo. Devolution is a species of canonical vacancy.

VACANCY of the Throne. See Right of Crown, and Revolution.

VACANT Effects, Pradia Vacata, or Vacca, are such as are abandoned for want of an heir, after the death or flight of the former owner.

In our law-books, vagantes terres, for vacantes, expresses forfaken or uncultivated lands.

A Romish benefice is said to be vacant in curia Romana, when the incumbent dies in Rome, or within twenty leagues of it; though it be only by accident that he was there. The pope nominates to all benefices vacant in curia Romana, excepting those of the neighbouring bishoprics.

VACANT Cylinder, in Gunney. See CYLINDER.

VACARIA, Aucaria, or Cucaria, in Ancient Geography, a place of Africa Propria, on the route from Hippone to Carthage, between Vicus Augusti and Tuburbo Minus, according to the Itinerary of Antonine.

VACARIA, in Geography, a town of Egypt; 8 miles N. E. of Habafesh.

VACARICA, a town of Portugal, in the province of Beira; 18 miles S. E. of Bragança.

VACAS, a river of Mexico, which rises in the province of Guatemala, and runs into the Pacific ocean, N. lat. 14° 22’. W. long. 92° 48’.
VACAS, a small island near the W. coast of Lewis. N. lat. 58° 11'. W. long. 6° 57'.

VACATAMA, a river of Peru, which runs into the Pacific ocean, S. lat. 9° 25'.

VACATING, in Law. See IMPEZZLE.

VACATION, Non-term, all the time included between the end of one term, and the beginning of the next succeeding one. See Terms.

This intermission was called by our ancestors pass Dei, and ecclesiæ; and sometimes, the time or days of the king's peace. Among the Romans, it was called jujticiam or ferie, or dies nefastus.

The time from the death of a bishop, or other spiritual person, till the bishopric, or other dignity, be supplied by another, is also called vacation.

During the vacation of a bishopric, the dean and chapter are guardians of the spiritualities, by the canon law; and of common right they are so at this day in England, and the archbishop hath this privilege only by prescription or composition, to whom with us, during the vacancy of any see within his province, all episcopal rights of the diocese belong; and all ecclesiastical jurisdiction is exercised by him and his commissiories. But when an arch-episcopal see is vacant, the dean and chapter of his diocese are guardians of the spiritualities, and exercise the spiritual jurisdiction of his province. And the perquisites that happen by the execution of such power belong to the guardian, but the newly-elected bishop may by law, after election and confirmation, execute the fame. See Custos Spiritualium.

The custody of the temporalities of every archbishopric and bishopric within the realm, in the time of vacation, belong to the king by his prerogative; and upon the filling of a void bishopric, the king, and not the new bishop, hath the temporalies of it from the time that the fame became void to the time that the new bishop shall receive them from the king; which the king ex gratia may grant him by his letters patent after his confirmation, and before his consecration: but after he is consecrated, invested, and installed, he may sue for his temporalies out of the king's hands by a writ directed to the executor; the metropolitan testifying the time of consecration. See Custos Temporalium.

During the vacation of a benefice, the profits, by the common law of the church, were to be laid out for the benefit of the church, or reserved for the successor; and by special privilege or custom the bishop or archdeacon might have the same, wholly or in part; and it is said, the king might take the profits of a free chapel, and the patron, those of a donative. But by statute 25 Hen. VIII. c. 11, it is enacted, that the tithes and profits of spiritual promotions, offices, benefices, and dignities, during the time of their vacation, shall belong to the person next preferent, promoted, instituted, inducted, or admitted, towards the payment of his first-fruits. Anciently, upon the death of an incumbent, the rural dean, without any formal fequestration, took the vacant benefice into his custody; but in process of time, the chancellor of bishops, or their archdeacons, laid claim to this jurisdiction, and by forms of fequestration aigned vacant churches to the acomini or lay guardians of the church: and now the ordinary way of managing the profits of vacation is by fequestration granted to the church-wardens, who are to manage all the profits and expenses of the benefice for the successor; whose right to the profits commences from the voidance of the benefice, and to whom the fequestrators are to account for such as they have received, deducting their reasonable expenses, and those of supplying the cure during the vacation. By 28 Hen. VIII. c. 11, an incumbent before his death may make his testament of all the profits of the corn growing upon glebe lands which he has maimed and fown: but if his successor is inducted before the fequestration of it from the ground, the successor shall have the title of it; otherwise, if the parcnon dies after the fequestration of it, and before it is carried off, the successor shall have no title. Where there is no proper lease of tithes, the person who receives them shall be accountable to the executor for such received by him, and which became due before the incumbent's death, and to the successor for tithes which he received, and which became due after the incumbent's death; but glebe lands, and tithes demised or leased, are comprehended under statute 11 Geo. II. c. 19, which enacts, that the executors or administrators of a tenant for life may, in an action upon the acafe, recover of the under tenant, if such tenant for life die on the day on which the rent was made payable, the whole, or if before such day, a proportion of such rent, according to the time such tenant for life lived, of the last year, or quarter of year, or other time in which the said rent was growing due. As to modes in lieu of tithes, which, if taken in kind, would have been due before the death of the incumbent, whereas the modus for the same is not due till after his death, it seems that the executors are not entitled to the said modus, nor any part thereof, but that the whole shall go to the successor.

Cicero, in his Orations, mentions a law, by which the priests were exempted from service in all wars, except only in upproars, and civil tumults; which exemptions he calls vacations.

VACCA, in Ancient Geography, a town of Spain, in the Pyrenean mountains, according to Isidore.

VACCA, Vacca, Bata, or Vagenje Oppidum, thus differently named by Sallut, Ptolemey, Plutarch, and Pliny, Bayjeh, a town of Africa, in Numidia, 10 leagues from Metternic Oppidum. According to Sallut, it belonged to Jugurtha, and he says, that when it revolted, he established it in Italics. Metellus was sent to reduce it.

VACCA, or Vacca, a river of Spain, in Lusitania, which pursuas its course from E. to W. passed to Talavera, and soon after ran into the sea.

VACCA, La, in Geography, a small island in the Mediterranean, near the S. coast of Sardinia; 3 miles S. of St. Antioco.

VACCA, in Zoology, the female of the ox-kind. See Cow.

VACCARIA, in Botany, so named from vacca, a cow, because, according to Ambrofines, cows are fond of the plant. His Vaccumia, like that of Dodoneus and Geraert, is the Linnaean Sophorai Vaccumia, referred by the writer of this to Gypsophila, see that article; with which genus its bell-shaped angular calyx, roundish capsule, and whole habit, accord so exactly, that we are at a loss to account for Linnaeus's having placed it elsewhere. The Vaccaria of Tabernamentus is very different, being our Tartritis glabra: an herb agreeing with the former in the glancious, smooth, entire leaves, of its stem at leaf, but otherwise having no character or property in common therewith, and certainly of too unfrequent occurrence, as well as too slender a habit, to afford much support for a dairy. The above Gypsophila belongs to a natural order of plants to which farmers have, as yet, scarcely recurred for any fort of fodder, the Campian tribe. Might not the name before us authorize an experiment at leaf, upon the qualities of this plant, as well as on those of its near relation Silene inflata? Spergula arvensis, one
VACCINATION.

one of this order, is reported to enrich the milk of cows, but has not come into any general notice. See Silent, sect. 2, and Spergula, n. 1.

VACCARY, VACCARIA, in our Old Writers, a house or place to keep cows in; a dairy-house, or cow-pasteur.

VACCEI, VACCÆANS, in Ancient Geography, a people of the interior of Hither Spain, S. of that part of the country which was inhabited by the Asturis. According to Diodorus, the Vacceans were the most genteel and polished of the Celtihrians. They were subjigated by L. Lucullus and Ch. Marcellus. It appears that they were a considerable people by the number of towns which Ptolemy assigns to them.

VACCINATION, or the Cow-pox inoculation, in Surgery, one of the greatest and most important discoveries of modern times. The discovery of the circulation of the blood, made by the celebrated Harvey, has unquestionably been the source of infinite improvement in every part of the healing art, and produced incalculable benefit; but vaccination, the discovery of another Englishman, the immortal Jenner, is a thing, which in its consequences certainly outdoes every previous innovation in practice, since it may be said to have annually the lives of millions.

Vaccination being the only known means of arresting altogether the fatal ravages of the small-pox, the most depopulating contagion upon the face of the earth, mankind will probably for ever feel a deep interest in the subject. In fact, nothing less than the well-stablished total extermination and permanent cessation of the small-pox, could ever justify a diminution of the laudable solicitude of the public for the continuance of vaccination. For it is not to be presumed, that a still milder and more effectual means of rendering the human body insusceptible of the effects of the small-pox contagion, will ever be discovered. A milder method, indeed, is hardly conceivable; since the symptoms produced by it amount only to a very slight indisposition, which never has any fatal or unpleasant consequences. Its efficacy also is now fully confirmed by abundance of evidence, collected from the united observations and experience of the best informed practitioners, who, it is obvious, can have no interest in the success of vaccination, but the general good of their fellow-creatures. Were medical men so bald as to suffer their judgment to be influenced by mercenary considerations, they would decry with all their force the practice of vaccination, which occasions too trifling an indisposition to put many fees into their pockets; and they would necessarily praise the small-pox inoculation, by which a frequently long and lucrative attendance on their patients might be calculated upon as a matter of certainty.

A general account of the origin of vaccination has been delivered in the article Cow-pox, and on this interesting part of the subject we shall therefore merely recapitulate a very few particulars. As, however, it is an object of the first-rate importance to be perfectly acquainted with every criterion of the genuine disease, we mean to introduce into this article some valuable instructions, which have been published by the late and best medical writers, or which have been circulated by the National Vaccine Establishment, respecting the appearances of the true affection, and of some others, which are either spurious, or not to be depended upon. In this account will be comprehended a brief explanation of the method of practicing vaccination. The rest of the article will be principally devoted to the consideration of the occasional failures to which the practice is liable.

It was an observation made long ago in several of the dairies in England, particularly in those in Gloucestershire, that the milk cows were frequently affected with an eruption upon their udders and teats, which was communicated not only from one cow to another, but frequently also to the hands of the milkers; and farther, that much of the milkers as had been thus affected, were never afterwards infected with the small-pox, either by inoculation, or by exposure to the most virulent contagion of that disease, even although such persons had not previously undergone that dreadful malady.

It is curious, that the knowledge of a fact so singular a nature, and one of so much importance to the general interests of society, should have been confined, from time immemorial, almost entirely to those occupied in the business of dairies, without being fully investigated by such persons as could duly appreciate its value.

Dr. Jenner, a physician at Berkley, in Gloucestershire, was the first person who set himself about examining this subject with that care and attention which its importance seemed to demand.

In the year 1798, after much diligent labour and investigation, Dr. Jenner published "An Inquiry into the Causes and Effects of the Variolæ Vaccinæ," and his observations soon excited the attention of the whole medical world. For a considerable time, the accuracy of the account was received among medical men with hesitancy. The character, however, of Dr. Jenner, and the singularity and important nature of the ailment, led to farther investigation; and although many arguments were urged, and circumstances fixed, which seemed adverse to the plan of the general introduction of cow-pox among mankind, yet the great utility of it was at last clearly evinced. Every statement made by the accurate Jenner was confirmed, and the credit of the cow-pox, as a preventive of small-pox, was established on a basis too firm to be shaken by the shafts of envy, malice, or ignorance—the basis of immutable truth.

Dr. Jenner, not satisfied with the afferptions of the dairy farmers and servants, that persons who had been affected with cow-pox were rendered thereby secure against the attacks of small-pox, determined to ascertain the truth of this fact by the test of experiment. He inoculated for small-pox many persons who had formerly undergone the cow-pox, some long as thirty and even fifty years previously; and these he uniformly found, as had been predicted to him, completely refisisted that disease.

So far the nature of cow-pox was known to others before it was known to Dr. Jenner. In the year 1798, however, this ingenious gentleman published his investigation farther; and on the 14th of May, he first intentionally infected the human constitution with the virus of cow-pox by inoculation, with the design, as he informs us, of observing more accurately the progress of the infection. The experiment succeeded; and the affection, though remarkably slight, was clearly marked in all its stages.

Dr. Jenner next conceived the idea of inoculating this person with the virus of small-pox, in order to ascertain whether its slight an affection as had taken place from the cow-pox, could possibly give security from that dreadful disease. Several flight punctures and incisions were accordingly made in both arms, and the virus of small-pox was carefully infected, but no disease followed. Some months afterwards, the same person was again inoculated for small-pox, but still no sensible effect was produced upon the constitution.

This is to be reckoned the first discovery of Dr. Jenner respecting the nature of cow-pox, viz. that the matter of cow-pox, taken from the vesicles on the cow, and intentionally infected into the human subject, produces an affection,
VACCINATION.

The want of vaccine matter now prevented Dr. Jenner from prosecuting his experiments until the spring of the year 1798, when the cow-pox again became prevalent among the cows in the dairies in his neighbourhood, and afforded him an opportunity of investigating farther this interesting subject.

With matter taken from cow-pox vesicles on the teats of a cow, Dr. Jenner now inoculated several persons; and from these persons he propagated the affection to others, also by inoculation, even so far as the fifth change, without recurring to the original source, the vesicles on the teats of the cow. The experiments were completely successful. The affection, in all those inoculated, was regularly produced. All the persons who had been thus infected, were afterwards subjected to inoculation with the virus of the small-pox, but ineffectually, no disease in any instance succeeding to this operation. See Jenner’s Inquiry, p. 43.

From these experiments, we derive another most important fact concerning the nature of cow-pox, viz. that the virus of cow-pox may be propagated from one human subject to another, through several gradations, and still retains the power, not only of producing the affection, regular in all its stages, but also of rendering those constitutions which are infected, secure against the attacks of small-pox.

By unwearied attention to all the circumstances under which he was accustomed to observe this ailment, Dr. Jenner was led to conclude, that persons who have already had small-pox, are still susceptible of the action of cow-pox, though not to such a degree as those who have never been subjected to that of small-pox.

That in the cow-pox no eruption takes place, unless on the part where the virus is applied to the skin.

That the cow-pox, even under the most unfavourable circumstances, has never proved fatal.

That the cow-pox cannot be propagated by contagion, not only by actual contact, or inoculation with the virus.

That the virus of the cow-pox, inflected into the human body, may produce an affection which is merely local, the general constitution remaining unaltered; and that, in such cases, the person is liable to be infected with the small-pox.

Soon after Dr. Jenner’s publication appeared, viz. in November, 1798, Dr. George Pearson published “An Inquiry into the History of Cow-pox, principally with a View to Supercede and Extinuish the Small-pox.” In this treatise, the positions and conclusions of Dr. Jenner are examined with that candour and attention, which their importance demand. The evidences adduced are numerous and acceptable, and the result is highly favourable to the general introduction of inoculation for the cow-pox among mankind, not only as a preventive of small-pox, but also as a certain mode of ultimately extirpating that loathsome malady.

In May, 1799, were published “Reports concerning a series of Inoculations for Cow-pox, with Remarks and Observations on this Disease, considered as a Substitute for small-pox, by Dr. Woodville, Physician to the Small-pox and Inoculation Hospital in London.” The account here given by Dr. Woodville is very different from that given by Dr. Jenner, and by no means favourable to the general introduction of the new inoculation as a substitute for small-pox. Such a report, coming from a man of Dr. Woodville’s known character and reputation as an accurate observer, naturally produced a strong sensation in the minds of medical men concerning the discoveries of Dr. Jenner. The circumstances, however, under which Dr. Woodville’s observations were made; and upon which his reports were founded, were such as led him to be much deceived respecting the true nature of the cow-pox.

This report of Dr. Woodville, so very different from the general statement of Dr. Jenner, naturally called for a reply from the latter, who accordingly, in 1800, published “A Continuation of Facts and Observations relative to the Variola Vaccine.” In this publication, Dr. Jenner is anxious to recover his favourite subject from that degree of shade, which had been thrown upon it by the hasty reports of Dr. Woodville; and this he appears to have done with great success, both by further observations of his own, and by the concurring evidence of many respectable correspondents. See Bryce’s Practical Observations on the Inoculation of Cow-pox, chap. 1. edit. 2.

With regard to Dr. Woodville’s publication, we shall merely add in the present place, that the cases reported by him as examples of inoculated cow-pox, attended with many severe symptoms, and particularly with an eruption over the body, have been fully proved, and indeed have been since allowed by that respectable physician himself, to have been in fact cases of genuine small-pox, the infection having been contracted in the place where the patients were inoculated with cow-pox virus, before this latter affection had produced the effects and changes in the constitution, which render it a preventive of the other loathsome malady.

For additional particulars relative to the first progress of vaccination, we must refer to the article Cow-pox: suffice it here to say, that every objection to the practice was gradually removed; the public became convinced of its value and beneficial consequences; the great founder of it received an honourable remuneration from his country; both neighbouring and remote nations soon took a deep interest in the subject, and imitated our example; public establishments for the gratuitous inoculation of the poor were in a short time established in every civilized country; and the great benefits of the new plan were quickly extended to all the four quarters of the globe.

Description of the regular vaccine Vesicle.—When vaccination succeeds, a small red spot is observable on the third day, the day upon which the operation is being reckoned the first. If the spot be touched, an elevation is felt; and if examined with a magnifying glass, the little tumour appears to be surrounded by a very slight effu-rence.

The spot gradually enlarges; and between the third and sixth day, a circular vesicle appears. The edge of the vaccine vesicle is elevated; the centre depressed. The colour is at first of a light pink, sometimes of a blueish tint, and changes by degrees to a pearl colour. The centre is somewhat darker than the other parts.

The vesicle is hard to the touch.

In its internal structure it is cellular, the cells being filled with transparent lymph.

The vesicle commonly augments, till the tenth or eleventh day.

In the early stages, there is usually round the base an inflamed ring; or this takes place on the seventh or eighth day. About the ninth, it spreads rapidly; and near the tenth, it forms an areola of an inch and a half in diameter. This areola is of the usual colour of inflamed skin; it is hard, and accompanied with some degree of tumefaction.

It
VACCINATION.

It continues out for a day or two, and then begins to fade, sometimes forming two or three concentric circles.

After the areola is formed, the vesicle begins to decline. The centre first turns brown, and the whole gradually changes into a hard smooth scab, of a very dark mahogany colour. This dry crust usually drops off about the end of the third week, leaving a permanent circular cicatrix, about five lines in diameter, and a little depressed; the surface being marked with very minute pits, or indentations, denoting the number of cells of which the vesicle had been composed.

Varieties in the Progress and Appearance of the Vaccine Vesicles, not preventing the Success of Vaccination.—The first appearance is seldom earlier, but often later, than has been described. In some rare instances, the vesicle commences even a fortnight or three weeks after vaccination; and if the progres is then regular, it is equally efficacious.

When the vesicle is ruptured at an early period, if the progres continue regular, successe is not prevented; nor is it when the crust of a regular vesicle is rubbed off in the decline of the disease, though ulceration should ensue.

Of irregular and imperfect Vesicles and Pustules, which are not to be depended upon.—In the deviations, there is usually a premature itching, irritation, inflammation, vefication, or supuration; or the progres of the vesicle is too rapid, its texture fott, its edge not well defined, its centre elevated, and the contents discoloured or purulent; or, instead of a proper areola, a veficular effuence of a fufky purple hue takes place, and the scab is of a light brown or amber colour.

The irregular vesicle or pufatile is more liable to be broken than the other, both from its more pointed form and fotté texture, and also from its being usually fo irritable as to provoke scratching. When broken, or even without this happening, ulceration often ensues.

A veficle, apparently regular at first, sometimes does not augment to the proper fize, but dies away without completing the regular progres. This usually leaves no cica-

When these, or any other conßiderable deviations from the regular course of the disease, take place, no dependence can be placed upon the operation, and vaccination should be repeated.

Probable Causes of irregular Vesicles and Pustules.—These accidents may be occasioned by matter or lymph being taken from an irregular vesicle or pufatile at any period, or from a regular veficle, at too late a period; or by lymph, though originally pure, which has been injured by long keeping, by heat, or otherwise. Or it may be caufed by performing the operation with a rufty or unclean lancet, or in a rude manner, or by destroying the veficle at an early stage, and thereby exciting too much inflammation, or interrupting the regular progres of the disease. Herpetic eruptions, and other cutaneous affections, have also been supposd to be the caufe of these irregularities; and occasionally to prevent the vaccine lymph having any effect.

As Dr. Bateman observes, there are two caufes for these imperfect inoculations: the one is the infection of effete or corrupted virus; and the other the presence of certain cutaneous eruptions, acute and chronic.

The lymph of the vaccine veſicle becomes altered in its qualities, soon after the appearance of the infalted areola; so that if it be taken for the purposes of inoculation after the twelfth day, it frequently fails to produce any effect whatever; and, in fome cafes, it suddenly excites a pufatile, or ulceration; in others, an irregular veficle; and, in others, erythemas. If taken when fcas are formed over the

vehicle, (as in the cafe of pufules of small-pox) the virus is occasionally fo putrefcent and acrid, that it excites the fame violent and fatal disease which arises from flight wounds, received in defuccing putrid bodies.

"Again, the lymph, although taken from a perfect vehicle, on the fith, feventh, or eighth day, may be fo injur'd, before its application, by heat, expoure to the air, moifure, ruft, and other caufes, as to be rendered incapable of exciting the true disease.

"The moft frequent caufe of these imperfections, however, seems to be the presence of chronic cutaneous eruptions, or the concurrence of eruptive fervers, or even of other febrile diseases. The chronic cutaneous eruptions, which sometimes impede the formation of the genuine vaccine vehicle, have been defcribed by Dr. Jenner under the ordinary indefinite term herpes and linea capitis. In the more accurate pharacoology of Dr. Willan, they are herpes, (includign the hingiles and vefecular ring-worm,) piorialis, and impetigo (the dry and humid tetter); the lichen, and moft frequently the varieties of porrigo, comprising the contagious eruptions denominated by authors cru$fus la$x$ea, arca, achores, and favo. Dr. Willan thinks that the itch and prurigo likewise have the fame influence.

"Of the interference of eruptive fervers, meafeles, scarlet fever, and chicken-pox, with the progres of the vaccine vehicle, when they occur foon after vaccination, numerous infances have been recorded. The fulferion of its progres, indeed, would be expected, under fuch circumstances, from the known facts respecting the reciprocal action of these contagious fervers on each other. But the action of the vaccine virus is not only fupended by these fervers, fo that the veficle is very flow in its progres, and the areola not formed till after the fourteenth day, or later, and sometimes not at all; but it is occasionally rendered altogether inefficient. Even typhous fever, and the influenza, have been obferved to produce a fimilar interruption in the progres of vaccination.

"Finally, the vehicle without an areola, takes place if the perfon inoculated have previously received the infection of small-pox, or if he be affected with some other contagious disease during the progres of vaccination.

"Other irregularities may probably have occurred. At all events, though the constitution is sometimes fully secured from the infection of small-pox, even by the irregular vehicles; yet as it is more commonly but imperfectly guarded by fuch vehicles, the propriety of Dr. Jenner's caution is obvious, that, when a deviation arises, of whatever kind it may be, common prudence points out the necefly of re-inoculation." See Bateman's Synopsis of Cutaneous Difeases, p. 219—221, edit. 3.

The Methods of taking Vaccine Lymph for Vaccination.—The lymph of a regular veficle is efficacious from the time it is secreted, till the areola begins to spread. It may, therefore, commonly be taken till the ninth day; but not after the areola is fully formed.

The lymph is to be taken by small superficial punctures made in the vehicle, with the point of a lancet introduced horizontally. Time should be allowed for the liquid to exude, which will form small pellicled drops. When requisite, a very light pressure may be cautiously applied with the flat surface of the lancet. Great delicacy is requisite in this operation; for if the vehicle is improperly treated, or too much opened, inflammation and ulceration may ensue.

Lymph intended to be used immediately, or in a few days, may be received on a lancet; but this is an improper instrument for preferring it longer; for the lymph soon rufts the lancet, and it is then liable to be injurious, or injurious. Quills and tooth-picks succeed; but small bits of
of ivory, shaped like the tooth of a comb, and properly pointed, are the most convenient instruments; and to render them more certain, they should be charged repeatedly.

In order to preserve lymph for a long period, the best method is by two bits of square glass. The lymph is to be received on the centre of one of them, by applying it to a punctured vessel. When fully charged and dry, it is to be covered with another bit of glass of the same size, and wrapped up in paper or in gold-beater's skin.

In whatever way the lymph is taken, it should be allowed to dry without heat, in the shade, and be kept in a dry and cool place. When inclosed in a letter, if great care is not taken, it may be injured by the heat of the melted wax in sealing the packet.

The Mode of Vaccinating.—Liquid lymph is better than dry, because it seldom fails, and the operation is more lightly and quickly performed. Therefore in every instance, where it is practicable, the patient from whom the lymph is to be taken should be present, and the lymph should be transferred immediately from him to the person who is to be inoculated.

Vaccination is generally performed in the arm, near the insertion of the deltoid muscle; but in order to hide the scar, and in adults who are likely to use the arm much, it may be advisable to vaccinate the outside of the leg, a little above or below the knee.

The lancet being charged, the skin should be stretched, and a small superficial puncture made with the point of the lancet, held nearly in a horizontal direction.

The lancet should be dipped in water and wiped after each operation, even when several successive inoculations are to be performed.

Dry lymph on glass may be moistened with a very little cold, or tepid water, on a point of a lancet, allowing it some time to dilute, and blending it by a little friction with the lancet. It must not be much diluted, but ought to have a thick consistence; it is to be infected in the same manner as the recent fluid.

When quills, ivory lancets, or tooth-picks charged with dry lymph are used, the lymph should not be diluted, but a puncture having been made with a common lancet, the point of the instrument is to be infected, and held in the puncture half a minute or more, that the lymph may gradually disolve and remain in the wound. If the part of the instrument which is charged be afterwards wiped repeatedly upon the edges of the puncture, it will tend still farther to enure success.

Vaccinated patients must be cautioned not to wear tight sleeves, nor to injure the vehicle by pressure, friction, or any other violence, lest inflammation or ulceration should ensue.

One perfect vaccine vehicle is sufficient; but for various reasons it may often be prudent to make two or three punctures, especially when the danger of receiving the small-pox is imminent, the lymph dry, or the patient's refidence distant.

Besides, greater security is obtained against a chance of failure from the derangement or destruction of one vehicle by accidental injury, or by the taking of matter for vaccination. When two punctures are to be made in one limb, they should be at least two inches asunder, on account of the irritation they may occasion. And one of them should be always permitted to go through its course undisturbed.

Lancets for vaccination should be kept clean and bright.

Constitutional Symptoms.—Constitutional symptoms sometimes occur at a very early period, but more commonly from the seventh to the eleventh day. These are drowsiness, restlessness, a chilliness succeeded by heat, thirst, head-ache, and other marks of febrile affection. Now and then sickness or vomiting takes places, especially in infants.

The constitutional symptoms are in general flight and transient, and such as require no remedy.

In a great proportion of cases, there is no perceptible indisposition; nevertheless, the person vaccinated is not the less secure from the future infection of the small-pox, provided the progress of the vehicle has been regular and complete.

Care should be taken not to confound the symptoms of other diseases with those produced by vaccine inoculation.

Medical Treatment.—In general, no medicine is required in this mild affection; but if the symptoms happen to run a little higher than usual, the same remedies are to be applied, as if they proceeded from any other cause.

No preparatory medicines are necessary before vaccinating, and commonly no cathartics need be given afterwards.

Should the local inflammation exceed the usual bounds, which rarely happens, unless from tight sleeves, pressure, or friction, it may be checked by the frequent application of compresses of linen dipped in water, in aqua lithargyri acetati composta, or in a solution of one drachm of cerussa acetata in a pint of water. These are to be applied cold.

If the scar be rubbed off prematurely, and ulceration take place, cooling and astringent applications may be used; such as a drop of aqua lithargyri acetati, which should be allowed to dry on the part, and then be covered with compresses dipped in water, or in either of the preparations of lead above-mentioned, and frequently renewed.

When the ulceration is deep or extensive, a poultice either of bread and milk, or of bread with any of the preparations of lead, may be applied, as the case seems to require. They must never be applied till they are nearly or quite cold.

In such foul and obdurate forse as resist the foregoing applications, the unguintum hydrargyri nitriti, mixed with an equal quantity of unguintum cere, or other similar applications, may sometimes be resorted to with advantage. And at other times, these forse may be healed with the unguintum cerussae acetata, or the mildew applications.

The irregular vehicle and pustules are frequently followed by ulceration at an early period, and this ulceration is to be treated in the same manner, as if it proceeded from the regular vehicle.

When the patient has been previously exposed to the infection of small-pox, this disease will be either superceded or not, according to the time which may have elapsed before vaccination.

Observations on the occasional Inefficacy of Vaccination.—When the vaccine vehicle poses the above-described characters, and passes through the regular gradations, whether accompanied with any perceptible disorder of the constitution or not, it effectually and permanently secures the individual from the danger, and almost universally from the contagion of the small-pox.

It is now nearly twenty years since the first promulgation of Dr. Jenner's discovery; and yet the truth of the preceding observation remains unimpeached. As a well-informed physician has remarked, the very exceptions to this statement may be said, without a folecium, to corroborate it. For, in the very small number of cases, (such as that of the son of earl Grosvenor), where an extensive eruption of small-pox has occurred subsequently to vaccination, the controlling influence of the cow-pox has been invariably and strikingly manifested, by the sudden interruption of the small-pox in the midst of its course, and the rapid convalescence of the patient. See Bateman's Synoposis, p. 216.
With very few exceptions, indeed, persons who have undergone both the local and constitutional affection of cow-pox, are thereby rendered unfusceptible of small-pox. It is not meant to assert, however, as has been too generally imagined, that every person who has been inoculated for the cow-pox, is rendered secure against the contagion of small-pox. As Mr. Bryce has ably explained, there are many circumstances, besides the mere inoculation, absolutely necessary to be ascertained, before this security can be guaranteed.

Again, says Mr. Bryce, it is well known, that a person having undergone the small-pox is not absolutely secure from a future attack of the same malady, as well authenticated instances are recorded, where the same person has undergone this disease a second time, and these attacks were neither of them local, but very certainly general constitutional affections. See the case of Mr. R. Langford, recorded in the fourth volume of the Memoirs of the Medical Society of London. This gentleman was infected with the small-pox at a very early period of life, and was much marked from the severity of the disease. Many years afterwards, he was again infected with the small-pox, which was of the confluent kind, and proved fatal on the twenty-first day from the attack. See also Dr. Woodville’s History of Inoculation, p. 217; Mr. Ring’s Anfwer to Dr. Mofeley, where many such cases are recorded; and the cafe of Lord Wortormeath’s child, published in the Medical and Physical Journal, vol. xiv. p. 256.

Now, as Mr. Bryce remarks, with regard to the cow-pox, it may also happen, that a person who has undergone that affection, may yet be afterwards affected with small-pox; but, as is well known in the former, in relation to small-pox, so also in the latter relative to cow-pox, the instances of the second attack from small-pox, or of the failure of the cow-pox to prevent the small-pox, are so very rare, as by no means to affect the general established rule; that persons who have once undergone the small-pox, or the cow-pox, as a constitutional affection, may thenceforth be reckoned secure against all future attacks of various contingencies. (See Bryce’s Practical Observations on the Inoculation of Cow-pox.) Besides the examples of the recurrence of small-pox a second time in the same individual, to be found in the publications already specified, additional instances are recorded by Dr. Jenner himself, Mr. Bryce, and in the Reports of the National Vaccine Establishment.

We shall here present the reader with the history of two remarkable cases published by this last institution; the one illustrating the occurrence of small-pox a second time in the same person, the other exemplifying the equally uncommon circumstance of an individual who had perfectly undergone vaccination, being afterwards affected with the small-pox.

Dr. Bree was called to visit Miss Sarah Booth, of Covent Garden theatre, on Monday, June 25th, 1811. She was said to be ill with the small-pox, and the following circumstances were reported by the mother and sisters.

Miss Booth was then eighteen years of age. She had been inoculated for the small-pox at five years of age, and had been affected with the usual degree of fever. The arm had been violently inflamed, and an eruption of small-pox pustules had appeared round the inoculated part, from which matter had been taken by Mr. Kennedy, the surgeon who attended her. Mr. Kennedy expressed himself satisfied that Miss Booth had passed regularly through the disease.

The usual fear of small-pox inoculation was perfectly evident on the arm.

On Thursday, June 20th, 1811, Miss Booth was seized with fever, distinguished by vomiting, violent headache, and pains in the back and loins. The symptoms continued till Saturday, June 22d, in the evening of which day, some pustules came out on the forehead and scalp.

Sunday, June 23d, a more complete eruption appeared on the face and neck, and the was relieved from the violence of the fever. The vomiting however continued, the throat became very sore, and a salivation began.

Monday, June 24th, the eruption extended itself on the body, the fever was still more abated, but the salivation, foreheads of the throat, and vomiting, were urgent symptoms.

Tuesday, June 25th, the fourth day of the eruption, the salivation and retching continued, with foreheads of the throat.

Wednesday, June 26th, fifth day of the eruption, pustules were noticed on the lower extremities, those on the face advanced, the eyes were swollen; and the number of pustules on the head and face was about two dozen.

Thursday, June 27th, sixth day of the eruption, the pustules on the face began to turn. She still suffered from sore throat and salivation.

Friday, June 28th, the pustules on the face turned, those on the lower extremities were few in number but well filled, and not yet changed.

Saturday, June 29th, eighth day of the eruption, the only complained of sickness. After this day, the pustules turned and dried on the lower extremities, and no complaint remained.

Dr. Bree considered this as a mild case of distinct small-pox.

On Sunday, May 26th, 1811, the Hon. Robert Grosvenor, who was recovering from the hooping-cough, became much indisposed and threw up his dinner. Fever followed, and he complained most particularly of excruciating pain in his back. He dwelt on this symptom until Thursday, when he became delirious, and there were observed on his face about twenty spots.

He had been vaccinated by Dr. Jenner, in his infancy, about ten years ago, and the mark left in his arm indicated a perfect disease.

On Friday morning, the eruption had not increased materially in point of number, but the appearance of the spots and the previous symptoms, suggested strongly a suspicion that the disorder was the small-pox.

Sir H. Halford had occasion to go to Windsor in the afternoon of Friday, and did not see Mr. Robert Grosvenor until the Monday following, (June 2d,) but he learned from Sir W. Farquhar, who attended him most carefully during Sir Henry’s absence, and subsequltly, that the eruption had increased prodigiously in the course of Friday; that on the evening of that day, Mr. Robert Grosvenor began to make bloody water, and that he continued to do so until Monday morning.

On the tenth day of the disease, the pustules began to dry upon the face, which was swollen to a considerable degree, but not to the extent of closing his eyes, and was attended by a salivation which lasted several days. Petechiae had occurred in the interstices of several of the spots, particularly on the limbs, and there was that particular smell from the whole frame which is remarkable in bad cases of confluent small-pox.

It was obvious that the first symptoms of which Mr. Grosvenor complained, were such as indicated a violent disease about to follow, and Sir Henry confesses that he entertained a most unfavourable opinion of the issue of such a malady, when it was fully formed; having never seen an instance
influence of recovery under so heavy an eruption attended by such circumstances. It seemed, however, that the latter stages of the disease were passed through more rapidly in this case than usual, and it may be a question whether this extraordinary circumstance, as well as the ultimate recovery of Mr. Grovenor, were not influenced by previous vaccination.

The Board of the National Vaccine Establishment are of opinion, that the case of the Hon. Robert Grovenor was a case of confluent small-pox: that the attack and progress of the disorder were attended by symptoms which almost invariably announced a fatal termination. But they observe, that the swelling of the face, which is generally so excessive as to close the eyes, and is considered as a favourable symptom, was slighter than usual; that on the tenth day the pustules began to dry upon the face, and that from that time the disease passed with unusual rapidity through the period when life is generally esteemed to be in the greatest hazard.

Those who are acquainted with the nature of the confluent small-pox, are aware that this peculiarity cannot be attributed to the effect of medical treatment.

In most cases of small-pox which have succeeded to vaccination, the pustules have been observed to dry more rapidly, and the disorder has concluded at an earlier period than usual.

If allowance be made for the relative periods in which the confluent and distinct small-pox complete their course, the rapid progress towards recovery through the latter stage of confluent small-pox, as exhibited in the case of Mr. Grovenor, may be compared with the rapid defecation of the pustules in the distinct and peculiarly mild form of the disorder which is considered as small-pox modified by vaccination. Both forms of the disorder proceed in the usual course, the one attended with violent, the other with mild symptoms, till they arrive near to the height, when they appear to receive a check, and the recovery is unusually rapid.

From this correspondence of circumstances, the Board are induced to infer, that in the case of Mr. Grovenor, which has been more violent than any yet submitted to them, the progress of the disease, through its latter stage, and the subsequent abatement of symptoms, were influenced by an anti-variolar effect produced upon the constitution by the vaccine procès.

The occurrence of small-pox after vaccination, has been foreseen and pointed out in the report on vaccination made to parliament, by the College of Physicians, in the year 1807, to which the Board are dièrous of calling the attention of the public; in which it is stated, that,

"The security derived from vaccination against the small-pox, if not absolutely perfect, is as nearly so as can perhaps be expected from any human discovery; for amongst several hundred thousand cases, with the refults of which the College have been made acquainted, the number of alleged failures has been surprizingly small; so much so, as to form certainly no reasonable objection to the general adoption of vaccination; for it appears that there are not nearly so many failures in a given number of vaccinated persons, as there are deaths in an equal number of persons inoculated for the small-pox. Nothing can more clearly demonstrate the superiority of vaccination over the inoculation of the small-pox than this consideration; and it is a most important fact, which has been confirmed in the course of this enquiry, that in almost every case in which the small-pox has succeeded vaccination, whether by inoculation, or by casual infection, the disease has varied much from its ordinary course; it has neither been the same in violence, nor in the duration of its symptoms; but has, with very few exceptions, been remarkably mild, as if the small-pox had been deprived, by the previous disease, of its usual malignity." Report of the College of Physicians, p. 23.

The peculiarities of certain constitutions with regard to eruptive fevers, form a curious subject of medical history. Some individuals have been more than once affected with scarlet fever and measles; others have been through life exposed to the contagion of these diseases without effect; many have refisted the inoculation and contagion of small-pox for several years, and have afterwards become susceptible of the disorder, and some have been twice affected with small-pox.

Among such infinite varieties of temperament, it will not appear extraordinary, that vaccination, though so generally successful, should sometimes fail of rendering the human constitution unrefistible of small-pox; especially since it has been found that in several instances small-pox has occurred to individuals over whom the small-pox inoculation had appeared to have produced its full influence. Three instances of this kind have taken place within the last month, and, in another instance, the natural small-pox has occurred a second time. See Report of the National Vaccine Establishment, July 1811.

It has been imagined by some, that although the human constitution is apparently shielded from the action of small-pox by having undergone the cow-pox, yet that this security may not be permanent; but that, at the end of a certain period of time, the person will again become susceptible of small-pox. This objection, however, must now have little weight; for Dr. Jenner himself inoculated with the virus of small-pox, persons who had been affected with the cow-pox twenty-five, twenty-seven, thirty-one, and fifty-three years before; but who had never been infected with the small-pox, and thence he found completely refistless this disease.

For further evidence and reasoning on this point, see Fer- mor's Reflections on the Cow-pox; Edin. Rev. No. XVII.; and Bryce's Practical Obs. on the Cow-pox.

Experience has proved that, in certain instances, the cow-pox virus has merely a local action, and such cases have been mistaken for the regular constitutional affection; a thing very likely to happen, when it is remembered that the general ailment of the system is seldom marked by any very strong symptoms; and that, in the cases alluded to, the local appearances would pursue a regular progress. Yet, in these circumstances, the patient is left unproteeted from an attack of small-pox. As Mr. Bryce has pointed out, therefore, a certain test of the constitution being really affected in every inoculation of cow-pox must be a most important deriteratum. Indeed, until there be demonstrated and generally known some unequivocal mark of a constitutional affection, which does constantly occur during the course of cow-pox when efectual, and which may be as easily distinguished as the fever and eruption consequent to the inoculation for small-pox, this new inoculation ought never to be performed, except by persons well acquainted with every appearance of the ailment. For, as much as it is more difficult to distinguish between the cow-pox and some other affections, and also more readily to ascertain the presence of a constitutional affection, than to form a similar judgment in the inoculated small-pox, the more does the cow-pox inoculation require attention to every symptom which may occur during its progress, in order that mankind may reap every advantage which has been promised from the general adoption of cow-pox as a preventive of small-pox.

Mr. Bryce has endeavoured to discover a criterion of the

Vol. XXXVI.
VACCINATION.

patient being constitutionally affected with the cow-pox, and the following observations upon this important subject merit particular attention. "I recollected (says he) some experiments which had been made with regard to the inoculation of small-pox. It was found, that if the same person was inoculated every day, until the fever induced by the first inoculation supervened, all the other punctures quickly advanced in their progress; and that, in the course of a day from the time the fever or general affection began, even that puncture which had been last made, perhaps only twenty-four hours before, equalled in maturity the one first made, perhaps eight or nine days before, and from which the fever had arisen.

"In this case it appears to me evident, and I think it must be admitted by every person, that even had no other pustules appeared on the body but those occasioned by the repeated inoculations; nay, had there even been no fever observed in consequence of the inoculation; yet as the pustule occasioned by the last puncture had been suddenly accelerated in its progress to maturation, at the time the general or constitutional affection should have appeared; this alone was a sufficient proof of the presence of the various action in the system.

"Judging again from analogy, I expected that the same thing, which thus happened in the small-pox inoculation, might also take place in that for the cow-pox; and the unexpected appearance of one or two vesicles upon children that I had inoculated, which vesicles were quite characteristic of the ailment, and the appearance of which I could only account for from a second and accidental inoculation during the course of the disease, strengthened my hope. And, certainly, if we find in cow-pox, where the inflamed and hard areola does not take place, at least in the regular course of that affection, until the end of the seventh, or beginning of the eighth day from inoculation, that a second inoculation, performed, for example, at the end of the fifth, or beginning of the sixth day, is so much accelerated in its progress, about the time the general affection of the system usually takes place, as to have an areola formed within a few hours, or very shortly after the first, and that this areola increases with the first, and again fades at nearly the same time, we must be struck with the similarity, and be forcibly led to draw the same conclusions in this case as in the former, respecting the small-pox, viz. that although the inoculated affection had appeared very quickly, and no fever had been observed, yet that a certain action had been excited in the constitution. That this was the true constitutional affection of cow-pox, may be judged by the acceleration of the second vesicle to a state of maturity five days before this could have happened, had there been no confen-aneous general action, or change in the system."

Mr. Bryce next details a series of experiments, which tend to prove, that if, during the regular progress of cow-pox, a second inoculation be performed a certain number of days after the first, the affection produced by this second inoculation will be accelerated in its progress so as to arrive at maturity, and again fade at nearly the same time as the affection arising from the first inoculation; and that this will take place, although the constitutional affection be so slight as otherwise to pass unnoticed.

From several examples related by Mr. Bryce, and a great many other cases, in which the second inoculation was performed at different periods of the primary affection, it is concluded, that the most proper time for performing the second inoculation, is about the end of the fifth, or beginning of the sixth day, from the first inoculation; reckoning each day to consist of twenty-four hours. Thus, if the first inoculation be performed on Wednesday at noon, the second inoculation should be performed on Monday, at the same hour, at which time the fifth day is considered to be finished, and the sixth day to begin. If the second inoculation be delayed beyond the sixth day, the affection produced by it will be very indistinct, and of short duration; and if performed at an earlier period than the fifth day, the contrast between the progress of the two affections, with regard to duration, will not be so great as may be thought necessary.

"These observations, however, (says Mr. Bryce,) are applicable to those cases only, in which the first inoculation advances by a perfectly regular course, and in which the areola begins to form about the end of the seventh, or beginning of the eighth day; for in those cases, in which the first inoculation is from certain causes accelerated or retarded one or two days, as frequently happens, then the second inoculation should be performed at a more early or late period accordingly.

"In short, my observations on this point lead me to conclude, that in order to obtain the proposed criterion in the greatest perfection, the second inoculation should be performed between thirty-six and forty-eight hours before the areola of the first inoculation begins to appear. This is necessary in order that the secondary affection may have proceeded some length, and that a small vesicle, containing virus, may have been formed by it, before the constitutional action from the first inoculation begins, otherwise no areola, but merely a slight degree of hardening will take place from the second puncture.

"As, on the one hand, the acceleration of the second inoculation in the manner above-mentioned, is to be regarded as a certain mark of a constitutional affection in cow-pox, so, on the other, if it shall be found that no such acceleration takes place, but that the second inoculation proceeds by a slow progress through all the stages, and has the duration of a primary affection, it is to be concluded that no constitutional action has taken place from the first infection of the virus; and when this is the case, the second inoculation must be regarded as a primary affection, and a third puncture be made according to the plan laid down for conducting the second inoculation; and thus we may go on until the proper test be obtained, or until we be satisfied that the constitution completely refits the action of cow-pox." See Bryce's Practical Observations on the Inoculation of Cow-pox, edit. 2.

Many other particulars relating to the subject of vaccination will be found in another place (see Cow-pox), and we shall therefore merely add, that the new practice is on every account deserving of the confidence and encouragement of the public. The cow-pox is greatly milder than the small-pox, even under the most approved mode of treatment; being never attended with danger, seldom with sickeffs, and never producing pustules generally over the body, nor indeed any disfigurement of the skin, except at the part where the virus has been directly infected by the inoculator. The small-pox is one of the most contagious diseases to which the human race is subject; and, when propagated in this way, it is one of the most fatal. On the other hand, the cow-pox is not at all contagious, and can only be communicated by the application of the vaccine virus to the part affected, as happens in the accidental inoculation of the hands of milkers, and the ordinary practice of vaccination.

Many hundreds of thousands have now been vaccinated in these kingdoms, and yet there is not on record a single unequivocal instance of the cow-pox having proved fatal. Corresponding agreeable accounts are also received from every part of the civilized world. The weight which this consideration ought to have may be well conceived, when it
VACCINIUM.

The genus before us, mostly confined to Europe and North America, is peculiarly abundant in the latter country. It is very remarkable that, as no Erica occurs in America, so no Vaccinium has been found at the Cape of Good Hope. These genera, similar in many of their flowers, differ no lefs widely in the situation of their germens, and texture of their fruits, than in the inflorescence and habit of their foliage, which in Vaccinium is scattered, dilated, generally membranous and deciduous; always indeed simple and undivided; but totally unlike the narrow, whorled, evergreen leaves of Erica. The flowers in Vaccinium are copious, stalked, either solitary, simply racemose, or tufted, drooping, nodorous, generally very elegant, tinted with various shades of red or pink, with a few, scarlet yellowish. Berries black, blue, blue-black or red, generally edible, though not pleasant, nor always wholesome, in a rude state. Stem thorny, bulky, of humble stature. Stirpular none.

The species of Vaccinium were ill understood by Linnaeus, but we hope to trace the origin of many of his errors, which have never been cleared up, and have led all following authors astray. Murray defines but fifteen species in the fourteenth edition of Syll. Veg.; Willdenow has twenty-seven, of which five are American, three natives of Japan, one of Otago, one of Otago, and one of the North American. Pursh has twenty-five species of Vaccinium, besides three of Oxyoccus, from North America only. In reviewing the whole of the genus, we find something to add, though we have many specimens that are dubious. We are obliged to follow the distribution of Linnaeus, by which the evergreen species are separated from those which are deciduous, though some uncertainty must always attend that character, respecting species known from dried specimens only.

See. 1. Leaves deciduous.

1. V. Myrtillus. Common Bilberry, or Bleaberry. Linn. Sp. Pl. 498. Willd. n. 1. Fl. Brit. n. 1. Eng. Bot. t. 465. Fl. Dan. t. 974. (Vaccinia nigra; Ger. Em. 1415. Myrtillus; Matth. Valgr. v. 1. 210. Camer. Epit. 135.)—Stalks solitary, single-flowered. Leaves deciduous, furred, ovate, smooth. Stem acutely angular. Calyx scarcely divided.—Native of heaths, floy mosses, and mountainous woods, throughout most parts of Europe, especially the more northern, flowering in May. Dr. Sibthorpe gathered it also on the Bithynian Olympus. The root is woody. Stem from six to eight inches to two feet high, erect, bushy, smooth; the young green branches leafy, in a little zigzag, furnished with very acute dilated angles. Leaves about an inch long, on short footstalks, pubescent, veiny, rather acute, copiously furred; paler beneath. Flowers pendulous, simple, naked, smooth, small, axillary stalks. Calyx dilated, angular, seldom so much lobed as in Eng. Bot. Corolla globosus, generally five-cleft, of a very delicate wax, pink hue. Anther horned. Germen glaucous. Berry the size of a currant, blue-black, acid, eaten in tarts, or with cream, in the north and west of England. In the eastern counties this plant is not plentiful. Its fruit is sometimes sent into Norfolk from Devonshire. Mr. Menzies brought, from the west coast of North America, what we can scarcely make more than a gigantic variety of this species, seven or eight feet high, larger in every part, with less distinctly furred leaves.

2. V. ovalifolium. Oval-leaved Bilberry. Stalks solitary, single-flowered. Leaves deciduous, oblong, obtuse, pointlets, entire, smooth, strongly veined beneath. Stem angular. Calyx scarcely divided.—Brought by Mr. Menzies from the west coast of North America. A four, ten or twelve feet high, whose smooth branches are less acutely angular than in the foregoing, and whose leaves are very effensively different, being
being either perfectly elliptical, or slightly ovate, blunt, and quite entire, about an inch and a half long, copiously terminated with fine veins, quite smooth on both sides; rather paler beneath. Flowers solitary at the base of each tuft of budding leaves, drooping, each accompanied, at the base of its stalk, by a large ovate, acute, coloured bracteae. The flowers seem to agree with those of *V. Myrtillus* in size, colour, and structure, except that the corolla is more oval at the ovate. The berries are black, crowned with the cup-shaped, slightly four-lobed, calyx.

3. *V. parvifolium*. Small-leaved Red Bilberry.—Stalks solitary, single-flowered. Leaves deciduous, elliptical, obtuse, pointed, entire, smooth; glaucous, and slightly veiny, beneath. Stem acutely angular. Calyx scarcely divided. Stalk of the fruit club-shaped.—Gathered by Mr. Menzies on the west coast of North America. The thrubby stem is eight or ten feet high, with smooth zigzag branches, whose angles are as much dilated and prominent as in our first species. The leaves most agree with those of *ovatifolium* in shape, but are at their full growth scarcely a quarter so large, and each tipped with a small point; their under side rather glaucous, with less copious, and far less prominent, veiny reticulations. We have seen no flowers. The berries are red, and make excellent tarts. They appear to be smaller than the last, crowned with a similar calyx, but their stalk is shorter, meafuring scarcely half an inch, more drooping, and very remarkably swelling upward, so as to be quite club-shaped, contracted at the summit, of which the foregoing sheets but slight traces. There is no doubt of these two species being very distinct from each other, as well as from all hitherto described by authors.

4. *V. pallidum*. Pale Whortle-berry. Ait. n. 2. Pursh n. 6.—"Clusters bracted. Corolla cylindrical-club-shaped. Leaves ovate, acute, finely serrated, deciduous."—Native of North America, from whence it is said to have been sent to Kew garden in 1772, by Dr. Samuel Martin. Mr. Pursh never met with this species, nor was he able to ascertain it, even by a strict examination of the Bankian herbarium. Neither are we furnished with a specimen, nor with any information concerning this plant, which, on account of its inferiority, seems here misplaced.

5. *V. hirtum*. Hairy Japan Whortle-berry. Thunb. Jap. 155. Wildl. n. 3.—Stalks solitary, single-flowered. Leaves deciduous, ovate, serrated, hairy all over as well as the young branches.—Gathered on hills between Misco and Jedo in Japan, by profcssor Thunberg, one of whose specimens is before us. A taller shrub than our *Myrtillus*, flowering in April. The bracteae are round. Leaves like that species in size and shape, but covered with soft hairs; their under side rather pale. Flowers drooping, on very short stalks.

6. *V. uliginosum*. Great Bilberry. Linn. Sp. Pl. 499. Wildl. n. 5. Fl. Brit. n. 2. Engl. Bot. t. 581. Fl. Dan. t. 231. Pursh n. 15. (Vitis idea magna quibusdum, five Myrtillus grandi; Bauh. Hist. v. 1. 578. Rau. Syn. 457. V.idea folis subrotundis major; Ger. Enc. 1416.)—Stalks somewhat aggregate, single-flowered. Leaves deciduous, obvate, entire, smooth. Branches round.—Native of marily mountainous heaths, and alpine bogs, in Sweden, Germany, Switzerland, Savoy, Scotland, and the north of England; as well as in the more northern parts of America, and on its west coast; flowering in April or May, and ripening the berries, which are cattable, but not either very grateful or wholesome, in August. Talller than the Common Bilberry, and of a more glaucous hue. Leaves smooth and even above; veiny and glaucous at the back; quite entire, by which this species is readily distinguised from all that in other respects bear any resemblance to it. Flowers drooping, flesh-coloured, mostly four-cleft, with eight long-horned filaments. Calyx short and blunt. Berry large, juicy, black, with a glaucous hue. Seeds finely thrated. A variety with slightly pointed leaves, was published by an apothecary at Berne, in 1787, as *V. mucronatum*, an an imaginary species, of which we shall speak at the end of our eighth.

7. *V. calycinum*. Large-capped Whortle-berry.—Stalks solitary, single-flowered. Leaves deciduous, ovate, serrated, smooth, with downy ribs. Branches angular. Segments of the calyx deep, ovate.—Gathered by Mr. Menzies, in woods, upon lofty mountains, in the Sandwich islands. This appears to be of a much taller stature than the preceding. The leaves at the flowering feauon are an inch and a quarter long, near an inch wide, plant, with fine, copious, pointed, incurred ferratures, and a small, blunt, terminal point; their under side pale. Flowers about the lower part of each young leafy branch, axillary, drooping, each on a simple, naked, slightly downy stalk, an inch long. Calyx in five, rather unequal, deep, ovate, entire, blunting, smooth, finely reticulated segments, exceeding the germen in length. Corolla oblong, with five angles, enclosing the andthers and style. Of the fruit we have no knowledge.

8. *V. flaminifum*. Green-wooded Whortle-berry. Linn. Sp. Pl. 498. Wildl. n. 4. Ait, n. 3. Pursh n. 1. Andr. Repof. t. 263. (V. album; Pursh n. 2, excluding the synonym of Wildenow. Arbutus americana baccifera, foliolis comisis, &c.; Pluk. Mant. 22. Phys. t. 339 f. 3.)—Clusters downy, with oval bracteae as long as the flowers. Anthers twice as long as the spreading bell-shaped corolla. Leaves elliptical, acute, entire; glaucous and rather downy beneath.—Common in dry woods, from New England to Florida, flowering in May and June. The trunk is firm, about two feet high, with numerous green branches, downy when young. Leaves an inch and a half or two inches long at the flowering season, on very short downy stalks. Flowers copious, white, with remarkably conspicuous, tawny, linear anthers, spurred near the base. Corolla broader than long. Berries greenish, or white, called Deer-berries. Analogy leads us to consider the inoffiscence of this species as racemose. Indeed the bracteae, though resembling the leaves in every respect but size, are usuallly but one-fourth as large, and sometimes not a quartor of an inch in length. Mr. Pursh's album can scarcely, by his definition or Andrews's figure, be marked even as a variety, though he says the flowers are larger, and berries more globose, than in the common *flaminifum*. That his plant is not the Linnaean album, appears from the original specimen, sent by Kalm to Linnaeus, under the denomination of "a Vaccinium with white berries," but which proves *Xylopleum cilatum Ait.* Pursh 161. No wonder that no subsequent investigator could ever ascertain *V. album*! We must notice another error of Linnaeus, to prevent mistake. He cites under *V. flaminifum* the proper figure of Pluenet, but with a wrong synonym or definition. Here also it falls to our lot to correct our great master respecting another of Kalm's plants, *V. mucronatum*, which has ever remained as unintelligible as the album. His described specimen is certainly one of the *Mespilus* or *Pyrus* tribe; but, not in a condition for us precitely to ascertain the species, nor can we refer it to any thing in Mr. Pursh's work.

9. *V. arboresum*. Shining-leaved Tree Whortle-berry. Marsh. in Michaux Boreal.-Amur. v. 1. 238. Pursh n. 3. (V. dilatatum; Ait. n. 5. Wildl. n. 8.)—Stalks axillary and solitary, or terminal and racemose, naked. Leaves ovate, acute, with flight glandular ferratures; pubescent above;
VACCINIUM.

above; rather downy beneath. Corolla bell-shaped, acute.
Stamens the length of its tube.—In dry woods, on the rocky
banks of rivers, from North Carolina to Florida.
flowering in May and June. A large flower, sometimes
twenty feet high, very elegant. Flowers white, tinged
with red. Berries globular, black, almost dry. Pursh.
Our numerous wild as well as cultivated specimens,
compared with the Bankian herbarium, and answering to
every particular of the published accounts of this plant, leave
no doubt of its identity, and therefore we do not scruple to
adopt Michaux's name, in preference to the older one, dif-
fusum, the latter being founded in some mistake. The
branches are round, downy when young. Leaves peculiarly
shining, and strongly reticulated with veins. Flower-flatts
an inch long, angular, marked with two or three glands;
some of them axillary, solitary, from several of the lower
leaves of each branch; others forming a nearly leafless clayer,
at the end of the same branch. In one instance we find two
such clusters, with a small leafy bracteae, or two in the middle,
terminating a short lateral branch whose leaves are fallen.
This proves that Nature has drawn no precise line of
decimation between the racemose and the solitary inflorescence
of this genus, which in many species, by the ambiguous
nature of their floral leaves, run into each other.

10. V. augufifolium. Narrow-leaved Whortle-berry, or
Bluits. Ait. n. 6. Wildl. n. 9. (V. myrtillodes;
Michaux Borel.-Amer. v. 1. 234. Pursh n. 16.)
Stalks scattered, morellofty, single-flowered, naked.
Leaves lanceolate, nearly entire; downy at the ribs and
margin.—In America, about Hudson's Bay and Labrador,
flowering in April and May. Berries large, blueish-black,
known by the name of Bluits. Pursh. Michaux says this
species has the habit of V. Myrtillus; its leaves being mem-
branous, of a narrow lanceolate form. We have been no
specimen. Dr. Solander's original name, in Hort. Kew.
and Willdenow, appears preferable to that of Michaux
adopted by Pursh.

(V. frondosum; Michaux Borel.-Amer. v. 1. 230. V.
hirtellum; Ait. n. 12, according to Pursh, from a com-
parison with the Bankian herbarium.)—Clusters downy,
with oval bracteae; partial flatts with two lanceolate ones.
Leaves obovate, pointed, entire, downy and virid.
Germ hairy. Corolla bell-shaped, obtuse, longer than the
flamas.—In dry sandy woods, particularly pine forests,
from New Jersey to Florida, flowering in June and July.
A low bufty flower, with round branches. Leaves an inch
and a half long, varying in breadth, reticulated with veins;
paler beneath, but not all glaucous; covered all over,
epecially when young, with short vivid pubescence, and
angular dots, as are also the branches, flatts, and bracteae.
The latter are as long as the flowers, and leafy, like those
of V. flamineum, n. 8; but each partial flower-flatt bears
also, about its middle, two smaller, lanceolate, sometimes
coloured, partial bracteae. The germ is particularly
shaggy. Segments of the calyx deep, ovate, fringed, col-
loured. Corolla white, tinged with pink, rather large.
Berries black, globular. A comparison of the two figures
above cited will shew the ambiguous nature of the infor-
ence, and account for this species having been described
twice in the accurate publication of Mr. Aiton.

Michaux Borel.-Amer. v. 1. 234. Pursh n. 17.—Flowers
lateral, solitary, nearly sessile. Leaves somewhat wedge-
shaped, rounded, obtuse, serrated, membranous, very
smooth.—In the more northern regions of America, parti-
cularly about Hudson's Bay. A little flower, with many
crowded flamas, from two to four inches high, very smooth
in every part. Corolla of a short pitcher-shape. Berry
nearly sessile, globose, glaucous-black. Michaux.

amenum; Ait. n. 13. Wildl. n. 18. Pursh n. 9. Andr.
Repos. t. 138. V. difomorphum; Michaux Borel.-Amer.
v. 1. 231.)

Andr. Repof. t. 181.

7. V. fucatum; Ait. n. 8. Wildl. n. 13. Pursh n. 11.
(V. formosum; Andr. Repos. t. 97.)

Flowering branches nearly leafless. Clusters corymbose,
dropping. Bracteae membranous, shorter than the downy
flower-flatts. Leaves elliptical, acute, minutely serrated,
smooth, with downy ribs.—Native of swamps and wet
woods, from Canada to Carolina and Georgia, flowering in
May and June. A tall flower, sometimes seven or eight
feet high, with numerous roughish round branches; some-
what angular and downy when young. Leaves for the most
part following the flowers, an inch and a half or two
inches long, elliptic-oblong, acute at each end, various in
breadth, veiny, but not liltingly reticulated; very
minute, more or less evidently, serrated; tipped with a
glandular point; smooth, except the rib and veins, which
are finely hairy or downy, especially at an early period.
Flower-flatts short and broad, downy. Clusters from branches
of the preceding year, seldom accompanied with leaves,
alternate, about an inch long, and rather compact, often
corymbose, or fix or eight drooping flowers, whose partial
flatts are finely downy, with short curved hairs, and fur-
nished at the base with membranous, reddilh, smooth,
fringed, deciduous bracteae, varying in length and acutenes,
but more much shorter than their corresponding flatts.
Segments of the calyx broad and hollow. Corolla white or
reddilh, cylindrical, somewhat angular, contracted at the
mouth, with five shallow, spreading, marginal segments.
Stamens ten, downy. Anters within the corolla, having a
double pouch at the base, but no spurs. Style sometimes,
but not always, a little prominent. Berries black, inipid.
Some apology may seem necessary for our thus uniting four
reputed species, a measure of which Michaux first, in part,
fittelg the propriety. With respect to the coromycum and
amenum, original specimens of each, and the total want
of any distinctive character in authors, will abundantly
justify us. The calyx spreads equally in both. Indeed the
former being always unknown, by name, in our gardens,
and its specific character in Linnaeus being insufficient, if
not incorrect, that species could be ascertained by his
herbarium only, which in this instance was neglected, and
under the name of amenum, acquired in England. It had
here once been called elevatum, as appears by a specimen
given to the younger Linnaeus. Some gardeners subse-
cquently transferred to flamineum the name of amenum,
and hence perhaps when the latter appeared after from America,
it received the new appellations of virgatum and fucatum,
perpetuated likewise in Hort. Kew., between the original
specific characters of which there can be little discovered
that is essential. In Mr. Andrews's plate of virgatum in-
cdeed the clayers are accompanied by leaves, of which we
have seen no example in coromycum, and the flowers are
smaller than usual in this latter; but Mr. Pursh, under the
name of amenum, allows that it " has a number of varieties
in size, shape, and colour." The elegant fucatum, as
figured by Mr. Andrews, evidently betrays a close affinity
to
to corymbosum, colour being avowedly of no importance, and the erect calyx we have good reason to mistrust. Having formed our opinion from the best materials in our power, we leave its refutation or confirmation to those who may have opportunities of future inquiry, without any intentional disrespect to the great authorities from which we differ.

14. V. bracteatum. Bracteate Japan Whortle-berry. Thunb. Jap. 156. Wild. n. 11. — Clusters axillary, longer than the smooth, acute, ferrated leaves. Bracteas lanceolate, ferrated; partial flasks with two smaller awl-shaped ones. — Gathered by Thunberg in the island of Niphon, Japan, flowering in June. The branches are always smooth, leafy, slightly angular when young. Leaves eliptic-lanceolate, acute at each end, an inch and a half long, on short flasks, sharply but not deeply ferrated, very smooth on both sides; paler, and more reticulated, beneath. We should suspect them to be evergreen, as they accompany the flowers, on what seem to be last year's shoots; but having no particular information, we, like Willdenow, place this species among those to which it appears to be naturally related. Clusters two or three inches long, axillary, solitary, simple, slender, many-flowered, very smooth. Partial flasks short, drooping, turned all one way, each having at its base a lanceolate, acute, smooth bractea, mostly twice its own length, and about the middle two others of a very small size. Segments of the calyx short, acute, spreading. Corolla cylindrical, white. Nothing is known of the fruit. The Japanese call this plant Ki Fu. Thunb. Jap. 156. Wild. n. 12. — Clusters axillary, longer than the ovate, brilily, nearly entire leaves. Bracteas lanceolate, smooth.— Native of Japan, where it is called Saizoku. The stem is smooth, ash-coloured, with upright villous branches. Leaves ovate, acute, unequal, from one to two inches long, ribbed; the ribs bifid all over. Flowers red, turned one way, in terminal, solitary, ferrated clusters, as long as the finger. Bracteas about one-third of an inch in length. Calyx very short. Thunberg. We formerly examined this species in professor Van Royen's herbarium, but are not possessed of a specimen. It must be presumed that by "folia integra" is not meant undivided leaves, the true sense of that expression; because no Vaccinium has any other. The learned author evidently contrasts this phrase with the folia ferrata of the preceding species, and means that the leaves are nearly entire; in contradistinction to integrerrima.

15. V. cilium. Hairy-ribbed Japan Whortle-berry. Wild. n. 7. — Clusters axillary, longer than the ovate, brilily, nearly entire leaves. Bracteas lanceolate, smooth. — Native of Japan, where it is called Sajoku. The stems are smooth, ash-coloured, with upright villous branches. Leaves ovate, acute, unequal, from one to two inches long, ribbed; the ribs bifid all over. Calyx red, turned one way, in terminal, solitary, ferrated clusters, as long as the finger. Bracteas about one-third of an inch in length. Calyx very short. Thunberg. We formerly examined this species in professor Van Royen's herbarium, but are not possessed of a specimen. It must be presumed that by "folia integra" is not meant undivided leaves, the true sense of that expression; because no Vaccinium has any other. The learned author evidently contrasts this phrase with the folia ferrata of the preceding species, and means that the leaves are nearly entire; in contradistinction to integrerrima.

16. V. gallicum. Larger Gale-leaved Whortle-berry. (V. glandens; Michaux Borel.-Amer. v. 1. 232. Pursh n. 12.) — "Flowers on very short flasks, in small tufts. Leaves serrate, lanceolate-wedge-shaped, slightly serrated, downy. Calyx pointed. Corolla ovate, much contracted at the mouth. Style prominent." — Found in the sandy woods and swamps of Virginia and Carolina, flowering in May and June. Flowers small, yellowish-white. Berries small, glabrous, black. Pursh. Michaux describes this shrub as having the aspect of Myrica Gale, with slightly downy branches. Leaves veiny. The flower-flasks, shorter than the flowers, burst from a bud, composed of numerous crowded scales, but become naked and corymbose as the fruit advances. We trust that we need not labour under the necessity of precisely retaining the original specific name. V. tenuilimum of Hort. Kew., cited doubtfully by Michaux, is not known to us; but Mr. Pursh describes it as distinct from the present species; see n. 20.

17. V. frondosum. Blunt-leaved Whortle-berry or Blue Tangles. Linnae Sp. Pl. 499. Wild. n. 14. Ait. n. 9. Pursh n. 5. Andr. Repof. t. 140. (V. glaucum; Michaux Borel.-Amer. v. 1. 231.)" β. V. venusifum; Ait. n. 10. Wild. n. 15. Herb. Banks. Pursh. — Clusters lax. Bracteas oblongate, not half so long as the slender partial flower-flasks, which bear two smaller linear ones. Leaves oblong-oblong, pointets, entire, smooth. — In open woods, on a sandy loam, from New Jersey to Carolina, flowering in May and June. About three feet high. Flowers small, almost globular, white. Berries large, blue, globular, eatable, called by the country people Blue Tangles. Pursh. The branches are round, smooth, and slender. Leaves from two to three inches long, thin and plant, generally obtuse, but in the variety β acute; bright green above; glaucous beneath, sprinkled with minute resinous dots, and reticulated with copious veins. Clusters lateral, from the last year's wood, about the length of the leaves, loose, slender, and spreading. Partial flowers-flasks about an inch long, with a small obviate, pointed, entire bractea, covered with resinous dots, at the base, and two, much smaller and narrower, deciduous ones about the middle. Flowers drooping, greenish-white, shaped like Lily of the Valley, but smaller. Segments of the calyx broad, deep, nearly triangular.

18. V. liggurianum. Privet-leaved Whortle-berry. Michaux Borel.-Amer. v. 1. 232. Pursh n. 13, excluding the synonym of Willdenow. "Flowers nearly sessile, in sessile tufts. Leaves nearly sessile, erect, lanceolate, pointed, finely ferrated, veiny, downy. Corolla longish-ovate. Branches angular. — In dry woods, from Pennsylvania to Virginia; common on the mountains, flowering in May and June. An upright straight stalk. Leaves membranous, furnished with conspicuous, often purplish, veins. Scales of the flower-buds also purplish. Tufts of flowers sometimes springing leaflets from the branches, sometimes axillary. Corolla purplish-red. Berries black. The leaves vary extremely in shape and size. Pursh, Michaux. We adopt this species, which we have never seen, from the authors quoted, under the name by which they have distinguished it. But the Linnaean V. liggurianum is a nonentity, or rather no Vaccinium, being the very same plant with Andromeda paniculata; Linnaeus having received it in flower, from Kalm, as a Vaccinium, and in fruit, as an Andromeda. The latter species, having flowers of another species annexed, could not but mislead him, though we must allow that he too implicitly trusted his pupil, in all the strange blunders, which we have had the mortification of recording and explaining, relative to this genus.

