1819.
TOLERIUM, in Ancient Geography, a town of Italy, in ancient Latium, and one of those which were taken by Coriolanus, according to Plutarch and Steph. Byz. 

TOLESCAPATAM, in Geography, a town of Hindoos, in the Carnatic; 28 miles S.E. of Tanjore.

TOLETUM, Toledo, in Ancient Geography, a town of Hispания Citerior, belonging to the Carpetani, to the S.W. upon the Tagus. According to Silva and other Spanish historians, this city was founded by a confederate body of Jews, who, on their emancipation from captivity, 540 years before the vulgar era, established themselves here, and called the place Toledoth, or Toledath, that is, mother of the people. However this be, Toledo became in process of time a Roman colony. Caesar made it a place of arms, and Augustus rendered it the principal seat of justice for the provinces of Spain in his department. Many ancient remains, such as an aqueduct, a road, &c. have been discovered at Toledo; which fee.

TOLETUS, (de Toledo,) Francis, cardinal, in Biography, was born at Corduba in 1532, and studied at Salamanca, where he took the degree of doctor in theology, and was made professor of philosophy. At the age of twenty-seven years, he entered the society of Jefuits, and in the following year he went to Rome, and read lectures on Aristotle and theology. He acquired great popularity as a preacher, and, in 1562, when he was compared with other preachers, it was said "Toledo teaches, Panigarola pleads, and Lupo moves." He was employed by several popes in various legations, and in 1593 Clement VIII. invested him with the purple, being the first Jefuit who obtained that dignity. He died at Rome in 1596, at the age of sixty-four. Toledo was one of those theologians who were employed by Sixtus V. in revising his bible. Of his various works, we shall only mention his "Sum of Cafes of Con.

Vol. XXXVI.

TOLFA, in Geography, a town of the Popedom, in the Patrimonio, in the environs of which are mines of alum and iron, with warm baths, and quarries of alabaster and lapis lazuli, about four miles from the sea-coast; 25 miles N.W. of Rome.

TOLHAR, a town of Hindoos, in Lahore; 18 miles S. of Rotas.

TOLHUES, a town of Gueldeland, on the Rhine; where the French paused that river in the year 1672, and the Hanoverians in 1758; 6 miles W.S.W. of Emmerick.

TOLI, a town of European Turkey, in Macedonia; 85 miles N.W. of Saloniki.

TOLITZIN, a town of Rouflia, in the government of Mogily; 70 miles N. of Mogily.

TOLKEMIT, a town of Prussia, in the province of Ermeland, on the Frich Haf; 12 miles N.E. of Elbing. N. lat. 54° 18'. E. long. 19° 33'.

TOLL, Telonium, a Saxon word, though derived originally from the Latin tollere, to take away, or rather the Greek τολος, tribute, tax. It has two acceptations, denoting, first, a liberty to buy and sell within the bounds of a manor: and, secondly, TOL is also used for a tax or custom paid for passage, or for vending goods in a market, fair, or the like.

This tax originated in the expence attending the construction and preservation of highways, bridges, and canals: and it is evidently just that a traveller, and especially a merchant, who derives advantage from a bridge, a canal, or a causeway,
TOLL

Tollgate, in his own passage, and in more commodiously conveying his merchandise, should contribute to the expence of these useful establishments, by a moderate contribution; and if the state thinks proper to exempt the citizens from paying it, it is under no obligation to gratify strangers in this particular. But a law so just in its origin, frequently degenerates into a great abuse. There are countries where no care is taken of the highways, and where they nevertheless require considerable tolls.

Some records make mention of toll-ter, or thorough toll, which is money paid for passage in or through some highways, or over ferries, bridges, &c. Toll traves, for palling or driving cattle over a private man's ground. And toll-turn, or turn-toll, which is paid at the return of beasts from fairs and markets, though they are not fold.

By the ancient laws, the buyers of corn and cattle in fairs or markets were made to pay toll to the lord of the market, in testimony of the contract there lawfully made in open market, because private contracts were held unlawful.

Some interpret toll a liberty, as well to take as to be free from toll; for that they who are indebted with toll are custom-free.

Of this freedom from toll the city of Coventry boasts an ancient charter, granted them by Lefrick, or Luriche, earl of the Mercians, in Edward the Confessor's time, who, at the importunity of Godiva, his lady, granted this freedom to the city.

Toll-bar, or Stop, on a canal, is a beam for stopping boats at the toll-houses.

Toll-Houses, habitation conducted on the banks of a canal or navigation for the toll-clerks.

TOLLAND, in Geography, a county of America, in

the state of Connecticut, divided into ten townships, and containing 13,779 inhabitants. — Also, a town of the same state and county; 65 miles W.S.W. of Boston, containing 1610 inhabitants. N. lat. 41° 38'. W. long. 72° 26'.

TOLLEIT, a town of Austria; 6 miles S.W. of Erfu-derg.

TOLLEN, a lake of Anterior Pomerania, near Trepto.

TOLLENON, among the Romans, a warlike machine, formed in this manner: one beam was fixed very deep in the earth, and on the top of it another more than half as long, and moveable upon a centre. On one end of this crofs-beam was placed a covering of hurdles or planks, within which a few soldiers were put, and, by pulling down the other end with ropes, these were raised above the walls of a besieged town.

TOLLERON was also an engine for raising water out of a draw-well.

TOLLERSHAM, in Geography, a town of Auffria; 4 miles N.E. of Zwetl.

TOLLES, or TOLLE, names given by some to the tolfs, and by others to the glandular abscesses sometimes affecting the limbs.

TOLLESIO, in Geography, a town of Sweden, in West Gothland; 23 miles E.N.E. of Gothenburg.

TOLLET, Thomas, in Biography, a composer for, and a performer on, the common flute, when it was in its highest favour in England. He published likewise directions for playing on the French flageolet. And, in conjunction with John Linton, whose instrument was the flute, one of King William and queen Mary's band, published a work entitled "A Confort of Muick in Three Parts." A ground composed by Tollet, was much in favour during our own time.

TOLLING a Bell. See Ring.

TOLLIUS, Cornelius, in Biography, a man of learning in the 17th century, was born at Utrechts, and became secretary to Isaac Vossius, by whom he was dismissed under a charge of unfaithfulness. He was afterwards professor of eloquence and Greek at Harderwyk, and secretary to the curators of that university. His works were numerous: and the time of his death is unknown.

TOLLIUS, James, M. D., brother of the preceding, professor of eloquence and Greek in the university of Utrecht, was the author of many learned works, and made several journeys for literary purposes, an account of which was given in a posthumous work, entitled "Epitome Itinerarium," published with notes, by Henninsius at Amsterdam. A work of somewhat similar title, viz. "Signa Itinerarii Italici," was published by himself at Utrecht in 1696, and contained the writings of some ancient ecclesiastical authors in Greek and Latin, with the editor's notes. He had also previously published an edition of "Aulisius, cum Notae Variorum," 1671: of "Ciceronis Oratio pro Licinio," with notes and a commentary, 1677; and of "Longinus," Gr. and Lat. with Boileau's French translation, and notes by himself and others. He had also directed his attention to alchemy, as appears by his "Manuductio ad Colum chemicum;" "Sapientia insensis, five Promissi chemici," and "Fortuita Sacra, in quibus, praeter critica nonnulla, tota fabularis Historia Graeca, Phæniecis, Egyptiana, ad Chemiam pertinere spirurit." From this work were selected comparisons between the Greek and Latin poets, printed at Leyden under the title of "Dissertationes selecte criticae de Poeticis Graecis et Latinis." Tollius died in 1696.

Another brother of this family, named Alexander, presented to the public an edition of "Appiani Alexandri Romanæ Historiarum," Gr. and Lat. Morey.

TOLLUNDY, in Geography, a town of Hindoostan, in Cude; 18 miles N. of Bareilly.

TOLMEZO, a town of Italy, in Friuli, with a castle, on the Tajamoto. Near the town is an extensive and celebrated linen manufacture, which, in the year 1782, produced 40,000 pieces of printed linen for exportation; 12 miles N.W. of Gemona. N. lat. 46° 23'. E. long. 12° 52'.

TOLMIDESSA, in Ancient Geography, a town of Syria, in the small country called Chaleidica. Ptol.

TOLMINO, in Geography, a town of Germany, and capital of a district, in the duchy of Carniola; 9 miles S.S.W. of Feldes. N. lat. 46° 12'. E. long. 13° 47'.

TOLNA,
TOLNA, a town of Hungary, on the Danube; 50 miles S. of Buda. N. lat. 46° 29'. E. long. 18° 41'.

TOLNÁI, a town of Hindeofoan, in the country of Baghna; 70 miles W. of Barhpaupur. N. lat. 21° 15'. E. long. 75° 5'.

TOLI, a town of Spain, in Catalonia; 22 miles N. of Balaguer. - Allo, a town on the E. coast of the island of Morty. N. lat. 2° 12'. E. long. 128° 18'.

TOLI Bay, a large bay on the E. coast of the island of Celebes, very broad at its entrance, and becoming narrower towards the bottom. S. lat. 1° 50' to 3° 5'. E. long. 121° 18' to 123°.

TOLOMETO, a seaport of Africa, in the country of Tripoli, anciently called Tripolitani; 350 miles E. of Tripoli. N. lat. 32° 30'. E. long. 20° 40'.

TOLOMMEI, Claudius, in Biography, a patron of literature and the arts, was born at Siena, of an ancient and noble family, in 1412. Having spent many of his earlier years at the court of Rome in the service of cardinal Ippolito de' Medici, he attacked himself to the duke of Parma and Placentia. Upon his death he removed to Padua, and in 1549 was nominated to the bishopric of Corioli, an island in the Adriatic. In 1552 he became one of the sixteen conservators of the public liberty of Siena, and joined three other citizens in an embassy to France. Having spent about two years in that country, he returned to Rome, and died there in 1555. Tolommei took pains in cultivating the Italian language, and contended that it ought to be denominated the Tuscan. With a view of reducing Italian verse to the measure and harmony of the Latin, he published, in 1539, his "Verifi e Regole della Poesia Nuova," but his scheme did not succeed. To him was ascribed the foundation of the academy "Della Virtù" at Rome, for the purpose of explaining the architectural work of Vitruvius; and for which he was eminently qualified by his classical and antiquarian learning.

TOLON, in Geography, an island in the Grecian Archipelago. N. lat. 37° 35'. E. long. 23°.

TOLONES, one of the smaller Philippine islands, near the N. coast of Samar. N. lat. 12° 30'. E. long. 124° 57'.

TOLOSA, or TOLOSA, a town of Spain, and capital of the province of Guipuscoa, celebrated for its fleet manufacture, particularly of sword-blades; 7 miles S. of St. Sebastian. N. lat. 43° 12'. W. long. 2° 7'.

Tolosa, in Ancient Geography, a town of Gaul, in the Narbonnese province, and diocese of Toulouf.

TOLTOÉ, a people of Africa, in Mauritania Caferiana.

TOLUM, in Geography, an island in the East Indian sea, of a triangular form, and about 45 miles in circumference, confidered as one of the Salibano islands. N. lat. 4° 12'. E. long. 126° 28'.

TOLPAS, in Ancient Geography, a place of Spain, between Ilerda and Pertusa. Anton. Itin.

TOLPIAS, in Geography, a river of Ruffia, in the province of Ullinj, which runs into the Schegur, N. lat. 63° 40'. E. long. 58° 22'.

TOLPIAS, in Botany, a word of which we can trace neither the derivation nor meaning; and which seems to have been actually invented by Adanfon; nor is it the only instance of such a kind of forgery to be found in his book. We have sometimes been tempted to suppute these seemingly original names of Adanfon might be reduced from some remote sources of nomenclature or literature; but the search has always proved vain. He was no scholar, nor is his new French orthography founded in any extensive knowledge, much less any refined taste, in language, but in more affectation. Gartner cannot be excused for adopting the above name, when he had the choice of an excellent one, (see DREPANA,) given by Jussieu to this same genus. Nevertheless, Tolpis is now established, and cannot without inconvenience be set aside. - Adanfon. Fam. des Pl. v. 2. 112. Gärtn. v. 2. 371. t. 166. Willd. Sp. Pl. v. 3. 1668. Alt. Hort. Kew. v. 4. 461. Sm. Prodr. Fl. Grac. Sibth. v. 2. 140. Lamark Illust. t. 651. Bivona Monogr. delle Tolpids. (Drepania; Juss. 169. Desfont. Atlant. v. 2. 232.) - Chais andoder, Synonyem Polyanthus-equalis. Nat. Ord. Compotis seminifolius, Linn. Chloeares, Jull. Gen. Ch. Common Calyx ovate, of many linear, nearly equal, parallel, close scales, with a distinct series of somewhat scattered and lax, awl-flaped, incurved scales at the base. Cor. compound, imbricated, uniform; the florets numerous, equal, all perfect, each of one petal, ligulate, abrupt, five-toothed. Stom. Filamenta five, capillary, short; anthers united within a cylindrical tube. Pfl. Gemere ovate-oblong: style thread-shaped, the length of the stamens; stigmas two, recurved.Periph. none, except the cloven permanent calyx, tumid at the base. Seeds solitary, small, obovate, frariated; down felli; that of the radius of numerous, little, membranous, equal, acute, marginal teeth, or scales; that of the disk of similar scales, accompanied by two, four, or ten straight, rough bristles, longer than the seed. Recip. cellular, with crenate edges to the cells.

Eff. Ch. Receptacle cellular. Calyx equal, with many awl-flaped scales at the base. Seed-down of the circumference toothed: that of the disk toothed, accompanied by several bristles.

The present genus agrees most with Crepis in habit. (See that article.) The seed-down affords a clear distinctive character, and the outer scales of the calyx do not assume that enlarged, dilated, tumid appearance so remarkable in Crepis.

1. T. barbata. Purple-eyed Succory-hawkweed. Willd. n. 1. Ait. n. 1. Prodr. Fl. Grac. n. 1942. Bivona Tolp. 13. t. 3. Savi Etrusc. v. 1. 183. (Crepis barbata; Linn. Sp. Pl. 1131. Curt. Mag. t. 35. Hieracium medio negro batticum majus; Hern. Parad. 185. t. 185. H. calyce barbattum; Column. Eophr. v. 2. 28. t. 27. f. 1. H. medio nigrum, flore majore; Ger. Em. 1625.) - Leaves elliptic-lancolate, toothed. Outer scales of the calyx falcate, dient, longer than the inner. Bristles of the seeds two or four. - Native of sandy fields, or waste ground, especially near the sea, in the south of France, Italy, and the Levant, flowering in May and June. This elegant hardy annual, very easily of cultivation, has, for two hundred years past, been common in gardens, where it produces, from midsummer till the autumnal frosts, abundance of flowers. The stems are branched, erect, spreading or decumbent, rather downy, lefthy, repeatedly subdivided at the top, in a corymbose, or somewhat forked manner, the flowers, which are at first terminal and solitary, being copiously overtopped by their successors. The scales of their outer calyces are partly scattered down the stalk. Corolla expanded in the early part of the day only, and in sunshine, an inch, more or less, in diameter, of a delicate pale lemon-colour; a number of the central florets of a dark purplish chocolate hue, forming an almost black velvet-like spot, or eye, in the middle, which constitutes the chief beauty of the flower. The leaves are rather regularly toothed, alternate, sessile, green, slightly roughened; the upper ones mostly entire.

TOLRE, in Geography, a town of Hindoostan, in the Carnatic; 15 miles E. of Volconda.

TOLSEY, in our Old Writers, denotes the places where merchants meet in a city or town of trade.

The word is compounded of the Saxon tol, tributum, and see, fedes.

TOLSTÁ, in Geography, a town of Sweden, in Welf Gothland; 30 miles W.S.W. of Linköping.

TOLSTAN, in the P. coast of the island of Lewis. N. lat. 58° 22'. W. long. 6° 6'.

TOLSTONSKOJ, an offshoot of Ruffia, in the government of Tobolkin, on the Eniefi; 280 miles N.W. of Turuchank. N. lat. 70° 16'. E. long. 85° 14'.

TOLT, in Law, a writ whereby a cause depending in a court-baron is removed into the county-court. Old Nat. Br. 4. See Pone.

TOLSTEN, in Geography, a river of Chilli, which runs into the Pacific ocean, S. lat. 38° 50'.

TOLTERCAIZTLI, in Natural History, the American name of a flume, much resembling the nucivarius lapsus, but variegated with red and black spots. They use the powder of this flume and crystal, calcined together, for difcates of the eyes.

TOLU, in Geography, a sea-port town of South America, in the province of Carthage, with a harbour open to the Spanish Main; in the environs of which is found the celebrated balsam from which it gives name; 50 miles S.E. of Carthage. N. lat. 9° 45'. W. long. 75° 25'.

TOLU Balfam. See BALSAM.

TOLU-Tree, Balfam of, in Botany. See TOLUIFERA.

TOLVA, in Geography, a town of Naples, in Baolfiaca; 9 miles S.S.E. of Acranza.

TOLUCO, a town of Mexico, in the province of Mechocan; 100 miles W.N.W. of Mechocan.—Also, a town of Mexico; 28 miles S.W. of Mexico.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, five-toothed, nearly equal; one angle (or tooth?) more dilatant than the rest. Cor. Petals five, inserted into the receptacle; four of them equal, linear, somewhat longer than the calyx; the fifth twice as large, infebrly heart-shaped, its claw the length of the calyx. Stam. Filaments ten, very short; anthers longer than the calyx. Pijf. Germen oblong; style scarcely any; stigma acute. Peric. and Seed not described.

Eff. Ch. Calyx five-toothed, bell-shaped. Petals five; the lower one very large, infebrly heart-shaped. Style none.

1. T. Balfamum. Balfam of Tolu. Linn. Sp. Pl. 549. Willd. n. 11. Woodv. Med. Bot. t. 191. (B. tolutanum; Dale Pharmæ. 304. B. tolutanum, folis cerasi foliis filmis, quod candidum est; Bauh. Pin. 401.)—Native of the province of Tolu, in South America. We have never seen any original specimen of this plant, nor any figure, except Dr. Woodville's, drawn from a dried specimen in Sir Joseph Banks's collection, the authority for which is not mentioned. Miller appears to have raised plants from seeds sent by Houltom, but they probably did not prosper long. Perhaps the specimen just mentioned was obtained from the
fame source. Authors describe the tree as lofty, with large branches, and a thick greyish bark; the leaves like those of the Carob. If so, they are pinnate, as the natural order of the genus should indicate; but of which the Rev. Woodville seems not to have been aware. The flowers in his figure are racemose. All we can make out respecting the characters of this tree confirm the account of Mutis, of its close affinity to Myroxyylon, see that article, p. 1; the long-flaked germen of the latter appearing to be the only difference which is even obliquely hinted. The generic name of Toluifera therefore, though the most ancient, should give way to Myroxyylon, as the most comprehensive.

*T. cochinchenensis, Loureir. Cochinich. 262, having simple leaves, and a berry with one or two seeds, should be, as Poiré observes, in Lamark's Dict. v. 7. 696, to be very different from the original Toluifera, and more probably a Bursera.

Toluifera, in Gardening, comprises a plant of the exotic tree kind for the flove, of which the species cultivated is the balsam of Tolui tree (T. balfani).

Method of Culture.—This tree is raised from seeds, which should be obtained from its native situation, and be sown as soon as possible afterwards in pots of light earth, plunging them in the bark-bed of the flove. When the plants have three or four inches growth, they should be potted off separately, giving them water, and replunging them in the bed. They afterwards only require to be managed as other woody flove plants.

They afford variety in flove and hot-house collections among other potted plants. A balsam of great use in medicinal compositions is extracted and prepared from this tree.

TOLZ, in Geography, a town of Bavaria; 24 miles S. of Munich.

TOM, a river of Ruffia, which rises 80 miles S.E. of Kufnetz, in the government of Kolivan, and runs into the Obby, 32 miles W.N.W. of Tomk. N. lat. 56° 40'. E. long. 84° 14'.—Also, a river of China, which runs into the Heng, 5 miles S. of Heng-chan.

Tom Zil, a town of the Arabian Irac, on the Tigris; 118 miles S.E. of Bagdad.

TOMADÆORUM INSULÆ, in Ancient Geography, islands situated in the Arabian gulf. Ptol.

TOMEUS, a mountain of the Peloponnesus, in Messenia, near the premontary Coryphanthus. Thucydidès.

TOMAHABI, in Geography, a town of Peru; 60 miles S. of Potoú.

TOMAN, or Touman, a kind of imaginary money used among the Persians in the keeping of their books, and to facilitate the reduction of money in the payment of considerable sums. The toman contains 50 ababhis, 100 mamoids, 200 frightrees, 1000 dinars bifi, or 10,000 dinars simple. The toman and dinar are imaginary monies. An ababhi is worth 2 mamoids, 4 frightrees, 40 kafefquis, 20 dinars bifi, or 200 dinars.

D'Herbelot derives the word from the language of the Moguls, where it signifies the number of ten thousand. Eben Arabicchah says, that the word toman, when used to express a weight, or money, contains ten thousand silver Arab drachmex, called mehtkal; which are a third lighter than the Attic.

The Moguls, &c. frequently use toman for ten thousand men; and say, e.g. that the city Samarcand contains seven tomans of people fit to bear arms; and that of Andechan nine tomans.

TOMAN, in Geography, a kingdom of Africa, situated on the side of the river Gambia, W. of Kantor.

TOMANANISA, a town of Japan, in the island of Niphon; 75 miles W. of Mexco.

TOMAR, a cairn of Bengal, bounded on the N. by Sillee, on the E. by Pachete, on the S.E. by Singboon, and on the W. by Nagpour; about 20 miles long from N. to S., and from 10 to 20 broad.—Also, a town of Bengal, and chief place of a cairn of the same name; 145 miles W. of Calcutta. N. lat. 23° 10'. E. long. 85° 53'.

TOMAR. See THOMAR.

TOMARA, in Ancient Geography, a town of India, on this side of the Ganges. Ptol.

TOMARE, a mountain on the confines between Thethroia and Chonisia, two countries of Epirus.

TOMATO, in Botany, a word whose origin we have not ascertained, is the name of the Love-apple, or Solanum Lycopersicum. See SOLANUM.

TOMB, in Geography. See TUMB.

Tomb, includes both the grave or sepulchre, wherein a dead body is interred, and a monument erected to preserve his memory.

The word is formed from the Greek, ταφα, taphos, sepulchre; or, according to Menage, from the Latin, tumba, which signifies the same.

Among the Romans, none but the emperors, vellals, and perfons signalized by great actions, were allowed to have tombs in the cities, the rest were all in the country, near the high roads; whence those common words, Sifles, &c. viator, which are still retained in the inscriptions of our monuments, though set up in churches, &c.

At Anchiale was anciently seen the tomb of Sardanapalus, with this inscription in verse: "Sardanapalu built Anchiale and Tarfas in one day: go passenger, eat, drink, and be merry; the rest is nothing." Strab. Geo. lib. 14.

The Romans had a kind of empty tomb, called cenotaphium, an honorary tomb, in which the body of the deceased was not laid. See CENOTAPHI.

The occasion of this was a superstitious notion, that the souls of those who had not funeral honours, wandered a hundred years by the banks of the rivers of hell, before they were admitted to pass over. The cenotaphium being made, the same ceremonies were practised as at real funerals.

The cenotaphium were inscribed with the words ob hono-

rom, or memoria factum, whereas other tombs in which the asbes were really deposited, were inscribed D. M. S. q. d. facer to the manes. When the words ταφοτιον were added, it declared the asbes enclosed therein belonged to a person infamous for some crime.

TOMB-Stones, Characters on. See CHARACTER.

TOMB-Stones, Epitaphs on. See EPITAPH.

TOMBA, in Geography, a river of Peru, which runs into the Pacific ocean, S. lat. 17° 35'.

TOMBAC, a name given by the French to a yellow metal, very nearly approaching to what we call Prince's metal, and made by mixing and fusif together a large quantity of zinc with a smaller of copper. See GOLD-Coloured Metal.

TOMBAHONDA, in Geography, a town of the kingdom of Burfalli. N. lat. 15° 56'. W. long. 14° 57'.

TOMBALY POINT, a cape on the west coast of Africa. N. lat. 10° 48'. W. long. 3° 36'.

TOMBAY, a town of Pegu; 6 miles S. of Pegu.

TOMBEBEUF, a town of France, in the department of the Lot and Garonne; 12 miles N.W. of Villeneuve d'Agen.
TOMBI, a town of Africa, in Quoa. N. lat. 6° 50'.

TOMBIGHE, a river which rises in the northern part of Georgia, enters West Florida, and joins the Alabama to form the Mobile, N. lat. 31° 32'. W. long. 87° 50'.—Alfo, a town of West Florida, on a river of the same name. N. lat. 32° 52'. W. long. 82° 50'.

TOMBUCTOO, or Tombuctoo, a city of Africa, the capital of a rich and populous kingdom, said to have been built in the 15th century by Sulliman, pretended to be of the royal race of Morocco. The extent of its territory is very imperfectly ascertained; but it is said to extend northward to the conines of Sahara or the Desert, comprehending a tract of country about 90 miles in breadth; its western boundary being 130 miles W. of the city, and the eastern extending to the Bahar Soudan, or Sea of Soudan, which is a lake formed by the Nil-El Abbeed or Niger, whose opposite shore is not discernible. The city is situated on a plain, surrounded by sandy eminences about twelve miles N. of the Niger, and three days' journey from the confines of Sahara. It is said to be twelve miles in circumference, but without walls. The town of Kabra, situated on the banks of the river, is its commercial depot, or port. By means of a water-carriage E. and W. of Kabra, the trade of Tombuctoo acquires great facility; and hence the various articles of European as well as Barbary manufactures brought by the akkabahs, or caravans, from the N. of Africa, are distributed to the different empires and states of the Soudan and the South. This great mart is retorted to by all nations, whither they bring the various products of their respective countries, to barter for the European and Barbary manufactures. The houses at Tombuctoo have, in general, no upper apartments; they are spacious, and of a square form, with an opening in the centre, towards which the doors open. Contiguous to the door of entrance is a building, confining two rooms, called a duara, in which visitors are received and entertained, so that they do not see the women, who are very handome. The men are so excessively jealous of their wives, that when the latter visit a relative, they are much muffled up, in order to disguise their persons; their face is also covered with their garment, through which they peep in order to explore their way. The king, whose authority has been acknowledged at Tombuctoo ever since the death of Muley Ithmael, emperor of Morocco, is the sovereign of Bambarra; his name in 1800 was Woolo; he is a black, and a native of the country which he governs; his usual place of residence is Jinnie, though he has three palaces at Tombuctoo, which are said to contain an immense quantity of gold. Many of the civil appointments at Tombuctoo, since the decease of Muley Ithmael, and the consequent decline of the authority of the emperor of Morocco, have been occupied by Moors of Maroquin origin; but the military appointments, since the forementioned period, have been distributed among Negroes of Bambarra, assigned to them by the king Woolo. The inhabitants are chiefly Negroes, who resemble the Arabs in hospitality, and value themselves on their attention to strangers. The various costumes exhibited in the market-places and streets indicate the variety and extent of the commercial intercourse with the different nations of Central Africa; the individuals being each habited in the dress of his respective country. The toleration prevalent at Tombuctoo is worthy of notice. The divan, or Palama, never interferes with the religious tenets professed by the different people who resort thither for commercial or other purposes. The police of this place is extolled; robberies and house-breaking are fearedly known; the inhabitants of the town are peaceable and orderly. The government of the city is intrusted to a divan of twelve alejma, or men learned in the Koran, and an umpire, who retain their appointments, received from the king of Bambarra, for three years. Their power is great. The civil jurisprudence is directed by a cali, who decides all judicial proceedings according to the spirit of the Koran; he has twelve attorneys, called tallaks, who attend him, and to each of these belongs a separate department of justice. It is asserted that till of late no Jews were permitted to enter the town; and it is said, moreover, that those Jews who now resort thither, are obliged to become Mahometans. The probable reason of the exclusion of the Jews is deduced from the extreme jealousy of the individuals of the Moorish factory, whose avarice induces them to prevent any perfom from sharing their emoluments, whenever a plausible pretext can be found.

The climate of Tombuctoo is much extollcd as salubrious and invigorating; infomuch that there is no man of the age of eighteen, who has not his wives or concubines; and it is a disgrace for a man to attain the age of puberty without being married. The natives possess an elegance and frugality of manners, a great flow of animal spirits, and an invincible attachment to their country. The accommodation for travellers is very simple; camels, horses, drivers and merchants, rendezvous at a large house, with an open space in the middle, round which are rooms sufficient for containing a bed and a table. The merchants are accommodated with houses during the period of their stay, for bartering and exchanging their commodities, which they invest in the produce of Soudan as speedily as possible, so that they may be ready about September for the akkabah, and proceed to Morocco, Cairo, Jidda, or some other place. The manufactures of different kinds of apparel are prepared chiefly by the women in their own houses, whenever they cannot procure European cloths and linens, or when there is a great scarcity of Fez and Taffilet manufactures of silk, cotton, and woolen. The soil about Tombuctoo is generally fertile, and near the river produces rice, millet, Indian corn, and other grain; wheat and barley grow in the plains, and are cultivated principally by the Arabs of the tribe of Braebeh, who receive a tribute from the town for forbearing to plunder the caravans from the north which pass through their territory. Coffee grows wild here, as also indigo, which latter is occasionally cultivated, and produces a very fine blue dye used in their various cotton manufactures. The husbandmen are very expert in the management of bees: honey and wax are abundant, the former being used at Tombuctoo as an article of food, and the latter for candles. The river about Kabra affords a supply of fish. The mines of gold which lie S. of the bed of the river belong to the sultan Woolo, who refides at Jinnie; but his gold is deposited in his palace at Tombuctoo. The exact bearing and distances of places from Tombuctoo are not satisfactorily ascertained. The city appears, says Mr. Jackson, to be situated 1500 miles S.S.E. of Fez, 1750 miles about S.S.E. of Akka, Tatta, and Wedinoon; 1300 miles in nearly the same direction from Morocco; 1320 miles from Taffilet; about 230 miles E. of Jinnie; and 1000 miles E. of Houafl. Major Rennell, in his Geographical Elucidations annexed to the Proceedings of the Association for discovering the Interior of Africa, says that Tombuctoo is fifty days' caravan travelling from Tatta, a place situated on the frontiers of Morocco, Drah, and Zenhaga, and on the route from Morocco and Suez to Tombuctoo. Tatta is found to be nine and a half days' journey from Morocco; and one day short of a station on the Wad-drah or Drah river, which station is four days, or sixty-six miles lower down than Tinguleen, a place in D'Anville's and Delisle's map of Africa.
Africa. It was also twelve days' journey from the city of Nun, or Non, which city, by Ben Ali's account, is two days from the sea-coast, and well known to be opposite to a cape of the same name. These authorities, says the major, enable us to place Tatta 170 miles S.S.E. from Morocco. Thus, 50 days from Tatta to Tombuctoo, at 13 miles each day, produce 650 miles. By Ben Ali's report, Tombuctoo is 48 days from the capital of Sultan Fullan, lying within the district of Gallan, on the river Senegal: 48 days, at 13 each day, produce 650 miles; and this line of distance meets that from Tatta in lat. 19° 40', and nearly midway between Gallan and Caffina. In this position it falls only 28 miles to the N.W. of D'Anville's Tombuctoo.

The country north of Tombuctoo is inhabited by a powerful tribe of Arabs, called Brabeehs, whose original Rock emigrated in the eighth century, and took possession of a tract of country bordering on Egypt westward: they are a turbulent, refractory, and warlike tribe, but much afraid of fire-arms, as they have no such, being armed only with the lance, and occasionally with knives or daggers. There is another nation, situated many journeys south-east of Tombuctoo, who worship the fun, and abstain from animal food, subsisting on milk and vegetables. In a part of the country between Tombuctoo and Caffina, is discovered a race of people, compared by the Arabs to the English, who speak a language different from all the others known in Africa, and resembling the whistling of birds, to which they compare the English language. They ride on saddles like those used in England, and wear ruffled jupons, which are peculiar to themselves. Their faces are covered by turbans, and their weapons are swords, bows, arrows, and lances. They are said to be a very superstitious people; their bodies, as well as their houffes, being covered with charms or amulets. It is said that there is a water communication between Tombuctoo and Cairo; but the expense of land-carriage by camels being more moderate, the other is not used.

Tombuctoo has, from time immemorial, been the great emporium of Central Africa; an extensive and profitable trade having been carried on with the various maritime states of North Africa, viz. Morocco, Tunis, Algiers, Tripoli, Egypt, &c. by means of akka-bahas, or accumulated caravans, which cross the Sahara, or Great Defert, generally between the months of September and April: these akka-bahas consist of several hundred loaded camels, accompanied by the Arabs who let them to the merchants. The articles transported from Fez to Tombuctoo are principally the following; viz. various kinds of German linens, Irish linens, muffins, canbriac, fine cloths, coral beads, amber-beads, pearls, Bengal raw silk, bras nails, coffee, fine hyson teas, refined sugar, and various manufactures of Fez and Tarflet, such as shawls and falsies of silk and gold, hawks or pieces of silk, of cotton and silk mixed, of cotton and wool: to which may be added red woollen caps, turbans, Italian flaxs, nutmegs, cloves, ginger, and pepper, Venetian beads, cowries, tobacco and salt. The produce of Soudan in return for these articles, consists principally in gold-dust, twisted gold rings of Wangara, gold rings made at Jinnie, bars of gold, elephants' teeth, gum of Soudan, grains of Sahara, or grains of paradise, odoriferous gums, and a great number of slaves purchased at Tombuctoo of the flaxies, or slave merchants, and brought from those regions which border on the mountains of the Moon. To these we may add ostrich-feathers and ambergris, collected on the confines of the Defert. The circulating medium at Tombuctoo is (tubber) gold-dust, which is exchanged for mer-
fent fashion; the lines being from two to five in number, cut on each cheek-bone, from the temple straight downwards: they are also stained with blue. These incisions being made on the faces of both sexes when they are about twelve months old, the dyeing material which is infected in them becomes scarcely visible as they grow up. The ornaments of the natives are similar to those which are generally found among savage tribes. It does not appear that they hold any public exercise of religion, or have any house of worship, or ever meet to pray, though some ceremony, seemingly religious, was observed at the burial of the dead: but Adams was probably not a very accurate inquirer into these matters. Park describes the natives of Soudan as saying a prayer on the appearance of the new moon; and if the religious observances of these people were so rare of occurrence, it is not surprising that they escaped the feaman's notice.

Adams says that he saw no shops at Tombuctoo. The articles bought for sale, which consisted chiefly of tobacco, tar, gunpowder, blue nankeens, blankets, earthen jars, and some flks, are obtained from the Moors, and remain in the king's house until disposed of. The only other objects of trade seemed to be slaves. Gunpowder appeared to be more valuable than gold, since a greater weight of the former was given in a barter of the two articles. The exports of this people were chiefly gold-dust, ivory, gum, cowries, ostrich-feathers, and goat-kins, the latter stained red and yellow. Slaves were procured by purchase, and also by predatory incursions into neighbouring states. The king of Tombuctoo seemed to be delphic, but the government was mildly exercised; he and his wife were old and grey-headed: blue nankeen, adorned with gold lace, formed the usual dress of both; and the queen was accoutumeth to fit and look at Adams and Stevens for hours together. The palace consisted simply of eight or ten small rooms on a ground-floor, not even white-washed, and built of clay and grais. To the surplice of the African committee, Adams did not recollect to have heard there of the Joliba river, a subject of such interesting research; but we should consider that the fame river would probably pass under different appellations in the territories of different states. The name of La Mar Zarah closely corresponds with that of the Zayr, or Congo river, presumed by Park to be the termination of the Niger in the Atlantic ocean; but the distance from Tombuctoo to that mouth renders it highly improbable that the river should possess its name throughout. It should be added, also, that the Tombuctoo river is supposed to fall into the Niger at twelve miles distance from that town; yet the breadth ascribed to it by Adams will not allow us to consider it as a mere tributary stream. The editor draws two simple conclusions from this information relative to Tombuctoo; the one, he says, propitious, and the other adverse to the progres of discovery and civilization: viz. "the mild and tractable manners of the Pagan Negroes of Soudan, and their friendly deportment towards strangers," on the one hand; and on the other, "the extended and baneful range of that original feature of African society—Slavery."

TOME, a small island near the west coast of France. N. lat. 48° 50'. W. long. 3° 24'.

TOMÉ, a bound book or writing that makes a volume.

TOMEION, formed from town, section, a general name used to express any sharp or cutting instrument, used either in surgery or in the mechanic arts.

TOMELLOSO, in Geography, a town of Spain, in New Castile; 58 miles S.E. of Toledo.

TOMETOSE LEAF, among Botanists. See Leaf.

TOMETUM, properly signifies flocks or locks of wool, but by botanists is used for that soft downy matter which grows on the leaves of some plants, hence denominated tomentose; as verbaecum tomentosum, carduus tomentosus, &c.

TOMETUM Cerebri, in Anatomy, the flocculent internal surface of the pia mater, with its waving productions belonging to the intervals of the convolutions. The vessels, which enter the cerebral substance, give to the whole a completely villous appearance: it is best seen when the vessels have been injected, and the membrane floats in water.

TOMEMPDA, in Geography, a town of South America, in the audience of Quito; 5 miles S.E. of Jaen de Bracamoros.

TOMERIT, a mountain of European Turkey, in Albania; 12 miles E. of Dulcigno.

TOMEROS, in Ancient Geography, a river of Asia, in Carmania. Arrian.

TOMERUS, a river of India, W. of the Indus and Arabus, so named by Nearchus. It had its source towards 27° 20' of lat. traversed the country of the Oritez, and discharged itself into the sea about 25° lat.

TOMESOSBI, in Geography, a lake of Lower Canada, whence issues the branch of the river St. Francois, on the borders of Vermont.

TOMEX, in Botany, from tomentum, woolly down, alluding to the pubescence of the plant. The original Tomex of Linnaeus proving a Callicarpa, see that article, f. 5. Thunberg transferred the name to a new Japanese genus, with which it now remains. Such adaptations of disordered names are not entirely to be condemned, and yet we cannot but think them more allowable than the too frequent practice of Linnaeus, of applying ancient Greek or Latin ones to new genera, awesomely different from the original plants, though the latter could not be averteded.

TOMI, in Ancient Geography, a town of Lower Media, towards the mouth of the Danube, near the Euxine sea. This town was considerable, and was the place of Ovid's exile. It was the metropolis of Pontic Scythia. According to this poet, in his third book of Triltes, this city was founded by a colony sent thither from Miletus. Tori was declared the metropolis of Scythia under the emperor Theodosius, and it was the seat of the bishop of that country.

TOMIAS, in Antiquity, an appellation given to the sacrifice offered at the ratification of solemn leagues. It was so called because they cut out the topicles of the victor, and took the oath standing upon them.

TOMIDA, in Geography, a town of Japan, in the island of Nipphon; 5 miles S.S.W. of Quano.

TOMIN, in our Old Writers, a weight of twelve grains, used by goldsmiths and jewellers.