19. V. reflexum. Clammy Whortle-berry. Ait. n. 11. Wild. n. 17. Pursh n. 7. Curt. Mag. t. 1288. (V. parviflorum; Andr. Repof. t. 125. "Andromeda bacatta; Wangenh. Amer. t. 39. f. 69.") — Clusters leaflets, villous, downy, with lanceolate bracteas on the partial flasks. Leaves obvate-lanceolate, blunfit, pointets, entire, covered with resinous dots. Calyx in five deep ovate segments, longer than the germen. — In woods and on mountains frequent, from Canada to Carolina, flowering in May and June. From two to four feet high. Berries black, eatable. Pursh. The branches are round; downy when young. Leaves usually an inch and half long, bright green on both sides, more or less obtuse, villous; veiny beneath. Clusters lateral, from last year's wood, drooping, lax, shorter than the leaves. Flowers small, either red or purple, or of a greenish-yellow. Calyx reddish or brown, remarkably large in proportion to the germen, not well expressed in either of our English figures.

22. *V. padifolium*. Madeira Whortle-berry. (V. Arctofothaphylos; Ait. n. 16. Curt. Mag. t. 974. Andr. Repof. t. 36. Pallas Rolf. v. 1. p. 45.)—Clusters lateral. Bracteas all at the base of the partial flalks. Leaves ovato-lanceolate, acute, finely ferrated, smooth on both sides, except the mid-rib. Stamens nearly as long as the bell-shaped corolla, with smooth, slightly ferrigated, filaments. Calyx five-lobed.—Native of the loftest parts of the island of Madeira, where it forms impenetrable thickets, flowering in July, according to Mr. Maffon, who lent a specimen to the younger Linnaeus in 1777. This so precisely agrees with Mr. Edwards’s figure in Curtis’s Magazine, drawn from a plant obtained from Mount Caucufus, by Mr. Lodidges, that we cannot doubt its being what Pallas found in the alpine beech forests of that neighbourhood. The younger Linnaeus obtained a specimen of the same, from the English gardens; and we received one in flower, from the present duke of Marlborough’s garden, at White Knight’s, in June 1806. So far therefore our cultivated plant is identified, nor can any thing be more distinctly, from the true *V. Arctofothaphylos*. The leaves, well compared by Pallas to those of the Bird-cherry, are of a more rigid texture, and not half so large as the former; they are more rounded at the base; their ferrurations, though small, more evident; under surface quite smooth, except at the very base about the mid-rib, which is also a little hairy on the upper side. *Footforks* longer. *Calyx* more decidedly five-lobed, though it appears to vary in the depth of its segments. *Corolla* larger, pale green, with a purple tinge; sometimes it seems to be all over purple externally. Partial or internal *bracteas* rather broader. *Germen* very glaucous. The *filaments* differ essentially, in being flat, quite smooth at each side, and only slightly ferrigated in the margin, especially about the top. We can discern no spurs on the *anthers*, which moreover are rather shorter with respect to the *corolla*. The *style* is sometimes a little prominent, but not conically. Pallas says the *berries* are black, juicy, eatable, gratefully acid. Sometimes, though very rarely, he found the flowers four-cleft.

23. *V. cymodoacamum*. Azorian Whortle-berry. —Clusters lateral. Bracteas ferrated, all at the base of the partial flalks. Leaves elliptic-lanceolate, acute, finely ferrated, quite smooth, except the base of the mid-rib. Stamens half the length of the cylindrical corolla, with hairy ferrurations. *Calyx* slightly five-lobed.—Native of mountains in the Azores, where this species is called *Uva de ferras*, or Mountain Berry. We believe our specimen to have been gathered by Mr. Maffon. The *fruit* appears to be arborescent. The *branches* are round, thick only of the present year leafy, and finely downy at the two opposite sides. *Leaves* like the last, but rather larger, more tapering at the base, and quite smooth, except a little shorter down at the bottom, about the mid-rib and *footfork*. *Clusters* numerous, on the leafless branches of the preceding season, under the leafy shoots of the present year, spreading the length of the leaves, with smooth, angular, red *filaments*; and deciduous *bracteas*, of which the inner ones are lanceolate and sharply toothed. *Flowers* drooping, nearly an inch long, apparently red or purple. *Calyx* with a dilated border, very finely and obtusely five-lobed. *Corolla* twice as long as the last, cylindrical, with five erect, short, marginal segments. *Stamens* but half the length of the corolla; their *filaments* mostly hairy all over; *anthers* shorter than the filaments, delitute of spurs. *Style* rather longer than the corolla. Of the *fruit* we have no account, nor do we know whether this species has ever found its way into the English gardens.

---

**VACCINUM.**

Lamarck Dict. v. r. 74. —Michaux Boreale-Amerr. v. t. 232.—Flowers in dense fessile tufts. Leaves nearly fessile, ovato-lanceolate, pointed, finely ferrated, smooth, except the rib and margin. Branches angular, with a downy line at each side. *Calyx* in five deep acute segments.—On dry hills on a grassy soil, from New England to Virginia, flowering in May. A low, very branching *flrub*. *Flowers* pale red. *Calyx* green. *Berries* large, blue-black, extremely sweet and agreeable to eat. The mountains of Pennsylvania produce an immense variety of this species, in size and shape of the fruit, leaves, and flowers. *Purpuf.* Specimens from the late Rev. Dr. Muhlenberg, which we cannot but refer to this, have green rather warty *branches*, distinguished by a fine downy line along each side. The *leaves* are an inch long, resembling those of some dwarf Willows, beautifully reticulated, sometimes purplish; most shining beneath; their ferrurations minute, glandular, downy, as well as the mid-rib. *Flowers* few, in tufts, from fealy axillary red *buds*, about the tops of the branches. *Calyx* very smooth.

21. *V. Arctofothaphylos*. Oriental Bear-berry, or Whortleberry. Linn. Sp. Pl. 500. Willd. n. 21. (Vitis indica orientalis maxima, ceratifi folio, flore variegato; Tournefort Cor. 42. Voyage v. 2. 98, with a figure.)—Clusters lateral. *Bracteas* all at the base of the partial flalks. Leaves elliptical, acute, minutely ferrated; hairy beneath. Stamens as long as the bell-shaped corolla, with very hairy filaments. *Calyx* slightly five-lobed.—Gathered on the coalt of the Black Sea, by Tournefort, two of whose specimens are before us. He describes this *flrub* as the height of a man, with a trunk as thick as one’s arm. The young leafy *branches* are downy on two opposite sides, like the foregoing, but more broadly. *Footforks* extremely short and broad, hairy. *Leaves* plant, broadly elliptical, tapering at each end, two inches and a half long, and nearly one and a half broad, bright green, sometimes reddish above, and quite smooth, except the midrib, on that side; paler beneath, and besprinkled with short prominent hairs, especially about the lower part of the rib; their margin furnished with copious, but blunt and shallow, ferratures. *Clusters* from the wood of the preceding year, below the fresh leafy shoots, drooping, one and a half or two inches long, somewhat hairy, composed of eight or ten pendulous *flowers*, of a dirty white, striped or stained with purple. *Bracteas* several at the base of each partial flower-flalk, fringed; one of them large, ovate, often half an inch, or more, in length; the rest linear-lanceolate, much smaller, one or two in number, scarcely more, being analogous to those found about the middle of the partial flalks, in several species already described, though differently situated in the present species and its allies. *Calyx* with five shallow, more or less evident, marginal segments, smooth. *Corolla* bell-shaped, five lines long and four wide, with five shallow, recurved, marginal segments. *Filaments* ten, nearly half as long as the corolla, round, gibbous, extremely hairy at the back. *Anthers* longer than the filaments; yellow, smooth, and tubular above, furnished with two granulated pouches, defending much below their insertion, at the inner side of the filament, and with two small dorcal spurs, at the base of the tubes above those pouches. *Style* shorter than the corolla. The *berries* were seen by Tournefort in an unripe flat only. He judges this plant, with great probability, to be the *eugenia* or Bear-grape of Galen.

What the variety β of Linnaeus may be, we know not, as nothing anfwerable to his reference is to be found in Tournefort’s *Corallarium*.
VACCINIUM.

24. V. meridionale. Jamaica Whortle-berry. Swartz Ind. Occ. 676. Willd. n. 22. Ait. n. 17.—Clusters erect, downy. Bracteas solitary, ovate. Leaves ovate, crenate, permanent, smooth. Stem arborescent. Native of the lofty Blue mountains in the southern part of Jamaica, flowering in February, and ripening fruit in August. This is from ten to thirty feet high, with a very straight smooth trunk, and hard wood. Branches straight, spreading, leafy, round; downy when young. Leaves rigid, an inch or rather more in length, on short, broad, downy stalks, flat, and somewhat shining, veiny; paler beneath. Clusters solitary near the end of last year's branches, twice as long as the leaves; their partial stalks naked, except a large, solitary, ovate, smooth, coloured, deciduous bractea, at the base of each, and equal to it in length. Flowers drooping, reddish-white. Calyx in four broad, acute, permanent segments. Corolla ovate, quadrangular before expansion, contracted at the mouth, with four acute, recurved, marginal segments. Stamens eight, as long as the corolla, their filaments hairy in the middle. Dr. Swartz mistakes the tubular points of the anthers for horns or spurs. Style the length of the corolla. Berry roundish, juicy, pleasantly flavoured, pale red, resembling that of V. Vitis idea. The flowers are very rarely five-cleft and deciduous.

25. V. cereum. Otaheite Whortle-berry. Forst. Prodr. 28. Willd. n. 25. (Andromeda cerea; Linn. Suppl. 238.)—Stalks axillary, solitary, single-flowered, with two lanceolate bracteas about the middle. Leaves roundish-ovate, serrated, smooth, permanent. Calyx in five broad pointed segments.—Gathered by Forster in Otaheite. The branches are round, smooth, leafy; slightly downy when young. Leaves about an inch long, pointed, coriaceous, veiny, twice the length of the smooth simple flower-stalks. Corolla ovate-oblong, with five angles, and five erect small segments. Anthers, according to Linnæus, with two dorsal horns.

26. V. Vitis idea. Red Whortle-berry, or Cow-berry. Linn. Sp. Pl. 500. Willd. n. 24. Fl. Brit. n. 3. Engl. Bot. t. 598. Pursh n. 18. Fl. Dan. t. 40. (Vaccinium rubra; Ger. Em. 1415; Vitis idea rubra; Camer. Epit. 136.)—Clusters terminal, drooping; with ovate concave bracteas, longer than the flower-stalks. Leaves obovate, revolute, minutely toothed; dotted beneath. Corolla bell-shaped. Native of dry barren rocky woods and heaths, in the north of Europe, plentiful in Scotland, Wiltshire, Devonshire, Wales, &c. Flowering in June, and ripening fruit in August. Mr. Pursh says it occurs on rocks near the sea-coast, from Canada to New England, but the American plant is more robust than the European, with considerably larger leaves. The roots are creeping, woody. Stems ascending, in England about a span high, wavy, but little branched, smooth, leafy; young branches round, downy. Leaves evergreen, somewhat like box, but darker on the upper side, smooth and shining. Flowers pale pink, four-cleft, in elegant, dense, solitary, pendulous clusters. Calyx in four deep, broad, ovate, red segments. Anthers without horns. Stigma small, slightly notched. Berries blood-red, acid, astringent and bitter, lasts palatable in tumors than either the Cranberry or Bilberry, but excellent in a roeb or jelly, for colds and chronic diseases, as well as to eat with roast meat, to which latter purpose this jelly is universally applied by the Swedes.

28. V. crafisfolium. Thick-leaved Whortle-berry. Andr. Repof. t. 157. Ait. n. 19. Pursh n. 20. Curt. Mag. t. 1132.—Clusters lateral and terminal, corymbose. Bracteas shorter than the flower-stalks. Leaves elliptical, crenate, smooth; paler and veiny beneath. Corolla bell-shaped. Stem diffuse.—Brought by Mr. Frazer from Carolina, in 1787. It flowers in May and June. A trailing evergreen species, requiring some shelter from our variable winters and springs. The leaves are not an inch long; their upper surface very smooth and even, with a little minute pubescence on the midrib and flower-stalk. Flowers five-cleft, prettily variegated with pink and white, drooping, on red corymbose flanks. Stamens hairy. We have no account of the fruit.

29. V. villosum. Hairy Mexican Whortle-berry. Clusters longer than the leaves. Flower-stalks, calyx, corolla and lanceolate bracteas densely hairy. Leaves elliptical, entire, revolute, coriaceous, with a blunt point; hairy on the upper side.—Sent by M utilis to Linneus from Mexico. The branches are round, leafy, densely hairy when young. Leaves crowded, an inch long, on thick downy flower-stalks; their upper side convex; under paler, veiny, scarcely hairy, except the rib. Clusters towards the ends of the younger branches, axillary, dense, drooping, nearly twice as long as the leaves, very hairy all over, the niger particularly. Bracteas coloured, internally smooth; those of the partial stalks very narrow. Calyx in five deep, lanceolate, densely fringed segments. Corolla purplish, oblong, with five hairy angles, and as many small recurved teeth. Fruit unknown, but the habit, and the inferior niger, sufficiently announce the genus.

30. V. reticulatum. Reticulated South-sea Whortleberry. Stalks axillary, solitary, single-flowered, downy. Leaves ovate, more or less serrated, coriaceous, with a blunt point; strongly reticulated on both sides and nearly smooth. Germin hairy.—Gathered by Mr. Menzies, in woods on high mountains, in the Sandwich islands. The branches are leafy; when young angular and finely downy. Leaves an inch long; remarkable for their reticulated veins, prominent on both sides; their margins somewhat revolute, strongly serrated, but sometimes nearly entire. Flower-stalks numerous, erect, about an inch long, swelling upwards, without bracteas; reflexed as the fruit advances. Calyx in four or five deep, oblong, ribbed, downy, coloured segments, at length involute. Corolla cylindrical, thrice as long as the calyx, purple, slightly hairy, with four or five upright blunt teeth. Style hairy, shorter than the corolla. Berry globular, depreised, nearly or quite smooth.

31. V. dentatum. Toothed South-sea Whortle-berry. Stalks axillary, solitary, single-flowered, smooth. Leaves ovate, with sharp tooth-like serrations, coriaceous, veiny, very smooth. Calyx longer than the smooth germin. Found by Mr. Menzies, in woods on the lofty mountains of the Sandwich islands. The branches of this are angular, always smooth, like every other part. Leaves rather longer than the last, more strongly and uniformly toothed, with less prominent veins. Flower-stalks naked and smooth; recurved when in fruit. Calyx in five deep, oblong, obtuse, smooth, keeled segments, longer than the germin, even after the corolla is fallen, which latter is wanting in our specimens.

VACCINIUM.

37. V. Oxycoccus. Common Cranberry. Linn. Sp. Pl. 500. Willd. n. 25. Fl. Brit. n. 4. Engl. Bot. t. 319. Fl. Dan. t. 80. Lamarck f. 3. (Vaccinium palustris; Ger. Em. 1419. Lob. C. v. 2. 109. Oxyccoccus; Cord. Hift. 142. f. 1. Oxyccoccus vulgaris; "Perf. Syn. v. 1. 419." Purf. 263.)—Corolla deeply four-cleft. Leaves ovate, entire, revolute, acute, smooth. Stems creeping, thread-shaped. Flowers terminal.—Native of turfy molly bogs in the mountainous parts of Europe; common in Switzerland, Ruffia, Scotland, Ireland, and the north of England, as well as in Lincolnhire, and the neighbouring part of Norfolk, flowering in June. Mr. Purf. speaks of it as common on the boggy mountains of North America, from Canada to Pennsylvania, flowering from May to July. Few plants are more elegant. The wiry shrubby stems creep among bog-mofs, with long, branching, fibrous roots, which often appear to imbibe nourishment from the clear water alone. Branches scattered, procumbent, smooth, reddish, leafy. Leaves evergreen, flalked, from a quarter to half an inch long, coriaceous; convex and of a dark shining green above; glaucous beneath. Flowef-flalks few together about the tops of the branches, somewhat corymbose, above an inch long, fimple, red, flightly hoary, bearing two minute bracteae in the lower part, and a solitary, drooping, very beautiful, four-cleft flower at the top. The gemin is smooth. Calyx-lobea broad and fallow. Corolla pink, with reflexed oblong segments, a quarter of an inch in length. Filaments purple, downy. Anthers yellow, converging, without spurs. Berry pear-shaped or globular, often spotted, crimson, of a peculiar flavour, somewhat like black currants, with a strong acidity, grateful to most people, in the form of tarts, for which purpose they are largely imported from Ruffia. We can remember Cranberries from Lincolnhire, and the north-west corner of Norfolk, being sold in cart-loads about the streets of Norwich; but the extensive enclosures have, in many parts, deftroyed and drained their native bogs. Light-foot records that at Longtown, on the borders of Cumberland, not less than twenty or thirty pounds-worth were sold each market-day, for five or six weeks together, and dispersed over different parts of the kingdom. In Sweden these berries serve only to boil silver plate to its due degree of whiteness, their sharp acid corroding the superficial particles of the copper alloy.

38. V. macrocarpus. American Cranberry. Ait. Hort. Kew. ed. 1. v. 2. 13. t. 7. ed. 2. n. 22. Willd. n. 27. Lamarck f. 4. (V. Oxycoccus; Michaux Boreal.-Amer. v. 1. 228. "V. hispidulum; Wangenh. Amer. 108. t. 30. f. 67." Oxyccoccus macrocarpus; Purf. 263.)—Corolla deeply four-cleft. Leaves elliptic-oblong, entire, flightly revolute, obtuse, smooth. Stems ascending. Flowers lateral.—In bogs principally in a sandy foil, and on high mountains, frequent, from Canada to Virginia, flowering from May to July. A larger and more upright plant than the last, with less convexp, more oblong, much larger leaves. Several flowers come forth at the ends of the last year's branches, surmounted by the flouths of the present year. Their bracteae are fntuated towards the top of each flalk, and, as well as the segments of the corolla, are larger than in the Common Cranberry. The filaments however are shorter in proportion to their anthers, which are uncurly long. The berries are larger, and of a brighter red, than the last, collected in great abundance, for making tarts, in America, and exported from thence to Europe; but they, always prove here far inferior in quality to the Ruffian Cranberies,
berries, however excellent in America. The best method of having American Cranberries in Europe, is by cultivation in an artificial bog with great plenty of water, as first contrived by Sir Joseph Banks. A very few square yards of ground thus employed, will yield as many Cranberries as any family can use. If allowed to hang till they are full ripe, as late as October, they are even better than the Oxycoccus, and may be kept dry in bottles throughout the year. Our wild Cranberries have generally been gathered too early; as may also be the case with those brought from America.

We have seen no specimen of this species. Its fruit might be an acquisition to our tables, if raised in the same mode as the last.

In the above ample detail of the genus Vaccinium, which we trust will prove acceptable to those who have ever attended to its former confusion, we have removed eight of Wildenow's species. Four of these are album, mucronatum, ligustirum and hirsutum of Linnaeus, the latter being referred by Mr. Pursh to Gaultheria by the name of perpilia; see that article, where this species should be introduced next to procumbens, with the following character.

The other four divided species of Wildenow are fasciatum, svenstum, amenum and virgatum of Dr. Solander, in Alt. Hort. Kew. ed. 1.; the reasons of which rejection are to be found under our 15th and 17th species.—On the other hand, we have augmented this genus with seven entirely nondescript species, for most of which we are obliged to the bounty of our often-mentioned friend Mr. Archibald Menzies; as well as with twelve others from Michaux, Pursh, and our several English garden botanists and publishers. On this subject we would particularly direct our fellow-labourers to the plants hitherto confounded under V. Arctophyllos, and the still-upaded varieties of that interesting species; relating to which, dicycories are probably yet to be made, in the wilds of Tartary and the Levant, and possibly even in the greenhouses of France and England.

VACCINIUM, in Gardening, comprehends many sorts of hardy, dwarf, under-shrubby, lignious, evergreen, and deciduous plants, among which the species most commonly cultivated are those of the black whortle, or bilberry (V. myrtillus); the white Pennsylvania whortle, or bilberry (V. album, see the preceding article); the red whortleberry (V. vitis idaea); the cranberry, moss, or moor berry (V. oxycoccus); the marsh whortle, or great bilberry-bush (V. uliginosum); the hispid-flaked American whortleberry (V. hispidulum, see the preceding article); the corymbous-flowering American whortleberry (V. corymbosum); the privet-leaved Pennsylvanian whortleberry (V. ligustrininum); and the flammeous American whortleberry (V. flammeum).

Theertia has flender, branching, shrubby stalks, about two feet in height, and produces large eatable berries of a blackish-red colour. The second is a similar plant, producing small berries of a whitish colour. The third is a more dwarfish plant, producing clusters of nodding, red berries, and red juicy berries of very great value for tarts, and other culinary uses. The fourth has flender creeping stalks, which produce reddish eatable berries of very great value and importance for different culinary well-known purposes, as in pies, tarts, &c. The fifth has a woody, shrubby, branching stalk of some height, and affords whitish purple flowers, and large berries. The sixth grows with flender, trailing, rough stalks, and yields large red berries. The rest are all American plants.

Method of Culture.—They may all be raised from seeds, or offset root-fuckers, creeping roots, and trailing rooting stalks. Those also growing with several rooted stalks and branches, may be divided in the root and top, into separate plants, in which way they succeed very well.

The seeds should be sown, where that method is purposed, in the autumn as soon as they are ripe and gathered, in a shady border, or the places where the plants are to grow and remain; and when the young plants are up, they should be kept clean, and be removed with earth about their roots, as there may be occasion.

The offsets and root-plants may be set out in the same season in proper places, which for the first four sorts are those where the soil is of a cold, light, sandy, heathy, mossy, moorly, or woody nature, and for the two succeeding ones in marshy and boggy situations; as these have the most resemblance to those in which they grow naturally, and are the most prosperous. It may likewise be advisably in many cases to take the plants from their native situations with balls of earth about their roots. Some, however, succeed in the common borders and other parts. They may in some cases be removed in the spring season, but the other is the better way.

They are admitted into gardens and pleasure-grounds for the sake of variety, curiosity, and ornament, and some of them are cultivated for the use of their fruit. In its natural situation, that of the cranberry is often an object of very great importance, affording the poor gatherers of its berries considerable employment as well as much money. It delights moss in rather wet, mossy, mossy situations.

The vaccinium oxycoccus of Linnaeus, or cranberry, may be preferred perfect for several years, merely by drying it a little in the sun, and then stopping it closely in dry bottles. The vaccinium myrtillus, or bilberry, yields a juice, which has been employed to flax paper, or linen, purple. In autumn the moor-game chiefly live upon the product of this shrub.

VAERII. See Druids.

VACH, in Geography, one of the smaller Lipari islands, in the Mediterranean.

VACH, or VACH, in Mythology, a name of the Hindoo god-faes Saraswati; fakti or comfort of the creative power in the Trimurti, or divine Triad of the East. The name Vach, or Vachi, is derived from speech, Saraswati being goddes of eloquence; and hence called also Vachdevi. Vachapati, a title equivalent to lord of eloquence, is sometimes applied
to the regiment of the planet Jupiter, whom the Hindoos call *Vr̥ṣapāti*; which see.

**VACHA**, in Geography, a town of Germany, in the principality of Upper Helfe, on the Werra; 20 miles N.E. of Fulda.—**Alto**, a town of Germany, in the margravate of Anpachch, on the Rednitz; 25 miles N.E. of Anpach.—**Allo**, a town of Peru, in the diocese of La Paz; 8 miles S.W. of La Paz.

**VACHE**, or *Cow's Island*, an island about twelve miles from the south coast of Hispaniola, about twenty-four miles in circumference. It was formerly a place of rendezvous for pirates and freebooters, and is provided with three ports, one of which can receive vessels of 300 tons. N. lat. 18° 51'.

**VACHE et le Torreau, or Cow and Bull Rocks**, rocks on the south coast of Newfoundland, a little to the east of Placentia bay.

**VACHELUSE**, one of the Lipari islands; 3 miles S. of Stromboli.

**VACHIER**, a town of France, in the department of the Upper Loire; 9 miles S. of Le Puy en Velay.

**VACHON, Pierre**, in Biography, an eminent performer on the violin, was born in Provence, 1730. After performing at the concert spirituel with great applause, he was placed at the head of the prince of Conti's select band. In 1781 he was appointed concert-master to the king of Prussia at Berlin, after refiding some time in London, and leading at the Opera. He was one of the most certain and agreeable performers on the violin of his time, particularly in trios and quartets. He was likewise a composer of considerable merit, having furnished the different theatres of Paris with fixed or eight successful musical dramas, and the performers on his instrument with several books of solos, quartets, and concertos, which were practicable and in a pleasing style. He had an extreme melancholy expression of countenance, of which he was insensible, and used to say, in pleasantry, "Ma triste contenance m'a fait beaucoup de mal auprès des dames."

**VACIA, or Vacz**, in Geography. See Waitzen.

**VACIAN**, a town of Abalica; 15 miles S. of Alkasy.

**VACKALEER**, a town of Hindooaltan, in Mylof; 27 miles E.N.E. of Calcutta.

**VACOMAGI**, in Ancient Geography, a people of the isle of Albion, S. of the Caledonii, whose towns were Banatica, Tamaa, the Winged Camp, or Alata Caftra, and Tusells.

**VACONE**, in Geography, a town of the Popedom, in the duchy of Spoletto; 8 miles S.E. of Narni.

**VACONTIUM**, in Ancient Geography, a town of Lower Pannonia, at a distance from the Danube.

**VACUA, Ital., in Myfie, a white open note; in old English, a void; in opposition to notes with black heads, like crotchetts and quavers. In the first time-table all the notes were black, till the invention of the fermubre and minim.**

**VACUNA**, in Mythology, a goddess held in high veneration among the Sabines.

**VACUNALIA**, a festival kept in honour of the goddeess Vacuna, who presided over those that were unemployed or at rest.

It was celebrated in December by the country labourers, after the fruits were gathered in, and the land tilled.

Ovid speaks of it in his *Fasti*, lib. vi.

"Nam quoque cum funt antiquæ sacra vacuna, Aut vacunæ flautæque, lenteque flutes."

The worship of Vacuna was very ancient in Italy, and embellished among the Sabines long before Rome was founded. Some take her for Diana, Venus, or Ceres, and others for Bellona or Victory. Varro thinks she was Minerva.

**VACUP**, in Geography, a town of Bosnia; 32 miles S. of Zerje.

**VACUUM, Vacuity**, in *Physics*, a space empty or devoid of all matter, or body.

Whether there be any such thing in nature as an absolute vacuum; or whether the universe be completely full, and there be an absolute plenum, is a thing that has been controverted by the philosophers of all ages.

The ancients, in their controversies, distinguished two kinds; a *vacuum coacervatum*, and a *vacuum interpersum*, or *dispersinatum*.

"Vacuum coacervatum, is conceived as a place destitute of matter; such, e. gr. as there would be, should God annihilate all the air, and other bodies within the walls of a chamber."

The existence of such a vacuum is maintained by the Pythagoreans, Epicureans, and the Atomists, or Corpuscularians; most of whom assert such a vacuum actually to exist, without the limits of the sensible world. But the modern Corpuscularians, who hold a *vacuum coacervatum*, deny that appellation; as conceiving, that such a vacuum must be infinite, eternal, and uncreated.

According, then, to the later philosophers, there is no *vacuum coacervatum* without the bounds of the sensible world; nor would there be any other vacuum, provided God should annihilate divers contiguous bodies, than what amounts to a mere privation, or nothing; the dimensions of such a space, which the ancients held to be real, being by them held to be mere negations; that is, in such a place, there is so much length, breadth, and depth wanting, as a body must have to fill it. To suppose, that when all the matter in a chamber is annihilated, there should yet be real dimensions, is to suppose corporeal dimensions without body; which is absurd.

The Cartesians, however, deny any *vacuum coacervatum* at all; and assert, that if God should immediately annihilate all the matter, e. gr. in a chamber, and prevent the ingress of any other matter, the consequence would be, that the walls would become contiguous, and include no space at all. They add, that if there be no matter in a chamber, the walls can be conceived no otherwise than as contiguous; those things being said to be contiguous, between which there is not any thing intermediate; but if there be no body between, there is no extension between; extension and body being the same thing; and if there be no extension between, then the walls are contiguous, and where is the vacuum?

But this reasoning is founded on a mistake, viz. that body and extension are the same thing. See Matter.

**Vacuum dispersinatum, or interpersum**, is that supposed to be naturally interpersed in and among bodies, in the pores of the same body, and in the interstices between different bodies.

It is this kind of vacuum which is chiefly disputed among the modern philosophers; the Corpuscularians strenuously afforting it; and the Peripatetics and Cartesians as tenaciously impugning it. See *Cartesian* and *Leibnitzian*.

The great argument the Peripatetics urge against a *vacuum interpersum* is, that there are divers bodies frequently sent to move contrary to their own nature and inclination; and that for no other apparent reason, but to avoid a vacuum; whence they conclude, that nature abhors a vacuum, and gives us a new class of motions ascribed to the *fuga vacui*, or nature's flying a vacuum. Such, they say, is the rife of water in a syringe, upon the drawing up of the piston; such also is the ascent of water in pumps, and the
But motion, circles but It the material. motion other-and, it both. ” There a can from the vacuum, at the same time that he admits it. Des Cartes, if we may believe some accounts, rejected a vacuum from a compliance to the table which prevailed in his time, against his own first sentiments; and among his familiar friends used to call his system his philosophical romance.

On the other hand, the corpuscular authors prove, not only the possibility, but the actual existence of a vacuum, from divers considerations; particularly from the consideration of motion in general; and that of the planets, comets, &c. in particular; from the fall of bodies; from the vibration of pendulums; from rarefaction and condensation; from the different specific gravities of bodies; and from the divisibility of matter into parts.

1. It is argued, that motion could not be effected without a vacuum. This is what Lucretius urged long ago. “Principium quoniam sedendi nulla dare res—unde materies quoniam ripata fuifeit.”

The force of this argument will be increased from the two following considerations; viz. first, that all motion is either in a straight line, or in a curve, which returns into itself, as the circle and ellipsis; or in a curve that does not return into itself, as the parabola, &c. And, secondly, that the moving force must always be greater than the resistance.

From hence it follows, that no force, even though infinite, can produce motion where the resistance is infinite; consequently, there can be no motion either in a straight line, or in a non-returning curve; because, in either of those cases, the propulsion, and consequently the resistance, would be infinite. There remains, therefore, only the motion of a revolving curve practicable; this must either be a revolution upon an axis, or an annular motion round a quiescent body; both which are, again, impossible in an elliptic curve; and, consequently, all motion must be in circles geometrically true; and the revolving bodies must either be spheres, spheroids, cylinders, or portions of them, exactly geometrical; otherwise the revolutions in a plenum would be impossible: but such motions, or such figured bodies, we do not know in nature. Therefore there is a vacuum.

2. The motions of the planets and comets demonstrate a vacuum: thus Sir Isaac Newton,—“That there is no such fluid medium as ether,” (to fill up the porous parts of all sensible bodies, as the air and interstellar parts, and so make a plenum,) “seems probable; because the planets and comets proceed with so regular and lasting a motion through the celestial spaces, both from and to all parts; for hence it appears, that those celestial spaces are void of all sensible resistance, and consequently of all sensible matter. For the refitting force of fluid mediums arises partly from the attrition of the parts of the medium, and partly from the inactivity of matter. Now, that part of the resistance of any medium, which arises from the tenacity or attrition of its parts, may be leifened by dividing the matter into smaller parts, and rendering those parts more smooth and slippery: but that part of the resistance which arises from the inactivity of matter, is always in proportion to the density of the matter; nor can it be diminished by dividing the matter, nor by any other means, except by diminishing the density thereof.

“Consequently, if the celestrial regions were as dense as water, or as quicksilver, they would resist almost as much as water or quicksilver; but if they were perfectly dense without any interfered vacuity, though the matter were ever so fluid and subtle, they would resist more than quicksilver does: a perfectly solid globe, in such a medium, would lose above half its motion, in moving three lengths of its diameter; and a globe not perfectly solid, such as the bodies of the planets and comets are, would be stopped still sooner. Therefore, that the motion of the planets and comets may be regular and lasting, it is necessary the celestial spaces be void of all matter, except perhaps some few, and much rarer effulgia of the planets and comets, and the paling rays of light.”

3. The same great author deduces a vacuum also from the consideration of the weights of bodies; thus: “All bodies about the earth gravitate towards the earth; and the weights of all bodies, equally distant from the earth’s centre, are as the quantities of matter in those bodies. If the ether, therefore, or any other subtle matter, were altogether destitute of gravity, or did gravitate less than in proportion to the quantity of its matter; because (as Ariflotle, Des Cartes, and others, argue) it differs from other bodies only in the form of matter; the same body might, by the change of its form, gradually be converted into a body of the same constitution with those which gravitate most in proportion to the quantity of matter: and, on the other hand, the most heavy bodies might gradually lose their gravity, by gradually changing their form; and therefore the weights would depend upon the forms of bodies, and might be changed with them; which is contrary to all experiment.”

4. The descent of bodies proves, that all space is not equally full; for the same author goes on, “If all spaces were equally full, the specific gravity of that fluid with which the region of the air would, in that case, be filled, would not be less than the specific gravity of quicksilver or gold, or any other the most dense body; and therefore neither gold, nor any other body, could descend therein. For bodies do not descend in a fluid, unless that fluid be specifically lighter than the body. But, by the air-pump, we can exhaust a vessel, till even a feather shall fall with a velocity equal to that of gold in the open air: the medium, therefore, through which this feather falls, must be much rarer than that through which the gold falls in the other case.

“The quantity of matter, therefore, in a given space, may be diminished by rarefaction: and why may not it be diminished in infinitum? Add, that we conceive the solid particles of all bodies to be of the same density; and that they are only rarefiable by means of their pores: and hence a vacuum evidently follows.”

5. “That there is a vacuum, is evident from the vibrations of pendulums; for since those bodies, in places out of which the air is exhausted, meet with no resistance to retard their motion, or shorten their vibrations; it is evident there is no sensible matter in those spaces, or in the occult pores of those bodies.”

As to what Des Cartes urges of his materia subtilis, that its tenity prevents its resistance from being sensible; and that a small body, striking against a greater, cannot in the least move, or reft the motion of that other; but is reflected
VACUUM.

flecked back again with all its momentum; it is contrary to all experience. For Sir Isaac proves, that the densit

y of fluid mediums is proportionable to their refifiances, very nearly; and that they are exceedingly mistaken, who sup-

pose the refifiance of projectiles to be infinitely diminished, by dividing the parts of the fluid, even in infinitum (Prin-

cip. lib. ii. prop. 38.); when, on the contrary, it is clear the refifiance is but little diminished by the subdivi-

"on of the parts (ibid. prop. 40.), and that the refifling forces of all fluids are nearly as their densities.—For why should not the fame quantity of matter, whether divided into a great number of minute parts, or into a few larger ones, have the fame refifling force? If then there were no vacuum, it would follow, that a projectile moving in the air, or even in a space where the air is exhausted, should move with as much difficulty as it would in quicksilver; which is contrary to experience.

Nor will it avail to suppute the particles of the subtile fluid, constituting a plenum, to move contantly and equally in all directions; and by favour of this hypothenes, to imagine that they act, but do not refit. Becauze the motion of a fluid favours the motion of a body in it, only as far as it is in the fame direction; and an intellent motion of the parts of the fluid, equal in all directions, cannot make the refifiance less; if there was no motion of the parts. It is suppute by many that the particles of common fluids, e.g. water or air, are in a contant intellent motion, but this does not hinder those fluids from refifiting in proportion to their densi-

ty.

If it should be alleged, that by supposing this dense fluid which replenifhes space to penetrate the pores of bodies with the utmost freedom, (as light paffes through transparent bodies, and the magnetic and elec
ctric effluvia through moft kinds of bodies,) its refifiance will then be incomparably less than in proportion to its densi-
y; the refifiance in this cafe not being measured by the densi-
y of the fluid, because the greater part paffes through the pores of the body in motion freely, without refifiance; yet even on this hypothenes, the refifiance of a golden ball in a plenum would be still very great. For this subtile fluid, how penetrating ever it be, must refit the solid parts of the ball; which cannot move in the fluid without displacing its parts, and losing as much motion as must be communicated to those parts; and this refifiance depends on the quantity of solid parts in the ball; whereas the refifiance which the same ball meets with in quicksilver (which we suppute to have no paf-
fage through the ball), depends on the quantity of the solid parts in an equal bulk of the quicksilver, which must be moved to make way for the ball. And this being less than the quantity of solid parts in an equal bulk of the golden ball, in proportion as the specific gravity of quick-
silver is less than that of gold, it follows that the refif-
inance of a golden ball, moving in quicksilverpenetrating plenum, would still be greater than its refifiance in quick-
silver. The refifiance of a golden ball in a plenum (how freely ever the matter constituting it paffes through the pores of the ball, and how large and numerous pofee these pores may be) must correspond to the solid matter in the ball; which is greater than the solid densiti in any equal bulk of any of our fluids, upon which their refi-

fiance depends.

6. That there are interfpered vacuities, appears from matter's being actually divided into parts, and from the figures of those parts; for, on supposition of an abolute plenitude, we do not conceive how any part of matter could be actually divided from that next adjoining, any more than it is poible to divide actually the parts of abolute space from one another: for by the actual division of the parts of a continuum from one another, we conceive nothing else under-

stood, but the placing of those parts at a distance from one another, which, in the continuum, were at no distance from one another: but such divisions between the parts of matter must imply vacuities between them.

7. As for the figures of the parts of bodies, upon the supposition of a plenum, they must either be all rectilinear, or all concavo-convex; otherwise they would not adequately fill space; which we do not find to be true in fact.

8. The denying a vacuum, supposes what it is impossi-

ble for any one to prove to be true; viz. that the material world has no limits.

However, we are told by fome, that it is impossi-

ble to conceive a vacuum. But this purely must proceed from their having imbibed Des Cartes's doctrine, that the effence of body is conflituted by extenfion; as it would be contra-
dictory to suppute fpace without extenfion. To suppute that there are fluids penetrating all bodies and replenifhing fpace, which neither refit nor act upon bodies, merely in order to avoid admitting a vacuum, is feigning two forts of matter, without any necelility or foundation; or is tacitly giving up the qeuestion.

Since then the effence of matter does not confit in ex-
tenfion, but in solidity, or impenetrability, the univerfe may be faid to confit of solid bodies moving in a vacuum: nor need we at all fear, left the phenomena of nature, moft of which are plausibly accounted for from a plenitude, should become inexplicable when the plenum is fet aside. The principal ones, fuch as the tides: the fufpenfion of the mercury in the barometer; the motion of the heavenly bodies, and of light, &c. are more eafily and satisfactorily accounted for from other principles. See Tides, &c.

VACUUM, or Vaccum Boyleanum, is also used, somewhat more abutively, to express that approach to a real vacuum, which we arrive at by means of an air-pump.

Thus, any thing put in a receiver fo exhausted, is faid to be put in vacuo; and thus, most of the experiments with the air-pump are faid to be performed in vacuo, or in vacuo Boyleanum. Some of the principal phenomena observed of bodies in vacuo, are; that the heaviest and lighteft bodies, as a guinea and a feather, fall here with equal velocity: that fruits, as grapes, cherries, peaches, apples, &c. kept for any time in vacuo, retain their nature, freihness, colour, &c. and thofe withered in the open air recover their plump-

ness in vacuo:—all light and fire become immediately extinct in vacuo:—the collifion of flint and fteel in vacuo, produces no fparks:—no sound is heard, even from a bell rung in vacuo:—a fquare phial, full of common air, well clofed, breaks in vacuo: a round one does not:—a bladder half full of air will heave up forty pounds weight in vacuo:—cats, and moft other animals,foon expire in vacuo.

By experiments made in 1754. Dr. Derham found, that animals that have two ventricles, and no foramen ovale, as birds, dogs, cats, mice, &c. die in fles less than half a minute; counting from the firft exfutation: a mole died in one minute, a bat lived seven or eight. Infetts, as wafps, bees, grafs-hoppers, &c. feemed dead in two minutes; but, after being left in vacuo twenty-four hours, they came to life again in the open air:—flies continued twenty-four hours in vacuo, without appearing much incommoded.

Seeds planted in vacuo do not grow:—small beer dies, and loses all its taffe, in vacuo:—lukewarm water boils very vehemently in vacuo:—and air, refuming through mercury into a vacuum, throws the mercury in a kind of shower upon the receiver, and produces a great light in a dark room.

The
The air-pump can never produce a perfect vacuum; as is evident from its structure, and the manner of its working; in effect, every exsuction only takes away a part of the air: so that there will still be some left after any finite number of exsuctions. Add, that the air-pump has no longer any effect than while the spring of the air remaining in the receiver is able to lift up the valves: when the rarefaction is come to that degree, you may come nearer to a vacuum. Sir Isaac Newton, observing that a thermometer suspended in vacuo, and in that state removed to a warm or a cold room, receives the heat or cold, and rises, or falls, almost as soon as another in open air; takes thence occasion to infer, that the heat of the warm room is conveyed through the vacuum, by the vibrations of a much subtler medium than air, which remained in the vacuum after the air was drawn out. Opt. P. 323.

VACUUM. Torricellian. See Torricellian.

VADA, in Ancient Geography, a place which belonged to the Batavi, W. of Batavodurum. VADA Sabatia, Vai, a town of Italy, in Liguria. VADA Volaterra, a place of Italy, in Etruria. VADA, in Geography, a sea-port town of Etruria, at the mouth of the river Cecina; 18 miles S.W. of Volterra. N. lat. 43° 17'. E. long. 10° 30'. VADACOURCHY, a town of Hindoostan, in Calcut; 10 miles S.W. of Palicaudchery. VADAGARY, a town of Hindoostan, in Madura; 25 miles W. of Coillpetta. VADAMADERRY, a town of Hindoostan, in the province of Dindigul; 15 miles N.E. of Dindigul. VADAMI, a town of the Arabian Iрак, on the Euphrates; 105 miles W.N.W. of Baflora. VADARI, in the Civil Law, denotes a person to pledge, undertake, or give security, in behalf of another, that he shall, on a certain day, appear in court, to prosecute, or answer.

If he fails, his surety has an action vadimoni dediti against him; that is, an action for defecting his bail. See Wager.

Properly speaking, vadari reum, among the Romans, was the act of the plaintiff himself, who here demanded surety, or bail from the defendant, that he would appear before the pretor on a certain day. VADALL, in Geography, a town of Hindoostan, in Soonda; 27 miles S.E. of Goa. VADDAR, Louis de, in Biography, an eminent landscape painter, was born at Bruxelles in 1560. It is not known under whom he studied, where he resided, or how long he lived; but he has left works behind him which exhibit him as a diligent observer of nature, with taste and feeling to select her most fascinating effects, and ability to execute what he attempted, so as to afford the greatest pleasure to all admirers of the art.

It is not improbable that he resided some time in Italy, and had studied the pictures of Titian; perhaps wrought in the same scenery; for his finest works have a great degree of resemblance to those of the Venetian, in the choice of forms and colour however more than in the execution, in which he more resembles Pynacher in freshness and fulness.

Two large pictures by Vadder found their way into this country some time ago, and fully justify these remarks; but in general his works are scarce, or most probably have been introduced under fictitious names. In his native country he is better known and justly esteemed. He has left a few spirited etchings in the style of Lucas Van Uden.

VADE, John Joseph, was born at Ham, in Picardy, and is distinguished as the inventor of a kind of humorous French poetry. In his youth he resided at Paris, and led a dilapidated life; but in more advanced age he perceived the defects of his early education, and endeavoured to supply them by a perusal of the best French authors. As he was original in his mode of thinking, he adopted a new kind of writing, to which he was led by his familiarity with vulgar life. This species of writing was called the "Poifarde manner," and he was hence denominated the "Teniers" of poetry. His productions, which consisted of tales and fongs, were amusing and popular; and as he professed many amiable qualities, he was generally beloved in the gay societies which he frequented. But he was thus led to pursue a course of debauchery, which terminated his life in 1757, at the early age of 37 years. His works, consisting of comic operas, parodies, fongs, &c. have been collected in 4 vols. 8vo., to which has been added a volume of poetical pieces of a familiar nature, though of superior merit, and indicating talents of a higher clafs, which he might have cultivated to advantage. Moreri. Nouv. Dict. Hill.

VADELECT. See Valet.

VADE-MECUM, or a VENI-MECUM, a Latin phrase, used in English, to express a thing that is very familiar; and which any one usually carries about with him: it is chiefly applied to some favourite book.

Some make Virgil, others Horace, their va de mecum; others an Epictetus, &c.

This is what the Greeks call εκποίησις, or manual. The Arabs have a phrase of equal import; viz. Habib al fat' ir, comes itineris, companion of the journey. In Latin it is better expressed by comes; as comes theologicus, comes ruf ticus, &c.

VADENAGORCHY, in Geography, a town of Hindoostan, in Combeatore; 15 miles W. of Damicotta.

VADIANUS, Joachim, in Biography, was born in 1484, at St. Gall in Switzerland, where his father, Leonard Von Watt, was a senator. Having studied at Vienna, he was chosen professor of the belles lettres, and rector of the univeristy. In 1514 he was honoured at Lintz by the emperor Maximilian with the poetical title. In his subsequent travels, he applied to the study of geography, and in 1518, having taken the degree of M.D. at Vienna, he returned to St. Gall, and devoted himself to the practice of physic, to which he joined theology upon the principles of the reformers, whose cause he promoted as a senator, and also by his discourses and writings. Having been honoured eight times with the office of confal, he died in 1551, and bequeathed his library to his fellow-citizens. On the various subjects of mathematics, geography, antiquities, medical, and theology, he published works, as well as several Latin poems. His "Commentary on Pomponius Melas de Situ Orbis," and his "Scholia on the second Book of Pliny's Natural History," are the most generally known of his literary performances. Scaliger regarded Vadianus as one of the most learned men in Germany; and on account of his able conduct of public affairs, Thuanus prays him to notice, as an example, that men of letters and philosophers are not, such, disqualified for business. Moreri.

VADINATION. See Vadar.

VADICASSES, in Ancient Geography, a people of Gaul, who have been distinguished by different denominations: the Bodicasses of Pliny being the same with the Vadicasses of Ptolemy, and both are supposed to comprehend the ancient inhabitants of Bayeux, anciently called Neomagus.

VADILCORA, or Vadi al Kera, in Geography, a town
VLG

town of Arabia, in the province of Hedjes; 36 miles N.
of Medina. N. lat. 25° 30'. E. long. 38° 20'.

VADIMONIS LUCUS, in Ancient Geography, a lake of
Italy, in Etruria, in the vicinity of Ameria.

VADIMONIUM, in the Civil Law, a promontry, or
bond, given for appearance before the judge upon a
day appointed. See VADARI.

VADIN, in Geography, a town of European Turkey,
in Bessarabia, on the Danube; 32 miles W. of Nicopoli.

VADIVUM. See GAGE and PONI PER VADIVIUM.

VADNIA, in Ancient Geography, a town of Hither
Spain, belonging to the Cantabri. Potenomy.

VADO, or VADI, in Geography, a sea-port town of
the Genoese, situated in a bay of the Mediterranean, with
a good harbour; 3 miles S. of Savona. N. lat. 44° 14'.
E. long. 8° 30'.

VADO, il., a town of Naples, in Aburuzzo, in the
Adriatic; 16 miles E.S.E. of Lannfano.

VADO SERTIA, a town of Naples, in Capitanata; 6 miles
S.E. of Troia.

VADOCONDES, a town of Spain, in old Catfide; 26
miles W.S.W. of Olma.

VADORANUM, a town of Hindooftan, in the Car-
natic; 12 miles S. of Negapatam.

VADUTZ, a town and castle of Germany, in the
province of Lichtenstein; 26 miles S. of Lindau. N.
lat. 47° 5'. E. long. 9° 51'.

VÆIPO, a small island in the Baltic, near the north
coast of Lolland. N. lat. 55° 57'. E. long. 10° 46'.

VÆLUE, a river of the island of Ceylon, which runs
into the sea, near Mago.

VA-EMBU, in the Materia Medica, a name given by
some authors to the curcus Asaticus, or Asiatic sweet
flag.

VAENA, in Geography, a town of Spain, in the pro-
vince of Cordova; 18 miles E.S.E. of Cordova.

VÆRO, a small island in the North sea, about 20
leagues from the coast of Norway. N. lat. 67°.

VÆSPA, in Ancient Geography, a town of Asia, in
the Lesser Armenia, towards the mountains, and at a
distance from the Euphrates.

VAG BESTER, in Geography, a town of Hungary, on
the river Vag; 6 miles N.E. of Bolesko.

VAGA, PIOERINO DEL, in Biography, whose real name was
Pietro Buonacorso, was one of those ingenious painters em-
ployed by Raphael to assist him in adorning the Vatican.
He was born at a village near Florence in 1500, of indigent
parents. His father was killed in battle, and his mother
died of the plague before he was two months old. He is
said to have been reared by goat's milk, and as a destitute
orphan, was taken under the protection of an indigent
artist named Andrea de Ceri, whose house was frequented
by several young artists of Florence.

As Pierino had discovered an decided inclination for paint-
ing, he was placed, when eleven years old, under the tu-
thion of Ridolfo Ghirlandajo, and with his affilience soon
came to be a very able designer, and more particularly, as Vafari ob-
erves, by studying with many other Florentine youths as
well as strangers the Cartoon of M. Angelo, known by the
name of the Cartoon of Pisa.

His talents acquired for him the attention and approba-
tion of a Florentine painter of inferior quality, but who had
nevertheless much employment, and was in want of a skil-
ful designer to assist him in conducting his undertakings.
With the consent of his guardian Ceri, Pierino accom-
pnied this man, whose name was Vaga, to the neighbour-
hood of Rome, whence, when the work was completed which
he had undertaken, he was conveyed by his employer to Rome
in 1515, and there introduced to several painters, to whose
care and assistance II Vaga recommended him during his ab-
ence; and thence he was called Pierino del Vaga. In Rome
he endured great miseries, and obtained bread with diffi-
culty; but ever intent upon improvement, he studied
hard the pictures of Angelo di Sifilini, and designed
from the pieces of antique sculpture which by chance came
to his hand, and after a short time, his ardent exertions
were reaided by a degree of success, which led to his adop-
tion into the school of Raphael.

Julio Romano and Francesco Penni first did justice to his
talents by recommending him to their master, who, upon the
first sight of his productions, placed him under Giovanni da
Udine, who had the management of the ornamental parts of
the works then going on in the Vatican. But Pierino
was soon found equal not only to assist Giovanni in the gro-
tique ornaments and in the tuccoss, but also Polidoro da
Caravaggio in the antique subjeets in chiaro-creo, and
sometimes also in executing the sculpture subjects from the
sketches of Raphael, as among others may be seen, accor-
ding to Vafari, in the Hebrews crossing the river Jordan,
the surrounding Jericho, the combat of Joshua with the
Amorites, Abraham preparing to sacrifice Isaac, Jacob
wrestling with the angel, Joseph and his brethren, &c. &c.
The praise which he gained by these labours inspired him
only with a more earnest desire to improve, and the mildna-
and attention of his manner procured for him the esteem
and even love of his master Raphael.

After the death of Raphael, he was employed, with
J. Romano and G. F. Penni, to continue and complete the
adornment of the Vatican, great part of the execution of
which is the work of Del Vaga.

For a short time he went to Florence, when the pope
Leo X. was there, but quickly returned to Rome and pur-
shed his labours, adding to them many original ones, the
inventions of his own mind. Among them was the hall of
the house of Machiome Baldallini, which he adorned with
subjects from the Roman history, with arms, trophies, &c.
Perhaps the most perfect of these minor works was the
birth of Eve, which he painted in the church of S. Mar-
cello, and in which he exhibited his decided predilection
for the style of the Florentine school, and the successes
which he had studied the works of M. Angelo.

Pierino was in full possession of public repute when he
was compelled to fly for safety from Rome, by the lacking
of that city in 1527. He took refuge in Genoa, where he
was graciously received by prince Doria, who at that time
projected the embellishment of his superb palace near the
gate of St. Thomas. He had here a full opportunity of
displaying his imagination, as well as his executive powers;
and here he indulged in those inventions which breathe the
spirit of Raphael himself, and rival the exertions of his
fellow pupil J. Romano, in the palace del T at Mantua:
both do honour to the school they had studied in, and the
patron who employed them. He is said not to have been
sufficiency scrupulous in the choice of his coadjutors,
and the grandeur of his designs is consequently weakened
by their imperfect execution. He died at Rome in 1547,
age 47.

VAGA, TAGADUMPT or FUSUMA, in Ancient Geography, a
town of Africa, in Mauritania Caesariens, E. of Cieta.
Potenomy. This town, named Baga by Plutarch, was
situated S.E. of Victoria. It was one of the episcopal
sees of Numidia.

VAGA, in Geography, a river of Ruffia, which rises
near Poprovilco, in the government of Vologda, and runs
into
into the Dwina, at Ut Vagkoi, in the government of Archangel.

VAGABOND, a person that wanders about, having no certain dwelling; or a sturdy beggar, &c. mentioned in divers statutes.

"De vagabundis, et alius hominibus mendicantibus, qui se nominant."—Travelling men, &c. Charta 22 Hen. VI.

All itinerant beggars, fortune-tellers, collectors for gaols, fencers, bearers, players of interludes, minstrels, jugglers, gypsies, &c. shall be reputed vagabonds, rogues, and sturdy beggars. 39 Eliz. c. 4.

The court of Areopagus at Athens punished idlenes, and exercised a right of examining every citizen in what manner he spent his time. The civil law expels all sturdy beggars from the city; and, in our own law, all idle per- sons or vagabonds, (whom our ancient statutes desirous to be "such as wake in the night, and sleep in the day, and haunt cumbous taverns, and alehouses, and routs about; and no man wit from whence they come or whither they go;" or such as are more particularly described by statute 17 Geo. II. c. 5. called the Vagrant Act, and divided into three classes, idle and disorderly persons, rogues and vagabonds, and incorrigible rogues,) are offenders against the good order, and blemishes in the government, of any kingdom.

Idle and disorderly persons are thus described by the said statute: viz. all persons who threaten to run away, and leave their wives or children to the parish: all persons who shall unlawfully return to the parish or place from whence they have been legally removed by order of two Justices, without bringing a certificate from the parish or place whereunto they belong: all persons, who, not having where- with to maintain themselves, live idle without employment, and refuse to work for the usual and common wages given to other labourers in the like work, in the parishes or places where they are: all persons going about from door to door, or placing themselves in streets, highways, or passages, to beg or gather alms in the parishes or places where they dwell. And by 32 Geo. III. c. 45: all persons who by their wilful default and neglect permit their wives and children to become chargeable to their parishes or places; and it shall be made appear to two Justices that such persons do not use proper means to get employment, or being able to work do neglect to work, or spend their money in ale- houses or places of bad repute, or in any other improper manner, and do not employ a proper proportion of the money earned by them towards the maintenance of their wives and families, by which they or any of them become chargeable to such parish or place; and these shall be deemed idle and disorderly persons.

Rogues and vagabonds are, by the same statute, such as follow: viz. all persons going about as patent-gatherers, or gatherers of alms, under pretence of love by fire, or other casualty; persons going about as collectors for prisons, gaols, or hospitals; fencers; bearers; common players of interludes, and all persons who shall for hire, gain, or reward, act, represent, or perform, or cause to be acted, represented, or performed, any interlude, tragedy, comedy, opera, play, farce, or other entertainment of the stage, or any part therein, not being authorized by law; minstrels; jugglers; and all persons pretending to be gypsies, or wandering in the habit or form of Egyptians; fortune-tellers, or persons pretending to have skill in physiognomy, pal- mistry, or like crafty science, or to tell fortunes; or using any futile craft, to deceive and impose on any of his ma- jefty's subjects; or playing or betting at any unlawful games or plays; all persons who run away, and leave their wives or children, whereby they become chargeable to any parish or place; all petty chapmen, and pedlars, wandering abroad, not being duly licensed, or otherwise authorized by law; all persons wandering abroad, and lodging in alehouses, barns, out-houses, or in the open air, not giving a good account of themselves; all persons wandering abroad, and begging, pretending to be soldiers, mariners, or seafaring men (but by 43 Geo. III. c. 61. soldiers, sailors, marines, and the wives of soldiers therein mentioned, are relieved against the penalties of the vagrant acts); or pretending to go to work in harvest, without a certificate signed by the minister, and one of the churchwardens or overseers where he shall inhabit, that he hath a dwelling-house or place there; illegally dealing in lottery tickets and shares; per- sons to the number of two or more assembling to destroy game in the night-time (39 & 40 Geo. III. c. 50.); and all other persons wandering abroad and begging, shall be deemed rogues and vagabonds. By 23 Geo. III. c. 88. any person apprehended, having upon him any picklock key, crow, jack, bit, or other implement, with an in- tent feloniously to break and enter into any dwelling-house, warehouse, coach-house, stable, or out-house, or who shall have upon him any pistol, hanger, cutlises, bladgeton, or other offensive weapon, with intent feloniously to assault any per- son; or shall be found in or upon any dwelling-house, warehouse, coach-house, stable, or out-house, or in any in- closed yard or garden, or area belonging to any house, with intent to steal any goods or chattels, shall be deemed a rogue and vagabond within the meaning of the statute of the 17 Geo. II. So also by 39 & 40 Geo. III. c. 87. suspected persons and reputed thieves frequenting the Thames, and the quays and warehouses, &c. adjoining, with a felonious intent.

Incorrigible rogues are by 17 Geo. II. c. 5. thus de- scribed: all end-gatherers offending against the statute of 13 Geo. I. being convicted of such offence, which offence, by 13 Geo. I. c. 23. is this, viz. the collecting, buying, receiving, or carrying any ends of yarn, wefts, thrums, short yarn, or other refuse of cloth, drugget, or other woollen goods; and the punishment of such persons is in order to prevent their committing abuses, by such practices, in the woollen manufacture: all persons apprehended as rogues and vagabonds, and escaped from the persons apprehending them; or refusing to go before a justice; or to be examined on oath before such justice; or refusing to be conveyed by such pass as is hereinafter directed; or knowingly giving a false account of themselves on such examination, after warn- ing given them of their punishment: all rogues or vagabonds who shall break or escape out of any house of correction, before the expiration of the term for which they were com- mitted or ordered to be confined by this act: all persons who, after having been punished as rogues and vagabonds, and discharged, shall again commit any of the said offences: all these shall be deemed incorrigible rogues. To which may be added, any person convicted of a third offence against the 6 Geo. III. c. 48.

Idle and disorderly persons are punishable by the statute 17 Geo. II. c. 5. with one month's imprisonment in the house of correction, upon conviction before one justice, by his own view, confession, or oath of one witness. Any per-
person may apprehend or carry before a justice any such person, going about from door to door, or placing themselves in streets, highways, or passages, to beg alms in the parishes or places where they dwell; and if they shall refuse, or escape from the person apprehending them, they shall be punished as rogues and vagabonds. The reward for apprehending is 5s., to be paid under order of the justice, by any overeer where such offender shall be apprehended.

Rogues and vagabonds are to be apprehended by a constable, or any other person, and conveyed to a justice of the peace. The reward for apprehending is 10s. by order of the justice, payable by the high constable, or, in case of no high constable, by the petty constable; and on refusal, the justice may, by his warrant levy the sum of 20s. by distress and sale of the constable's goods, &c. (17 Geo. II. c. 5.) But the justice shall not order the reward to be paid until the rogue or vagabond be publicly whipped (women excepted), or sent to the house of correction, and till the examination required by the said act shall be actually transmitted to the next sessions. (32 Geo. III. c. 45.) The penalty for not apprehending such offender shall be, on conviction before a justice, or view or oath of one witness, a forfeiture of 10s. to the poor by distress. The justices, or any two of them, shall, four times a year at least, order by warrant search for and apprehension of rogues and vagabonds. (17 Geo. II. c. 5.) And by 25 Geo. II. c. 36. two justices may examine persons apprehended on a privy search on oath as to their settlement and means of livelihood; and upon their failure of shewing that they have a lawful way of getting a livelihood, or of procuring some responsible housekeeper to testify to their character, and to give security (if required) for their future appearance, the justices may commit them to some prison or house of correction, for any time not exceeding six days, and order the overeers of the poor to advertise and describe them, &c.; and if no accusation shall be laid against them, they shall be discharged, or otherwise dealt with according to law. After examination by a justice, such justice shall order the offender apprehended to be publicly whipped by the constable, petty constable, or some other person appointed by them, or order him to be sent to the common gaol (32 Geo. III. c. 11.), or house of correction, till the next sessions, or for any less time (such time not being less than seven days, 32 Geo. III. c. 45.) as such justice shall think proper.—N.B. It is only here expressed generally, that he shall be publicly whipped; the form and manner thereof may perhaps be best collected from the provisions of former vagrant acts. By the 22 Hen. VIII. c. 12. the vagrant was to be carried to some market-town or other place, and there tied to the end of a cart naked, and beaten with whips throughout such market-town or other place, till his body should be bloody by reason of such whipping. By the 39 Eliz. c. 4. he was to be stripped naked from the middle upwards, and only whipped till his body should be bloody.

The justices of the next sessions, after commitment of the offender, may, after examination, order a rogue or vagabond to be detained in the house of correction to hard labour, for any further time not exceeding six months, and an incorrigible rogue for any further time not exceeding two years, nor less than six months; and during the time of confinement, to be whipped in such manner, and at such times and place, as they shall think fit. Such person may, if the justices think convenient, afterwards be sent away by a pass; and if such person, being a male, is above the age of twelve years, the court may, before he is discharged from the house of correction, send him to be employed in his majesty's service by sea or land; and if such incorrigible rogue, so ordered by the justices to be detained in the house of correction, shall break out or make his escape, or shall offend again in like manner, he shall be guilty of felony, and be transported for seven years. 17 Geo. II. c. 5.

By 13 & 14 Car. II. c. 12. the justices in seessions may transport such rogues, vagabonds, and sturdy beggars, as shall be duly convicted, and adjudged to be incorrigible. By 17 Geo. II. c. 5. if the child of any vagrant, above the age of seven years, shall be committed to the house of correction, the justices in seessions, if they see convenient, at any time before such child be discharged, may order such child to be placed out as a servant or apprentice to any person who is willing to take such child, till such child shall be of the age of 21 years, or for a less time; and if any offender, who was found wandering with such child, shall be again found with the same child which was so placed out, he shall be deemed an incorrigible rogue. Where any vagrants have been committed to the house of correction till the next sessions, if, on examination of such persons, no place can be found to which they may be conveyed, the justices shall order them to be detained and employed in the house of correction, until they can provide for themselves, or until the justices in seessions can place them in some lawful calling, as servants, apprentices, soldiers, mariners, or otherwise, either within this realm, or in the plantations in America.

After such whipping or confinement as aforesaid, the justice may, if he think convenient, by a pass under hand and seal, cause the offender to be conveyed to the place of his last legal settlement; but if it cannot be found, then to the place of his birth; or if he be under the age of 14 years, and have any father or mother living, then to the place of the abode of such father or mother, there to be delivered to some churchwarden or overseer. 17 Geo. II. c. 5.

And it shall be certified in the pass, that such person has been actually publicly whipped, or confined in the house of correction as aforesaid. 32 Geo. III. c. 45.

The justice shall make a duplicate of the pass and examination, and sign the same; and shall afterwards transmit the duplicate of the pass, annexed to the examination, to the next sessions, there to be filed and kept on record; and shall annex the duplicate of the examination to the pass, and send it with the same; and the said pass, examination and duplicate thereof, shall and may be read in any court of record as evidence. 17 Geo. II. c. 5.

And the justice who shall make the pass shall with the pass cause likewise to be delivered to the constable a note or certificate, ascertaining how they are to be conveyed, by horse, cart, or on foot, and what allowance such constable is to have for conveying them. The constable who shall receive such pass and certificate, shall convey the person accordingly to the direction of the pass, the next direct way to the place whither he is ordered to be sent, if it be in the same county, riding, division, corporation, or franchise; if not, he shall deliver the said person to the constable of the first town, parish, or place, in the next county, riding, division, corporation, or franchise, in the direct way to the place whither he is to be conveyed, together with the pass and duplicate of the examination, taking his receipt for the same. And such constable shall, without delay, apply to some justice in the same county or division, who shall make the like certificate, and deliver it to such constable, who shall with all speed convey such person unto the first parish town or place in the next county or division, in the direct way to the place to which he is to be conveyed; and so from one county or division to another, till they come to the place to which such person is sent. And the constable, who shall deliver
deliver such person to the churchwarden or other person ordered to receive him, shall at the same time deliver the said pafs, with the duplicate of the examination, taking their receipt for the same. And whereas the present mode of conveying vagrants in the custody of a constable is frequently insufficient, it is enacted, that the justices in seissen may order that all rogues and vagabonds apprehended within their liberties, and ordered to be conveyed by pafs, shall be conveyed by the master of the house of correction, or his servants, or by a constable, as they shall think proper; and they may make an order, that all constables, to whom rogues and vagabonds brought from another county are delivered, shall forthwith convey them to the nearest house of correction or within their liberty, to be afterwards removed by such master or his servants as aforesaid, and according to the provisions of the aforesaid act. 32 Geo. III. c. 45.

The passing of vagrants may be suspended on account of sickness by 33 Geo. III. c. 101.

By 49 Geo. III. c. 124. it is enacted, that in all cases whenever the execution of any order of removal, or of any vagrant-pafs, shall be suspended by virtue of the 33 Geo. III. c. 101. any other justice of the peace of the county, or other jurisdiction within which such removal or pafs shall be made, may direct and order the same to be executed, and the charges incurred to be paid, and may carry into execution any such amended orders, as fully as the same can be done by the justices who shall make the order of removal, or the justice who shall grant the pafs.

Any justice before whom a vagrant shall be carried may order him to be examined, and his bundles to be inspected, by the constable or other officer in his presence; and if it shall appear that such vagrant shall be found to have sufficient wherewithal to pay for his passage, either in whole or in part, the justice shall order so much of the money to be paid, or other effects found upon such vagrant to be sold, and employed towards the expense of taking up and passing such vagrant, returning the surplus, after deducting the charges of such sale. 17 Geo. II. c. 5.

The justices in seissen shall limit what rates and allowances, by the mile or otherwise, shall be made for conveying or maintaining rogues, vagabonds, or incorrigible rogues; and make such other orders for the more regular proceeding therein, as they shall think proper. 32 Geo. III. c. 45.

If any petty constable or governor of any house of correction shall counterfeit any such certificate or receipt, or knowingly permit any alteration to be made therein, he shall forfeit 50l. And if he shall not convey or cause to be conveyed such vagrants, or not deliver them to the proper person; or if any constable shall refuse to receive any such person, or to give such receipt, he shall forfeit 20l. by dirftress and sale, by warrant of the justices in seissen, where the offence shall be committed; half to the informer, and half to the treasurer, to be applied by him as part of the public stock; returning the overplus upon demand, charges of dirftress being first satisfied. 17 Geo. II. c. 5.

The parish or place to which any rogue, vagabond, or incorrigible rogue, shall be conveyed, shall employ in work, or place in some work-house or alms-house, the person so conveyed, until he shall take himself to some service or other employment; and if he shall refuse to work, or not betake himself to some service or other employment, the overseers may cause him to be carried to some justice, to be sent to the house of correction, there to be kept to hard labour. 17 Geo. II. c. 5.

But if the churchwarden, or other person who shall receive any person so sent, shall think the examination to be false, he may carry the person so sent before a justice, who, if he see cause, may commit such person to the house of correction till the next seissions; and the justices there, if they see cause, may deal with such person as an incorrigible rogue; but the person so sent shall not be removed from the place to which sent, but by order of two justices, in the same manner as other poor persons are removed to the place of their settlement.

If any person shall knowingly permit any rogue, vagabond, or incorrigible rogue, to lodge or take shelter in his house, barn, or other out-house or building, and shall not apprehend and carry him before a justice, or give notice to the constable so to do; and shall be convicted thereof by confession, or oath of one witness, before one justice, he shall forfeit not exceeding 40s. nor less than 10s. half to the informer, and half to the poor, by dirftress and sale; and if any charge shall be brought on any parish or place by means of such offence, the same shall be answered to the said parish or place by such offender, and be levied by dirftress and sale of his goods as aforesaid. And if sufficient dirftresses cannot be found, such offender shall be committed to the house of correction by the justice, for any time not exceeding one month. 17 Geo. II. c. 5.

To defray the expenses of apprehending, conveying, and maintaining rogues, vagabonds, and incorrigible rogues, and defraying all other expenses necessary for the execution of this act not herebefore provided for, the justices in seissen may cause such sums as shall be necessary to be raised in the same manner as the general county rate.

Any person aggrieved by any act of any justice out of seissen, in or concerning the execution of this act, may appeal to the next general or quarter-seissen of the county, riding, liberty, or division, giving reasonable notice thereof; whose order thereupon shall be final.

Persons sued for any thing done in the execution of this act may plead the general issue; and if they recover, shall have treble costs.

In all cities and towns, where by virtue of special acts of parliament the charge of passing vagrants is to be defrayed in other manner than by this act directed, or where such vagrants, by virtue of special statutes, are to be apprehended and conveyed by any person or officer, other than those named in this act, the same shall not be altered hereby. And persons conveyed in London, shall not be delivered in any other precinct within the city, but in the next county. 17 Geo. II. c. 5.

VAGAL, in Geography, a river of Russia, which runs into the Irithk, 8 miles S.E. of Tobolik.

VAGAL, in Ancient Geography, a town of Africa, in Mauritania Cæsariensis, on the route from Rufucurrum to Catama, between Gadaus Caelra and Callæum Tingitanum, according to the Itinerary of Antonine.

VAGENI, BAGENI, or Vagiani, a people of Italy, in Liguria, towards the sources of the river Erinon, according to Silius Italicus. Pliny calls them Vagianæ Ligures.

VAGERA, in Geography, a town of Arabia, in the province of Nendsch; 90 miles N.E. of Mecca.

VAGESAA, in Mythology, a name of the Hindoo god Siva. He is also called Vagesevara, or the lord Vaga; sometimes pronounced Bagis, and Bagilwar. His consort Parvati, as his energy or fakti, is named Vagefwari. (See Parvati and Siva.) In the latter article, it will be seen that some etymo-logists, from this similarity of name, strengthened by other characteristic coincidences, conceive Bagesa and Bacchus to be names of the same person.

VAGESWARA, a name of the Hindoo god Siva; meaning the lord Vagefa, as noticed under that article.

VAGINA,
VAGINA, a Latin term, literally signifying a sheath, or scabbard; used on divers occasions. *As,

VAGINA, in Architecture, is used for the lower part of a terminus; because resembling a sheath, out of which the statue seems to issue. See Terms.

The vagina is that long part between the base and the capital; and is formed in divers manners, and with divers ornaments.

VAGINA, in Anatomy, the membranous canal leading from the external organs of generation to the neck of the uterus, and receiving the male organ in coitus. See Generation.

The vagina is liable to an inflammation after delivery, occasioned by the head of the child being long retained in the pelvis. If the swelling and inflammation are not very great, they are generally removed by the discharge of the fochia; but if the internal membrane of the vagina be inflamed, emollient injections must be occasionally used, and a piece of prepared sponge should be introduced, to prevent its coagulating. The sponge may be thus prepared: Take a piece of a proper size for keeping the vagina open, when it is expanded; soak it in warm water; then roll it tight from end to end with a string; cut off any hard lumps, and lay it to dry; then take off the string, anoint it with lard, and introduce it into the vagina, the moisture of which will expand it. If the pressure on this part was so long continued, as to obstruct the circulation in it, a mortification will ensue, which may be either total or partial: if it be total, the patient will die; if partial only, the mortified parts will slough off. This may be known by great pain after delivery; a fetid smell, and a discharge of sharp ichor at first from the vagina, then pus and matter. When this is the case, emollient fomentations may be thrown up from time to time; doffs of lint may be dipped in some proper balm, and applied to the parts in order to deterge and heal them; and when the sloughs are all call off, great care should be taken to prevent the vagina from growing together, either by introducing doffs of lint, or pieces of sponge into it.

VAGINA, Imperforate. The vulva is liable to two different kinds of imperforation, which ought to be discriminated. First, the labia and symphysis may be every where united and blended together, the orifice of the meatus urinarius being totally covered by them, so that no urine can be voided. Secondly, the hymen may form a complete septum, or else some part of the vagina may be closed with a membrane of similar structure; in which circumstances, although the vagina be imperforate, there is no impediment to the free issue of the urine.

The first cafe constitutes a species of malformation, attended with the greatest urgency, and which indeed admits of no delay of that operation by which the conjointed parts are to be separated. The kind of raphé, situated where the natural opening ought to be, should be immediately sought for, and here the requisite division of the parts is to be made, the incisions being carried to the necessary depth, yet always with a cautious hand, lest an opening be made into the bladder, or rectum. Concretions of the labia and symphysis together may be the consequence of ulcerations of these parts; but the closure of the vulva is then never complete. The frequent evacuation of the urine separates the parts; and, if not capable of preventing their union entirely, it is at least sufficient to maintain an aperture opposite the meatus urinarius. The narrowness of the external opening, however, may obstruct the free discharge of the urine; and urinary calculi may even form more or less deeply in the vagina. Now, without taking into the account other functions of the sexual organs, the motives already explained are quite prepossessing enough to make the removal of the deformity right and advisable.

Before the age of puberty, no inconvenience can arise from the vagina being completely shut up by the hymen, or some other analogous membrane. But, at this period, the menstrual blood collects first in the vagina, and then in the uterus. Severe periodic colic pains, a gradual dilatation of the uterus, the absence of the menstes, impairment of the health, a variety of nervous complaints, and sometimes even inflammatory symptoms, which recur, or are exacerbated periodically, afford strong presumptive grounds for supposing an imperfection of the vagina. More information may be acquired from a careful examination of the parts. In the greater number of instances, the membranous septum is diffused with the menstual blood, and even sometimes protrudes from the vulva, in the form of a brownish, blastic, fluctuating tumour. Almost an immediate stop has been often put to alarming symptoms of long duration, by making an incision through the membrane causing the obstruction. A crucial wound will be sufficient, without cutting any of the membrane away; but we are recommended not to neglect to keep the newly divided parts affixed for a few days, by means of a tent, or a doff of lint.

Labours are sometimes so difficult, and attended with such injury, that inflammation, and even ulceration of the vagina, may be thus produced. These effects may be followed by considerable contractions of this canal, arising from the shrinking of the cicatrices. However, such a case is not what we have now to consider, our remarks being at present restricted to examples in which the vagina is altogether impervious.

The os tincæ may be entirely obliterated by congenital malformation, the effects of difficult labours, or any other circumstances producing inflammation in the part. In all these cases, menstruation and conception are rendered impossible, and a train of phenomena is observed, resembling those of the congenital imperforation of the vulva, and vagina. But the os tincæ may become clofed, from some accidental cause, subsequently to conception, and then the defect cannot be known until the period of delivery. In this last case, it is highly important to ascertain correctly whether the orifice of the womb is really obliterated; or whether an obliquity of that organ, or some other derangement of it, may not impede upon us?

The re-establishment of the natural opening is always indispensabie, and it is materially facilitated by the diffused state of the uterus. The operation can be most conveniently done, either with the instrument called a pharyngotomus, or a curved bistoury, which has a cutting edge that extends only a short distance from the point. See Delpech, Précis Élémentaire des Maladies reçus Chirurgicales, tom. i. p. 497, &c.

VAGINA, Prolapsus of, denotes, in Surgery, a species of bearing down, arising from a protrusion or defect of the vagina. The vagina is liable to two kinds of prolapsus. In one case, all its tunics are included in the protrusion, and at the same time that the part falls downwards, it becomes inverted. In the other example, it is only the relaxed lining of the vagina which descends and makes a protrusion.

The first species of prolapsus vaginae is subject to varieties. For instance, sometimes the whole circumference of the part falls down; sometimes only a portion of one of its sides. In the first event, the prolapsus forms a cylindrical tumour, which consists of all the coats of the vagina, presenting an opening at its lower termination, and having an external covering, which is composed of the internal lining.
of the vagina. But when the protrusion comprehends only a portion of one of the sides of this tube, the tumour occurs in the form of a cul-de-sac, which can be put back into the vagina with the finger or probe, and the lower end of which is without any aperture. The following differences are also remarkable in cases where the lining of the vagina constitutes the prolapsus. In some instances, the lining of the whole circumference of the part protrudes in the form of a cylindrical swelling, consisting of a duplicature of that coat. In other examples, the membrane lining the vagina is relaxed and elongated only at one or more particular points, and produces one or more external swellings of the cul-de-sac figure. This last case is liable to be mistaken for polypi of the vagina.

The possibility of a prolapsus of the whole of the vagina, together with all its coats, has been doubted by Sabatier and Levret; but, as Richter conceives, without any real foundation. If, as the latter author observes, it is possible for the inner coat of the vagina to separate from the external, with which it is intimately connected, an event which every body admits as happening in the second kind of prolapsus vagina, why should it be impossible for the whole of this tube, together with all its coats, to be separated from the surrounding parts, to which it is not so closely adherent? Sometimes the rectum, inclusive of all its coats, forms what is termed a prolapsus ani, and why may not the vagina be displaced in a similar manner, since it must be much more liable than the rectum to be propelled downwards in the violent straining which takes place during parturition? Richter asks, whether every prolapsus uteri is not accompanied with such a displacement of the vagina? Cases are upon record, where the prolapsus of the vagina happened all on a sudden, in consequence of falls, the starting of a horse, &c. (Hoin, Levret, Journal de Médecine, tom. xl.) Here it cannot be supposed, that the case was merely a protrusion of the inner coat, which can only be gradually relaxed and elongated. Lastly, instances in which the prolapsus of the vagina was several inches in length, have been gradually reduced by means of external pressure. (Hoin.) How can we imagine, says Richter, that such cases could proceed from any degree of relaxation, to which the membranous lining of the vagina is liable?

It must be acknowledged, however, that this species of prolapsus is much less common than the second kind; that when it occurs, it is generally as a consequence of a prolapsus of the uterus; and that it cannot easily happen at all, except about the time of delivery. A prolapsus of the inner coat principally occurs in married women who have had many children, and been frequently troubled with flux album. It has, however, been occasionally met with in young unmarried females. The prolapsus of one particular portion of the inner coat of the vagina, is generally the consequence of a hernia in this part; but sometimes in cases of droopy, a portion of the vagina, containing fluid, protrudes in the form of a cyst, or fac.

When the whole circumference of all the coats is involved in the prolapsus, if a finger, or probe, be introduced into the cylindrical tumour, which the vagina then forms, the os uteri will be found to be situated closely behind the external pudenda; for this fort of bearing down is always attended with a displacement of the womb, in the direction downwards. In many instances, particularly when the prolapsus has taken place suddenly, and is quite recent, the patient experiences a variety of complaints about the bladder and rectum, and the evacuation of the urine and faces becomes more or less interrupted. That the protrusion comprehends all the coats of the vagina, is frequently quite manifest from the thickness of the cylinder. Also, when the accident has occurred suddenly, or it can be easily reduced, there is always reason to conclude that the prolapsus is of the preceding description.

The prolapsus of the inner membrane of the vagina generally arises gradually, and often as a consequence of a long-continued fluor album. It either does not admit of reduction, or, if reduced, it lies in the vagina, and fills its cavity. It has very little effect upon the uterus itself, which usually remains in its natural position, and it seldom produces any difficulty in the evacuation of the urine and faces. When only a part of one side of the inner membrane of the vagina is relaxed, elongated, and protruded, the swelling can be pushed back into the vagina with the finger, and thus the nature of the complaint becomes manifest. The prolapsus, arising from a hernia in the vagina, can only be ascertained by attending to the symptoms which characterise this sort of rupture, and which are noticed in the article Hernia.

A prolapsus of all the coats of the vagina, while it is small and recent, can be reduced by pressure without difficulty. But the thing which demands the greatest care, is to hinder a relapse. This is accomplished by the employment of a pessary, and the use of astringent applications.

When, however, the last species of prolapsus has existed a long while, its reduction is more difficult; for the vagina, after it has remained displaced a certain time, begins to be affected with swelling and induration. According to the reports of Hoin and Levret, a large protrusion of this kind, ten inches in length, was so diminished by keeping the patient invariably confined upon her back, that in the course of a month the rest of the tumour admitted of being reduced. Indeed, as Richter observes, there can be little doubt, that the treatment which has been advised by some authors for the diminution of very old enormous omental ruptures, would here be equally applicable; viz. long confinement in bed upon the back, with the buttocks somewhat elevated; continued, well-directed, external pressure; a very low diet, and repeated mercurial purges. By such means, no doubt, the swelling might be in many instances sufficiently lessened to admit of reduction.

During the state of pregnancy, a prolapsus of the foregoing kind may be attended with considerable embarrassment, and even danger. In one case, where such a prolapsus, five inches in length, took place during labour, it became necessary to turn the child, and the displaced vagina was also lacerated. The woman, however, recovered. (Pietteh, Journal de Médecine, tom. xxxiv.) In another case, where the prolapsus became as large as a man's head at every return of the labour-pains, the practitioner succeeded in holding the parts back, while the woman was delivered with the aid of the forceps. (See Loder's Journal, i. p. 490.) When this is impracticable, it is necessary, according to Richter, to make an incision through both sides of the prolapsus; a proceeding, says he, to which the practitioner may the more readily make up his mind, inasmuch as the parts have even been lacerated, without any ill consequences, as we have already related.

The prolapsus of the inner membrane of the vagina, while small and recent, may perhaps be removed by astringent applications. When, however, it is of long standing, indurated, and of large size, much expectation of successe from this treatment cannot be entertained. Richter sees no reason why, in such a case, the redundant relaxed part should not be cut away, especially when the discharge is accompanied with ulceration, and other serious complaints. As he observes, there can be no doubt that a prolapsus of the inner membrane of the vagina, when limited to one part of this
this canal, may always be safely extirpated either with a
knife or a liguature. Richter's Anfanglgr. der Wundarzney-
kunst, b. 7. Vierte Kapitel.

VAGINE Femina Tinctor, in Anatomy, a name given by
Albinus to a muscle in the thigh, called by others the me-
embranous, and the muscle fuscis late; and by some musculus
APONEUROTICUS; which see.

VAGINE Utri Spinther. See Generation.

VAGINE Foliorum, in Botany and Vegetable Physiology,
the sheath of the leaves, (See LEAF and SHEATH,) most
peculiarly observable in grasses, and their allies, confiims
of that part of the leaf which is below the stipula, by which it
is crowned. The Vagina embraces the item, or fraw,
more or less closely. Its infide is usualiy quite smooth,
and polished, while the outside is generally ribbed, rough,
or hairy, though commonly less so than the leaf itself. The
pubescence in some infiinaces is directed contrariwise to
that of the leaf. In most grasses, particularly the corn tribe,
the sheaths of one or two of the uppermost leaves are much
dilated, serving the important purpose of protection to the
young panicle or spike of flowers. A singular theory re-
specting the cause of fmrit in grass was, many years since,
published by the Rev. Henry Bryant, of Heydon, Norfolk.
(See Smir.) The mischief was, by this writer, attributed
to an accidental tightness in the fummit of the sheath of the
leaf, by which the young ear was, in a manner, strangled;
an hypothesis totally insufficient to account for the pheno-
memon.

The term vagina is, in like manner, applied to the lower
part of the foliage of the Crocus, the Snow-drop, and
various f ilemif species related to one or the other, in which
the leaf tapers down into a sheath of eathing ftockfalt. But
it is erroneously exemplified by proferor Wildenow, in his
Principles of Botany, by the genus Polygonum, whose cy-
lindrical membrane, attached to the inner ride of each foot-
flalk, and surrounding the item above every joint, is a real
sheathing SFIPULA, fee that term; the ftockfalt being in-
terposed between it and the leaf. So in Spermacoce, and
other plants of the extenfive and various order of Rubiaceae,
the membranous intradulcous stipula must not be taken for
a vagina, though it be connected, ever fo closely, with the
footflalks at each side; because the analogy of molt plants
of that order shew it to be a real stipula, which from its
situation, and the varieties in its form, structure and aspect,
is of peculiar botanical importance.

VAGINALIS GUBA, in Anatomy, the mucous arca-
tum surrounding the mucous membrane of the æsophagus.
See DEGLUTITION.

VAGINALIS TETIS, the serous membrane surrounding the
tetflake, and forming the bag, in which it is included. There
is also a covering, composed of condensed cellular mem-
bane and the fibres of the cremaster, which surrounds the
permatic cord and the tettsis with its membranes. This
is called tunica vaginalis communis. See GENERATION.

VAGINALIS, in Ornithology, a genus of the order Gralle
of birds, of which there is one species, viz. the V. alba, or
white sheath-bill of Latham. Found in New Zealand, and
other islands of the Southern ocean.

VAGINARIA, in Botany, named from vagina, a
sheath; because the item is clothed with leaflets sheaths.
Pursh 58. This genus is adopted by Pursh from Perfoon,
and its distinctive character confines in the fact being sur-
rounded at the base with three scales, and three intermediate
bristles. One or the other of these parts doubtfuls origi-
nates in the three flaments. The flignas, moreover, are laid
to be three.

The only species mentioned by Pursh is V. Richardi.

(Virensa scirpoidea; Michaux Boreol.-Amer. v. 1. 35. (7.)
—"Stem leaflets, sheathed. Spike ovate, mostly foliary.
Scales lanceolate-fpatulate." —Native of inundated fields,
from Georgia to Florida. Perennial. Purf. The aspect of
the plant is like a Restio; see that article, Furena,
and Scirpus. When we advert to the many different ap-
pearances of these scales, or bristles, in different species of
the lat-mentioned genus, and even their absence in some, we
hesitate to admit the Vaginaria, without examining one
species at least, or being informed of any others on which it
is founded.

VAGIOW, in Geography, a town on the W. coast
of the island of Celebes.

VAGLIANO, a town of Italy, in Friuli; 10 miles
W. of Udina.

VAGNEY, a town of France, in the department of
the Voges; 4 miles E. of Remiremont.

VAGNIACIS, in Ancient Geography, a place of Great
Britain, marked in the 2d Iter of Antonine, between Novi-
ogamus, situated, according to Camden, Gale, and Horflcy,
at Woodcoke near Croydon and Durobrivae or Rochester;
and pupposed to be Northfleet.

VAGOS, in Geography, a town of Portugal, in the
province of Bisara, near the Atlantic coast; 6 miles S. of
Bragança Nova.

VAGRAM, a town of the archbishopric of Salzburg;
6 miles S. of Salzburg.

VAGRANTS, in Law. See VAGABOND.

VAGSKOI, Ust., in Geography, a town of Russia,
in the government of Archangel, at the union of the rivers
Vaga and Dwina; 20 miles N.N.W. of Schenkurk.

VAGUM, in Anatomy, a name given to the eight pair
of nerves of the medulla oblongata, called the par vagum,
because dispersed to divers parts of the body. See NERVOUS
System.

VAGUM, in Ancient Geography, a promontory situate, ac-
 accordance to Ptolomey, on the easter coast of the isle of
Corfica.

VAGUS, in Geography. See WAAG.

VAHALIS, or VACHALIS, Wahal, in Ancient Geography,
a name given to the left branch of the Rhine, after its sepa-
ration at its entrance into the country of the Batavi, which
afterwards joined the Meuse. The territory between these
rivers was denominated Insula Batavorum.

VAHAN, in Hindu Mythology, is the general name of
the different vehicles by which their gods and godesses are
carried. The godesses are usually seen accommodated with
the vehicles of their lords; being indeed, as is declared,
the fate. We will here notice such vehicles as are appro-
priated to the different deities. Brahma, being a personif-
cation of the earth, or matter, and remotely participant also
in representing humity, rides the semi-aquatic bird, the
flugifh swan or goose, called Hahna; his confont Sarawati,
godesses of harmony and arrangement, is sometimes seen
mounted on a species of heron. See SARASWATI and
SIVA.

Vifluna, the confrator, is the air; and he, like his bro-
other Jupiter of Greece, cleaves his own element on a tower-
ing eagle, which the Hindoes call by several names; among
them Garuda and Superna.

Siva, the changing or destroying power, is a personifi-
cation of fire; he also corresponds in character with some
of the Jupiters of the Weff, and rides a white bull, called
NAND. His faksi or confrout, Parvati, is often seen turret-
crowned, in a car drawn by tigers or lions. Virgil's de-
scription of Cybele applies equally to the mountain-godeffs
Parvati.

"Alma.
"Alma pares Idaca deum, cui Dindyma cordi, Turrigereque urbes, bijugique ad fratera leones."  
_En. x. 258._

Dryden changes her lions into tigers.

"Hear thou great mother of the deities, With turrets crowned, on Ida's holy hill, Fierce tigers reined and curbed obey thy will."

Pitt, however, in his invocation, restores the lions.

"Great guardian queen of Ida's hills and woods, Supreme, majestic mother of the gods! Whole strong defence proud tow ring cities share, While roaring lions whir thy mighty car."

In most languages of the East, it may be observed, the same word means both lion and tiger. The Greeks or Romans, borrowing the attribute from the East, may easily have misconceived its name. (See _Cyclebe and Parvati_.) It might be flown that most of the mythical ceremonies practiced by the Western heathens in honour of the goddesses Cybele, were, and are, common also in India in honour of Parvati. The peacock is likewise facred to the latter, and is, as we shall presently notice, the vahan of one of her family, Kartikya, otherwise called Komara; and the being deemed his fakli is called _Kaumari_, and is likewise fo conveyed.

Having thus seen that the vehicles of the three great powers compounding the Hindu triad are severally the fwan, the eagle, and the bull, we proceed to notice how the inferior deities are accommodated.

_Surya_, or the sun, rides sometimes a lion, but generally in a golden car drawn by seven horses, or by one horse with seven heads. The horse is sometimes called _Oechebros_ (which fee); but we are in some doubt if correctly. _Soma_, the moon, is drawn in his silver car (the moon is masculine in India) by an antelope. _Pavaka_, the god of fire, rides an ardent ram. _Kama_, the Indian Cupid, rides a luri, or parrot. _Varuna_, genius of the waters, borefrides a fish, as does also _Ganga_, the Ganges, primal goddes of rivers. _Ganeha_, the god of prudence and policy, has an elephant as his vahan, it being supposed the animal of greatfet forcethe: a rat is also deemed a very fagacious animal, and Ganeha is sometimes seen fo mounted. He is reputed the eldest son of Parvati, and is otherwise named _Pollar_; which fee. _Kartikya_, her second son, or rather her lord's son, is borne by a peacock, as before noticed. _Indra_, regent of the firmament, has a three-trunked elephant, named _Iravan_. _Vairava_, a son of Siva, rides a buffalo, sometimes a dog, _Vagyabathi_, and _Vrksadwaja_, are names of Parvati and Siva, meaning tiger-mounted, and one who rides a bull.

Astrologers have mounted the reft of the planets, as well as the sun and moon. _Mangala_, or Mars, on a horfe, sometimes on a ram: his fiery nature connects him sometimes with the igneous Pavaka, who rides the latter animal. _Bodha_, or Mercury, being by some accounts a manifestation of Vishnu, at any rate bearing the fame name with a disputted avatar or incarnation of that god, shares his vehicle, and the planet is mounted on an eagle. _Vrksaspati_, or Jupiter, on a boar. _Sukra_, or Venus, on a rat, sometimes on a camel. The slow-moving _Sani_, or Saturn, on the heavy elephant, or ill-omened raven. _Rahu_, the dragon's head, on a tortoise or owl: and _Ketu_, the tail or descending node, on a frog.

The word _vahan_ is usually pronounced as one broad syllable; and it has been surmised that the English _van_ and _vahin_ may bear some etymological affinity to it.

**VAHARA.** In Geography, a town of Arabia Deserta; 150 miles W. of Jamama.

**VAHINGEN.** See VAYHINGE.
coloured plates, not highly finished, but expressive and correct. The principal object of this work was, in the first instance, to illustrate Forskål's discoveries, very incorrectly displayed in his own posthumous Flora; and the materials for the exemplification of which are, it seems, but partially and imperfectly preferred. Vahl's Symbols are moreover enriched with descriptions and figures of new or rare plants, from various other sources. The communications of the author's numerous correspondents, particularly of Von Rohr and others from the Danish West Indian colonies, are added to the acquisitions of his own journeys; and the whole forms a large body of valuable practical information. His Eclips Americana, published in 1796, are a sequel to the Symbols, on the same plan, but devoted to American plants.

In 1809 and 1800 professor Vahl received the pecuniary support of the Danish government in a second tour to Holland and Paris, for botanical purposes; chiefly, we presume, with a view to the composition of a great work, long in his contemplation, on the model of the Linnaean Species Plantarum. Of this he just lived to publish the first volume, under the title of Enumeratio Plantarum, in 1804, in 8vo, including the classes Monandria and Diandria. The second, containing only the Triandria Monogyna, was published by his widow in 1805. The copious introduction of new species, the ample original descriptions, the well-chozen synonyms, and judicious remarks, render this work far superior to any other of its kind, giving it all the merit of an original performance. Besides the addition of the essential generic characters, as in the Systema Vegetabilis of Linnaeus, Vahl's Enumeratio is enriched with a copious description of the peculiar habit of each genus, after a plan first introduced by Gouan, in his Flora, as well as Hortus Montesefonis, and which Linneus justly commended, as leading the way to improvement in natural classification. Nor mutt we pass by, without commendation, the excellent generic and specific index to each volume, an appendage of whose value we are seldom duly sensible, but from its inaccuracy or omission in other inclusions. The neglect, or bad construction, of indexes, and the omission of references to pages, are defects of the modern French school, which may be avoided by any botanical writer, even of the most humble scientific pretensions, and which the most learned ought not to neglect. The sequel of professor Vahl's last publication, as far as concerns grasses, was reported to have been left by its author in considerable forwardness, and was, if we mistake not, announced for publication. Something to this effect is found in the preface to the second volume; but we know not that any part of these valuable materials has appeared. The botanical professorship at Copenhagen was conferred on Mr. Vahl, after his return from his second visit to France, but he lived not long to enjoy his well-merited fame and distinction. He died on the 24th of December, 1804, in the 54th year of his age, leaving a widow and six children. His library, herbarium, and manuscripts were purchased by the king of Denmark for 3000 dollars, about 675l, besides an annual pension of 400 dollars, or 90l, to his widow, and of 100 dollars to each of his children. It was intended that the above-mentioned manuscripts, including a finished treatise on the class dyngeina, should be edited by the successor of professor Vahl, Mr. Hornemann, to whom the continuation of the Flora Danica was likewise confided. We are not informed of the progress of either. Besides the botanical writings of professor Vahl, he has published some zoological papers in the Danish language, especially relating to birds; and has described a fifth, constituting a new genus, by the name of Holocentrus leaginognus, in the third volume of the Transactions of the Natural History Society of Copenhagen.—A more detailed review than we could here undertake, of the first volume of the Enumeratio Plantarum, may be seen in Sims and Konig's excellent Annals of Botany, v. 2. 179, where Mr. Konig has noticed every new article of information, and corrected every incidental mistake, with consummate accuracy and knowledge. We have already advanced an opinion similar to that of this able critic, respecting Vahl's removal of the Linnaean Sci- taminee, see that article, from the class Monandria to Gynandria; a measure barely to be excluded by our supposition, and not at all to be justified by any alleged reason.—Vahl's Works. Sims and Konig's Ann. of Bot. v. 1 and 2.
VAHLIA, in Botany, received that name from Thunberg, in honour of his contemporary professor Vahl. (See the last article.) The fame genus was originally defined by the great Linneus to commemorate Jean Jacques Roufeau, as appears by specimens in the Linnaean herbarium, marked Roufeana capensis; but he did not live to publish this genus, which his son, through inadvertence probably, introduced into the Supplementum Plantarum, by the name of Russellia, see that article and Rousseau. Those names being otherwise appropriated, the Vahlia is finally established. —Thunb. Nov. Gen. 36. Schreb. 176. Willd. Sp. Pl. v. 1354. Mart. Mill. Dict. v. 4. Juff. 318. Lamareck Illutr. t. 183. (Ruffelia; Linn. Suppl. 24. Murr. in Linn. Syst. Veg. ed. 14. 270.)—Clafs and order, Pentandria Dicygnia. Nat. Ord. Calycanthem., Linn. Onagre, Juff.

Gen. Ch. Col. Perianth superior, of five lanceolate, acute, concave, spreading, permanent leaves. Cor. Petals five, ovate, concave, spreading, undivided, not half so long as the calyx. Stam. Filaments five, inserted into the calyx, between the petals, and full as long as its leaves, thread-shaped, erect; anthers incumbent, oblong, with four furrows. Pf. Germen inferior, roundish; styles two; thread-shaped, thinly spreading, longer than the flaments; stigmas simple, obtuse. Peric. Capule ovate, abrupt, marked with five elevated lines, and crowned with the calyx, of one cell and two valves. Seeds numerous, minute.

Eif. Ch. Calyx of five leaves. Petals five, alternate with the flaments. Capule inferior, of one cell and two valves, crowned with the permanent calyx. Seeds numerous.

1. V. capensis. Cape flah. Thumb. Nov. Gen. 36, with a plate. Prod. 48. Willd. n. 1. (Ruffelia capensis; Linn. Suppl. 175.)—Gathered by Thunberg, in sandy ground, near the valley of Verkeerde, at the Cape of Good Hope, flowering in December. It has not yet been brought to England. The root is woody and perennial. Stems feveral, herbaceous, erect, a span or more in height, simple or branched, leaffy, clothed with short, soft, prominent, vivid pubescence, like all the rest of the herbage. Leaves opposite, feffile, linear-lanceolate, entire, pale green, an inch or inch and half long. Flowers yellow, in small, axillary, nearly feffile, tufts, about the upper part of the branches, accompanied by a small lanceolate bracteae. The petals and filaments assume a violet hue when dried.
VAHNI, in Mythology, a name of the Hindoo regent of fire, who is more commonly called Pusaka; which see. A similar name, usually indeed written Vani, is given to Sarawati, consort of Brahma. See SARA.WATI and MARUK.
VAIDYA, the name of a respectable class of Hindoos, who follow the profession of physic. Individuals of different religious sects are comprised in this denomination. (See SECTS OF HINDOOS.) Sir W. Jones, speaking of the Vaidyas, says, "they have more learning, with far less pride, than any of the Brahmas; they are usually poets, grammarians, rhetoricians, and moralists; and may be esteemed, in general, as the most virtuous and amiable of the Hindoos." (Aliatic
When town called little " reported a the Subhavati. consequence, a vols. Sante the 50 from the that r Geography, 1, He paradife a town between Nova Zembia, and the continent of Russia.

VAIGAL, in Geography, a town of Hindoozla, in Golconda; 25 miles S.S.E. of Combamet.

VAIGAR, an island of Russia, in the Frozen ocean, on the N. side of the straits of Vaigatskoi, about 24 miles in length, and about 8 broad. N. lat. 75° 30'. E. long. 52° 24'.

VAIGATSKOI, PROLIV, or Straits of Vaigats, between Nova Zembia, and the continent of Russia.

VAIGE', a town of France, in the department of the Mayenne; 12 miles E. of Laval.

VAIHEND, or Scanderie, a town of Perisia, in the province of Segestan, anciently Alexandria; 50 miles E. of Akrohage. N. lat. 31° 10'. E. long. 66° 40'.

VAI-HIO, in the Materia Medica, a name used by some authors for a kind of lignum aloes, which is brought from China, and is very black, and scented.

VAI'JAYANTA, the name of a palace of the Hindoo god Indra, situated in a celestial city named Amrohati. (See Indra.) Another of his abodes is called Sitanta, which see. See also VAiKONTHA.

VAIKONTHA, the paradise of the Hindoo god Vishnu. It doth not precisely appear whether this abode is celestial, terrestrial, or subterranean. Sometimes it is described as the latter fort in a sea of milk, called Kripamudra, where Vishnu is pictured reposeing on a mighty serpent-named Sesa, accompanied by his delightful companion Lakshmi. (See LAKSHMI and Sesa.) A commentator on a Sanscrit work entitled Khetra Nirmana, the most ancient perhaps of Hindoo geographical books, places Vaikontha in the Frozen ocean; a circumstance which would have afforded curious confirmation to an idea of Buffon and Baillic as to the seats of Eden, had these eminent men been aware of it: an idea more ancient, indeed, than the day of these philosophers, as Ptolemy had a similar notion. See Paradise.

Several of the Hindoo deities have residences especially alluded to them, by European writers usually called the paradise of those deities respectively; thus Indra's abode is called Sitanta, Swarga, and Vaijayanta; that of Siva, Kailasa; that of Varuna is Subhavati. Generally, these places or places of the Hindoo gods are described as situated on a mythical terraced hill named Meru, to which word we refer the reader for some of the extravaganzas connected with the Olympia of the Hindoos.

VAILYATA, in Geography, a town of Italy, in the department of the Adda; 18 miles E. of Milan.

VAIYALL, a town of France, in the department of the Lot; 15 miles N. of Cahors.

VAILLANT, Jean Fois, in Biography, an eminent antiquary and medallist, was born at Beauvais, in Picardy, in the year 1632. His maternal uncle, to whose care his education was entrusted, designed him for the profession of the law; but inheriting the fortune of this relation, he devoted himself to the study of physic, in which faculty he took a degree. Having accidentally gained possession of a box of medals, he relinquished his medical pursuits, applied to antiquarian and medallic pursuits, and soon formed a valuable cabinet, to the increase of which his various travels very much contributed. In one of his excursions for this purpose, he was attacked by an Algerine corsair and carried into slavery; and after his release, he was on another occasion attacked by a Tunisian; and in order to secure fifteen or twenty gold medals which he had in his possession, he swallowed them, and in process of time nature relieved him of his burden, which he disposed of to an amateur with advantage. On his return to Paris, he distinguished himself by various dissertations on medals. He was thus recommended to the court, and employed on a commission for the protection of the same object. His adoration urged him to visit Egypt and Persia, and he was recommissioned by obtaining a rich cargo of medals. To the Memoirs of the Academy of Inscriptions and Belles Lettres, of which he was a member, he communicated several valuable papers on his favourite subject: his reputation gained him the post of keeper of the duke of Maine's cabinet of medals: and even at Rome he was so highly esteemed, that he obtained a dispensation from the pope to marry successively two sisters. His private character was highly estimable. His labours were terminated by death in 1706, at the age of seventy-four years. The titles of some of his principal works, independently of several separate dissertations, tending to illustrate medallic science in its connection with history, are as follows: "Numismata Imperatorum Romanorum," 1674, 4to. of which an enlarged edition was published by Baldini at Rome in 3 vols. 4to. 1743: "Seleucidarum Imperium, five Historia Regum Syriae ad fidem Numismatum accommodata," 1681, 4to. : "Selecta Numismata antiqua ex museo Petri Seguini," 1684, 4to.: "Numismata Aere Imperatorum, Augustarum, et Caesarum in Colonia, Municipiis, et Urbibus, &c." 2 vols. fol. 1688: "Numismata Imperatorum, &c. Graecae," 1698, 4to.: "Historia Ptolemaei Regum aedem Numism. &c." 1725, 4to.: "Achzemenidarum Imperium, &c." 1725.

The son of the preceding, viz. John-Francis Fois-Vaillyant, born at Rome in 1665, was instructed by his father in medallic science, and was graduated for the profession of physic. He published several dissertations on medals in the Memoirs of the Academy of Inquisitions, of which he was a member, and also a dissertation on the "Di Cabiri." His life terminated in 1708, in the 44th year of his age. Moreri.

Vaillyant, Sebastian, a distinguished French botanist in the early part of the 18th century, was born May 26th, 1669, at Vigny, near Pontoise, being the eldest son of a shopkeeper in that town. He is described as having, like many other botanists of eminence, imbibed a taste for plants at a very early age, and even before his fifteenth year to have cultivated, in a little garden of his own, with which his father indulged him, all the plants he could collect from the country around, or from the gardens of his neighbours. We can hardly wonder that his illustrious biographer Boerhaave, should, as a physician, delight also to record an instance of Vaillyant's early medical talents, in curing himself clandestinely of an intermittent fever, with lettuces and vinegar. He is reported to have made a rapid proficiency at the grammar-school of Pontoise, where he gave extraordinary proofs of attention to study, as well as of attachment to practical botany. His father was anxious to have him instructed in music, in which he made such progress, that he was found competent, at the age of eleven years, to succeed his master, as organist in the Benedictine convent of St. Maclou, in the town above-mentioned. Soon afterwards, he obtained a similar appointment, in a neighbouring nunnery, where he was accommodated with board and lodging as a remuneration. The decided bent of young Vaillyant's mind appears to have been towards medicine and surgery, in consequence, probably, of his primary disposition to an observance of natural objects, and a consideration of the qualities of plants. Hence he was led to frequent the public hospital, and even to become an assistant to the surgeon of the house, and in his leisure hours he read medical books, and pursued anatomical enquiries. In this manner he palled his time till he reached his nineteenth year, when
when he removed to Evrues in Normandy, to place himself under another surgical teacher. Here he gained the good opinion of the marquis De Givole, captain of the royal fullifiers; who engaged M. Vaillant as surgeon to his company, with the rank of lieutenant. Thus the peaceable botanist, the organist of a nunnery, became a soldier; encountered the dangers of a campaign; came off with honour and safety; performed the last duties to his patron, who fell in the battle of Fleurus, July 1, 1690; and after visiting several towns in Flanders, returned to Evrues, which he quitted next year to pursue his studies, with more advantage, at Paris.

On the theatre of the metropolis, the talents of our young candidate for scientific distinction and improvement found every possible encouragement and advantage. Here, although the practice of surgery seems to have been his first object, probably with more direct views to a maintenance; he soon resigned every other pursuit for the first passion of his youth, and botany henceforth engaged all the faculties of his mind. He soon discovered the science to be just then in a flate to make the scientific fortune of a man of enterprise and genius. Botany had, for some time, become a leading topic among persons of rank and opulence, by which the materials for its improvement had accumulated, but the advancement of the science itself had not, by any means, kept pace, with its riches. Men of the first rank in human intellect, who had fixed everlasting landmarks in other departments of knowledge or literature, though they had done much in botany and other branches of natural history, had but imperfectly accomplished any great sylphematic plans of technical distribution or discrimination, without which mere practical knowledge is but an indigested chaos. The lucid order, and rapid perceptions, of Tournefort's mind, with whom Vaillant was now soon familiarized, as one of the most diligent of pupils, could not but strike him with peculiar force, while supplying light of which he so fenfibly felt the necessity. But as a lamp, however brilliant, serves to betray the surrounding darkness in an unlimited unexplored cavern; so the achievements of Tournefort, like those of his predecessors and contemporaries, tended as yet to display more of the arduous nature of their undertaking, than of its perfect accomplishment. The common herd of their pupils and admirers, are like the animalcules on a blue-bottle-fly; who, as a witty writer observes, "doublets think their fly the greatest and the blueb object in the universe," and they can only go where it pleases to lead. But Vaillant, though adoring the genius of Tournefort, and loving his truly amiable social qualities, could not but perceive the imperfect execution of much of his plan, and detected at once perhaps many of those faulty principles, which have gradually displaced themselves to subfequent observers.

That he had performed an Herculean task, could not be denied, but that much remained to be done, was but too evident to an acute observer. The great preceptor soon became aware of the talents of his pupil; he held him up as an example to his colleagues, and adopted him as a condutor in the elucidation of the plants about Paris.

After residing some time at Neuilly, Vaillant was chosen secretary to Father de Valois, a Jesuit, confessor to the younger branches of the royal family. Here he became known to M. Fagon, first physician to the king (see Fagon); who finding him investigating and arranging moffs, was much struck with the specific definitions, written in Vaillant's beautiful hand under each, as they still remain. Fagon soon afterwards took him under his immediate protection, promised to further his wishes of travelling, and invited him to reside at Paris, till he could procure him an appointment of that kind from the king. This object however was soon given up. Vaillant became secretary to his patron, and was taken into his house. Having free access to every part of the royal gardens, he enriched his own herbarium, and those of Fagon and Tournefort, with exotic, as well as native, specimens, which he prepared with skill and dexterity. He likewise added daily to the collection of living plants, and became, under M. Fagon, the director of the Jardin du Roi. At length, in 1708, this faithful and disinterested friend resigned, in favour of Vaillant, his own appointment, of professor and subdirector of plants in that garden, which Tournefort had repeatedly solicited from him in vain. To this great benefit, which Vaillant was anxious, by all possible exertions, to deserve, was added the construction of new and ample hot-houses, at the wish of the new professor, and the formation of a splendid cabinet of Materia Medica. His lectures on botany, and especially a "discourse on the structure of flowers," since published, were received with great applause. He was admitted, without solicitation, into the Academie des Sciences; it is even said that he was defirous of declining this honour, which his friends had great difficulty in persuading him to accept. A piece of self-denial, or excellece modestly, the reasons for which are not very apparent.

In the intervals of his other occupations, Vaillant visited, at different times, various parts of France, for the sake of botanical enquiries; but it does not appear that, except his martial expedition into Flanders, he ever extended his travels beyond the limits of his native country. His foreign correspondence, nevertheless, was very extensive, and by this means he greatly augmented the riches of the royal garden.

Notwithstanding Vaillant's original admiration of Tournefort, and his personal intimacy with that great and amiable man, of whom we have given an account in its proper place; he very soon, as we have already hinted, became dissatisfied with some of the fundamental principles of his preceptor. He adopted and clearly explained the fexes of plants, and consequently asserted the importance of the flaments and pistils, in a physiological as well as sylphematic point of view. This was the subject of his discourse above-mentioned, delivered June 10th, 1717, before his pupils at the Jardin du Roi. On the 15th of December, 1721, he read a professed criticism on the method of Tournefort, before the Academy of Sciences, printed in the Memoirs of that learned society for 1723. We regret to find, in both these performances, much difrepeftful mention of his illustrious predecessor; which has been but too severely retaliated upon himself, by the neglect which his own just pretensions have received from his countrymen. To have been more in the right than Tournefort, was of itself a sufficient offence; and to have asserted his opinion with asperity and indecorum, served only to authorize part of the hostility which he incurred. Whatever progresses Vaillant had made towards the foundation of a new system of classification, he did not live to lay it in any regular form, before the public. His active life was devoted to the acquisition of materials, which he had no opportunity of employing. His difficulties, doublets, increased with his progres. What parts did perfet are admirably done; particularly his elaborate exposition of the genera and species of the syngenous, or compound flowers, published in the Memoirs of the Academy, between the years 1718 and 1722. But the observations and enquiries of this great botanist had been extended to various other classes and families of plants, though they never ripened into any complete sylphematic work. The writer of the present article has long ago recorded, Tr. of Linn. Soc.
v. 1. 24, that the herbarium of Vaillant, preferred at Paris, displays astonishing instances of his profound knowledge and acute judgment, with respect to the genera, species, and synonyms of plants. The specimens are copious and fine, especially of Tournefort’s oriental plants, which are far more perfect and abundant than in that author’s own collection. These were obtained by Vaillant, either from Gun- delheimer, the travelling companion of Tournefort, or from others who subsequently pursued the same track. We know not that any competition, or open controversy, arose between these distinguished men, during Tournefort’s life, who dedicated a genus to his pupil. (See *Valantia.*) Vaillant is reported to have critically examined the whole of the *Institutiones Rerum Herbariae*, as soon as that great work appeared, in 1702, and to have communicated his remarks to M. Fagon. This intelligent friend declared, that though in the morning he had admired the performance of Tournefort, he could not withhold his approbation of Vaillant’s remarks by the light of mid-day. Tournefort died in 1708, and Vaillant’s first public attack, except what might incidentally fall from him in lecturing, was made, as we have said, in 1721. We are informed thus much of the principles and aims of Vaillant, that, having established the doctrine of the sex of plants, he proposed to distinguish his clavyses by the parts of the flower, and his genera by characters taken indirectly from the whole plant, according as might best suit his purpose. In this latter respect, he was but returning towards the dogmas of former ages, and we can have nothing to regret. His boldest and most meritorious attempt respected nomenclature. He wished to distinguish every genus by an expressive name, by which its essential characters might at once declare themselves. He flattered himself with extending the fame principle to every species of plant, so that a word or two might give its name and character together. The learned reader will be aware of the similarity of this scheme to that of Rivinus, and of its failure, even on the very limited theatre of that writer’s scientific operations. (See *Rivinus.*) He will also recollect that it succeeded with Linnaeus, only because the latter had the good fortune, or good sense, after discovering that these two objects, of nomenclature and clear discrimination, were in themselves incompatible, to reconcile both by division.

While these pursuits engaged the mind of Vaillant, his bodily constitution was yielding to the fatigues he had too long imposed upon it. Exposure to cold and wet, and to the night air, in many of his botanical rambles, did but ill suit a delicate frame, prone to pulmonary diseases. In proportion as he perceived a decay of strength, he only exerted himself the more, to complete the undertakings which had been the object of his life, and which might have demanded something like a patriarchal term of existence. He suffered for about four years under a consumptive attack, in the course of which he expected little hard concretions, amounting, says Boerhaave, to above 400, and at length expired, in a tranquil manner, on his birthday, May 26th, 1722, aged fifty-three. He was tall, well-proportioned, and active; of an open and generous disposition, hating flattery, and militefulness even of his due praise. The character of his criticisms upon Tournefort is rather, as we should hope, to be attributed to blunt sincerity, than to any portion of jealousy or envy, of which his conduct in other instances, betrays no traces. He had the satisfaction of soothing, by the most affiduous care, the sufferings of his friend Fagon, who underwent an operation for the stone at a very advanced age; and who would gratefully have ceded to Vaillant, as a recompense, the profits of an import which he enjoyed upon mineral waters. This Vaillant had the still higher gratification and honour of declining.

His rich and splendid herbarium, comprehending that of M. Fagon, which had been given him by the son of his old friend, as well as his own cabinet of various natural curiosities besides, were purchased by the king, Louis XV., and deposited in the museum at the Jardin du Roi, where they have fortunately remained in safety amid the wreck and the restoration of a kingdom. His library was left in the hands of his widow, whose name was Françoise Nicole Boffonet. Vaillant married this lady on the 14th of October, 1701, and enjoyed with her twenty-one years of great conjugal happiness, but had no offspring.

The greatest object of temporal concern, on his death-bed, was a work on the plants around Paris, which he had long been preparing, and for which Claude Aubriet, the inimitable botanical draughtsman of that day, had made, under the inspection of the author, above 300 drawings. Anxious that his labours should not prove altogether fruitless, Vaillant wrote, a year before his decease, to the famous Boerhaave, requesting him to take this orphan work under his protection. To this request, backed by their mutual friend William Sherard, Boerhaave readily acceded. Vaillant declared that he had particular and very strong reasons, which he could not explain, for making this request. He probably feared that his countrymen, venerated of Tournefort, who no longer stood in their way, might not be over-anxious to preserve the relics of his rival, whose fame and activity had so lately eluded with their own. Whatever were his feelings on this subject, Vaillant was satisfied with Boerhaave’s acceptance of this trust, and awaited his long-expected change with the piety and composure becoming a Christian and a true philosopher.

Boerhaave published the work of his departed friend in 1727, under the title of *Botanicon Parisiense*, making a very handsome folio volume, with thirty-three admirable plates, comprehending above 300 figures, of rare or obscure species, in which the cryptogamic plants are very abundant. The flowers alone of all the Orchis tribe are exhibited; their herbage being so nearly uniform as to be deemed less necessary. These figures, though uncoloured, leave scarcely any thing to be desired. The arrangement of the work is alphabetical, and its language, except the specific definitions, French, like all the author’s compositions. The elegancies of style, or refinements of language, do not seem to have made a part of his studies, and he was rather a scientific than a learned botanist, except what was necessary for the accurate appropriation of synonyms, in which no one, so far as we have traced his progress, was superior to Vaillant. Dillenius, a professed and elaborate botanical critic, was undoubtedly, by many degrees, below him. Certain imperfections of this popular work, justly indicated by Haller, arose, as he observes, from Boerhaave’s inability to bestow sufficient time on the correction of the unfinished manuscripts. Hence many repetitions occur, and some of the figures want references. Following authors have generally cited the beautiful figures, without advertising to the text; in which, notwithstanding, much may be found worthy of notice, especially all the practical observations, and original descriptions, of Vaillant himself. We cannot too strongly commend him as a botanist of originality, acuteness and accuracy, who has contributed to the general stock of botanical knowledge, and whose genius, had he lived longer, might have greatly extended the limits of philosophical speculation, on the subject of arrangement.—*Vaillant’s Works,* and his life by Boerhaave. *Haller Bibl. Bot.*

**VAILLY,** in *Geography,* a town of France, in the department
Vair, in Heraldry, a kind of fur, or doubling, consisting of divers little pieces, argent and azure, resembling a Dutch U, or a bell-glas.

Vairs have their point azure opposite to their point argent, and the base argent to the azure.

When there are only two or three vairs, the ancient heralds call it great vair; and when there are more, small vair.

Vair is intended to represent a kind of skin, used anciently by the kings of France, in lieu of a fur, and with which the gowns of the prelates à mortier, the counsellors of the court, the heralds' coats, &c. were lined till the fifteenth century.

It was properly the skin of a kind of squirrel, called also in French vair, and in Latin frivus; which was white underneath, and of dove-colour at top. It is described by Aldrovandus under the name of servio vario, and is the same, according to Gefsner, with the mus Penticus of Aristotle and Pliny; which the Latins call varus or varius, from the variety of its colour. Its two skins, joined together, make the figure of the vairs in armories; being naturally white and azure.

Vair, Colombiere observes, is the second sort of fur anciently used as a lining of the garments of great men, consisting of little pieces, fewed by the barbers on white skins: and because these pieces were usually blue, those who first settled the rules of heraldry, decreed, that this fur, in its natural azure, should always be argent and azure. So, if it be absolutely said, such a family bears vair; it is supposed to be argent and azure.

Regularly there must be but four rows or ranks of vair in the shield; if there be either more or less, the number must be specified. The smallest number, being three rows, is called bessoy de vair; the most, being five or six, is called menu, or small vair.

The bessoy is also known by the first figure on the dexter side of the escutcheon being always of metal, and in form of a belt; whereas that of menu vair is in shape of a glass.

Vair, Counter. See Counter-Vair.

Vajra, the name of the weapon placed in the hand of the Hindoo god Indra, regent of the firmament, and of atmospheric phenomena. It is in fact lightning, or the thunder-bolt or fulmen of the western Jove. Indra is hence named Vajrapani, or "grasper of the thunder." (See Indra.) It is usually described as a discus or quoit, with a central hole, on which it is whirled round on the forefinger of the right hand, and sent whirling with a terrible effect. This is similar to the chakra, or circle, the common attribute of the god Vishnu. (See Vishnu.) Such things are now seen in the hands of holy mendicants variously called Saniyas and Yogi. (See Sects of Hindoos, and Yogis.) They are usually a foot or less in diameter, of metal or hard wood, sharp at the edge. In pictures, fire is sometimes flaming from its periphery, as if from the vehemence of its centrifugal energy. The only representation we ever saw differing from this description, is in the frontispiece to Kirkpatrick's account of Nepal. The god Siva, sometimes appearing in the character of the thunderer, is named Vajreswara, which is: it means riding on the thunder.

Vairaca, in Geography, a town of France, in the department of the Loire; 4 miles N.E. of Martel.

Vairava, in Mythology, a name of the Hindoo god Siva. It is sometimes written and pronounced Bhairava; and, derived from Bheru, means the tremendous. The Maharratas extensively worship Siva under this name, which in their mouths is corrupted into Bheroba. They have legends relating to an avatar or incarnation of Siva under this name and form; and images are very common of him in the Maharrata country. Other accounts make Vairava and Virabadra the offspring of Siva, and give the former name likewise to Parvati, when speaking of her in her terrific characters, such as Kali; which see. Sometimes all the offspring of Siva are denominated the Bhairavas. See Virabadra.

The Maharratas assign to Bheroba a comfort or fakti, whom they name Jogafry; it would perhaps be more correctly written Tugafri. In the Hindoo Pantheon several representations are given of this couple, and the author of that work says that he has in his collection nearly a hundred metallic casts of them, mostly rude and old, with an appearance of having been buried. The figures are usually accompanied by Sivean attributes, such as the trisula or trident, the pata or cup, the linga, &c. (See Trisula, &c.) Sometimes he rides a buffalo. See Vaiyan.

There are fables in Hindoo legends of Brahma having had one of his heads cut off. This decapitation is by some accounts attributed to Vifnu, or Narayana, by others to Siva and to Vairava, and the latter is in pictures sometimes represented holding the ghastly head, and a cup or pata to receive the blood; with a collar of blanched skulls, and attended by a dog. Sometimes he, usually four-handed, and his wife, are represented as skeletons.

The sect who exclusively, or especially adore Siva, are called Saiva. It appears that this sect has spread to Java; for an image of him has been recognized in the interior of the island, and a well-executed drawing of it is in the possession of Mr. Marfden, author of the Malayan Grammar and Dictionary. Batu-Bharave is the name under which this tremendous pair are known in Java; where, as Mr. Marfden is informed, our officers, during the late service, frequently recognized Hindoo figures, especially of Polleor, to which they had been familiarly accustomed on the continent of India. See Polleor.

Sommeret notices this deity as honoured in the Carnatic: he calls him Vairevert, third son of Siva, produced from his breath to humble the arrogance of Brahma, one of whose heads he wrenched off, and used the skull to receive the blood of his other antagonists. He is described as mounted on a dog.

Vaire, in Geography, a river of France, which runs into the Var, about 3 miles N.W. of Glandevens.

Vajreswara, in Mythology, a name of the Hindoo god Siva, derived, it is said, from the weapon more usually given to Indra, called Vajra, meaning lightning or thunder. Siva under this name will therefore correspond with the Jupiter fulminator or tonans of the West. Siva's companion, Parvati, is furnamed Vajreswari, pronounced sometimes Bajreswari; the initials being so extensively interchangeable.

Vairoxe, in Geography. See Vaire.

Vairaye, Vaire, Ferry, or Varry, is applied to a coat, or the bearings of a coat, when charged, or chequered, with vair.

When the colours are argent and azure, or white and blue, it is vairer proper: if it be otherwise, the colours are to be expressly named; vair of such a colour or metal. He bears vairye, or, and vert; this is particularly called vair compos'd. The bearings are likewise said to be vairy, when they are charged with vairs. When their chiefs, crofles, pales, fetles, &c. happen to be vairy, the number of ranks are to be specified.

Vairy gowns are observed, by Julius Pollux, to have been
the habit of the ancient Gauls, as ermines were of the Armenians.

VAIRY-cuppy, or Vairy-taffy, or Potent-counter, Counter-potent, is a bearing in heraldry, composed of pieces representing the tops of crutches, or potents counter-placed. In blazon, the colours must be expressed; as azure, argent, &c.

VAISSETTE, Joseph, in Biography, a native of Guillin, in the diocese of Alby, was born in 1685, and entered among the Benedictines of St. Maur, at Toulouse. In 1713 he settled at Paris, and engaged, in concurrence with Claude de Vio, of the fame fraternity, in the history of Langueoc, of which the first volume appeared in 1750, in folio; and upon the death of his coadjutor in 1734, it was continued by himself, four more volumes having been published, and a fifth being in preparation at the time of his own death. This history is highly commended, on account of both the learning and moderation displayed by the author. An abridgment of this history, in 6 vols. 12mo., was published by Vaiette in 1740; and he was also the author of an "Universal Geography," in 4 vols. 4to., and 12 vols. 12mo., 1755, which at the time of its publication was generally approved. The author's erudition was extensive, and his disposition amiable, so that he died, much regretted, in 1756. Moreri.

VAISNAVAD, the general name of all the different sects of Hindoos who worship Vishnu, either directly or indirectly, through his comfort Lakshmi, or in one of his incarnations called avatars. In the article SECTS OF HINDOOS, we have concentrated the chief of what we have to offer on the subject of the numerous individuals comprehended under the denomination of Vairahava; which, in its most extended sense, includes considerably more than half of the whole race of Hindoos. The distinction of Saiva, or Siva-Bakht, comprehends the other portion. See SAI.

The second plate of the Hindoo Pantheon contains many sectular marks, or symbols, by which the different sects distinguish themselves: generally speaking, horizontal lines on the forehead mark the Saiva, while perpendicular forehead indicates some fect of Vairahava. These lines are red, white, or yellow, with different coloured spots over, under, or between them; all of which are said to have some mythological allusion.

VAISNAVAD, in Hindoo Mythology, is a name of the goddes Lakshmi, the comfort or energy of Vishnu; as such, she is called his faksi. In the different incarnations of Vishnu, Lakshmi accompanied him, either under her own name, or under some other denomination.

VAISHISHIKI, in Philosophy, is the name of one of the six Hindoo schools, or systems. Under the article PHILOSOPHY OF THE HINDOOS, we have enumerated the principal schools of that thinking race. The Vaisshika is a division of the Nyaya, and we refer to the latter word for some notice of the doctrines of its followers.

VAISON, in Geography, a town of France, in the department of the Aude, on the Gave de Pau; before the French revolution the fee of a bishop, suffragan of Avignon; the old town has been long in ruins; 22 miles N.N.E. of Avignon.

VAISRAVA, in Mythology, a name of the Hindoo Pluto, who is more commonly called Kubera; which signifies, in the Sanscrit, their father, and they are then named Vaivraava.

VAISSEUX ENFILE, a term used by the French writers in Chemistry, for the vessels used in distilling in an open fire, or in sand, which do not consist in the common way of a retort, joined immediately to a receiver, but have a receiver with a double opening, and a neck at each end, placed between the retort and the ordinary receiver. The neck of the retort is let into one of the necks of this middle vessel, and its other neck is thrust into that of the receiver; by this means the receiver, into which the liquor is to fall, stands at a greater distance than otherwise would from the fire, and the vapours are more easily condensed in it by its coldness, while they have also a double or treble space to expand in, and by that means are not so likely to burst the vessel.

VAIVASVAT, in Mythology, a name of Surya, the Hindoo regent of the sun, as noticed in the article SURYA, where he is under this name styled, on the authority of sir William Joades, "Lancer of the golden ray." The very important deity Surya is frequently called in Hindoo books by the title of Vaivasha; and those personages who, like the ancient Incas of Peru, are pretended to be of solar origin, are called Vaivaswata. In the Gita, Krishna says, "This immutable system of devotion I revealed to Vaivasha, (or, says the commentator, the sun,)" Vaivasha declared it to his son Menu; Menu explained it, &c. This Menu is the author of the celebrated Institutes that bear his name; he is also named Satyavara, and is reasonably believed to be the same with the Noah of Scripture. (See Menu and SATYAVARTA.) These offspring of the sun are likewise called Suryavasa; which fee: and some farther notice of their curious coincidence with the solar race of Peruvians will be found in our articles RAMA and SITA. The Hindoo Pluto is sometimes called Vaivaswata Yama; denoting, we conclude, his solar origin.

VAKES, in Geography, a town of Arabia, in the province of Nedshe; 100 miles N. of Jamama.

VAKIA, in Commerce, a weight in Persia and Arabia. At Bafiorah, the weights for merchandise are, the maund attary, the maund seyf, and the oka of Bagdat. The maund attary contains 25 vakias tary (sometimes reckoned at 24 or 26 vakias), and weighs 283 lbs. avoirdupois, or the vakia 19 ounces. The maund seyf, or maund Bagiorah, contains 24 vakias seyf (called okaes of Bagiorah), equal to 76 vakias tary, or 90 lbs. oz. avoirdupois. The oka of Bagiorah is 2½ vakias tary, or 47¼ Oz. avoirdupois. In sales of ginger, pepper, and coffee, 26 vakias are allowed to the maund; in sales of cardamoms, fugar-candy, and benzoine, 25 vakias per maund; and in sales of sugar and metals, 25 vakias per maund. The vakia tary, which should be about 115 mifals (the mical weighing about 72 English grains), varies from 110 to 118, and the others in proportion.

At Betlefagni, or Betlefackee, in Arabia, a rattle of coffee contains 14½ vakias, and a farcel, or farzil, of the same, 290 vakias; of dates, candles, and iron, 16 vakias are reckoned to a rattle; of all other sorts of goods, 15 vakias make a rattle. At Mocha, gold and silver are weighed by the vakia of 10 cofals, or 160 carats: 24 carats = a mical, and 1½ vakia = a beak = 100 Spanish dollars weigh 87 vakias, so that a vakia weighs little more than 1 oz. English troy weight, the bahar contains 15 farzils, or 150 maunds; the maund = 40 vakias. A rattle is = 15 vakias, but in coffee, 14½ vakias are reckoned for a rattle, 2 rattles for a maund, and 10 maunds, or 290 vakias, for a farzil. Kelly's Univ. Cambilt.

VAKUNAIKA, in Geography, a river of Russia, which runs into the Kifenga, N. lat. 56° 16', E. long. 88° 14'.

VAL, in Geography, a town of France, in the department of Mont Blanc; 20 miles E. of Montlief.

VAL
VAL, Le, a town of France, in the department of the Var; 3 miles N. of Brignoles.

VAL di Comparato. See Teka.

VAL de Morea, a town of Spain, in the province of Leon; 12 miles E. of Ponferrada.

VAL de Prades, a town of Portugal, in the province of Tras os Montes; 16 miles E.N.E. of Mirandela.

VAL Ribi, or VAL di Ribey, a town of France, in the department of the Calvados; 12 miles N.W. of Caen.

VAL Rotando, a town of Naples, in Lavora; 15 miles S.E. of Sora.

VAL de Salas, a town of Spain, in Galicia; 22 miles S. of Orense.

VAL de Santiago, a town of Portugal, in the province of Alentejo; 27 miles S.W. of Beja.

VAL de Travers, a district of the principality of Neuchâtel, about 18 miles in circumference, and containing about 3500 inhabitants. It is situated between Neuchâtel and Pontarlier.

VAL di Tramopia, a valley of Italy, in the Brescian, containing 19 parishes, and about 13,000 inhabitants, chiefly employed in the manufacture of iron.

VAL di Vara, a town of Spain, in the kingdom of Seville; 10 miles from Lucena.

VAL de Us, a town of Spain, in the province of Valencia; 17 miles S.E. of Segorbe.

VALA, in Ancient Geography, a town of the interior of Thrace. Ptolemy.—Alfo, a town of Africa, in Mauritania Tingitana. Ptol.

VALADARES, in Geography, a town of Portugal, in the province of Entre Ducro e Minho; 5 miles S.W. of Melgafa.

VALAGODE, a town of the island of Ceylon; 60 miles S. of Candy.

VALAIS, or VALLAIS, an independent republic in alliance with the thirteen cantons of Switzerland, and which has formed a particular league with the seven Catholic cantons, for the defence of their religion. This tract of country stretches from E. to W. about 100 miles, and contains 100,000 inhabitants, professing the Roman Catholic religion. It is divided into Upper and Lower Valais; the former reaching from the Furca to the Morge, below Sion, which is its capital; and the latter, from that river to St. Gingou, situated upon the lake of Geneva. From the mountain of Furca, its eastern boundary, two vast ranges of alps incline the Valais: the southern chain separates it from the Milaneze, Piedmont, and part of Savoy; the northern from the canton of Bern. These two chains, in their various windings, form several small valleys, watered by numerous torrents that rush into the Rhone, as it traverses the whole district, from the Furca to St. Maurice. A country thus entirely inclosed with high alps, and consisting of plains, elevated valleys, and lofty mountains, may be naturally supposed to exhibit a great variety of situations, climates, and productions. Accordingly, the Valais prefers to the curious traveller a quick succession of prospects, as beautiful as diversified. Vineyards, rich pastures covered with cattle, corn, flax, fruit-trees, and forests, occasionally bordered by naked rocks, crowned with everlasting snow.

The productions of the Valais vary according to the great diversity of climates by which this country is distinguished. It supplies more than sufficient wine and corn for interior consumption, and exports a considerable quantity of both; the soil in the midland and lower districts being exceedingly rich and fertile. In the plain, where the heat is collected and confined between the mountains, the harvest is usually finished in July; whereas, in the more elevated parts, barley is the only grain that can be cultivated with any success, and the crop is seldom cut before November. About Sion, the fig, the melon, and all the other fruits of Italy, come to perfection. In consequence of this singular variety of climate, the traveller in the same day may indulge himself with strawberries, cherries, plums, pears, and grapes, each of which is the natural growth of the country.

Both the hills and valleys of the Valais breed cattle in abundance, and yield plenty of game. The mountains are suffused to contain lead, copper, and silver mines; but the produce, it is supposed, would not defray the expense of working them. Here is likewise pit-coal. The Valais is noted for two hot-baths of celebrated virtue, as those of Brug, or Gleuf, and Leuck, the latter of which is commonly known by the appellation of the Vallais bath. In the upper tythings the prevailing language is the German, but the inhabitants of Sion, in the Upper Valais, with all in the Lower, speak a corrupt French; though in both parts, especially in the chief burg, they apply themselves to the German, French, Italian, and Latin; being all indifferently necessary to them in their intercourse with the cantons of Bern and Uri, Savoy, Piedmont, and the Milaneze; therefore a stranger cannot but be surprized at the fluency with which the most ignorant people here speak those four tongues.

The ancient inhabitants of this country were the Lepantii, Viberi, with the Seduni and Veragri, who fold their liberty dear to Sergius Galba, general of Julius Caesar. In the middle ages it came to be called Vahlia, and in 1032, under the emperor Conrad II., devolved to the German empire, as a part of the second Burgundian kingdom. In the year 1035, that prince made over the Lower Valais to the counts of Savoy. The inhabitants of the Upper Valais refusably maintained their liberties, as well against the dukes of Zaringen, who, in the year 1157, were by Frederic I. appointed guardians of the bishoppry of Sion; as against the bishops of that see, who assumed the title of counts of the Valais, and after that drove out the families of the barons Tour and Raren, who had usurped a dangerous authority among them. In 1475, the bishop of Geneva fell on the Upper Valais with a body of 18,000 men, confining the Lower Valsiens and Savoyards; but the Upper Valsiens, being affiend with 3000 troops by Bern, Friburg, and Solothurn, their allies, defeated the bishop, and even made a conquest of the Lower Valais, which ever since that time has been subject to them. In the same year, also, they formed a perpetual alliance with Bern, which was renewed in 1643, and in 1529, with the whole Helvetic body. In 1533 they entered into a more particular union with the seven popish cantons.

At an early period of the French revolution, the disaffected party of the Lower Valais appealed to France to emancipate their country from their subjection to the Upper Valais, but the French not having matured their scheme of fraternalization, their petition was rejected.

In February 1798, however, the people of the Lower Valais were enfranchised, and admitted to an equality of rights by the Upper Valais; but after the conquest of Bern, and the revolution of the greater part of Switzerland, the inhabitants of the Upper Valais rejected the new constitution, took up arms, and defended themselves with great spirit. After several bloody defeats, and the capture of the castle of Sion, which was formed by the French, the natives submitted, and both districts were moulded into one department, called the Valais.

There are no manufactures of any consequence; and indeed the general ignorance of the people is no less remarkable.
able than their indolence; so that they may be considered, in regard to knowledge and improvements, as some centuries behind the Swis, who are an enlightened nation. The peasants seldom endeavour to meliorate those lands where the soil is originally bad, or to draw the most advantage from those which are uncommonly fertile: having few wants, and being satisfied with the spontaneous gifts of nature, they enjoy her blessings without much considering in what manner to improve them.

The Upper Vallais is sovereign of the Lower Vallais, and comprises seven independent dixains, or commonwealths; namely Sion, Goms, Brig, Vifp, Leuck, Karen, and Siders; of these, Sion is arithotactical, and the others democratical. They are called dixains, because the Upper Vallais being divided into seven, and the Lower into three districts, each division is a dixain, or tenth of the whole.

The bishop of Sion was formerly absolute sovereign over the greater part of the Vallais; but his authority is at present limited to a few particulars. He has the sole power of pardoning criminals, and signs the warrants for executions; the money is coined in his name, and with the arms of the republic. In his acts he styles himself bishop of Sion, prince of the German empire, and count and prefect of the Vallais: in days of high ceremony he dines in public, and is waited upon by the first noble of the Vallais, who is hereditary treasurer. He nominates also the bailifs or governors of the two bailiffages of Martigny and Arden, and poises considerable influence from his patronage of church prerogatives. Upon a vacancy in the see, the canons of the chapter of Sion present from their own body four candidates, one of whom is appointed bishop by the landfrah, or general diet.

The seven dixains form, conjointly with the bishop, the republic of the Vallais, and all affairs are transacted in the diet, called landfrah, which meets twice every year at Sion. This assembly consists of nine voices; the bishop; the lands-hauptmann, who is chosen or confirmed by the diet every two years; and the seven communities. The bishop presides; the lands-hauptmann collects the votes; and all resolutions are decided by the majority. Each dixain, although it has but one vote, sends as many deputies as it pleases; they generally consist of four; a judge, a banneret, a captain, and a lieutenant. The judge and the lieutenant are appointed every two years: the two others hold their offices for life.

In all civil causes of a certain importance, an appeal lies from the inferior courts of justice to the diet in the last resort. Thus, by the institution of this supreme council, the communities in this country are firmly united, and form in conjunction one body politic, or republic, for the general affairs of the nation. In other cases, each of the commonwealths is governed by its own particular laws and customs.

Both the Upper and Lower Vallais were formerly dependent upon the bishop of Sion; but the inhabitants of the two districts united in order to limit his power; and, having succeeded, quarreled for superiority. A bloody war ensued; which terminated in 1475, by the total defeat of the Lower Vallais. Since that period, they have continued subject to the Upper Vallais, with the enjoyment, however, of some considerable privileges.

The inhabitants are generally of low stature, and those of that part of the Vallais in which the capital (see Sion) is situated, are very subject to goiters, or large excrescences in the neck, which frequently increase to an enormous size, and what is more extraordinary, idiocy is no leas prevalent. The weather in this inclined vale is exceedingly sultry and oppressive. This languid heat is probably one of the causes which occasion the inconceivable indolence of the inhabitants: much, however, must at the same time be attributed to the richness of the soil, which precludes the necessity of labour by almost spontaneously producing the fruits of the earth. In fact, the people affect nature very little; they suffer the vines in the vineyards to trail upon the ground; whereas, if the branches were properly supported, the owner would be well rewarded by the superior quality and quality of the produce.

The uncleanness of the common people is disgusting beyond expression. Although the Lower Vallais exhibits much uncleanness, its natives are not altogether so indolent as those of Sion and its environs. This imputation of indolence will not hold good with respect to all the inhabitants of the Upper Vallais; for in the eastern part of that district, the soil, though far inferior, was much better cultivated, and the people tended industriously. Some physical reasons may be assigned for this difference; for there the weather is not so sultry, the water is not unwholesome, the air remarkably salubrious, and none of those goitrous pernicious or idiots were observed common in the midland parts. See MArtigny and St. Maurice.

VALANTIA, in Botany, was originally so named by Tournefort, in honour of his pupil Sebastian Vaillant, see that article. The latter, as Linnaeus remarks, was diffatisfied with this appropriation, and wished, on that account, to set aside all names of botanists, as applied to genera, because he perceived the Valantia of Tournefort not to be distinct from Crucia, the name of a famous author. He was too correct; but there have been several species referred since to Valantia, which appear to constitute a good genus, whose limits the writer of this has attempted to define, in the Flora Graeca and its Prodomus, and which will here be exemplified—"Tourn. in Mem. de l'Acad. des Sc. for 1706. t. 3." Sm. Fl. Gr. T. 2. v. 28. Prodr. v. 1. 95. Linn. Gen. 543. Schreb. 728. Willd. Sp. Pl. v. 4. 947. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 434. Dill. Gen. 147. t. 8. Mich. Gen. t. 7. Juss. 179. Lamarck Illuir. t. 843. (Galium hifpidum; Gern. t. 24.)—Clais and order, Tetrandria Monogyenia. (Polygama Monoeoca; Linn.) Nat. Ord. Stellate, Linn. Rubiacceae, Juss.