TOMINA, in Geography, a government of Peru, in the vicereignty of Buenos Ayres, and archbishopric of La Plata, which begins about sixteen leagues south-east from the city of La Plata. The climate here is hot, and consequently its productions are such as are common to hot countries. Some parts have vineyards, and in others are made considerable quantities of sugar. It also abounds in cattle and sheep. Its extent in some parts is nearly forty leagues. The vicinity of some free Indians is a continual uneasines to the towns in this jurisdiction, and even to the city
city of Plata itself, as they have often attempted to surprize it. Tomina, the chief town, is situated 80 miles E.N.E. of La Plata. S. lat. 10° 10'. W. long. 65° 35'.

TOMINE, in Commerci, a weight for gold and silver in Spain. Gold is weighed by the Cahillian mark of 50 cattallos, 400 tomen, or 4800 grains. Silver is weighed by the same mark, but it is divided into 8 ounces, 64 ochavos, 128 adarines, 384 tomen, or 4680 grains. The Cahillian mark weighs 3557 English Troy grains; hence 144 such marks correspond nearly to 89 lbs. English Troy weight; and, therefore, 96 Cahillian ounces = 89 Troy ounces.

TOMINEIO, in Ornithologia, a name by which some authors have called the guanaimbi, or humming-bird, the smallest of all birds.

The name seems derived from the Spanish tomine, a grain weight, as if they would call it a bird of a grain weight.

TOMINY, in Geography, a town on the east coast of the island of Celebes, in a bay to which it gives name. S. lat. 0° 45'.

TOMINY Bay. See Gunong-Tellu.

TOMISA, in Ancient Geography, a small country of Asia Minor, which separated Cappadocia from Mount Taurus.—Alfo, a town of Asia, upon the easterh bank of the Euphrates.

TOMISUM, or TOMISUS, a town of Asia, in Greater Armenia, in the country named Sophene. Strabo.

TOMKIN and TOMSPON. See TAMPION.

TOMKINS, THOMAS, in Biography, a disciple of Bird, M. B. and gentleman of his majesty's chapel (James I.) was an excellent musician. He published fongs of three, four, five, and six parts, without a date. But it appears by a copy of these fongs in the library of Chrift-church college, Oxon. that they were published in 1622.

There are two very curious compositions by Tomkins, in the 3d vol. of Dr. Tudway's "Collection of Cathedral Music," in the Britifh Museum: the one is a full anthem, in twelve parts; and the other an anthem in canon through-out of four parts in one, both well worthy the disciple of the admirable Bird. Indeed, by the compositions we have offered, or examined in score, of Tomkins, he seems to us to have had more force and facility than Morley. In his fongs there are melody and accent, as well as pure harmony and ingenious contrivance.

Thomas Tomkins, the father of Bird's disciple, was chanter of the choir at Gloucefter, whose family produced more able musicians, during the 16th and 17 centuries, than any other which England can boast. Thomas, the younger, had several brothers, musicians, &c. who distinguished themselves both in composition and performance; among whom was Giles Tomkins, according to Anthony Wood, a most excellent organift of the cathedral at Salfbury; John Tomkins, organift of St. Paul's cathedral, and afterwards gentleman of the chapel-royal; and Nicholas Tomkins, one of the gentlemen of the privy-chamber to Charles I. Thomas, the subject of the present article, the disciple of Bird, and bachelor of music, was afterwards organift of the cathedral of Worcester, gentleman of his majesty's chapel, and, at length, organift. Though he contributed to the "Triumph of Oriana?" in the reign of queen Elizabeth, he was living after the breaking out of the grand rebellion, about which time he published a work in ten books, or separate parts, entitled "Mufica Deo facra et Ecclefiæ Anglicana," consisting of anthems, hymns, and other compositions suited to the church-service. The copy of these compositions, in Chrift-church college, Oxford, is dated 1664. If this was not a second edition, it is probable that his son was either the author, or at least the editor of the work. By a copy of his fongs, in the fame collection, that have been paid above to be of uncertain date, they appear to have been printed in 1622.

Butler, in his "Principles of Music," published 1636, speaking of the Lydian mood of the ancients, which he seems to have perfuaded himself he underfood, says, "of this mood is that passionate lamentation of the musical king, for the death of his fon Abafalom, composed in five parts by Mr. Thomas Tomkins, now organift of his majesty's chapel; the melodious harmony of which, when I heard it in the music-school (Oxon.), whether I should more admire the sweet well-governed voices, with confonant instruments, of the fingers, or the exquisite invention, wit, and art of the composer, it was hard to determine." And he calls Mr. Thomas and Mr. J. Tomkins aureum par Musiciorum.

A fet of his vocal church music, in four and five parts, MS. is lodged in Magdalen college, and a printed copy in Chrift-church, Oxford. The manuscript copy was presented to Magdalen college by James Clifford, who, in 1663, published a collection of the words, with the names of the composers of such services and anthems as continued to be sung in our cathedrals. To this book Ant. Wood and others frequently refer in speaking of our choral music.

Beside the compositions by Tomkins, mentioned above, in the collection made for lord Harley, Britifh Museum, there are likewise several very learned and curious compositions by this author; particularly full anthems in eight, ten, and twelve real parts, fugato. About this time there was a rage for multiplying parts in musical compositions all over Europe; and Herculaneus labours of this kind, have been accomplished by Talbis, Bird, Benevoli, and others, who have already been mentioned.

TOMLINSON'S RUX, in Geography, a river of Virginia, which runs into the Ohio, N. lat. 40° 29'. W. long. 80° 41'.

TOMMASI, GIUSEPPE-MARIA, in Biography, a learned cardinal, was born at Alicata, in Sicily, in 1649, and at the age of fifteen entered among the Theatines at Palermo. He finished his studies at Rome, where he devoted himself to ecclesiastical literature, and from the accuracy of his mode of life, and the frequency of his devotional exercises, he was regarded as a model of the religious character. In order to the more successful prosecution of his favourite studies, he obtained access to the principal libraries at Rome, and in 1680 he published his "Codices Sacramentorum nongentis annis vetustissimorum," 40. dedicated to Chriflina, queen of Sweden. This was followed by some other works, and particularly, in 1688, by his "Sacrorum Bibliorum Tituli, &c." 40. in which he directed at his attention to the ancient mode of dividing the Bible. Indefatigably employed in the kind of study to which he was addicted, he published several works in Latin and Italian, chiefly on subjects of religious worship. In consequence of these labours, Clement XI. raised him to the dignity of cardinal in 1712, against his own inclination; but though his revenue was thus increased, he retained his former mode of life, and devoted the residue of his income to the benefit of the needy. He was a regular preacher, a diligent instructor of the poor, and a zealous promoter of a general reformation of manners in Rome. But death prevented the full execution of his laudable purpoieses in 1713, in his 64th year. The sanctity of his life procured
TONGA ISLANDS, a cluster of islands in the South Pacific ocean, confiding of the island of Tonga, which gives name to the whole of the cluster called Haapea, and the island of Vavao. It is a part of the group to which captain Cook gave the name of Friendly islands, but he did not include in his chart Vavao or Vavaou, which he did not visit; though this is the largest, and now comparatively the most important of all those belonging to the fame Archipelago, which, in his time, were under the fame government, and fill speak precisely the fame language, and observe the fame customs.

An account has been lately published from documents furnished by Mr. William Mariner, four years resident in those islands; 2 vols. 8vo. 1817. See FEEEJEE, FRIENDLY, HAAPEA, TONGATABOO, VAVAIO, &c.

TONGATABOO ISLAND, one of the Friendly islands in the South Pacific ocean, first discovered by Tasman, who called it Amsterdam; seen by captain Cook in the year 1773, and visited by him again in 1777. Tongataboo, or Tonga, is about sixty miles in circuit, somewhat oblong, though much broadest at the E. end; and its greatest length from E. to W. The south shore is straight, and confiils of coral rocks, eight or ten feet high, terminating perpendicularly, except in some places, where it is interrupted by small sandy beaches; on which, at low water, a range of black rocks may be feen. The west end is not above five or six miles broad, but has a shore somewhat like that of the south side; whereas the whole north side is environed with islets and islands, and the shore within them long and sandy. The east side or end is most probably like the south; as the shore begins to assume a rocky appearance towards the north-east point, though not above seven or eight feet high. The island may with the greatest propriety be called a low one, as the trees on the west part, where captain Cook lay at anchor, only appeared; and the only eminent part which can be seen from a ship, is the south-east point; though many gentle rilling and declining grounds are observable by one who is ashore. The general appearance of the country is that of great want of fertility. At a distance the surface seems entirely clothed with trees of various sizes; forms of which are very large. But above the reef, the tall cocoa-palms always raile their tufted heads; and are a very considerable ornament to any country that produces them. The boogo, which is a species of fig, with narrow pointed leaves, is the largest tree of the island. The winds are, for the most part, from some point between north and east; and when moderate, are commonly attended with fine weather. The bays of the island, as far as it could be observed, is entirely a coral rock, which is the only fort that presents itself on the shore. Of cultivated fruits, the principal are plantains, of which they have fifteen different sorts or varieties; bread-fruit; two sorts of fruit found at Otaheite, and known there under the name of jambu and eeeceve, the latter a kind of plum; and a vail number of shaddocks, which however are found as often in a natural state as planted.

The roots are yams, of which are two sorts; one black, and fo large that it often weighs thirty or pounds; the other white and long, seldom weighing a pound; a large root, called kappe; one not unlike our white potatoes, called mawhaha; the talo, or cocos of other places; and another named jeecje. Besides great numbers of cocoa-nut trees, there are three other sorts of palms, two of which are very scarce. The only quadrupeds, besides hogs, are a few rats, and some dogs, which are not natives of the place, but produced from some left by captain Cook in the year 1773, and by others got from FEEEJEE. Fowls, which are of a large breed, are domesticated here. Amongst the birds are parrots, somewhat smaller than the common grey ones, of an indifferent green on the back and wings, the tail blue, and the crest of a footy or chocolate brown; parroquets not larger than a sparrow, of a fine yellowish-green, with bright azure on the crown of the head, and the throat and belly red; besides another fort as large as a dove, with a blue crown and thighs, the throat and under part of the head crimson, as also part of the belly, and the rest a beautiful green; owls, cuckoos, king-fishers, and a bird of the thrush kind. The other land birds are rails, fly-catchers, and three sorts of pigeons. Of water-fowl, and such as frequent the sea, are ducks, blue and white herons, tropic birds, noddies, and white terns. The only noxious or disfiguring animals of the reptile or insect tribe are sea-snakes, scorpions, and centipedes. The infects amount to about fifty different sorts. The sea abounds with fish, though the variety is less than might be expected. The most common sorts are mullets, several sorts of parrot-fish, silver-fish, and albicorns; some harks, rays, pipe-fish, a sort of pike, and some curious devil-fish. The many reeds and islets on the north side of the island, afford shelter for an endless variety of shell-fish; amongst which are many that are esteemed precious in Europe, such as the hammer-oyster, of which, however, none could be obtained entire; a large indented oyster and several others, but none of the common sort; bananas; cones; a sort of gigantic cockle, found also in the East Indies; pearl-shell oysters, and many others. There are likewise several sorts of sea-eggs, and many fine star-fish, besides a considerable variety of corals, amongst which are two red sorts, the one most elegantly branched, the other tubulous. And there is no less variety among the crabs and cray-fish, which are very numerous. To which may be added, several sorts of the sponge, the sea-hare, and the like. See TONGA, S. lat. 21° 9'. E. long. 185° 14'. Cook's Third Voyage, vol. i.

TONGATORE, a town of Hindoosfan, in Golconda; 30 miles S.E. of Hyderabad.

TONGBLOW; a town of Burmah; 12 miles from Raymangong.

TONE, NIEUWE, a town of Holland, in the island of Overflakkee; 3 miles S. of Sommereyck.

TONE, Ouwe, a town of Holland, in the island of Overflakkee; 4 miles S.E. of Sommereyck.

TONGELREP, a river of Brabant, which runs into the Dommel, near Eynhoven.

TONGEREN, or TONGERS, a town of France, in the department of the Lower Meuse, late in the bishopric of Liege. This town is ancient, and was formerly governed by dukes. The collegiate church of Tongres is very ancient; they say it was the first on this side the Alps, built by St. Materne, who was sent by St. Peter to preach the gospel in Lower Germany, and became the first bishop of Tongres; which was erected into a diocese. It has three parish churches, and several religious houses. The French, in the year 1677, committed a thousand facrilleges and infeclences,
TONGERLOO, a town of France, in the department of the Dyle; 9 miles N. of Aerschot.—Alfo, 5 river of France, which runs into the Meufe, 3 miles below Maefyck. —Alfo, a town of France, in the department of the Lower Meffe; 4 miles N. of Stockem.

TONG-GIN, a city of China, of the firft rank, in Koei-tcheou, on the borders of Houquang. In the environs are gold and copper mines; 850 miles S.S.W. of Peking. N. lat. 27° 30'. E. long. 108° 37'.

TONGHIO, a town of Birma, and capital of a province, strongly fortifie. Here are manufactures of cotton cloth, and the environs produce the best beetle in the empire.

TONGKEL, one of the Sooloo islands. N. lat. 6° 2'. E. long. 121° 50'.

TONG-KIN-TSIN-FOU, a town of Corea; 48 miles W.S.W. of King-ki-tao.

TONG-LAI, a town of Corea; 70 miles S. of Koang-tcheou.

TONG-LAN, a town of China, of the second rank, in Quang-fu; 1075 miles S.S.W. of Peking. N. lat. 24° 27'. E. long. 106° 26'.

TONGOL-PATCHI, a town of Thibet; 30 miles N. of Oramchii Hotam.

TONGOLORE, a town of Hindooflan, in the Carnatic; 10 miles S. of Ongole.

TONGY, a river of Chili, which runs into the Pacific ocean, S. lat. 35° 40'.

TONG-PIN, a city of China, of the second rank, in Chat-tong, on the river Ta-tsin; 190 miles S. of Peking. N. lat. 36° 0'. E. long. 115° 50'.

TONG-POTRA, a town of Pegu; 50 miles S. of Lundey.

TONG-TCHANG, a city of China, of the firft rank, in Chat-tong, on the grand canal; 212 miles S. of Peking. N. lat. 36° 34'. E. long. 115° 40'.

TONG-TICHIEN, a city of China, of the second rank, in Se-tcheou; 720 miles S.W. of Peking. N. lat. 31° 0'. E. long. 114° 44'.—Alfo, a city of China, of the firft rank, in Se-tcheou. This city is strongly fortified, and is called a military city, because the inhabitants are all soldiers; the profefion defending from father to fon. Besides their pay, they have the lands which surround the city. These troops are difband in time of peace, and come to them in amusing, giving them in the garrifions that are in the frontier of the empire; 1000 miles S.W. of Peking. N. lat. 25° 20'. E. long. 103° 2'.

TONG-TCHUEN, a town of Corea; 85 miles E.N.E. of King-ki-tao.

TONG-TIN-HOU, a lake of China, in the province of Hou-quang, more than 80 leagues in circumference.

TONGTREE, in Rural Economy, a term applied to the pole of an ox-cart, or that of a waggon, and perhaps some other forts of carriages.

TONGUE, Lingua, in Anatomy, an oblong member, whose form and situation are sufficiently known, and whose ufes is to be the organ of taste, and the principal instrument of speech and deglutition. See DEGLUTITION.

The upper edge of the tongue is covered with a papillary nervous tissue, which is spread two membranes. The outer of these membranes is pretty thick, and full of papillae, of a pyramidal figure, especially towards the tip, which pizzle fland pointing towards the root of the tongue in a bending posture, which makes their figure be concavo-convex. These papillae, or papillae, are fo very minute and slender in men, that they make the cattle appear on the upper part villous, especially as they approach nearer to the root. The figure of the papillae, in human tongues, is not exactly distinguishable from the naked eye as not to need the microscope. In brutes they are generally larger, fliffer, and more conspicuous; and in some almost cartilaginous, as may be felt in the tongues of cats and oxen, but more feñibl in lions. On the upper side, at a little distance from the tip, this membrane becomes thin, smooth, and glibrous, and, as it were, polished by the lower parts of the mouth on which it folds.

Under this lies a thin, soft, reticular kind of coat, punched through with innumerable holes, and always lined with a thick and white, or yellowish mucous. This membrane is fo exceedingly tender, and full of mucus, that it is not to be examined by the naked eye, unless boiled; by which it grows tough, and easily separable from the external membrane, and from the nervous part of the tongue, which lies immediately under it. After boiling, it appears like a kind of gauze, between whose threads innumerable holes appear, through which the edges of the papillary body underneath it are exerted. This membrane on the upper side, next the outward, appears white, with a coat towards yellow, but is black on the side next the tongue.

Many authors do not allow this to be a membrane, and will only have it to be a mucous hardened by boiling; but since it has so much of the resemblance of a membrane, and that authors agree in allowing two membranes to the tongue, Dr. Drake does not scruple to number it among them. Thus there does not appear to be any other second membrane; reckoning, with Malpighi, the smooth part under the tongue a part of the outer membrane, some, however, have considered it as a continuation of a distinct membrane, which covers that of a papillary texture.

Immediately under this appears a nervous papillary body, spreading itself to a moderate thickness over the whole surface of the tongue. This body, on the under side, is every where level and smooth, except in some few places, where it is connected to the subjacent fuscous part by some nervous twigs which it sends into it. Malpighi distinguishes the papille, which make the principal part hereof, into three kinds, from their different magnitudes and figures when observed with the microscope; of which those feated on the sides and tip are very singular, resembling little round pyramids, with globes on their tips like the horns of rams. All these papille, which are the immediate organs of tasting, send their apices, or extremities, through the mucous membrane into the pyramidal papille of the outer membrane, which are hollow to receive them, and seem to be nothing else but a kind of cases to defend these nervous papille from injuries, which the faults and apertures of those bodies which we might take into our mouths might do them. See TASTING.

However necessary an organ the tongue be in speech, &c. yet infirmities have occurred, in which persons, who have lost their tongues, have spoken distinctly.

We have had in England an instance of this kind in one Margaret Cutting. See Philof. Tranf. N. 464. or Abr. vol. vi. p. 12irst. Idem. vol. xiv. p. 621.

Another occurs in Lambert's Memoirs, and another in the Memoirs of the Academy of Sciences.

To the infirmities briefly mentioned above, we may add the following account of a man at Montagu, in the Bas Poitou, who being feized with the small-pox in his fifth
or sixth year, loft his whole tongue by gangerne, or putrefaction; yet, notwithstanding, performed in perfection the five actions belonging to the tongue, viz. speaking, talking, spitting, chewing, and swallowing; nature having, with infinite artifice, given a new conformation to the mouth, proper to supply the want of the left organ. See J. R. Rolandi Agglomonomographia, five Descriptionis orae lingua quod perfecte loquiuntur et relinquae fuerunt Functiones naturaliter exercet; first published in French at Saumur, in 1639, translated into Latin by Car. Ruygerus, and published in the Ephem. German. D. an. 3.

For speech, instead of the ordinary provision, the little salivary part of the tongue remaining was infefted in the middle towards the palate, the teeth inverted, and long inwards, the mucous buccinators easily contracting between the dentes molares. In fine, there was a disposition in all the organs to produc speech without a tongue; for the breath issuing at the oval aperture of the larynx, was farther broken, and rendered vocal by the inflaction of the salivary body, the motion of the lips, the retraction of the buccinators, the tremulous agitation of the uvula, and the com motion of the lower jaw. Lastly, by the inversion of the teeth, the depression of the palate, the abundance of saliva, and the capacity of the mouth, the found was still farther modified and determined, so as to render it articulate. Habit, too, and the repeated attempts to speak at an age when the parts were easily flexible, had contributed greatly to the diftinofit of it.

For talking, it is evident from this, as well as other considerations, that the tongue is not the only organ of it, but that the palate is also a feat of this fene. For chewing, the office of turning the meat in the mouth was here performed by the lips and cheeks, the mucous of which repelled towards the maxillares such parts as in maflication might fall from one fide to the other. For the frit morfel he took, he could only chew on that fide into which he put it with his hand; the fecond he put in like manner on the other fide, and thus varied and supplied each alernately. For swallowing, the gravity of the food contributed fome thing to this, which he farther promoted by ftretching out his neck, inclining his head, and drawing back the buccinators within his teeth; all which were feconded by the mouth and fauces being well moistened with plenty of fialva. In effect, divers animals, as the tortoife and the crocodile, flock, &c. swallow without any tongue; and fifth, though their tongue is fixed inmoveable to their palate. For spitting, it was performed by the lips, aided by the internal contraction of the mouth, and the retraction of the buccinators over the grinders.

Roland’s infance was fingular at that time, but a parallel one has been fince observed in a girl at Lisbon, fifteen years old; of which an account was given, in 1718, to the Royal Academy of Sciences, by M. de Joffuen. Upon infpecting the mouth of this girl, there appeared nothing in all that part ordinarily polifhed by the tongue, but a little eminence in form of a papilla, between three and four lines high, in the middle of her mouth, fcarcey perceivable by the eye. Upon prefling this with the finger, a kind of motion of contraction and dilatation was perceived in it, which fhewed, that though the tongue was wanting, the mucous of which it was formed, and which were defined to give it motion, were nevtherdefe there. With the help of thofe the fpoke as diftinftly and easily as if nothing had been wanting: the diftinguifhed fakes like other people. For malformation, it was chiefly efrected by the motion of the lower jaw, which the drew nearer to, or farther from, the grinders of the upper, under which the food to be chewed was. In this action the fometimes alfo made ufe of her fingers, but much more in the action of swallowing, in order to protrude the mafiicfated food towards the orifice of the cefophagus. For drinking, she performed it like other people, excepting the attention the employed to prevent the liqour going down too faft; in order to which the kept her hand a little inclined forwards. Lastly, the actiion of spitting was supplied by the mucous of the papilla, which filled the lower part of her mouth; these rifting almost to a level with the teeth of the lower jaw, and the buccinators approaching towards both jaws, expressfed the saliva, and conducted it to the fphinfter of the lips, from whence the air, driven with violence from the larynx, served as a vehicle to expel it out of the mouth. Mem. de l’Acad. Scien. ann. 1718, p. 6—16. Juffieu, loc. cit. p. 7, feq.

Dr. Mortimer, from a MS. account of the life of the Rev. Mr. Henry Wharton, chaplain to archbishop Sancroft, informs us, that he was born with two tongues. Phil. Trans. vol. lxi. p. 232.

**TONGUE.**

**Injuries and Diseases of.** Wounds of the tongue have generally been divided, by writers on Surgery, into longitudinal and transverse. The former rarely happen, and seldom demand any but ordinary treatment. The fame may be said of punctured wounds of this organ; cases which are occasionally met with in practice.

The most frequent wounds of the tongue are those which are transverse. They are hardly ever produced by outward means; but usually by the teeth, when the lower jaw is forcibly and spasmodically brought against the upper one, while the tongue is out of the mouth, as sometimes happens in epilepsy and falls upon the chin. In this way, transverse wounds of considerable extent frequently happen, almost separating, in some instances, the apex from the body of the tongue. In such cases, the injury may easily be converted into a sort of cleft, which may remain for ever afterwards, and more or less interfere with the functions of the organ. This disagreeable consequence is more likely to happen, when no care is taken to keep the opposite sides of the wound in proper contact, and hinder them from becoming distant from each other.

Hence, certain writers on surgery have recommended all wounds of the tongue to be immediately closed with a future; and Richter, though by no means a conflant advocate for this method, is candid enough to allow, that it has succeeded in the bell manner, even in cases where the tongue was bitten nearly through. Anfangsgr. der Wundbur. b. iii. p. 24.

The application of a future to the tongue being attended with some pain and difficulty, a very simple bandage has been proposed for uniting transverse wounds of this part. (Pibrac, Mem. de l’Acad. de Chirurgie, tom. ix. p. 22. Le Blanc, Precis d’Operations.) Richter maintains, however, that the invention referred to does not anifer expectation. The main portion of it is a little fort of bag, in which the fore part of the tongue is confined. Thus all motions of this organ forwards, or laterally, may be effeetually prevented; but the patient is not deprived of the power of drawing it backward, that very action, which has a direct tendency to make the sides of a transverse wound separate from each other. In some cases, indeed, as Richter observes, the apparatus seems rather to do harm. Children, to whom it proves exceedingly irkitome, are made refilts by it, so that they keep moving their tongue and jaw about, to the great irritation and disturbance of the wound.

Richter further objects to Pibrac’s bandage, that it is decidedly unneceffary; for, such motions of the tongue, as it directly refrains, namely, those forwards, or to either side,
TONGUE.

side, may be hindered by applying a bandage to the jaw, and making the patient refrain from talking and mastication. The same author affirms, that such treatment has answered as well as could be desired, in numerous cases, some of which were large transverse wounds in reflexes and unmanageable children. During the treatment, however, the patient is to be allowed only liquid nourishment, which must be imbibed through a tube.

Perhaps, however, on the whole, the propriety of employing a future must depend entirely on considerations of the following kind. When the transverse wound is deep, and extends quite across the dorsum of the tongue; when it is situated towards the apex, and is conveniently within reach; and when the patient is uncontrollable, and cannot be made to keep the tongue and lower jaw quiet; a future may be advantageous. On the other hand, when the wound is at the back part of the tongue, (a cafe by the bye which is unfrequent,) and a future must be difficult of application; when the wound is trivial, likely to heal of itself, and there is no risk of its occasioning any material chief in the part; and when the patient is docile, and attentive to the advice given him; the most judicious practice is to apply such a bandage as is recommended for the fractured jaw, and to forbid all motion of the tongue and lower jaw, by lacerating, masticating, &c. nothing but liquid food being allowed to be drunk through a tube.

If the wound should be too deep, as almost to separate the anterior part of the tongue from the rest of this organ, the remaining connection is not to be divided; but an endeavour made to bring about an union. There are numerous cafes on record, encouraging the practitioner to expect the best consequences from the attempt. Richter’s Anfangsgr. der Wundartz. b. iv. p. 26.

With regard to other circumstances, relating to wounds of the tongue, the treatment of these causes does not differ from that of wounds in general.

Bleeding from the Tongue.—An hæmorrhage from the nasal vessels sometimes follows accidental wounds, and surgical operations on the tongue. When it is an artery that bleeds, the accident may prove dangerous, and even fatal, especially in children, who, by moving the tongue and jaw about, and continually promoting, promote the hemorrhage, and render the adoption of the measures necessary for its suppreffion extremely difficult. As, in these cafes, a ligature, compression, and fyphtics, hardly admit of being applied, the bleeding cannot be stopped, without much trouble. Whether the nasal arteries can be tied in the manner fugged below, remains to be proved; but, certainly, they are rather too far out of reach to be tied in the common way. Nor can compression, as ordinarily performed, be trusted, since it operates against soft yielding parts, and not upon any fixed point. Strong fyphtics, even were they deemed worthy of trial, could not well be employed, since they would be apt to mix with the saliva, and be swallowed. Yet, there are some means, by which the most perilous bleedings of this sort have been stopped.

Among the most celebrated of these last methods is the actual cautery, which is preferred by several of the continental surgeons, and may, perhaps, in this solitary instance, seem almost justifiable to British surgeons, averse as they properly are to this barbarous practice.

Another plan is that of directing an affiant to keep a compress on the bleeding vessels, as long as necessary, with his finger; while, with his thumb, he takes care to make counterpressure under the jaw. M. Jourdain stopped a considerable hemorrhage from the nasal vessels, by laying a piece of ice under the tongue. M. Petit was the inventor of an apparatus for stopping such bleedings, which is at once simple, ingenious, and effectual. The surgeon is to get a piece of birch, and cut it through below the place where two branches of equal size unite. It is to be made to resemble a fort of fork, the prongs of which are to be about eight lines long, and the handle four. It is then to be covered all over with linen, and put under the tongue in such a way, that the end of the handle is to rest against the middle of the concavity of the arch of the jaw, while the prongs embrace the frenulum, and compress the bleeding vessels. The middle of a roller is next to be applied to the dorsum of the tongue, as far back as possible; and the ends, after crossing each other under the chin, are to be pinned to the child’s night-cap.

If a surgeon were to arouse these plans, or find them unavailing, there is yet one resource left, namely, that of cutting down to, and tying the trunk of the lingual artery, just where it passes over the cornu of the os hyoides.

Hæmorrhage from the nasal vessels occasionally arises quite independently of a wound. In one such example, the bleeding proceeded from a varicoæ vessel under the tongue, and was effectually stopped with the cautery. See Default’s Journ. de Chirurg.

Dangerous Enlargement of the Tongue from Inflammation.—Sometimes when this organ is infamed, it swells so prodigiously, that it protrudes between the teeth, entirely fills the cavity of the mouth, and obstructs speech, deglutition, and even respiration. In such a case, the most prompt affistance is demanded. Ordinary evacuations of blood, and other antiphlogistic meafures, here seldom bring relief with sufficient celerity. According to surgical authors, the most certain plan consists in making two longitudinal cuts along the edges of the dorsum of the tongue, from one to two inches in length. A copious bleeding generally follows, which soon brings about a diminution of the swelling. No troublesome confequences are to be apprehended from such incisions, which heal with ease, and scarcely leave any scar behind. De la Male, Mem. de l’Acad. de Chir. tom. v. Jourdain succeeded in affording prompt relief, by taking blood from one of the nasal veins. This method seems liable to no objection, except perhaps that of being difficult, when the tongue is enormously swelled. Traité des Maladies de la Bouche, &c.

In one example, the difeafe refified every means until a blister was applied to the throat. Richter’s Anfangsgr. band. iv. p. 29.

Some inflamations of the tongue have been observed to originate from the lodgement of foreign bodies in it, which ought to be extracted; as, for infiamae, a fish-bone, or a needle. (Jourdain, Traité des Mal. de la Bouche, &c.) Other caufes have arisen from the injudicious employment of mercury, and the excitement of a fudden and immoderate falivation. Many examples are connected with violent inflammation of the parts about the throat.

Sometimes inflammations of the tongue terminate in suppuration. Such abecfes rarely admit of being opened, and hardly allow the use of any means, except emollient gargles.

Cafes have occurred, in which inflammation of the tongue has induced mortification, and the loss of the greater part of this organ. The treatment of fuch infiammes must conform to the general rules delivered in the article Gan-grene.

When, in confequence of any enlargement of the tongue, or other difeafe in the mouth, the necfary food and medicines are, for a considerable time, prevented from being taken, they may be injected into the fomach through an elastic
elastick catheter, which is to be passed through one of the nostrils into the oesophagus. It has been recommended to have the outer end of the instrument to turn upward out of the nostril, and shaped like a funnel, whereby it is suppos'd fluids might be more conveniently introduced. (Libron, Journal de Médecine, tom. xxxiv.) But we do not consider this any material improvement, since all liquids may be easily injected with an elastick gum syringe, such as is used for injecting hydrocoele, without having the external end of the catheter made in the manner above suggested.

Ulcers, Indurations, and Tumours of the Tongue.—Ulcers on the tongue, of an exceedingly painful, obtinate, and malignant looking nature, are sometimes produced by the sharp or rough edge of a tooth. This mechanical kind of cause is easily detected on examination with the finger. If the tooth be found, the projection or roughness must be filed off; if it be curious, the best plan is to extract it. When these objects are accomplished, the sore usually heals without further trouble.

Some very obtinate ulcers, which originate on the tongue, and are connected with disorder of the digestive organs, may be cured by a long perseverance in the use of the antm. tart. exhibited alternately in small doses, and then in larger ones, so as to excite vomiting.

Ulcers, deriving the epithets malignant and cancerous, not unfrequently form on the tongue. Sometimes the malady, in its most incipient state, appears as a sore. Sometimes a circumscibed moveable, or immovable, feirrhous swelling is first observable, which gradually becomes painful, and ulcerates. In other instances, there is, in the beginning, only an induration in the substance of the tongue, without the smallest appearance of any swelling. The ulcers, under consideration, are always surrounded by hardness. They may make their first appearance either at the edges or at the apex of the tongue. In certain cases, the whole, or a large portion, of this organ is covered with numerous small feirrhous tubercles, which gradually fall into a state of ulceration. These we have seen greatly diminished by a gentle course of mercury. All the medicines, tried in other cases of cancer, may be exhibited in the present ones; but, on the whole, the timely employment of the knife merits the most confidence.

However, the following kinds of cases have yielded to particular remedies.

A malignant exceedingly painful ulcer on the tongue, surrounded with a good deal of inflammatory hardness, has been cured by the continued internal use of opium. The dose is to be gradually augmented; patients are flated to have taken, at last, eighteen grains in one day.

One species of malignant ulcer yields to the long continued exhibition of tartar emetic. The doses must be increased, in proportion to the time which elapses from the first taking of the medicine.

Very malignant and unyielding sores on the tongue are said to have been cured by repeatedly applying 
v
leeches to the under surface of this organ. Med. Comm. vol. ii.

It would be inexcusable to pass over in silence such ill
conditioned ulcers of the tongue, as originate during violent
follations. Sometimes similar sores, produced by the same
caufe, take place, at the same time, on the tonsils; and, in
this circumstance, inexperienced surgeons, or mistaken prac-
titioners, who are blinded with the fear of typhus, are very
apt to suppose the sores to be venereal ones. This error
leads to the free use of mercury; the sores frequently slough, and the patient's health becoming greatly deranged, he is thrown into a state of great peril. In this case, it is
hardly necessary to observe, that the use of mercury must
be immediately omitted, and the mouth very frequently
washed with a solution of alum.

Violent inflammations, followed by ulcerations of this
kind, are particularly apt to occur, when patients catch
cold, while they are under the influence of mercury.

For the removal of a cancerous portion of the tongue, a
blister is the best instrument; and the patient's mouth
should be kept open during the operation, by the interpo-
tion of something between the teeth. The hemorrhage is
generally what is most apprehended; but we have instances
related of large portions, and even of the anterior half of
the tongue, being amputated, and of the bleeding being
easily suppreffed, either by the actual cautery, or fome of
the ordinary means for the suppression of hemorrhage.

It appears to us, that a tolerably dexterous man might tie
the mouth of an artery in this situation, with the assistance
of two pair of forceps to tighten the ligature, when the noofe
has been put over the tenacula round the bleeding point.

Certainly, cancerous disfrees of the tongue may have ad-
avanced to such a degree, that an operation cannot be pru-
dently undertaken. The bleeding would be a serious objection; the whole deltemper of the tongue itself might
not be removable; and the contaminated state of the ad-
jaent lymphatic glands below the jaw, usually existing in
this advanced state of the malady, would, according to re-
ceived opinions, render a radical cure quite impracticable.

When the disease is not in the vicinity of the apex of the
tongue, the operator may find it difficult to draw the part
sufficiently forwards, and keep it in this position. In this
circumstance, surgical authors recommend the employment
of a pair of forceps for the purpofe, the blades of which are
fre to be covered with rag. Should this instrument be found
ineffectual, they advise the surgeon to use a pair of forceps,
the blades of which terminate in two short double hooks.

As being painful, one should always avoid, if possible, the
employment of such an instrument.

Here, as in all other cancerous cases, it is the duty of the
surgeon to take care that no point, suspected of parti-
pating in the disease, be left behind. Unless this maxim
be attended to, the operation will mostly be followed by a
relapse.

Abroad, surgeons have sometimes effected a cure by ap-
plying the cautery, notwithstanding the wound after the
operation had put on an unhealthy and fugal appearance.
(Journ. de Med. tom. xvii.) In this country, practi-
tioners might hope for similar success from the cautious
employment of caustic; for the revival of the cautery, under
any circumstances, is an idea now almost intolerable to every
British practitioner.

After the exition of a diseased portion of the tongue, local
applications cannot be very well used; nor are they
in general necessary, when the patient moves the part as
little as possible, and avoids putting stimulating food and
liquids into his mouth.

Cancerous portions of the tongue may also be extirpated,
by passing a double ligature through this organ, and firmly
tying one part of the ligature over each side of it.

This plan must be infinitely more painful, than the re-
moval of the diseased part with a knife. To the latter
method, the hemorrhage is the only objection; and, not-
withstanding all that has been said, we think no surgeon
ought to venture to cut away a diseased tongue, without
having first made up his mind respecting what method
should be adopted for stopping the bleeding.

When much of the tongue has been lost, there certainly
is reason to expect, that its functions will afterwards be
performed in a very imperfect manner. However, there
are
are on record several examples, in which the greater part of this organ was lost, and yet the patients retained the faculties of talking, malificating, swallowing, and articulating words, with considerable perfection. See Mem. Physiol. &c. for la Langue par M. Louis in Mem. de l'Acad. de Chr. tom. xiv.

The removal of sceilous and sarcomatous tumours of the tongue may be most conveniently accomplished with a secalpel and a tenaculum. Encysted swellings of this organ are generally of the melanies kind, and ought, if possible, to be diffused out, without opening the cyll at all.

Authors relate examples, in which the tongue has been of extraordinary magnitude, either in consequence of original malformation, or a peculiar fort of disease. Excepting the deformity, arising from the projection of the part out of the mouth, some of these patients experienced no particular inconvenience, as they could speak, malificate, and swallow tolerably well. Under such circumstances, the removal of the redundant portion would not be advisable; but if the disfigurement were combined with much inconvenience, the operation would be proper, especially as the cut part would be so forward in the mouth, that the bleeding vessels could be tied. First Lines of the Practice of Surgery, by S. Cooper, edit. 3.

Tongue-grafting. See Engrafting.

Tongue-tied, the popular name for a distemper of the tongue in children, when it is tied down too close to the bottom of the mouth, by a ligament connected all along its middle, and called its frenulum, which requires to be divided to give the tongue its proper motion.

This is sometimes the case in adults, but oftener in children, who cannot then exert their tongues to suck. This is, however, by no means so common as the women usually imagine; not so much as one child in a thousand being afflicted with it; nor is the operation in cutting it of little consequence, since often bad accidents follow it, and sometimes the loss of a child’s life. When the infant can put its tongue out of its mouth, the frenulum wants no incision; but when the tongue cannot be extended beyond the teeth, the operation is necessary.

To perform this, the end of the tongue should be covered with a linen rag, and held with the fingers to prevent its flipping, and the ligament of the tongue running between the ranular veins and internal salivary ducts, is to be divided by a pair of obtuse pointed scissors, till the goes room enough for sucking or speaking; but in doing this, great care must be taken not to wound the salivary ducts, or the proper veins and arteries of the tongue; for children have been known to perish upon the spot from cutting the ranular veins in this operation. Midwives often tear this ligament with their fingers as soon as the child is born; but this is a dangerous practice. Heilier. See Infants.

Tongue of Fish. All fih have either a perfect tongue, or the rudiments of one, in their mouth; but this organ is very different in the various species, in its figure, mobility, and other qualities and properties; as to the figure, it is in some pointed before, as in the eluce; in others it is rounded in this part, as the perch and clarie have it; and in others it is somewhat blid, as in the pike. In some it is smooth on the upper part; as in the gar, cyprinid, and mackarel; in others it is rough and dentated in this part, as in the salmon, mullet, &c. In many fih, the tongue is immovable, adhering firmly to the bottom of the mouth, as in the perch, cyprinid, and, indeed, in the greater part of fish; in others it is loose, as in the whale.

In the cetaceous fih, the tongue being loose, as in quadrupeds, it is used by the animal in the same manner; but in other fishes it is of no use in the moving of the food about in the mouth, nor is it the genuine organ of taste, being in many a cartilaginous substance, and therefore not proper for receiving the notices of that sense. The principal use of the tongue in these fishes seems to be in its serving as an assistent organ of swallowing, its being more elevated than the other parts of the mouth, rendering it fit for the toffing of the food down the throat. The true use of the tongue in those fishes which have it dentated is, that it serves to retain the prey from running out of the mouth, and afterwards in the swallowing of it; what renders them more fit for this use is, that they have always the prickles turning inwards. It is the opinion of Mr. Ray, that the tongues of the cartilaginous kinds have some sense of taste, and this is more probable, than that the more hard and rigid ones should have any such sense. Artedi de Pisci. See Fish.