Gen. Ch. Cal. Perianth none. Common Receptacle threeflowered, variously shaped, enlarged after flowering, containing the follicular fruit. Cor. superior, of one petal, flat; that of the central flower with four, of the lateral, or male, ones with three, deep ovate segments. Stam. Filaments in the central flower four, in the lateral ones three, thread-shaped, curved, alternate with the segments, and half as long; anthers roundish, of two cells. Pyr. germinal follicular, inferior, concealed in the receptacle, belonging to the central flower, with the rudiments of two seeds; hyle in the central flower only, deeply divided, scarcely fo long as the flaments; fligmas obsolete. Peric. formed of the enlarged permanent receptacle, gibbous, inflated, of one cell. Seed generally follicular, sometimes two, ovate, concealed in the receptacle, smooth.

Obf. The above limitation of the genus before us excludes V. pedemontana, Willd. n. 4; bunifolia, Willd. n. 6; taurica and cernifera, Willd. n. 9 and 10; with V. Aperina, articulata, Crucia and globula, of Linnaeus, all which eight species belong, if we mistake not, to Galium. Willdenow has already properly removed from this genus V. hypoparca, which is, as Browne and Pursh make it, a species of Rubia, very remarkable, however, for its apparently superior.
VAL

V R I I rior german. But we apprehend that what looks like an inferior calyx, may be four bracteae, and that this species, like Rubia tinctorum, may have no real perianth.

1. V. muralis. Wall Crofts-wort. Linn. Sp. Pl. 1490. Wild. n. 1. Ait. n. 1. Sm. Fl. Grac. Sibth. v. 2. 28. t. 137. (V. annua quadrifida verticillata, floribus ex viridi pallecentibus, fructu echinato; Mich. Gen. 13. t. 7. Crucia nova romana minima muralis; Colonna. Ecphr. 298. t. 297. f. 2. Rubia quadrifolia, verticillata femene; Bauh. Hist. v. 3. 718.)—Fruit lobed; its angles fringed with teeth. Whorls crowded.—Native of walls and dry banks in Italy and the south of France, as well as in Greece. Dr. Sibthorpe gathered it on Mount Hymettus, near Athens, and on the hills of the country of Argos. The root is small and annual. Stems several, about a finger's length, ascending, clothed with numerous whorls of small, obovate, entire leaves, four in a whorl, a little hairy on each side. Flowers axillary, one to each leaf, small, sessile, pale yellow. Fruit of a singular appearance, much larger than the flowers, deflexed; gibbous and smooth at the base, lodging a solitary, ovate, smooth seed; its lobes divaricated and toothed.

2. V. bifida. Briffly Crofts-wort. Linn. Sp. Pl. 1490. Wild. n. 2. Ait. n. 2. Sm. Fl. Grac. Sibth. v. 2. 29. t. 138.—Fruit brittle. Whorls rather remote.—Native of the south of Europe. Dr. Sibthorpe gathered it on the mountains of Crete, and has supplied the only figure that exists of this species. An annual herb, twice the size of the foregoing, and differing from it by its longer, narrower, more diffusely-leaved leaves; but more effantly by the oblong form of its common receptacle, or fruit, becket with pale rigid bristles, and not fringed, in which gibbous smooth base is lodged a solitary seed, whole infructescence erroneously represented by Gartner. Miller cultivated both these species, but nothing can be less likely to interest a mere flower-garden botanist. To those who study natural genera, and their affinities, these plants are highly curious, and sufficiently demonstrateValantia to be distinct from Galiana.

3. V. filiformis. Leaflet Crofts-wort. Ait. n. 3. Wild. n. 3.—Fruit cylindrical, falcifer, without prickles, longer than its falc. Leaves lanceolate, somewhat fringed. Gathered by Mr. Maillon, in Teneriffe. Root annual. Stems simple, a span long, bifid. Leaves four in each whorl, somewhat falcated, reticulated with veins; the lower ones rounded. Common receptacle becket with minute, lanceolate, chaffy scales.

4. V. Culcatoria. Hooded Crofts-wort. Linn. Sp. Pl. 1491. Amoen. Acad. v. 4. 296. Wild. n. 5. Ait. n. 5. (Cuculatoria; Buxb. Cent. 1. 13. t. 19. f. 2.)—Bracteae ovate, falcated, delixed, concealing the oblong furred hairy fruit.—Gathered by Buxbaum, in Cappadocia, and by Hafellquitt in Arabia, on hills, flowering in May. A small, branching, annual herb, with square rough-edged stems. Leaves ovate, falcated, revolute, rough with minute prickles. Flowers very small, yellowish, on bracted axillary stalks, each stalk bearing three flowers, and as many large, pale, reticulated, smooth, overshadowing bracteae, which well mark this species, and caused Buxbaum to distinguish it as a genus, by the name of Culcatoria. The plant is, however, a true Valantia.

VALARSA-KERD, in Geography, a town of Turkish Armenia; 15 miles W. of Diadin.

VALAY, a small island near the west coast of North Uist. N. lat. 57° 37'. W. long. 7° 29'.

VALBAS, a town of Spain, in Old Castile; 15 miles W.S.W. of Burgos.

VALCA, a river of the Pedi, which runs into the Tiber, about 5 miles above Rome.

VALCALDE, or Villa Calde, a town of the Genoese republic; 10 miles N. of Genoa.

VALKENBURG, a town of Holland; 3 miles N.W. of Leyden.

VALKENSTEIN, a town of the duchy of Wurzburg; 5 miles N. of Gerolzhofen.

VALCOUR. See Walcourt.

VALDAGNO, a town of Italy, in the Vicentia; 17 miles W. of Vicenza.

VALDA, or VADAY, a town of Ruffia, in the government of Novgorod; 72 miles S.E. of Novgorod. N. lat. 57° 50'. E. long. 35° 44'.

VALDARACETE, a town of Spain, in New Castile; 22 miles S.E. of Madrid.

VALDASNES, a town of Portugal, in the province of Tras os Montes; 9 miles E.S.E. of Miranda.

VALDAY, or Valday, a town of Russia; in the government of Novgorod, which are crost in travelling from Petersburg to Moscow, and are probably a continuation of the Lapland mountains. They were known to the ancient geographers by the name of Mons Alumnus. At present they are indifferently called Vhifokaya Plofchade, high rising ground, or the mountains of Valday, from the town and the lake Valdach, which are situated on their summits. The country about Valday, being the highest point of the mountain, is extremely pleasant. Fine, flow-rising hills, a charming pellicid lake, with an island on which stands a noble monastery, delightful groves, and an extensive fenery, form the most pleasing variety. These mountains afford numerous and large blocks of granite, quartz, and sandstone, together with felspar, hornblende, mica, felspar, porphyry, jasper and silex. The granite blocks are covered with sand and clay. The Valday eminence, which is the highest ridge of these mountains, shapés its courfe from the north, and appears to take its departure from between the lakes Ladoga and Onega. It then stretches across the Mita, runs between the Iemen lake and the Seliger, and extends its foot as far as into the governments of Smolensk, Orel, and Novgorod-Sewerki. About its western, southern, and eastern declivities, are several strong lirata of chalk and marl, which in farther progress are lost in marshy and fandy plains. Some naturalists are of opinion, that the whole of this Valday chain of mountains is the effect of violent inundations, and that it entirely consists of a chalk-like rime from crumbled and defroyed marine productions. But it is no lefs probable, that the middle part is a primitive mountain, having granite for its principal stratum, which, through a long interval of time, and perhaps under water, is so much decayed as to be in a manner smoothed. No chalk-pit has yet been opened on its summit. Upon the whole it is suppos'd, that all these elevations may be an original mountain decayed and defroyed on its surface, on which, round about its declivities, the loofe chalk and marl are floated and deposited. Among these mountains no mine has yet been explored. Some specimens have been obtained of copper and lead; but here is plenty of iron and slate. The extreme elevation of the Valday mountains is very moderate, as the highest point is scarcely 200 fathoms above the level of St. Petersburg. Besides the Valday lakes, there are others of inferior note; and at the western foot is the great lake Ilmen, at the southern, the Seliger, &c. Of the rivers, some spring from the mountains, and others are supplied by the lakes that lie at their feet; such are the Volga, the Duna, the Volkof, the Lovat, the Pola, the Tihagredo, the Kolp, the Dnieper, the Don, the Oka, &c. These mountains are sparingly
sparingly clothed with forests, but so much the more with beautiful meadows and fields, so that the graziers derive from them considerable profit. The species of wood are the several sorts of pines and firs, the birch, the linden, the alpen, the elder, &c. The soil in the valleys mostly consists of clay and marl, and is generally fertile. Tooke’s View of the Russian Empire, vol. i.

VALDEBURON, a town of Spain, in the province of Leon; 34 miles N.N.E. of Leon.

VALDECONA, a town of Spain, in Catalonia, on the borders of Valencia; 15 miles S. of Tortosa.

VALDEMANZANAS, a town of Spain, in the province of Leon; 8 miles S.W. of Alorqa.

VALDEMORO, a town of Spain, in New Castile; 13 miles S. of Madrid.—Alfo, a town of Spain, in New Castile; 18 miles E.N.E. of Ceneca.

VALDENSES, in Ecclesiastical History. See VAUSSOIS.

VALDEPENAS, in Geography, a town of Spain, in the province of Jaen; 8 miles S.W. of Jaen.—Alfo, a town of Spain, in New Castile; 22 miles S.E. of Ciudad Real.

VALDERAS, a town of Spain, in the province of Leon; 23 miles S. of Leon.

VALDERIES, a town of France, in the department of the Tarn; 6 miles N.N.E. of Alby.

VALDES, John, in Biography, a Spanish reformation and a lawyer, was knighted by Charles V. During a tour in Germany he imbibed the principles of Luther; and afterwards settling in Italy, and chiefly at Naples, he became secretary to the king. During his abode in this city, he communicated his sentiments to several persons, and particularly to Peter Martyr and Ochino. But though in his religious sentiments he concurred with the reformers, and in his notions with respect to the Trinity with those that were denominated Unitarians, he does not appear to have formed any separation from the church of Rome. His discourses, however, were numerous, and attracted the notice of the Inquisition; the dread of which induced several of them to quit the country, and others to retract their opinions. Valdes died at Naples about the year 1540, with an established character for piety and virtue, and leaving several works, particularly “Commentaries on various parts of the New Testament, &c.” Some of which have been inserted in the Index of the Inquisition, and others confiscated by the reformers. Beza condemns his treatise entitled “Considerations,” charging it with being the source of the errors of Ochino. Bayle.

VALDEZIA, in Botany, a genus in the Flora Pedemontana, page 57, so named in memory of Don Antonio Valdez, a Spaniard, minister of the Spanish marine, founder of a botanical garden. De Thésis.

VALDÍA. See OVIEDA.

VALDIGEM, in Geography, a town of Portugal, in the province of Beira, near the Duero; 3 miles N.E. of Lamego.

VALDIVIA, a river of Chili, which runs into the South Pacific ocean, near Valdivia.

VALDIVIA. See BALDIVIA.

VALDORE, a town of Hindoostan, in the Carnatic; 8 miles W.N.W. of Pondicherry.

VALDORF, or WALDORF, a town of Welfphalia, in the county of Ravenberg; 3 miles S.W. of Bielefeld.

VALDROMO, a town of France, in the department of the Drôme; 18 miles S.S.E. of Dieu.

VALDU, or WALDU, Peter, in Biography, was the son of a rich merchant of Lyons, who lived in the twelfth century, and derived his name from Vaux in Dauphiné, the place of his nativity. With a mind deeply impressed by the sudden death of a friend, he directed his views entirely to another world, distributed his wealth in alms, and employed himself in propagating just sentiments, as he conceived them to be, of true religion. From another account of this reformer we learn, that about the year 1160, he employed a priest in translating the four gospels from Latin into French, and by the perusal of them adopted opinions very different from those of the Romish church. In 1180, connecting himself with a small society of sentiments similar to his own, he assumed the character of a public preacher. Attempts were made to seduce him, but they proved ineffectual; and the number of his followers gradually increased. Expelled from Lyons, he retired to the mountains of Dauphiné and Savoy, and propagated his opinions, which were eagerly adopted by the multitude through the adjacent valleys, where they took deep root, so that no persecution or violence could eradicate them. From him, as some say, sprung the sect of the Waldenses. For other particulars, we refer to the article VAUSSOIS.

VALE or a Pump, at Seca, a term for the trough by which the water runs from the pump along the ship’s sides, to the scupper-holes.

VALE or Valley Lands, in Agriculture, are terms applied to any of those which lie in low, narrow, hollow tracts or depressions between hills or rising grounds on their different sides. They are, for the most part, applicable in a more particular manner to grasses and dairy practices than others, but sometimes, when suitably dry, to those of the arable kind. They are in many cases very quick in vegetation, and extremely productive; being readily capable of improvements by warping, watering, and other such means, at but little expense, which should always be well attended to, in all such lands where there is the possibility of effecting them.

The latter is likewise a term sometimes applied to a gutter or channel in a road or other such situation.

VALEDEA, in Geography, a sea-port town of Africa, in the kingdom of Fez, situated on the coast of the Atlantic, in a fliny plain; here is a very spacious natural baflon, surrounded by rocks, capable of containing above 1000 ships; but the entrance, which is entirely open to the west, is extremely difficult and dangerous. The coast is lined with rocks near 30 feet in height, which anciently must have been washed by the sea, the Moors living in the caverns hollowed out by the water. At the bottom of the rocks, the sands heaped up by time have formed a plain, laid out into gardens and cultivated: the town is little more than a circle of walls, containing but few inhabitants; 27 miles S.S.W. of Mazedan.

VALEGAR, a town of Hindoostan, in Coimbatore; 15 miles W. of Damiecte.

VALEGGIO, or VALEZZO, a town of Italy, in the department of the Benaco, on the river Mincio; 14 miles S.W. of Verona.

VALEGIO, a town of Italy, in the department of the Gogna; 4 miles N.E. of Lumello.

VALENÇA, a town of Portugal, in the province of Entre Duero e Minho, on the S. side of the Minho, opposite Tuy in Spain, and said to have been founded by the soldiers of Viriatus. It contains two parih-churches, an hospital, two convents, and about 900 inhabitants; 16 miles W. of Oporto. N. lat. 42°. W. long. 8° 20’.

VALENÇA de Alcantara, a town of Spain, in Estremadura, on the borders of Portugal; 24 miles S.W. of Alcantara.

VALENÇA de Duero, a town of Portugal, in the province
of Boira, situated about half a league from the Duero; 12 miles W. of St. Joao de Pefqueira.

VALENCIA, a town of France, and principal place of a district, in the department of the Lot and Garonne; 12 miles S.W. of Agen. N. lat. 44° 6'. E. long. 0° 59'.—

Alfo, a city of France, and capital of the department of the Drôme, on the left side of the Rhöne; anciently a Roman colony, called Julia Augusta. Before the revolution it was the fee of a bishop, and capital of a principality called Valentinois. An university was brought hither from Grenoble in the year 1453; 16½ pôts N. of Avignon. 

VALENCIA, a town of France, in the department of the Tarn; 12 miles N.E. of Alby.

VALENCIA, a province of Spain, bounded on the N. by Aragon and Catalonia, on the E. and S.E. by the Mediterranean, on the S.W. by Murcia, and on the W. by New Cañille, about 220 miles in length from N. to S.; the breadth is unequal, from 20 to 45. Valencia is, in proportion to its extent, one of the best peopled provinces of Spain, and contains few cities: has four sea-ports, the most considerable of which is that of Alican; the soil is extremely fertile, although divided by mountains. These contain mines of finopica, or blood-stone, iron, and alum. There are also found quarries of marble, jasper, plater, laps calaminaris, and potter's-clay, of which different kinds of earthen vessels are made. The climate is mild and pleasant, but there is something enervating and faintish in the air; vegetables with the finest outward show imaginable are not good to the table. No women work in the fields; but this may proceed from their constant employment within doors, as much as from any remains of Moorish jealousy, though the Valencians still retain much of the features and manners of their old Saracen masters. To this day the farmers will not allow their wives to fit at table, but make them stand at their elbow and wait upon them. The inhabitants of this province are said to have more of the silken and full-puffed manners of the old Spaniards, and to have adopted less of foreign improvements in civilization, than most other parts of Spain. This kingdom and city were conquered by the Moors under Abdallah Iis, and recovered in 1094, when the famous Cid Ruy Dias de Vivar, taking advantage of the confusion and civil war that raged in Valencia, after the murder of Sultan Hiyas, made himself master of the city by storm, at the head of a chosen band of valiant knights. This was the last exploit of that hero, so long the terror of the Muffulens. A few days after his death, the king of Cañille, finding it too far distant from his other dominions to be conveniently foguced in cafe of a sudden attack, thought proper to withdraw his troops, and suffer the Moors to repose themselves of it. It was again taken from them by James I., king of Aragon, in the year 1238, and for ever united to that crown, the fate of which it has ever-since followed through all its various revolutions. In the beginning of the reign of Charles V. this province was distracted by civil commotions and struggles between the nobility and commons. The population of the whole kingdom of Valencia amounts to 79,221 vecinos, or 716,884 souls, resident in 570 towns and villages. The manufactures of silk are the cause of a population that may be reckoned considerable, if compared with that of other provinces of Spain. The produce of this article, on an average of one year with another, amounts to about 500,000 pounds, worth a doubloon per pound, in the country. Government has prohibited the exportation of Valencia raw silk, in order to lay in a stock to keep the artificers constantly employed in bad years; for it has sometimes happened, that half the workmen have been idle for want of materials. The great nurseries of mulberry plants in the plains of Valencia are produced from seed, obtained by running a rope of Esparto over heaps of ripe mulberries, and then burying the rope two inches under ground. As the young plants come up, they are drawn and transplanted. The trees, which are all of the white kind, are afterwards set out in rows in the fields, and pruned every second year; in Murcia only every third year; and in Granada never. The Granada silk is esteemed the best of all, and the trees are all of the black sort of mulberry. The fruit exported from Valencia to the N. of Europe may be estimated, communis annis, at two millions of pesos, about 3,344,000 ½ sterling. The annual crop of hemp may be worth 300,000 pesos, at three pesos per arroba, 140,000 loads of rice, at 10 pesos a load, make 7,000,000 pesos. The vintage of 1767 produced 4,300,000 meafures of wine, which, at three reals a measure, come to 861,133 pesos. There is also much cotton made in this province from the cotton-plant, which rife to the height of three feet at molt, and very much resembles the raspberry-bush. They make in good years 450,000 arrobas, worth 1,350,000 pesos, and in middling years 285,000 arrobas. Notwithstanding all this abundance, nothing can be more wretched than the Valencia sheep-farming, who can with difficulty procure food to keep their families from starving. Valencia is watered by 35 rivers, all of which run towards the E. It was formerly inhabited by the Celtiberians, the Turdetani, the Lusonis, &c. &c. Valencia was erected into a kingdom, in the year 788, by Abdalla, governor of Valencia, who revolted from the king of Cordova, but was however obliged to pay an annual tribute of 17,000 maravedis. This kingdom continued till the 13th century, when the last king, Zaben, was dispossessed of his capital, and compelled to leave his dominions with 50,000 Moors.

VALENCIA, a city of Spain, and capital of the province so called. Its ancient name is unknown; but it is said to have been taken and fortified by Scipio, destroyed by Pompey, and rebuilt by Cesar. It was taken from the Romans by the Goths, and from the latter by the Moors, who twice possessed it 230 years; for it was taken in 1094, by the famous Cid Ruy Diaz de Vivar, and, during four years, the name of Valenciana. The Moors retok it, but it was finally conquered in 1238, by the king Don Jayme, and embellished as well as enlarged by Don Pedro IV. king of Aragon. It is about half a league in circumference, and the walls are built for ornament rather than defence. Mariana the historian says, that in Valencia cheerfulness enters at the doors and windows: the description he gives of this city is in many respects devoid of truth, and such that the author proves himself more a poet than an historian. Several geographers who have had implicit faith in Mariana, have even exaggerated his account of Valencia, and said the houses here are all palaces, on which account the name of Bella was given to the city, an epithet difficult to reconcile with narrow, crooked, and unpaved streets, impassable after rain; and in which there are but two or three houses built with talle, and a few churches distinguished by their architecture. It is the see of an archbishop, and an univerfity, instituted in the year 1470. Here is a tribunal of inquisition, with a royal audience, in which the governor, the captain-general of the province, and a royal regent, preside. The number of inhabitants is estimated at 100,000, but perhaps 80,000, or between both, is nearer the truth; 170 miles N.E. of Madrid. N. lat. 39° 27'. W. long. 0° 27'.

Accounts are kept at Valencia in libras of 20 soldi, or 240 ducros; also in reals of new plate of 24 ducros. The libra of Valencia is equal to the peso of plate, or

Vol. XXXVI.
or dollar of exchange; it is, therefore, worth 8 reals of old plate, 10 reals of new plate, or 15 reals 2 maravedis reals. The real of Plata Valenciana, 13/1 of which make a libra, is worth 1½ fueldos, or 18 ducers, that is, 2½ths of a real of new plate. The libra is worth 39½d. Railing nearly; or, more accurately, 1/12 railing = 6 libras, 1 fueldos, 5 ducers of Valencia. A carga or carica weighs 3 quintals, or 12 arrobas; the arroba, 24 lbs. pecho grueso, or 36 lbs. pecho fitile: the former pound is 18 oz. the latter 12 oz.; and the ounce is 1/4 heavier than the Castilian ounce; hence 50 lbs. pecho grueso, or 75 lbs. pecho fitile, answer nearly to 55 lbs. avoirdupois. The fitile, or lighter weight, is used for bread, sugar, tobacco, and spices; the grueso, or heavier weight, for most kinds of merchandise.

Corn is measured by the cahiz of 12 barfellas, or 48 caleones; 100 cahizes produce 5½ English quarters. The cantera, or arroba, liquid measure, contains 4 azumbres; and 25 such arrobas = 88 English wine gallons nearly. The carga of wine consists of 15 arrobas; the carga of oil of 12 arrobas. The vara or ell is divided into 4 palmos, and is about 4½th longer than the Castilian vara, measuring, therefore, 36½ English inches. Kelly’s Un. Camb.

Valencia, a town of South America, in the government of the Caraccas; 16 miles S.W. of Caraccas. This city was founded in 1555, under the government of Villacinda, with a view of establishing a port near to Caraccas, in order to facilitate the conquest of the country, which had been much extended by Faxardo. But Alonzo Dias Moreno preferred a situation farther distant from the lake Tacarigua, now Valencia, or half a league W. of it on a beautiful plain, where the air was pure and the soil fertile. N. lat. 10° 9’. W. long. from Paris 70° 45’. Its population in 1801 consisted of 65,487 persons, according to some reports, but according to others, said to be more accurate, of 80,000 souls. The inhabitants are generally Creoles, and the issue of very ancient families, excepting some from the Canaries, and very few Biscayans. The streets are wide, and for the most part paved. The houses are built like those of Caraccas, but not with stone. There is one church tolerably well built, and in the eastern part of a beautiful square, from which it receives, and to which it gives an embellishment, that constitutes the principal decoration of the city. In 1804 another church was erected, and dedicated to our Lady of la Chandeleur. The Franciscans have a monastery, occupied by eight monks, which has a very neat and elegant church. The inhabitants had formerly the character of being the most indolent in the whole province; but in consequence of some vigorous measures that have been lately adopted, a spirit of greater activity and industry has been excited among them. The situation of Valencia is particularly favorable for trade; being separated by only ten leagues of good road from Porto Cavolette, it may transport its commodities thither to a small expense; and besides, every commodity from the interior of the country shipped at Porto Cavolette goes through Valencia, and that which is destined for Guayaquil passes through Caraccas. The adjacent country produces every sort of provision and fruit in the greatest abundance, and of a most exquisite flavor; and its plains furnish its markets, at a very low price, with every kind of animal which they can consume. Depon’s Travels in South America, vol. ii.

Valencia, Lake of, called by the Indians Tacarigua, but different from the bay or lake of the same name, (see Tacarigua,) a lake of the government of Caraccas, less extensive but more useful than that of Maracaibo. This lake stretches 13½ leagues from E.N.E. to W.S.W., and its greatest breadth is four leagues. Its form is oblong; it lies at the distance of one league from Valencia, and is situated in a valley surrounded with mountains, excepting on the W. where it extends into the interior of the country. It receives the water of twenty rivers without any visible outlet. It is five leagues from the sea, and separated from it by inaccessible mountains. It probably discharges itself by a subterraneous passage, as well as by evaporation, so beneficial to vegetation. Its eastern part is appropriated to the cultivation of tobacco for the king’s benefit; and this tract being divided into five plantations, employs 15,000 persons. The remainder of the land gained from the lake is laid out in other kinds of culture. Its vicinity is enriched by a variety of birds, whose plumage is beautiful, and whose notes are melodious. It also abounds with aquatic game, and its borders are embellished with unending verdure. It is intercepted with a number of small islands, which are inhabited; and one of them, called Carayapona, contains a population sufficient to raise provisions, fruits, and vegetables for market. It furnishes a great quantity of fish, that called by the Spaniards, guayana, being the most abundant. Many reptiles are seen upon its borders; and among these are two kinds of lizards, which are particularly distinguished; and of which the Indians and some Spaniards make their most delectable meals. Depon’s Travels, vol. i.

Valenciennes, a city of France, and principal place of a district, in the department of the North, situated on the Scheldt, which runs through the town in several places, and here becomes navigable. It is supposed to have derived its name from the emperor Valentinian I., who, taken with the temperature of the climate, and charming situation of the place, laid the foundation of a town, about the year 367, endowing it with many privileges and immunities, and particularly of being an asylum for debtors and criminals. This privilege, which extended over the greater part of the town, was called “banlieue;” but it has since been limited, to prevent abuse from fraudulent bankrupts and affiants. Before the revolution, it belonged to Hainaut, and contained several churches and convents. The town-house is an ancient building of free-stone, founded in the 14th century; the square or grand place is handsome, but the streets are in general narrow, dark, and crooked. The form of its municipal government was considered so good as to serve for the model of several republics, particularly Venice and Nuremberg, which sent deputies to collect the laws. Near the town is a coal-mine. Valenciennes was one of the first towns which revolted against Philip II. king of Spain; it took part with the States and the Protestant religion, and refused to receive a garrison sent by Margaret of Parma; in consequence of which it was besieged, in the year 1567, by John de Noircames, baron of Selles, and at the end of three months surrendered at discretion; thirty-six of the principal ringleaders were punished, and the town deprived of its privileges. It was afterwards several times taken and retaken by the duke of Alva and the States General. In the year 1656, it was besieged by the French, under the command of marshals Turenne and La Ferté; but they were compelled to raise the siege, after the loss of 4,000 men killed and wounded, in several assaults. In the year 1677, it was besieged by Louis XIV., in person; and after 17 days, taken by assault. It remained to France by the peace of Nimeguen, which happened in the following year, when a new and handiwork citadel was built, at the expense of the citizens, and other fortifications added. In 1793, Valenciennes was invaded by the allies, under the conduct of the duke of York, and the governor Ferrand summoned to surrender. On the 14th of June, the trenches were opened. The British commander then summoned the
but receiving an unsatisfactory answer, the artillery began to play upon the town with great vigour, and in the course of the night above 500 red-hot balls were poured upon it. Towards the beginning of July, the besiegers were able to bring 200 pieces of heavy artillery to play without intermission on the town, and the greater part of it was reduced to ashes. The mortal sickly fact in the history of this siege is, that a considerable part of the was carried on underground, mines and counter-mines innumerable having been formed both by the besiegers and besieged. The principal of these, on the side of the former, were one under the glacis, and one under the horn-work of the fortres; these mines were completed and charged on the 25th of July, and in the night between nine and ten o'clock were sprung with the molten complete success. The English and Austrians immediately embraced the opportunity to throw themselves into the covered way, of which they made themselves masters. The die was now cast, and on the 26th the duke of York again summoned the place, which surrendered on capitulation the succeeding day; the duke of York taking possession of it in behalf of the emperor of Germany. The following year, however, in consequence of the success of the French arms, Valenciennes surrendered to the republicans, by capitulation, on the 26th of August. The garrison were made prisoners of war, but to be conducted to the first post of the imperial and Dutch armies, on condition that they were not to serve against the republic till regularly exchanged. Considerable stores of every kind, with 200 pieces of cannon, 1,000,000 pounds of gunpowder, and 3,000,000 florins in specie, and 6,500,000 livres, were found in Valenciennes; 100 head of horned cattle, and great quantities of oats and other corn, were also included within the fortresses. So earnest indeed had the emperor been to retain this important place, that he is said to have expended 3,000,000l. in repairing and improving the fortifications. What is the most to be lamented is, that upwards of 1000 unhappy emigrants were surrendered on this occasion to the vengeance of their enraged countrymen. The principal manufactures are lace, cambric, and woollen mitts, camlets, &c.; 4½ posts E. of Douay. N. lat. 50° 21′. E. long. 3° 36′.

VALENGIN, or VALENGIN, or VALENGIN, a town and capital of a lordship, in the county of Neufchâtel; 3 miles N.N.W. of Neufchâtel. See Neufchâtel.

VALENS, FLAVIUS, in Biography, a Roman emperor, was born at Cibalis in Pannonia, and associated in the empire with his brother Valentinian A.D. 364, at the age of thirty-six. To him his brother, to whom he was much attached, affixed the eastern portion of the Roman dominions, comprehending the whole of Asia, with Egypt and Thrace: upon this division, Valens made Constantinople the seat of his empire. Alarmd by the movements of the Persians on the borders of his territory, he departed for Syria, and at Caesarea, in Cappadocia, he was informed that Procopius had taken possession of his capital. The emperor was so terrified by this intelligence, that he intended to negotiate with the usurper, and to propose to him an abdication of the empire. His ministers, however, advised him to detach a body of troops, in order to suppress the insurrection at its commencement; but these troops joined Procopius, and contributed to his success. At length many of the insurgents abandoned their commander, who rendered himself unpopular by his rapacity and tyranny, and he was ultimately betrayed to Valens, who ordered him to be beheaded. The emperor was thus establisht on the throne; but his conduct was such as to cool the ardour of his friends, and to excite enmity and opposition. In process of time, from the year 366 to 369, he contended successfully with the Goths, and having reduced them to great distress, contented to conclude a treaty with them, which was ratified with great magnificence in barges upon the Danube. Having accomplished this object, Valens returned in triumph to Constantinople.

Valens, having received his Christian creed from Eudoxus, the Arian bishop of Constantinople, disgraced himself by becoming a persecutor of the Athenians: and in a contest between these two parties, he acted in a manner so rigorous and violent, as to entail indelible reproach on his memory. In 371 he lost his only son, and in the following year he defeated the Persians, and afterwards readily condescended to a truce. Whilst he was passing the winter at Antioch, in the year 374, he manifested, in his treatment of persons who recurred to magical practices for ascertaining the name of the future successor to the imperial throne, the jealous cruelty of his character. Many perfons were involved in real or supposed guilt, and confined to the punishment of torture, banishment, or death. Having reigned five years at Antioch, watching the motions of the Perisan king, preparing the inquisitions of the Saracens and Ifaurians, and conducting state inquisitions and religious perfections, his attention was excited by a terrible inroad of the Huns upon the territories of the Visigoths, and these Goths, having obtained permission to cross the Danube, penetrated into the cultivated part of Thrace. The Gothic tribes were joined by the Huns and Alans. The emperor arrived at Constantinople in 378, and urged by the clamours of the people, marched against the enemy to the vicinity of Constantinople. An engagement ensued, which proved singularly disastrous to the Romans. Valens, defeated by his guards and wounded, betook himself to a cottage, in which his attendants were dresting his wound: the cottage was betet by the enemy, who being resisted, set fire to a pile of faggots, that consumed the emperor and all that were with him. Thus did Valens terminate his life at the age of fifty, and in the sixteenth year of his reign. His character, as it has been delineated by historians, merits in many respects contempt and detestation. He was nevertheless modest and temperate in his mode of living; addicted to no private vice or superfluous expense; ready to listen to the complaints of his subjects, and to protect them from the oppression of the military, among whom he preferred exact discipline; and it has been said that the Eastern provinces in general were never happier than under his government. Anc. Un. Hist. Gibbon's Rom. Emp. Gen. Biog.

VALENSONE, in Geography, a town of France, in the department of the Lower Alps; 18 miles S. of Digue.

VALENTANO, a town of the Popeden, in the duchy of Calfo; 14 miles S.W. of Orvieto.

VALENTIA, in Ancient Geography, a town of Hispiania Citerior, upon the Turia. See VALENCIA.

VALENTIA, a town and colony of Gallia Narbonenensis, belonging to the Segalauni, according to Ptolemy, but to the Cavares, according to Pliny. In the Itinerary of Antonine, this town is marked on the route from Mediolanum to Lugdunum, between Augusta and Urfae. As the fall of the Roman empire this town became subject to the Burgundians, afterwards to the Merovingians; but under the Carolingians, it belonged to the kingdom of Burgundy and Arles.-Alfo, a country of the ile of Albion, according to Ammianus Marcellinus. It was conquered by Theodorus the elder, and made a fifth Roman province. (See OTODIN.-)

Alfo, a town of Italy, in Meffapia, between Clipiae and Civitas Brundis, according to the Itinerary of Jerusalem.-Alfo; a town situated in the interior of the ile of Sardinia._

VALENTIA, in Geography, a small island on the coast of Kerry,
VALEN'TIA. See Cape ad Valentinam.

VALENTINE, Peter, in Biography, was born at Colomiers en Brie in 1605, and studied some time under Simon Vouet, but leaving that master before he had made any considerable progress, travelled to Rome, where he palled the remainder of his life: he may therefore be rather considered of the Roman than the French school. The powerful and vigorous style of Michael Angelo Caravaggio made so strong an impression on him, that he attached himself to an imitation of it, with a devotion that was never diminished. Like that artist, he indulged in an extravagant, but effective contrast of light and shadow; like him, he was a faithful follower of nature, and was equally indifferent and unfortunate in his choice of it; like him, he was frequently incorrect, and always ignoble. He was, however, an intelligent master of the chiaroscuro, and his masses are disposed so as to produce the most striking effect. Though he occasionally painted altar-pieces for the churches, his powers appear to have been better adapted to other subjects, which he also appears to have painted in preference. His best pictures represent fortune-tellers, gamblers, concerts of music, and corps de garde; to which his taste was more competent than to the dignity of historic painting. The patronage of cardinal Barberini, nephew to Urban VIII., procured him the commissio to paint a large picture for the Basilica of St. Peter, representing the Martyrdom of S. S. Proceffio e Martiniano, which is esteemed his best historic picture. He also painted for his patron, the Decollation of St. John, in the Palazzo Barberini; and there is an admired picture by him in the Corsini palace, of Peter denying Christ. This pleasing painter died in 1632, at the early age of thirty-two, of a fever, being brought on by going into a cold bath when he was heated.

VALENTINE, in Geography, a town of France, in the department of the Upper Garonne; 2 miles S.W. of St. Gaudens.

VALENTINE'S Bay, a bay on the south-east coast of Terra del Fuego, west of Cape Success.

VALENTINI, Michael Bernhard, in Biography, a native of Gießen, in Germany, where he was born in 1657, and became a medical professor, and where he died in 1729. The subjects of his writings, which are numerous, chiefly comprehend botany and the materia medica: of these we shall here mention his "Letters from the East Indies;" "Praxis Medica," in two parts; "Amphitheatrum Zootomicum," fol.; and a "Corpus Juris Medico-legalis," fol. referring for other works to the botanical article VALENTINIA. Haller.

VALENTINI, Pietro Francesco, of Rome, who flourished about the year 1645, and whose patience and abilities in the construction of canons seem to have made every subsequent canonist despair of emulating his faculties and dexterity in the art. Indeed he appears to have surpassed all that the most determined canonists had ever achieved, by the several works which he published on the subject, in the following order: "Canon to the words Illas duas misericordes oculos ad nos convertite, with the Resolution in more than two thousand ways, for two, three, four, and five Voices, Rome, 1629;" "Canon, called the Knot of Solomon, for ninety-six Voices, Rome, 1631;" "Canon on four Subjects for twenty Voices, Rome, 1645." The first and most curious of these works seems to have been reprinted in 1655, as M. Marpurg of Berlin, and several other musical writers, in speaking of it, refer to an edition of that date. But P. Martini, who is in general very accurate in dates and citations, mentions Valentini's first canonical work under the year 1629. Kircher gives the subject, and an account of this canon, in his Musurgia. M. Marpurg, in a periodical work called Umbierte Riffte, or "Critical Letters on the Art of Music," vol. ii. 1763, 4to. has bestowed upwards of fifty pages on this canon, and not only given it a hundred different ways in notes, but explained more than two hundred of the several contrivances used by Valentini in the construction of canons on the subject given.

Numerous musicians of the name of Valentini have been recorded by musical writers; among whom Gerber gives an article to a nameake of the canonist, Pietro Francesco Valentini, an opera composer at Rome in the middle of the seventeenth century, who, besides Intermezzii, set to music several dramatic fables written by good poets, such as "La Metra," a Greek fable; "The Death of Orpheus;" "Pythagoras finding Musical Proportions," 1654; "The Transformation of Daphne," a moral fable. His Intermezzii were the Rape of Proserpine, and the Captivity of Mars and Venus in the Net.

VALENTINI, Roberto, an Englishman, a voluminous composer for the common flute, whose works were chiefly published by Roger, at Amsterdam.

VALENTINI, Giuseppe, about the latter end of the seventeenth century, among other composers for the violin, a deszina, published in Holland nine different works for that instrument, the seventh and last of which were "Concerti Grossi," for four violins, tenor, and two basses; but they have been long since configned to oblivion, without any loss to the public, or injustice to the author.

VALENTINI, Urbano, the first soprano opera singer who appeared on our stage, arrived in England 1707, after the attempts that were made at operas upon the Italian model.

VALENTINIA, in Botany, received that appellation from Dr. Swartz, in memory of two writers of the name of Valentini, who have both of them contributed to the general flock of botanical information, particularly with relation to the Materia Medica. Michael Bernard Valentini, professor of medicine at Gießen, who died in 1729, aged 72, published Prodromus Historiae Naturalis Haffii, in 1707, Viridarium reformatum, in 1719, Museum Mufatorium, in 1704, and Historia simplicium reformato, printed at different times; besides several dissertations, illustrative of the natural history of Sago, Cloves, Nutmegs, Pepper, Cinnamon, Dates, Aloes wood, &c. His son, Christopher Bernard Valentini, published Tournofortis contratuus, being an arrangement of Tournfort's Institutiones in the form of tables; with some other works.—Swartz Prodr. 63. Ind. Occ. 687. t. 14. Schreb. Gen. 801. Wildl. Sp. Pl. v. 2. 344. Mart. Mill. Diet. v. 4.—Clafis and order, Othanda Monogynia. Nat. Ord. uncertain.

Gen. Ch. Cal. Perianth inferior, of one leaf, concave, coloured, in five deep, obtuse, concave, spreading, undivided segments. Car. none, unless the calyx be taken for such. Stam. Filaments eight, awl-shaped, erect, rather shorter than the calyx; anthers roundish. Pfl. German superior, roundish; style one, the length of the stamens, thick, cylindrical; sigma
On the 3rd of August, 1962, the Emperor Milan, and his son, the young Emperor, were defeated and killed near the river Campa, near the town of Nostra formosa. The Emperor Milan was killed in the battle, and his son, the young Emperor, was taken prisoner. The Emperor Milan's widow, Theodosia, was taken captive, and the young Emperor was later executed. The Emperor Milan was succeeded by his son, the young Emperor, who reigned from 362 to 365. He was succeeded by his son, Valentinian II, who reigned from 365 to 375. Valentinian II was succeeded by his son, Valentinian III, who reigned from 375 to 392.
cidia, sister of the emperor Honorius, by Constantine, one of that emperor's generals, was born in the year 418, and after the death of Honorius, declared emperor of the West. In 437, he was married to Eudoxia, the daughter of Theodotus II.; but during the life of his mother, who died in 450, he took no part in the government. The dread of Attila caused him to retire from Ravenna to Rome, where he professed terms of accommodation with this formidable enemy, which were accepted. The weaknesses and timidity of this emperor occasioned a jealousy of the famous general Actius, and base measures were secretly concerted for putting him to death. Valentinian himself perpetrated the foul deed of his affixation; and this act was followed by the murder of several of his friends. This detestable act, which took place in 454, was succeeded by the violation of the chaste and beautiful wife of Petronius Maximus, a wealthy senator. Her husband, as soon as he was informed of it, determined upon revenge; and for this purpose engaged two of the imperial guards who had served under Actius. One of these seized the opportunity of some military sports in the Campus Martius to stab the emperor to the heart. This event happened in March 455; when Valentinian was thirty-four years of age, and after he had borne the title of emperor twenty-nine years. He was the last emperor of the race of Theodosius, and had all the weaknesses, with none of the virtues of that line. Anc. Un. Hist. Gibbon. Gen. Bon.

VALENTINIAN, in Ecclesiastical History, an ancient and famous sect of Gnostics; thus called from their leader, Valentinus, an Egyptian by birth, who was eminently distinguished by the extent of his fame, and the multitude of his followers. His sect, which took rise at Rome towards the close of the second century, grew up to maturity in the isle of Cyprus, and spread itself through Asia, Africa, and Europe, with amazing rapidity. His principles were much the same with those of the Gnostics, though, in many respects, he entertained opinions peculiar to himself. He placed in the pleroma, as the Gnostics called the habitation of the deity, thirty æons, half male and half female: to these he added four others, which were of neither sex, viz. Horus, Christ, the Holy Ghost, and Jesus. The youngest æon, called Sophia, or Wisdom, conceived an ardent desire of comprehending the nature of the Supreme Being, and by the force of this propensity, brought forth a daughter, named Achemoth; who being exiled from the pleroma, fell down into the undigested mass of matter, and arranged it; and, by the assistance of Jesus, produced the demigurge, the lord and creator of all things. This demigurge separated the animal from the terrestrial matter; and out of the former created the superior world, or visible heavens; and out of the latter, the inferior world, or the terraqueous globe. He also made man, uniting in his composition the animal and terrestrial matter, to which Achemoth added a spiritual and celestial substance. The demigurc, according to Valentine, arrogating the honours of God alone, sent prophets to the Jewish nation to urge his claims; and his ambition was imitated by the other angels that predece over the different parts of the universe. In order to chastise this lawless arrogance, and to illuminate the minds of rational beings with the knowledge of the true and supreme Deity, Christ appeared on earth, composed of an animal and spiritual substance, and clothed, moreover, with an aerial body. The Redeemer, in defending upon earth, passed through the womb of Mary; and Jesus, one of the supreme æons, was united to him when he was baptized by John in Jordan. The creator of this world, perceiving that the foundations of his empire were shaken, caused him to be apprehended and nailed to the cross; but before Christ submitted to this punishment, not only Jesus the Son of God, but the rational soul of Christ, ascended up on high; so that only the animal soul and the ethereal body suffered crucifixion. Those who, abandoning the service of false deities and the worship of the God of the Jews, live according to the precepts of Christ, and submit the animal and senfual soul to the discipline of reason, shall be truly happy; and when all the parts of the divine nature, or all souls, are purified thoroughly and separately from matter, then a raging fire shall spread its flames through the universe, and dissolve the frame of the corporeal world. Such is the doctrine of Valentine and the Gnostics; and such, in general, are the tenets of the oriental philosophy. The sect of the Valentinians was divided into many branches. See Ptolemaists, Secundians, Heracleonites, and Marcionists. Motheim's Eccl. Hist. vol. i.

VALENTINUS, the founder of a sect of heretics, for an account of which, see VALENTINIAN.

VALENSA, in Geography, a town of Italy, in the department of the Gognio, on the Po; 6 miles N. of Alexandria.

VALEPONGA, in Ancient Geography, a town of Hispania Citerior, at the eastern foot of mount Ubeda, near the source of the river Turia. In the Itinerary of Antonius it is marked on the route from Laminum to Toletum, between Ad Putea and Uribia.

VALENS. See PERINIDE VALERE.

VALERIA, VALERIA, in Ancient Geography, a town in the interior of Hispania Citerior, S. of Ergavic. Pliny reckons it in the number of colonies, and Ortelius gives it the epithet of Julia. It was situated in Celtiberia, E. of Suecro, and W. of Lobetum.—Alfo, a town of the ile of Corfica, which had the title of a colony, according to Ptolomy.—Alfo, a country of Germany, comprehending a part of Pannonia, and so called by Maximian, after the name of Valeria, his wife, the daughter of Diocletian. It was situated between the Danube and the Drave.—Alfo, the thirteenth province of Italy, to which Nurtia was annexed. It was between Umbria, Campania and Picenum, and comprehended the country of the Marfs and their lake, called "Fucius."—Alfo, a town of Italy, in Latium, on the Valerian way.

VALERIAN, P. LICINIUS VALERIANUS, in Biogrophy, a Roman emperor, the descendant of an illustrious family at Rome, was betimes so distinguished by his attention both to civil and military affairs, that he was appointed consul and prince of the senate, and also censor. He occupied other stations of considerable trust and importance. At length his own troops proclaimed him emperor, in which choice every individual of the empire was disposed to concur. Accordingly he was invested with the purple A.D. 253, after having passed his sixtieth year. The commencement of his reign was rendered illustrious by many popular and laudable acts, from which eloquence, however, we must except the appointment of his son Gallienus, a vicious youth, to be his colleague in the empire; more especially as in the progress of it he had many enemies with whom to contend; among whom we may enumerate Franks, Goths, Allemans, and Persians, the latter of whom may be deemed the most formidable. When Aetius was surprized and pillaged, under the instigation of Sapor, king of Persia, by Cyriades, who assumed the title of emperor, Valerian marched to the restoration of this city, and having expelled the Scyths, who had taken possession of it, he hastened to cross the Euphrates, in order to relieve Edessa, which was besieged by Sapor. After a vain attempt for this purpose, he was reduced to the necessity of negociating with the Persian king. The result, however, was, that
that he became a captive to Sapor, A.D. 260, and was treated cruelly and ignominiously in his captivity. This di-
trofl was aggravated by the ingratitude of his son Gallienus, who afforded him no relief in his captivity, but took advantage of a report of his death to raise him to the rank of a

god. After languishing in this state for a considerable time, he died in Persea; and it was rumoured, that after his death, his skin, fluffed with straw, was hung up in a temple, where Sapor exhibited it as an humiliating spectacle to the ambas-
dadors from Rome. Valerian, whose administration was
charged with want of vigour and activity in reuniting the
foes of the empire, was not unjustly reproached as a per-
feator of the Christians. Regarding them as the enemies of
paganism, he inflamed an edict, which produced the eighth
perfection, as it has been called by ecclesiastical historians, and
which was both general and severe, and lasted from the year
257 to the period of his captivity. The calamities which he
suffered have been represented as a judgment upon him for
this cruelty. He was twice married, Gallienus being the
offspring of the first marriage; and by the second he had at

**VALERIANA.** In *Botany*, a name which seems to have
originated with the physicians of the dark ages, and which
is evidently derived from *valere*, to be powerful, or efficacious,
in allusion, as Caepar Baulinus and Ambrosius tell us, to the
many virtues of the plant. Linnaeus, in Phil. Bot. 1713,
accountably ranks this name among those derived, like
*Gentiana*, *Euapotium*, &c. from kings.—Linna. Gen. 22.
Gertn. t. 86.—Clas and order, *Triandra Monogynia*. Nat.

Gen. Ch. Calyx obsolete. Corolla superior, of one petal, gibbous on one side, at the base. Seed solitary.

Obs. Linnaeus remarks as follows on the wonderful dif-
ferences of form and number in the parts of *fructification*,
among the various species of this genus.

The *calyx* in some is a scarcely discernible border; in
others five-fert. Tube of the *corolla* in some oblong; in
a few furnished with a four-flaped nectary: in others very
short. Its limb in some equal; in others two-lobed, the
upper lip divided. *Stamens* in several three; in some two;
in others one, or four; in some removed to a different flower
from the pistil. *Stigma* in some three-fert; in others emar-
ginate; in others globose. *Pericarp* in some scarcely any;
in others a thick capsule; in others of two cells. Seed
sometimes crowned with feather down, whose form is va-
sious; sometimes without any.

By the above detail, the reader will be able to see that
Lin-
naeus includes under this genus the *Festa* of Adanson, (see
that article,) which is what Tournefort, Vaillant, and re-
cently Decandolle, have called *Valerianella*. The fame
genus is adopted, under the last-mentioned name, by our
worthy friend Mr. W. J. Hooker, in his continuation of
Curtis's *Flora Londinensis*. Such diminutives of already
established names, however, being contrary to the laws of
Linnaeus, *Phil. Bot. fett.* 227 and 228, and, which is still
more important, repugnant, in the highest degree, to good
sense, have never been admitted by any writer, even the least
correct, since Linnaeus first promulgated found principles of
nomenclature, and can have been refuted to by the above
excellent botanists, through inadvertence only. *Fedia*, being
unexceptionable, and received by Vahl in his *Enumeratio
multuperfide Valerianella*, provided the genus be allowed
to remain, of which we have already expressed our doubts.
We have indeed little scruple, all things considered, in
rejecting it. (See our 33d, 45th, and following species.)
But having already noticed *Fedia* in its proper place, we
shall here confine ourselves to the generally admitted *Val-
rianas*, which constitute an ample genus, recently augmented
by Vahl, whose arrangement of species we follow, from the
*Flora Peruvian*, and other sources; to which we have also
something to add.

The genus under consideration is composed of herbaceous
plants, either perennial or annual, with an upright round
stem, and opposite leaves; which are mostly simple; rarely
ternate or pinnate. *Flowers* terminal, numerous, opposite;
corymbose or panicled; generally reddish, or flesh coloured;
rarely yellowish; and rarely blue. The *roots* of some are di-
finguished by a mull potent and very peculiar odour.

(V. rubra Dodonza; Ger. Em. 678. V. marina; Rivn.
Monop. irr. t. 3. f. 2. Phu peregrinum; Camer. Epit. 24.)
—Stamen one. Spur of the flower elongated. Leaves lance-
olate, nearly entire.—Native of walls, waste ground,
chalk-pits, and dry hilly places, in England, Switzerland,
France, the north of Africa, Greece, and other parts of
the Levant. Certainly wild in the chalk-pits of Kent;
flowering from June to September. The plant is common
in gardens, and on old walls. A deep red *variety* is usually
preferred for cultivation. The *root* is perennial, fetid, or
rather flabby. *Whole herb* very smooth, a little glaucous,
eighteen inches or two feet high. *Upper leaves* often
toothed, broadly ovate, with a long point. *Flowers* pink,
very rarely white, slender, not inelegant, very numerous,
in a dense repeatedly branched *corymb*. *Seed-crown* of
many feathery entangled rays, gradually unrolled after the
flower is past.

n. 2. Vahl n. 2. Ait. n. 2. Cavan. Is. v. 4. 32. t. 553.
Sm. Fl. Graec. Sibth. v. 1. 22. t. 29. (V. rubra &; Linn.
Sp. Pl. 44. V. rubra angustifolia; Bauh. Hist. v. 3.
part 2. 211.)—Stamen one. Spur of the flower elongated.
Leaves linear-lanceolate, blunted, entire.—Native of hilly
situations in France, Italy, Switzerland, and the Levant,
but not yet observed in England. Dr. Sibthorp gathered it
on the highest hills about Athens. This is very nearly
related to the former, with which it agrees altogether in
habit and flowers; but the leaves are all uniformly narrow,
almost linear, quite entire, and more obtuse at the ex-
tremity.

44. Willd. n. 3. Vahl n. 3. Ait. n. 3. Sm. Fl. Graec.
Sibth. v. 1. 22. t. 30. (V. folis calcitrapa; Morff. feot. 7.
t. 14. f. 7. V. annua, feu ævita; Cuf. Hift. v. 2. 54.
Ger. Em. 1077.)—Stamen one. Corolla slightly flurred.
Leaves all pinnatifid and fefile.—Native of Portugal, the
north of Africa, the Levant, and even of Peru; but Vahl juftly
suspects its having been transported thither from Europe.
It is become a weed on many walls about Chelsea, having,
doubtful, escaped from the physic garden there. An an-
nual upright herb, fearely branched, flowering in May
and
and June; the leaves slightly lyrate; flowers small, rose-coloured. Seeds spiky, with a feathery crown.

4. V. arboiculata. Round-leaved Valerian. Sm. Fl. Græc. Sibth. v. t. 23. t. 31, marked rotundifolia.-Stamen one. Corolla slightly spurred. Lower leaves stalked, orbicular, somewhat heart-shaped, slightly toothed.—Gathered by Dr. Sibthorp and Mr. Ferdinand Bauer, on hills in the isle of Cyprus, flowering in the spring. Annual, and agreeing in habit with the last, but of rather humber growth, and especially distinguished by its round leaves, hardly an inch broad, purple beneath; the uppermost pair only being pinnatifid at their base. Flowers variegated with red and white, in twofold flaked fikes, much elongated as the seeds ripen.

5. V. oblongifolia. Oblong-leaved Valerian. "Fl. Peruv. v. l. 40. t. 65. f. a." Vahl n. 4.—"Hairy. Radical leaves oblong, toothed, obtuse; those of the stem linear, with tooth-like deep ferratures."—Found on the lofty mountains of Peru. Root fibrous, rather thick. Stems several, striated, almost leafless, except under the flowers; the central one taller, eighteen inches high. Radical leaves stalked, daintily toothed; the floral ones leafy, linear-lanceolate. Flowers fifele, in a dense corymb. Vahl.

7. V. Phu. Garden Valerian. Linn. Sp. Pl. 45. Willd. n. 7. Vahl n. 6. Ait. n. 6. (V. hortensis; Ger. Em. 1875; Rivin. Monop. Irr. t. 2, Philum minimum; Fuch. Hill 856. Matth. Valgr. v. 1. 36.)—Radical leaves elliptical, undivided; the rest pinnatifid, somewhat lyrate; the upper ones with lanceolate, acute, entire segments.—Native of Germany. An old inhabitant of our gardens, where it was anciently called Setwall, or Cettiwall. A large perennial species, flowering from May to July. Stems three or four feet high. Herbage smooth, light green, with spreading leaves, mostly lyrate; except those at the bottom. Flowers corymbose, pale purplish bluish-coloured. The flaky root has a peculiar aromatic scent, and is supposed to partake of the virtues of the Officinal Valerian. Cats are extremely fond of it, and delight in rolling themselves among the flasks and leaves, which they hence frequently deftly.

9. V. crispa. Curled Valerian. "Fl. Peruv. v. l. 41." Vahl n. 8.—"Lower leaves ovate-oblong, with tooth-like ferratures; the rest somewhat pinnate, with ferrated undulated leaflets."—Native of meadows, fields, and cultivated ground, in Chili. Root with many small fibres. Stem two feet high, branched, brittle, frigate, hollow. Leaves stalked; those of the stem more or less perfectly pinnate; their leaflets sessile, reflexed, wavy and crisp, gradually smaller downward; the odd one very large. Clusters forked. Vahl.

10. V. interrupta. Interrupted-leaved Valerian. "Fl. Peruv. v. l. 42. t. 67. f. a." Vahl n. 9.—"Radical leaves interruptedly pinnatifid; their longer segments also somewhat pinnatifid. Stem nearly leafless."—Found on the lofty mountains of Peru. Root perennial, thick, divided. Herb juicy and smooth. Leaves all radical, except a pinnatifid pair under the corymb, not much unlike those of Scorzonera lociniata. Stalks terminal, three together, each bearing a head of scifele flowers, with linear bracteas to each. Corolla white, five-cleft. Vahl.

11. V. lyrata. Lyrate Valerian. Vahl n. 10.—"Radical leaves lyrate; segments oblong, with tooth-like ferratures; the terminal one somewhat pinnatifid; those of the stem leaves linear-lanceolate."—Native of Peru; seen by Vahl in Jussieu's herbarium. Stem smooth, a spain high, bearing two leaves. Radical leaves stalked, half the length of the stem; their terminal lobes very large, measuring two inches; lateral ones alternate; deeply and bluntly ferrated; leaflets sessile, half an inch long; all smooth. Partial flower-flaks racemose, three-cleft, forked. The aspect of the plant is like V. calcitrapa. Vahl.

15. V. polyficala. Many-spikeled Valerian. Sm. Pl. 1c. t. 51. Willd. n. 19. Vahl n. 14.—Leaves pinnate; leaflets deciduous, nearly entire. Spike compound, whorled.—Gathered by Commeron, in watery situations at Buenos Ayres. Stem two feet high at leaf, ascending, frigate, smooth, leafy. Leaflets smooth, nearly uniform, about an inch and half long; the odd one now and then slightly toothed; the lowermost much diminished. Flowers white, very numerous, in dense cypions whors, subtended by lanceolate
ceolate **bracteae**, and forming a compound spike, not unlike that of some *Menitza*. It is doubtful whether the seed has any feathery crown.

This plant having, till very lately, seen the next species, been generally taken for the famous *zoo*; or Valerian, of Dioscorides, has been universally employed in medicine, for the cure of nervous head-aches, hysterical and epileptic disorders. The mountain kind, being less acrid and more aromatic, is preferred for use, and is kept in all apothecaries' shops, in whole “compound of villainous smell” its flavour notably predominates.

17. *V. Dioscoridis*. Ancient Grecian Valerian. Sm. Fl. Græc. Sibth. v. 1. 24. t. 33. (ζωή; Dioec. book 1. chap. 10.)—Stamens three. Leaves all pair; leaflets of the lyrate radical ones ovate, with wavy teeth. Root tuberous.—Gathered by Dr. Sibthorp near the river Li-murys in Lycya, as we are informed by Mr. Hawkins, the learned companion of his tour. The profferor himself first, of all modern botanists, discovered this plant, and justly concluded it to be the real ζωή, for which our common wild Valerian has been always mistaken. The oblong tuberous perennial root has a much more pungent, peppery, more durable, and yet less nauseous, odor than the leaf described. The stem is hollow, simple, about two feet high. Herb feathery. Radical leaves numerous, lyrate, dilated with the ovate form, and wavy margin, of all their leaflets, of which the odd one is much the largest, and somewhat heart-shaped; those of the stem few, lanceolate, narrow, partly serrated. Flowers very like the last.

18. *V. italic A*. Italian Valerian. Lamarck Illufr. v. 1. 92. Vahl n. 16. (V. tuberosa; Imperato Hilt. Nat. 656; Bauh. Hilt. v. 3. part 2. 207. V. tuberosa Imperati; Tourn. Cor. 5. Barcel. le. t. 825. V. annanthes radice; Morif. fect. 7. t. 15. f. 4.)—Stamens four. Leaves all pair; leaflets of the radical ones ovate, nearly uniform, sharply toothed. Root tuberous.—Gathered by Imperato on the mountains of Liguria. We have only his figure, which all authors have copied, to guide us; except Vahl’s description, made from a specimen in Jussieu’s collection.

This appears very nearly the same with our *V. Dioscoridis*, especially the root, which is said to smell like Nard. The leaves however are represented as much more strongly toothed, more equally pair, and not lyrate; the upper pair indeed have narrow entire leaflets, refembling our last. The flowers are white, more densely corymbose, and afforded by Lamarck to have four *flamens*, which, if correct, and con-

**VALERIANA.**

19. *V. fysymbriafole*. Water-cresf-leaved Valerian. Vahl n. 17. (V. orientalis, fysymbri Matthioli folio; Tourn. Cor. 6.)—“Leaves all pair; leaflets roundish-ovate, entire.”—Native of the Levant; examined in Juffieu’s herbarium by Vahl, who declares it, contrary to Buxbaum’s opinion, to be totally distinct from *V. dioica*. The plant resembles *Symbrium Naifurrium*. Stem from six to twelve inches high, finely fingered, smooth, as well as our other part. Leaves stalked, pair, of two or three pair of leaflets; the innermost of which are small, alternate, and somewhat fingered; the outer fingered and opposite; the odd one an inch long, ovate or roundish, very blunt, obscurely ribbed; sometimes the top leaves are ternate only. Flowers in a dense, level-topped, nearly simple corymb, resembling those of *V. officinalis*. Bracteae linear, shorter than the flower. *Stamens* three. *Style* three-cleft. This appears, by the above description of Vahl, to be likewise related to *V. Dioecorus*. We have seen neither specimen nor figure.

20. *V. capensis*. Cape Valerian. Thub. Prodr. 71. Willd. n. 5. Vahl n. 18.—“Leaves pair; leaflets ovate, toothed. Stem hairy at the joints.”—Found by Thunberg at the Cape of Good Hope. The stem is said to be furrowed; smooth, except the joints. Corymba forked.

22. *V. decussata*. Cross-branched Valerian. “Fl. Peruv. v. 1. 42. t. 70. f. b.” Vahl n. 20.—“Leaves pair; leaflets lanceolate, finely toothed; hoary and downy beneath. Branches of the panicle forked and diversified.”—Gathered about hedges, and rocky places, in Peru. Stem herbaceous, though somewhat climbing, three feet high, frigated, hollow, a little downy. Leaves on short stalks; leaflets gradually larger downwards, daintily and minutely toothed; downy above; more densely so beneath. Panicule very large, with horizontal partial flower-flalks. **Bractea** under each division linear. Corolla minute, white. Seed crowned with ten or twelve rays. *Vahl.*

24. *V. Fangisforbofia*. Burnet-leaved Valerian. Cavan. Le. v. 5. 34. t. 456. Vahl n. 22.—Leaves pair; leaflets ovate, toothed. Corymba compound. Stem hairy at the joints.—Native of the Cordilleras of Chili, flowering in January. The stem is about a foot high, ascending, leafy. Radical leaves stalked, of about six pair of small,
Valeriana.

25. *V. virgata*. Many-twig’d Valerian. "Fl. Peruv. v. 1. 42. t. 66. f. b." Vahl n. 23.—Leaves pinnate; leaflets cloven or three-leaf, with linear segments. Branches of the corymb forked.—Native of precipices in Peru. Smooth, with the habit of *Tagetes minuta*. Stem rather shrubby, three feet high, much branched, square, fricated, scarcely hollow, obscurely downy; the branches upright and wand-like. *Leaves* minute; some undivided; others with two, three, or four, linear, emarginate or entire, segments; thinning on the upper side. Partial *flower-flanks* forked, with opposite linear *bracteas*. *Flowers* feffile in the forks. Seeds fricated on one side, gibbous on the other. *Vahl*.

26. *V. montana*. Mountain Valerian. Linn. Sp. Pl. 45. Willd. n. 9. Vahl n. 24. Ait. n. 8. Jacq. Auct. t. 269. (V. alpina, scrophulariae folio; Bauh. Prodr. 87.)—Leaves ovate-oblong, simple, unequally toothed; the lower ones flaked; upper pointed. Stem fimple, rather downy. —Not very uncommon in ftony ground, on the alps of Switzerland, the Grifens, Germany, and the Pyrenees, flowering in July and August. The root is long, creeping, perennial, with a flight degree of the flavour belonging to this genus. *Stems* a foot high, more or less, ascending, leafy, unbranched. Radical *leaves* on long flanks, heart-shaped or spatulate, acute, smooth, an inch or two in length, with various broad, shallow, wavy teeth; the rest more oblong and pointed, on short flanks. *Flowers* numerous, corymbose, small, pale fleshy-coloured.

27. *V. intermedia*. Ambiguous Valerian. Vahl n. 25. —"Leaves fimple, nearly entire; the lowermost oblong-heart-shaped; uppermost lanceolate; three pair on the stem." —Brought from the Pyrenees by Mr. Hornemann. Akin to the laft, though the *leaves* being not heart-shaped, nor toothed, as in that, but lanceolate and entire, induced professor Vahl to except it from the last.

28. *V. tripteris*. Three-leaved Valerian. Linn. Sp. Pl. 45. Willd. n. 8. Vahl n. 26. Ait. n. 7. Jacq. Auct. t. 268. (V. alpina prima; Bauh. Prodr. 86. V. alpina faxatilis minor, folio albo; Barcel. t. 1. t. 742. V. alpina miior, et minima; Pluk. Phyt. t. 234. f. 7. 8.)—Leaves toothed; the radicals one heart-shaped, simple; thefe of the stem ternate, ovate-oblong; their lateral leaflets lanceolate. —Found on the alps of Austria and Switzerland, intermixed with *V. montana*, but flowering a little earlier, and the *flowers* are more generally white. Nevertheless, thefe two species are fo very nearly akin, that we could almofit fuppeft them to be varieties of each other, and that Vahl’s *intermedia* may belong to one and the fame species.

29. *V. villosa*. Downy Valerian. Thunb. Jap. 32. t. 6. Willd. n. 18. Vahl n. 27.—Stamens four. Corolla equal. Leaves densely downy; the radical ones auricled; floral ones toothed. —Native of various places in Japan, flowering in September and October. The root appears to be perennial. Whole herb densely downy or hairy, a fpan high, unbranched. *Leaves* all toothed; the radicals one flaked, oval, near two inches long, with a pair of much smaller confluent auricles. *Panicle* corymbose, forked. *Flowers* yellow. Willdenow refers this species, like *V. flbrica*, to the *Fed~a*, but Vahl makes it a *Valeriana*. Having feen no fpecimen, we are unable to form a decided opinion, the fruit root having been noticed by Thunberg, whose figure and defcription are our only authority.

30. *V. pyrenaica*. Heart-leaved Valerian. Linn. Sp. Pl. 46. Willd. n. 14. Vahl n. 28. Don. Herb. Brit. falc. 4. 77. Sm. Compend. ed. 2. 8. Engl. Bot. 1. 1591. (V. maxima, caerule folio; Pluk. Phyt. t. 232. f. 1. V. canadensis; Rivin. Monop. Irr. t. 4.)—Stem leaves heart-shaped, ferrated, all flaked; the upper ones pinnate or ternate.—Native of the Pyrenees, and of Scotland; having been found by the late Mr. George Don, about ditches and walls at Blair-Adam, Kinroifhire, and fubfequently near Glasgow and Edinburgh, flowering in June. Dr. Brown of Glasgow has also met with this plant in feveral woods of the froth of Scotland, widely feparated from each other. It is perennial, from three to five feet high, of a ftony habit, and dark green hue, nearly smooth, poifoning the smell, probably the *Valeriana officinalis*, *Dioscorides*, &c. Stem downy about the summit, as are the upper *flower-flanks* all over. *Leaves* large, with copious, unequal, tooth-like ferratures; the radical ones, sometimes the others, fimple; but for the moft part the *flames* bear one or two pair of small lanceolate *leaflets* on their flanks. *Flowers* rofe-coloured, in a feafe, large, compound, terminal *corymb*. *Spur* obfolete. *Stamens* three.

31. *V. alliarifolia*. Garlick-mustard-leaved Valerian. Vahl n. 29. (V. orientalis, alliafio flio, folio albo; Tourn. Cor. 6. Buxb. Cent. 2. 19. t. 11.)—Leaves heart-shaped, unequally toothed, all fimple; the upper ones fefile. —Gathered by Tournefort in Capadocia. Diftinifhed from the laft, with which Linneus confounded it, by being perfectly smooth, with thinner *leaves*; besides what is expreffed in the specific definition. Vahl examined Tournefort’s original fpecimens. The *flowers* are white.

32. *V. lapathifolia*. Dock-leaved Valerian. Vahl n. 30. —"Leaves heart-shaped-ovate, undivided, nearly entire; the upper ones fefile." —Gathered by Commeron, in the *fruits* of Magellan. *Root* perennial. *Stem* a foot or more in height, as thick as a goose-quill, ifrated, smooth. Leaves three inches long, gradually smaller upward, acute, entire, or fometimes slightly crenate, ribbed, obscurely veined, smooth, except the upper side of the ribs; thofe at the root, and lower part of the *flent*, flaked; upper pair fefile; lowest ferial leaves linear, obtufe, fringed at the fide. *Flower-flanks* corymbose; the axillary ones opposite, of few flowers; terminal ones three-forked, many-flowered. *Stamens* three. Vahl. We fud no fpecimen of this species among the large communications of M. Thounin to the younger Linneaus.

33. *V. carnosa*. Feffhy-leaved Valerian. Sm. Plant. 1. c. t. 52. Willd. n. 22. Vahl n. 31. (V. magellanicas; Lamarr. Illlfr. v. 1. 63.)—Leaves oval, toothed, fleshy, glaucous; the radical ones on long flanks.—Gathered by Commeron, in the *fruits* of Magellan. *Stems* about a foot high, erect, fimple, smooth. *Leaves* all, according to Commeron, thick, fucculent and glaucous; radical ones fubfite, an inch or inch and half long, with broad unequal teeth; tapering at the bafe, into a *footflank* twice or thrice their own length; *flent-leaves* about three pair, much fmalier, nearly fefile. *Flowers* purple, nearly regular, triandrous, in small, dense, level-topped *corymb*. Seed crowned with teeth, rather than with feafhery down; so far at leaft as we can judge from our fpecimens. It is not imposfible that this species may be a *Fed~a*, as Willdenow makes it; though the *fed~* and that of *Fed~a* (or Valeriana) *Cornucopia* reemines true Valerianas. Indeed our *carnosa* and *poliflachy* appear to form, through *V. Cornucopia*, the connecting links of these two genera.

34. *V. tuberosa*. Tuberous-rooted Valerian. Linn. Sp. Pl. 46. Willd. n. 11. Vahl n. 32. Ait. n. 10. (Nardini...
VALERIANA.