Tongue of a Mouse. What is vulgarly called the tongue in this fish from its shape, is truly an organ, by means of which it spins a fort of threads in the manner of spiders or caterpillars, to fix itself to the rocks by. See Muscle.

Tongue, in the Manse. The aid of the tongue or voice, is a fort of agreeable clacking, or a certain sound formed by the cavalier, in striking his tongue against the roof of his mouth, when he means to animate the horfe, and fullain him, and make him work well in the managed. See Aid.

Tongue, To swallow the. A horfe is said to draw in, or swallow his tongue, when he turns it down his throat, which makes him wheeze as if he were short-winded. This fault is cured by giving him a bit with a liberty for the tongue.

Tongue, Serpent’s, in Botany. See Adder’s Tongue.

Tongue, in Maft-making, the taper part at the lower end of a pindle, or of a farl. In Rigging, a short piece of rope spliced into the upper part of landing-backfells, &c. to the fize of the top-mast-heads; it is ferved over with fpun-yarn, and its use is to keep them open to the fize of the main-heads.

Tonic Accent. See Accent.

TONICAL Echo. See Echo.

TONICHI,
TONICHJ, in Geography, a town of New Mexico, in the province of Higuas; 25 miles N. of Rosichio.

TONIKKY, an island in the East Indian ocean, near the north coast of Celebes. N. lat. 5° 51'. E. long. 99° 37'.

TONINA, in Botany, an unexplained name of Aublet's.

TONIQUE, in French Music, is equal to key-note in English music, or the principal found of a composition which generates all the rest.

TONISKA, in Geography, a town of Russia, in the government of Irkutsk: 46 miles E.S.E. of Sertuchik.

TONKER. See Lassa.

TONKER-SONG, a town of Thibet; 524 miles E. of Lhasa. N. lat. 23° 57'. E. long. 95° 40'.

TONKEY, in Agrimetry, a term provisionally made use of to signify short-legged and deep-carcassed, as is the case in the Chinese breed of swine. It is consequently a term sometimes applied to such breed of swine. See SWINE.

TONKIN, in Geography. See TONQUIN.

TONNA, See TANNA.

TONNAGE, the weight of goods carried in a boat; also, the water, tolls, or sums per ton, per mile, or otherwise, which are payable to the proprietors of the navigation for the liberty of using the same. See TUNNAGE.

TONNAGE, Duty of. See DUTY.

TONNAGE, in Ship-building, the cubical content, or burthen, of a ship in tons; which is commonly estimated by a given rule not answering the above purpose, but producing what is designated the builder's tonnage. The real burthen a ship is to carry, when brought down in the water to the loadline and water intended in the construction, may be nearly found by the rules given in the article SHIP-BUILDING (TONnage or BURTHEN). See also BURDEN OF A SHIP.

The word is derived from a ton, or weight of water equal to 2000 pounds; for it appears that, anciently, a cubic foot of water, weighing 62.4 pounds, was assumed as a general standard for liquids. This cubic foot, multiplied by 32, gives 624, the original weight of a ton. Hence eight cubic feet of water made a heaped ton, and four heaped tons, in capacity and denomination as well as weight.

TONNAGHAN, or DONAGHAN, in Geography, a river of Canada which runs into lake Superior, on the side of which is found a quantity of virgin copper.

TONNAY-BOUTONNE, a town of France, in the department of the Lower Charente; 10 miles W. of Rochefort.

TONNAY-CHARENTE, a town of France, in the department of the Lower Charentes; 5 miles E. of Rochefort.

TONNEAU, in Commerce, a measure of capacity in many parts of Germany, both for wine and dry commodities. The tonneau, as a measure for corn, contains 8 scheffels, or 92 viertels, 100 of which tonneaux yield about 29 English quarters. A tonneau of beer consists of 178 quarters, or 25 English beer gallons. At Koningsberg, a last contains 24 tonneaux, 564 new scheffels, 60 old drits, 240 viollets, or 960 metzgers. A new scheffel contains 510 English cubic inches, and 25 scheffels = 65 English bushels nearly, and 20 Koningsberg lasts = 295 English quarters. The last of Spanish and French salt is reckoned at 18 tonneaux, or 6600 lbs.; the last of earrings at 12 tons; a last of green marbled soap at 5 tonneaux, or 62 viertels. See TEN.

TONNEAT, a corn measure in some parts of France.—Also, a weight of 2000 lbs. French, by which the burden of ships is reckoned.—Also, a general term in France for a cake.

TONNEINS, in Geography, a town of France, and principal place of a district, in the department of the Loir and Cherene; 14° 40' S.E. of Bourdeaux. N. lat. 44° 52'. E. long. 1° 30'.

TONNERRE, a town of France, and principal place of a district, in the department of the Yonne; 10 miles E.N.E. of Auxerre. N. lat. 47° 51'. E. long. 4° 50'.

TONNERRE, a mountain of France, which gives name to a department; 15 miles N.W. of Corbeil.

TONNING. See TUNNING.

TONNINGEN, in Geography, a seaport town of Denmark, in the district of Skodsborg, situated on a peninsula, formed by the Eider. In the year 1613, the harbour was enlarged and repaired at a considerable expense; but in 1679, during the war with Sweden, the duke, pursuant to the treaty of Rendsberg, was obliged to close this town to the king, who ceased the fortifications of it to be demolished. But when the dukedom recovered the town in the year 1679, they were repaired, and improved with additional works; so that when king Frederick IV. believed it, he was not able to make himself master of it. In the year 1719, the Swedes were obliged to surrender themselves prisoners of war to Denmark; and in the year 1744, the king having got possession of the town, the fortifications were demolished a second time. Tonningen has been in a defenceless condition ever since that time. It had once a noble castle, but that was likewise demolished by the king's orders, in the year 1734; 57 miles N.N.W. of Hamburgh. N. lat. 52° 23'. E. long. 6° 00'.

TONNOMAIA, one of the smaller Friendly islands; 11 miles S. of Amamooka.

TONO, a town of Chili; 70 miles S. of St. Yago de la Nouvelle Espiruadura.

TONON. See THONON.

TONORUM, in Ancient History. Roman cities, though not constantly accompanied by a flute, had their voices frequently regulated by an instrument which Quinctillian calls a sonarium. Cicero, a fidelis, and Plutarch, supplicem, or harmonium, which is the same thing; and this instrument served as a kind of pitch-pipe. Both Cicero (De Orat. lib. iii.) and Plutarch (In Vit. C. Gracch.) relate the well-known story of the voice of the famous tribune, Caicus Gracchus, being brought down to its natural pitch, after he had left it in a transport of passion, by means of a servant placed behind him with one of these instruments. Cicero tells us that this tribune, with his finger, qui sine locutio post ipsum, and was not seen by the people, does not confine his employment to appeasing the passion of his master: he was, upon occasion, to incite it: "Qui instinet cordis suscitant, quo ille amat rem, ut el Nord imperialism, ut suae consistat evocatet."

TOSOS, a word used by Hippocrates, to express in general any nerve, whether arising from the brain or spinal marrow. It is also used to express a tension in any part.

TONOSA, in Ancient Geography, a town of Asia, situated on the river Mius, W. of Godasa.

TONOSA, or TUNOS, a town of Asia, in Cappadocia, on the route from Seleucia to Corisoum, between Sebasthe and Arabia. Anton. Iun.

TONOUHWAH, in Geography, a kingdom of Africa. S. of the Niger, the capital of which is Affricus (the Affricus of D'Anville), situated midway between Kantepe, a dependency of the kingdom of Tonouwa; and the sea-coast: that is, about eighteen days' journey from each. It is said that there is no communication between this coast (probably the Gold Coast) and the country of Garjah; at the king of Affricus;
Allentai, who poises the intervening space, prohibits his inland neighbours from passing through his country. On the other hand, a gentleman (Mr. Norris) who resided many years in Whydah, says, that there are other states (that is, the Fantees, and their confederates) lying between Allentai and the sea; and that the Allentais have often attempted, but without success, to open a communication with the coast, from that part of the Niger which forms the southern limit of the great empire of Calhina. In the kingdom of Tonou-wah, which is said to border on the coast of the Christians, and of which, as we have said, Allentai, or Allentaté, is the capital, a succession of hills, among which are mountains of a stupendous height, diversifies, or constitutes the general face of the country. Some of the lands are cleared, but other districts are still incumbered with woods of a vast extent; and though for the most part the highlands are pastoral by innumerable flocks of sheep, and by herds of cows and goats, and the vales exhibit the captivating view of succulent vales, encompassed with corn and rice, and fruits of various kinds, yet these are places of native fertility and eternal barn-sacks.

TONQUIN, or Tonquin, signifying "the Court of the East," because when this country was a province of China, it was the imperial residence; though, with regard to its position with respect to China, it should rather be called "the Court of the West," and denominated by the natives An-nam, Anam, or Ngan-nan, i.e. the repose of the fourth, is separated from Cochin-china by a small river, and may now be considered as incorporated with it by conquest. It is bounded on the E. and N. by China, on the S. by Cochin-china, on the W. by the kingdoms of Laos and Boas, the latter being unknown to geographers. Tonquin may be regarded as consisting of eleven provinces; that of the North being the largest; its boundaries being Laos on the W., China on the N. and E., and Boas on the N.W. With regard to its aspect and surface, it may be divided into two portions, the mountains and the plain. Towards China, Cochinchina, and Laos, the mountains are extensive, but neither rocky nor precipitous; and they are partly covered with forests. In this part are found mines of gold, silver, and iron, and also of copper, which is in high estimation. The lower part of Tonquin much resembles Holland, being partly land and partly water, and intersected by canals and dykes, and also by numerous rivers and lakes. The province denominated "of the West" is watered by seven great rivers, which unite about fifteen leagues above the royal city, and form a kind of sea, or large lake, which sends out various branches. The southern part of the kingdom, though in the torrid zone, superabounds with waters covered with boats. A navigable river, called Songkoy, traverses the kingdom from N. to S., and receives various streams, which are also partly navigable; and canals which serve for the cultivation of rice are numerous. The rivers of Tonquin rise from the mountains of Yunnan, and in the rainy season, from May to September, inundate the adjacent country. The chief of these is the Holy Kian, which, after receiving the Li-fien, passes by Kecho the capital. The population of this country is said to be considerable. Although it has but few towns, it has several villages which contain many inhabitants. The capital of the kingdom and royal residence is Kecho, Kecho, or Kefo (which see). The next remarkable town is Hean, containing about 2000 houses, situated on the right bank of the river, at the distance of four or five days from its entrance into the sea. Formerly the French had a factory in this place, and the trade was considerable. (See Hean.) At the distance of five or six leagues from the mouth of the river is another town, called Domea, much less than Hean. These towns, as well as most of the villages, and some houses belonging to persons of wealth, are surrounded with live hedges of bamboo; and to the houses and gardens are annexed alleys of areca trees, which exhibit a picturesque appearance. The high roads, which are scarcely passable in the wet season, are maintained at the public expense. The rich rail horfes, or litters carried by men. In the mountains the houses are differed, and the people almost savage. The chief product of agriculture is rice, which affords two harvests annually in the low country, but in the high lands only one. The rivers and canals abound with fish of various kinds: wheat and rice are unknown: the mulberry-tree is common: silk is in general use among the poorer people; the sugar-cane is indigenous, but the art of refining the juice is unknown. The plough used in agriculture, consists of three pieces of wood, a pole, a handle, and a third piece, almost at right angles with the last, for opening the ground, and they are simply fixed with straps of leather: this plough is drawn by oxen or buffaloes. The horses are small, but lively and robust: but they are little used, as the inhabitants prefer travelling by water. Horses and sheep are unknown; goats are few, and swine abundant. The people eat dogs, cats, and rats: poultry, ducks, and geese abound, and are found wild in the forests. The eggs of ducks are heated in ovens, and produce young, which swarm on the canals and ponds. The forests contain deer, hogs, peacocks, a peculiar kind of partridge, and quails. The tigers are large and destructive; one of which is said to have entered a town, and to have destroyed eighty-five people. The wild elephants are also very dangerous: apes are found in these forests, and some of them of large size: thefe and the parrots are not a little destructive of the rice and fruits. The manners of the people are very highly civilized than those of the Chinefe: they are in general of middle stature, with broad faces, not so flat as those of the Chinefe; and, in some particular points, they are much finer than the Chinese. The men have long hair, and do not shave. Few of the people are deformed, and the women are rather handsome. The complexion of people of rank approaches that of the Portuguese and Spaniards. At the age of seventeen or eighteen they begin to blacken their teeth, regarding white teeth as the praise of dogs; like the Chinese, the fashion of shaving their heads and faces is restricted to the Mandarins, the men of letters, and other distinguished persons. The ladies drape their heads with red, and sometimes their hands and feet. The dress of the men consists of a piece of silk, several yards long, wrapped about the loins, and a long robe with loose sleeves, thrown off in travelling or during labour. The women of the lower orders are modestly clothed in a long petticoat, and one or more robes like those of the men. They cover their bosoms with a piece of linen of silk in form of a heart: they use ear-rings and bracelets of gold or silver. They commonly appear with naked legs and feet, like the men; but the rich and persons of dignity wear long drawers. The most general colour of the silk and linen is white. Black is only worn by persons of distinction. The men and women fasten their hair behind in a knot; but in the presence of a superior they let it fall, in token of respect.

The people are indolent, and loaded with heavy taxes. The public services required from them occupy about six months in the year. The learned language in Tonquin is that of China, but it degenersates into a kind of dialect which cannot be understood by a Chinefe, and the words are all in single syllables, and expressing different things according to the accents and mode of enunciation. The language of Tonquin, and also of Cochin-china, called
the Anam language, says Dr. Leyden, is simple, original, and monosyllabic. It has little affinity to the Mandarin or court language of China, to that of Canton, to the copious polysyllabic and inflected Japanese, or to any other of the Indo-Chinese languages. Barrow, in his voyage to Cochinchina, seems to consider it as a derivative from the Chinese; but Dr. Leyden perceives no similarity between the Chinese and Anam, unless that they are both monosyllabic languages, and that the signification of terms is regulated, as a great measure, by their accentuation. But though the same monosyllables occur, and though they are also accented frequently in a similar manner, yet even in this case, the signification of these monosyllables is for the most part totally different. In the syntax or construction of the two languages, there is also a very great difference. The Anam language has neither genders, numbers, nor cases, moods, tenses, nor conjugations; all which are supplied by the use of particles and the juxtaposition of words, as in the other monosyllabic languages. The same word has often the signification of both a noun and a verb, and its particular use, in such a case, is to be determined by the context, and the collocation of words in the sentence. The principles of collocation in sentences are equally simple as in the other monosyllabic languages; many usages of which are specified by Dr. Leyden. The accents in the Anam tongue are of such indispensable utility, that they have been very properly termed the soul of the language, while the primary monosyllables, varied by accent, have been made to represent its body. The Anam style is sometimes highly bold and figurative, and attains a degree of animation which is not very common among the Indo-Chinese nations of the continent. The ancient code of Tonquin laws possessed great celebrity, and was highly venerated previous to the conquest of that country by the Cochinchinese. It is represented by the missionary Le Roy, as composed in the most elevated style of Chinese, and full of uncommon modes of expression. He also mentions, that it was printed with an Anam translation, composed by an ancient Tonquin Mandarin. The religion of the Anam nation is a modification of the Buddhist system, nearly resembling that which prevails in China. Many local and peculiar superstitions, however, are blended with it, such as the worship of the dog and tiger, to the altar of which human sacrifice, and to the second, human flesh is offered. Traces of this worship are found among the mountaineers on the borders of India, as well as in the proper Indo-Chinese countries. There the tiger is worshipped by the Haji tribe, in the vicinity of the Garraw or Garadas.

The Quau-no, an ancient race, as the genealogies, who inhabit Kaubang, or the mountainous range which divides the Anam countries from China, regard themselves as the original inhabitants of Tonquin and Cochinchina, and consider the Anam as a Chinese colony. The Quau-no have a peculiar language, and write with a style, on the leaves of a plant, termed in Anam "jwaa." The Moi and Muong are also mountaineer tribes, who speak languages different from the Anam; but it is hitherto unknown, whether they are original races, or only branches of the Quau-no. Aatific References, vol. x.

Marriage is contracted without priest or ceremony, the consent of the parents forming the only ceremony. The husband may repudiate or sell his wife, but the wife cannot leave her husband without his consent. The right of primogeniture predominates, and daughters derive little benefit from the estate of their father. Polygamy is common; divorces are rare: children are not exposed as in China. The inhumanity of creditors equals that of ancient Rome, and the accumulation of usury renders the state of debtors very perilous. An abominable and cruel custom prevails, which is that of putting some peculiars death at the beginning of a new year, and with this view they poison the fowls and fruit which are brought to market: examples of this horrid practice, which, it is thought, will secure them good fortune, are frequent, but the punishment is rare. The chief amusements are plays, dances, and cock-fighting. The general food is rice, and pulse is also in request. The nets of a species of swallow are also held here, as well as in China, in great esteem. The chief drink is derived from a kind of coastal tea, but arrack is also much prized.

The climate of Tonquin is not very hot. From the month of September till March, it is temperate and healthy; in January and February the weather is cold, but neither snow nor ice is seen, and hail is very rare; the temperature of the air becomes rather insalubrious in the months of April, May, and June, which is the season of fogs and heavy rains; and great heat is felt in July and August. In the first country, and on part of the mountains, the winds regularly blow six months from the N. and six from the S., the first beginning in November. Among the aversions of this country, the most grievous is a kind of leprosy, which devours the extremities of the hands and feet. The funeral ceremonies resemble those of China: pieces of gold or silver, or small pearls, are put into the mouths of the dead, that they may not enter poor into another world. Their religion resembles that of the Chinese, but the sect of Foo is most regarded. Every town or village has a tutelary genius. Sometimes the supposed genie is a vile animal, as serpents, dogs, cats, oxen, fish: but more frequently men, who have defiled well of their country. The natives are not a little addicted to magic. The sciences, like those in China, are chiefly sought in the writings of Confucius and his commentators; the principal branches being morality, mathematics, physics, and astronomy, with the history and laws of the country. Knowledge is highly esteemed; and the men of letters are regarded as the pride of the kingdom. All the offices and dignities of the state are the consequence of literary merit. Printing is known here, as in China; but painting and sculpture are in a low state. The chief trade is with China, which supplies Tonquin with fine teas, porcelain, silks, and painted linens, prepared sugars, wheat and barley, flours, kitchen utensils, iron, spades, fish and birds, wax, cotton, gists, and toys. Strangers export from Tonquin vanilla, silk raw or wrought, chiefly strong fruits, beautiful cloth resembling linen, made of the bark of trees, different works of mother of pearl, ebony, ivory, tortoiseshell, cinnamon, copper, cotton, and several other articles. Calamine is also exported from Tonquin by the Dutch and carried to Japan, where it is sifted in the manufacture of brass. The interior commerce of Tonquin is considerable, consisting chiefly of fruits of different kinds, silk and cotton cloths, with those made of the inner bark of the paper-bearing mulberry. The cinnamon, duly cultivated, would be valuable. The trees that produce this vanilla fulfill a juice refishing tartar, and the quantity is increased by incisions. Sugar might form a considerable article, if the people knew how to prepare it. Paper, made of the bamboo, mulberry, elm, cotton-tree, and all kinds of white and happy wood, is a considerable article. Silk procured from the sea, is a commodity of great demand in the interior of the country. The troops of Tonquin amount to about 120,000, of which about 6000 or 8000 are cavalry. Elephants were formerly used in war, but the introduction of firearms has diminished their number. Since the revolution in Cochinchina, when the Chowa rendered himself independent,
TONG. TON.

p resident of Tonquin, and assumed the royal title, a body of 10,000 men has been stationed on that frontier. Every governor of a province has at his dispose 700 men and an elephant. The remaining force, amounting to about 100,000, is placed in the royal city, or in an adjacent camp.