36. V. elongata. Long-clawed Valeriana. Linn. Sp. Pl. 1664. Willd. n. 13. Vahl n. 34. Jacq. Enum. 205. t. 1. Aufr. t. 219. (Nardo celtica simili alia, five Valeriana alpina minor; Linn. Am. Acad. v. 1. 155.).—Radical leaves ovate, ovate; those of the stem, fimple, ovate, somewhat heart-shaped, broad, toothed, and cut. |Panicule loose, elongated.—Native of the Austrian mountains of Carinthia, and one found by Scopoli in Carniola. This is one of the rarest alpine plants, and appears never to have been seen by Vahl. It is perennial, flowering in June and July. Stem from four to six inches high, simple, leafy, smooth like the rest of the herb. Leaves from an inch to an inch and half long, mostly ovate; the upper pair small, narrow, and jagged. Flowers small, pale yellow, with a tawny tinge, forming a lax, racemose, forked, compound Panicle; about two inches long. We have not seen the crown of the seed, nor does any author describe it.

37. V. supina. Dwarf Valeriana. Linn. Mant. 27. Willd. n. 17. Vahl n. 35. Ard. Spec. fasc. 2. 13. t. 3. Wulf. in Jacq. Misc. v. 2. 114. t. 17. f. 2.—Leaves simple, spathulate, entire, fringed; the uppermost lanceolate. Found about the boggy fandy margins of mountain rills, on the alpine heights of Austria, Carinthia, and the Tyrol, near the limits of perpetual snow. The creeping perennial roots throw out many trailing feyns, and are crowned with severa dense tufts of stalked, obvate, bright-green leaves, smooth on both sides, finely fringed with short hairs. Stems two or three inches high, more or less leafy, corymbose at the top. Bracteas long, lanceolate, acute, fringed. Flowers of a delicate rose-colour. Stamens occasionally four. Seed-crown long and feathery.

38. V. faxatilis. Rock Valeriana. Linn. Sp. Pl. 46. Willd. n. 12. Vahl n. 36. Ait. n. 11. Jacq. Aufr. t. 267. (V. sylvestris alpina alcea faxatilis; Clof. Hilt. v. 2. 56. V. alpina angustiiola; Ger. Em. 1077.).—Leaves simple, undivided; radical ones elliptical, three-ribbed, rather hairy, entire, or slightly toothed; those of the stem linear. Corymbs racemose.—Native of the Alps of Styria, Italy, and Austria, but rarely in the latter country, as we are informed by professor Jacquin, jun. to whom we are indebted for specimens. The root is perennial, crowned with fibrous remains of old leaf-flakes. Stem a span high, slender, smooth. Radical leaves on long stalks, erect, an inch and half or two inches long, obtuse, almost perfectly entire, a little hairy occasionally; tapering at the base; those on the stem long and narrow, stalked, sometimes a little jagged, scarcely more than one pair, about half way up the stem, except the still narrower and smaller bracteas at the base of the inflorescence. Flowers few, white, corymbose, each little tuft supported by a very long slender stalk. Jacquin affirms them to be dioecious. He gives no account of the structure of the seed-crown, nor do we find that part any where described.

39. V. Salicaria. Italian Nard Valerian. Allianz. Pedem. v. 1. 3. t. 70. f. 1. Vahl n. 37. (Salicaria neapolitana; Dackeh. Hilt. 982. Nardus ex Apulia; Bauh. Pin. 165.).—Leaves linear-narrowed, entire or partly toothed, rather fleshy, quite smooth. Flowers in a dense round tuft.—Native of the mountains of Italy and Dauphiny. The root is cylindrical, woody and perennial, branched at the top, and crowned with many tufts of oblong-lanceolate, or spathulate, stalked leaves, more or less obtuse, of a much thicker texture than the leaf, an inch and half long. Stems solitary, two or three inches high, bearing about the middle a pair of combined smaller leaves, occasionally jagged or pinnaflid at the base. Sometimes there is a similar pair lower down. The flowers are crowded into a rounded head, sometimes accompanied with two small corymbose branches just below, and subtended by two or four oblong entire bracteas, as well as intermixed with smaller ones, all slightly fringed. Stamens three. Seed frilled, with a feathery bracteas. The herb is smooth in every part, except the bracteas, and very strongly scented.

40. V. celtica. Celtic Nard Valerian. Linn. Sp. Pl. 46. Willd. n. 10. Vahl n. 38. Ait. n. 9. Jacq. Coll. v. 1. 24. t. 1. (V. n. 209; Hall. Hilt. v. 1. 91. Nardus celta; Ger. Em. 1799. Spica celta; Camer. Epit. 14.).—Leaves oblong, obtuse, entire, rather fleshy, quite smooth. Flowers racemose; partial flacks capitate.—Native of the Alps of Austria, Switzerland, &c. Root oblong, creeping, ficy, with a very powerful and oppfensive peppery smell. Herb of the stature of the leaf, with fleshy, smooth, but always entire, leaves. Inflorumence widely different, so that these species can never be confounded by those who have seen in them flower. The cluster of the preffent is about two inches long, lax; each branch, whether fimple or forked, terminating in a little bracteas head, of three or four fefile yellowish flowers, with three flaments. The seed has a feathery crown, and is sometimes covered with dense hairs.
of Peru. The habit of this species is like Polygonum Perfoliata. Stems several, much branched, with a grey bark; branches ascending, straight, jointed, somewhat theaded, hollow; marked when young with two downy lines, alternately crooking each other, of a dark tawny colour, fibrated. Leaves tapering and fringed at the base, but otherwise smooth. Common flower-transverse; petals vary, in size and shape. Lower petals ovate, oblong, acute, smooth, fringed, with a rather pungent point; lying over one another in an imbricated manner, the innermost being gradually smaller. Flower-flakes, if any, very short, in the centre of the leaves, compressed, white, tapering at the base. Flowers with a general, as well as partial, involucrum, each of one leaf, sheathing, divided. Calyx a very minute border. Stigma cleft. Seed naked. Vahl.

48. V. tenuifolia. Taper-leaved Valerian. "Fl. Peruv. v. t. 39. t. 65. f. d." Vahl n. 46. — Stem none. Leaves linear-awl shaped, aggregate, sessile, imbricated, spreading; the outermost very long. Native of the mountains of Peru. Root perennial, spindle-shaped. Radical leaves numerous, unequal, spreading in the manner of a star, entire, velvety, smooth and shining, with a rather rigid point; dilated and membranous at the base; ciliate in their lower part. In other respects this species agrees with the last, both being widely different in habit from the rest of the genus. Vahl.

VALERIANA, in Gardening, contains plants of the hardy, herbaceous, perennial kind, among which the species cultivated are, the common or broad-leaved red valerian (V. rubra); the narrow-leaved red valerian (V. angustifolia); the cut-leaved valerian (V. calcitrapa); the garden or white Allatian valerian (V. phu); the three-leaved valerian (V. tripeteris); the mountain valerian (V. montana); the Celtic valerian (V. celtica); the tuberos root valerian (V. tuberoa); the Pyrenean valerian (V. pyrenaica); the officinal valerian (V. officinalis); and the common corn-fallad, or lamb's lettuce (V. olitoria).

The first sort differs in some degree in the colour of its flowers; they being in some plants of a deep red, in others of a pale red, a bright red, and there are others which have white flowers. The second sort has bright red flowers, smaller than those of the former. The third is an annual plant, which has the flowers shaped like those of the fourth sort, but smaller, and tinged with flesh-colour at the top; and it varies with the lower leaves pinnatifid. The fourth sort has the branches terminated by bunches of small white flowers, the odour of which is very agreeable. The fifth has the flowers numerous, white, and in loose bunches. In the sixth sort the stem is upright, simple, a foot or eighteen inches high, with the flowers of a whitish or purplish colour, in a bunch. The seventh sort has the stem flatter, simple, and terminated by a few small white flowers in a bunch. The eighth sort is easily distinguished by its tuberous roots; and there is a variety with the roots in the form of an olive. The ninth sort has the stem and branches terminated by umbels of pale flesh-coloured flowers, with very short spurs. The tenth sort has the stalks two feet high, all of which and the branches are terminated with umbellate clusters of flowers tinged with purple. The last sort has the flowers very small, of a pale blue or purple colour, and collected into a close little bunch. It is used in salads in the spring and winter, under the name of corn-fallad, or lamb's lettuce.

There is a variety which is smaller, with jagged leaves; the size of the leaves also differ much, being in some narrow, and in others broad, and likewise in the shape; but they are all used indifferently as fallad herbs while young.

Method of Culture.—The two first sorts may be increased by parting the roots, and planting them out in the autumn or spring, where they are to grow. They may also be raised from seed sown at the same times, in the situations where the plants are to grow. The third may likewise be raised from seeds, by sowing them as above, without any trouble. The fourth may be increased by parting the roots, and planting them out in the autumn, on fresh ground where they are to grow. The fifth may be raised.
VALEIRIANA.

The powdered root, infusied in water, or digested in rectified spirit, impregnates both meniftra strongly with its fnell and taste, and tinges the former of a dark brown, and the latter of a brownish-red colour. Water distilled from it fnells considerably of the root, but no effential is separable; the extract obtained by infifipating the water, exfufion, which is about one-fourth the weight of the root, has a pretty strong taste, difagreably sweetish, and somewhat bitterish; the ipirituous extract, which is about one-eight the weight of the root, is difagreable, and more perfctly resembles the root itself.

Tinctures of it are prepared in the shops, by digifting four ounces of the powdered valerian in a quart of ipirit, in the fame quantity of the volatile aromatic spirit, or of the dulled spirit of fal ammoniac. The root in fubstance, however, is generally found to be more effecual than any preparation of it: and its fame may be laid to be confined with wace. Lewis and Woodville.

VALEIRIANELLA, in Botany, the diminutive of VALEIRIANA, fee that article and FEDA.

VALEIRIANO BOLZANI, Pietro, in Biography, was born at Belluno, in 1477, in fuch a low condition, that he had no opportunity of acquiring the firft elements of literature till he attained the age of fifteen years. After having been reduced to the neceffity of entering into the fervice of a noble perfon at Venice for fupport, he devoted himfelf to study under eminent teachers; and agreeably to the practice of the age in which he lived, changed his baptismal name of Giampietro for Pietro. In his 23d year he engaged in the study of philofophy at Padua, and pafled three years in a retreat at mount Olivet, in the Veronef. Upon his return to his native place, he found it poifoned by the imperial army
army in 1509, so that he was obliged to make his escape to Rome. Here he fortunately became known to cardinal Giovanni de Medici, by whom, when pope Leo X., he was honourably provided for in his court. At the termination of this pontificate, he passed some time at Naples; but upon the accession of Clement VII. he returned to Rome, and was promoted to the chair of eloquence, with the title of prothonotary and private chamberlain, to which was added a canonry, and some other benefice in Belluno. Having employed himself in Latin poetry, he reinstituted the composition of elegies and amatory pieces, by which he had acquired reputation, upon taking holy orders. To him Leo X. committed the instruction of his two nephews, Ippolito and Alessandro de Medici, and he accompanied them to Florence, where he resided in the year 1527, when they were expelled from that city. After sharing their misfortunes, he attended them to Florence in 1530. Upon their death, he withdrew first to Belluno, and then to Padua, where he closed his life in 1558, at the age of eighty-one years.

The work by which he is principally known, is his treatise "De Infelicitate Literatorum," first printed at Venice in 1620, and often reprinted. Another of his publications was entitled "Hieroglyphica, live de facris Aegyptiorum alias ubique Gentium literis Commentariorum," Lib. LVII.;" Bafil, 1566. Some of his other performances were, "De Fulminum Significationibus," Rome, 1517; "Pro Sacerdotum Barbis defenso," 1531; "Calligations Virgiliane Lecture," first printed in R. Stephens's edition of Virgil, Paris, 1532, and since annexed to various other editions; and "Antiquitates Belunenses." He also published two volumes of his Latin poems. Moreri. Tiraboschi. Gen. Biog.

VALENIUS FLACCUS. See Flaccus.

VALENIUS MAXIMUS, a writer whole history is little known. The work which has been ascribed to him, and entitled "De Dictis et Factis Memorabilibus Antiquorum, Lib. IX." appears to have been written in the reign of Tibcrinus, probably after the death of Scjanus, and dedicated with high eulogy to Tibcrinus. It is cited by Pliny the elder, Plutarch, and A. Gellius; and it was much read and quoted at the revival of literature in Europe. One of the early editions, which were numerous, is supposed to have been prior to 1460; of the later editions, the most esteemed are the "Variorum," Lugd.-Bat. 1670; the "Delphin," Paris, 1679; "Torrensi," Lugd.-Bat. 1726; and "Kappii," Lipf. 1782.

VALENIUS POPPLICOLA, PUBLIUS, an eminent Roman, and one of the founders of the republican government, distingulished by his simplicity, eloquence, and liberality. In a contention about the confulate, at the expulsion of the Tarquinian family, he was elected to supply the place of Collatius, who was removed from office, and lived on terms of the utmost harmony with his colleague, the celebrated Junius Brutus. In the subsequent battle with the allies of Tarquin, in which Brutus was slain, Valerius gained a victory, for which he obtained a triumph, B.C. 507. Delaying the election of a new conful, and having built a house on the Palatine hill, that overlooked the forum, he excited the fulpicion of the people; but as soon as he understood the ground of their jealousy, he ordered the house to be levelled in the night, and gave orders for supplying the vacancy in the con- fulate. The father of Lucretia was chosen, but by his death soon after his election, Valerius was again the sole chief magistrate. In the exercit of his office he enacted several laws, abridging the confular authority, and meliorating the condition of the people; and hence obtained the name of Poplicola, or the people's friend. As a proof of his inte-

VALENIUS, Lucas, an eminent mathematician, acquired great celebrity at Rome as professor of geometry, and was honoured by Galileo with the appellation of the Archimedes of his time. He died in this city in 1618. He profecuted the discovery of the centres of gravity of solids, and shewed how to determine them in all the conoids and spheroids, and their respective forms formed by planes parallel to the bases.

The refult of his investigation was published in 1604, in a work entitled "De Centro Gravitationis Solidorum." He also proposed a quadrature of the parabola different from that of Archimedes. His method was published in 1666, and annexed to the fore-mentioned treatise. Montucla.

VALES, or Royal Bonds, in Commerce, are a kind of paper currency, which was first issued by the Spanish government in the year 1800, for the following sums:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>600 dollars</td>
<td>= 9235 reals 10 maravedis vellon</td>
</tr>
<tr>
<td>300 ditto</td>
<td>= 4517 ditto 22 ditto</td>
</tr>
<tr>
<td>150 ditto</td>
<td>= 2258 ditto 28 ditto</td>
</tr>
</tbody>
</table>

These bonds are transferrable only by indorsement: they bear an interest of 4 per cent. per annum, and were made a legal tender for their full amount, with any interest that might be due upon them; but, from various caufes, they have experienced a considerable depreciation. Kelly's Un. Cambift.

VALESIANS, VALESIUS, in Ecclesiological History, ancient fectaries, so called from one Valēsius, a peron un-known to Epiphanius, who, however, makes mention of this feet, Hær. 58. though he owns he knew but very little of them; only this, that they admitted none into their society but eunuchs; at last, if any were admitted before castration, they obliged them not to eat any meat till the operation was performed. For then, being no longer subject to the motions of the flesh, they allowed them to eat any kind of meats. Whilton says of them, that they sprung up about the year 240, and that they rejected the law and the prophets.

VALESIUS, in Biography. See Valois.

VALESTRA, in Geography, a town of Italy, in the department of the Panaro; 12 miles S.W. of Modena.

VALET, or VALECT, a French term, anciently written varlet.
In France, valet is a common name for all domestic servants employed in the lower and more servile offices; including what we call groom, footmen, coachmen, bailiffs, &c. But the word is not used among us in this sense, nor any otherwise than in the phrase valet de chambre; which is a servant, whose office is to dress and undress his master, to look to his bed-chamber, wait on him at table, &c. the same with what we otherwise call his gentleman.

In the History of Lewis XII. by Seifel, we always find valet de chambre du roi, valet de la gard-robe, &c. But valetes, like known, and divers other words, is now degenerated into a term of reproach.

Valet, valett, vaulet, and valet, Camden observes, were ancienly used at our court for a gentleman of the privy-chamber.

Selden, in his Titles, relates, that valets anciently signified young gentlemen, and heirs of great estate and quality; especially such as were to be knighted.

In the accounts of the Inner Temple, valet is used for a benchers clerk, or servant. The butlers of the house still call them varlets.

Valet, in the Manges, a flieck armed at one end with a blunted point of iron, to prick and aid a leaping horse.

Formerly, a valet was called aiguillon, i.e. goad, and some of them had four-rows upon them, only the points beaten down; and when a horse was first begun round a pillar, without a rider, they used to prick his flanks with the valet, to make him know the spur, and obey it, without resisting. At present the valet is not used for that purpose, and the name of goad is suppressed, as being only proper for oxen.

VALETTA, or CITTA Nuova, in Geography, a city of Malta, and capital of the island, which, in the year 1566, was built by the grand-master Frederic John de Valette, on a hill, in form like a neck of land extending itself into the sea, and was called by his name. Its walls are of large square stones, dug out of the rock, and planted with several batteries. On the point towards the sea stands the castle of St. Elmo, a fortres which defends both the harbours; one of which, called Marfa Mafcletto, lies at the entrance from the sea to the right of the town, and incloses a small island, on which stands both a fort and a lazaretto. The other harbour, on the left side, is simply called Marfa, or The Great Harbour, being the largest, safest, and most commodious in this island, and having some bays. Its entrance, besides the castle of St. Elmo, is guarded by Fort Riccioli, which stands on the Punta del Orfa, to the left. The town of Valetta lies on its right, and on its left the towns Il Borgo, or Vittoriafia, and Senglea. In Valetta is a handsome palace, where the grand-master resides, and before it a spacious area for exercises. Each of the seven nations, or tongues of this order, has its peculiar hall. The principal church is dedicated to St. John the Baptist. The Jesuits had a college here; besides which are several convents and nunneries, a large hospital, and a building where Turkish slaves are kept. The number of the inhabitants is computed to be about 2000. See MALTA.

VALETUDINAR, VALETUDINARIUS, a term sometimes used by the writers on medicine, for a person of a weak, sickly constitution, who is very frequently out of order, &c.

Dr. Cheyne, by all means, directs the weakly, the fluxious, the sedentary, and the valetudinary, to a low, spare diet.

VALEUR des Notes, Fr.; Value of Notes, in Music. Besides the position of the notes on the staff, which fix the tone with respect to gravity and acuteness, they have all some peculiarity of figure, which marks their duration as to time, or comparative value as to length. In the ancient primitive time-table, in which all the notes are black or full, except the semibreve and minim, which are white and open, the shorthest notes then in use are the longest now, and all that are open. The breve, indeed, equal to two semibreves, is still to be found in church-music of some antiquity, known by the titles alla breve, or à capella; but in all secular music, the semibreve is placed at the head of the other characters for time; and that note, divided into its aliquot parts, furnishes all the fractions in the most rapid compositions.

The dual measure, or common time, is governed by even numbers; as 2 minims, 4 crotchets, 8 quavers, 16 semiquavers, 32 demisemiquavers, all which only amount to a semibreve.

Triple time, or ternary measure, is governed by the number 3; as ; ; ; ; . In these numbers, the upper figure tells how many notes there are in each bar, and the under, of what kind in the time-table; as ; implies 3 minims, ; three crotchets, ; three quavers.

One-third is added to the value of a note by a point or dot: as a semibreve equal to two minims, by a point is equal to three; a minim equal to two crotchets, the point makes equal to three, &c. See Musical Characters, Time, and Plate Time-table.

It was to John de Muris, who flourished about the year 1330, that the characters for time in music were long ascribed; but on examining and collating MSS. in the several great libraries of Europe, it has been clearly proved that it was not John de Muris who invented the characters, as he himself owns in one of his tracts, but Magister Franco de Collign, author of a treatise "De Musica Menfurabilis," written in the eleventh century, long before De Muris was born; in which the form of the notes is given, and their relative value explained.

This very scarce treatise is preferred in the Bodleian library. 842, f. 40. See FRANCO and DE MURIS.

VALEY ISLAND, in Geography, a small island in the North sea, separated by a strait called Valet Sound, from the south-west coast of the island of Shetland. N. lat. 60° 15'. W. long. 1° 58'.

VALFROICOUR, a town of France, in the department of the Volges; 6 miles S. of Mirecourt.

VALGI. When the legs were deformed in such a manner that the feet were twisted outwards, the perons thus disfigured were termed valgi; while others, who were deformed by an inclination of their toes inward, received the appellation of vari.

VALGOM, in Geography, a town of the island of Ceylon; 6 miles N. of Candy.

VALGOREGE, a town of France, in the department of the Ardèche; 9 miles N.W. of Largentiere.

VALGRANA, a town of France, in the department of the Stura, 9 miles W. of Cont.

VALHERMOSA, a town of Portugal, in the province of Estremadura; 9 miles N.E. of Leyria.—Alsó, a town on the north-west of the island of Gomera.—Alsó, a town of Spain, in New Castle; 12 miles E.S.E. of Guadalajara.

VALI, in the mythological romances of the Hindoos, is a name given to a monkey, begotten by their god Indra, on
on a damsel of the semi-feral tribe, called Upbara. We
may just notice, that this warlike monkey was killed by
the Great Rama, the hero of the extraordinary poem Ramayana.

VALLAM, in Geography, a small Russian island, in the
Lake Ladoga; 92 miles N. of Petersburg.

VALLIANO, a town of Etruria; 10 miles S.S.W. of
Cortona.

VALID, a term applied to acts, transactions, expendi-
tions, &c. which are clothed in all the formalities requisite
to their being put into execution, and to their being ad-
mitted to a court of justice.

A contract by a minor is not valid, or is invalid: a mar-
rriage is not valid, unless performed with the solemnities
enjoined.

VALIERO, Agostino, in Biography, a celebrated pre-
late of the church of Rome and a voluminous writer, was
born of a noble family at Venice in 1531. Having studied
both at Venice and Padua, with a view to the ecclesiastical
profession, he graduated both in theology and canon law.
In 1558, having previously been employed in several public
offices, he became professor of moral philosophy at Venice,
which post he occupied till the year 1565, when he was elected
successor to his uncle as bishop of Verona, and he presided over
that fee for forty-one years. In 1583 he was created a cardinal
by Gregory XIII. Through the whole of his life, which terminated at Rome in 1606, in the 75th year of his age, he distinguished himself as the patron and promoter
of literature, as well as by his zeal, charity, and munificence.
The catalogue of his writings includes one hundred and
twenty-eight. Of those that were printed, many being in
MS., the most important are, "De Acolytorum Disciplina;" "De
Rhetorica Ecclesiastica;" "Epistolographia, seu de Op-
timo Episcopi formæ;" "Cardinalis, i.e. de Optima Cardi-
nalis formà;" "De recta philosophandi ratione;" "De
Cautione adhibras in edendis libris." That his sentiments
were liberal for the time in which he lived, appears from his
treatise designed to prove that comets are not prefigurations
of calamities, and from another against the barbarism of
the scholastics. He also wrote on the order and connection
of the sciences and arts, and a large work on the Venetian his-

VALIGA, a name given by some medical writers to an
infusion or tincture of jalap in spirit of wine, or spirit of
citron, with the addition of a little saffron.

VALIMONT, in Geography, a town of France, in the
department of the Moiselle; 8 miles N.W. of Morhange.

VALLINCOURT, John-Baptist du Troustet de, in
Biography, was born of a noble family at St. Quentin, in
Picardy, in 1653, educated at the Jesuits' college in Paris,
distinguished himself as a man of letters. In 1685 he
was appointed, by the count of Toulouf, admiral of France,
his secretary-general, and afterwards secretary of the marine;
but through life he cultivated polite literature, and became
a member of the French Academy in the room of Racine,
an honorary member of that of Sciences, and an associate of
the Academy della Caffica. He succeeded Racine as joint-
historiographer with Boileau; but his labours on the reign
of Louis XIV. were confounded with his library in 1725, a
loft which he bore with philosophical composure, observing
to one of his consofing friends, "I should little have profited
by my books, if I had not learned how to lose them." He
was an active promoter of literature and a protector of
learned men, who had always free access to his house; and
his character was distinguished by probity, sincerity and
good sense. He was held in such estimation, that Boileau
dedicated to him his satire on True and False Honour. His
time was so much occupied, that his writings are few; they
confult of a critique on the celebrated novel of "The Prince-
of Cleves;" "A Life of Francis Duke of Guise, surnamed
Le Balafre;" "Critical Observations on the Ædipus of
Sophocles," and a few poems. Such was his regard for
religion, that towards the close of life, he held several
conferences with ecclesiastics, for the purpose of terminating
the divisions of the church with respect to the bull Unigeni-
tus. He died at Paris, generally esteemed, in 1730, aged
fifty-seven years. Moreri.

VALINSAY, in Geography, a town on the W. coast of
the island of Loon. N. lat. 16° 18'. E. long. 120° 6'.

VALLIODA, a town of Hindooftan; 15 miles E.N.E. of
Travancore.

VALLJOVA, a town of European Turkey, in the pro-
vince of Servia; 50 miles N. of Jemibafar.

VALLISQUERVILLE, a town of France, in the depart-
ment of the Lower Seine; 6 miles N.N.W. of Cauderbec.

VALIZ. See BALIZE.

VARK, a town of Russia, in the government of Riga;
72 miles N.E. of Riga. N. lat. 57° 50'. E. long. 25° 44'.

VALKI, a town of Russia, in the government of Chark-
ow; 16 miles S.W. of Charkow. N. lat. 49° 36'. E.
long. 35° 44'.

VALKENBURG. See FAUQUEMONTE.

VALKOVAR, or Barkevar, or Valkö, a town of
Selovia, near the right bank of the Drave; 15 miles S.E.
of Ezececk.

VAL, or VALE, in Commerce, a weight for gold and
silver at Bombay and Surat. See TOLI.

VAL, in Geography, a town of Sweden, in Warmeland;
28 miles E.S.E. of Carlstadt.

VALLA, Giorgio, in Biography, a native of Piacenza,
and professor of polite literature in the university of Pavia
in 1471 and 1476, from which he removed to the chair of
eloquence at Venice in 1486. As he was one morning pre-
paring to go to his school, where he explained Cicero's
Tusculan Questions, and held daily disputations on the
immortality of the soul, he died suddenly at the close of
the 15th century. He was the author of many works, which
are for the most part collections and transcripts from ancient
writers, and translations from Greek authors, useful in that
age, but not distinguished by judgment or accuracy.

Bayle.

VALLA, Lorenzo, was probably a relation of the pre-
ceding Valla, and born at Rome, as it has been said, in the
year 1415, but as Tiraboschi says, before the year 1406.
He was educated in his native city, and continued there till
his twenty-fourth year. Having visited Piacenza to take
possession of the inheritance bequeathed to him by his rela-
tions, he settled at Pavia as professor of eloquence in the
university. Here he was chargable with some influences
of misconduct, so that he changed his abode several times,
till he became attached to Alphonso, king of Naples, in
which city he resided for some time; but in 1455, on the
return of pope Eugenius to Rome, he settled in that city.
Investi-
gating the pretended donation of Constantinople to the holy
feet, which he discredited, and reflecting on the characters
of several popes, he incurred the displeasure of Eugenius,
and found it necessary to withdraw first to Oltia, then to
Naples, and finally to Barcelona. From hence he ad-
ressed an apology to the pope, and a defence of his writings
on moral philosophy and dialectics, without any reference to
Constantine's donation. He afterwards returned to Naples
under the protection of Alphonso, and there opened a
school of eloquence, to which many scholars repaired; but
notwithstanding his popularity as a teacher, he was accused
and brought into danger on account of the freedom with
which
which he maintained his peculiar opinions. Of these, we may mention his rejection of the letter of Chrifi to Abgarus as a fiction, and his reproach of a celebrated preacher for asserting that each article in the apostles' creed was composed by one of them separately. For the latter of these offences he was brought before the Inquisition, and owed his escape from the interposition of Alphonfo, after a private flagellation in the cloister of monks. At length, he was invited to Rome by pope Nicholas V., who was distinguished by his patronage of literature; and in this metropolis he opened a school of eloquence, A.D. 1450. Here he entered into a dispute with George of Trebifond, secretary to the pope, on the respective merits of Cicero and Quintilian, to the latter of whom he gave a decided preference. His next conflict was with Poggio Bracilini, who attacked him in five invectives, to which Valla opposed as many antidotes, or dialogues, against Poggio. The manner in which this literary conflict was prosecuted was disgraceful to both parties, and has been severely condemned by Tiraboschi. Although Valla was much occupied with disputes of this kind, he pursued his studies, and by order of Nicholas V., undertook a version of the Greek of Thucydides into Latin, for which he received from the pope a recompense of 500 gold crowns, a canonry of St. John Lateran, and the place of apostolic scribe. For these favours on the part of the pope, Valla is charged with ingratitude. In the latter years of his life he visited King Alphonfo at Naples, who exhorted him to translate Herodotus, but his death prevented his finishing the proposed version; however, for the part which he completed he was liberally rewarded. This translation was concluded by another person, and dedicated to Pius II. Valla's death occurred in August, 1457. The character of Valla is thus sketched by one of his biographers. He was a man confident of his talents and acquirements, intolerant of other men's opinions, and free in his own, arrogant and contentious. His conduct was probably far from correct, though his enemies may have brought false and exaggerated charges against him. His philosophy was professedly Epicurean, placing the highest good in pleasure, which, however, he might explain in the least obnoxious sense. He was never married, but he confided in one of his answers to Poggio, that he took a young woman to live with him, by whom he had three children, and whose fidelity to himself he extols, adding, that he hoped to procure for her a husband; but concubinage was at that time very common among the scholars attached to the court of Rome. In the capacity of a reviser of letters he has always held a high rank, which he merited by unwearied application, and an enlarged course of study, comprehending history, criticism, dialectics, moral philosophy, and theology. That in the latter his notions were liberal, may be conjectured from some of the circumstances above related, and also from his notes on the New Testament, in which he was one of the first to consider the sense as a critic rather than as a divine, whence he was led to make many corrections in the received translations. He is however said to have been but moderately versed in the Greek language, and Huet speaks very disparagingly of his versions of Thucydides, Herodotus, and Homer's Iliad. Of his numerous writings, his 'Elegantiae Latinae Sermonum, containing the grammar of that tongue, and rules for composing in it, has been the most generally esteemed, and still retains its reputation: his own style, however, was defective in point of purity and elegance. He had has many eulogists among the learned, and has been particularly praised by Erasmus, as one of those who have most contributed to the revival of true learning." -- Tiraboschi. Gen. Biog.

VALLABREGUES, in Geography, a town of France, Vol. XXXVI.

VALLADOLID, a town of Spain, in the province of Leon, on a small river called Eiquava, near the Pifnera; the site of a bishop, and an university, founded in the year 1346. Several of the churches of Valladolid, those especially of the Dominicans and of San Benito, are elegant, agreeably to the Spanish taste, that is handloom, and full of altars richly gilt. Valladolid is not wholly without manufactures; some stuff and coarse cloths are made there from the wool of the sheep which are kept in the neighbourhood. There are also gold and silver-smiths; and one store is entirely inhabited by jewellers: this is very lively, and full of business, as are all the others, which terminate in the great square. An academy of the belles lettres was established here in the year 1752. Here was a palace, in which Philip II. was born, now reduced to bare walls; 84 miles N.N.W. of Madrid. N. lat. 41° 42'. W. long. 4° 47'

VALLADOLID, a town of South America, in the audience of Quito; 40 miles S. of Loza.—Alfo, a town of Mexico, in Yucatan. N. lat. 19° 50'. W. long. 68° 5'.

VALLADOLID, or Comapagua, a town of Mexico, in the province of Honduras; the site of a bishop, who takes the title of bishop of Honduras. N. lat. 14° 30'. W. long. 88° 19'.

VALLADOLID. See Mechoacan.

VALLAGAM, a town of Hindoostan, in Golconda; 21 miles S. of Combatem.

VALLAIS. See Valla.

VALLENCE, a town of France, in the department of the Gers; 4 miles S. of Condom.

VALLAR, Vallaris, formed from wallum, a flake with branches, of which they made the palisade of a camp, called lorica, in Antiquity, an epithet given to a kind of crown, which the Roman generals bestowed on him who, in attacking the enemy's camp, first broke in upon the line of palisades.

The corona vallaris was the name with what was otherwise called corona caesariana, from caesare, a camp. Aulus Gallius assures us, that it was of gold, as the mural and naval crowns also were: yet, though they were made of that precious metal, they were not the most valued; for Pliny, lib. xxxiii. cap. 3, gives the preference to the corona obductionis, which was yet only of gramin, or grats. See Crown.

VALLARIOS, in Geography, a town of Spain, in Aragon; 15 miles W. of Balbipro.

VALLARIS, in Botany, so called by Burmann, apparently from walla, to incline, because it serves in Java and Ambonza, to make bowers and fences, whose shade is very grateful in a tropical climate.—Burman, Ind. 51. Brown Tr. of Wern. Soc. vol. 1. 63.—Cliffs and order, Pentandria Manyporia. Nat. Ord. Conteria, Linn. Aponeare, Cliff.

Eff. Ch. Corolla salver-shaped; mouth and tube perivious, without scales; limb in five obtuse segments. Stamens prominent; filaments inserted into the throat, very short, with a fleshy tubercle externally, at the top; anthers arrow-shaped, adhering to the stigma. Germs of two cells; style thread-shaped; stigma conic-ovate. Scales at the base of the germs five, combined below, fringed at the points. Follicles . . . .

Obf. Mr. Brown remarks, that "this, the Flos Pergularis of Rumphius, was considered by Linnaeus as the first species of his genus Pergularia." It does not, however, belong to the same order with the plant that afforded his generic
neric character, and to which the name has been since generally applied. See Perigalaria.

1. V. Pergulanus. Sweet Bower-vine. Burm. Ind. 51. (Flores pergulanus; Rumph. Amboin. v. 6. book 7. 51. t. 29. f. 2.) Carack nachi of the Malays. Pergalaria glabra; Linn. Mant. 53. Willd. Sp. Pl. v. 1. 1247.)—This, the only known species, is a native of Java and Ambonya, used for bowers and trellis-work, as it makes a very thick shade. The Malay women are fond of adorning their hair with its fragrant flowers. The stem is perennial, shrubby and twining. Leaves opposite, stalked, ovate, acute, entire, thick and shining, five inches long, two and a half or three wide, with strong pale veins. When the leaves or twigs are wounded, they discharge a thick, viscid, yellow milk. Flower-stalks, from between the footstalks, forked, corymbose. Flowers white, and highly fragrant, compared by Rumphius to those of jasminum, (probably Jasminum Sambac,) but having a shorter tube, with five shining bodies in the middle. He speaks of the scent of these flowers as too strong for Europeans, though highly esteemed by the natives of the country where they grow.

Valle, Pietro Della, in Biography, a Roman patrician, who, in the year 1614, commenced his travels into Egypt, Turkey, Persia, and India. At Bagdat he fell in love with a young female of the Maronite sect of Christians, and married her. She accompanied him in his journey, and on his return towards Italy, she died near the Persian gulf. The loss so much affected him, that he had her remains embalmed, and carried them with him during his subsequent travels, and on his return to Rome, they were magnificently interred in the church of Ara Coeli; and he himself pronounced her funeral eulogy, which was printed. The account of his travels, written by himself in Italian, and contained in fifty-four letters, was published at Rome in 1650. They have been often cited as authority, though not deficient of marks of credulity, and still bear a respectable rank among books of travels. The style is pure and elegant, though the narration is prolix. Doni has spoken of him in terms of high commendation, and represents him as well acquainted with the Oriental languages, and with music. He wrote on other subjects besides his travels, and was a member of the Academy degli Umoristi. His second wife was a Georgian, attached to his first wife, and the companion of his travels.

Moreri.

For the opinion of this agreeable writer concerning the music of his own times, we refer to the article Opera, inserting here his account of the manner in which the first opera, or musical drama, was exhibited at Rome, which is extremely amusing and curious. "Though no more than five voices, or five instruments, were employed, the exact number which an ambulant cart could contain, yet this afforded great variety: as, besides the dialogue of single voices, sometimes two, or three, and, at last, all the five fung together, which had an admirable effect. The music of this piece, as may be seen in the copies of it that were afterwards printed, though dramatic, was not all in simple recitative, which would have been tiresome, but ornamented with beautiful palliages, and movements in measure, without deviating however from the true theatrical style; on which account it pleased extremely, as was manifest from the prodigious concourse of people it drew after it, who, so far from being tired, heard it performed five or six several times; there were some even who continued to follow our cart to ten or twelve different places where it flopped, and who never quitted us as long as we remained in the street, which was from four o'clock in the evening till after midnight."

This narration seems to furnish a curious circumstance to

the history of the stage, which is, that the first opera, or musical drama, performed in modern Rome, like the first tragedy in ancient Greece, was exhibited in a cart. It has been imagined by many of the learned, that the recitative in modern operas is a revival of that species of melos in which ancient dramas were sung; and here the moveable stage on which it was performed, like that used by Thespis at Athens, furnishes another resemblance.

"—Plautus versus, Poemata Thespis."—Hor.

Della Valle, after having proved that the singing of his time was better, and the compositions more varied, more rational, and amiable to poetry, than the more ancient, proceeds to speak of instrumental music; and after discriminating the different kinds of playing on an instrument, in a solo, in a full piece, in accompanying a voice, or leading a band; he says, he must agree with his friend, that solo playing, however exquisite and refined, at length tires; and that it had frequently happened to organists of the highest class, when loll and immered in carrying on a happy subject of voluntary, to be silenced by a bell; which never happened to fingers, who, when they leave off, diffuse the congregation or audience, to whom their performance seems always too short.

After discussing instrumental music, he comes to singing, and this he considers in solosongs, and in music of many parts. His friend, among the sopranos, or treble voices, of his youth, had greatly prized the falcelli, which used to sing in the pope's chapel, and elsewhere; and Della Valle says he remembered one of them, Gio. Luca Falletto, who had great execution, and went up to the clouds; and mentions Orozzietto, a very good finger, either in a sfallet or tenor; Ottavincello and Verovio, famous tenors, who all three sang in his cart. "However, he," he adds, "trills, graces, and a good partimento, or direction of voice, excepted, were extremely deficient in the other requisites of good singing; such as piano and forte, swelling and diminishing the voice by minute degrees, expression, afflicting the poet in fortifying the sense and passion of the words, rendering the tone of voice cheerful, pathetic, tender, bold, or gentle at pleasure; these, with other embellishments in which fingers of the present times excel, were never talked of even at Rome, till Emilio del Cavaliere, in his old age, gave a good specimen of them from the Florentine school, in his oratorio, at the Chiesa Nuova, at which I was myself, when very young, present."

What follows is extremely curious and satisfactory concerning a delicate point of musical history, which is, the first establishment of recitative in the pope's chapel, and the use of them in early operas.

It is astonishing how much sooner Della Valle got rid of the pedantry of the then old school, than any of his contemporaries. He manifests as much good taste in his reflections on imitative and dramatic music, as any writer of the last century.

Della Valle's biographers seem to have known nothing of the correspondence with Guidiccioni, or of his skill and good taste in music. This agreeable and intelligent traveller died in 1652, aged 66.

Valle, in Geography, a town of Norway, in the province of Christianland; 16 miles S.W. of Christianland.

—Allo, a town of Norway, in the province of Christianland; 44 miles N. of Christianland.—Allo, a town of Thrilis, and chief place of a district; 8 miles N. of Pola. N. lat. 45° 9'. E. long. 13° 57'.—Allo, a town of Italy, in the department of the Adda and Oglio; 8 miles N.N.E.
of Breno. — Alto, a town of Italy, in the department of the Gogna; 5 miles W. of Lumello. N. lat. 45° 8' E. long. 8° 40'.

Valle Calamuchita, a town of South America, in the province of Tucuman; 40 miles N.E. of St. Louis.

Valle Rayas, a town of the island of Corfica, in the district of La Porta.

Valle di Spagna, a town on the east coast of the island of Cephalonia.

Valle, in Botany, owes its name to Mutis, who sent the plant to Linnaeus. In the Supplementum it is said to commemorate a person named Valle, "praefato by Allioni." No one having vouchsafed to indicate where this praefer is bestowed, and De Theis having transferred the honour of the present genus, with true French patriotism, to one of his own countrymen, Robert Valle, of Rouen, who published, in 1746, some Commentaries upon Pliny, we have thought it necessary to inquire into the matter; especially as the genus is well worth claiming. In a note to Allioni's Rarioh Pedemontii Stirpiurn, Specimen primum, page 23, the mystery is unravelled, by a narrative, of which the following is the substance. Dr. Valle, a physician of Turin, a botanist of no common merit, after having attentively investigated the plants around that city, and those of the neighbouring alps, was led by an ardent love of botany, and other branches of natural history, to procure, in 1746, the appointment of physician to the army in Corfica, in order to examine the productions of that country. There he made ample collections of plants, seeds, flowers, insects, and other things worthy of notice. But being more anxious to acquire knowledge than to take care of himself, the heat of the climate threw him into a violent fever, which carried him off in three days. His dried he was Corfican plants, falling into the barbarous hands of ignorant people, were all destroyed. Whatever his friend Allioni could meet with, by the affection of the family, he purchased; and thus became possessed of numerous specimens, gathered by Dr. Valle, about Savona, as well as in various parts of the Alps, of which he had drawn up a description, after Tournefort's folium; but this was completed no further than the first four classes. The name of Valle therefore desires to be embalmed with those of Bartich, Borone, Lippi, and other premature martyrs to botany, who have justly been thought worthy of such an enduring memorial. — Linn. Suppl. 42. Sehreb. Gen. 363. Willd. Sp. Pl. v. 2. 1212. Jull: 434. Poiret in Lam. Dict. v. 8. 318. — Ch. Linn. Polyandria Monegynia. Nat. Ord. Tiliaceae. Jull: 666.

Gen. Ch. Cal. Perianth inferior, of one leaf, in four or five deep, ovate, flirated, coloured, deciduous segments. Cor. Petals four or five, white, obovate, three-cleft, rather larger than the calyx. Nectary a flattish, undulated, shining, coloured border, under the ceraon. Stam. Filaments numerous, 30—40, awl-shaped, flattened, coloured, incurved, shorter than the calyx, inserted into the receptacle, beneath the nectary; anthers linear, erect, with two pores at the summit. Ptil. Germen superior, ovate; style nearly cylindrical, as long as the calyx; stigma four or five slender divisions. Peric. Capsule with four or five angles and as many valves, each valve appropriated to two cells. Seeds several.

Eff. Ch. Calyx in four or five deep segments, inferior. Petals four or five, three-cleft. Stigmas four or five. Capsule with four or five valves, as many as cells, and several seeds.

1. V. filipulac. Linn. Suppl. 266. Willd. n. 1. — Native of the colder parts of New Granada. A tree, twelve feet high, with round, flirated, leafy, hairy branches. Leaves alternate, on hairy stalks an inch long, spreading, simple, heart-shaped, acute, entire, two or three inches long and half as broad, fingle-ribbed, beautifully reticulated with innumerable veins; smooth and shining above; paler, clothed with flabby tawny hairs, especially about the rib and larger veins, beneath. Stipulae rather large, leafy, kidney-shaped, entire, flirated, in pairs at the base of each footstalk, and clasping the stem above it. Flowers blood-red, near an inch in diameter, in forked, cymose, hairy, axillary, and terminal panicule, shorter than the leaves.— Linnaeus cites Mutis, Amer. v. '7. 10, by which botanists have been led to understand, that Mutis had published an important work on American plants, extending to seven volumes, at leaf. But in fact no such work exists. The reference is, in every point, erroneous, and alludes merely to a collection of thirty-two Indian ink drawings of Mexican plants, sent by that learned Spaniard, with numerous dried specimens, to Linnaeus. (See Mutis.) From his drawing of the Vallea, compared with the specimen, we have, as our readers may observe, ventured to correct some part of the generic characters. By that drawing the "colulbula" appears to have four valves, sometimes, it seems, varying to five, each of which has indented edges, besides a central partition; and these, all meeting at a central column, may easily be conceived to form a "capsule of eight or ten cells," explaining the strange expression in the Supplementum, of "biloculibicoloribus." Several circumstances indicate the affinity we have hinted above, of this genus, to Jussieu's Thiasae; see that article.

Vallefreda, in Geography, a town of Naples, in Lavora; 8 miles N.W. of News.

Vallelonga, a town of Italy, in Calabria Ultra; 18 miles E.N.E. of Nicolarea.

Valleoley, a town of France, in the department of the Indre; 21 miles N. of Chateaurolx. N. lat. 47° 10' E. long. 1° 38'.

Vallerauche, a town of France, in the department of the Gard; 6 miles N. of Le Vigan.

Valle, a town of France, in the department of the Indre and Loire; 12 miles W.S.W. of Tours.

Gen. Ch. Cal. Perianth inferior, small, of one leaf, in five acute segments. Cor. of one petal, funnel-shaped; tube much longer than the calyx, swelling upwards; limb flat, in five ovate, equal, spreading segments. Stam. Filaments five, very short, inserted into the upper part of the tube; anthers arrow-shaped, in the mouth of the corolla. Ptil. Germen superior, ovate, cloven; style thread-shaped, as long as the tube of the corolla; stigma obtuse. Peric. Drupes two, ovulate, obtuse, disarticulated, of one cell. Seed. Nut solitary, oval, woolly, fibrous, flattened, with a solitary kernel.

1. V. filipulac. Linn. Suppl. 266. Willd. n. 1. — Native of the colder parts of New Granada. A tree, twelve feet high, with round, flirated, leafy, hairy branches. Leaves alternate, on hairy stalks an inch long, spreading, simple,
lanceolate, acute, entire, smooth, thinning, single-ribbed, two or three inches long and one broad. *Parnices or cyrnus* small, forked, opposite to the leaves. *Flowers* small, white. *Fruit* whitish. *Poirier, after the Fl. Pers."

**VALLEY,** in Geography, a town of France, in the department of the Lower Loire; 12 miles E. of Nantes.

VALLEY, in Natural History and Geology, is a tract of ground bordered by hills or mountains on two opposite sides, between which it extends in a straight or waving line. If the valley be short, and the length is not much greater than the breadth, it is called an opening, or pafs, through a mountain or chain of mountains.

Large valleys have generally a number of small valleys joining them, like branches to a main trunk. In almost every valley there is either a lake or a river, and the magnitude of the river bears some proportion to the valley. The lower end of a valley, where the river empties itself into a larger river or lake, or into the sea, is generally much broader than its upper or higher end. Some valleys are nearly closed at each end, forming elliptical hollows in mountainous districts. Such valleys have once been lakes, but the water having worn itself a passage at the lower end, has reduced the lake to a small stream in the middle, or the lakes have been filled up by the debris from the adjoining mountains.

Sauflure divides valleys into two orders, which he calls *longitudinal valleys* and *transversal valleys.* Grand mountain chains are commonly formed of many ranges of mountains running parallel to the highest or central range, each range diminishing in height as its distance from the central range increases. It is between these parallel ranges that longitudinal valleys are situated. Sauflure cites the valley of the Rhone as a striking example of this kind of valley.

Transversal valleys are those openings which communicate between the longitudinal valleys, either at right angles with them, or obliquely. It is observed by Patrin, that the transversal valleys which cut through the central range of mountains, are sometimes nearly horizontal, at least for a short distance; but those which cut the collateral chains have always a more or less rapid descent; and as they are frequently excavations formed by water-courses, they sometimes present corresponding fan-like and retiring sides, like the valleys in secondary mountains; but it is evident that this effect is accidental.

One of the essential characters of longitudinal valleys is, that their direction is parallel with the line of bearing, or range of the beds of which the mountains are composed. Transversal valleys cut through the beds in the direction of their line of dip or inclination. See Plate II. Geology, fig. 2, in which the side of the mountain fronting a represents the beds of a mountain in their line of bearing; and a spectator placed at the flat a, may be supposed to be placed in a longitudinal valley, in which the edges of each bed in the opposite mountain would appear to range horizontally. The same appearance would present itself to the spectator placed at B, fig. 5. A transversal valley cutting through the beds at right angles to the former, would show the true dip or inclination of each bed to a spectator placed at B in the former fig. 2. The side E of the mountain represents the direction of a longitudinal valley, the side G, the direction of a transversal valley.

The Alps present many longitudinal valleys. The valleys in the Pyrenees are transversal. This difference has been supposed to arise from the central parts of the Pyrenees ascending more precipitously above the lower beds; hence the waters, falling with great impetuosity, have cut passages through the lower beds in direct lines, and taken the shortest course to the plains below.

In the Alps, the currents, being less violent, have followed the course of the longitudinal valleys, which had been traced out by nature in the original formation of those mountains.

Some mountain groups are disposed in forms nearly circular, so as to include great tracts of flat country, as is the case with Swabia, Hungary, Transylvania, &c. Those circular bays or valleys have formed lakes, when the relative level of the ocean was much higher than at present; and on inspecting the belt maps, where the inequalities of the surface are delineated, we may be led to suppose that a considerable part of Europe has once been covered by these lakes, the present mountain chains forming the boundaries.

The Rhone and the Rhine pass through several smaller circular valleys in their course; and the river Don, in Aberdeenshire, has its course through valleys of this kind. At the mouth of the Don, the rocks confine it to a narrow channel, and give it an aspect which would convey the idea of its flowing through a mountainous and rugged country, where no space was left for forming even a commodious road along its banks; but on ascending it for about one mile, the hills recede on either side to a great distance; then it closes again; and after another temporary confinement among rocks, hills, and woods, its waters once more open into another plain of great extent. Such is the general character of this river.

The Danube, whose history has been so well illustrated by the count de Marigli, has its source in the mountains of Swabia, from whence it passes through Swabia, Bavaria, Austria, Hungary, and Walachia, into the Black sea. Swabia is a great circular valley, from which the Danube escapes by a narrow opening into Bavaria: during its progress through Bavaria, it passes through several circular valleys into Lower Austria, which is also a circular valley. It flows through Austria, and at Presburg, where the valley is nearly shut up, it forces its way through rocks and hills into Hungary, which is one of the most extensive circular valleys in Europe. At the lower extremity of Hungary, the river is again forced to seek its way through a narrow rocky channel to Orfova, which is the only opening between Hungary and Walachia. It now continues its course through Walachia, and at length falls into the Black sea. We have a continuation of this chain of valleys, although filled with water, in the Black sea, the sea of Marmora, and the Mediterranean.

The valley of Cashmere presents one of the most striking examples of a circular basin or valley, containing a small lake, which has probably once filled a considerable part of the great cavity formed by the surrounding mountains. "This happy valley," says Mr. Pennant, "this Hindoostan paradise of the Indian poets, is of an oval form, about eighty miles long, and forty broad, and is supposed to have been once entirely filled with water, which having burst its mound, left the vale nourished to the most dilatant ages by the fertilizing mud of the river, which fed its expanse. This delicious spot is surrounded by mountains of vast height and rude aspect, covered with snow, and enchafted in glaciers, in which this enchanting jewel is firmly set."

The formation of valleys has been by some philosophers ascribed
When the elevation of parts of the earth's surface, and the subsidence of other parts, are also proved by the fractures and dislocations of the strata which mountainous districts almost everywhere present. There are likewise evident marks that the ocean has been thrown suddenly, and with great violence, over our present continents, tearing away and transporting to distant countries various parts of the surface, scooping out hollows in the softer strata, breaking down the boundaries of immense lakes, and thus changing the course of rivers, and opening new valleys where none before existed. Great and sudden risings of the sea have been known to take place in our times, by the agency of subterranean fire operating on a small extent of the globe; and we have only to conceive the fame agent operating more powerfully, to explain the changes which may have taken place from the ocean suddenly rising and sweeping over a large portion of the globe. See System of Geology.

The theory of the formation of valleys by the action of rivers has been supported by Dr. Hutton and professor Playfair. "Every river (says the latter) appears to consist of a main trunk, fed by a variety of branches, each running in a valley proportioned to its size, and all of them together forming a system of valleys communicating with one another, and having such a nice adjustment of the dérivatives, that none of them join the principal valley either in too high or too low a level, a circumstance which would be infinitely improbable, if each of these valleys was not the work of the stream that flows through it. When the usual form of a river is considered, the trunk divided into many branches, and these again subdivided into an infinity of smaller ramifications, it becomes strongly impressed upon the mind, that all these channels have been cut by the waters themselves, and that they have been slowly dug out by the washing and erosion of the land." This is an accurate description of the structure of many valleys, but there are others in which the smaller valleys do not join the larger at the same level, but terminate abruptly, and the rivers which flow through them fall in cascades to the lower valleys. The valley of Watten-lagh, in Cumberland, is a striking instance of this kind. The lower extremity joins the vale of Keswick, in which the lake of that name is situated, but it does not enter it at the same level, but terminates in a precipice between two cliffs, down which the water is thrown, forming the cataract of Lodore, which empties itself into the lake.

Where the corresponding strata on each side of a valley have nearly the same elevation as is represented in Plate III. Geology, fig. 4, it is obvious that the excavation between the opposite hills has been formed by water which has once flowed at a much higher level than at present. Also, where the strata on the opposite sides of a valley have the same angle of inclination with the horizon, (see Plate II. Geology, fig. 5;) we may infer that it has been excavated by water; but where the strata on the sides of a valley dip in an opposite direction, or have a much greater dip on one side than on the other, the original formation of the valley may be attributed to the elevation or subsidence of the strata, forming a fissure through which the water has run, and in the course of ages has worn down and enlarged the passage. Some circular valleys and lakes may have originated in the subsidence of the surface, forming a large cavity, the sides of which are gradually worn down in many parts into gentle slopes. An accurate examination of the true line of dip of the beds, can alone discover to which of these causes the formation of any particular valley can be ascribed; and it is frequently more difficult to ascertain the true angle of inclination than is generally supposed, and still more difficult to determine whether a slight variation in the angle is occasioned by a fracture, or by an original inequality or waving of a stratum.

That lakes are palling to the state of valleys, and that many of the present valleys have been lakes, is obvious to the most common observer who will attend to the appearances which they present. A lake, says professor Playfair, is but a temporary and accidental condition of a river, which is every day approaching its termination; and the truth of this is attested not only by the lakes that have existed, but by those which continue to exit. Where any confderable stream enters a lake, a flat meadow is usually observed increasing from year to year: the foil of this meadow is displaced in horizontal strata; the meadow is terminated by a marsh, which marsh is acquiring solidity, and is soon to be converted into a meadow, as the meadow will be into an arable field. All this while the sediment of the river makes its way slowly into the lake, forming a mound or bank under the surface of the water, with a pretty rapid slope towards the lake. This mound increases by the addition of new earth, mud, and gravel, poured in over the slope, and thus the progress of filling up gradually advances. By an accumulation of vegetable matter in shallow lakes, marshes and peat bogs have been formed at the bottom of valleys where the waters have not flowed with sufficient rapidity to drain away the moisture. These are common in various parts of the Highlands, and in Ireland. The filling up of lakes, and the enlargement of valleys, by the processes above described, may be distinctly seen in the vicinity of the lakes of Cumberland and Westmoreland. Larger lakes exemplify the same processes. Where the Rhone enters the lake of Geneva, the beach has been observed to receive an annual increase; and the Portus Valea, now Prevallais, which is at present half a league from the lake, was formerly close upon its bank. Indeed the sediments of the Rhone appear clearly to have formed the valley through which it runs, to the distance of about three leagues from the place where the river now discharges itself into the lake. The ground there is perfectly horizontal, composed of sand and mud, little raised above the level of the river, and full of marshes. The deposition made by the Rhone, after it enters the lake, is visible to the eye, and may be seen falling down in clouds to the bottom.

Where lakes are situated at a considerable elevation above the sea, or the adjacent country, they may be emptied by the wearing down of the strata which forms the outlet. Many of the North American lakes are connected by small straits or rivers, which have a rapid descent. On some of them are prodigious water-falls, which are constantly enlarging the passage from one to the other, and will ultimately drain the upper lakes. The falls of Niagara are observed to be progressively shortening their distance from the upper lake, since the banks have been inhabited by Europeans; and when it has completed its progress, the upper lake will become an extensive valley, surrounded by rising grounds, and watered by a river or smaller lake, which will occupy the lowest situation.

Valleys constitute the most fertile and habitable parts of almost
almost every country. Their superior fertility is derived from a constant supply of fresh soil, and from natural irrigation, and a more equal temperature; the vegetation being sheltered and protected from the boisterous winds that sweep over extensive plains, and the more elevated parts of the globe. It has been observed, however, that low valleys are not so favourable to the longevity of the human race as dry and mountainous districts.

Valley of Heros, in Geography, a name given to the delightful plains of Oujan, which are said to produce the finest pasture in Persia. It is so called by the natives, from having been formerly the favourite hunting park of the kings and heroes of Iran, and particularly of Bahrâm Gour, who had seven palaces of different colours in the neighbourhood. This prince, passionately devoted to the chase, took his throne of Gour from the gour khur, or wild aows, with which this valley abounds. In one of the roads from Perpoxis to Isfahan there is a pass or defile, called Imam Zada Ilmael, two furfings in length, and commencing at the 38th mile from Perpoxis, which leads into the above-mentioned plains.

Valleys, in Buildings, denote the gutters over the sleepers in the roof of a building.

VALLI, in Ancient Geography, a people of Asia, upon the Gordian mountains, near the Caucasian gates, which were in these mountains, according to Pnyx.

VALLI, in Botany, Juss. Gen. 267. — Rheede Hort. Malab. v. 7. t. 6—11, the name of several East Indian climbing ferns, which Influen confiders as belonging to the genus Vitis, hereafter to be described in its proper place. (Ardia-Valli of the same volume, t. 45, is referred by him to the neighbouring genus Cissus)

VALLI, in Geography, a town of Naples, in Lavora; 12 miles E.S.E. of Capua.

VALLIERE, a town of France, in the department of the Crente; 6 miles S.W. of Aubillon.

VALLIES, Four, Distriét of, otherwise called The District of Pinerolo, a province of Piedmont, bounded on the north by the marquisate of Susa, on the west by France, on the south by the marquisate of Saluzzo, and on the east by Carmagnola. The four vallies are those of Peroufa, Lucerna, St. Martin, and Angroina. The province is about 24 miles long, and from eight to eleven broad. The principal towns are Pinerolo, Lucerna, Peroufa, St. Martin, and Feneitelle. These vallies are watered by the Cluson, and several other smaller rivers; they are all surrounded with mountains and sharp rocks, in which are found white hares, foxes, pheasants, partridges, wolves, and bears; and in the most lofty of the neighbouring alps is found the marmotte, a creature something larger than a rabbit, but more of the nature of the badger; the chamois; and the bouquetin, an animal something like a goat or chamois, but more fleet than either. Among the tame animals is the jumart, produced by a bull and a mare, or a bull and a fheaf. The vallies are fertile in pasturage, and the mountains in fruit, particularly chestnuts. These vallies are celebrated for the cruel persecution of the inhabitants, who were called Waldenfes, on account of their religion, about the year 1655. But now they enjoy in peace the worship they embraced, though they have a Catholic church in each parish. The number of inhabitants is reckoned at about 8000, of whom 7000 are suppofed to be Proftantts.

VALLIS, in Ancient Geography, a town of Africa Propria, upon the route from Carthage to Cirta, between Sicilia and Coreoa, according to Antonine's Itinerary.

VALLIS Acker, Valley of Acker, a valley of Palestime, north of Jericho.

VALLIS Agyas, Valley of Agyas, a valley of Palestime, in the tribe of Dan, between Thammathe and Bethhehem.

VALLIS Artificem, Valley of Craftmen, a valley of Palestime, in the tribe of Benjamin, near Jordan.

VALLIS Aurantis, Valley of Oranges, a valley of Palestime, near the Dead sea.

VALLIS Beneficentiarum, Valley of Bliffsing, a valley of Palestime, in the tribe of Judah, west of the Dead sea.

VALLIS Cariniana, a place of Pannonia, on the route from Sompiane to Aquincum, between Pons Sociorum and Corvin or Gorgium. Anto. Itin.

VALLIS Caudaverum, Valley of Tophef, the slaughter-house of Jerusalem. It lay south of the city, in the valley of the children of Hinnom. It is said, that a fire was constantly kept here for burning the carcases, and other filth, which were brought hither from the city. (IIaiah, xxx. 33.) Others think, that the name of Tophef is given to the valley of Hinnom, on account of the sacrifices offered there to the god Moloch, by beat of drum, to drown the cries of the confuming children; a drum in Hebrew being called topf.

VALLIS Dominiæ, a place of Lower Mafia, upon the route from Atrabium to Nicemia.

VALLIS Gibon, Valley of Gibon, a valley of Palestime, west of Jerusalem, so named from the fountain of Gibon, whose spring is in this place, and runs from west to south.

VALLIS Emona, a town of Judea, in the tribe of Benjamin.

VALLIS Jerusel, a valley of Palestime, having the chain of mount Hermon to the north-east.

VALLIS Illuftris, the Illuftrious Valley, a valley of Palestime, near Sichem. This was the vale or plain of Moreh.

VALLIS Montium, the Valley of Mountains, a name given by the prophet Zachariah to the valleys round about Jerusalem, where the inhabitants of that city took shelter, when the city was besieged by the Romans.

VALLIS Rephaim, or Valley of the Giants, called in Greek the Valley of the Titans, and in the Vulgate, the Valley of the Giants (2 Sam. xxvii. 15.), lay near Jerusalem, and belonged either to the tribe of Judah or that of Benjamin.

VALLIS Sabina, the Valley of Salt or Salt-pits, generally placed in the southern part of Idumæa, S. of the Dead sea, but situated, according to Calmet, in the eastern part of Idumæa, between Tadmor and Bozrah.

VALLIS Sylvestris, the Vale of Woods, a valley of Palestime, in which were situated the cities of Sodom and Gozarah, and where the lake Asphaltites, or the Dead sea, was formed. This was called the vale of Siddim.

VALLIS Tabernaculorum, the Valley of Succoth, or Vale of Tents, lay beyond Jordan, near the city of Succoth. The palmits puts the valley of Succoth for the whole country beyond Jordan.

VALLIS Teninthi, called the Valley of Elah (1 Sam. xvii. 2.), or of the Oak, lay S. of Jerusalem, towards Sochoh and Azekah. The valley of the Terebinths is also a name given to the valley of Mamre, on account of the terebinthus under which Abraham entertained the angels.

VALLIS SNERI, Anthony, in Biography, a celebrated Italian naturalist, was born of a good family, May 3d, 1661, at the cattle of Trefilico, of which his father was governor for the duke of Modena. He was first instructed in the rudiments of the learned languages by the Jesuits, at Modena, and was afterwards taught rhetoric, and the Ariflotelian philosophy, under the fame apfices, at Reggio, where he defended his theses on that subject in 1682. Nevertheless, he began, even at this period, to be dissatisfied with the prevailing lyfleum, which he called a philosophy of words; and having to have a more liberal and enlightened preceptor
preceptor than usual, his attention was directed to natural and experimental philosophy, and the then prevalent hypothesis of Descartes. His tutor Biagi, a Jesuit, had the good sense and honesty to avow, that the philosophy of Aristotle might suit theologians and monks, but that he himself knew many able and distinguished men, at Bologna, and elsewhere, who, so far from being indebted to that great person, never thought of his doctrines but to refute them. Vallisneri therefore removed to Bologna in 1683, and very soon gave up theories and hypotheses for the observation of nature. Here the great Malpighi, to whose particular favour he was recommended by the princes of the house of Este, directed his anatomical enquiries, and from him he received, at his first introduction, a valuable lesson on the presumption of those physicians, who boast of a specific for every disease. The learned and experienced Malpighi, confined to his bed by illness, declared that he was unable to cure his own disorder. A candid confession, which then astonished his hearer; but of the truth of which Vallisneri declared himself subsequently more and more convinced by his own practice of physic, when he found the most boasted specifics daily deceiving his expectations.

The father of the young Vallisneri, himself a doctor of laws, offered his son a choice between law and physic; but his earliest inclinations and inquiries were too much allied to the latter profession to allow of hesitation. An anatomist of animals from his youth, he devoted himself so assiduously to dissections, in the instructive and flourishing school of Bologna, that his health became a sacrifice to his curiosity, and Malpighi was obliged to check the dangerous ardour of his promising pupil. Vallisneri would doubtless have graduated in this famous university, then in its meridian glory; but at the time when this should have taken place, the duke of Modena put forth an edict, prohibiting his subjects from taking degrees, except at Modena or Reggio. Vallisneri chose the latter, and took his doctor's degree in 1694; but in order to study with advantage the necessary sciences of chemistry and botany, as well as to improve himself in practical surgery and physic in the hospitals, he was obliged to return to Bologna; as our doctors of Cambridge or Oxford find it expedient to accomplish themselves in London and Edinburgh. He spent about three years more under the auspices of Malpighi, who at length dimissed this favourite pupil, with the found advice of studying nature, and communicating matters of fact. "Systems," said he, "are ideal and mutable. Observation and experience are solid and unchangeable."

The years 1687 and 1688 were usefully passed at Padua, Venice and Parma, and at length Vallisneri settled as a physician at Reggio. Here he planted a botanic garden, and employed his leisure hours in excursions among the neighbouring mountains; to collect herbs, minerals and petrifications; to observe the strata of the rocks, and the origin or nature of the various mountains; as well as to take the pleasures of the chase, of which he was very fond. The first particular object of investigation to which this ingenious philosopher devoted his attention, was the anatomy of the Silkworm, by which he was led to the study of the metamorphoses and generation of other insects. Malpighi and Redi were his guides; but he soon found, in the intricacies to this new and recondite course of inquiry, that he was able to extend their information, and correct some of their remarks. He gave his discoveries to the world in the form of two Dialogues in Italian, supposed to take place between Pliny and Malpighi, on the arrival of the latter in another world. These brought great reputation to their author, both for the value of their contents, and the elegance of their language and composition. They introduced him to the acquaintance and correspondence of several learned men, engaged in similar studies; amongst others to that of our distinguished Dr. Martin Lister. He was soon afterwards invited to Padua, where he rose successively from one medical professorship to another, till he obtained, in 1711, the first chair of the Theory of Medicine. When Vallisneri first took his place among the teachers of physic in this long-established university, he was well aware of the caution necessary in opening the eyes of the blind, and in teaching the lame to walk. He had already exercised his own powers, and was a proficient in the practical, or experimental, philosophy, of medicine, as well as of anatomy and physiology. But those accustomed to lean upon others, do not at once acquire, or even desire, the use of their own faculties. Established bodies naturally cling to established authorities, and it perhaps becomes them to be cautious of embracing, without due deliberation, any unauthorized novelty. To this duty, whatever others they may neglect, they must be allowed to be piously attentive. Nothing therefore could be more judicious than the subject of our new professor's first thesis, when he took the chair on the 14th of December, 1703; that "the Studies of the Moderns do not overturn, but confirm, the Medical knowledge of the Ancients." He pointed out in Hippocrates traces of the greatest discoveries, which the moderns by their superior opportunities had fully explained, such as the circulation of the blood; and thus without invalidating the merits of the latter, he dexterously confirmed the authority of the former, and flattered, instead of alarming, their disciples. He thus stimulated them to enlarge the sphere of their own knowledge, so that by improving the practical sciences of chemistry, anatomy, &c., they might further elucidate what the ancients had not fully understood or explained. In the progress of his lectures, however, Vallisneri was too judicious, and too honest, to sacrifice truth, to any ancient or modern authority. He attacked, without scruple, Avicenna's theory of fevers, and the erroneous practice founded thereon; as well as the doctrines of the putsreence of the humours, the stagnation of the liver, with many mechanical hypotheses of the old school. All this did not indeed pass without animadversion, especially the new doctrine of glandular secretion; but Vallisneri, supported by truth and experience, finally prevailed, and wrought a great change in the theoretic medicine of his day. Improvements in practice followed of course; and whenever the enlightened teacher met with any troublesome opposition, or, as usual, was attacked with misrepresentation and calumny, he found an able protector in Frederick Marcello, procurator of St. Mark, who being charmed with his earliest writings, had first recommended him to his appointments at Padua.

The intervals of his academical duties were often devoted by Vallisneri to rural excursions, for the improvement of his knowledge in natural history, as well as for the restoration of his bodily and mental powers, amid the wild and majestic, or the variously beautiful, scenes of nature, which lay profusely within his reach. In the summer of 1704 he visited the recesses of the Appennines, and climbed their stupendous precipices. The scenery which inspired the genius of Salvator Rosa, enlarged the mind, and enriched the acquisitions, of our philosopher, and he defended, like a fertilizing river, to benefit the world below. The following year, he undertook a less laborious journey, to visit his literary friends at Lucca, Pisa, Leghorn and Florence, and was invited by prince Ferdinand of Tuscany to Fratallino, where he met with a mort flattering reception, the prince's hospitality.
hospitability being extended to the personal, as well as literary, accommodation of Vallisneri at Florence itself, where every
door and cabinet were opened to him. From Leghorn he proceeded to Genoa, not without the usual adventure of a
shipwreck of his wretched felucca, by which accident he had the advantage of seeing for the first time a noble Date
Palm, in the open ground. He returned from Genoa to Padua by land. These and many similar excursions, in
several following seasons, were productive of much information to a man, who could not pursue the most beaten track
without picking up something. Indeed his line of study was new at that period. He contributed to open a new
world to microscopic observers, and to direct their enquiries to advantage. He had by this time collected an ample
museum, and choice library, both of them the more valuable and useful, for being collected by himself with
some particular object.

His studies were not impeded nor embittered by domestic
cares or quarrel; for though he married in 1692, and his
wife brought him eighteen children, she was a woman of
prudence and good sense; she directed his family in such a
manner as to render his home comfortable and happy.
The children, four only survived their infancy; a son
who bore his father's name, and inherited his activity of
disposition, and three daughters, two of whom became nurses at
Padua. The third, named Claudia, a woman of rare
talents, and the highest moral worth, remained unmarried at
home.