The arms of the Tonquinese are the ancient musket fired with a match, the modern firelock being unknown there, bows, sabres, pikes and half-pikes, and a defensive buckler. The troops of the king's household, which are reckoned among the best troops of the East, are clothed in blue and red. The navy amounts to about two or three hundred galleys, navigated with oars, and fitter for the rivers of the country than for the open sea. The king of Tonquin is reckoned among the rich sovereigns of the East, as he possesses valuable treasures and an ample revenue, derived from rice, a tax upon land, a capitation tax, the sale of dignities, and the duties on merchant-veffels, amounting to about one-tenth of the merchandise. The laws of Tonquin, like those of China, are founded on the simple principle of paternal authority and filial obedience. The magistrates are denominated Mandarins, from the Portuguese mandar, to command, by the Europeans; but in the native languages both of China and Tonquin, the appellation is "Quan." The tenure of lands and right of inheritance are respected even by the sovereign; and the succeffions in land are determined by one tribunal, and that of houfes and personal property by another. The judges are corrupt, and justice is fole. The military and civil offices are venal. Executions are rare, not exceeding through the whole kingdom twenty or thirty in a year. Decapitation is counted ignominious: princes and perfons of rank have the privilege of ftrangulation. Female criminals are trampl'd to death by elephants. The dignity of public executioner is hereditary. Other punishments are exile, perpetual imprisonment, and personal chattelment, fometimes with the mutilation of a finger or ear. The prizes are paid to be in a shocking state. On a general view of Tonquin, the country and the defpot are extremely rich, and the people are very poor. The Jefuits, soon after the commencement of the 17th century, made an attempt to introduce into this country the Christian faith; but their efforts have not been very fucceflful; feveral illufces having occurred of the perfecution of Christians.

In the gulf of Tonquin there is a small isle, which is faid to afford the mulk animal; and in the vicinity is a pearl fishery. The chief entrance of the river, called Dometa by the Europeans, is obstructed by a bar, and requires the guidance of a native pilot. In this gulf, as well as the adjacent Chinefe sea, the "tufoons," or "typhons," are tremendous. They are preceded by very fine weather; a prefaging cloud appears in the N.E. black near the horizon, edged with copper-colour on the upper part, fading into a glaring white. It often exhibits a ghastly appearance twelve hours before the typhon bursts; its rage lasts many hours from the N.E., attended with dreadful claps of thunder, large and frequent flatches of lightning, and exccfive hard rains; then it roars into a dead calm, after which it begins again with redoubled rage from the S.W., and continues for an equal length of time. Abbé Richard's compilation from the papers of the abbé St. Phalle, a misfionary in Tonquin for twelve years, who died at Paris in 1766; cited by Mr. Pinkerton, in his Geography, vol. ii. For an account of the revolutions in Tonquin from the earliest period of historical account, see Grofer's China, vol. i.

TONQUIN Bean, in Botany, sometimes called Tong Bean, is the seed of DIPTERYX odorata. See that article.

TONQUIN Medicine. See HYDROPHOBIA.

TONS de l'Eglife, Fr.; Twni ecclesidlicii, Itai.; the ecclesiastical modes or tones in canto fermo. See PLEN-CHANT, CANTO FERMO; and ECCLESIASTICAL MODES, AUTHENTIC and PLagal.

For the history of the establishment of the modes at Milan and at Rome, see St. AMBROSE and St. GREGORY.

The modes of the Roman church are eight: four authentic, and four plagal. The four authentic, or principal, are the odd numbers: 1st, 3rd, 5th, and 7th; the plagal are the even numbers: 2nd, 4th, 6th, and 8th; which answer to D and A minor, and C and D major, for the authentic; and G and A minor, and F and G major, for the plagal. These are defcribed by Dr. Pepusch, Padre Martini, and Roufeau, and all their feveral fcales may be seen in Burney's General History of Music, vol. ii.

We have drawn out the fcales of all the eight modes or tones acending and defcending (see Plates of Music), by which it will appear from the imperfection of these fcales in most of the tones, that they are only capable of melody; and all the common fervice of Roman Catholic churches, when the priests perform the duty without the afliftance of profefled musicians, no harmony is attempted to be given to mere canto fermo. In cathedrals, the motets and parts of the mas are sung by choirmen and children, as the anthems and fervices are in our cathedrals.

Notwithstanding the imperfection of the fcales, and little variety of keys in the ecclesiastical chants, secular music seems for many ages to have had no other rules, but to have been chiefly confined to a few keys in the diatonic genus, without the liberty of transpoftions. Hence came the timorous pedantry of excluding all other keys and fcales but thofe used in the church; which kept every kind of melody meagre and infipid, and in fubjeftion to the rules of ecclesiastical chanting. For it appears, that the only major keys used in canto fermo are C and its two fifts F and G; and the only minor keys A, E, and D. And in four of these keys the fcale is deficient, as there is no feventh or notefifte to G, A, or D. This accounts for fo small a number of the twenty-four keys which the general fytem and fcale of modern music furnifhes, having been ufed by the old compoferf; as well as for the temperament of the organs by which these modes were afterwards accompanied. And as all music in parts feems, for many ages after the firft attempts at counterfop, to have been compofed for the service of religion upon canto fermo and its principles; it likewise accounts for the long infancy and childhood of the art, till it broke loofe from the trammels of the church, by which it was bound in Gothic times; and by the cultivation of the musical drama sacred and fecular, the ideas of compoferf were enlarged, and the talents of performers improved by new exerfions, which brought the art nearer perfection during the two lat! centuries, than it had attained in feven hundred years from the time of Guido.

In implicit and religious obedience to the laws of canto fermo, no accidental flat or sharp was ever to appear; all the eight tones being rigidly in the diatonic genus in the keys of C and A natural, with no other femitones than from E to F, and B to C. When the fcales of these tones are drawn out at full length, they feem nothing more than different fpecies of octavc.

All these fcales defcending, might, however, be made perfecf by a fingle flat or sharp at the clef: as the firft tone by a flat, the third by a sharp. The 2d is perfect, defcending; the 4th wants a sharp or two at the clef to determine it to be in the key of E or B minor. A flat would make the 5th complete in the key of F; and a sharp the 7th in that of G. The
G. The 6th is in the key of C natural, ascending complete; and with a flat to B in the key of F, descendent; the 8th with one sharp would be in G, and with two sharps in D major. But these were licences which no one thought of, or at least had the courage to practice, till counterpoint began to gain ground. And even then, the mufica fina, or falle music, as that in transposed keys was called, no one dared to write till lately. Even the orthodox and good Padre Martini, at length vanquished his fears of the impropriety of using an accidental flat or sharp in the inward parts of canto fermo.

Lorentz, author of the famous Spanish treatise called "El por de la Mufica," without which Germanians made Dr. Worgan believe it impossible for any one to understand counterpoint, has written the scales of the eight tones as we have done; but has not ventured to harmonize them, as accidental sharps and flats must have been expressed or understood in the additional parts.

TONSA, in Geography, a river of European Turkey, which runs into the Mariza, near Adrianople.

TONSE, among the Romans, the blades of oars, or that part of them which beats against the water.

TONSBerg, in Geography, a city or town in Norway, in the province of Agderhus, situated on a bay of the Baltic; built upwards of 800 years since. It formerly contained nine churches, but now has only two. The inhabitants carry on a considerable trade in furs and butter. In the year 1536, it was laid in ashes by the Swedes, since which, it has greatly declined; 42 miles S. of Christiania. N. lat. 59° 23'; E. long. 10° 12'.

TONSELLA, in Botany, a name made by Schreber, out of the Pontea of Aulbert, which is itself taken from the Caribbean appellation of the same shrub, Rassona-tonella. Schreber perhaps meant to give the word a classical air, by approaching it either to Tonfa, an oar, or Tonfella, a mooring post, or a cable, for which indeed there seems no foundation in any recorded use of the plant. Possibly he might have in view tonella, a word applied to the box, or other trees fit for chopping. This idea is, however, no less applicable to our Tonfella than to the former.—Schreyl. Gen. 34. Willd. Sp. pl. v. 1. 192. Vahl. Enum. v. 2. 29. Mart. Mill. Dig. v. 4. (Tonselea; Aubl. Guian. v. 1. 31. Jull. 436. Lamarck Illistr. t. 26.)—Clads and order, Triandra Monogynia. Nat. Ord. uncertain, Jull.—It seems akin to Eunymus, and therefore probably belongs to his Rhamn. Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, permanent, in five deep, ovate, acute segments. Cor. Petals five, ovate, thick, permanent, longer than the calyx, inserted into the receptacle. Nectary cup-shaped, entire, surrounding the german. Stam. Filaments three, thread-shaped, reflexed, inserted into the inside of the nectary, rather shorter than the petals; anthers roundish. Fil. German superior, roundish, surrounded by the nectary; style cylindrical, shorter than the filaments; stigma simple. Peric. Berry spherical, seated on the permanent calyx and corolla, of one cell. Seeds four.

Obs. Jullien appears to have been underrated about the natural affinity of this genus, from having preconceived the germes to be inferior, which it purely is not.

1. T. fiscandens. Climbing Tonfella. Willd. n. 1. Vahl. Symb. v. 2. 17? (T. fiscabra; Vahl. Enum. n. 1. Tonselea fiscandens; Aubl. Guian. 31. t. 10.)—Leaves pointed, entire. Branches round, warty.—Gathered by Aublet in the forests of Guiana, near the river of Sinemari, thirty leagues above its mouth; flowering in October.—Von Rohr is said to have found the same in the island of Trinidad. The former terms it a shrub, climbing to the tops of the loftiest trees, and covering them with its opposite, repeatedly compound branches, which at length become pendant, even to the ground. In his own specimen before us they are slender, round, covered with minute warts burrowing through the cuticle, and bear several short opposite florets, leath at the extremity. We find no sign of hairiness. The leaves are opposite, on thick, channelled, smooth stalks elliptical, entire, two or three inches long, with a short blunt point; they are smooth on both sides, coriaceous, rather thinning, with one rib, and many reticulated veins. Flowers green, very small, about the ends of the branches, in partly terminal, partly axillary, small clusters, whose partial stalks are opposite.

Vahl describes the plant of Von Rohr as a tree, whose branches have a purplish roughish bark, and are hairy in their upper part. The branches are roughish on both sides; their veins villous at the back. Flower-stalks downy. Calyx and petal hoary; the latter fringed. We have been so speci- 

2. T. angustif. Toothed African Tonfella. Willd. n. 2. Vahl. n. 3.—Leaves oblong, with glandular teeth.—Native of Guinea. Similar to T. scandens, but different, having smaller and obtuse leaves, furnished with very dilatant glandular teeth; a larger corolla, and terminal anthers. Berry, according to Vahl, the size of an apricot, smooth, orange-coloured, globular with three flight angles, and from six to ten seeds.

3. T. angulif. Entire-leafed African Tonfells. —Leaves pointed, entire. Branches angular, smooth.—Brought from Sierra Leone, by prof. Gervis. The dried specimens are of a peculiarly fresh light green, and quite smooth. Branches with four, not very prominent, angles, slender and wavy. Leaves two and a half inches long, elliptical, with a linear blunt point, quite entire, veiny. Flowers small, green, in small, axillary, twisted tufts, whose common stalks, like the footstalks, are about a quarter of an inch long. Fruit the size of a pea, apparently a tough-coated berry.

4. T. decussata. Crooked-branched Tonfella. Vahl. n. 2. (Anthodon decussatum; Fl. Peruv. v. 1. 453. t. 74. f. 1.)—Leaves oblong-ovate, obtusely serrated, poliished. Filaments forked.—Native of woods upon the Andes. A shrub, with crooked greenish copious branches; purplish when young. Leaves pointed, smooth on both sides, or twisted stalks. Flower-stalks opposite, square, shorter than the leaves, compound, forked. Flowers small, yellow. Fruit unknown, but the affinity of the plant to T. angustif. has induced Vahl to place it in the same genus.

5. T. senegalensis. —Senegal Tonfella. Vahl. n. 4. (Hippocratea senegalensis; Lamarck Illistr. v. 1. 101.)—Leaves oblong, pointed, smooth, poliished; serrated towards the extremity. Stalks crowded, single-flowered. Branches rough.—Native of Senegal. Branches alternate, delicate of hairiness. Leaves about an inch long, with a bluntish point, half as long as the nail, their margins obscurely serrated, and appearing under a magnifier to be bordered with a yellow thickened line. Flower-stalks capillary, about half an inch long, numerous, from a short axillary tube. Petals linear, smooth.
polished, nearly entire. 'Stalks crowded, single-flowered. Branches rough.'—Native of Madagascar, as the unchristian name, which ought to have been changed, implies. The branches are said to be opposite, leprous, but not downy nor hairy. Leaves an inch and half long, or somewhat more, rather coriaceous, sometimes slightly toothed towards the end. Flower-stalks very numerous, from each axillary tubercle. Flowers drooping, smooth. Petals linear.

7. T. multiflora. Many-flowered Tonfella. Vahl, n. 6. (Hippeastrum multiflora; Lamarck Illust. v. 1. 101. H. obovata; Richard Ag. Soc. Hist. Nat. Paris. v. 1. 106.)—'Leaves obovate, entire, polished. Stalks crowded, each bearing two or three flowers.'—Found by Richard in Cayenne. Branches opposite, smooth. Leaves three or four inches long, sometimes oblong-ovate, very smooth, deltiform of veins. Flower-stalks numerous, scarcely half an inch long, each divided into two or three simple partial stalks, about the same length, with minute bractæ at the base of each. Petals oblong, smooth. The fruit of these three half plants has not been examined, but Vahl was induced, as in the similar cafe of our fourth species, to remove them blither, on account of their very close affinity to T. africana.

The author just mentioned considers this genus as very nearly related to the Linnaean Salacia, see that article. This opinion is extremely probable, and if it be correct, the name of Tonfella must give place to Salacia. In the habit of the plants we find no grounds for any distinction.

TONSET, in Geography, a town of Norway, in the province of Agderhus; 143 miles N. of Christiania.

TONSILS, in Anatomy, the glandular bodies, also called from their size and shape amygdale, placed at the pассив from the mouth to the pharynx. See DEGLUTITION.

TONSILS, Difeased, and Extirpation of. The tonsils are exceedingly liable to inflame; and sometimes the swelling thus produced is so great as to obstruct deglutition and respiration in a very dangerous degree. Prompt succour is now most urgently required; and relief may commonly be obtained by lacerating the enlarged tonsils, and promoting the bleeding with warm gurgles.

This operation may be done with an ordinary lancet, or with a broad one contained in a sheath, and constructed so that its point can only be pushed out to a certain distance. Pharyngotomus is the name usually given to this instrument. Abscesses in the tonsils are also to be opened, when the swelling causes serious inconvenience.

When lacerations cannot be made, the best means are venefication, applying leeches to the throat, exhibiting mercurial medicines, inhaling the steam of hot water, and using proper gargles.

Abscesses of the tonsils have been observed of considerable extent, not burting in the mouth, as is usual, but in the Enforthian tube, or even the maxus auditorius externus, attended with caries of the mitoad procés, deafness, and fissula. Such cases are frequently incurable.

The tonsils sometimes become enlarged, without being inflamed. This swelling is improperly termed febrifous. The glands are only swollen and of moderate firmness. A portion of a tonsil, thus enlarged, may be cut off, without the least danger of the rest assuming a malignant nature. This preternatural swelling of the tonsils is mostly owing to repeated inflammations. Sometimes there is no palpable cause. The malady is constantly free from pain. When the tumefaction is considerable, it obstructs the speech, deglutition, and respiration.

Diurent and astringent applications here prove ineffectual. The tumour admits of being removed; but it is unnecessary and improper to take away the whole tonsil, as a dangerous and even fatal haemorrhage might be the consequence. Only so much of the swelling should be removed, as is sufficient to afford relief. The remaining portion in general heals, without the least difficulty; a clear proof that the discharge is not of a malignant nor cancerous nature.

The extirpation of a part of a tonsil, thus diseased, has been accomplished with caulis, the actual cautery, the ligature, and cutting instruments. The first of these plans was successfully practiced by Wiseman; but is now quite abandoned. The second is also relinquished, as no modern farceous employ it, except now and then, with a view of destroying fungous excrecences, which, in a few instances, originate after a part of the tumour has been removed by some other operation.

A variety of instruments has been devised for putting a ligature round diseased tonsils.

There are very good farceous, who still prefer tying diseased tonsils to cutting them away, and the mode to be adopted differs according to the swelling has a narrow or broad base.

The ligature ought to be made of silver wire, or catgut. When the tumour has a narrow neck, the ligature is to be doubled, and introduced through the nostril, so that the nose may be seen in the throat. With the aid of a pair of forceps, the nose may then be easily placed round the neck of the tumour. The ends of the ligature are then to be brought through a double cannula, and the latter instru- ment introduced as far as the tonsil. The ligature on each side is then to be drawn tightly, and fastened round rings—at the end of the cannula. The instrument may next be twisted, till a due degree of contraction is produced.

Default employed an instrument, called a ferre-neud, for putting the nose of the ligature over a diseased tonsil, and producing the necessary degree of contraction. The ferre-neud was nothing more than a little ring, mounted on a longitudinal, narrow piece of steel, about five inches long, the other end of which was grooved, or rather forked. The diseased tonsil was first taken hold of with a double hook. With the ring, the nose was conducted along the hook, and put over the tonsil; the ligature was then drawn out, while the ring pressed the nose downward and backward. Thus the due contraction was made, and it was next maintained by twisting the ends of the ligature round the forked extremity of the instrument, on the outside of the mouth. Default par Bichat, tom. ii. p. 233.

When the diseased had a broad base, and was of a conical shape, so that the ligature was apt to slip off, Celsfelden has recommended the use of an instrument like a crooked needle, set in a handle, with an eye near the point, threaded with a ligature, which is to be thrust through the bottom of the gland, and laid hold of with a hook. The needle is then to be withdrawn. The double ligature is next to be brought forwards, and one part tied above, the other below the tumour. The ligatures are now to be cut off near the knots.

We have already observed, that the removal of the whole enlarged tonsil is unnecessary, and therefore injudicious. We may now notice, that a portion of the tumour may be cut away, without any just ground for fearing a dangerous bleeding. The application of a ligature occasionally produces a most perilous swelling of the diseased tonsil, attended with such hazard of suffocation, as to compel the farceous to cut and remove it. Bertrand, and many other eminent farceous, have been in the habit of cutting away enlarged tonsils, without ever meeting with an instance of danger from the subsequent bleeding.

Default sometimes employed a flat sheath, made of silver,
and having a notch in it for the reception of the bale of the tenon. The latter part being thus taken hold of, a spring was touched, when a concealed blade immediately moved across the notch, and made the requisite division, without any risk of injuring the adjacent parts in the mouth.

The operation may be done with a pair of scissors, constructed with three blades and long handles; or it may be performed with a bistoury, which, in general, must be the best instrument.

The hemorrhage may usually be stopped by repeatedly washing the mouth with very cold water.

When the enlargement of the tenon is really of a circular nature, a circle which is possible, though not common, in operations performed so as to remove only a part of the indicated enlargement, would not be followed by success.

Calculous concretions have been known to form in the tonsil, occasioning troublesome coughing, feverishness, &c. The propriety of excising them, when their existence is clearly ascertained, is almost too obvious to require being mentioned. Part I. Lines on the Practice of Surgery, by Samuel Cooper, ed. 5.