In the beginning of 1728, Rinaldo I., duke of Modena,
sent Vallisneri an unfoiled patent of knighthood, for him-
self, his son and their descendants. This honour was the
more just, as he had, eight years before, declined an invitation
from pope Clement XI. to become physician to his
holiness in the place of the famous Lancisi. He had also
refused to accept, from king Victor Amadeus, the appoint-
ment of first professor of physic, at Turin, with a very
large stipend. Nor were academical honours wanting to his
fame. He was associated with the Academy Nature Curio-
sum, the Royal Society of London, and almost every
learned body in Italy. Thus in the indefatigable pursuit of
knowledge, and well-merited fame, he completed his sixty-
eighth year. On the 12th of January, 1730, he was at-
tacked with a fort of epidemic catarrh, accompanied with
great debility, which, falling on his lungs, carried him off
on the 18th. He was interred in the church of the Erci-
tani at Padua, where his son erected a monument to his
memory with the following just and elegant inscription.

D. O. M.
Antonio Vallisnerio
Artis Mediceae afferenti eximio
Naturalis Historiae ac Philosophiae
Rediturus celebrerimo
Summis honoribus undeque audeo
Antonis filius mar. p.
MDCCXXXI. Act. LXVIII. Mens. VIII.

The filial piety of the younger Vallisneri accomplished a
more lasting memorial for his distinguished parent, in a complete and splendid edition of all his works, making three
folio volumes, printed at Venice in 1753, and illustrated with
plates, in one of which the fructification of the Lema
is exhibited. These writings, being frequently in the form
of letters, are diffuse, but the Italian style of the author is
esteemed by his countrymen. The whole work might be
epitomized with advantage, and would be found rich in
originality and acuteness. An ample life of Vallisneri is
prefixed to this publication, from whence we have extracted
the above account. He is certainly entitled to rank with
Redi, Malpighi, Reaumur, and Swammerdam, as an or-
iginal observer of the intricate and obscure physiology of
insects, and the lower tribes of the animal kingdom. He
co-operated with those philosophers in clearing away the
theory of equivocal generation, and other rubbish of the
schools. In medicine his merit is of a very high order, and
his name marks an epocha in the history of that science
in Italy. Those who had so long flumbered over the mazy
folia of ancient lore, were by him turned unawares out of
their dormitories and easy chairs, before they had time to
awake, much less to defend their pols. He exalted the
science from the study of books, to that of nature, and
fuccesse was the natural result. In practice he had the good
sense to promote the use of the Peruvian Bark, which, at that
period, had much prejudice to contend with. His prescrip-
tions were generally simple, and all his inquiries were free
from credulity and prejudice. We cannot here enumerate
the titles of all his various pieces. What relates to the
theory of generation is most esteemed; and he had the
courage to oppose the then famous vermicular hypothesis
of Lceuwenhoek. The memory of Vallisneri has been pre-
erved by his countryman Micheli, in the name of a very
curious and interesting genus of plants. See the next
article.

VALLISNERIA, in Botany, was dedicated by Micheli,
to the honour of his distinguished countryman, of whom we
have given an account in the preceding article. No genus
could have been more fortunately selected, as its history is
now, in the writings of Linnaeus, identified with that of the
generation of plants; of the theory of which, as taught by
that illustrious botanist, it affords one of the most conclu-
usive and celebrated proofs. Yet Micheli was ignorant of this
striking fact; and has absolutely, as we shall find, described
the two sexes as distinct genera. The male plant is his
Vallisneroides. We can offer no apology for this oversight
of so faithful an observer, but his attachment to Tourne-
fort, who shut his eyes against the sexual doctrine, and
Micheli durst not take the liberty of opening his own—Michi.
t. 10.)—Clavis and order, Dioecia Didriandia. Nat. Ord.

Gen. Ch. Male, Cal. Common Sheath of one leaf, in two
deb, oblong, often cloven, reflexed segments, including a
comical, compressed Common Spadix, covered all over with
fleshy flowers forming a spike. Cor. of one petal, in three
deb, obvate, widely spreading, or reflexed, segments,
without a tube. Stam. Filaments two, erect, the length of
the corolla; anthers roundish, simple.

Female, on a different plant, Cal. Sheath of one leaf,
single-flowered, cylindrical, elongated, with two erect seg-
ments at the extremity. Perianth superior, in three deep,
ovate, equal, spreading segments. Cor. of one petal, in
three deb, linear, abrupt segments, shorter than the calyx.
Pet. Germen inferior, cylindrical, longer than the sheath;
style very short; stigma in three deep, oval, convex seg-
ments, downy on the upper side, cloven half way down,
rather longer than the calyx, and bearing at the back a
small oblong appendage. Peric. Capsule cylindrical, of
one cell, not burrting. Seeds numerous, ovate, inferted in
many rows into the sides of the capsule.

Eff. Ch. Male, Sheath in two deep segments. Spadix
covered with flowers. Corolla in three deep segments.

Female,
Female, Sheath divided, single-flowered. Perianth in three deep segments, superior. Corolla in three deep linear segments. Stamens three, cloven. Capsule cylindrical, of one cell, with many seeds.

Obs. Such is the original genus, of which Micheli’s figure is more clear than his description. There can be no doubt that the part marked A, B, in the middle of his plate, below, represents the under side of the three stigmas. Linnaeus, who never saw a living flower, must have taken this point; but has corrected himself in manuscript. We have profited of this, and partly of Mr. Brown’s definition. V. orientalis of Roxburgh, if he thought the same genus, must lead to some further correction of the generic characters.

1. V. filipendula. Spiral Vallicentia. Linn. Sp. Pl. 1441. Wild. n. 1. Brown n. 1. (V. palustris, alge folio, italic, foliis in summum denticulatis, flore purpureo; Mich. Gen. 12. t. 10. f. 1. female. Vallicentoides palustris, alge folio, italic, foliis in summum tennesse denticulatis, floribus albis, vix conficibus; Mich. Gen. 13. t. 10. f. 2. male.) — Stalk of the female flower spiral. Leaves floating, linear, obtuse, finely serrated at the summit; tapering at the base.—In ditches in Italy, especially near Pisa. Communicated from near Arles, in Provence, by the late Dr. Brouillonet, in 1783. Mr. Brown found, what he is almost certain of being the same species, in New South Wales, about Port Jackson. This plant is perennial, flowering in summer and autumn. The root consists of long fibres, and propagates itself very widely by means of runners, so that the canals, in which the Vallicentia grows, are choked up with its foliage, and rendered not navigable for boats. Stem none. Leaves all radical, very long, linear, flaccid, pellucid, ribbed, smooth, entire, except at the end. Stalks of the female flowers very long, thread-shaped, unbranched, nerved, single-flowered, curiously spiral, but becoming more or less straight when the flower is ready to open, by which means the latter floats on the surface, and after impregnation, the stalk coils up again, and lodges the fruit at the bottom of the water. This fruit is three or four inches long; and judged by Mr. Brown to be rather of the nature of a berry than a capsule. The male flowers grow on a separate plant, on short, simple, straight, radical stalks. Each minute white flower separates from the common spadix, and rises cloaked, like a little bubble, to the surface of the water. Burbling there, these flowers float about in immense numbers, covering the water, and impregnating the females above described. Micheli has faithfully described the economy of this interesting plant, though blind to its physiology.

2. V. americana. American Vallicentia. Michaux Boreal—American. v. 2. 220. Wild. n. 2. Pursh n. 1. — "Stalk of the female flower nearly straight. Leaves erect, linear." — At the bottom of muddy and slow rivers in North America, flowering from August to October. Michaux observed it in the Mississipi and St. John’s rivers, Florida; Pursh in the Delaware, near Philadelphia, and elsewhere. The latter doubts whether it is a distinct species from V. spiralis; for he found the stalk of the female flowers to be, in deep water, really spiral. Michaux remarks, that the leaves are erect, less elongated than in the foregoing, and not tapering at the base. These circumstances may call all owing to the shalows and stillness of the water.

4. V. orientalis. Orientalis Vallicentia. Roxb. Coromand. v. 2. 34. t. 105. Wild. n. 3.—Stalk of the female flower straight. Leaves linear, taper-pointed. Stamens eight.—Native of shallow, stagnant, sweet water, on the coast of Coromandel. Roxburgh. Roots annual, fibrous. Leaves radical, erect, flat, smooth, entire, gradually tapering to a point, from nine to twelve inches high. Stalks all radical, straight, cylindrical, erect, simple, much shorter than the leaves. Stalk of the male flowers near three inches long, turbiniform, tapering upwards, containing many flaked flowers, which, by the elongation of their partial flasks, rife one by one out of the sheath. Each has a three-leaved calyx; three longer linear white petals, or segments of the corolla; eight unequal stamens, with oblong anthers; and an abortive germen, with three linear stigmas.

The flasks of the female flowers, on a separate plant, are shorter than those of the males, single-flowered. Stalk as in the male, but the flower is elevated above it and the germen by a partial stalk, or receptacle. Calyx shorter than in the male; petals longer and narrower, white. Stigma long, thread-shaped, white. Seeds roundish, flaked, ranged numerously along one side of the tapering capsule.

We have already hinted the affinity of this plant to Loureiro’s Physiolum; see that article.

VALLISNERIOIDES, Micheli’s name for the male plant of his Vallisneria; see that article.

VALLOR, in Geography, a town in France, in the department of Mont Blanc; 9 miles S.S.E. of St. Jean de Maurienne.

VALLON, a town in France, in the department of the Sart; 10 miles W. of Le Mans.—Also, a town in France, in the department of the Ardèche; 9 miles N.E. of Pont St. Esprit.

VALLONISE, a town in France, in the department of the Higher Alps; 9 miles S.W. of Briançon.

VALLOR, or Vail, among country people, a hollow mould, in which a new-made cheese is pressed.

VALLOTTI, Padre Francesco Antonio, in Biography, an ecclesiastic, and maestro di capella of the church of St. Antonio at Padua in 1770, was born in Piedmont in 1705. He was esteemed one of the best composers for the church in Italy. Tartini speaks of him in his Trattato di Musica, p. 100, in the following manner: "Padre Vallotti was formerly a most excellent performer on the organ, and is now an admirable composer, and master of his art." This good father was of so amiable a character, that it was impossible to know and not esteem him. He composed an anthem for the public funeral of Tartini, March 31, 1770; and in 1779 published at Padua the first book of a treatise entitled "Della Scienza Teorica e Pratica della moderna Musica." This first book is purely theoretical. The author promised three other books, the publication of which has not arrived at our knowledge. Book the second was to contain the practical elements of music; the third, the precepts of counterpoint; and the fourth, rules of accompaniment. It is to be feared, that this venerable author did not live to complete his design, as we have been informed that he died in 1785, at the age of 75.

VALLIS, in Geography, a town in Spain, in the province of Catalonia; 9 miles N. of Tarragona.

VALLUCE, a small island in the English Channel, near the coast of France. N. lat. 47° 26’. W. long. 2° 55’.

VALLUM, in Roman Antiquity, denote a kind of parapet with which they fortified their camps. In the vallum, some dilligent two parts; theagger, which was no more than the earth call up to form the vallum; and the jubes, which were a fort of wooden stakes to secure and strengthen it.

VALLY CREEK, in Geography, a river of Pennsylvania, which
which runs into the Schuylkill, N. lat. 40° 7'. W. long. 75° 30'.

Vally Forge, a place in Pennsylvania, near the union of Vally Creek with the Schuylkill. Here general Washington lay encamped in the winter of 1777, 1778; 20 miles N.W. of Philadelphia.

VALMAROSA, a town of Ilioria; 8 miles E.S.E. of Capo d'Ilioria.

VALMASEDA, a town of Spain, in the province of Bifey; 13 miles S.W. of Bilbao.

VALMIKI, in Biography, the name of a very celebrated Hindoo poet, author of that extraordinary poem in the Sanskrit language, entitled Ramayana, under which word we have given some account of its contents. Sir William Jones, in his ninth anniversary discourse to the Asiatic Society of Calcutta, delivered February 1792, gives his opinion that the Cuh of Moses and Valmiki were the same personage. (See Ramayana and Triveni.) But we are not in possession of any biographical particulars respecting him. His great work, the Ramayana, is esteemed the earliest epic poem, and is cited as nearly equal in authority with the more fanciful of the Hindoo books, such as the Purana and Veda, ascribed to Vyasa. See these articles.

VALMONT DE BOMARE, JAMES CHRISTOPHER, was born at Rouen, in September, 1731. He was intended for the bar, but his inclination to natural history induced him to devote himself entirely to that pursuit, and having obtained an order from the duke d'Argenfon, the minister at war, to travel for the improvement of science, with sufficient funds for the purpose, he spent several years in visiting the principal cities of Europe, and examining the most famous collections in natural history. Mines and metallurgical establishments engaged his particular attention; having visited Lapland and Iceland, he described its volcanoes; and returned, with many curious objects, to Paris in July 1756. He then began a course of lectures on natural history, which were continued till the year 1788. These lectures contributed to establish his reputation, and he had many advantageous offers from the courts of Russia and Portugal, the acceptance of which he declined. His works are as follow: v.z; "Catalogue d'un Cabinet d'Histoire Naturelle," 1758, 12mo.; "Extrait Nomenclature du Systèm complet de Minéralogie," 1759, 12mo.; and "Nouvelle Exposition du Regne Mineral," 1761, 1762, 2 vols. 8vo. But his capital work was his "Dictionnaire raisonné Universel d'Histoire Naturelle," in 6 vols. 8vo. This has passed through several editions in 8vo. and 4to., and being the first of its kind, served as the basis of all the dictionaries of natural history that have appeared since that time. One of the latest editions appeared at Lyons in 1800, 15 vols. 8vo. This celebrated naturalist died at Paris, in August, 1807. Gen. Biog.

VALMONT, or Vallemont, in Geography, a town of France, in the department of the Lower Seine; 6 miles E. of Fécamp.

VALMONTONE, a town of the Popedom, in the Campagna di Roma; 6 miles S. of Palestrina.

VALNORD, a town of Hungary; 5 miles S.W. of Szepen.

VALOE, an island of Sweden, in the bay of Christiania; 7 miles S.S.E. of Toniberg.

VALONGES, a town of France, and principal place of a district, in the department of the Channel. In 1546, it was pillaged by the English; 7½ miles N. of Coutances. N. lat. 49° 31'. E. long. 1° 23'.

VALOIS, HENRY DE, or VALESIUS, in Biography, born at Paris in 1603, and educated in the Jesuits' school, was admitted an advocate of the parliament of Paris, after having previously studied the civil law at Bourges. Declining the prosecution of the law, he devoted himself to literature, and particularly to the study of Greek and Latin authors. The affability of his application inspired his fight, the imperfection of which was in some degree counterbalanced by the retentiveness of his memory. Besides some private poems which were granted him, he was appointed, in 1660, hitorigorapher of France, with a considerable salary. At the age of sixty-one he married a lady, by whom he had seven children; and died in 1767, at the age of seventy-three years. His temper was harsh and irritable; fond of praise, and sparing in bestowing it on others; impatient and querulous under bodily indisposition, but unfeeling to the sufferings of others. With many infirmities and failings, he was a learned, discriminating, and accurate critic. His principal publications were, an edition of the "Ecclesiastical History of Eusebius," with a Latin version and notes; the "Ecclesiastical Histories of Socrates and Sozomen," as well as of "Theodore and Evagrius;" a valuable edition of "Ammius Marcellinus;" "Remarks upon Harperoition;" "Emendationum Lib. V.," with other pieces, printed after his death at Amsterdam, in 1740, under the care of Peter Burman. Moreri.

VALOIS, ADRIAN DE, brother of the preceding, was born at Paris in 1607, and studied in the Jesuits' college. Although he acquired a competent knowledge of the Greek and Latin languages, he attached himself principally to the study of French history; and in 1646 appeared the first volume in folio of his "Gelfa Francorum," which was followed by two more in 1658. He began with the reign of the emperor Valerian, and traced the history of the Franks to the deposition of Childeric, and his work was generally admired. As a recompose, he was associated with his brother in the office of hitorigorapher, and in the pension annexed to it. In 1675 he published "Notitiae Gallorum," fol. comprising, in alphabetical order, an account of the geography, towns, monasteries, &c. of France, deduced from its early records and histories. He followed the example of his brother, with whom he lived on terms of intimate union, by marrying a young wife, who brought him two children. He published, besides the works already mentioned, an edition of two poems written in the middle ages, a second edition of his brother's "Ammius Marcellinus," and some other pieces relating to antiquities. He died in 1692, at the age of eighty-five years. His son, CHARLES DE VALOIS DE LA MARE, was also a man of letters, and became a member of the Academy of Inscriptions and Belles Lettres, and antiquary to the king. He published a collection of critical, historical, and moral reflections, and Latin poems under the title of "Valefanæ," and edited two poet-humorous works of Vaillant the medallist, and wrote several papers for the Academy, of which he was a member. He died in 1749, aged seventy-six. Moreri.

VALOMBROSO gives its name to a congregation of Benedictine monks, founded in the Apenines by Cualbert of Florence, in the 11th century; who, in a short space of time, propagated their discipline in several parts of Italy.

VALON, in Ancient Geography, a river of Africa, in Mauritania Tingitana. Ptolemy.

VALONA, in Geography, a sea-port town of European Turkey, in Albania, on a gulf of the Adriatic, gained by the Turks from the Christians in the year 1464. In the year 1690, it was taken by the Venetians, but retaken by the Turks the year following; 68 miles S. of Durazzo. N. lat. 40° 36'. E. long. 19° 28'.

VALONGO, a town of Portugal, in the province of Beira; 21 miles S.E. of Lamego.
VALONIA, in Botany. See Velania.

VAROR BENEFICORUM, in Law. See First-fruits.

VALORE MARITAG, Value of Marriage, a writ which
anciently lay for the lord, after having proffered suitable
marriage to an infant who refused the same: to recover the
value of the marriage. See Guardian.

VALORSINE, in Geography, a town of France, in
the department of the Leman; 15 miles S.E. of Nître
Dame d'Abondance.

VALOYEA, a town of European Turkey, in Mol-
davia; 52 miles N. of Jaffy.

VALPARAYSO, a town of Spain, in New Caftle;
15 miles S. of Hucte.

VALPARAYSO, a fea-port town of Chili, fittuated on a
bay of the South Pacific ocean. This town was at first very
mean, confifting only of a few warehouses, built by the
habitants of St. Jago, for laying up their goods till shipped
off for Callao, the harbour of Valparayfo being the nearest
port of that city, from which it is only 60 miles distant.
The only inhabitants at that time were the few fervants left
by their repective masters for taking care of the ware-
houses, and managing their mercantile affairs. But in pro-
ceds of time, the merchants themselves, together with fev-
eral other families, removed from St. Jago, in order to be
more conveniently flituated for trade; since which it has
gradually increafed, fo that at present it is both large and
 populous; and would be still larger, were it not for its in-
convenient fituation, flanding near to the foot of a moun-
tain, that a great part of the houses are built upon its acclivity,
or in its breaches. Valparayfo, besides its parish-church,
has a convent of Francifcans, and another of Augufines;
but very few religious, and the churches belonging to them
small and mean. It is inhabited by families of Spaniards,
calls both of Mulattoes and Mefitzos. Here is a mi-
litary governor nominated by the king, who having the com-
mand of the garrifons in the several ports, and of the militia
of the place and its dependancies, is to take care that they
are properly disciplined. The proximity of this port to St.
Jago, has drawn hither all the commerce formerly carried
on at that city. To this it owes its foundation, increafe,
and prefent prosperity. All the Callao fhips which carry
on the commerce between the two kingdoms come hither.
In this port they take in wheat, tallow, cordovan-leather,
cordage, and dried fruits, and with these return to Callao;
and a ship has been known to make three voyages in one
summer between November and June. Valparayfo is abun-
dantly supplied with provisions from St. Jago and other places
in its neigbourhood. Among the several kinds of game
there is here such a plenty of partridges in their feafon, which
begins at March and lasts several fucceding months, that
the muleteers knock them down with flicks, without going
out of the road, and bring great numbers of them to Val-
parayfo. But few of these or any other birds are feen near
the town. It is the fame with regard to fish, very little
being to be caught either in the harbour or along the cofit,
in comparison of what may be taken in the other parts. The
harbour is every where free from rocks and shoals, except
to the north-eaft of the breach De los Angeles, where, about
a cable's length or two from the land, is a rock, which must
be more carefully avoided, as it never appears above water,
but sometimes has not a depth fufficient for a fhip of any
burden to pass over it; 225 miles N. of Conception. S. lat.
33° 1'. W. long. 72° 16'.

VALPERGA, a town of France, in the department of
the Dora; 11 miles S.S.W. of Ivrea.

VALPERSCHWEIL, a town of Switzerland, in the
cantton of Berne; 10 miles N.W. of Berne.

thors for what is now the Sphæria of benztals; see that
article.

VALSALVA, ANTON-MARIA, in Biography, an emi-
ten anatomift, physician, and surgeon, was born in 1666,
at Imola, in Romagna. Having received the firit elements
of literature in the Jefuits' feminary, he was fend to the
university of Bologna, and placed under the immediate tuti-
on of the celebrated Malpighi, and here he purfued his
various studies with an affiduity which impaired his health.
He graduated at Bologna in 1687, and connecting surgery
with phyfic, acquired high reputation. He fimplified and
improved furgical instruments, bafhted from Bologna the
furfet practice of cauterizing the arteries after amputation,
and in the cure of deafnefs employed manual operations. In
1697 he was chosen professor of anatomy in the university,
and appropriate buildings were erected for his ufe at the
anatomical theatre. The school of Bologna acquired cele-
brity under his direction, and some of his pupils became
eminent in their profession. Of this number was Mor-
gagni. In advanced years Valfalfa grew corpulent and
lethargic, and was carried off by an apoplectic stroke in
February 1723, at the age of fifty-seven years; leaving a
widow and three daughters. His anatomical museum was
bequeathed to the Institute of Bologna, and his various ap-
paratus of chirurgical instruments to the hospital for incur-
able. The principal of his works is a treatife "De Aure
Humana," reprinted at Bologna in 1704, 4to. and again
with Morgagni's Epiftles, at Venice, 1740. After his death,
Morgagni published three of his "Differtations" on anato-
mical fubjects, which had been read before the Inftitute.
This great anatomift's work "De Sedibus et Caufis Mor-
borum," contains a number of defcriptions by Valfalfa.

VALSECA, in Geography, a town of Spain, in Old
Caftle; 11 miles N. of Segovia.

VALSTAGNO, a town of Italy, in the Vicentin; 18
miles N. of Vicentin.

VALSTAGNO, a town of Italy, in the Vicentin; 18
miles N. of Vicentin.

VALTANAS, a town of Spain, in the province of
Leon; 15 miles E. of Valencia.

VALTELINE, a lordhip of Italy, at the foot of the
Alps; bounded on the N. by the Grifons, on the E.
by the county of Bormio and the Breffian, on the S.
by the Bergamafco and the Milanefe, and on the W.
by the county of Chiavenna and the Milanefe. This
country, which is called by the Grifons Pellin, or Véllin,
and by the inhabitants Valhe Téllin, is a valley inclosed
between two chains of lofty mountains, about fifty miles in
length, and from eight to twenty in breadth. It is exceed-
ingly fruitful, and throughout its whole extent watered by
the Adda, which, after receiving all the streams infuifng from
the foret, difcharges itself into the Como lake. In some
parts the heat is intenfe, but in others more moderate,
and on the hills and the greatefl part of the adjacent valleys
the air is mostly cool. Of this variation in its temperature,
the neceffary confequence is a variation in the products of
the earth. The levels in this valley, through which the Adda
purses its courfe, and the breadth of which in some parts

D 2

is
is not less than a mile, exhibit a delightful variety of corn-fields, meadows, vineyards, and orchards of chestnuts and other fruits. The vineyards on the mountains towards the north produce the best wine in the whole country, and above them are corn-fields, meadows, and pasture-lands. The hills on the south side are covered with fine woods of chestnuts, fields, meadows, and rich pastures, in which graze numerous herds of cattle. This country abounds also in excellent red wine, of a most delicious flavour, and of so good a body that it will keep for a whole century, improving both in taste and wholesomeness, and gradually turning paler, till at length its redness totally disappears. Great quantities of this wine are exported. The apples and pears in most places are not much esteemed; but the peaches, apricots, figs, and melons, are exquisite. Here is likewise plenty of lemons, citrons, almonds, pomegranates, chestnuts, and other delicious fruits. Its soil also would produce all kinds of grain and pulse; but the levels being intersected with swampy places, which have hitherto remained without culture, and the wine-trade chiefly engrossing the attention of the inhabitants, it does not yield a sufficiency for their consumption without importation. Some parts grow hemp, and in the levels, particularly on the higher grounds and the mountains, are fine pastures. Bees and silk-worms are bred here in vast numbers. The Adda yields plenty of fish, and is noted for its trout, which often weigh from fifty to sixty pounds. The whole of their mine-works here confit in a few iron-founderies.

The chief commerce of the Valteline is carried on with Milan and the Grisons. The principal exports are wine and silk, which turn the balance of trade in its favour; they enable the inhabitants to exist without any manufactures, and help to supply the money which is exacted by the governors.

The wine is sent into the Grisons, Germany, the Venetian states, Bormio, and occasionally to Milan. Upon a rough calculation, 73,000 fona, or horse-loads, are annually exported. The silk is sent to England, Zurich, and Bale. The district of Delebio and Talomara produces the finest silk, the neighbourhood of Sondrio the next in quality, and the district of Tirano supplies an inferior fort. Three thousand pounds of the finest silk, which is esteemed as good as the silk procured from Piedmont, is sent annually to England by way of Olland. The greater part is wound in the Valteline, for which purpose there are silk-mills in the principal districts.

Besides these commodities, the Valteline exports planks, cheese, butter, and cattle. The inhabitants receive from Milan, corn, rice, salt, silk, flax, linens; from Germany and Switzerland, cloth and linen; from Genoa, spices, coffee, and sugar.

There are no manufactures in the Valteline, and almost all the menial trades are exercised by foreigners. The population of the Valteline may be estimated from the following rough sketch:

<table>

The cottages of the peafants, which are built of stone, are large, but gloomy, generally without glass windows; and exhibit an uniform appearance of filth and poverty.

Perhaps no part of Europe is more fruitful than the Valteline, and yet there is no country in which the people are more wretched. Many reasons may be assigned for the misery to which they are reduced. The first and principal cause is the form of government. The governors generally abuse the exorbitant authority entrusted to them by the laws; the peafants are imprisoned upon the slightest information; and as all transgressions are punished by fines, an accused person is seldom acquitted; so that a considerable number are annually ruined in the courts of justice.

Beside the individuals who are oppressed to suffer for their own guilt, the parishes are subject to continual affluences, towards defraying the expenses for the trial and imprisonment of the poor parishioners; if they are unable to pay the sum required, it is demanded from the parish to which the criminal belongs. In this case it frequently happens, that the affluences, instead of being laid upon the landholders, are imposed upon each hearth, by which means the chief burden falls upon the poor.

Another cause of wretchedness proceeds from the present state of property. Few of the peafants are landholders; as from the continual oppression under which the people have groaned for above two centuries, the freeholds have gradually fallen into the hands of the nobles and Grisons, the latter of whom are supposed to possess half the estates in the Valteline. The tenants who take farms do not pay their rent in money, but in kind; a strong proof of general poverty. The peasant defrays the costs of cultivation, and delivers nearly half the produce to the landholder; the remaining portion would fill compensate his labour and expense, if he was not in some measure befriended by the fertility of the soil. The ground seldom lies fallow, and the richest parts of the valley produce two crops; the first is wheat, rye, or spelt, half of which is delivered to the proprietor; the second is generally millet, buckwheat, maize, or Turkey corn, which is the principal nourishment of the common people; the chief part of this crop belongs to the peasant, and enables him in a plentiful year to support his family with some degree of comfort. Thos who inhabit the districts which yield wine are the most wretched; for the trouble and charge of rearing vines, of gathering and pressing the grapes, is very considerable; and they are for apt to confine the share of liquor allotted to them, in intoxication, that, were it not for the grain intermixed with the vines, they and their families would be left almost destitute of subsistence.

Besides the business of agriculture, some of the peafants attend to the cultivation of silk; they receive the eggs from the landholder, rear the silk-worms, and are entitled to half the silk. This employment is not unprofitable; for although the rearing of the silk-worms is attended with much trouble, and requires great caution; yet as the occupation is generally entrusted to the women, it does not take the men from their labour. With all the advantages, however, derived from the fertility of the soil, and the variety of its productions, the peafants cannot, without the utmost difficulty, and continual exertion, maintain their families; and are always reduced to the greatest diffircs, whenever the season is unfavourable to agriculture.

To these causes of penury among the lower classes, may be added the natural indolence of the people, and their tendency to superfluity, which takes them from their labour.

This country is without so much as one city, but has some considerable towns, with many thriving villages. Its language is a corrupt kind of Italian. The Roman Catholic is the only religion. Their clerics are under the jurifdiction
dition of the bishop of Como. They are not responsible to the ordinary courts, their immunities being so exorbitant as to render them almost independent of the civil authority; they are only amenable to the court of the bishop of Como. If a priest is guilty of any misdemeanour, his person cannot be secured without the concurrence of the bishop and governor of the district in which the crime was committed. It is therefore extremely difficult to bring an ecclesiastical to justice; as impunity is easily purchased, either by securing the favour of the bishop's vicar or of the magistrate. Nor are these pernicious privileges confined merely to the clergy, but extend to all persons wearing an ecclesiastical dress, with the permission of the bishop of Como.

All civil causes of the clergy, below the value of two hundred livres, are decided by the vicar of the bishop of Como: above that sum, they are brought before the bishop. An appeal from his decision lies to the pope's nuncio at Lucerne, from him to the ecclesiastical tribunal at Aquilea, and from thence to Rome.

The whole country is divided into three districts, or duchies, called Sopra, Mezzo, and Sotto, or Upper, Middle, and Lower. Tirano is the capital of the first, Sondrio of the second, and Morbegno of the last. It is divided into five governments; viz. those of the upper district; of the middle district, called also the government of Sondrio; of Treviso, of Morbegno, and of Tirano.

Each of these five governments is subject to a magistracy appointed by the Grifons, who is changed every two years. The magistracy over the middle district is called governor of the Valteline, and polysells in some respects a superior degree of authority to the others, who are styled podestas; he is also captain-general of the Valteline.

All public concerns, which do not fall under the jurisdicition of the Grifons, are discussed and determined by a council composed of five representatives, one from each district, which meets as occasion requires at Sondrio.

The Valteline, together with the counties of Chiavenna and Bormio, (which had long been the constant source of hostility between the bishops of Como and Coire,) came, in the year 1336, under the dominions of Azzo Visconti, sovereign of Milan, who quietly transmitted them to his successors. Upon the death of John Visconti, one of Azzo's successors, his territories were divided between his nephews Galeazzo and Barnabas. Upon the demise of Galeazzo, his son, John Galeazzo, secured the person of his uncle Barnabas, and having confined him in the castle of Trevio, until his death, which happened in 1395, annexed his dominions to his own, and became by this union the greatest and most powerful prince in Italy. Matteo, son of Barnabas, took shelter, upon his father's imprisonment, with Hartman, bishop of Coire, and died in exile, without recovering any share of his inheritance. Previous to his death, he formally ceded all his right and title over the Valteline, Chiavenna, and Bormio, to the bishop of Coire, as a mark of gratitude for his protection. To this cession, at that time of no avail, the Grifons owe the possession of these provinces. The claim lay dormant for above half a century, until some discontent arising in the Valteline, in 1487, the Grifons made an irruption into that country, in support of the bishop's rights, but their arms not being at that time attended with success, they purchased a peace by renouncing all pretensions to the Valteline. They renewed, however, their claim in 1512, when Ludovico, called the Moor, duke of Milan, was taken prisoner by Louis XII.; and the whole Milanese, comprising the Valteline, occupied by that monarch. Upon this revolution, the Grifons, in conjunction with the bishop of Coire, entered the Valteline, and having expelled the French troops, took possession of the country: they were received with joy by the inhabitants, who did homage to their new sovereigns, and in return obtained from them the confirmation of all their privileges. A compromise was immediately entered into between the bishop of Coire and the three leagues to share between them the sovereignty of this country. In the following year, Maximilian Sforza, raised to the ducal throne of Milan upon the expulsion of the French, ceded in perpetuity the possession of the Valteline, Chiavenna, and Bormio, to the bishop of Coire, and the Grifons; and this cession was ratified by Francis I. in the treaty of peace which he concluded with the Swits and their allies, the Grifons, in 1516, when he obtained possession of the Milanese. In 1520, the republic of the Grifons acquired the whole dominion of the Valteline, to the exclusion of the bishop of Coire, under pretence that the latter had not furnished his quota of men and money in the war with James of Medicis, in defence of these ceded countries; accordingly they compelled the bishop to sell his share of the sovereignty over the Valteline, Chiavenna, and Bormio, for a yearly income of 575 florins, to be paid to the bishop and his successors out of the customs of Chiavenna. From that period, these provinces were possessed by the Grifons with molestation, until the rival interests of France and Spain, the intrigues of the pope, religious enthusiasm, the zeal of party, and the actions of the Grifon governors, kindled an insurrection, which commenced with a massacre of the Protestants, and raged for a series of years with the most savage and unrelenting fury.

During the constant wars, which from the accession of Philip II. the restless ambition of the Spanish court entailed upon Europe, the German and Spanish branches of the House of Austria were incomparably united; and the council of Vienna were directed by the cabinet of Madrid. Under these circumstances, the Valteline, which, by connecting the Tyrol and the Milanese, afforded the only secure passage for the junction of the Austrian and Spanish troops, became of signal importance.

The same reasons which rendered the Spaniards desirous to secure the Valteline, induced the French to obstruct their designs. The Spaniards, however, pursued their projects upon the Valteline without opposition, when they were freed from their most formidable rival, the count of Fuentes, governor of Milan, by assassination, and availed themselves of the domestic dissensions between the Grifons and the inhabitants. When all the Protestants were either destroyed or driven out of the country, the remaining inhabitants renounced their allegiance to the Grifons, and framing a new form of government, threw themselves under the protection of the king of Spain, who sent an army to their support. The people of Bormio followed the example of the Valteline, with this difference, that they did not massacre, but only expelled the Protestants. Having entered into an offensive and defensive alliance with the inhabitants of the Valteline, they also formed an independent commonwealth.

The Grifons, divided among themselves, were totally unequal to the chastisement of their revolted subjects. The Catholics were desirous of employing the mediation of Spain, for the purpose of recovering the Valteline; the Protestants, inclined to vigorous measures, proposed an application to the Swits cantons, Venice, and France. After violent dissensions, which were not terminated without bloodshed, the Protestant interest prevailed, and a deputation was sent to those powers.
When cardinal Richelieu acquired ascendency, and effected a revolution in the French politics, he perceived the importance of the Valteline, and adopted measures, which proved successful; so that in two campaigns the Spaniards were driven from the Valteline, Chiavena, and Bormio. Under the administration of Richelieu, it was agreed, that the Valteline should again be restored to the Grifons, upon the following conditions: no other religion but the Roman Catholic to be tolerated; the inhabitants to elect their own governors and magistrates either from themselves or from the Grifons, but always from persons of the Roman Catholic persuasion; and the governors to be confirmed by the Grifons. In return for these privileges, it was stipulated that the inhabitants should pay an annual tribute, the amount of which was to be settled by mediation. In consequence of this treaty, concluded on the 5th of March 1626, the French resigned the forts of the Valteline into the hands of the pope, and evacuated the country.

When Richelieu had completed the reduction of the Hugonots by the capture of Rochelle, he turned the whole force of France against the House of Austria; and among other enterprises, directed his attention to the Valteline; but the Grifons, encouraged and aided by the Spaniards, drove the French from the country; the treaty of Milan produced a close alliance between the Spaniards and the Grifons; and the Valteline was restored.

This treaty, contracted in the year 1635, secured to the Spaniards the passage of the valley, which was the great object of the war, and restored the Valteline, Chiavena, and Bormio, to the Grifons, under the following conditions: an act of oblivion; the immunities of the subject countries to be confirmed as they existed before the revolution of 1610; no religion but the Catholic to be tolerated; no person of any other persuasion to be permitted to reside, excepting the governors, during the two years they should continue in office, and the Protestant nobles of lands, who should not be allowed to remain in the country above three months in the year; the privileges of the ecclesiastics to be restored in their full latitude.

Since the pacification of 1637, no material change took place in the state of affairs. The sovereigns of Milan have always cultivated the friendship of the Grifons; and the inhabitants of the Valteline endured a regular course of tyranny under the government of a free state; confirming a fact notorious in the annals of ancient Greece, that no people are more oppressed than the subjects of a democracy.

During the progress of the French revolution, Bonaparte confirmed the union of the revolted provinces with the Cisalpine republic; so that after a period of nearly three centuries, the Valteline, Chiavena, and Bormio, were again incorporated with the Milanese under a republican government; but the expulsion of the late French emperor has restored the ancient arrangements in Italy, and the Valteline returns to its former possessions. VALVA, in Geography, a town of Naples, in Abruzzi Citra, the fee of a bishop; 18 miles S.S.W. of Civita di Chieti.

VALVANO, a town of Naples, in Principato Citra; 6 miles N. of Cangiano.

VALVASONE, a town of Italy, in Friuli, on the Tajo; 14 miles W.S.W. of Udina.

VALVASOR, or VALVASOUR. See VAVASOR.

VALUATION OF Land, in Agriculture and Rural Economy, the business of ascertaining its real worth. It is an undertaking which requires considerable knowledge of the nature and application of all sorts of landed property, as well as of the various improvements of which they are capable by cultivation and different other means.

It is necessary, before entering upon it, that the nature of the tenure, title, and other matters should be well understood. The writer of the work on "Landed Property," however, supposes, that the value of the free, or pure freehold tenure, being properly ascertained, that of any inferior sort of holding may readily be found from it, by means of the general rules of calculation: but that the free, or pure freehold tenure, is worth in another sense not merely, though principally, on account of the rental value, or the current price they will let for to tenants in different situations; but through other less permanent caucaes; such as the quantity of land at market; the number and importance of the demands for it in the given district; as well as the spirit which prevails in it at the time, in regard to the temporary polleflation of landed property at the particular period.

There are circumstances that are constantly worthy of the attention of those whole views in the obtaining of land are not confined to any particular spot or district.

It is fixed, that the usual method of coming at the free, or pure freehold tenure, is first to ascertain the fair rental value or price by the year, and to multiply this by the number of years' purchase which the existing demand for land will bear, in the given situation, at the time. But that the number of years' purchase, or the ratio between the rent and the value of lands, varies greatly, as from 20 to 40, 25 to 30 being the more ordinary numbers. Consequently, a parcel of land, the fair rental value of which is 100l., is, in common cases, worth from 2500l. to 3000l. But the real rental value, which is the only true and firm groundwork to proceed upon, whether in the purchase or the management of landed property, cannot be easily obtained. Speaking generally of the lands of this country, it is, it is thought, what very few men are able to set down. It is true, that, in almost every district, or almost every township, there are persons who tolerably well know the rate at which the lands of their respective neighbourhoods are usually let. But reciprocally interchange them into each other's districts, and their errors would, it is said, be egregious. Nor can a mere provincialist, especially in a district which is unenlightened by modern improvements, be aware of the value even of his own farm, under the best course of management of which it may be capable: nor can he see, through the double veil of ignorance and prejudice, the more permanent improvements that may be made upon it, so evidently as one who has a more general knowledge of rural subjects and concerns, and is in the habit of discovering and prosecuting such improvements. It is consequently necessary to have different persons to accomplish the business in a complete manner in many instances.

The particular circumstances that require to be considered as giving value to land, are chiefly these: 1. The quantity of
of the land, which is the ground-work of the calculation; though it has little weight in the scale of valuation. The fee-simple value of an acre of land may be less than twenty shillings, or it may be more than an hundred pounds. Nevertheless, it is on the quantity the rental value is calculated; and it is usual for the person who pays it to exhibit a "particular" of the estate or property on its dispoal: shewing, or which ought to be shewn, not only the aggregate quantity, but the number of acres that each piece or parcel contains, as well as other matters; and ought, most particularly, to specify the distinct quantities of the lands of different qualities; in order that their several rental values may be ascertained with greater ease and accuracy.

2. The intrinsic quality of the land, which is essential in forming the estimate. But even this, in a general view of the value of lands throughout the kingdom, is often, it is said, of secondary consideration: for, in many cases, their values are given by situation, rather than by soil and subfrata. In some cases, as has been seen, the value of the situation may be a great many times more than that of the intrinsic value of land. But this excessive influence of situation is, however, limited in its effects, and is chiefly confined to the environs of large towns, and other extra-ordinary markets for produce of the farm-kind. A great majority of the lands of this country owe their values less to situation than to intrinsic quality; and to come to this with sufficient accuracy, is the most requisite, and, at the same time, the most difficult part of valuation; as it depends almost wholly on extemporary judgment, exercised on the frequently few data which rise to the eye in passing over the field of estimation. It is therefore, almost needless to state, that to acquire the degree of judgment which is necessary to the execution of this difficult critical task, it is required to know and be perfectly acquainted with the nature and productiveness of lands of different appearances: a sort of knowledge which scarcely any thing but mature practice in the cultivation and use of lands of different qualities can sufficiently teach; though long habit may do much in ordinary cafes towards hitting off the value of lands, without an extensive knowledge of the practice of agriculture.

There are cafes, however, it is said, in which both of these qualifications are found insufficient to give any accuracy of judgment, even among provincial values of land. And a person who ventures to leap forward as an universal valuer, should have either an extraordinary talent for the purpose, or should, after a suitable initiation, have had great experience in rural concerns in different parts of the kingdom.

3. The situation; which, although it has been already stated, that the value of the lands of this country, aggregatedly considered, depends less on situation than on intrinsic quality, yet in every part it has great influence. Thus, an acre of land, the intrinsic quality of which renders it, in an ordinary situation, in what regards locality merely, worth twenty shillings the acre, would not, if it is observed, in some districts or places, be worth more than fifteen shillings, while in others it would bear to be estimated at twenty-five shillings, or even a higher price of rent, to a farmer on a large scale, and away from the immediate environs of a town, or any populous district of manufacture; for reasons that will be seen in examining the different particulars of situation. In the temperature of situation too, whether it be given by elevation, aspect, or exposure, a powerful influence is found, which is capable of altering exceedingly the value of lands. The fame sort of soil and subsoil, it is said, which is not unfrequently seen on exposed mountains, and hanging to the north, and which in that situation is not worth more than five shillings an acre, would, if situated in a sheltered vale tract, and lying well to the sun, be worth twenty shillings, or a greater rent. Even on climate, something considerable in this business, it is thought, depends. In the southern part of the country, the harvest is, in general, a month earlier than in those of the north; though it is not regulated exactly by the climate, or the latitude of the places: this is consequently a circumstance that requires to be attended to by those who estimate the values of estates or lands. For an early harvest is not only advantageous in itself, but gives time to till the ground, or to take an autumnal crop, which are advantages that a late harvest will not so well admit of being had. And another kind of temperature of situation has still, it is supposed, more influence on the value of lands, which is that of the moistness of the atmosphere. A moist situation not only gives an uncertain and often late harvest, but renders it difficult and hazardous; as is so frequently experienced on the western coastal-plies of this island. Even in the turn of surface, exercise is found, it is said, for the judgment. Lands lying with too deep or too flat surfaces, particularly when of the arable kind, and retentive, are of less value than those which are greatly shelving, so as to give a sufficient discharge to surface-water, without their being difficult of cultivation. Steep-lying lands are not only troublesome and expensive under the operations of tillage, but in taking out manures, and getting off the produce. Lands lying with an easy descent, or on a gently billowy surface, may be worth more by many pounds an acre in the money they will bring, than others of the same intrinsic quality, hanging on a steep. Another consideration of the same weight in valuing an estate, or other landed property, is a supply of water for domestic purposes, for the uses of live-stock, and for the purpose of irrigation. There are situations, it is said, in which a copious stream of calcareous water would enhance the fee-simple value of a large estate some thousand pounds. Likewise a sufficient supply of manure, whether dung, lime, marle, or other melioration, being at a moderate price, and within a moderate distance of land-carriages, materially adds to the intrinsic value of lands. And the established practice of management of the district or county in which an estate or land lies, is capable of enhancing or depressing the value of it exceedingly. Even the single practical point of ploughing light and loamy lands with two oxeen, or two active horses, instead of four heavy ones, is capable of making a difference, on good land which is kept alternately in herbage and corn-crops, of from five to ten shillings a year, on the acre; or ten pounds an acre in the money value which it is worth.

The price of labour is also flated as another regulator of the marketable value of land in a given district. It is always right, however, to compare this with the habits of exertion and industry which prevail among farm workmen, before the next amount of labour can be safely let down. The price of living too, or exigence of house-keeping, prevalent among farmers, has its share of influence on the value of lands. In the more recluse parts of the north of this country, the farmers, especially of the lower and the more inferior claes, and their servants, are fed, clothed, and accommodated, at nearly half the exigence of those of a similar degree in many parts of the more central and southern districts. In a county where frugality prevails too, lands of a given quality will ever, it is laid, bear a higher rent than they will where a more profuse manner of living has gained a footing. Hence, likewise, the spirit of improvement, or the prejudice against it, which prevails in a district, is a circumstance of some value, it is supposed, in this intention. For
if the former be in a progressive state, especially if it be still in the more early stages of its advancement, a rapid increase of rent may, with a degree of certainty, be expected: whereas, under the leading influence of the latter, half a century may, it is thought, pass away before the golden chariot of improvement can be profitably put in motion. And lastly, may be noticed, it is said, the attractive centre to which the labours of the husbandman will ever tend,—markets, in which, more than in any other circumstance, we are to look for the existing value of lands. Their influence is not confined to towns and populous places of manufacture, for in ports, and on quays, whether of inlets, estuaries, rivers, or canals, markets are met half way: even by good roads their distance from the farm-head may be said to be shortened.

In this detail of the particulars of situation in respect to the value of landed property, it is observed, the attention requisite to be employed by a valuer who is called upon to act in a county that is new to him is perceived. A provincial, or even a professional valuer, who acts in a district, the existing value of the lands of which he is sufficiently acquainted with, determines at sight, and according to the hold of his judgment, on their respective values: for he knows, or ought to know, their current prices; what such and such lands let for in the neighbourhood; what he and his neighbours give, or would give, for lands of the same quality and state, without advertizing to the particular circumstances of the situation, they being considered and given as the established amounts arising out of them; refting his judgment solely on the intrinsic quality and existing state of each field or parcel as it paffes under his eye. But let his skill be what it may in a county or district in which he has acquired a habit of valuing lands, he will, in a distant part or district, the current market prices of the lands of which may be ten, twenty, or fifty per cent. above or below those: which he has accustomed to put upon lands of the same intrinsic qualities and existing state, find himfelf at a loss; until he has learnt the current prices of the place or county, or has well weighed and considered the circumstances of situation: to which, in every case, he must necessarily attend, before he can determine their value under an improved practice, or venture to lay down general rules for their improvement.

4. Another class of circumstances which influence the marketable value of lands still remains, it is said, to be enumerated and considered. These relate to their existing state, or the manner in which they lie at the time. Their state in respect to inclosure is a matter of great consideration. Open lands, though wholly appropriated, and lying well together, are of much less value, except for a sheep-walk, or a rabbit-warren, than the same lands would be in a state of fituitable inclosure. If they be disjoined and intermixed in a state of common field, or common meadow, their value may be reduced one-third. If the common fields or meadows be what is often termed Lannister land, and become common as soon as the crops are off, the depression of value may be felt down at one-half of what they would be worth in well-fenced inclosures, and unincumbered with that ancient custom. The difference too in the value between lands which lie in a detached state, though within well-fenced inclosures, and those of the same quality that lie in a compact form, or, in the familiar phrase, within a ring-fence, is considerable. The disadvantages of a scattered estate are, it is said, similar to those of a scattered farm. Even the single point of a want of convenient access to detached fields and parcels is, on a farm, a serious evil. And it is on the value of farms that the value of an estate or land is to be calculated. The state of the roads, whether public or private, within an estate, and from it to the neighbouring markets, or places of delivery of produce, is further an object of consideration. And in this view, the state of the water-courses, or fewers and ditches, within and below an estate, likewise requires to be examined into; as the expense of improvement or reparation will be more or less, according to their existing state at the time; or, perhaps, by reason of natural causes, or through the obliquity of a neighbour, and the defective nature of the present laws of the country in this respect, the requisite improvements cannot be effected at any expense. The state of drainage of lands that lie out of the way of floods, or col-lected water, requires also to be taken into consideration. For although the art of draining be now pretty well understood, it cannot be practised on a large scale, without much cost. The state of the lands too, as to tillage and manure, is entitled to more regard than is generally bestowed on it, in valuing them. But even to a purchaser, and still more to a tenant for a term, their state in these respects demands a share of attention. Lands that are in a high state of tillage and condition, so as to be able to throw out a succession of full crops, may be worth five pounds of purchase-money an acre, more than those of the same properties, which are exhausted by repeated crops, and lie in a useless state of founfees; from which they cannot be raised, but at a great expense of manure and tillage. Their state, as to grazs or arable, is, it is thought, better understood, and generally more attended to. Lands in a state of profitable herbage, and which have lain long in that state, are not only valuable as bearing a high rent while they remain in that condition, but, after the herbage has begun to decline, will seldom fail to throw out a valuable succcession of corn-crops.

Hence the length of time which lands, under valuation, have lain in a state of herbage, especially if it has been kept under pasturage, is a matter of inquiry and estimation in the execution of business of this sort. And, lastly, the state of farm buildings and fences is, it is conceivable, a thing of serious consideration. Buildings, yards, and inclosures, which are much let down, and gone to decay for want of timely reparation, incur a very great expense to raise them again to their proper state. And when great accuracy of valuation is called for, as where the purchase value of an estate is left to reference, and when the tenants are not bound, or if bound are not able, to put them in the required state, it becomes requisite to estimate the expense which each farm, in that predicament, will require to put it in sufficient repair, so as to bring the whole into a suitable state of occupation. This comes, however, more properly under the head of deductions, encumbrances, and outgoings, which are considered below. The same principle of valuation as the above holds good too in ordinary cases.

In speaking of encumbrances and deductions, it is said, that it appears, by a long lease, that the fee-simple value of an estate may be in effect annihilated. Even a lease for lives, with a mere conventional rent, may reduce it to nearly one-third of its fee-simple value. And every other kind of lease, if the rent payable be not equal to the fair rental value at the time of the disposition, is an encumbrance, even to a purchaser who has no other object in view than that of securing his property on land, and receiving interest in rent for the money laid out. If personal convenience be immediately wanted, or improvements required to be done, a lease, though the tenant pays a full rent, becomes an obstacle to the purchase, and is consequently to be considered in fixing the value. And an error, which is not unfrequently committed in estimating the encumbrance of a lease for
for a term of years, is here, it is said, to be noticed. The difference between the lease rent and the full rental value, encumbered with the same outgoings and repairs as the lease rent, being ascertained, it is multiplied by the number of years unexpired, and the produce is in full deducted from the value of the land, free from such encumbrance. But from the produce, thus found, ought to be deducted half the interest thereof, during the said number of years, together with that of one half-year over, if the rent be payable half-yearly, or of one year, if payable annually. For all that a purchaser has a right to expect is to receive the full rent for his land, during the continuance of the lease. The tenant pays him what the lease stipulates; and if the seller were to make up the remainder, at the end of every six or twelve months, whenever the tenant is to pay his part, the purchaser would receive the full rent, the same as if no encumbrance had existed. But if the seller pay down the whole sum in ready money, at the time of the sale, which in effect he does, he is certainly entitled to some discount for prompt payment. Thus, supposing the difference of rent, occasioned by the lease, to be ten pounds a year, and the length of the term to run to be ten years, the produce would be one hundred pounds. And supposing, for the sake of calculation, the stipulated payments to be annual, the interest to be deducted would be the half of fifty pounds, (the interest of one hundred pounds for ten years, at 5 per cent.) with the half of five pounds (one year's interest), together amounting to twenty-seven pounds ten shillings; which being deducted from one hundred pounds, the gross produce, leaves seventy-two pounds ten shillings, the clear sum to be deducted. And the truth of this rule of calculation may, it is thought, be familiarly proved; for if the seller were only to pay the deficiency of rent, as it should become due, he would, during the first year, hold the whole hundred pounds in his hands, the interest of which, at 5 per cent., is 51.

| The first ditto | 500 |
| The second ditto | 410 |
| The third ditto | 300 |
| The fourth ditto | 120 |
| The fifth ditto | 100 |
| The sixth ditto | 40 |
| The seventh ditto | 30 |
| The eighth ditto | 20 |
| The ninth ditto | 10 |

In respect to tithes, where in valuing lands they are considered as tithe-free, the tithe or modus, if any, requires to be deducted, as an encumbrance; and from the great variation in the values of tithes and moduses, according to custom, and plans of occupation, it is the plainest way of proceeding to value all lands as free of tithe, and afterwards to make an allowance for whatever they may be estimated to be worth. In regard to taxes, too, although it may be called the custom of the country for proprietors to pay the land-tax, and the occupier all the other taxes; yet this is not the universal practice; nor is it, in valuing an estate on sale, to be let at will, a matter to be inquired into. The annual amount of payable taxes, and other outgoings, are the facts to be ascertained: for who soever discharges them, they come as a burden upon the gross value of the lands, out of which they are payable. For if a tenant pay them, his rent is, or ought to be, estimated and fixed accordingly. But if an estate on sale is already let under lease, for a term to come, it is highly requisite to ascertain what parts of the annual outgoings and repairs are discharged by the tenants, and what the proprietor will be liable to, during the term to run. The land-tax, where it still exists, is extremely uncertain as to its value; and the poor-tax is generally varying in different situations. The church, highway, and county rates are, taking them on a par of years, liable to local uncertainty, and are consequently levied to be adjusted, by a value of lands. And the fixed payments, or rent charges, such as chief rents, quit-rents, annuities, endowments, schoolmasters' salaries, charitable donations, and others of the same kind, to which an estate is liable; also repairs of public works, buildings, roads, &c. incumbent on the estate, are subjects of inquiry and estimation; as well as the ordinary repairs. Further, too, the hazard or risk under valutation, as that of their being liable to be inundated in summer, or to be torn away by floods at any season, is entitled to mature consideration. For although these evils may generally be remedied by river-breaks and embankments, the erecting of them is mostly attended with great expense; and the estimated value of this becomes, in course, a fair deduction to be considered by the land-value. It is noticed that there are two practical methods of valuation, with respect to taxes and other outgoings, as in regard to tithes; namely, either to set down the gross value of the lands, and then to deduct the outgoings; or to view them under their encumbrances, and to estimate in a summarily way their net rental value. The latter is the more general, but the least accurate, manner of performing the business.

This, it is laid, is what relates to the purchase value of the lands, but that, appertaining to an extensive estate, there are generally other valuable considerations; as minerals and foils, whether metals, fuels, calcareolities, or groferer earths; waters, whether they are valuable for fisheries, ditches, mills, domestic uses, or the irrigation of lands; and timber, as of woods and hedge-rows. Buildings, too, that are not let with the farms, but which bear rent, independent of the lands; which, when scattered over an estate, may well be considered as belonging to landed property. To these may be added, the estimated value of evident improvements: and, lastly, the abstract rights which arise out of appropriated lands, or their appurtenances, as the right of commonage, which is generally of some value, even when commons be open, and may be of more, when they shall be inclosed; provided the cost of inclosure do not turn out to be more than the extra value of the appropriated lands, above that which naturally or fortuitously attends the lands of the common right in their open state. The right of seigneur to fee-farm rents, or other chief rents, payable to the seigneur of lands on sale out of the lands of other proprietors. These rents, though small, are of certain value in themselves; and the idea of seigneurity, which they convey to the minds of some, may be worth more than the pecuniary value; which indeed, where the sums are very small, as is often the case, is much lowered by the expense of collecting them. The rights of feudality, or manorial rights, are at present, if not in their original, very different from those last mentioned; and the value of which is to be estimated by the quit-rents, fines, heirlooms, advowments, and small payments, which long custom and a train of circumstances have attached to the given court. And beside what relates to the appropriated lands of the manor, the lord has a profit arising from the comminable lands, if they lie within it, as lord of the soil; which cannot be broken without his permission: hence the minerals and foils which it covers belong to him, as well as the timber which grows upon the waste, and the waters
winters that are connected with it. Moreover, in ordinary cafes, he is lord of the game which inhabits or roams upon his manor. This being, however, a right of pleasure rather than profit, has no fixed standard of estimation. The right of title, when attached to an estate, is the most definable of abstract rights arising out of landed property. For as far as the right extends, whether to a lay rector or a vicarial proprietary, the lands which it covers becomes in effect title-free; as every judicious proprietor incorporates the rents of the title with those of the lands out of which it is payable; thus, if the right, as it generally is, be rectorial, freeing them wholly from the encumbrance of tithes, as a tax on improvements, and as an obstacle to the growth of grain. The right of advowson, or the privilege of appointing a pastor to propagate religion and morality upon an estate, properly enough belongs to its possessor; as no other individual is so intimately concerned in the moral conduct of its inhabitants. The right of representation, or election, or the appointment, in whole or in part, of a legislator to assist in promoting good order in the nation at large. And what else of the community, it is asked, can produce a fairer claim to this right than the proprietors of the country? The value of these rights is left for others to estimate and determine. See Timber and Tithes.

The chief circumstances to be considered having thus been pointed out, and their importance and influence explained, in concluding the subject it may be observed, that the difference between the particulars that give value to a landed estate, and the encumbrances to which it is liable, is the net value of the property under valuation.

VALUE, Valor, in Commerce, the price or worth of any thing.

Value, Intrinsic, denotes the proper, real, and effective worth of any thing; and is used chiefly with regard to money: the popular value of which may be raised and lowered at the pleasure of the prince; but its real or intrinsic value, depending wholly on its weight and fineness, is not at all affected by the lamp or impression thereon.

It is generally on the foot of this intrinsic value, that species are received in foreign countries; though in the places where they are coined, and where the sovereign power makes them current, they sometimes pass for much more.

It is, in good measure, on the difference of those two values, one of which is, as it were, arbitrary, and the other, in some sort, natural, that the difference of exchanges depends; and those still rising and falling, as the rate at which a species is current, comes nearer or farther off the just price of the metal of which it consists.

Value, in Bills of Exchange, is used to signify the nature of the thing (as ready money, merchandizes, bills, debts, & c.) which is given, as it were, in exchange for the sum specified in the bill.

From four different manners of expressing this value, some distinguished four kinds of bills of exchange. The first bears value received, simply and purely, which comprehends all kinds of value; the second, valued received in money or merchandizes; the third, value of myself; and the fourth, value underfoot.

The first is dangerous, and the fourth but little used: accordingly, to have the value well expressed, and to prevent the ill consequences of overfights therein, it is well provided by the French ordinance of 1673, that bills of exchange should contain the name of the person to whom the contained sum is to be paid; the time of payment; the name of him who has given the value; and whether it was received in money, merchandize, or other effects.

VAL, Valor, or Valen'tia, in Law. Well gives us a nice difference between value and price; the value (lase he) of things in which offences are committed, is usually comprised in indictments; which seems necessary in theft, to make a difference from petty larceny; and in trespasses, to aggravate the fault and increase the fine.

But no price of things Fere nature may be expressed, as of deers, hares, &c. if they be not in parks or warrens. And where the number of things taken is to be expressed in the indictment, as of young doves in a dove-house, there must be said preti, or Ad valentiam: but of divers dead things, ad valentiam, and not pretii: of coin not current, it shall be said preti; but of coin current, neither pretii nor ad valentian; the price and value being certain.

VALVE, VALVULA, formed from valve, folding-doors, in Hydraulics, Pneumatics, &c. is a kind of lid, or cover, of a tube or vessel, so contrived as to open one way; but which, the more forcibly it is prefed the other way, the closer it shuts the aperture: so that it either admits the entrance of a fluid into the tube or vessel, and prevents its return; or admits it to escape, and prevents its re-entrance. For water, these valves are the belft which intercept the passage leaf; and none appear to answer this purpose better than the common clack-valve of leather, which is generally wireless, or divided into two parts; but it is sometimes composed of four parts, united so as to form a pyramid, nearly resembling the double and triple valves which are formed by nature in the hearts of animals. A board, or a round flat piece of metal, divided unequally by an axis on which it moves, makes also a very simple valve. Where a valve is intended for intercepting the passage of fluids, it must be of metal: such a valve is generally a flat plate, with its edge ground somewhat conically, and guided in its motion by a wire or pin. For air, valves are commonly made of oiled silk, supported by a perforated plate or grating.

Valves are of great use in the air-pump and other wind-engines; in which they are ordinarily made of pieces of bladder, or oiled silk.

In hydraulic engines, as the emboli of pumps, they are frequently of leather; the figure round; and they are fitted to shut the apertures of the barrels or pipes.

Sometimes they are made of two round pieces of leather, inclosed between two others of brass; having divers perforations, which are covered with another piece of brass, moveable upwards and downwards, on a kind of axis, which goes through the middle of them all.

Sometimes they are made of brass, covered over with leather, and furnished with a fine spring, which gives way upon a force applied against it: but, upon the ceasing of that, returns the valve over the aperture. (See Pump.) See also for the construction of different sorts of valves for the buckets of pumps, Délargiers, Exp. Phil. vol. ii. p. 156, &c.; and for the description of a new valve by M. Belidor, ibid, p. 180.

VALVE, in Anatomy. See VALVULA.

Conflantin Varolius, a Bolognefe, and phyfician of Gref-
striking with too much violence against that of the lower: and Mr. Winflow, who has considered it very diligently in the Memoirs of the Royal Academy of Sciences, is much of the same opinion.

But as it gradually dwindles in children, and at length becomes quite lost in adults, till diminishing as the foramen ovale does, it should seem to have some other office, and that chiefly regarding the circulation of the blood in the fetus.

In effect, by means of it, M. Winflow reconciles the two opposite systoles of the circulation of the blood in the fetus. See Circulation of the Blood, and Foetus.

Valve, in Gardening, the divided parts of a feed-veffel, or properly the external division of a dry feed-veffel, such as a capulce or pod; as in the pea, bean, vetch, and many others, which, when ripe, splits into two or more divisions, in order to throw out the contents, each of which divisions is denominated a valve. The valves of culinary vegetables are of several different kinds, according to the number of divisions, but principally of the univalve and bivalve kinds.

Valverde, or Val Verde, in Geography. See Is.

Valverde, a town in Spain, in New Castile; 20 miles S. of Cuenc.

Valverde del Camino, a town in Spain, in the province of Seville; 17 miles N.E. of Moguer.

Valverde de Fresno, a town in Spain, in the province of Leon, on the borders of Portugal; 24 miles N.N.W. of Cordia.

Valuki, a town of Raffia, in the government of Voronez; 103 miles S.S.W. of Voronez. N. lat. 50° 2'. E. long. 37° 44'.

Valuntuown, a town of the rate of Connecticut; 10 miles N.N.E. of Norwich.

Valvula, Valve, in Anatomy, a name given to various parts in the body. See Valve.

Valvula Collis, or Ile, the valve placed at the communication of the large and small intestines. See Intestine.

Valvula Conniventis, folds of the mucous membrane of the small intestine. See Intestine.

Valvula Eutachii, Nobilis, or Recticulata, a small fold at the entrance of the inferior vena cava into the right auricle. See Heart.

Valvula Magna Cerebri, or Veiculifera, a part of the brain. See Brain.

Valvula Mitralis, the valve of the left auriculo-ventricu-lar orifice of the heart. See Heart.

Valvula Semilunaria, or Discoides, valves placed at the entrance of the aorta and pulmonary artery. See Heart.

Valvula Tricuspidales, or Triglobina; the valve of the right auriculo-ventricular opening of the heart. See Heart.

Valvula Venarum, folds of the internal membrane of the veins, preventing the reflux of the blood. See Heart.

Vama, in Ancient Geography, one of the navigable rivers of India, which discharged itself into the Ganges. Pliny.—Allo, a town of Spain, in Bautica, belonging to the Bautic-Celtic. Ptolemy.

Vaman, in Mythology, a name or title of the Hindoo deity Vishnu. It means a dwarf; and was applied in consequence of an incarnation of Vishnu in this humble form. See the next article.

Vamanavatara, one of the ten grand incarnations of Vishnu; called, by way of pre-eminence, daftavatara, or the ten deities, to distinguish them from others of the same deity of less importance. As noticed under the article Vishnu, this manifestation was the fifth of the ten; but the first that occurred after the golden or virtuous age of the Hindoos. It was followed by a less virtuous age, in the course of which Mahabeli, a monarch reasonably virtuous, became so elated, that he omitted the essential ceremonies to the gods; and Vishnu, deeming it expedient to check the influence of such an example, resolved to punish the arrogant rajah. He, therefore, condescended to become the son of Kasyapa and Aditi; and, as the younger brother of Indra, was incarnated in the person of a wretched Brahman dwarf. (See Indra and Kasyapa.) Appearing before the king, he asked a boon; which being promised, he demanded as much as he could pace in three steps. Nor would he desire farther, though urged by Beli to demand something more worthy of the donor.

Mahabeli, it would appear, had resorted to some of these procresses; and the boon asked and yielded, was, as usual with mighty rajas, the sovereignty of the universe, which includes the three regions of the earth, heaven, and hell. To avert the effects of the abuse of this power, dangerous even to the gods, and to refuse their sovereignty, Vishnu resorted to the artifice we are describing.

On obtaining the king's promise, the dwarf required a ratification of it; which was done, as is still practiced, by pouring water on the hand of the suppliant. This Beli proceeded to do, though warned of the consequences; for not to ratify that for which his royal word was pledged.

As the water fell into his hand, the dwarf's form expanded till it filled the world; and Vishnu now manifesting himself, deprived Beli at two steps of heaven and earth; but he being, in some points, a virtuous monarch, left Patala, or the lower regions, still in his dominion. (See Patala.)

In this character, Vishnu is sometimes called Trivikrama, or Trivikara, meaning the three-step-taker. Beli, as king of the infernal regions, seems to correspond with Tama; which fee. Sir William Jones deemed this king the same with the Belus of western history. See Belus, and Mahabeli.

Writers of the sect of Vaishnava maintain, that the ratifying stream poured on the hand of Vishnu, was the origin or source of the river Ganga, or Ganges; which falling from the hand of the miraculous dwarf, descended thence upon his, now Vishnu's, foot; and, hence, expanding like its fount, it gushed a mighty river, and was received on the head of Siva. In pictures and carvings of the latter deity, the goddes Ganga is frequently seen half concealed in the folds of his hair, and Siva is hence named Gangadhara, or Ganges-bearer: a name assumed also by a class of itinerants who fell that holy water through the streets of all Indian cities; it being among Hindoos equal, in fum-expelling potentiality, to the holy water of papacy. This mythological source of the blessing and blessed river is a favourite subject with Hindoo poets.

In the Hindoo Pantheon, where this article is partly taken, are many legends connected with it.

In pictures of this avatara, the dwarf is usually represented receiving the water from the hand of Beli, through a spouted vessel; sometimes accompanied by the evil counsellor Indra, or Sakra, who is represented either with only one eye, or holding his hand before the other. As the regent of the planet Jupiter, named Vishkapatî, is the counsellor or preceptor to the gods and Suras; to Sakra is the adviser of the demons or Asuras; and is constantly watchful in counteracting the divine beings, and their endeavours for the good of man; and the pious endeavours likewise of holy men. To prevent the conferring power in this avatara from accomplishing the projected end, in the punish-
ment of impiety and arrogance, personified in Beli, Sakra apprized him of the deceit under which he was promoting the universe away. But as the monarch had too much pride to recant his royal word, the evil counsellor assumed the form of a mosquito; and intimidating himself into the spout of the vessel through which the satirical stream was to pass, arrested its passage; when the dwarf, taking a straw to clear it, thrust out the eye of the gnat, a defect ever after retained by Sakra in all shapes. It is said to indicate the half enlightenment of evil counsellors: still, when the one-eyed admirer of ill should be the thousand-eyed god, has not been explained. Nor will it, perhaps, be deemed worth while to enter into any lengthened explanation of the apparently ridiculous fables mentioned in this article; though we believe they might be explained from a consideration that all Hindoo history, religion, arts, and science, are buried in a mass of mythological legends. We will just mention, that the fabulous source of the Ganges, whether from the head of Siva, or from the foot of Vishnu, the latter being the principle of humidity, the former of heat, is merely a physical dispute between what in Europe would be called Neptunits and Vulcanists, but what in India assumes the form of theological controversy. Whether the Ganges be of volcanic origin, or descends from the eternal fountains of Nepaul, is perhaps the point here disputed between the Saivas and Vaishnavas. (See of this under the articles Siva and Siva.) As to the mosquito, Indra is the god of showers, regent of the firmament; closely allied to Vishnu, air being a form of humidity; and the mosquito partakes, like Vishnu, of both its forms; it is born, or repoves, like the god, in water, and lives in air. But we shall pursue these mythological allegories no farther.

One of the eighteen sacred poems, called Purana, is named after this avatar, (see Purana,) and details a great mass of poetical incident connected with it. The reader may perhaps smile in hearing that England is the supposed theatre of several of the incarnations of Vishnu, and of this of Vamana among them. On this point, we refer to the second article of the 11th volume of the Asiatic Researches.

VAMBA, in Geography, a river of Angola, which runs into the Coanaza, near Caboio.

VAMIGELA, in Ancient Geography, a town of Africa, in Mauritania Caxaricanis. Ptol.

VAM-KOSSE, in Geography, a small island in the Chinefne archipelago, where the celebrated St. F. Xavier was buried; 62 miles S.W. of Macao.

VAMPYRE, in Mythology, a name given to an imaginary demon, which, it is pretended, sucks the blood of persons during the night, and thereby destroys them. These vampires were supposed to animate the bodies of dead persons, which when dug up were found fresh, florid, and full of blood. Those who were killed by vampires were said to become vampires themselves: the way to destroy them was to drive a stake through them, at which time they would give a horrid groan; and to burn the body to ashes. This species of superstition occasioned, some years ago, great disturbances in Hungary and other places.

VAMPYRE, in Zoology, the Vespertilio vampyrus of Linnaeus, called also tormeas, and by Buffon la rougette and la rouget. is a species of bat with large canine teeth, four cutting-teeth above, and the same below; sharp black nose; large naked ears; tongue pointed, and terminated by sharp aculeated papilla; external toe detached from the membrane; the claw flrong and hooked; five toes on the hind-feet; talons very crooked, strong, and compressed sideways; no tail; the membrane divided behind quite to the rump; varying in colour, some being entirely of a reddish-brown, and others dusky; and also in size, some having the extent from tip to tip of the wings four feet, others five feet four inches; and others extending farther than a man can reach with his extended arms. This animal inhabits Guinea, Madagascar, and all the islands from thence to the remotest in the Indian ocean. They are also found in New Holland, the Friendly Islands, the New Hebrides, and New Caledonia. They fly in flocks, obfuscating the air with their numbers; beginning their flight from one neighbouring island to another, immediately on fun-fet, and returning in clouds from the time it is light till fun-rice, and during the day lodging in hollow trees: they live on fruit, and are so fond of the juice of the palm-tree, that they will intoxicate themselves with it till they drop on the ground. In New Caledonia, the natives use their hair in ropes, and in the taffels of their clubs. The Indians eat them, and declare their flesh to be very good. The French who live in the Ile de Bourbon, boil them in their bouillon, to give it a relish. While they are eating, they make a great noise; their feet and their bite, relishance, and fierceness, very great when taken. The ancients had some knowledge of these animals, and M. de Buffon apprehends, that from the account of them the poets formed their fictions of harpies. Linnaeus calls this species vampyre, conjecturing it to be the kind which draws blood from people in their sleep. The bat is so dexterous a bleeder, as to intoxicate its aculeated tongue into the vein without being perceived, and then suck the blood till it is fatigued; all the while fanning with its wings, or agitating the air so as to cast the sufferer into a silll funder sleep. In certain parts of America they have destroyed all the great cattle introduced there by the missionaries. Pennant's Hist. Quadrupeds, vol. ii. p. 548, &c.

VAMPYRE is also a name given by M. de Buffon to the vespertilio spectrwm of Linnaeus, or bat with a long nose, large teeth, long, broad, and upright ears; with a long, conic, erect membrane at the end of the nose, bending at the end, and flexible; hair on the body cinerous, and pretty long; wings full of ramified fibres; a membrane extending from one hind leg to the other; no tail, but three tendons extending from the rump, and terminating at the edge of the membrane. This animal inhabits South America, lives in the palm-trees, and grows very fat. Buffon supposes it to be the species that sucks human blood. Pennant. See Andira.

VAN, VAN, of Vanent, (of the French avent, or avant, before,) is the term used in composition with several words in our language. As,

VAN-Couriers, are light armed soldiers, sent before armies to beat the road, upon the approach of an enemy.

VAN-Poufs, a ditch dug without the counterfcarp, and running all along the glaciers; usually full of water.

VAN, or Vannt-Corps. See Corps.

VAN, or Van-Guard. See Guard.

VAN-Lay. See Vaunt.

VAN, in Agriculture, a name sometimes used to signify an implement or contrivance for winnowing, or cleaning corn with. See Winnowing Machine.

VAN, in Sea Language, denotes the foremost division of any naval armament, or that part which usually leads the way to battle, or advances first in the order of failing. See Engagement and Fleet.

VAN, in Mining. To make a van, is to take a handful of the ore or tin-fluit, and bruife, wash, and cleanse it on a shovelf; then, by a peculiar motion of the shovelf, to shake and throw forth upon the point of it almost all the ore that is freed from waife. This operation being repeated, the ore
is collected and referved, and from thence they form an
effimate how many tons of copper ore, or how many hundred
weight of block-tin, may be produced out of one hundred
facks of that stuff, of which the ore is made. Pryce's

Van. (Artemia), in Geography, a city of Armenia, situated
five miles from a lake of the same name. It is surrounded
with a good wall and deep ditch, and has four gates. On the N.
is a castle, built on a high and perpendicular hill, which rifes
abruptly from the plain. This fortress can only be ap-
proached by one passage, so narrow as to admit only two
persons abreast; it is always supplied with corn and military
stores, and in the centre of the work stands the palace of the
aga of the janizaries. This city is abundantly furnished
with water and provisions; the houses are built of stone and tile;
the streets are spacious and well paved, and the population is
said to number 50,000 souls, of whom number two-thirds
are Turks, and the rest Kurds and Armenians. The air is
pure, and the environs of the city delightful. It is four
days' journey from Bayazid, a city of one of the Turkish
pachalics of Armenia, twelve from Erzeroom, another of
them, five from Batsik, and about the same distance from
Khoi.

The lake (Arshis of Ptolemy) is about 168 miles in cir-
cumference; and although the water is more sweet than that
of Urumea, it is so brackish as to be unfit for the common
purposes of life, according to the common opinion, though
some fay it is very good. There are four islands in the lake,
one of which is an Armenian monastery, and 300 pilgrims.
The traffic of the surrounding country is carried on by about
20 or 30 small boats, N. lat. 58°. E. long. 43° 55'.

On the N.W. side of the lake, three days' journey from Van, is
Argih (the ancient Arzes), containing 6000 inhabitants.
And in a westerly direction from Argih is Moodh, the ancient
Moxocon, occupying a small eminence, washed by the
Emirates, over which is a bridge of 15 arches, badly built,
and thinly inhabited, but situated in a country entirely fertile
and populous. The natives of this district, amounting to
about 80,000 souls, of which 12,000 are Yezidis, are a
base and degenerate race. Tobacco and maconia are exported
from hence in considerable quantities. McKinnon's Map
of Persia.

Van, a town of Norway, in the province of Aggerhus;
20 miles N. of Christiana.—Alto, a river of South Wales,
which runs into the Bristol Channel, about 5 miles below
Cowbridge, in Glamorganshire.

VANAHON, a river of America, which runs into lake
Michigan, N. lat. 42° 52'. W. long. 89° 10'.

VANAMALI, in Mythology, a name of the Hindoo
god Krijna; which see. This name is said to be derived from
a pendent garland of flowers, with which this
proceicmea deity is usually decorated. In the following
paffage he contrives his appearance, thus decorated, with that of
Mahefa, or Siva.

"I am not the terrible Mahefa: a gar-
land of water lilies, with subtile threads, decks my thou-
ders; nor ferpents with twisted folds: the blue petals of the
lotos glitter on my neck; not the azure gleam of poison:
powdered sandal-wood is sprinkled on my limbs; not pale
ashes." This is addrefed to his enchanting mulletes Radsb,
under which article a farther extract from the same "Song"
will be found. The gleam of poison on his neck alludes
to his having drank the poison produced by the churcan of
the ocean, as described in our articles KURMAVATARA and
SHITAKOONTHA; and being powdered with ashes, is noticed
in the latter part of the article SECTS of Hindoo.

VANANCOUPAN, in Geography, a town of Hindoo-
flan, in the Carnatic; 15 miles S.W. of Trivady.

VAN-BALEN, in Biography. See BALE.

VANBRUGH, Sir John, a dramatic writer and an
architect, was a descendant of an ancient family in Chehire,
and was first known to the public as an officer in the army,
being confidered as a man of wit and a pleasant companion.
The first play which he finifhed was "The Relapse,"
and it was acted with great succefs in 1697. This was
followed, in the succeeding year, by "The Provoked
Wife," and in the fame year appeared his "Epif",
blending humour with satire and useful morality. In
1702 appeared his "False Friend," and he was now
knighfed, and advanced to the polt of Clarenceux king-
arms. When a theatre was erected in the Haymarket,
it was placed under the management of Vanbrugh and
Congreve by Betterton and the other paten ties; and it
was opened in October, 1705, with a comedy by Vanbrugh,
titled "The Confederacy," which, though the best
written, is the most licentious of this author's dramatic pro-
ductions, besides three more pieces, imitated from the
French; but finding the concern irkome, he difpofed of
his share. The popular comedy of "The Journey to
London" was begun by him, but finifhed by Cibber.
In speaking of Vanbrugh, Pope has blended praise with cen-
scure, when he fays,

"How Van wants grace, who never wanted wit.'

His taste and talents as an architect were firft exhibited
in the theatre in the Haymarket, for which he obtained sub-
scriptions; and to him was committed the erection of the
palace of Blenheim, voted by the nation to the duke of
Marlborough. In 1716, king George II. appointed him
surveyor of the buildings at Greenwich-hospital, com-
troller-general of the royal works, and surveyor of the gar-
dens and waters. On a visit to France, he employed himfelf
in taking views of the fortifications in that kingdom, which
caufed him to be apprehended and committed to the Bafville;
but when he was obferved to amufe himfelf in prison by
making sketches of comedies, he was liberated, as a har-
rifing perfon, without any application from home in his favour.
As an architect, he was engaged to build feveral great
houfes in England, besides Blenheim; but in this capacity
he has unfortunately been transmitted to posterity rather as an
object of ridicule than of admiration. Mr. Walpole has
paffed upon him a fevere cenfure, when he fays that "he
wanted all ideas of proportion, convenience, and propriety.
He undertook vafli designs, and compos'd heaps of little-
nels. The fyle of no age, no country, appears in his
works; he broke through all rule, and compounded for it
by no imagination. He feems to have hollowed quarries
rather than to have built houfes; and should his edifices, as
they feem formed to do, outlive all record, what architec-
ture will posterity think was that of his anccftors?" The
following epigrammatic epitaph was written for Vanbrugh
by Dr. Evans, and accords with the above character of his
works:

"Lie heavy on him earth, for he
Laid many a heavy load on thee.'

Notwithstanding the obloque above cited, some modern
amateurs have vindicated the character of Vanbrugh's archi-
tecture, particularly that of Blenheim, admiring its gran-
deur, and the magnificence of the whole, as well as the
picturesque variety displayed in this and in other of his
buildings.

In society Vanbrugh bore a respectable character, and
had no personal enemies. Swift and Pope have expreffed
their wilh, that they had not indulged their raffleony against
one
with inhabitants, they soon afterwards pursued an eastern route, and driving out the Scavi, who occupied the territory that lay between the Bosphorus Cimmerius and the Tanais, and taking possession of their country, assumed the appellation of the ancient inhabitants. Some of them, several ages after, in the reign of Mauritius, which began in 586, settled in Dalmatia and Illyricum, to which they gave the name of Scalvonia; and others migrated to the eastern parts of Dacia beyond the Danube, a province which comprehended the countries now denominated Transylvania, Moldavia, Walachia, and the eastern parts of Upper Hungary. From those who remained in Germany, the present Poles and Bohemians are generally said to have derived their origin; but the Vandals, who, under Godegisius, their king, entered Gaul, and afterwards settled in Spain and Africa, came, as Procopius says, from Dacia and the vicinity of the Palus Mæotis. As the Vandals were a Gothic nation, they retained the customs, manners, religion, and form of government, that subverted among the Goths. The first of their kings mentioned in history is Godegisius, under whose command they entered Gaul in 406. He was succeeded by Gunderic, who puffed, in 409, from Gaul into Spain, and settled in Galiaca. His successor, Geniferic, abandoned Spain in 428, and passed with his vaifes into Africa, which the Vandals possessed till the year 533, when, under Gelimer, an end was put to their dominion by Belisarius, and Africa was reunited to the empire. Although the Vandals are said to have been inferior in power and courage to all the other barbarous nations, they nevertheless made themselves masters of the most fertile provinces of the empire. They became profiteers to Christianity at the same time with the Goths, embracing the sentiments of Arius, in common with the other Goths, and becoming irremovable enemies to the Catholic church. Salvianis extols their continence and chastity.

It was about the year 166 that they began to be troublesome to the Romans, in the reign of M. Aurelius and Lucius Verus; when forming an alliance with other barbarous nations, they invaded the empire, plundered several cities, and, having put to flight the Roman armies, committed every where unparalleled ravages. Having taken possession of Pannonia, they retained it till they were expelled in the year 170, by M. Aurelius. They afterwards entered into an alliance with the Romans; and in 180, it was one of the articles of peace concluded between the emperor Commodus and the Alemans, that they should not make war upon the Vandals. In the second year of Aurelian's reign, A.D. 271, the Vandals puffed the Danube, laying waste the neighbouring provinces; but Aurelian compelled them to retire with great precipitation, and having overtaken them in their retreat, obliged them to sue for peace; which was granted, on condition of their delivering, as hostages, the sons of their two kings, and other persons of distinction. Two thousand of their best men were incorporated among Aurelian's own troops. After his death, they entered Gaul; but they were defeated by Probus in several battles, and obliged to withdraw themselves at the approach of the Roman army. Refuting the infatuts of the Roman soldiers, they made an attempt to recross the Rhine, but sustained a great defeat; and proving unfaithful to their engagements, after having obtained peace, Probus marched against them, put many to the sword, took a great number of prisoners, among whom was their king, and afterwards sent them into Britain, where they are supposed to have settled in the neighbourhood of Cambridge, giving name, as it has been said, to the village of Vandalsburg. Probus allowed several of them to settle in Thrace, which was almost depopulated.
The next mention of the Vandals that occurs is in the eighth year of the reign of Diocletian, when they engaged in a war with the Goths. About the year 406, or the twelfth of Honorius's reign, they made an irruption into Gaul; but in attempting to cross the Rhine, they were slaughtered by the Franks; and being relieved by the Alans and Suevians, they obliged the Franks to retire, and actually entered Gaul. Having passed through Germania Prima and Gallia Belgica, they took possession of Aquitania, the most fertile and opulent province of Gaul; and advancing as far as the Pyrenean mountains, they ravaged all the neighbouring provinces. Conflantinie, however, having been proclaimed emperor by the British legions, passed from Britain into Gaul with a powerful army, and defeated the Vandals and other barbarians in several battles, and at length granted them peace, without fluctuating as a condition their leaving the country. The Vandals soon afterwards took up arms, and seized several cities of Gaul, under Maximus, who assumed the honour of being emperor, in opposition to Conflants, the son of Conftantine. Finding themselves more vigorously opposed than they expected, they marched towards Spain, which was then in a distracted state, and in the year 409 entered the country; and before the end of the year 410, obliged Conflants to abandon it. After having reduced the provinces of Spain to a deplorable condition, they concurred with the Alans and Suevians in dividing the country between them, and devoted themselves to the operations of agriculture. In this partition, Galicia fell to the share of the Vandals and Suevians, and Beticca to those Vandals that were called Silingrians, who are supposed to have given to their portion the name of Vandalum, afterwards changed into Andalusia. In the year 416, Valla, king of the Goths in Gaul, having made peace with the Romans, undertook to drive the barbarians out of Spain; and in 422, Honorius, having heard of the reduced condition of the Vandals in Spain, in consequence of the conduct of Valla, determined to recover the provinces which they possessed. But his attempts for this purpose were rendered ineffectual by a signal defeat. In consequence of this victory, the Vandals became powerful, established themselves in Andalusia, almost destroyed the city of Carthage, and extended their ravages to the Balearic islands. In the year 428 or 429, Genferic, the king of the Vandals, assembled them together, with their wives, children, and effects, and abandoning Spain, crossed the straits of Gibraltar, and landed in Africa. After their arrival, they gained several victories over the Romans, and so overran the country, that Cirta and Carthage were the only two strong places in Africa possessed by the Romans. At length, viz., A.D. 435; a peace was concluded between Valentine and Genferic; but though the moderation of the Vandal sovereign was highly extolled, he nevertheles seized Carthage, A.D. 439, whilst the Romans were engaged in a war with the Goths in Gaul; and thus the Vandals remained masters of the proconsular province of Byzacene, Gætulia, and part of Numidia. The capture of Carthage created an alarm in Italy; and preparations were vigorously made for putting Rome in a state of defence, and for inducing all ranks of people to take up arms for the preservation of the country. In the year 455, Genferic took and plundered Rome; and carried over with him into Africa the empress Eudoxia, and her two daughters Placidia and Eudocia, where he detained them till the year 462, marrying Eudocia to Hunferic, his eldest son, who had by her Hilderic, afterwards king of the Vandals in Africa. Upon his return to Africa, Genferic subdued the countries that were still in the hands of the Romans. The emperor Majorianus, being disappointed in his views and plans for the conquest of Africa, concluded a peace with Genferic, who, after the death of the emperor in 461, sent a powerful fleet to pillage the coasts of Sicily and Italy, and even made himself master of Sardinia. He afterwards took occasion to ravage Peloponnesus and the Greek islands, whence were carried off many captives. Leo sent the affront offered by Genferic to the eastern empire, and prepared for revenge by carrying the war into Africa. In the progress of his powerful armament, Sardinia and Tripoli were recovered from the Vandals; but whilst Genferic solicited of the Roman admiral a truce of five days for settling the terms of his submission to Leo, he contrived to destroy the whole Roman fleet that was armed against him. In the year 475, he concluded a peace with Zeno, the successor of Leo, who, renouncing all claim to the provinces of Africa, yielded them for ever to Genferic and his descendants. Soon after this event, Genferic died, A.D. 477; but the peace was religiously observed by his successor, till the reign of Justinian, who, espousing the cause of Hilderic against his brother Gimer, who had usurped the crown, drove the Vandals out of Africa, and reunited those provinces to the empire. (See Belisarius.)

Africa had been their empire, it now became their prison; nor could they entertain a hope, or even a wish, of returning to the banks of the Elbe, where their brethren, of a spirit less adventurous, still wandered in their native forests. In the country between the Elbe and the Oder, several populous villages of Lusatia are inhabited by the Vandals; they still preserve their language, their customs, and the purity of their blood; support, with some impatience, the Saxon or Prussian yoke; and serve with secret and voluntary allegiance the descendant of their ancient kings, who, in his garb and present fortune is confounded with the meanest of his vassals. The name and situation of this unhappy people might indicate their descent from one common stock with the conquerors of Africa; but the use of a Sclavonian dialect more clearly represents them as the last remnants of the new colonies, who succeeded to the genuine Vandals, already scattered or destroyed in the age of Procopius. Anc. Un. Hist. vol. xvii. Gibbon's Hist. Rom. Emp. vol. i. vi. vii.

VANDELEVILLE, in Geography, a town of France, in the department of the Meurte; 9 miles N.W. of Mirecourt.

VANDELLIA, in Botany, was so called by Linnaeus, at the suggestion of Browne, after his correspondent Dr. Dominick Vandelli, who published at Padua, in 1761, a quarto volume in Latin, on the hot-baths of that neighbourhoood, with notices of some cryptogamic plants inhabiting therein. Being afterwards appointed superintendent of the royal botanical garden at Lisbon, he published there, in 1771, a small Fluctus Plantarum, dedicated to Sir Joseph Banks, describing some supposed new genera, and several new species, with a few figures. Dr. Vandelli is also the author of one or two zoological traits; and he wrote against Haller's doctrine of the insufficiency of the tendons and membranes, to the great displeasure of that illustrious physiologist. This veteran in botanical science visited London, in 1815, at a very advanced age, and, if we mistake not, is since dead.—Linn. Mant. 12. Schreb. Gen. 419. Willd. Sp. Pl. v. 3. 343. Mart. MILL. Dict. v. 4. Jaff. 122. Lamarck Illust. t. 522. (Matoureae; Abl. Guian. 641. Jaff. 119.)—Clasis and order, Didymium Angiospermatis. Nat. Ord. Peronate, Linn. Striphularie, jufi.
VAN

entire; lower dilated, two-lobed. Stem. Filaments four; two from the disk of the lower lip, curved upwards; two from the throat, higher up; anthers ovate, connected in pairs. Pfl. German oblong; fyle thread-shaped, the length of the stamens; stigmata two, ovate, membranous, reflexed. Peric. Capsule oblong, of one cell. Seeds numerous.

1. V. diffusa. Round-leaved Vandelia. "Vahl Eclog. v. 2. 42."—Leaves roundish, nearly fife, smooth above.—Native of the West Indian islands of Montserrat and Santa Cruz. Stem herbaceous, square, crofs-branched. Leaves roundish-ovate, blufhing, crenate, or bluntifh serrated, opposite, on short flalks; smooth above; rather hairy beneath. Flowers axillary, opposite, foliary, on short flalks. The habit and size of the leaves refeemble Veronica serpyUifosa.

2. V. praenitis. Obof-leaved Vandelia. "Vahl Eclog. v. 2. 48."—Willd. n. 2. (Matonrea praenitis; Aubl. Guian. 642. t. 259. Tupéica, five Scoparia; Pfl. Bræf. 246.)—Leaves flakled, elliptic-oblong, acute, finely downy on both fides.—Native of moif ground in Cayenne; about the borders of meadows near the town, flowering almost all the year. It is known by the name of Wild Basil (Bagiae famangae), and esteemed a good vulnerary. The flams are fveral, ereét, two feet high, leavy, square, forked. Young branches, as well as the leaves, foft to the touch, clothed with fine short pubefcence. Flowers blueifh, axillary, mollly foliary. They are delineated in Aublet's figure as having the upper lip in two lobes, the lower in three, which does not agree with the Linnean generic defcription, copied above from the Manifila. Yet the other characters, and the habits of the plants, answer fo well, that we are perfuaded they muft, as Schreber fuscpeeta, belong to one genus. This opinion is confirmed by Vahl, who mentions this fpecies as of very frequent occurrence, by the road-fides in South America, from Trinidad to Brazil. The root is annual. The fame learned botanift had, no more than ourselves, any opportunity of examining the rare Vandelia diffusa alive, nor does it appear whence Linneus took his defcription; except poifibly from two or three very incomplete dried fpecimens, which are now scarcely fufficient to affift in forming an opinion on the subject.

VANDEPUT, CAPE, in Geography, a cape on the well coast of North America, and eait point of Prince Frederic's found. N. lat. 57° 5'. E. long. 22° 12'.

VANDERWERF, ADRIAN. This ingenious painter was born at Ambacht, near Rotterdam, in 1659, and received the principal part of his education under Eglon Vander Nee. At the age of 18, he left that matter, and becoming acquainted with M. Fluyt, who posifled an extenfive collection of drawings by Italian masters, to which he had constant aces, he, by this aid, and also by drawing after casts from antique figures, formed a style of design much more elevated and pure than that of his countryman and contemporaries.

At about the age of 37, his works attracted the notice of the elector palatine, on his vift into Holland; and he commissioned him to paint for him a picture of the Judgment of Solomon, and also his own portrait, to be prefented to the Florentine gallery of artists; and he invited him to bring the pictures to Duffeldorf. The following year he executed that object, and the elector was defirous of retaining him in his service; but to this Vanderwerf would not consent, but engaged to devote to him six months of the year, for which he received a liberal pension. In consequence, the gallery of Duffeldorf is the theatre of Vanderwerf's glory, and his pictures there are numerous; but they are not very uncommon in this country. The character of them is given by Sir Joshua Reynolds, who, in his critical tour into the Netherlands, says, "they (the pictures by Vanderwerf at Duffeldorf) are twenty-four in number in one room, three of them as large as life; a Magdalen, whole length, and two portraiture. His pictures, whether great or small, certainly afford but little pleasure; one of the principal causes appears to me, to be his having entertained an opinion that the light of his picture ought to be thrown solely on the figures, and little or none on the ground or sky. This gives great coldness to the effect, and is so contrary to nature, and the practice of those by whose works he was surrounded, that we cannot help wondering how he fell into the mistake. His naked figures appear to be of a substance much harder than flesh, though his outline is far from cutting, or the light not united with the shade, which are the most common causes of hardships; but it appears to me, that in the present instance, the hardships of manner proceeds from the fondness and union being too general; the light being every where equally lost in the ground, or its shadow, and thus producing the appearance of ivory or plainer, or some other hard substance." There is also a want of tranparency in his colouring, and he has constantly the defect of Rembrandt, that of making his light only a single spot. However, to do him justice, his figures and his heads are generally well drawn, and his drapery is excellent. He died in 1737, aged 68.

He had a brother, Peter Vanderwerf, who copied his pictures, and imitated his manner. Though he occasionally painted histroy, yet his pictures more frequently represent domestic scenes; which, though not equal to his brother's, are very highly wrought, and have sometimes been mistaken for his. Peter died in 1718, aged 53.

VANDEVELDE, ADRIAN. This excellent painter was born at Amsterdam in 1639. He discovered, whilst he was yet at school, a decided predisposition for painting, and covered the walls of his father's house with sketches of all kinds of animals, drawn with an intelligence very unusual at that early period of life, and which induced his father to place him under the tuition of J. Wynants, where he made a very extraordinary degree of progress. Wynants taught him the practice of drawing from nature, and studying in the open air. It was his constant custom to pas his days in the fields, designing every thing essential to his portraits; and in this mode, infinitely more variety may be obtained than the most inventive genius can supply without it. Besides this useful mode of study, he also applied himself to draw from the human figure, and obtained a considerable degree of excellence. In this respect he very fur surpassed his master, who afterwards constantly employed him; as he had previously done wooversmans and Lingelbaek, to decorate his landscapes with figures and animals; as also did Hackaer, Hoobma, Vander-Heyden, and others, thus giving an additional interef to their admirable performances.

The scenes which Adrian Van develde chose for the exercise of his art are in general very confined, and seldom above the ordinary appearance of common nature; but they
are rendered with so much purity of colour, and fulness and perfection of execution, that they captivate, notwithstanding their simplicity. His animals, which are generally the subjects of his pictures, are designed with correctness, and painted to perfect imitation; particularly his cows, sheep, and goats; perhaps not with so much spirit as those of Paul Potter, but more soft and delicate. His pictures, which are generally small, are universally held in the highest admiration, and are sold at very high prices. Unhappily he died in the very prime of his life, at the age of 33; and yet his pictures are by no means scarce, as his industry was inconceivable, and his facility very great.

Though landscape and animals were his more regular objects of study, yet he felt himself qualified to undertake an historical picture for the Catholic church at Amsterdam; and the ability with which he executed a Defcent from the Cross for the altar-piece there, still testifies the power with which he might have disdained himself in history, had he more regularly pursued it. He died in 1672. There are about twenty etchings by him of cattle and landscapes.

VANDEVELDE, William, the Elder, was born at Leyden in 1619, and early in life followed the occupation of a mariner. It is not known at what time he turned his thoughts to painting, or by whom he was instructed in the art; but before he was 20, he had acquired considerable reputation for painting marine subjects in black and white. His skill recommended him to the notice of the States General; and Descamps says, that he was furnished by them with accommodations in a small vessel, for the purpose of attending its fleet, and making sketches of their different manoeuvres and actions. He was prefect at various engagements at sea, and frequently exposed himself to danger in the prosecution of his studies. He is said to have been present at the action between the Duke of York and the Dutch admiral Opdam, in 1665; and at the memorable one the following year, between the English and Dutch fleets, commanded by the Duke of Albemarle and De Ruyter. King Charles II. invited him to England, where he came some time before 1675; as in that year the king settled a salary upon him of 100l. per annum. He continued in the same capacity under King James II., until his death in 1693. He was buried in St. James's church, where is a tomb-stone to his memory.

VANDEVELDE, William, the Younger, the son of the preceding artist, was born at Amsterdam in 1633. He was initiated in the art of painting by his father, but obtained more knowledge of colouring and effect by studying under De Vlieger, an eminent marine painter; and at length arrived at a degree of perfection in the treatment of those subjects, which still remains unrivalled. After he had practiced with great success for some time in Holland, and enriched many cabinets there with his works, his father prevailed upon him to come to England, where he was soon noticed by the king, and complimented with an engagement and a salary such as his father's, and had also apartments provided for him at Greenwich.

During the life of his father, as appears by an order of the privy seal, he was much employed in painting pictures from his sketches, but doubtless rendered more agreeable by his own better taste and feeling. The exercise of his talents, however, was not confined to the service of his majesty; he was constantly employed by various persons, and his pictures are, therefore, to be found in almost every collection which has any pretence to admiration. One of his grandest compositions for chiaro-scuro is in the gallery of the marquis of Stafford, where the magisterial forms of the clouds, the motion of the waves and of the vessels, and the truth and imposing quality of the tone of colour, contend for pre-eminence.

The compositions of the younger Van de Velde are distinguished by a more tasteful arrangement of forms and objects, than is to be found in those of any other marine painter. His vessels are correctly drawn, and the falls, the cordage, and rigging, finished with a delicacy perfectly astonishing, and with unexampled freedom. No one ever surpassed the purity and truth of his tints: whether he represents the serenity of the calm, or the majestic obscurity of the storm, an undeviating correctness and fulness adorn his canvas, and render his works precious in the eyes of all beholders. He died in 1697, at the age of 74.

VAN-DIEMEN'S LAND, in Geography. See Diemen's Land.

VAN-DIEMEN'S ROAD, an anchoring place in the Southern Pacific ocean, on the coast of Tongatapu, one of the Friendly Islands. S. lat. 21° 4'. E. long. 185° 4'.

VAN-DIEST, in Biography. See Diest.

VANDORF, in Geography, a town of Germany, in the county of Henneberg, on the Werra; 6 miles E.S.E. of Meinungen.

VANDOSIA, in Ichthyology, a name by which some authors have called the Leiistes, the common dace.

VANDSHELLING ISLANDS, in Geography, a cluster of small islands in a bay of the Pacific ocean, on the north coast of New Guinea. S. lat. 3° 32'. E. long. 156° 15'.

VANDSIA, a town of Norway, in the province of Christiania; 43 miles W. of Christiania.

VANDUARA, in Ancient Geography, a town of Britain, belonging to the Danes; which being confederably to the north-west of Colonia, was most probably at or near Pailley.under the care of Henry Van-Balen, a painter of considerable reputation. He had made a rapid progress under that master, when the increasing fame of Rubens, and the beauty of his works, inspired him with a desire of becoming a disciple of so able an instructor; and his wishes were soon crowned with success. Rubens soon beheld with pleasure the value of the talents brought by Vandyck into his school, and found in him an able and useful assistant in forwarding his larger works from the sketches he himself had prepared; and it was not long ere an incident established Vandyck's superiority above his fellow pupils, and rendered him at once an object of interest and of envy. Whilst Rubens was employed upon his renowned picture of the Defcent from the Cross, his pupils were anxious to see it in its progress, and procured admission to his studio during their master's absence. One of them, in the wantonness of youth, pulled Diepenbeek, and he fell against the picture, and effaced an essental part of it, on the face of the Virgin, and the arm of the Mary Magdalen, which Rubens had just been painting. Conferration and alarm seized every one present; and to prevent, if possible, the discovery of the accident, John Van-Hoeck proposed that Vandyck should endeavour to restore the picture to the state in which they found it. He did so; and the next morning, when Rubens came into his room, on regarding the picture, he is said to have remarked, "there is a head and an arm which are by no means the worst of what I did yesterday;" and though

4 F afterwards
afterwards he might have discovered the mischief, he did not change the painting.

It has been ascertained by D'Argenville and others, that this circumstance, and the growing ability of Vandyck, alarmed the jealousy of Rubens, and that, in consequence of it, he advised his pupil to renounce historical painting, and adhere to portraiture. But this calumny must be regarded as refuted, by the mere consideration of Rubens having advised Vandyck to go to Italy, where he himself had reaped so much benefit, and where history would be the more sure to rivet the attention of a student. Had he, however, advised him to adhere to portrait painting, it is but a farther proof of his clear perception of the native turn of mind of Vandyck, and a liberal hint how to employ his talents to most advantage, not originating in the mean passion to which it has been ascribed, but in judgment and good-will. That they did not separate upon unfriendly terms is evident, by Vandyck acting upon his advice, as to going to Italy; and presenting his matter, previous to his departure, with two historical pictures, and a portrait of his second wife Helen Forman; and receiving from Rubens in return a present of one of his finest horses.

In 1619, when he was 20 years old, Vandyck left his native city for a residence in Italy, and first visited that emporium of colour, Venice, where he copied and studied with great attention, and imbibed the real spirit, of the works of Titian. At Pétworth, the seat of the earl of Egremont, are two portraits of sir James and lady Shirley, (who was a Persian lady,) in Persian costume, which exhibit, in the freedom and fulness of colour with which they are painted, the perfect understanding he had of the style of that great Venetian master. From Venice he went to Genoa, where his power was recognized, and his pencil employed, by the principal nobility in their portraits, as well as by several churches and convents, for which he painted historical pictures; and nothing is more astonishing in the history of the art, than the rapidity and facility with which so great a number of works was produced by this extraordinary artist. He is reported to have hung up in his studio, on his return from Italy, forty copies made by himself from pictures by Titian, though he was much engaged in original works during his residence there. After some stay at Genoa, he went to Rome, and was there introduced to that patron of elegant literature, the cardinal Bentivoglio, who had been nuncio from the pope in Flanders, and to whom, of course, his talents must have been already known. From this celebrated character he painted that prince of portraits, which for several years was an ornament of the gallery of the Louvre, but now is returned to its original situation, the museum at Florence. Nothing in painting has ever surpassed the life and vigour of the head in this surprising and agreeable picture. He painted some historical subjects for the cardinal, and also several portraits of distinguished persons; but not uniting with his countrymen, then at Rome, in the Bentogel society, they rendered his residence there unpleasant to him, and he returned to Genoa, where he was cared for and honoured, and met with constant employment. Whilst there, he was invited to Palermo, to paint the portrait of Philibert, prince of Savoy, the viceroy of Sicily, and was engaged in several commissions for the court; but the plague breaking out, obliged him to leave that place, and he soon after returned to Flanders.

The reputation of his growing talents had led his countrymen to an anxious desire of witnessing his power, and several religious communities advanced to employ his pencil. His first public work was his celebrated picture painted for the church of the Augustines at Antwerp. For a time it adorned the walls of the Louvre, but is now restored to the church whence it was taken. The subject is St. Agustine e Ecolap, supported by angels, with other saints; of which there is a print by De Jode. Of this performance, which procured him great reputation, Rubens was one of the most zealous admirers; but sir Joshua Reynolds observes, "that in some measure it disappointed his expectation: that it has no effect from the want of a large mass of light." In justness to both painter and critic, it must be observed, that as it was originally painted by Vandyck, St. Augustine was dressed in white, and with the two angels that support him, formed a principal mass of light; but that the monks infatuated upon their patron being dressed in black, and would not pay for the picture till it was so done.

Commisions now came hafly upon him, and most of the principal public edifices of Antwerp, Brufels, Ghent, and Mechlin, were embellished with the productions of his pencil. About this time he painted that beautiful series of portraits of the eminent artists of his time, which, for character, variety, and exquisite execution, remain unequalled. Several of them he etched himself, and the rest have been engraved by the best engravers of that day. One of his most excellent historical productions was painted for the church of the Recollects at Mechlin, which also paid a visit to the Louvre, but was returned with the rest of the spoil from Flanders. Its subject is the Crucifixion, and sir Joshua says of it, that, "upon the whole, it may be considered as the finest of Vandyck's works, and establishes his name to the title of an historical painter."

The taste and ability thus displayed by this great artist did not injure him from ill treatment by his contemporaries, by whom he was accused of tameness and insipidity; and in addition to this, he endured a great mortification from the canons of the collegiate church at Courtray, for whom he painted the Elevation of the Cross, belowing upon it all the power of his art. The picture being completed, it was sent to the place of its destination, when, instead of receiving the due meed of praise for its extraordinary merit, it was pronounced by the chapter to be a detestable performance, and they treated the author of it as a miserable artist; and with difficulty he could procure payment for his picture. It was not till the picture had been seen and commended by several artists and connoisseurs, that they became sensible of their error; and then, to secure it, violent and insensible conduct, they resolved to commission him to paint two more pictures for their church; but Vandyck, with becoming indignation, refused to waste his talents upon men so unworthy of regard, and so little capable to judge of works of art.

Soon after this, he accepted an invitation from Frederic, prince of Orange, to visit the Hague; and there he painted the portrait of that prince, and those of his family, with many of the principal personages of the court.

The patronage which it was understood was to be found at the Engtish court, where Charles I. then reigned, induced Vandyck to visit England in 1629, when he lodged with his friend Geldorp, the painter; but had not the good fortune to attract the notice of his majesty. Disappointed, he returned to Antwerp, with intent to pass the remainder of his life there, when a portrait of sir Kenelm Digby, which he had painted, was shewn to Charles, and he immediately gave orders for an invitation being sent to the painter to return; and accordingly in 1631 he did so, and was most graciously received by the king.

On this second arrival, he was lodged at Blackfriars, at the king's expense; and his majesty was much delighted with his performances, that he often went by water to visit
visit him, and see him paint; frequently sitting to him for his portrait, having others of his wife and children; and on the 5th July, 1632, conferred upon him the honour of knighthood, and soon afterwards granted him an annuity of 200l. a-year for his life.

Popularity and occupation now flowed in full tide upon him, and the rapidity of even his pencil could scarcely keep pace with the commissions he received, for portraits especially. There are few hours of the old nobility of the country wherein are not to be found some pictures by Vandyck. In the king's palaces, the portraits of Charles and his queen and family are numerous. One of a very fine quality adorns the Louvre. At Lord Digby's in Warwickshire, is a great number of his portraits. At Petworth, besides the two pictures mentioned above, painted at Venice, are eleven portraits by him, all of the Percy family, or their immediate friends. At Warwick Castle is the like number; and in each apart works of the first-rate quality. At Wilton, the grandest of his pictures painted here adorns a magnificent apartment: it is of William, earl of Pembroke, and his family. The style in which it is executed is large and grand, and of a much higher quality than his later productions exhibit, which, in comparison, have only delicacy to compete with the boldness and breadth of this. There are here also many others of his hand; but it would be an almost endless and needless talk to enumerate the pictures which he painted during the sixteen years he resided here, the greater part of which comprehended those of a large size. The prices he was paid confined them to the higher classes, and for them only he wrought. For a half length he had 40l., and for a whole length 60l. This, at that time, was a large sum, and the facility of his execution, together with his pension, enabled him to indulge a natural taste for splendour and luxury. He kept a splendid table, and often detained those who sat to him to dinner, both for society, and the opportunity of studying their countenances, and for touching their pictures after dinner. He was, however, indiffusible, as appears from the number of his works, which, though he died so young, are scarcely surpassed in number by those of Rubens. His practice was peculiar. Sir Peter Lely told Mrs. Beale, that Laniere the painter advised him, that he had sat seven entire days, morning and evening, to Vandyck, for his portrait; and that he would not let him look at the picture, till he was himself satisfied with it. He was addicted to pleasure, was fond of music, and treated musicians with liberality; was a generous patron of all ingenious men, and painted the portraits of many gratuitously. But he paid dear for his indulgence; his luxurious and sedentary life brought on the gout, and hurt his fortune; and he unwisely could not, like his master, resist the temptation of the time, the pursuit of the philosopher's stone; in which perhaps, as Mr. Walpole says, he might have been encouraged by his friend for Kenelm Digby. Towards the close of his life, the king bestowed on him the daughter of the unfortunate Lord Gowry (Maria Ruthven) for a wife; with whom he acquired only honour and beauty, and by whom he left one daughter, afterwards married to Mr. Stepney, who was an officer of the horse-guards on the re-establishment of the royal family.

Soon after his marriage he revisited his native city, and from thence went to Paris, hoping to be employed in the decoration of the gallery of the Louvre; but was disappointed, in finding the commission given to Poullin, who had been brought from Rome expressly for this purpose. Vandyck then returned to England, and still emulous of his great master's renown, was ambitious of being employed upon some great national work; and proposed to the king; by Sir K. Digby, to paint the walls of the banqueting-house (of which the ceiling had already been adorned by Rubens) with the history and procession of the order of the Garter, for which he asked 8000l; a proposal far more agreeable to the taste than to the purse of the king; and if it had been accepted, two events which soon after occurred, would have totally prevented its completion, viz. the double triumph of death over the patron and the artist. The former indeed lived some years after the decease of the latter; but his political demise followed shortly upon that event, which occurred on the 9th December 1641, when he had only attained the age of 42.

Though Vandyck produced many valuable works, as we have seen, in historical painting, yet it by no means appears to have been his forte; as he seldom exhibited much expression, but a tame sweetness of effect reigns in them. It is doubtful in portraiture that he stands most decidedly conspicuous, and he may be placed at least alongside of Titian: for if the palm of superiority be given to the latter for his heads, the former must have equal praise for every other part of his pictures, and particularly for the ordnance of the whole. His better compositions are conspicuous for their unity and propriety; but his great quality is his perfect understanding of the nature of all the parts, the head, the hands, drapery, fizzes, &c. and the delightful union of taste and beauty of execution, which he never failed to give. In identity of character he was not often conspicuous; perhaps the cardinal Bentivoglio is the most perfect exemplar; but Sir Joshua Reynolds has superadded that invaluable quality to all that he might have acquired from the works of Vandyck or of Titian.

VANDYCK, PHILIP, known by the name of the little Vandyck, was born at Amsterdam in 1609, of a different family to that of Sir Anthony, and was a disciple of Boonen, under whose tuition he remained till he had become almost capable of teaching his instructor. He painted small portraits, and from them obtained his cognomen; but was more successfully employed in painting conversation pieces, ladies at their toilette, gay assemblies, &c. which he composed and painted ingeniously. He died at the Hague in 1752.

VANDYKE'S ISLANDS, in Geography, two islands, Great and Little, in the West Indies, situated to the northwest of Tortola.

VANE, Sir Henry, in Biography, a person of peculiar talents and disposition, who exhibited a conspicuous character during the period of the English Commonwealth, was the eldest son of Sir Henry Vane, of Hadlow in Kent, and Raby castle in Durham, secretary and treasurer of the household to Charles I. He was born about the year 1612, educated at Westminster school, and at the age of sixteen admitted as a gentleman-commoner at Magdalen college, Oxford. Here he remained for some time without matriculation, of which he disapproved; and having visited France and Geneva, he returned with an avowed disaffection to the liturgy and government of the English church, which no efforts of bishop Laud were sufficient to overcome, although he was employed by the king for this purpose. In the year 1634 he joined a number of persons, who being made uneasy by the measures that were pursued at home, emigrated to New England; and being favourably received in that colony on account of his rank and talents, he was soon appointed governor of the province of Massachusetts. Here he incurred odium by his patronage of Antinomianism; and having taken an active part in delimiting those sentiments with regard to religion that occasioned contentions very injurious to the colony, he was excluded from his high office, and
and in consequence of this degradation, he returned privately to England in the year 1639.

Experience having taught him wisdom, and having produced a change in his principles and temper, he married a lady of good family, and occupied the place of joint-treasurer of the navy with Sir William Ruffell. Devoting himself to bufiness, he was chosen representative for Hull in the parliament of April 1640, and the subsequent Long parliament. He was also so much in favour with the royal party, that he was knighted by the king. His public conduct seems at this time to have justified the character given of him by Lord Clarendon, who says, "he was a man of extraordinary parts, a pleasant wit, a great understanding, which pierced into and discerned the purposes of other men with wonderful sagacity, which had himself vulturum clausum, that no man could make a guess of what he intended. He was of a temper not to be moved, and of rare diffimulation, and could comply when it was not reasonable to contradict, without losing ground by the conceitupon a crisis, however, was approaching, which required his taking a decided part; and accordingly he enlisted with those who were adverse to the court. On occasion of the trial of lord Strafford, he produced from his father's papers evidence against him, which served in no small degree to produce his condemnation. He also carried up to the lords, the articles of archbishop Laud's imprisonment. In 1643, he was nominated one of the Assembly of Divines for the settling of church government; and he was appointed in the same year one of the parliamentary commissioners for negotiating a treaty with the Scots. His persuasion induced the signature at Edinburgh of the Solemn League and Covenant; and in accomplishing this object, he overreached the Presbyterians of that country by an article which established the existing form of religion in Scotland, but left ambiguous the nature of the reform in the two other countries. About this time he became sole treasurer of the navy, but without any view to his own emolument: for he gave up his own patent for life from the king, and for an agent whom he substituted in his own place, he obtained a salary of 2000l. per annum, the residue being brought to the public account. Of his religious principles and character at this time, lord Clarendon speaks in the following terms: "Vane was a man not to be described by any character of religion, in which he had swallowed some of the fancies and extravagancies of every sect or faction; and was become (which cannot be expressed by any other language than was peculiar to that time) a man above ordinaries, unlimited or unrestrained by any rules or bounds prescribed to other men, by reason of his perfection. He was a perfect enthusiast, and without doubt did believe himself inspired, which so far corrupted his reason and understanding, that he did at some time believe he was the persecutor destined to reign over the saints upon earth for 1000 years." In connection with the party denominated Independents he opposed terms of peace, when he acted as one of the parliament's commissioners at the treaty of Uxbridge in 1645, and when he negotiated in the Isle of Wight in 1648. Although he had from artifice or feeling no concern in the king's death, he was one of the council of state invested with regal power after that event. He was a steady adherent to the republican government, under which he occupied an important station; and in 1641 he was one of the commissioners sent into Scotland for introducing the English government there, and for effecting an union between the two countries. On this occasion he is represented by Burnet as having fomented the division prevailing between two parties in the kirk, and as having discouraged all attempts to unite them, with a view of maintaining over them more easily temporal authority, whilst they disagreed among themselves. To Cromwell, in all his attempts to assume the supreme power, he was a determined adversary; and on account of his efforts for this purpose, he was summoned before the council by Cromwell in 1656, and ordered to give security that he would not disturb the nation, and for his refusal was for a short time imprisoned at Carisbrook castle; and though attempts were made to intimidate him by disputing his title to the Ruby estate, he remained inflexible during the period of the usurpation. In Richard's parliament of 1659, he was a representative of the borough of Whitechurch in Hampshire, and was active in his endeavours for restoring the republican government, and his spirited speech for this purpose, on record, is said to have had no small effect in subverting the new phantom of single authority. After the revival of the Long parliament, he was nominated one of the committee of safety, and proposed a new model of government, of which it was a fundamental principle, that in the delegation of the supreme power from the people to their trustees, there were some points which could not be ascertained by the latter; and of these he specified the admission of any king or single person to the legislative or executive power, and the exercise of compulsion in matters of faith and worship. Baxter affirms, that Vane's model was that of a "fanatic democracy;" and his notions have been as much reproached by Presbyterian writers as by Episcopallians. Vane maintained his adherence to the republican cause, and prosecuted his efforts for supporting it, till the contest was terminated by the Restoration. His conduct on this occasion, though he was not one of the regicides, caused his name to be inferred in the bill of those who were excluded from the act of indemnity. Apprehending no personal danger, he continued in his house at Hampstead, till he was taken into custody and committed to the Tower, as a person whom it was hazardous to permit to be at large. A petition, however, was presented to the king by the Convention parliament in favour of him and Lambert, that they should be pardoned as to their lives, to which was returned a gracious answer. Nevertheless in July 1661, in the succeeding parliament, an order was signified by the house of commons, that both Vane and Lambert should be proceeded against according to law. Upon this order Vane was brought from his prison in the Isle of Scilly, and committed to the Tower for trial. For his conduct after the death of Charles I., comprehending his active efforts in opposition to the present king, as a member of the council of state and a pension in office, he was indicted of high-treason. In June 1662 he was put to the bar, and is said to have defended himself with ability and resolution, or, as his enemies say, with arrogance and insolence. Among other pleas, he urged that treason could only be committed against a king de facto, and not de jure, which was the situation of Charles II. till the Restoration; and that he had in all changes adhered to the commons, as the fountain of all regal authority: a principle for which he had exposed himself to the tyranny of Cromwell, and for which he was now ready to undergo all the rigour of perverted law and justice. Nevertheless he was found guilty, and sentenced to suffer the whole penalty adjudged to high-treason, which, however, was commuted for beheading. It has been not unreasonably forgettled, that though the king could not easily be defended for breach of his promise to the former parliament on this occasion, his death was a retaliation for the part he had acted on the impeachment of lord Strafford. On the 14th of June he was brought to the scaffold on Tower-hill, and though con-
ndered as a person possessing little natural courage, he behaved with wonderful composure and firmness. In his address to the spectators, whilst he justified himself on certain points that were confined to reflect upon the government and judges, he was rudely interrupted by the lieutenant of the Tower, who repeatedly ordered the trumpets to sound that his voice might not be heard. He died about the 50th year of his age, and left one son. His writings, chiefly on religious topics, were confounded and obscure. Bishop Burnet says of him, "that though he fat up a form of religion of his own, yet it confuted rather in a withdrawing from all other forms, than in any new or particular opinions or forms, from which he and his party were called 'Seekers,' and seemed to wait for some new and clearer manifestations. In these meetings he preached and prayed often himself, but with so peculiar a darknesse, that though I have sometimes taken pains to see if I could find out a meaning in his words, yet I could never reach it. His friends told me he learned to Origen's notion of an universal sanitation of all, both of devils and the damned, and to the doctrine of pre-existence."

As to his political conduct, it is observed by one of his biographers, that "though he employed craft and dissimulation as his means, there seems no reason to doubt of his sincerity as to his ends, which appear to have been those of a visionary, but not of a selfish statesman. His enemies fearfully charge him with mercenary views, and his friends represent him as a real, though mistaken, lover of his country." Clarendon. Ludl. Mem. Biog. Brit. Hume. Gen. Biog.

Vane, in a Ship, is a thin slip of hunting hung to the main-head, or some other conspicuous place, to shew the direction of the wind. It is commonly fewed upon a wooden frame, called the flock, which contains two holes, by which to slip over the spindle, upon which it turns about as the wind changes.

Vane, Dog, in Sea Language, is a small light vane, formed of a piece of packthread of about two feet in length, upon which are fixed five or six thin slices of cork stuck full of light feathers. It is usually fastened to the top of a staff, two yards high, which is placed on the top of the ship's side, on the quarter-deck, in order to shew the direction of the wind to the helmsman, particularly in a dark night, or when the wind is extremely feeble. Falconer.

Vanes, on Mathematical Instruments, are sights made to move and slide upon cross-flaws, fore-flaws, quadrants, &c.

Vanes, or Vanes, of Feathers. See Feather.

Vanes, Weather. See Weather.

Vanes of Windmills. See Windmill.

Vaneëring. See Vaneëring.

VAN-ELLIOE, in Botany. See VANILLA.

VANELLUS, in Ornithology, a name given by many to the lapwing, more commonly known by the name capella.

VANELITTI, Clementino, in Biography, knight of the holy Roman empire, and lord of Villanova, was born at Roveredo in 1755; and being educated under the care of his uncle, after the death of his father, he became, by incessantly reading Plautus and Terence, so good a Latin scholar, that, in his 16th year, he wrote a Latin comedy, entitled "Lampadaria;" and, in the following year, recited an inaugural oration in the Academy degli Agiati at Roveredo, in the true language of Plautus. Before the age of 22, he was elected secretary of this Academy, and he had improved his talent by a familiar acquaintance with the works of Cicero. In 1776 he defended Tarabofchi against the attack of the Spaniard Serrano, for his censure of some passages in the epigrams of Martial; and the letter he published on this occasion, considered as the production of a young man 23 years of age, was much admired. Upon the death of his intimate friend, the abbé Zorzi of Venice in 1779, he paid an honourable tribute of respect to his memory by publishing his life, and a collection of letters that had passed between them, and also an examination of a question suggested by d'Alembert, whether any one at present should venture to write Latin, which he decided in the affirmative, but Vanetti's most humorous writing, in the Latin language, was a bitter satire on Cagliostrò, who deluded the people at Roveredo, in 1758, by his pretended prophecies and miracles. Vanetti, in order to expose this juggler, wrote a small work in the manner of the book of Chronicles, and in the Latin style of the Vulgate, entitled "Liber Memorialis de Cagliostrò." Encouraged by Betinelli and others, he became a classical writer in his native language, beginning with a well-written letter of the younger Pliny. But his chief fame was derived from his "Observations on the Poems of Horace, with Limitations of that Poet," which, with respect to matter and language, are said to exceed any thing of the kind in Italian. He also published fourteen dialogues in the manner of Lucian; and having tried his talents in various kinds of poetry, his "Sermons" in the true Horatian spirit are pre-eminent, and hence he obtained the name of the Italian Horace. Besides the reputation which he acquired as a poet, he also excelled in crayon painting. To the noise and bustle of the world he preferred the tranquillity of domestic life on his estate, which he compared to the Sabine farm of Horace, and never travelled farther from home than Verona, Mantua,
and Auch, and died at Toulouse in 1735. His other works were a volume of "Opuscula," containing essays on moral topics, epistles, odes, epigrams, &c.; a "Dictionary of Poetry," in Latin, quarto, a work in high estimation, and abridged for the use of students; and a "Dictionary, Latin and French," which he began, but did not live to finish. For his encouragement in his studies, the king allowed him a pension. Moreira. Nouv. Dict. Hist. Gen. Biog.

VANERIA, in Botany, received its name from Loureiro, in memory of father James Vaniere, a French Jefuit, who was born in 1664, and died in 1739; he celebrated a poem on rural life, in which various plant species are beautifully described. —Loureiro. Cochinch. 564.—Clafs and order, Mo- nocia Pentandria. Nat. Ord. Urtice. Juff. Gen. Ch. Male, Cal. Peruian in four deep, ovate, fleshy, erect, converging segments. Cor. none. Stam. Filaments fearedly any; anthers five, inserted in the calyx below its middle, of two kidney-shaped, compressed, pellucid lobes. 

Female, on the same common receptacle, Cal. as in the male. Cor. none. Pist. German superior, rounded, dimph, fimple; style capillary, very slender, the length of the calyx; stigma simple. Peric. none, except the permanent juicy calyx. Seed solitary, lenticular, smooth, tipped with the permanent style. Common Receptacle ovate, bearing from ten to twenty flowers, crowding each other into an angular shape, and mostly confluent, forming a roundish, compound, fleshy berry, tubercular externally, with small intermediate spacers.

Female, on the same receptacle. Calyx like the male. Style one. Seed one, enveloped in the pulpy calyx.

1. V. cochinchinensis. Cay lang 10 of the Cochinchine. —Stems prickly. Leaves alternate. —Native of thickets in Cochinchina, in which country it serves for the smaller kinds of fences. Stems shrubby, erect, numerous, branched, round, smooth, three feet high, beft with many long straight prickles. Leaves ovato-lanceolate, entire, smooth. Fruit roundish, about eight lines in diameter, very red, sweet, eatable, on fimple axillary twin flalks.

2. V. chinensis. Hoang bang Xiong of the Chinese. —Stems without prickles. Leaves tufted. —Native of bushy places about Canton. A shrub fifteen inches high, erect, branched. Leaves lanceolate, entire, smooth, collected into tufts. Flower a round head, on a long, simple, solitary, erect, axillary flalk. Common Receptacle flaky. Loureiro never met with any female flowers, and therefore conceived that this species might be dioecious. We have no acquaintance with any thing answerable to the above descriptions. The genus seems very near Morus.

VANIESA, or Devil's Key, in Geography, a small island in the Spanish Main, near the Mosquito shore. N. lat. 14° 5'. W. long. 82° 35'.

VANILLA, in Botany, a name of Spanish origin, or at least very common among the Spaniards in South America, adopted by Plumier as generic. Though barbarous, it may for its sound be tolerated; and we have little doubt that the writers of the Augultan age would have adopted such, had they, like Cazan, met with them in describing any new country. However this may be, we merely yield unwillingly to the example of writers of the first botanical authority, who have now establifhcd this name, and we should greatly have preferred Mr. Salisbury's appellation of Myro- broma.—Plum. Gen. 25. t. 28. Juff. 66. Swartz Ind. Occ. 1515. Act. Nov. Upfal. v. 66. t. 5. f. 1. Schrad. Journ. v. 2. 208. t. 1. f. 1. Schrad. Neues Journ. v. 1. 82.

Gen. Ch. Cal: Peruian superior, of three nearly direct, lanceolate, equal, coloured leaves, deciduous. Cor. petals two, lanceolate, of the size and colour of the calyx. Nectary a lip, proceeding from the lower part of the style, convoluted at the base, dilated at the margin, without a spur, falling off with the petals. Stam. Anther a hemispherical, moveable, terminal, deciduous lid, of two cells, attached by its posterior edge to the top of the style; masses of pollen globular, granulated. Pist. German inferior, elongated, nearly cylindrical; style erect, fuscicylindrical; stigma convex, towards the top of the style, in front. Peric. Capsule elongated, slightly triangular, fleshy, of one cell. Seeds very numerous, lenticular, delirious of a tunic, imbedded in pulp.

1. V. aromatica. Aromatic Vanilla, Vanillia, or Vanello. Willd. n. 1. Ait. n. 1. (V. flore viridi et albo, fruehtu uigiricatan; Plum. 1c. 183. t. 188. V. maxima; Merian Surn. t. 25. Epidendrum Vanilla; Linn. Sp. Pl. 1347.)—Leaves ovato-oblong, ribbed. Calyx and petals undulated. Lip acute. Capsule nearly cylindrical, very long.-Native of South America. Stem parasitical, climbing by means of simple, fleshy, fibrous, solidary radicles from each joint. Leaves a fapan long, fucculent, as thick as those of houseleek. Flowers large, variegated with green and white. Fruit eight or ten inches long, acquiring, after it is gathered, a peculiar and delicious fragrance, like the flowers of Orchis nigra, and some otheres of that family; on which account the Vanilla is used to perfume chocolate, and becomes a valuable article of commerce.

2. V. angulifolia. Narrow-leaved Japan Vanilla. Willd. n. 2. (Epidendrum Vanilla β; Linn. Sp. Pl. 1348. Angurek Warna; Kæmpf. Amoen. 867. t. 869. f. 2.)—Leaves linear-lanceolate. Calyx and petals flat. Lip acute.—Native of Japan. By Kæmpfer's account this is a parasitical climber like the last, and agrees with that in the colours of its flower, except being dotted with purple. Nothing is said concerning the fruit.

3. V. claviculara. Tendril-bearing Vanilla. Swartz Ind. Occ. 1515. Willd. n. 3. (Cereio affinis fcandens planta aphylla, &c.; &c. Sloane Jam. v. 2. 160. t. 224. f. 3, 4.)—Leaves lanceolate, acute, concave, rigid, recurved. Calyx and petals flat. Capsule somewhat triangular.—Native of woods, on a very dry calcareous foil, in the mountainous inland parts of Jamaica, Hifpaniola, &c. flowering in July. It is vulgarly called Green-with, and the negroes use a decoction of the whole plant for syphilitic complaints. The flem climbs to the height of twenty or thirty feet, and is swelled, as if jointed, at the infertion of each leaf, and tendril-like radicle. Leaves fleshy, an inch long. Flowers large, white, in axillary clusters. Fruit long and large, fleshy, with black thining seeds. Swartz. The figure of the flower in Swartz's plate belongs to this species.

4. V. planifolia. Fragrant Vanilla. Ait. n. 2. Andr. Repof. t. 538. (Myrobraena fragrans; Salib. Parad. t. 82.)—Leaves oblong-lanceolate, flat, slightly afirated. Calyx and petals even. Lip fringed, abrupt.—Native of the West Indies, said to have been introduced into our flowers by the present duke of Marlborough. In size this rivals the fift species, but the leaves are not so thick; the calyx and petals are not undulated, nor the lip pointed. We have no account
The flowers are said to be very fragrant, especially at night. Mr. Salisbury is erroneously charged, in Andrew's work, with having confounded this and the V. aromatica.

The species of this genus are far from being all known or understood.

The plant which produces the fruit called vanilla or banilla by the Spaniards, or the epidendrum vanilla of Linnaeus, has a trailing stem, somewhat like the common ivy, but not so woody, which fastens itself to any tree that grows near it by small fibres or roots produced at every joint; these attach themselves to the bark of the tree; and by them the plants are often nourished, when they are cut or broken off, from the root, at a considerable height from the ground, as is the case with the ivy in England. The leaves are as large as those of the common laurel, and are produced alternately at every joint. It rises to the height of eighteen or twenty feet, and the flowers are of a greenish-yellow mixed with white, which, when fallen, are succeeded by the fruit, which is eight or ten inches long.

The spots which are manufactured, grow not only in the bay of Campeachy, but also at Carthagena, at the Caracas, Honduras, Darien, and Cayan, at all which places the fruit is gathered and preserved; but it is rarely found in any of the English settlements, though it might be easily propagated in them: for the seed is so full of juice, that they will continue fresh, out of the ground, for several months.

When these plants are intended for propagation in the warm parts of America, nothing more is required than to make cuttings of three or four joints in length, which should be planted close to the stems of trees in low marshy places, and the ground about them kept clear of weeds.

The method used to preserve the fruit is, when it turns of a yellow colour, and begins to open, to gather it, and lay it in small heaps to ferment two or three days, in the same manner as is practised for the cocoa pods; then they spread them in the sun to dry, and when they are about half dried, they flat them with their hands, and afterwards rub them over with the oil of palma Christi, or of the cocoa; then they expel them to the sun again to dry, and afterwards rub them over with oil a second time: then they put them in small bundles, covering them with the leaves of the Indian reed to preserve them. These plants produce but one crop of fruit in a year, which is commonly ripe in May, fit for gathering, for they do not let them remain on the plants to be perfectly mature. When they are about half changed yellow, they effuse them better for keeping than when thoroughly ripe; at which time the fruit splits. While the fruit is green it affords no remarkable scent, but as it ripens it diffuses a mild grateful aromatic smell; but when it begins to open, the birds attack them, and devour the seeds greedily.

The fruit which is brought to Europe is of a dark-brown colour; wrinkled on the outside, and full of a vast number of black seeds, like grains of sand, of a pleasant smell, like balsam of Peru.

This fruit is only used in England as an ingredient in chocolate, to which it gives an agreeable flavour to some palates, though it is disagreeable to others; but the Spanish physicians use it in medicine, and esteem it grateful to the stomach and brain, good for expelling wind, for provoking urine, redressing sores, and curing the bite of venomous animals. Miller's Gard. Dict.

The vanilla, or vanillies, have an unctuous aromatic taste, and a fragrant smell, like that of some of the finer balsams heightened with musk. They are used chiefly in perfumes; scarcely ever among us in any medical intention; though they should seem to deserve a place among the principal medicines of the nervous clafs. By distillation, they impregnate water strongly with their fragrance, but give over little or nothing with pure spirit. By digestion, spirit totally extracts their smell and taste; and in great measure covers or suppresses the smell.

VANINI, LUCILIO, in Biography, a reputed atheist, was born about the year 1583, at Taurofano, in the district of Otranto, and kingdom of Naples. He studied philosophy and theology at Rome, where he changed his baptismal name for "Julio Cefare," and completed his education at Naples and Padua, comprehending medicine, law, and astronomy. Possessing himself unfortunately of the works of Cardan and Pomponazzi, he imbibed their errors; which, with the philosophy of Aristotle and Averrhoës, and the delusions of astrology, contributed to complete what may be called the confusion of his mind. Having entered into orders, and began to preach, his discourses were a medley of singular notions, which neither his nor any one else could understand. With a view of propagating his opinions, he travelled into Germany, the Netherlands, France, and England, in which latter country he was for a short time imprisoned, on account of his theological disputations. At Geneva, where he set up a school of philosophy, he was suspected of unfruitful and dubious faith, and therefore removed to France, passing some years at Lyons and at Paris. At this time, he was so far from being willing to acknowledge his defection of the Catholic faith, that he proposed to the apostolic nuncio at Paris to write an apology for the council of Trent. In 1615 he published at Lyon his "Amphitheatrum aeternae Providentiae, Divino-magicum; Christiano-physicum; Astrologico-catholicae, aduersus verecundos, Atheos, Epicuros, Peripatateticos et Stoicos," which was not suspected of atheism, and which indeed contains every thing incompatible with atheistical principles. In the following year he published at Paris another work, entitled "De admirandis Naturae Regimine Deaeque Mortalium Arcanis," which was printed with a privilege; but on a closer examination of its tendency, it was publicly burnt by a decree of the Sorbonne. As the author of this work ascribes to his goddes, Nature attributes which belong only to the Supreme Being, he is chargeable with the fame kind of atheism, that was maintained by some ancient sects of philosophers. He was likewise accused of stating arguments against religion, to which his replies were so unsatisfactory, as to furnish ground for suspicion that he designed to favour the cause of infidelity. Being under a necessity of quitting Paris, he withdrew in 1617 to Toulouf, where he taught medicine, philosophy, and theology; but there it was discovered, that he availed himself of his opportunities for general instruction to diffuse his impious and atheistical opinions; he was tried, and being found guilty, was condemned to have his tongue cut out, and then to be burnt alive. It is said, that on his examination, when he was asked if he believed in God, he took up a straw, and replied, "this is sufficient to convince me of the existence of a Creator," and that he afterwards made a long discourse on Providence. However, after his condemnation, he is said to have thrown off the mask; and to have uttered horrid impieties. He suffered death in 1619, (in 1629, according to Moheim,) at the age of 34, and on his memory has been entailed every kind of reproach which could have been suggested by a detestation of his doctrines. But Moheim says, "that several learned and respectable writers consider this unhappy man rather as a victim to bigotry and envy, than as a martyr to impiety and atheism; and maintain that neither his life nor
his writings were so absurd or blasphemous as to entitle him to the character of a deceiver of God and religion." An Apology for Vanini was published in Holland in 1712, by Peter Frederick Arp, a learned lawyer. Moreni, Mosheim, vol. v. VANISHING FRACTIONS, are fractions in which, by giving a certain value to the variable quantity or quantities entering into them, both numerator and denominator become zero, and consequently the fraction itself is then 0.

The idea of fractions of this kind first originated about the year 1702, in a contest between Varignon and Rolle, two French mathematicians of some eminence, concerning the principles of the differential calculus, of which the latter was a fierce opponent; and amongst other arguments against the truth of the doctrine which had then been recently introduced, he proposed an example of drawing a tangent to a certain curve, at the point where the two branches intersect each other; and as the fractional expression for the subtangent, according to that method, had both its numerator and denominator equal to zero, or 0, he regarded such a result as absurd, and added it as a proof of the fallacy of this mode of solution. But the mystery was soon explained by John Bernouilli; and upon a renewal of the dispute, still farther by Saurin, who showed that the fraction in the case here mentioned had a real value. These fractions were also the cause of a violent controversy between Waring and Powell in 1765, when these gentlemen were candidates for the mathematical professorship at Cambridge: Waring maintaining that the fraction

\[ \frac{x^n - a^n}{x - a}, \]

when \( x = 1 \), is equal to 4; and Powell, or rather Maferes, who is commonly supposed to have conducted the dispute on the part of the latter, that it was equal to 0, or indeed that it could have no value whatever; and it must be acknowledged that the fame difference of opinion relative to this kind of fractions still exists in all its force. Woodhou's, in his "Principles of Analytical Calculation," in treating of these quantities, after assuming the simple cafe of

\[ \frac{x^n - a^n}{x - a}, \]

the signification of this expression is, that \( x^n - a^n \), to be divided by \( x - a \), and the result of that division is \( x^n + a^n \), or putting \( x = a \), it becomes \( a^n + a^n \), or 2\( a^n \). This result, however, he remarks, is no direct and natural consequence arising from the principles of calculation, but, on the contrary, it is a result arbitrarily obtained, by extending a rule, and observing a certain order in the process of calculation.

To the question, what does

\[ \frac{x^n - a^n}{x - a}, \]

become when \( x = a \); the obvious and logical answer is \( \frac{a^n - a^n}{a - a} \), and the question is, whether in this form it will admit of any further reduction. It is true, if we operate upon this quantity according to the rules laid down in other apparently similar cases, we obtain

\[ \frac{a^n - a^n}{a - a} = a + a = 2a; \]

but here is evidently an extension given to a rule beyond what was first intended; for this rule was instituted for operating on real quantities, whereas in this case we have employed it on quantities having no value whatever, being in fact the division of 0 by 0, for which abstrusely no rule can be given. This, however, is not a case peculiar to these fractions. It is to the fame source we must attribute the introduction of the negative symbol, and all the mysteries attendant upon it, as well as to every kind of imaginary quantity.

In vol. i. p. 219., of Bonnycastle's Treatise of Algebra, we have the following rule for finding the value of vanishing fractions.

1. If both the terms of the given fraction be rational, divide each of them by their greatest common measure; then, if the hypothesis which is found to reduce the original expression to the form \( \frac{a}{b} \) be applied to the refult, it will give the true value of the fraction under consideration.

2. When any part of the fraction is irrational, observe what the unknown quantity is equal to, when the numerator and denominator both vanish, and put it equal to that quantity + and - 1; then if this be substituted for the unknown quantity, and the roots of the fods be extracted to a sufficient number of places, the refult, when \( i \) is put equal to 0, will give the true value of the fraction. From which rule the author obtains the following refults; viz.

1. \[ \frac{x^2 - a^2}{x - a} = 2a, \text{ when } x = a. \]
2. \[ \frac{x^2 - x^1}{1 - x} = -1, \text{ when } x = 1. \]
3. \[ \frac{b (x^n - a^n)}{x - a} = \frac{b}{a}, \text{ when } x = a. \]
4. \[ \frac{x^n - a^n}{x - a} = m a^n - 1, \text{ when } x = a. \]

See Bonnycastle's Algebra, Woodhouse's Principles of Analytical Calculation, and Barlow's Dictionary.

VANISI, in Geography, a town of Turkish Armenia; 21 miles W. of Akalzike.

VAN-LAER, in Biography. See BAMBOCIO.

VANLOO, CARLO, was the son of an artist little known, and was born at Nice in 1705. For some time he resided at Rome, and studied under Benedetto Luti. In 1723 he went to Paris, where he gained the first prize for an historical painting, and was employed with his elder brother, John Baptiste Vanloo, in repairing the paintings of Primaticcio, at Fontainebleau. In 1727 he again visited Italy, and afterwards passed some time at the court of Turin, where he painted a series of pictures from Tasso. On his return to his native country in 1734, he was admitted into the academy, the king conferred upon him the order of St. Michael, and appointed him his principal painter; and he repaid these compliments by his industry and his ability. He had acquired by his studies in Italy more correctness than his countrymen generally possessed, and he certainly prevented the French school from running further into the affected mode of Coupel and De Troyes, and yet his style can only be called loofe and mechanical, with little relish of the higher beauties of art. He died in 1765, at the age of sixty.