TONGSTALL, or TUNSTALL, CUMBERLAND, in England, an English family, was the natural son of a gentleman of good family, and born at Hunsford, in the ancient Richmondshire, about the year 1744. Having studied both at Oxford and Cambridge, he travelled for further improvement, and graduated doctor of laws at Padua. Recommended by the learned and character of archbishop Warham, he became his vice-general, and was married to the king by the request of Hunsford, in Middletown. Besides other preferments, he was appointed, in 1756, to the office of master of the rolls, and in this year accompanied the Thomsen More as ambassador to Charles V. at Brussels, where he formed an intimacy with Erasmus. After obtaining other preferments, and accomplishing another embassy to the emperor, he was promoted, in 1753, to the see of London, and in 1759, to the see of Limerick of the perry hall. He was afterwards employed in several missions of importance on civil affairs: and whilst he was at Antwerp, he manifested his religious zeal by burying all the unkind echoes of Tuxtall's translation of the Bible, in order to burn them in St. Paul's Crock. His zeal was finally engaged in urging Erasmus to write against Luther, and in infusing persecutions against heresy. In 1750, Tuxtall was promoted, in recompense of his services, to the see of Dacia. Floshing in his disputations and politics, he left a party and afterwards disapproved the divorce of Catherine of Aragon: he side defended Henry's assumed right of supreme head of the church, after having at first protested against it; and though he was not inattentive to the instructions of the papal see, he was firmly attached to the doctrines of the church of Rome. Respecting, as we hope, of having burnt the Bible, he joined with Heneage, bishop of Rochester, in revising an English translation of it in 1542. Under Edward VI., he conformed to all the ordinances relating to religion, whilst in parliament he protested against every change. As long as his rich bishoprick possessed a tenon, which those who sought preferment could not resist, and therefore Tuxtall was charged with misappropriation of treasuries, and a bill of complaint was brought into the house of lords, which, though supported by Cranmer, passed that house, but was stopped in the commons, the evidence being thought insufficient. His enemies, however, determined to discharge him, and a commission was appointed to examine him with regard to all complaints, &c.; and having been found guilty, he was degraded, and committed to the Tower, where he remained a prisoner to the end of this reign. The see of Dacia was converted into a county palatine, and granted to the duke of Northumberland. On the accession of Mary, he was restored to his see; and his temper being mild, he neither avenged himself on his enemies, nor were any persons brought to the stake in his diocese during this stagnant reign. His whole conduct seems indeed to indicate a favourable change in his temper, for he discouraged persecution, and afforded an asylum to his nephew, Bernard Gilpin. (See his article.) When Elizabeth succeeded to the crown, hopes were entertained that his moderate principles would have led him to acquiesce in the reformation, but he preferred the surrender of his episcopal to the complaints against which his conscience revolted. Refusing to take the oath of supremacy, he was deprived, and being committed to the custody of Parker, archbishop of Canterbury, he was treated with kindness, and by the prelate's reasoning induced to abandon some of the greater errors of popery. He died in 1559, at the advanced age of eighty-four, and was interred at the archbishop's expense, in the church of Lambeth. As to his personal character, he was much respected and attentive to his ecclesiastical duties; and in his private life, exemplary and amiable. He was author of several works, among which was a treatise on arithmetic. Some of his letters are preserved in Erasmus's collection. Dtg. Brit.”

TONSURE, formed from tonsure, or chore, the art or act of cutting the hair, and shaving the head. See Hair.

Tonsure was formerly a mark of infamy in France; so much so, that when they would render any prince incapable of succeeding to the crown, they cut off his hair and shaved him.

See Beard.

Tonsure, in the Roman church, is used for the entrance of admirers into holy orders.

In propriety, tonsure is the first ceremony used for devoting a person to God and the church, by presenting him to the bishop, who shaves him the first degree of the clerics, by cutting off part of his hair, with certain prayers and benedictions.

Some hold the tonsure a particular order; others, as Loyola, only the mark and form of ecclesiastical orders in general.

The tonsure suffices to make a clerk; the act is only to qualify him for the building of benefices. A person is capable of the tonsure at seven years of age; thence a benefice of simple tonsure is such an one as may be enjoyed by a child of seven years old. The tonsure is the basis of all the other orders.

Tonsure is also used for the crown, which priests, &c., wear, as the mark of their order, and of the rank they hold in the church. See Crown.

The barbers have the merchants and dimensions of the different kinds of tonsure, or clerical crowns, to be graded according to the different degrees and orders. A clerk's tonsure, a budonnel, tonsure, a dean's tonsure, a priest's tonsure, are each respectively bigger than the other.

Gen. Chr. Cal. Peruvian Superior, of one leaf, in four deep, ovate, acute, equal, spreading segments. Cor. of one petal, funnel-shaped; tube thence as long as the calyx; limb in four deep, ovate, acute, equal, spreading segments. Stam. Filaments four, thread-shaped, inserted into the throat of the corolla, between the segments, and about equal to them in length; anthers roundish, of two cells. Phil. Geranium roundish, inferior, crowned with an auricular disk; style rather
rather longer than the corolla, thread-shaped, divided half way down; stigma dilatant, obtuse. Peric. Berry ovate, crowned with the withered calyx, of two cells, cajly separable. Seeds numerous, convex on one side, concave on the other, winged, inserted into the transverse partition.

Eff. C. Corolla of one petal, funnel-shaped, four-crested, acute. Berry of two cells, with many winged seeds.

1. T. guianensis. Aubl. t. 42.—Native of moist woods in Guiana and Cayenne, flowering, and bearing ripe fruit, nearly all the year. A trailing herbaceous perennial plant, creeping by means of fibrous radices; the stem and branches round, slightly downy. Leaves opposite, flaked, ovate, fleshy, entire, hairy, an inch and half long, with a pair of infrafoliaceous stipules. Flowers white or blue, three or four together, in little, axillary, flaked, solitary heads. Berry blue, with a viscid juice. Schreber's Bellardia was named in honour of Dr. Charles Louis Bellardi, the co-adjutor of Allioni, and still living at Turin. His Appendix ad Floram Pedemontanam, and his Observazioni Botaniche, prove him an able and observing botanist. Bellardia ought to have been noticed by one of our predecessors in its proper place. We should adopt it here, in the place of the above faulcy name, Tontanea, there were not much doubt of the identity of the plants. Schreber describes his as having linear unequal segments to the calyx, a hairy or villous oblong corolla, very short flamin, linear anthers, and the nearly glabrous capsule, not a berry. Neither does he notice a wing to the seeds, which he describes as acutely angular, and dotted. Had he not cited Aublet, no one would have supposed its genera to belong to each other; nor does Schreber himself scarcely affect it. Of his Bellardia nothing is known, except from his own generic character, because he never published a Species Plantarum, to clear up the obscurities attendant on his new genera.

TONTAPILLI, in Geography, a town of Hindooftan, in the cirear of Rajamundry; 30 miles N. of Rajamundry.

TONTESCO, a town of Africa, in Bambouk; 10 miles N. of Combregoudou.

TONTELA, in Botany, Aubl. Guian. t. 10. See Tonailla.

TONTI, or TONTY, in Geography, a river of Canada, which runs into Lake Erie, nor far from the Orwell.

TONTINE, a loan raised on life-annuities, with the benefit of survivorship. Thus, an annuity after a certain rate of interest is granted to a number of subscribers, who are divided into classes according to their ages; and annually the whole fund of each class is shared among its survivors, till at last it falls to one, and on his death it reverts to the power that first established the tontine. The term is derived from the name of the inventor.

TON-TING, in Geography. See Tong-Ting-Hou.

TONTON, an African drum, which Peer Labat, in his voyage to Guinea, tom. ii. numbers among the musical instruments of the Negroes, and which is never used but upon the approach of an enemy, or on extraordinary occasions. It seems to furpafs in force the Stenterophonic tube of Alexander the Great; as it is said that it can be heard at the distance of fix or seven miles.

TONTORAL, Cape, in Geography, a cape on the coast of Chili. S. lat. 27° 30'.

TONTRAVERLORE, a town of Hindooftan, in the cirear of Condapilly; 25 miles W.N.W. of Mafulpitam.

TONVORE, a cape of Scotland, on the N.W. of the island of Illy. N. lat. 55° 51'. W. long. 6° 27'.

TONYES, a town of Mexico, in the province of Culican; 60 miles N.E. of St. Miguel.

Vol. XXXVI.

TONYN'S ISLANDS, a cluster of small islands in the East Indian sea, near the S.W. coast of the island of Celebes. S. lat. 6° 31'. E. long. 119°.

TONZI, in Ancient Geography, a town of Thrace, on the coast of the Euxine sea, between Apollon and Peroncticum.

TONTOS, or TONTUS, a town in the interior of Thrace.

TOOBIKAN, in Geography, a small island in the Sooloo Archipelago. N. lat. 6° 14'. E. long. 120° 44'.

TOOBIGHA, one of the Society islands, in the South Pacific ocean. Its greatest extent, in any direction, exclusive of the reef, is not above five or six miles. Small as the island is, there are hills in it of a considerable elevation. At the foot of the hills is a narrow border of flat land, running quite round it, edged with a white sand beach. The hills are covered with graw, or some other herbage, except a few rocky cliffs at one part, with patches of trees interpersed to their summits; but the plantations are more numerous in the valleys, and the flat border is quite covered with high strong trees, whose different kinds could not be discerned, except some cocoa palms, and a few of the etoa. According to the information of some men who captain Cook saw in the canoes, their island is stocked with hogs and fowls, and produces the several fruits and roots that are found at the other islands in this part of the Pacific ocean. This island is populous, and the inhabitants are more sedate than the natives of the Society islands, as well as less hospitable. Fletcher Christian, with his companions, mutineer of the Bounty, attempted to form a settlement here in the year 1789. They had a dispute with the islanders, and a severe engagement, in which one or two of the mutineers were wounded, and many of the natives were killed. Christian, after this, left the island of Toobouai, and failed to Otaheite, where some of the crew left him; nine only remaining on board, with some of the natives, men and women, with the Christian cut the cable, and put to sea, since which time he has not been heard of. The language is the same as that spoken at Otaheite. S. lat. 23° 25'. E. long. 210° 37'.

TOODIWAHI, town of Pegu; 35 miles S. of Lundey.

TOODIGUNTIA, a town of Hindooftan, in Golconda; 25 miles E. of Damippeta.

TOODY, a town of Hindooftan, in Canara, on the coast; 21 miles S. of Carwar.

TOOE, a town of Hindooftan, in Bahar; 12 miles E. of Bahar.

TOOFI, one of the Friendly islands, visible from Annamooka, by means of its height, and a volcano, which almost constantly emitted smoke, and sometimes threw up flames. Its shores are steep, and covered with black sand. The rocks are hollow, and in some places of a cylindrical form. The mountain, except in spots that appear to have been recently burned, is covered with verdure, shrubs, and trees. The coast is about five leagues in circuit. To the north-east of this island, and about two miles distant, is another of much less extent, but of thrice its height, which is called Kaö; it is a mountainous rock of a conical form. Both these were discovered by Tafman, and have been seen by every subsequent navigator of this group. Captain Cook pafted between them, and had no soundings in the channel by which they were separated. Each island was understood to be inhabited, but no European had landed upon either, at the time when the mutiny suddenly occurred in the Bounty two days after the departure of that vessel from Annamooka. Lieutenant Bligh was forced into a boat with eighteen of his people, when ten leagues S.W. from Toofea: he attempted...
therefore to get an immediate supply of bread-fruit and water at that island, which, as he understood, afforded these articles. The next morning, 18th of April, 1795, they landed in a boat on the south-west coast; they climbed the heights, but obtained only some coco-nuts and plantains, and a few gallons of water from holes in the rocks. The weather being too boisterous to proceed, they sheltered themselves by night in an adjacent cave. On the 19th of May, several of the inhabitants brought them a small supply, and retired peacefully in the evening. The next day their number greatly increased. Some principal persons also came round the north side of the island in canoes, and among them one of the chiefs whom captain Bligh had threatened to carry from Timor to keep him on board the Resolution, when the weather should become moderate; but some symptoms appearing of a design to obtain by force the articles that he could not afford to part with, he determined to depart that evening, as they were not inclined to return. They had previously loaded him with some of their weapons, and they now allowed his people to carry their property into the boat; but they would not suffer him to embark, and a contest ensued, in which most of the English were wounded by stones, and one of them was killed. The ship escaped, and bore away towards New Holland, from whence they reached the East Indies in their boat, enduring extreme hardship, but not further loss of lives.

TOOGAUM, a town of Hindostan, in Bagmati; 16 miles S. of Jumna.

TOOK, a town of Persia, in the province of Cohadran; 40 miles E. of Tihanauli.

TOOK, John Horne, in Biography, the third son of a provost in Newmarket, was born in Westminster, in June 1756, and having spent some years at Westminster and Eton schools, was admitted into St. John's college, Cambridge, in 1773, where he took the degree of B.A. After graduating for some time as an usher in a school at Blackheath, he took his master's orders, in compliance with the wishes of his father, and served as a curate in Kent. But the law being the object of his choice, he entered into the Inner Temple in 1786. Nevertheless, in 1780, he was ordained as a priest, and inducted into the chappelry of New Barnetford, parochial for him by his father. But as he entered very deeply and warmly into the political debates of the period in which he lived, he ceased officiating as a clergyman, and took an active part in the transactions of that period. When Wilkes returned from his exile to France, and became a candidate for the representation of the country of Middlesex, Horne was his zealous adherent, and was thought to have contributed to the success of his election. It is said that it was by his influence that Mr. Beckford had success in 1782, made a verbal reply to his majesty's answer to a remonstrance from the city of London; and thus he drew up that reply, as is said, on the occasion of Mr. Beckford's illness at Guildhall. He is regarded as the principal founder of the "Society for Supporting the Bill of Rights," of which he was an active member; and by his exertions Bingley, a printer, who had been convicted of sedition by lord Mansfield for refusing to appear for the purpose of answering to interrogatories, was at length liberated. In the years 1780 and 1781, a quarrel took place between Wilkes and Horne, in the presence of which the latter left the building, without incurring any suit charge against his political integrity. In 1782 he took his degree of M.A., though opposed by some members, among whom was Mr. Paking. To him for a time, the publication of the debates in the House of commons has been continued without interruption. At this time he had a literary controversy with Junius, in which he was thought to have the advantage. In 1793 he threw off his clerical garb, and proposed to refine his legal studies with a view to the profession. But at this time an incident occurred, which was of material importance with respect to his future fortune. Mr. Took of Parley, in Surrey, had indirectly opposed an income bill, which was likely to be detrimental to his estate, and as this bill was passing rapidly through the Commons, he applied to Horne for advice. After some deliberation he proposed to Mr. Took a remedy, which was to communicate with a friend on the speaker, which he was inclined to write. Accordingly he stated the case, accompanied by some severe reflections, and sent it to the Public Advertiser. When the paragraph was next day reported to the house and read, it occasioned great excitement, and a motion was made for calling the speaker before the house. Mr. Horne, as the acknowledged writer, was called to the bar; he immediately obeyed the summons, and in a respectful manner confuted, that through hatred to opposition, and zeal to serve a friend, he had been urged beyond the bounds of discretion. After a long debate, he was remanded from the bar in custody of the gentleman at arms, and upon being brought up some days after, he was, by the good offices of some friends, discharged upon paying his fees. His purpose was answered; time was thus given for reconsidering the obnoxious bill, and the objectionable clauses were either altered or withdrawn.

Mr. Horne was an ardent supporter of the American war; and when the news of the battle of Lexington arrived, the Constitutional Society voted 500l. to the widows and children of the Americans who had fallen in it; and the resolution on this subject, printed in the public papers, was signed John Horne. In this resolution the following were denounced:—Englishmen who, professing to love liberty, were, for that reason only, implicitly supported by the king's troops at Lexington. For this paragraph he was prosecuted, and tried at Guildhall in July 1775, and pleaded his own cause. Notwithstanding the spirit and warmth with which he defended himself, he was sentenced to twelve months' imprisonment, and to pay a fine of 100l. In the course of this trial he first appeared before the public as a grammatical critic; and in 1782, he printed a letter to Mr. Dunmore, which discussed the justice and meaning of certain observations and propositions employed in his article, and which was the foundation of a larger work afterwards published. In the following year, he was disbarred in his expectation of being called to the bar; for though he was eminently qualified for the profession into which he entered, he was rejected under the pretext of his being a clergyman. This he felt as a very grievous disappointment, and with a mind not a little exasperated he devoted himself to politics. Accordingly, in 1783, he published a pamphlet, entitled "Fame," firmly reversing lord North's administration, and containing two chapters on Finance, supplied by Dr. Price. Soon after the termination of the American war, parliamentary reform became a popular topic; and in 1786, Horne published a letter to Mr. Dunmore (lord Adderbury) under the sign of "A Letter to a Parliamentary Reformer, containing the Sketch of a Plan," of which we shall merely say, that he disapproved of universal suffrage, Mr. Part was at this time a fellow advocate in the same cause. Horne now avowed himself the friend of Mr. Pitt, in opposition to Mr. Fox, whose coalition with lord North he very much disapproved. In 1786 Mr. Horne, having assumed the name of his friend Mr. Tooke, published his "Epica Progressa, or Detractions of Parley," it called from
from the country residence of his friend. Of this work, founded on his letter to Mr. Dunning, already mentioned, the most prominent subject of discussion was the derivation of conjunctions and prepositions from verbs and nouns, whence they acquired a determinate meaning, often different from that which has been arbitrarily imposed upon them. This work attracted the notice of philologists, and gave to the author a high rank among writers on the philosophy of language. (See Grammar.) Politics, however, diverted his attention from subjects of this nature; and in 1788, he published "Two Pair of Portraits," the figures in which were the two Pitts, and the two Foxes, of the past and present generations. The first name was strongly illuminated, and the latter thrown into a dark shade. He might probably, however, at a later period, have adopted a different mode of colouring. In 1790 he opposed Mr. Fox and Lord Hood at the election of representatives in parliament for Westminster; and professing himself unconnected with party, and determined neither to open a house nor to give away a single cockade, he polled near 1700, without solicitation or corruption. On occasion of his defeat, he presented a petition to the house, in support of which he freely indulged himself in very bitter farcical invective. In the year 1794 he was brought to a trial, under the charge of high treason. During the progress of this trial, he maintained the most perfect composure and self-possession; and as he had little to apprehend after the previous acquittal of Hardy, the jury brought in their verdict of "not guilty," after being only eight minutes out of court. In consequence, however, of this trial, he became more cautious in his conduct, and declined the visits at Wimbledon, where he resided, of persons known to be violent in their principles and conduct. Upon the death of Mr. Tooke of Purley, he inherited, in consequence of a previous agreement, half of the property left by that gentleman to his nephew. In 1796 he offered himself again as a candidate for Westminster, and suffered a second defeat, after having polled 2819 votes. He was chargeable, however, with some inconstancy in the acceptance of a seat, in 1801, for the noted borough of Old Sarum, on the nomination of lord Camelford. Some attempts were made to exclude him, under the plea of his being a clergyman; but a compromise being proposed by the minister, Mr. Addington, by determining the future ineligibility of persons in holy orders, he retained his seat till the dissolution of parliament. Having published by subscription a second edition in 1804 of his "Diversions of Purley," a second part in 1805, in which he chiefly adverted to etymology, and to adjectives and participles, and their formation, intermixing fictitious Arcturus upon some literary characters of note. From this time his bodily infirmities, occasioned by a disorder to which he had been long subject, increased, though he retained his faculties in full vigour, and continued to enjoy life. His temper was little affected by mental or physical evil, and "no one more strenuously maintained," says one of his biographers, "the balance of good in human existence." - "His latter days, says the fame writer, "were cheered by early circumstances, and the attention of many friends, whom he entertained with great hospitality, and amused by his conversation, which was singularly pleasant and lively. With an unaltered brow, he could be either facetious or farcical, and his features seldom disclosed what was passing within. His manners were polished, and his appearance was that of a gentleman of the old school." His life at length terminated, by tedious and continued decay, in March 1812, in the 77th year of his age. As he was never married, his property was bequeathed to his natural children. Stephens's Memoirs of John Horne Tooke.