VANLOO, MAD, the daughter of Somis, the great violinist of Turin, concert-matter to the king of Sarainia, and wife to the celebrated painter Vanloo of Paris, was born in 1710, and in 1726 she was thought the best singer of her time. We have been a beautiful print of Mad. Somis, from a painting of Vanloo's previous to her marriage. After her nuptials, she settled at Paris, and was living there in 1754. The first wife of the elder Cramer, the excellent performer on the violin, and leader of a band, was a daughter by this marriage; which accounts for her good taste and captivating manner of singing to her own accompaniment on the pedal harp. She was a most accomplished
complied and elegant woman, and we never heard any thing more pleasing than her performance.

VAN-MALDER, concert-master and chamber-musician to prince Charles at Brussells, and leader of the band at that theatre; a composer of spirited and pleasing symphonies, which were long in favour at our national theatres. He composed a comic opera, “La Bagarre,” 1754, for the Italian theatre at Paris, and died at Brussells in 1771.

VAN-MANDER, a painter and author, was born at Meulebeke, near Courtray, in 1548, of a noble family, and received an education suited to his rank. His talents developed themselves at an early period of his life, and particularly a disposition to painting; and he was placed under the tuition of Lucas de Heere; afterwards he became a disciple of Peter Vlerick, an historical painter of some eminence at Courtray, and finished his education in art by a journey to Italy, where he studied for three years. From thence, after painting several pictures, he went to Vienna, accompanied by Spranger, whose friendship he had cultivated, and there received a preëmpted invitation to enter the service of the emperor; but love for his native country prevailed, and thither he returned. He then experienced much encouragement, and was in possession of full employment, when the wars in the Low Countries prevented his enjoyment of it. He took refuge in Haarem, and there with Goltzius founded an academy. Van-Mander united with the talents of a painter that of a poet, and composed tragedies and comedies, several of which were acted with success, with decorations painted by himself; and we are indebted to him for a very useful history of the painters of antiquity and of his own country. He died at Amsterdam, in 1606.

VANN/EUS, Lat., VANEO, STEFFANO, Ital., the name of an Augustine monk, born at Ricianati, a small town in the March of Ancona and Ecclesiastical State, was music director at Ascoli, who published at Rome in 1553, small folio, a most ample treatise on music, in which he has inserted all that preceding books on the subject contained. There is nothing that was new in this at the time of its publication; but no one book then published contains half its contents. Walther has given a long list of the divisions and subdivisions of this work, which is written in Latin, and which, perhaps, is all that will ever be read by those who may obtain possession of the book, which is now become very scarce.

VANNE, in Geography, a river of France, which runs into the Yonne, near Sens.

VANNEN, a small island in the North sea, on the coast of Norway. N. lat. 70° 10'. E. long. 19° 44'.

VANNES, a sea-port town of France, and capital of the department of the Morbihan, at the union of two small rivers, which form a harbour in the lake Morbihan; before the revolution, the see of a bishop. The principal commerce is in corn, bar-iron, and fish. It has two suburbs, one of which is larger than the town itself. In 1800, the royalists, under Georges, were defeated by the republicans, under Brune; 13 paff N.W. of Nantes. N. lat. 47° 39'. W. long. 2° 40'.

VANNES, La, a town of France, in the department of the Ardeche; 6 miles S.W. of Joyeuse.

VANNI, FRANCESCO, Cavalier, in Biography, was the son of a painter of little celebrity at Vienna, who died whilst he was very young, and was born in 1563. He went to Rome when he was about sixteen, and entered the school of Giovanni de Vecchi, and became an imitator of Barocci. He also went to Parma to draw from the fame fount as Barocci, viz. the works of Corregio and Parme-
grateful to the sheep than that on dry moory land on gravel, being often scanty, woody, and rigid. The excess of moisture, too, in them may probably, it is thought, affect the qualities and healthiness of the heath, as food for sheep. Besides, there is in such moors a greater proportion of the croft-leaved fern than is found on dry sheep-walks; and it is thought by many that sheep do not relish it so well as the common kind, when the shoots are young. From these accounts, it would seem that the true nature of the complaint is not yet well understood, but it is probably some defect in the lactic organs, by which a due supply of nourishment is prevented from being taken up, the consequence of which is a state of atrophy and emaciation in the animal.

The remedies which have been chiefly depended upon in these cafes by sheep-farmers, are those of either removing the sheep into fresh grassy lands, or the change of them from the peaty pasture to one that is sweet and dry, during the autumn and winter. The latter, it is said, not only proves a sure of the disease, but wholly prevents it. In some cafes, medicines of the mild stimulating balsamic kind might perhaps be used with benefit.

VANRHEDIA, in Botany, Plum. Gen. 45. t. 18. See Rhedia.

VANS, les Dames, or Vanaut, in Geography, a town of France, in the department of the Marne; 12 miles N.E. of Vitry le Choiseu.

VANSIRE, in Zoology, a species of weaflf with short ears: the hair brown at the roots, barred above with black, and ferrugineous; the tail of the same colour; the length from nine to about fourteen inches, and the tail nearly ten. This animal inhabits Madagascar.

VANSMER, Paul, in Biography, a portrait painter, born at Antwerp in 1576: he for a while resided at Amsterdam, and with his brother Bernard practised his art there with success. About 1605 or 1606, he visited England, and was very much employed here; as many of his portraits are to be found in the houses of our nobility. He had the honour to be employed to paint King James I., and his queen, Anne of Denmark. He died at about the age of 45, and was buried in St. Martin's, as appears by the register, January 5, 1621.

VANSTOWN, in Geography, a town of the Cherokees, on the river Alabama.

VANSWITZER, in Biography. See Switzen.

VANT, or VAUKT. See Van.

VANTANA, in Botany, Jull. 434: a name of Aublet's, which Schreber, according to correct rule, could not retain. See Lemisia.

VANT-CHIN, in Geography, a city of China, of the second rank, in Quang-nan; 1417 miles S.S.W. of Peking. N. lat. 23° 7'. E. long. 160° 51'.

VAN-TEN, a city of China, of the second rank, in Yun-nan; 1295 miles S.W. of Peking. N. lat. 24° 29'. E. long. 109° 14'.

VAN-UDEN, Lucas, in Biography, a landscape painter, born at Antwerp in 1595. He was principally his own instructor, and cultivated his talents by an affiduous attention to nature, and studying the landscapes of Rubens, whom he imitated, and who employed him to paint on the back-grounds of his pictures; which he did with so much courtesance of style, that they appear to be the work of the same hand. He lived to the age of 65: he had a brother, Jacques Van-Uden, also a landscape painter, but inferior to him.

VANVRY, in Geography, a town of France, in the department of the Côte d'Or; 6 miles E.S.E. of Châtillon-sur-Loire.

VANZE, a town of Naples, in Basilicata; 10 miles S.E. of Venice.

VAPINCUM, in Ancient Geography, Gap, a town of Gallia Narbonensis, between Caturiae and Alabon.

VAPORARIUM, or VAPOROSUM Balneum, Vapour-Bath, in Chemistry, a term applied to a chemist's bath, or heat, in which a body is placed, so as to receive the fumes of boiling water.

The balneum vaporosum consists of two vessels, disposed one another in such manner, as that the vapour raised from the water contained in the lower, heats the matter enclosed in the upper.

The vapour-bath is very commodious for the distilling of odoriferous waters, and the drawing of spirit of wine. On this subject, see Bath, in Chemistry.

We also use the term vapour-bath, when a sick person is made to receive the vapours arising from some liquid matter placed over a fire.

Many contrivances have been proposed for this purpose; and their expediency and utility are best known to those who are conversant in this business. See Aqueous Baths.

VAPORATION, Vaporatio, in Chemistry, a term applied to the action of a fume, or vapour.

Vaporation is a kind of bathing, or rather of fomentation, by which the warmth, or humidity, of a vapour is made to act on some other body, that is to be warmed or moistened.

VAPOROSUM Balneum. See Vaporarium.

VAPOUR, Vapour, in Meteorology, a thin vehicle of water, or other humid matter, filled or inflated with air; which, being raised to a certain degree by the action of heat, ascends to a certain height in the atmosphere, where it is suspended, till it returns in form of rain, snow, or the like. An assemblage of a number of particles, or vehicles of vapour, constitutes what we call a cloud.

Some use the term vapour indifferently, for all fumes emitted, either from moist bodies, as fluids of any kind; or from dry bodies, as sulphur, &c. But Sir Isaac Newton, and other authors, better distinguished between humid and dry fumes, calling the latter exhalations.

For the manner in which vapours are raised, and again precipitated, see Cloud, Dew, Rain, Barometer, and particularly Evaporation and Meteorology.

We shall here add, with respect to the principles of solution adopted to account for evaporation, that Dr. Halley, about the beginning of the last century, seems to have been acquainted with the solvent power of air on water; for, he lays, that, supposing the earth to be covered with water, and the sun to move diurnally round it, the air would of itself imbibe a certain quantity of aqueous vapours, and retain them like salts dissolved in water; and that the air, warmed by the sun, would sustain a greater proportion of vapours, as warm water will hold more dissolved salts; which would be discharged in dews, analogous to the precipitation of take in the cooling of liquors. Phil. Trans. Abrid. vol.i. p. 127.

Mr. Eales, in 1755, endeavoured to account for the ascent of vapour and exhalation, and their suspension in the atmosphere, by means of the electric fire. The sun, he acknowledges, is the great agent in detaching vapour and exhalations from their matrices, whether he acts immediately by himself, or by his rendering the electric fire more active in its vibrations; but their subflebent ascent he attributes entirely to their being rendered specifically lighter than the lower air, by their conjunction with electrical fire: each particle of vapour, with the electrical fluid that surrounds it, occupying a greater space than the same weight.
VAPOUR.

weight of air. Mr. Eales also endeavours to shew, that the ascendent and descendent of vapour, attended by this fire, are the cause of all our winds, and that they furnish a satisfactory solution of the general phenomena of the weather and barometer. (Phil. Trans. vol. xlv. p. 124, &c.) Dr. Darwin, in 1777, published remarks on the theory of Mr. Eales, with a view of confuting it; and attempted to account for the ascendent of vappours, by considering the power of expansion which the confluxent parts of some bodies acquire by heat, and also that some bodies have a greater affinity to heat, i.e. acquire it sooner, and retain it longer than others. On these principles, he thinks, it is very intelligible how water, whose parts appear from the zoëlipile to be capable of immeasurable expansion, should by heat alone become specifically lighter than the common atmosphere. A small degree of heat is sufficient to detach or raise the vapour of water from the mafs to which it belongs; and the rays of the sun communicate heat only to those bodies by which they are refracted, reflected, or obstructed, whence, by their impulse, a motion or vibration is caused in the parts of such bodies. Hence he infers, that the sphericles of vapour will, by refraction of the solar rays, acquire a constant heat, though the surrounding atmosphere remain cold. If it be asked, how clouds are supported in the absence of the sun? it must be remembered, that large mafs of vapour must for a considerable time retain much of the heat they have acquired in the day; at the same time reflecting, how small a quantity of heat was necessary to raise them, and that doubleafs even a leaf will be sufficient to support them; as from the diminished preffure of the atmosphere at a given height, a leaf power may be able to continue them in their preffent rate of rarification; and lastly, that clouds of particular shapes will be sustained or elevated by the motion they acquire from winds. Phil. Trans. vol. i. p. 246.

For the effect of vapour in the formation of springs, &c. see Spring and River.

The quantity of vapour raised from the sea by the warmth of the sun, is far greater than one would imagine. Dr. Halley has attempted to estimate it. The result of this estimate is contained in the following articles.

1. That water falted to about the fame degree as salt-water, and exposed to a heat equal to that of a summer's day, did, from a circular surface of about eight inches diameter, evaporate at the rate of six ounces in twenty-four hours. Whence, by a calculus, he finds that the thickness of the pellicle or flic of water, evaporated in two hours, was the fifty-third part of an inch; but, for a round number, he supposes it only a sixtith part; and argues, hence, that if water as warm as the air in fummer evaporates the thickness of one-fiftieth part of an inch in two hours, from its whole surface; in twelve hours it will evaporate the tenth of an inch; which quantity, he observes, will be found abundantly fufficient to fupply all the rains, springs, dews, &c.

In effeét, on this principle, every ten square inches of the surface of the water yield in vapour per diem a cubic inch of water; and each square foot half a wine pint; every space of four feet square, a gallon; a mile square, 6914 tons; and square degree of sixty-nine English miles will evaporate 33 millions of tons a day; and the whole Mediterranean, computed to contain 165 square degrees, at least 5280 millions of tons. Phil. Trans. N° 189, or Abr. vol. ii. p. 108, &c. See River.

2. A surface of eight square inches, evaporated purely by the natural warmth of the weather, without either wind or sun, in the course of a whole year, 16,292 grains of water, or sixty-four cubic inches; consequently the depth of water thus evaporated in one year amounts to eight inches. But this being too little to answer the experiments of the French, who found that it rained nineteen inches of water in one year at Paris; Dr. Heberden has found, that a rain-gage fixed below the top of a house, received above a fifth part more rain than another of the same size above the top of the same house; and that there fell upon Weilminfler Aby very much above one-half of that which fell in the same space below the tops of the houses; and by several experiments made by Dr. Dobson of Liverpool, it appears, that the quantity of rain received in a vessel placed on the ground exceeded that received by another of the same dimensions eighteen yards higher than one-third, and less than one-half. Phil. Trans. vol. lix. art. 47, and vol. lxvi. art. 13. p. 256. See Rain.

With regard to the cause of this difference, it may be observed, that as in chemical precipitations a greater portion of the precipitating substance will be received on the real bottom of a vessel containing the solution than on a euposed false bottom placed in any where above it, and that in proportion to its height above the real bottom; so a greater quantity of water, confidering rain as a precipitation of water before diffolved in air, ought, on parting with its former solvent, to fall on the surface of the earth than on an imaginary horizontal plane of the fame dimensions above it; and though the cafes are not exactly parallel, yet the drops of rain in their deacent must be somewhat increased either in number or size; partly by succedively impinging on the aqueous particles contained in the air through which they pass, and by attracting others in virtue of their being pollefled of a different electricity; and partly by the spontaneous separation and precipitation of that moisture, which is known to be contained in considerable quantities in the air at all times, and the appearance of which, dripping down the walls of our houses, &c. is one of the popular signs of approaching rain. (Monthly Review, vol. xlv. p. 322.)

Dr. Dobson states the annual evaporation at Liverpool, taking the medium of four years, at 35.78 inches. Dr. Halley fixes the annual evaporation of London at 48 inches. See Phil. Trans. vol. lxvii. part i. p. 252.

3. The effect of the wind is very considerable, on a double account; for the fame obervations shew a very odd quality in the vapours of water, i.e. that of adhering and hanging to the surface that exhaled them, which they clothe, as it were, with a fleece of vaporous air; which once invulelling the vapour, it thenceforward rifes in much less quantity. Whence, the quantity of water lost in twenty-four hours, when the air was very still from wind, was very small, in proportion to what went away when there was a strong gale of wind abroad to dissipate the fleece, and make room for the emulsion of vapour; and this, even though the experiment was made in a place as close from the wind as could be contrived.

Add, that this fleece of water hanging on the surface of waters in still weather, is the occasion of very strange appearances, by the refraction of the vapour's differing from and exceeding that of common air; whence every thing appears raised,
raised, as houses like steeples, ships as on land above the water, the land raised, and as it were lifted, from the sea, &c. 4. The same experiments shew, that the evaporation in May, June, July, and August, which are nearly equal, are about three times as great as those in the months of November, December, January, and February. Phil. Trans. No. 212. or Abr. vol. ii. p. 110, &c.

Dr. Brownrigg, in his "Art of making Common Salt," p. 189, fixes the evaporation of some parts of England at 73.8 inches during the months of May, June, July, and August; and the evaporation of the whole year at more than 140 inches. The evaporation of the four summer months at Liverpool, on a pond of four years, was found to be only 18.88 inches. Dr. Hales calculates the greatest annual evaporation from the surface of the earth in England at 6.66 inches; and therefore the annual evaporation from a surface of water, is to the annual evaporation from the surface of the earth in Liverpool, as 36 to 6, or as 6 to 1. Phil. Trans. vol. lxvii. ubi supra.

Vapours, Fiery, Habitum Ignei, a term used by some to express those exhalations from the earth, which either take fire of themselves on their burning forth into the air, or are readily inflammable on the bringing of a candle to them. See DAMP, GAS, HYDROGEN, METEOR, and VENTILATION.

Many of the supposed burning lakes are owing to these fumes burning up through the water, and not to any quality of the water itself. Our famous burning-well at Wiggon, in Lancashire, is of this kind. The common people affirm, that the water of this spring burns like oil; but there is nothing of truth in this. There burns up a vapour through the earth in this place, which keeps the water bubbling, as if boiling over in the fire, though it is not warm; and the stream of this breath may be felt issuing up in these places like a strong wind. This breath alone is inflammable, and takes fire at the approach of a candle, burning with considerable violence for some time. There are coal-pits in the neighbourhood, and the air is certainly of the same kind with that inflammable vapour often met with in those places, and which may also be prepared from iron disolved in a proper menstruum. The water itself, taken from the place, does not burn; and if the bottom be made dry, the vapour which ascends from it will burn as strongly as if the water were there. The flame is not discoloured like that of sulphureous bodies, nor has it any bad scent; and the fumes, as they are felt burning out of the earth, by the hand held over the place, are hot. Phil. Trans. No. 20.

Vapour-Boat. See VAPORIUM, and BATH.

Vapours, in Medicina, a disease popularly called the Basty, or the hypochondriac disease; and in men particularly the febren. See HYPochondriasis.

Vapours supposed to be emitted from the womb, in women, are what we otherwise call hysterical affections, or suffocations, or fits of the mother. See HYSTERIA.

VAPPA, a word used by the ancients to express dead wine, or wine deprived of all its spirituous part.

The word is also metaphorically applied to a peculiar state of the blood, when it is in a low, dispirited condition, as is the case even in healthy persons, when worn out with excessive labour, and in cachectic and scrofulous persons.

VAR, in Geography, one of the twelve departments of the S.E. region of France, formerly Lower Provence; a maritime territory in N. lat. 43° 30', bounded on the N. by the department of the Lower Alps, on the E. by the county of Nice, on the S. and S. E. by the Mediterranean, and on the W. by the department of the Mouths of the Rhone. Its territorial extent in kilometres is 7510, and in square leagues 378; and its population consists of 269,142 inhabitants. It is divided into 4 circles or districts, 32 cantons, and 210 communes. The circles are, Brignoles, containing 66,034 inhabitants; Draguignan, 71,383; Graffe, 55,242; and Toulon, 76,485. According to Haffenratz it is 30 French leagues in length, and 20 in breadth; its circles are 9, its cantons 80, and its population consists of 275,472 persons. Its capital is Draguignan. Its contributions in the eleventh year of the French era amounted to 2,258,028 francs; and its charges for administration, judiciary, and for public instruction, were 274,032 francs 28 centimes. The northern districts, covered with mountains, yield little grain; but throughout the department, grapes, fruits of all sorts, medicinal plants, forests and pastures abound. The plains of Brignoles and Toulon are planted with fruit-trees and vines. Here are mines of different metals, and quarries of marble.

VAR, a river which rises in the department of the Lower Alps, about 10 miles S. from Barcelonne, crosses the county of Nice, and, in part, separates it from France, till it runs into the Mediterranean; 4 miles W. of Nice. It gives name to the department.

VARA, in Ancient Geography, an etuary of Britain, which is the birth of Tayne in Sutherland.

VARA, in Commerce, a long measure in Spain and Portugal. At Lisbon, the vara is 5 palmos (or spans), and the covado (another long measure) is 3: the palmo is 8 inches of Lisbon, or 8½ English inches; the covado is 30½ French lines, or 26½ English inches. Goods not fold by the piece, are generally sold by the covado, except some sorts of coarse linens, which are sold by the vara. The Lisbon foot is half a covado, or 13½ English inches; and 9 feet of Lisbon are 10 English feet. At Oporto, the vara is always 5 palmos de craveira (see PALMO), or 40 Portuguese inches = 43½ English inches; and the covado is 3 palmos de craveira avançados (or good measure), and is 24½ inches of Portugal, or 26½ English inches. The vara (as a brais or wooden measure) is sometimes divided on one side into 43½ English inches, and on the other side it is marked at 26½ English inches. Each of these measures is divided into 3 tercas, 4 quartas, 6 sexas, and 8 oitavas. In Spain, the vara, a measure for cloth, linen, and silk, is 3 feet, or 4 palmos; and is, therefore, 33½ English inches; the palmo measuring 9 pulgadas, or 12 dedos, which equal 8½ English inches; but the palmo de riebeira, used for measuring masts, &c. is only 3 inches. A braza or tosea is 2 varas, or 6 feet; i.e. 66½ English inches: a paso or pace is 5 feet; an estadal, 12 feet, or 4 varas; and a cuerda, 84 varas. The distances in Spain, on roads made since the year 1766, are laid down at the rate of 8000 varas to the league, i.e. 7416 English yards; so that 5 such leagues are = 21 English miles nearly; but the juridical league is 5000 varas, or 4635 English yards; hence 8 of these are = 21 English miles. Kelly's Un. Camb. See Tables of Weights and Measures.

VARADA, in Ancient Geography, a town of Hifpania Citerior, belonging to the Carpetani. Ptolemy.

VARADEH, in Geography, a town of Egypt, on the coast of the Mediterranean; 22 miles N.E. of Cathe.

VARADES, a town of France, in the department of the Lower Loire; 6 miles N.E. of Ancenis.

VARAGE, a town of France, in the department of the Var; 4 miles N.W. of Barjols.

VARAGGLO, a town of Genoa; 5 miles N.E. of Savona.

VARAGIANS, VARANGIANS, or Vарangi, called also Northmanni, the name of a people who had a consider-
able share in founding the Russian state, and who were a northern tribe of Gothic descent and of warlike disposition and character. Their original country was probably Scandinavia; and they confided of a combined multitude of Danes, Swedes, and Norwegians, who, perpetually in quest of adventures, established governments in the western and eastern parts of Europe, and produced revolutions, especially in the fourth, the consequences of which extended through one quarter of the globe. The first trace of their maritime expeditions is discoverable about the year 516; though it is thought probable that they carried on their piracies at an earlier period, and were generally comprehended under the name of Franks, who already appeared under the emperor Probus as entreprensing mariners. In the year 795, they were first perceived in Ireland. About the year 813, they began their incursions by the Elbe into Frieland and Flanders; in process of time they advanced to Aquitaine and along the Seine; about the year 840, they ravaged France; and in 857, made the conquest of Luna, and afterwards of Pisa, in Italy. In the year 862, Rurik founded the Russian monarchy, and became the father of a dynasty which reigned above 700 years. Accordingly, in the ninth century the Varangians conquered from the Russians, a kindred northEuropean people, the earlist mention of whose name is in the year 839, before Rurik's reception in Novgorod, the modern districts of Reval, St. Petersburg, and Archangel; and subjected the Scavonians, Krivitanches, Tchudes, Vehlenians, and Marnes, to a tribute. The Russians retired to Finland and Karelia; but the Scavonians, in conjunction with the rest of the mentioned nations, drove out the Varangians, and formed themselves at the lake Ilmen, near Novgorod, into a federative democratic republic. Although the Varangians composped the predominant, and under Rurik the most consequential part of the people, yet Scavonians and Russions were soon blended into one nation. As piracy was the exercise, the trade, the glory, and the virtue of the Scandinavian youth, the Baltic was the first scene of the naval achievements of the northern adventurers; they then visited the eastern shores, the select residence of Finnic and Scavonian tribes; and the primitive Russions of the lake Ladoga paid a tribute, the skins of white squirrels, to these strangers, whom they saluted with the title of Varangians, or corsairs. Their superiority in arms, discipline, and honour, commanded the fear and veneration of the natives. In their wars against the more inland savages, the Varangians confederated to serve as friends and auxiliaries, and gradually, by choice or conquest, obtained the dominion of a people, whom they were qualified to protect At length Rurik appeared; his influence was extended by his brothers; the example of service and usurpation was imitated by his companions in the southern provinces of Russia; and their establishments, by the usual methods of war and affilution, were cemented into the fabric of a powerful monarchy.

As long as the descendants of Rurik were considered as aliens and conquerors, they ruled by the sword of the Varangians, distributed citadels and subjects to their faithful captains, and supplied their numbers with fresh streams of adventurers from the Baltic coast. But when the Scandinavian chiefs had struck a deep and permanent root into the soil, they mingled with the Russions in blood, religion, and language, and the first Wladimir had the merit of delivering his country from these foreign mercenaries. They had feated him on the throne; his riches were insufficient to satisfy their demands; but they listened to his pleasing advice, that they should seek, not a more grateful, but a more wealthy matter; that they should embark for Greece, where, instead of the skins of squirrels, silk and gold would be the recompense of their service. At the same time the Russian prince admonished his Byzantine ally to disperse and employ, to recom pense and restrain, these impetuous children of the north. Contemporary writers have recorded the introduction, name, and character, of the Varangians: each day they rove in confidence and ease; the whole body was assembled at Constantinople to perform the duty of guards; and their strength was recruited by a numerous band of their countrymen from the island of Thule. On this occasion, the vague appellation of Thule is applied to England; and the new Varangians were a colony of English and Danes who fled from the yoke of the Norman conqueror. The habits of pilgrimage and piracy had approximated the countries of the earth; these exiles were entertained in the Byzantine court; and they preferred, till the last age of the empire, the inheritance of spotless loyalty, and the use of the Danish or English tongue. With their broad and double-edged battle-axes on their shoulders, they attended the Greek emperor to the temple, the senate, and the hippodrome; he slept and feasted under their trysty guard; and the keys of the palace, the treasury, and the capital, were held by the firm and faithful hands of the Varangians.

About the time of Rurik, a Norman of a similar name, Rurich, became famous in the history of Holland. Soon after this, Olof and Dir founded another sovereignty at Kieff. In the tenth century Ravagual reigned in Polotk, from whose daughter, Rogned, the Russian annals derive the grand-dukes of Lithuania. About the year 1000, they took Apulia from the Greeks, and Sicily from the Harabians. They gave Normandy its name, after Rollo had wrecked that country from the kings of France. Even the conquest of England by the Danes, in some degree formed a part of the history of these northern adventurers. Took's Ruif. vol. i. Gibbon's Rom. Emp. vol. x. See Scavonians.

VARAHA, in Hindoo Mythology, a name of the god Vifhnu, meaning a boar; he having in one of his ten grand incarnations assumed that form, called Varahavatara; which see.

VARAHAVATARA, is one of the ten grand incarnations of their god Vifhnu. In this god assumed, as is commonly said, the form of a boar, Varaha; but is usually represented in pictures, with the head of that animal on the body of a man, four-armed, holding the attributes of Vifhnu. On the elevated bulbs of the boar rests a cresent, containing in its concavity an epitome of the earth, which had been submerged in the ocean, as a punishment for its iniquities. So that this avatar, or incarnation, the third of Vifhnu, seems to be a repetition of the story of the deluge, like the two former, which are named Maityavatara and Kurmavatara, noticed under those articles. The second combines with it a portion of astronomical allegory, and none of the other ten avatars have any apparent reference to the general catastrophe, so pointedly indicated by the three first, which are understood to have occurred in the earlist ages of Hindoo history; if such a chaotic mass as their fabulous records may be dignified by such a title.

There are many fables accounting for the shape assumed on this occasion by Vifhnu, which our limits will not allow us to recite.

VARALLO, in Geography, a town of Italy, in the department of the Gogna, on the Sepia; 24 miles N.N.W. of Novara. N. lat. 45° 49'. E. long. 8° 14'.

VARAMBON, or VAREMBON, a town of France, in the department of the Ain; 2 miles S.W. of Pont d'Ain.

VARAMUS,
VAR

VARAMUS, in Ancient Geography, a river of Italy, in Venetia, which discharges itself into the Alenus. Phin.

VARANASI, the classical name for the city of Benares, in the East Indies. (See Benares.) This name is said to comprise that of two rivers which form a junction near the city.

VARANGI. See Acoluthin.

VARANGUEBEC, in Geography, a town of France, in the department of the Channel; 10 miles W. of Careton.

VARANIA, in Ancient Geography, a town of Sciria, taken possession of in the year 1143 by Perigord, general of Manuel, emperor of Constantinople.

VARANO, in Geography, a lake of Naples, in Capitanata, which communicates with the Adriatic; 13 miles N.N.W. of Monte St. Angelo.

VARANO de Marchii, a town of the duchy of Parma; 12 miles W.S.W. of Parma.

VARASDIN, a town of Croatia, on the S. side of the Drave, with a castle and citadel; near it is a warm bath; 186 miles N.W. of Belgrade. N. lat. 46° 30'. E. long. 16° 25'.

VARASELLYGUNGE, a town of Hindoostan, in Bahar; 14 miles S.S.E. of Bahar. N. lat. 25° 2'. E. long. 85° 50'.

VARBRESIE, a town of France, in the department of the Rhône and Loire; 9 miles N.W. of Lyons.

VARCES, a town of France, in the department of the Ibre; 7 miles S. of Grenoble.

VARCHI, Benedetto, in Biography, was born at Florence in the year 1502, and destined to trade; but manifesting an inclination for literature, he was sent to the university of Padua. His progress in the belles lettres induced his father to educate him for the law at Pisa. But Benedetto, after the death of his father, devoted himself entirely to literature; and when the Strozzi, to whom he was attached, were obliged to quit Florence, he followed them, in 1534, first to Venice and then to Bologna. At Bologna, and also in Padua, he spent some years in study, and in cultivating an intercourse with learned men. At Padua he became a member of the Academy degli Infiarnati, and read public lectures on morals, and several dissertations on the poems of Petrarch, Bembo, and others.

Cosimo I., grand duke of Tuscany, apprized of his reputation, recalled him to Florence, and alligned to him the office of writing a history of the late revolution in that city, with a yearly stipend. Whilst he was thus employed, he was attacked in the night by several persons, who apprehended that his narrative would not be favourable to them, and inflicted on him many wounds. When he recovered, he declined, from motives of prudence or policy, to inform against the perpetrators, though he knew them. In the Florentine academy, of which he was one year confidul, he delivered lectures. Cosimo recompensed his services with the provostship of Monte Varchi, on which occasion he took holy orders; but before he could remove thither, he died of an apoplexy in 1553, at the age of sixty-three; and his eulogy was delivered, at his funeral, by Lionardo Salvisti.

Varchi was a man of general literature. He wrote a Florentine history, comprising the period from 1527 to 1538, in which he was chargeable with gross adulation to the house of Medici. He also published several harangues, academical and funeral; poetical pieces, and a comedy in Italian. As a grammarian, he gained reputation by his dialogue "Eroclano," treating particularly of the Tuscan language. His translations of "Seneca on Benefts," and of the "Philosophical Confutation of Boethius," into Italian, are deemed elegant. His "Lezioni lette nel Accademia Fiorentina" comprehends much various erudition. Upon the whole, Varchi ranked as a man of learning, to whom Italian literature was much indebted. Moreri. "Tiraboschi. Gen. Biog.

VARCIA, in Ancient Geography, a town of Belgic Gaul, upon the route from Cambrai to Andematunum, between Vefontio and Andematunum, according to Antonine's itinerary.

VARDA, in Geography, a river of Europe, which rises near Kolumbats, in Macedonia, and runs into the gulf of Saloniki; 16 miles W.S.W. of Saloni.

VARDEGUS, a small island of Ruffia, in the Frozen ocean; 100 miles N.N.W. of Kola. N. lat. 70° 25'. E. long. 30° 34'.

VARDEN, or Wardan, a town of Egypt, on the W. branch of the Nile, formerly called Latopolis. In modern times it has been famous or rather infamous for the abode of pirates, who robbed the vessels which navigated the Nile. These robbers were routed out, and dispersed by Ali Bey. Here Father Sigh burned heaps of ancient manuscripts, deposited in a dove-house, as books of magic; 18 miles N.N.W. of Cairo.

VARDHUYS. See Wardhuys.

VARDLE, in Rural Economy, a term applied in some cafes to the eye or thimble of a gate, which has a spike only. See Gate.

VARDON, in Geography, a town of Abafcia, on the Black sea; 28 miles W.N.W. of Mamak.

VARDONES, in Ancient Geography, a people of Germany, who formed a branch of the Vandals.

VARDULI, a people of Hispania Citerior, upon the coast, between the Pyrenees to the E. and the Carlttes to the W. Trolemy has assigned to them the town of Menorca.

VARECA, in Botany, a bad and merely temporary name, taken from Walchwarza, by which this fruit appears to be known in Ceylon. Gartner received it, with that appellation, from the collection of seeds at the Leyden garden, and thought it might constitute a new genus. We shall give his description.—Gartn. v. 1. 290. t. 60.—Cliffs and order, as well as the Nat. Ord., unknown.

Gen. Ch. Flower unknown. Peric. Berry superior, of one cell, half an inch long, ovate, with six angles, tipped with a short point; supported at the base by a small round disk, having six light notches. Coat coriaceous, thin. Pulp by age becomes fpongy and membranous, divided into partial cells for the reception of the seeds. Seeds numerous, rather large, nearly ovate, rendered variously angular by mutual pressure, their colour a smoky brown, all inclosed in separate partial cells; the outer seeds attached to the coat of the fruit; the inner imbedded in its pulp. Integument double; the outer thick, coriaceous; inner membranous, very thin. Albumen the shape of the seed, thick, white, of the substance of an almond. Embryo nearly the size of the alburnus, compressed, pale yellow. Cotyledons ovate, or rounded, leaft, flat, very thin. Radicle long, nearly cylin- drical, centripetal, or indeterminate.

Eff. Ch. Flower... Berry superior, of one cell; pulp in many partial cells, appropriated to each seed. Seeds inserted into the coat of the berry.

Gartner oberves, that the structure of this fruit agrees, in many points, with that of the Gourd tribe, Cucurbitaceae; but it differs from all hitherto known of that tribe, in being fuperior,
superior, and in having remarkably albuminous seeds, whereas the Cucurbitaceae usually have no albumen. We would remark, with due deference to this justly celebrated caryological gift, that the partial cells of the pulp appear to be merely what must occur, in the drying up of any such berry, and probably have no existence in a recent state of the fruit. They are therefore scarcely entitled to be mentioned in the essential character.

VAREILLES Sommeres, in Geography, a town of France, in the department of the Vienne; 7 miles N.E. of Civray.

VAREL, a town of Germany, in the county of Oldenburg; 22 miles N. of Oldenburg.

VARELLE, a small island in the Chiffenea, near the E. coast of Malacca. N. lat. 3° 18'. E. long. 104°.

VAREN, a town of France, in the department of the Aveiron; 18 miles N.W. of Alby.

VARENA, a town of Italy, on the lake of Como; 15 miles N.E. of Como.

VARENE, a town of Canada, on the right bank of the St. Laurence. N. lat. 45° 41'. W. long. 73° 10'.—Allo, a town of France, in the department of the Allier; 10 miles N. of Cuffet.—Allo, a town of South Carolina; 20 miles S.E. of Queenborough.

VARENNE le Grand, a town of France, in the department of the Saône et Loire; 6 miles S. of Châlons.

VARENNES, a town of France, and seat of a tribunal, in the department of the Meuse. In this town the king and queen of France, with the dauphin, the princes royal, and the princess Elizabeth, were stopped in their journey to Montmedy, when they attempted to escape, in the month of June 1791; 7 miles N. of Clermont en Argonne. N. lat. 49° 14'. E. long. 5° 7'.—Allo, a town of France, in the department of the Upper Marne; 6 miles S.W. of Bourgogne.

VARENTUM, Varentum, in Ancient Geography, a town of Italy, in Etruria, according to the Itinerary of Antonine.

VARESA, in Geography, a town of Genoa; 10 miles N.N.W. of Brugnato.

VARESIO, a town of Italy, capital of the department of the Verbano; 24 miles N.N.W. of Milan. N. lat. 45° 50'. E. long. 8° 49'.

VARGAS, Luis de, in Biography, a Spanish painter of celebrity, was born at Seville in 1528. He went to Italy to improve his talents, and passed seven years in Rome, where he principally directed his attention to Raffaello and P. Perugino's works. When he returned to Seville, he found a formidable rival in Pedro Campana, and he therefore returned to Italy to cultivate his powers still farther; and on returning a second time to his native city, obtained reputation, and employment. He painted for the cathedral two pictures, viz., Christ bearing his Cross, and Adam and Eve; the latter of which is regarded as his master-piece. He executed several other works for the churches in Seville, both in oil and fresco; and he was no less distinguished for his skill in portraiture, particularly in his portrait of Donna Juana Cortes, duchess of Alcala. He died at Seville in 1590, aged 63.

VARGAS Menia, Francesco de, a Spanish lawyer, who occupied several posts in the judicature under Charles V., and became advocate-şical in the supreme council of Castile, was sent by Charles, in 1548, to Bologna, to protest against the translation of the council of Trent to that city. After the dissolution of this council, he spent seven or eight years in a public capacity at Venice. Being ordered by Philip II. to act as resident deputy to the Spanish ambassador at Rome, his known learning and integrity caused him to be much consulted by the cardinals on the subject of episcopal jurisdiction. On his return to Spain, he was nominated a counsellor of state; but at length retired from the world to the monastery of Cifnos near Toledo. He was author of several works; particularly " De Episcoporum Jurisdictione, et Pontificis Maximis Authoritate," Venet. 1703; "Commentaries upon War against the Infidels," etc. In 1700, Le Vaflor published in French, at Amsterdam, "Letters and Memoirs of Vargas," relative to the council of Trent, which are said not to be very respectful to that assembly. Moreri.

VARGAS, in Geography, a town of Spain, in the province of Biscay; 11 miles S.S.W. of Santander.

VARGEL, or Vargula, an ancient town of Germany, in the territory of Erfurt; 10 miles N.W. of Erfurt.

VARGO, a town of Spain, in Catalonia; 14 miles N. of Sollona.

VARHELY, a town of Transylvania, built on the ruins of Sarmizagetusa, the ancient capital of Dacia, afterwards named by Trajan, Ulphia Trajana; 60 miles E. of Temefvar.

VARI. Persons were formerly so termed, when their legs were deformed, and their toes turned in an unusual degree inwards.

VARI, in Medicine, hard, inflamed tubercles, occurring on the face and neck of young people, of both sexes, after the commencement of the period of puberty.

This eruption, which disfigures the countenance at that period of life when personal appearance is usually of the greatest importance in the estimation of the persons affected, has been therefore the object of medical attention from the earliest ages, though in itself but a trivial complaint. Celsus oberves, that the Roman ladies in his time were so solicitous of maintaining their beauty, that he deemed it necessary to mention the remedies for this affection of the skin, which otherwife he considered as too trifling for the notice of the physician. "Pene ineptiae sunt, curare varia et lenticulas et phylites (freckles and fun-spots); fed eripi tamen femina cura cultis fui non potest." (De Medicina, lib. vi. cap. 5.) The circumstance of this eruption occurring at the age of puberty has given rise to the appellations given to it by the Greek physicians, namely, iontob and acme. The term iontob signifies the lanugo, or first down of the beard, during which it begins; and γαρδερ καιρων, implying that it appears at the acme, or period of full growth and evolution of the body. (See Julius Pollux, Onomasticon, lib. iv. cap. 25. Aétius, Tetrabibl. ferm. iv. cap. 13, &c.) Under this term acme, Dr. Willan arranged the disease in the order of tubercles, and described four varieties of the eruption, with the epithets simplex, punctata, indurata, and rofacea. See Dr. Bateman's Practical Synopsis of Cutaneous Diseases, according to the Classification of Dr. Willan, p. 275.

The acme, then, consists of an eruption of these vari, or distinct, hard, inflamed tubercles, which are sometimes permanent for a considerable length of time, and sometimes suppurate very slowly and partially, forming only a little matter at the top. They usually appear on the face, especially on the forehead, temples, and chin, and not unfrequently on the neck, shoulders, and upper part of the breast, to the extent that might be covered by a tippet; but never descending to the lower parts of the trunk, or appearing on the extremities. This, however, does not depend on the parts being uncovered; for the limitation is the same in both sexes. As the progress of each tubercele is slow, and they appear in succession, they are generally seen at the same time in their various stages of growth and decline; and, in the
the more violent cases, are intermixed also with the marks or velliges of those which have subfided.

In different cases, the progress and appearance of the eruption vary considerably, which has given rise to the subdivision into species suggested by Dr. Willan. Thus in the acne simplex, the eruption consists of small vari, which appear finely, and are not very numerous, nor accompanied by much inflammation, nor by any intermediate affection of the skin. Many of the tubercles do not proceed to supuration; but gradually rise, become moderately inflamed, and again slowly subside, in the course of eight or ten days, leaving a transient purplish red mark behind. But others go on to a partial suppuration, the whole processes of which occupies from a fortnight to three weeks. The tubercles are first felt in the skin like a small hard seed, about the size of a pin's head, and enlarge for three or four days, when they begin to inflame: about the sixth or seventh day they attain their greatest magnitude, are prominent, red, smooth, and shining, and hard and painful to the touch. After two or three days more, a small speck of yellow matter appears on the apices of some of the tubercles; and when these afterwards break, a thinner humour is secreted, which soon dries into a yellowish scab. The inflammation now gradually declines, the size and hardness of the tubercles diminish, and the small scab becomes loosened at the edges, and at length falls off at about the end of the third week. The individual tubercles, which rise and suppurate in succession, pass through a similar course.

In the acne indurata, the tubercles are larger, as well as more indurated and permanent, than in the former variety. They rise often in considerable numbers, of a conical, or oblong coniform kind, and are occasionally so acuminate, as if tending to immediate suppuration, being at the same time of a bright roseate hue; yet many of them continue in a hard and elevated state for a great length of time, without any disposition to suppurate. Others, however, pass on very slowly to suppuration, the matter not being completely formed in them, for several weeks, and then only a small part of the tubercles are removed by that process. Sometimes two or three coalesce, forming a large irregular tubercle, which occasionally suppurates at the separate apices, and sometimes only at the largest. In whatever mode they proceed, the vivid hue of the tubercles gradually becomes more purple or even livid, especially in those in which there is no tendency to suppurate. Slight crusts form upon the suppurating tubercles, which after some time fall off, leaving small scars, surrounded by hard tumours of the same dark red colour; and these sometimes suppurate again at uncertain periods, and sometimes slowly subside and disappear, leaving a purple or livid discoloration, and occasionally a slight depression, which is long in wearing off.

The tubercles, even when they do not suppurate, but especially while they continue highly red, are always fore and tender to the touch; so that walking, shaving, the friction of the clothes, &c. are somewhat painful. In its most severe form, this eruption nearly covers the face, breast, shoulders, and top of the back, but does not descend lower than an ordinary tippet in drefs; yet this limitation of the disorder is independent of the exposure of those parts; for it occurs equally in men and women. In a few instances in young men, an extensive eruption of acne indurata has been seen affecting the covered parts, while the face remained nearly free from it. By the successive rise and progress of the tumours, the whole surface, within the limits just mentioned, was spotted with the red and livid tubercles, intermixed with the purple discolorations and depressions left by those which had subfided, and variegated with yellow suppurating points and small crusts, so that very little of the natural skin appeared. Sometimes the black puncta of the sebaceous ducts were likewise mixed with the vari and their sequelae.

Cure of Vari.—Vari being generally a local disease, the acne is to be treated chiefly by external applications. Except in females, indeed, this variety of the eruption seldom calls for the attention of medical men. The ancients agree in recommending a number of stimulant applications, with the view of discharging the “thick humours,” which were supposed to constitute the vari. Lotions and liniments, containing vinegar and honey, sometimes combined with an emulsion of bitter almonds, and sometimes with turpentine, resin, myrrh, and other gums, or with alum, soap, and Cimolian earth, or the bruised roots of the lily, cyclamen, narcisius, &c. were the substanies which they principally employed. They were doubletis correct as to the principle, as a gentle stimulus to the skin is the most safe and effectual remedy. The apprehensions, which have been strongly expressed by the humoral pathologists, of producing internal disorder by the sudden repulsion, as it has been called, of these cutaneous eruptions, are not altogether hypothetical. Head-ache, and affections of the stomach and bowels, have sometimes been thus produced, which have ceased on the reappearance of the eruption; but, on the whole, as far as our observation goes, this alternation of disease is less frequent and obvious in this form of acne, than in the pustular and crutofe eruptions of the face and head.

The stimulant applications, which are most easily proportioned to the irritability of the tubercles, are lotions containing alcohol, which may be reduced or strengthened, according to circumstances, by the addition of any distilled water. It is not easy to describe the appearances of the eruption, which indicate any certain degree of strength in the lotion; but a little observation will teach this discrimination. If the tubercles are considerably inflamed, and a great number of them pustular, a dilute mixture will be requisite; containing, for example, equal parts of spiritus tenuior and of rose or elder-flower water. The effect of a very acrid lotion, under such circumstances, is to multiply the pustules, to render many of them confluent, and to produce the formation of a crust of some extent, as well as to excite an inflammatory redness in the adjoining skin. A slight increas of the inflammation, indeed, is sometimes occasioned by the first applications of a weak stimulus; but this is of short duration, and the skin soon bears an augmentation of the stimulant; until at length the pure spirit is borne with advantage, as the inflammatory disposition subsides. Under the latter circumstances, even a considerable additional stimulus is often useful; such as from half a grain to a grain or more of the muriate of mercury, in each ounce of the spirit; or a drachm or more of the liquor potass, or of the muriatic acid, in fix ounces. Acetic acid, as recommended by the ancients, and the liquor ammoniac acetatis, afford also an agreeable stimulant, in proper proportions. Sulphur yields a small portion of its substanse to boiling water, poured upon it, and allowed to infuse for twelve or fourteen hours; a quart of water being added to about an ounce of broken sulphur. A lotion of this nature has been found advantageous in slight cases of acne simplex, and especially in removing the roughness and dulness of the face connected with it.

Connected with the eruption of vari, and often giving rise to them, is that appearance of black points in the skin of the face and neck, surrounded by a raised border of cuticle, to which the appellation of acne punctata was given.
by Dr. Willan. These are vulgarly considered as the extremities of small worms or grubs, because, when they are pressed out, a sort of worm-like appendage is found attached to them; but they are, in fact, only little plugs of concreted mucus or flaccidaceous matter, moulded in the small ducts of the cuticular glands into this verrucous form, the extremity of which is blackened by contact with the air. In consequence of this diffusion of their ducts, the glands themselves sometimes inflame, and form small tubercles, or vari, with the little black points upon their surface, which partially suppurate, as in the preceding specks; but many of them remain stationary for a long period, without ever passing into the inflammatory state. Not unfrequently they are intermixed with a few vari, in which the pun[ita] have not appeared.

These concretions may be extracted, by preening on both sides of the specks with the nails, until the hardened mucus is sufficiently elevated to be taken hold of. A blunt curved forceps may be employed with advantage for this purpose; and such a one has been contrived by a surgeon's instrument-maker in London. When the plugs are removed, the disorder becomes simple vari, and requires the treatment above-mentioned. The formation of these concretions, indeed, seems to be in a considerable degree prevented, by increasing the tone of the skin, both by the use of the stimulant lotions before recommended, and by friction, using always a strong rough towel.

The preceding varieties of the eruption of vari occur only in young persons, of either sex, from the period of puberty to the age of thirty or thirty-five, and principally in those of the languid temperament, and they are generally accompanied by good health, and are totally disconnected with any disorder, or with habits of intemperance; but there is another variety of this eruption, which does not occur till after the age of forty, which is always, except from strong hereditary taint, sympathetic of some disea[se] of the digestive organs, or vice versa connected with them, and which therefore is not so easily cured, and is not even benefited by the fame local means which are so efficacious in the former species. This variety of the disea[se] is the gutta ro[sea] of medical authors, and the acne ro[sea] of Dr. Willan.

This eruption of vari, indeed, differs in its appearance very essentially from the preceding species. In addition to the eruption of small suppuring tubercles, there is also a shining redness, and an irregular granulated appearance of the skin of that part of the face which is affected, which is not the part usually occupied by the former species. The redness commonly appears first at the end of the nose, and afterwards spreads from both sides of the nose to the cheeks; the whole of which, however, it very seldom covers. In the commencement the redness is not uniformly vivid; but is paler in the morning, and readily increased to an intense scarlet after dinner, or at any time if a glass of wine or spirits be taken; or if the patient be heated by exercise, or by sitting near a fire. After some continuance in this state, the texture of the cuticle becomes gradually thickened, and its surface uneven or granulated, and variegated by reticulations of enlarged cutaneous veins, with smaller red lines stretching across the cheeks, and sometimes by the intermixture of small suppuring vari, which succcessively arise on different parts of the face. Where there is a strong hereditary predisposition, or by the constant immoderate use of wine and spirituous liquors, this disea[se] may affect the greater part of the face, even the forehead and skin; but the nose especially, in such cases, becomes tumid, and of a fiery red colour: and, in advanced life, it sometimes enlarges to an immoderate size, the no[tril]s being distended and patulous, or the ale[se] fissured, as it were, and divided into separate lobes.

Little can be done in way of cure for this species of vari, the visceral or constitutional malady being the root of the disea[se]; against which, of course, the remedies, both moral and physical, must be directed.

Vari, in Zoology, a name given to the maucacoe, or lemur catta of Linnaeus, with his tail marked with rings of black and white; it is about the size of a cat, and inhabits Madagascar and the neighbouring iles. The vari of Buffon is the ruffled maucacoe of Pennant, the black maucacoe of Edwards, and lemur caudatus gigas, collari bartolo, of Linnaeus. It has orange-coloured irides; long hair round the sides of the head, standing out like a ruff; long tail; the colour wholly black, but sometimes white spotted with black; the feet black. It inhabits Madagascar; it is very fierce in a wild state; and makes so violent a noise in the woods, that the noise of two may be easily mistaken for that of a hundred: when tamed, gentle and good-natured. Pennant.

Varia, in Geography, a town of Hindoostan, in Concan; 25 miles N. of Goa.

VARIA, in Ancient Geography, a town of Hispania Citerior, on the Iberus, N.W. of Caralagiis.

VARIA, Vico-Varo, a town of Italy, in the Sabine territory, but belonging to the Latins; situated on the Valerian way; 8 miles from Tibur, and 27 from Rome. It was also called Valeria.

Varia, in Zoology, a name by which some authors have called the lepord, or pardalis, from the beautiful variegations with which it is marked.

VARIABLE, in Geometry and Analytics, is a term applied by mathematicians to such quantities as either increase or diminish, according as some other quantity either increases or diminishes.

Thus, the semigordians and abscifics of an ellipse, &c. are variable quantities; because, if the one increase, the others increase likewise. They are then called, in contradistinction to constant, or given, or stable quantities; which are always the same though others change; as the femidiameters of a circle, which remains the same, though the abscicfs and semidiameters increase.

Variable quantities are usually denoted by the last letters of the alphabet, x, y, z.

Some authors, instead of variable and constant quantities, use the terms fluent and stable quantities.

The infinitely small quantity by which a variable quantity is continually increasing or diminishing, is called the increment or decrement, or difference; and the velocity with which it increases or decreases at any given point, is called its fluxion; the calculation of which is the subject of the new methodus differentialis, or doctrine of fluxions.

VARIABLE Wind. See Wind.

VARIAM, in Geography, a town of Persia, in the province of Irak; 120 miles E. of Hamadan.

VARIANA, in Ancient Geography, a town of Lower Media, upon the route from Viminacium to Nicomedia, between Auguste and Varilana. Anton. Itin.

VARIANE, a town of Pannonia, upon the route from Emona to Sirium, between Sifca and Meneliance. Anton. Itin.

VARIANCE, Variantia, in Law, an alteration or change of condition in a person, or thing, after some former concern or transmigration therewith.

Thus,
Thus, if the commonalty of a town make a composition with a lord, and afterwards bailiffs be granted by the king to the same town, there, if the lord commence any suit for breach of the composition, he must vary from the word commonly, used in the composition, and use bailiffs and commonly.

**VARIANCE** is also used for an alteration of something formerly laid in a plea; or where the declaration in a cause differs from the writ, or from the deed upon which it is grounded.

**VARIATION of Quantities, in Algebra.** See Changes and Combination.

**VARIATION, in Astronomy.** The variation of the moon, called by Bullialdus the reflection of her light, is the third inequality observed in the moon’s motion; by which, when out of the quadratures, her true place differs from her place twice equated. See Place, Equation, &c.

Sir Isaac Newton takes the moon’s variation to arise partly from the form of her orbit, which is an ellipse; and partly from the inequality of the parts of space, which the moon describes in equal times, by a radius drawn to the earth.

To find the greatest variation, observe the moon’s longitude in the sextants; and, for the time of observation, compute the moon’s place twice equated: the difference between the computed and the observed place is the greatest variation.

Tycho makes the greatest variation 40° 30'; Kepler makes it 51° 49'; Sir Isaac Newton makes the greatest variation, at a mean distance, between the sun and the earth, to be 33° 10'; at the other distances, the greatest variation is in a ratio compounded of the duplicate ratio of the time of the moon’s synodical revolution directly, and the triplicate ratio of the distance of the sun from the earth inversely. And, therefore, in the sun’s apogee, the greatest variation is 33° 14', and in his perigee, 37° 11'; provided that the excentricity of the sun be to the tranversal semidiameter of the orbs magnus, as 1644 to 1000. Or, taking the mean motions of the moon from the sun, as they are tabulated in Dr. Halley’s tables, and the greatest variation at the mean distance of the earth from the sun will be 33° 7', in the apogee of the sun 33° 27', and in his perigee 30° 51'. Phil. Nat. Prin. Math. prop. 29. lib. iii. apud Horley’s Newtoni Opera, vol. iii. P. 71.

**VARIATION, in Geography, Navigation, &c.** A term applied to the deviation of the magnetic needle, or compass, from the true north point, towards either east or west; called also the declination.

The variation, or declination, of the needle, is properly defined, the angle which a magnetic needle, suspended at liberty, makes with the meridian line on a horizontal plane; or an arc of the horizon, comprehended between the true and the magnetic meridian.

In sea-language, the variation is usually called north-easting, or north-westing.

All magnetic bodies, we find, range themselves, in some degree, to the meridian; but it is rare that they fall in precisely with it: in one place they decline from the north to the east, and from the south to the west; and in another place, on the contrary, from the north to the west, and from the south to the east; and that too different at different times.

The variation of the compass could not be long a secret, after the invention of the compass itself: accordingly, Ferdinand, the son of Columbus, in his life written in Spanish, and printed in Italian at Venice in 1571, afferts, that his father observed it on the 14th of September, 1492: though others seem to attribute the discovery of it to Sebastian Cabot, a Venetian, employed in the service of our king Henry VII. about the year 1500. And as this variation differs in different places, Gonzales d’Oviedo found there was none at the Azores; whence some geographers have thought fit in their maps to make their first meridian pass through one of these islands; it not being then known that the variation altered in time. See Gilbert de Magnete, Lond. 1600, p. 4, 5; or Purchas’s Pilgrims, Lond. 1625, book ii. sect. 1. See Variation of the Magnet.

Variations are the hypotheses framed to account for this extraordinary phenomenon; of which we shall mention some of the later, and more probable, only premising, that Mr. Robert Norman, the inventor of the dipping-needle (which see), disputes against Cortes’s notion, that the variation was caused by a point in the heavens, contending that it should be sought for in the earth, and proposes how to discover its place.

The first is that of Gilbert (De Magnete, lib. iv. p. 151, &c.) which is followed by Cabeus, &c.

This notion is, that it is the earth, or land, that draws the needle out of its meridian direction; and hence they argue, that the needle varied more or less, as it was more or less distant from any great continent; consequently, that if it were placed in the middle of an ocean, equally distant from equal tracts of land on each side, eastward and westward, it would not decline either to the one or the other, but point justly north and south. Thus they say, in the Azores islands, which are equally distant from Africa on the east, and America on the west, there is, in effect, found no variation; but as from the Azores you fall towards Africa, the needle begins to decline from the north to the east; and that still more and more, till you reach the shore.

If you still proceed eastward, the declination gradually diminishes again, by reason of the land left behind on the west, which continues to draw the needle.

The fame holds till you arrive at a place where there are equal tracts of lands on each side; and there again there is no variation.

The observations of our mariners, in their first East India voyages, seemed to confirm this fyltem; as they proceed towards the Cape of Good Hope the variation is still eastward; at length arriving at the Cape de las Aguilas, q, d. of the Needles, the meridian line, then dividing Africa into two equal parts, there is no variation at all; but as they proceed farther, and leave the African coast on the west, the variation becomes westward.

But the misfortune is, the law does not hold universally; in effect, a great number of observations of the variations, in various parts, made and collected by Dr. Halley, overturn the whole theory.

Some, therefore, have recourse to the frame and compartments of the earth, considered as interwoven with rocks and shifles, which being generally found to run towards the poles, the needle has been observed to have a general tendency that way; but which seldom going perfectly in the direction of the meridian, the needle, of consequence, has commonly a variation.

Others hold various parts of the earth to have various degrees of the magnetic virtue, as some are more intermixed with heterogeneous matters, which prevent the free action or effect of it, than others.

Others ascribe all to magnetic rocks and iron mines, which, affording more of the magnetic matter than other parts, draw the needle more.

Lately, others imagine earthquakes, or high tides, to have disturbed and dislocated several considerable parts of the earth, and so changed the magnetic axis of the globe, which originally was the frame with the axis of the globe itself.
VARIATION.

But still, that great phenomenon, the variation of the variation, i.e. the continual change of the declination in one and the same place, which the modern observations daily confirm, is not accountable for on any of these foundations, nor even is it consistent with them.

Dr. Hooke communicated to the Royal Society, in 1674, a theory of the variation, the substance of which is, that the magnet has its peculiar pole distant ten degrees from the pole of the earth, about which it moves, so as to make a revolution in 370 years; whence the variation (he adds) hath altered of late about ten or eleven minutes every year, and will probably continue to do so for some time, till it begins to become flower and flower, and will at length be rational and retrograde, and in all probability may return. Birch's Hist. of the Royal Society, vol. iii. p. 131.

Dr. Halley, in the Philosophical Transactions, No. 148, invented a new theory, founded on a great number of observations, many of which were made expressly for the purpose by order of the government; but as they do not extend to a more recent date than about 1680, and as perpetual changes are going on in the variation of different places, the table of results of this learned philosopher is now of little use; we shall therefore avail ourselves of the history of these changes, as published in a recent work on the variation of the compass by W. Bain, master in the royal navy, which contains much important information on this subject, and is deserving of the particular attention of every one engaged in the management and navigation of vessels.

At London, in 1680, the quantity of variation was found to be $11^\circ15' E.$; in 1662, $6^\circ E.$; in 1634, $4^\circ5' E.$; and in 1637, the needle coincided with the true poles of the world; so that a period of 87 years elapsed in changing the $11^\circ15'$ of easterly variation in that city to zero, or until the variation began to take a westerly direction. In 1672, the variation was $2^\circ30' W.$; in 1723, $14^\circ17' W.$; in 1747, $17^\circ40' W.$; in 1780, $22^\circ41' W.$; and in 1793, $23^\circ56' W.$; after which years the variation was zero, it was nearly $24^\circ10' W.$ and it is still nearly the same.

At Paris, in 1530, the variation was $8^\circ E.$; and in 1660, the needle pointed to the true poles of the world; in 1681, the variation was $2^\circ2' W.$; in 1760, $18^\circ20' W.$; in 1804, $22^\circ20' W.$. Hence it follows, that whilst the variation was undergoing an annual change of $10^\circ4'$ during a period of 213 years in London, the yearly change at Paris during a term of 254 years was only $7^\circ10' W.$.

At Dublin, in 1657, the needle coincided with the true poles of the world; and in 1791, the variation was $27^\circ23' W.$; exceeding the variation observed at London by $3^\circ$ or $4^\circ$; and, consequently, the annual change during 134 years, must have been about $12^\circ10' W.$.

While the variation was undergoing this change at London, Paris, and Dublin; we find very nearly a corresponding change at Cape Aguilas, and at the Cape of Good Hope.

At the former of these places there was no variation in 1600, and in 1692, it amounted to $11^\circ W.$; and at the Cape of Good Hope, in 1700, the variation was nearly $10^\circ W.$; and in 1791, it had increased to $24^\circ31'52'' W.$; so that during a period of 91 years, the annual change in the variation at the latter place, must have been about $9^\circ15' W.$.

At St. Helena, the variation in 1600 was $8^\circ E.$; in 1692, $1^\circ W.$; in 1776, $13^\circ15' W.$; and in 1794, it was found to be $16^\circ16' W.$; consequently, the mean annual change in the variation at this place, during a period of 194 years, has been at the rate of $7^\circ52'$.

At Cape Comorin, in 1620, the variation was $14^\circ20' W.$; in 1688, $5^\circ30' W.$; in 1736, $6^\circ15' W.$; and in 1816, there was still no variation at this place; therefore, during a period of 137 years, the mean annual change was $6^\circ15'$; but this includes a term of 60 years, in which there appears to have been a very small change in the declination, viz. about $15'$ annually.

The phenomena presented by the variation at Cape Horn and its vicinity, are extremely different from those observed at the Cape of Good Hope, Paris, and London.

In 1683, in S. lat. $57^\circ27' W.$; long. $57^\circ28' W.$, the variation was found to be $23^\circ10' E.$; in 1773, in S. lat. $56^\circ27' W.$; long. $54^\circ W.$, the variation was $24^\circ25' E.$; in 1786, in S. lat. $53^\circ W.$; long. $70^\circ W.$, the variation was $22^\circ47' E.$; and in 1793, in S. lat. $57^\circ W.$; long. $67^\circ W.$, the variation was exactly $23^\circ E.$ Hence it follows, that during a period of 112 years, the variation near Cape Horn has neither increased nor diminished in a perceptible manner.

At Cambridge, in Massachusetts, in 1708, the variation was found to be $9^\circ W.$; and since that period, it has been diminishing at the rate of $12''$ annually; whilst at Jamaica, Barbadoes, and Lima, the variation has undergone no change during a period of 140 years.

In the northern hemisphere, in the parallel of Spitzbergen, Davis's Straits, Hudson's Bay, &c. the same quantity of variation appears to have existed during the space of 150 years. The quantity or variation from Cape Comorin saltwater, towards Nicobar islands, Java, Ceram, Ambon, Timor, &c. is so very small, as to seldom induce navigators to advert to it in their calculations; and is subject to little or no change. It may, however, be worthy of remark, that 60 miles east from the coast of Coromandel, about the meridian of Madras, the variation changes from east to west; and the same local changes probably take place on the coasts of Chile, Peru, and Mexico.

In 1704, from Valparayfo to Acapulco, a distance of 50° of latitude, the variation was very inconsiderable; for, from the former of these places to Lima, it never exceeds $5^\circ E.$; and from Lima to the latter place, never more than $4^\circ W.$.

The greatest variation that the author, from whom the preceding abstract has been made, is acquainted with, is that which has been observed between Cape Farewell and Labrador, in Hudson's Straits and Baffin's Bay. In N. lat. $52^\circ W.$; long. $52^\circ$ W., it was found by the author above alluded to, to be $40^\circ10'53'' W.$; and as high as N. lat. $66^\circ$, in about the same longitude, it was found to be $50^\circ$ or $52^\circ$; but he expresses some doubt whether this great excess of variation might not have been partially produced by the effects of local attraction.

In 1616, in N. lat. $78^\circ W.$; long. $80^\circ$ (Baffin's Bay), the variation was found to be $57^\circ W.$; and in 1775, N. lat. $62^\circ W.$; long. $65^\circ W.$, the variation was $41^\circ W.$; and in the same year, in N. lat. $65^\circ W.$; long. $79^\circ$, the variation was $45^\circ W.$; and in all these high latitudes, the variation still continues nearly the same.

On the west side of America, in the same parallel of latitude as Davis's Straits, Cape Farewell, &c. we perceive the variation assuming another character, and seldom exceeding half the quantity found at the above-mentioned places.

In 1786, in N. lat. $53^\circ W.$; long. $145^\circ21'$ from Paris, the variation was from $23^\circ$ to $24^\circ E.$; in the same year, in N. lat. $58^\circ$, W. long. $138^\circ$, it was $25^\circ E.$; and in Port des Francois, in N. lat. $58^\circ37'$. W. long. $137^\circ30'$, the variation, as ascertained by the meridional line, amounted to $27^\circ E.$ In 1793, in N. lat. $53^\circ W.$; long. $129^\circ$, the variation was only $20^\circ41' E.$; and in 1794, in N. lat. $61^\circ17'$. W. long. $149^\circ7'29''$; easterly variation was found the greatest quantity observed by Vancouver while on that coast.
VARIATION.

But of all the places on the globe with which we are acquainted, none exhibit such wonderful phenomena in the variation as the coasts of China, Corea, Tartary, Japan, and Kamtschatka northward.

In 1787, from Macao to N. lat. 41°. E. long. 136° from Paris, the quantity of westerly variation never exceeded 2°; and from this last point to N. lat. 51°. E. long. 142°. where the variation was only 53° E., the quantity never exceeded 3°.

In 1804, in N. lat. 52°. E. long. 143° from Paris, there was no variation; 10° farther to the E., and 4° to the S., the change was 11° and 11° 45'; secondly, in the Ethiopian sea, from 5° N., to 20° or 25° S. lat., and from 10° to 15° or 20° E. long., the change in the variation was about 10°; and thirdly, at 50° N. lat., and between 15° E. and 10° W. long., the change was nearly 11°. In these different places, the variation has since continued to increase at nearly the same rate.

During the same interval it was also ascertained, that there were four places or points on the globe where the variation has undergone no change.

These were, first, from the eastern point of Africa to the farthest of the Bermudas; secondly, the environs of the Ile of Madagascar and part of the Zanquetar: thirdly, that part of the ocean which is to the S. and E. of the Sunda islands, between them and New Holland; and fourthly, in the same sea, about 4° S. lat., and 97° E. long., that is, in the middle of the space comprised between the western angle of New Holland and the southern point of Africa. In all these places, the variation did not vary perceptibly during 56 years. And it may be remarked, that observations made since the above period, have not shewn any change worthy of notice in its quantity at the above-mentioned places.

Some intelligent sea-officers are of opinion, that in the western part of the English Channel, the westerly variation has begun to decline, whilst others assert, that the variation is still increasing in the Channel, and as far westward as W. long. 15°, in N. lat. 51°, at which place they say the variation amounts to 30° W. Neither of these opinions, however, can, according to Mr. Bain, be relied on as correct, though each may have been deduced from observation. If the head of the ship is on the east point of the compass at the time of observation, from 20° to 25° of variation will be observed; but on the other hand, if the ship's head is at the west point at the time, the observed variation will amount to 30° or 33°.

The circumstance above alluded to, of the apparent variation being so much influenced by the local attraction of the ship, is certainly of the highest importance; and the means which Mr. Bain has adopted of making it generally known are highly laudable; at the same time, we cannot but feel considerable doubt, after this fact is once pointed out, of the accuracy of many of the observations stated in the preceding pages, as several of these were made by persons wholly unconscious of such an influence, which seems to have been entirely unknown till Mr. Wales, the astronomer, who failed with Capt. Cook, first noticed the phenomenon; and his observations have been since confirmed by Capt. Flinders; and Mr. Bain, in the work we have above alluded to, has added many additional facts to those before known, and to which we shall have again occasion to refer; but in the first place, it will be proper to infer a general table of variations in different latitudes, as given in the Philosophical Transactions for 1757, with additional observations of the above author.

It may not be amiss to add here, as belonging to the history of this subject, that we owe the first variation chart to Dr. Halley. Previously to this period he had collected, and made, a multitude of observations on the variation of the needle in many parts of the world, and was enabled to draw on a Mercator's chart, lines showing the variation of the compasses in the places through which they passed. But as the deviation of the magnetic meridian from the true one was then, as now, subject to continual alteration, this chart was soon found useless.

However, in 1744, Mountain and Dobfon published a new variation chart, adapted to that year; which being well received, they published a second, adapted to 1755; and a third in the following year: the last we know of.

Nicholson strongly recommends the employment of the variation as a means of finding the longitude at sea; but navigators are long since convinced of its inadequacy. Vancouver, speaking of this subject, says, "This very able seaman, Nicholson, still wedged to formerly-adopted opinions, strongly recommends the variation of the compass as a mean for ascertaining the longitude at sea; yet, had we been no better provided, we might have searched for the Cape of Good Hope, agreeable to his propositions, to little effect; for when we were in lat. 35° 7' S., with 20° 16' W. variation, we had only reached the long. of 60° 30' W.; and again, when in lat. 35° 22' S., with 22° 7' W. variation, we had only advanced to the long. of 110° 25', instead of being, according to Mr. Nicholson's hypothesis, in the first instance, nearly under the meridian of the Cape of Good Hope, and in the second, under that of Cape Aguilas; and it was not until we had nearly 26° W. variation, that we approached the meridian of the Cape of Good Hope. The observations for the variation were made with the greatest care and attention; and though generally considered as correct, they differed from one to three, and sometimes to four degrees; not only when made by different compasses, placed in different situations on board, and the ships on different tack, but by the same compasses in the same situation, and at moderate intervals of time; the difference in the results of such observations, at the same time, not preferring the least degree of uniformity. Hence the alteration amounts nearly to an absurdity, which states, that with 20° to 20° 10', or 20° 30' westerly variation, you will be certain of such and such longitudes; and it is greatly to be feared, that navigators who rely on such means for ascertaining their situation in the ocean, will render themselves liable to errors that may be attended with the most fatal consequences."

A Table
# VARIATION.

A Table exhibiting the Changes of Variation from the Year 1700, in the most frequented Seas.

VARIATION.

Of the Curve of No Variation.—In the preceding part of this article, we have principally alluded to the variation east or west, at different times and in different places; but it is no less interesting to trace the curve in which no variation is observed. We have seen, that there are certain points in the northern and southern hemispheres where the needle points to the true poles of the world; these points, however, are not all situated on the same meridian, but form an irregular curve, inflected different ways, and in perpetual motion.