TOOKOK, in Geography, a town on the W. coast of Borneo. S. lat. 2° 24'. E. long. 109° 40'.

TOOLAJEE, a town of Hindoostan, in Guzerat; 20 miles S. of Gogo.

TOOLEN, or TULLEN, (i.e. the Isle of Seals,) a small island in the Caspian sea, near the W. coast. N. lat. 44° 14'.

TOOLAPIOUR, a town of Hindoostan, in the country of Dowlatabad; 45 miles E.S.E. of Perinda. N. lat. 18° 20'. E. long. 76° 35'.

TOOLY, a town of Hindoostan, in Gowrdana; 10 miles W. of Coomtah.

TOOLMEDIN, a town of Hindoostan, in the circuit of Bopal; 25 miles S.W. of Bopaltol.

TOOLS, simple and popular instruments, used in more obvious operations, and particularly in the making of other more complex instruments.

The term tool is particularly used by canal-makers, for a kind of strong curved spade or shovel employed in canal-works.

Tools are divided into edge-tools, spring-tools, pointed-tools, &c.

Mr. Parke, in the fourth volume of his "Chemical Essays," has given a history of the origin and progressive improvement of edge-tools, and an account of the materials of which they were constructed. It appears from Goguet's "Origin of Laws," to which he refers, that as many of the ancient nations had no knowledge of iron, they used bones, flints, the horns and bones of various animals, the bones and shells of fish, reeds, and thorns for every purpose in which the moderns now ufe edge-tools of iron and steel. Spears and other instruments for exterminating wild beasts, and even implements of agriculture, were formerly made with gold and silver; and instead of these was afterwards substituted copper, as a metal more easily to be procured than malleable iron. The abundance of celts and other ancient instruments, found in various parts of the globe, shews that copper and bras were formerly in very general ufe. From the prodigious number of copper instruments of different kinds and sizes, which have been found in this country, such as axes, swords, spear-heads, arrow-heads, &c. known among antiquaries by the general name of celts, it is evident that our ancetors were well acquainted with the art of forming metallic copper in any way which they thought proper; whereas the ufe of metallic iron is comparatively of late introduction. At the time of the first Roman invasion, this metal was fo rare, that the Britons fabricated their money with it, and even their ornamental trinkets. But the Romans having made themselves masters of the country, established imperial founderies for making iron, and constructed forges for manufacturing spears, lances, battle-axes, and implements of every kind, in different parts of the kingdom. (See Cesar, de Bell. Gall. lib. v. c. 12. Henry's Hist. of Britain, vol. ii. p. 139, 140.) At the battle of Hamilton, in 1402, the repulse of the Scots appears to have been entirely owing to the excellent temper of the arrows which were employed by the English army. Swords also were then in ufe, and Sheffield was, even then, famous for its cutlery. Table-knives, it is said, were first made in London in 1563, by one Thomas Matthews of Fleet-bridge.

Good edge-tools cannot be made without steel; and of this there are various sorts (see Steel); such as blifered, sheet, spur, flar, and cast steel; besides which there is a kind of German steel, made immediately from the iron ore, by mifple fusions. (See also Wootz.) The cheapest
edge-tools, and other less important articles, are usually made with the first-mentioned kind, united to a large proportion of bar-iron. Clothiers' shears, firmer chisels, plane-irons, cooper's adzes, scythes, reaping-hooks, and large-knives, are commonly made with filet-steel: for the method of manufacturing it, see Steel. The spur and star filet are used only for particular purposes, according to the fancy of the master cutler. Call-filet is used for the best pen-knives, scissors, and razors; and fine faws, surgical instruments, and all edge-tools which require a fine polish, and various other implements employed in cutting iron, are all made with call-filet. The superior beauty of instruments made with call-filet would have occasioned a very great consumption of this article, if it had not been for the difficulty of welding, and uniting it properly with iron, and which occasioned its being used at first only for those smaller instruments, such as lancets and pen-knives, which are generally made entirely of filet. But since the discovery made by Sir Thomas Frankland (for which see Welding), call-filet has been brought into more extensive use, and the instruments that are thus constructed, are much better than those which are made entirely of call-filet. The circumstance of an instrument having its back made of iron, renders it not so apt to fly from the work to which the edge or filet part is applied, and eventually less liable to break.

Many artists, long after the invention of call-filet, used to unite it to the iron by means of rivets. Hoes are still made by riveting or screwing the back, together with the eye, upon a blade made with call-filet. We cannot minutely recite the various manipulations that are practiced in the manufacture of different edge-tools. The reader will find information of a more ample kind in the work of Mr. Parkes, above cited. (See also our article Cutlery.)

We shall, however, select the following particulars: the cooper's adze and the carpenter's axe are first formed by the white-smith, in iron, together with the eye for the handle. The instrument is then heated again, and the edge of the cutting part is slit down with a chisel, and this slit is filled with a thin piece of steel, of a corresponding face and form. The iron, that has been slit upon, is folded down upon the filet, and the whole again heated to a welding heat, when the filet-hammer quickly unites the iron and the steel into one compact mass. Scythes and such other large instruments are forged at the mill, by means of a large hammer, moved by water, and the process is called "fileping." Augers, gouges, large chisels, table-knives, razors, and other instruments of a similar bulk, are forged upon a large anvil by the principal workman, aided by an assistant called the "striker," who strikes occasionally with a filet-hammer. Pen-knives, lancets, gravers, surgical instruments, and other small edge-tools, are generally forged on a small anvil firmly fixed within a large one, in order to give greater steadiness. These are usually fashioned out of filet only, and forged by one workman singly and alone. Scissors are also forged by a single hand; but the anvil on which they are fashioned is of a peculiar construction, having boisse or dies, and beak-irons of various sizes occasionally adapted to it, so as to suit the different shapes and dimensions of the separate parts of these particular instruments.

It should have been noticed, that many other tools besides the axe and the adze are originally forged out of a piece of iron, with a little filet welded to it for the cutting part of the instrument.

The real Damascus sword-blades are said to be composed of slips or thin rods of iron and steel bound together with iron wire, and then firmly cemented together by welding. It is well known that it is the circumstance of drawing down the filet-steel under the tilt-hammer that gives it the superiority over common steel. (See Tilt-Hammer, and Tilling of Steel.) Mr. Bingley therefore suggests in his patent, that, if he could roll out his steel much thinner than it had ever been done before, he should much improve its quality: and accordingly a very thin piece of steel is let into the face of a plane-iron made of cast-iron; and, as the filet for this particular purpose has to go through the rollers several times to make it sufficiently thin, it becomes of a peculiar texture, and the tool made with it is found to suit the joiner much better than the plane-irons heretofore in use.

In the manufacture of edge-tools, the process which immediately succeeds the forging is that of hardening. All these cutting instruments are therefore fashioned when the metal is in its original soft state; and when they have attained the intended forms, they are heated afresh to a particular temperature suitable to the article. When they have acquired that degree of heat, they are instantly plunged into cold water, which gives them great hardness, and renders them capable of cutting soft iron, or even steel. See Tempering.

Tools, Draining, in Agriculture, are various kinds of tools which are employed in performing this sort of work, such as spades, shovels, scoops, draining augers, boring augers, or rods, file-knives, &c. See these heads.

Tools, Lopping or Pruning, in Rural Economy, are the various tools, such as hedge-bills, large knives, axes, faws, chisels, &c. used in taking off the side-shoots and branches of forest-trees. And lately an instrument uniting several of these properties has been invented, which is very convenient, and readily dispatches the business. It is described as below in the first volume of the Memoirs of the Caledonian Horticultural Society, where a representation of it is also given. It is perfectly simple in its form, having merely two edged hooks, projecting from a socket-shank three inches in length, the breadth of which, where the hooks spring off, is two inches and two-tenths of an inch; the hooks themselves project from the shank three inches; between them, and on the top or upper side, is placed a strong chisel, four inches in breadth, and one inch in depth; the whole tool or instrument being about eight inches in width. The length of the wooden handle must, of course, be in proportion to the height and size of the trees to be lopped or pruned, as in different lengths, from six to eighteen feet, which height, it is said, as long as a man can well and properly manage them. Where trees require lopping or pruning to a greater height than the above length of shaft or handle, a ladder is to be made use of for the purpose, and one of the short-handled tools or instruments.

It is noticed, that the hook part is what is principally made use of, which cuts the branch from the upper side; the chisel is only employed when fings are left, and where branches are too strong for the hooks; in which cases, the chisel is first made to strike the branch from below; but a mallet is never used.

It is observed that fir-trees will certainly be greatly improved by lopping and pruning with this tool, both as to growth and quality of timber; but that care should be had not to over-cut or prune them. Larches will, it is said, always live when that is the case with them, by breaking out into numerous unnatural branches; but it may not be so soon noticed in Scotch, fir-prune, and other trees, which, however, have generally a stinted appearance for some years afterwards, and that it sometimes occasions their death. Four or five tiers of branches should always, it is thought, be left, particularly on young trees; and that on larches there should be still more.

Tools, Scraping, in Agriculture and Rural Economy, the several
several sorts of tools and contrivances which are formed and made use of for cleaning and removing the mould, dirt, and other matters, that may adhere to different kinds of implements while they are in work, as those of the drill, roller, plough, and some other kinds; and to the surfaces in some other cafes, as those of wheels, roads, &c.

In the drill and the roller, the scrapers mostly consist of thin bars of iron or wood, fo constructed and fixed behind, as to take off the dirty or mouldy cloggy substances as they collect upon them. In ploughs it is usually done by a small bar of wattle, with a short handle used by the ploughman. The surfaces of wheels, in heavy carriages, are cleaned by tools of the scraping kind, properly contrived for the purpose. For tools of this kind, where the tires of the wheels, in such cafes, are made concave, it has been advised that a small item should be fixed to the body of the carriage, which may present a convex scraper; which, on account of the shifting of the wheel on its axis, sometimes a full inch or more at its perimeter, should be made to slide on the item, having a kind of bracket to embrace the thickness of the wheel; thus the thickens of the wheel having presented to it a convex scraper sliding on a square item; which, allowing one or two inches of play, has at its outer end a bolt-head, the two arms of which forming a bracket, will always keep the scraper opposite to the groove, or hollow in the wheel.

It is suggested that the blade of the scraper should be very shallow, as it would otherwise operate as a lever upon the bar; and either wrench it, or ultimately round off the corners, so as to allow the tool to be turned out of its proper direction, which should be at an angle of five degrees under the horizon. But it is supposed that the tool for scraping the fore-wheel of a waggon will be more difficult to fix, with proper firmness, on account of its traversing. It might, however, be thought, be effectuated by setting it on a leg- ment attached to the body of the carriage; but the necessary length of item would prove a formidable objection in such a cafe. The bolt mode would, it is thought, be to fasten it to the wooden axle, so as to move always with it, and consequently preserving its relative position to the edge of the wheel.

In other cafes, other sorts of light iron plan scrapers may be fixed fo as to allow them to act in removing the dirt from wheels where necessary.

In the scraping and cleaning of roads, tools of the cowrake headed kind are used by the hand, and large machines in other shapes by horses. See Road-Scraping Machine.

Tool, Skinning, in Agriculture, that fort which is employed in taking off the surface of the land in ploughing, in order to its being deposited in the bottom of the preceding furrow, and thus making neat clean tillage-work. Tools of this kind, with sharp paring and cutting edges, are differently formed, according to the purposes to which they are to be applied; but the mode of fixing them to a sort of fore-cutter in ploughs is considered by many as a great improvement, as they are found in that way to do the work much better than if attached to the common coulter, in which manner they sometimes do not work well. See TILLAGE.

TOOLUC, in Geography, a town of Hindooftan, in Mohurung or 36 miles N.W. of Harropriour.
TOOLUMBO, a town of Africa, in Banbarrat. N. lat. 12° 55'. W. long. 5°.
TOOM, a river of Hindooftan, which runs into the Tungbabad, 15 miles S.E. of Sanore.
TOOMANUA. See Orown.

TOOMBEWADY, a town of Hindooftan, in the Car
nen: 5 miles S.W. of Caroor.
TOOMBUCK, a town of some note on the Perfian gulf, between Congou or Kungoon, a large and populous town, and Tashir or Taluir.
TOOMCOUR, a town of Hindooftan, in Myore; 20 miles S.S.E. of Sera.
TOOME-BRIDGE, a port-town of the county of Antrim, Ireland, situated at the northern extremity of Lough Neagh, where there is a bridge over the narrow channel which separates that lake from Lough Beg. It is 27 miles N. by W. from Dublin, and 13 miles W. from Antrim.
TOOMISH, a town of Ireland, in the county of Kerry; 14 miles S. of Tralee.
TOOMRY, a town of Hindooftan, in the cirec of Hind:; 24 miles N. of Hurdah.
TOOMSIR, a town of Hindooftan, in Goondwana; 38 miles N.E. of Nagpore.
TOON, a town of Perff, in the province of Coflefan; 90 miles N. of Tabaskili. N. lat. 34° 32'. E. long. 57° 35'.
TOORDY, a town of Bengal; 38 miles S.S.E. of Curruckdcah. N. lat. 23° 58'. E. long. 86° 34'.
TOONE, a river of Ireland, which runs into the Lee, 15 miles W. of Cork.
TOONG, a town of Hindooftan, in Dowhatabad; 26 miles W. of Poorn.
TOORAMBADDY, a town of Hindooftan, in Myore; 13 miles W.N.W. of Aravacoury.
TOORATTEO, a town of the south coast of Celebes. N. lat. 5° 33'. E. long. 120° 4'.
TOORDA, a town of Africa, in Kaarta; 24 miles N. of Koomo.
TOORGOODY, a town of Hindooftan, in the Car
nen: 10 miles S.E. of Trichinopoli.
TOORSHA, a river of Bengal, which, after its confluence with the Mauna, changes the name of Yescoomar, and shaping its course through Baharbund, falls into the Berhampooter, properly (it is said) Brahmu poota, off- spring of Brahma.
TOOS, a town of Perff, in Khoraffan; 25 miles S. of Mectch.
TOOSANG, a town on the west coast of Celebes. S. lat. 0° 30'. E. long. 119° 38'.
TOOSCHONDOLCH, an Indian village, on the west coast of North America; of importance in the fur trade. N. lat. 53° 2'.
TOOSHOOR, a town of Hindooftan, in Myore; 5 miles E. of Namcu.
TOOSI, a town of Japan, on the south coast of the island of Nipon; 84 miles S.S.E. of Mexico. N. lat. 34° 35'. E. long. 137° 35'.
TOOSIMA, one of the small Japanese islands, near the N.W. coast of Nipon. N. lat. 46° 40'. E. long. 142° 48'.

TOOTH, Dens, in Anatomy. See Teeth.
Tooth-Ache. See Teeth, Disease of.
Tooth-Drawing. See Teeth.
Tooth, Wolf's. See Wolves-Teeth.
Tooth, in the Manage. It is by a horn's teeth, chiefly, that his age is known. See Teeth, in Rural Economy.
Tooth-Ache Tree, in Botany. See Zanthoxylum.
Tooth-Pick. See Daucus.
Tooth-Wort, a name applied to several plants, on account of a resemblance in their roots to the human teeth.
This is very striking in *Lathyrus Spumarius*, whose roots are furnished with smooth white scales, very accurately imitating, except in hardness, the *dentes incisores* or fore-teeth. This resemblance is perceptible also, though less exact, in the roots of the various species of *Dentaria*; see that article. *Ophiurus Cereiformis* of Lianzeus has, for a similar reason, been sometimes called *Dentaria*; which name, or *Dentella*, has also been given by Rondelius to the *Plumbago*, because of the teeth of its corolla; a character found in many other genera. *Dentella*, see that article, owes its name to the last-mentioned circumstance. It is hardly necessary to advert to the reputed qualities of the above tooth-rooted plants, which were founded on the resemblance in question. On this subject more may be said when we come to speak of the *Virtues of Plants*.

**TOOTHED**, in *Botany* and *Vegetable Physiology*, *den- tatus*, is properly applied to the margin of any leaf, petal, &c. when furnished with directly prominent teeth, which in a great part either towards the base or the point of such leaf or petal, or of their segments. Yet this term is not always so strictly limited as it ought, being sometimes negligently used, when *ferrata* would be more proper. *Stamen* however are said to be toothed, when they have any lateral prominence, or notch whatever, as in *Acanthus*.

**TOOTOOCH.** See *Erronan*.  
**TOP.** or **Toppe**, in *Commerle*, a wine-measure at Breslaw, and in other places of Germany. At Breslaw, an eimer of wine contains 20 tops, 80 quarts, or 320 quarters, and is equal to 14¼ English gallons.

**Top**, in *Geography*, a lake of Russia, in the government of Oloinet, about 44 miles in length, and 8 in breadth; 256 miles N.N.W. of Petrovofit. N. lat. 61°, E. long. 30°14'.

**Top of a Ship**, a sort of platform, surrounding the lower mast-head, from which it projects on all sides like a scaffold. Its principal intention is to extend the top-mast-sparrows, so as to form a greater angle with the mast, and thereby give additional support to the latter. It is surmounted by the trellis-trees and crosstrees. The top is also convenient for containing the materials necessary for extending the small sails, and for fixing or repairing the rigging machinery. In ships of war it serves as a kind of redoubt, and is accordingly fortified for attack and defence, being furnished with fowels, musquetry, and other fire-arms, and guarded by a thick fence of corded hammers. It is also used as a place for looking out, either in the day or night. The frame of the top is either cloze-planked like a platform, or open like a grating. In all ships of war, and in the largest merchantmen, the top is fenced on the aft-side by a rail about three feet high, stretching across and supported by flanchions, between which a netting is usually constructed.

The outside of this netting is generally covered with red bays, or red painted canvas, extended from the rail down to the edge of the top, and called the *top-armour*. By this name it seems to have been considered as a sort of blind, behind which the men may conceal themselves from the aims of the enemy's fire-arms in time of action, whilst they are charging their own muskets, carbines, or fowels. The dimensions of tops in the royal navy are as follow: the breadth of the top athwart-ships is one-third of the length of its corresponding top-mast; the length of all tops, from the foremost to the after-edge, is equal to three-fourths of their breadth athwart; and the square hole in the middle is five inches to a foot of those dimensions. The trellis-trees and crosstrees extend nearly to the edge of the tops.

The aft-side of the top is straight, and the fore and aft sides square from thence to the aft-side of the foremost crosstree; from thence the fore-part breaks in with an elliptical curve. Tops in the navy are separated in the middle by a fore and aft line, which makes them much more convenient to be gotten over head.

By a late order in the navy, the under sides of tops are to be planed, and the after-part of the fore and main tops is to be eighteen inches wider, and the after-part of the mizen top, one foot wider than at the chain-plate for the foremost-shroud; the inside of the tops on each side by the part called *rubber's* hole, is to have a flap and hinges, so that a top-sail yard, mast, or a top-sail, may pass inside of it.

**Tops, to lay ropes from a fix-thread rail to the largest cables, are conical pieces of wood, with three or four grooves, or scores, from the butt to the end, for the strands to lie in, and form a triangle. If too broad at the butt, the rope will not close well, nor the strands work to close as they should. A hole is made through the centre of the top, one-third the length from the butt-end, for the staff or bolt to go through, round which are put pieces of old rope, called tails, for the layers to clothe the rope with, and lay it hard or slack, according to the use it is for. A hole is likewise made through the middle of the top lengthways, for laying ropes with a heart. A collar is put on to stiffen the layer when the work is too heavy, and to enable him to hold the tails, and clothe the rope well.

**Tops, to lay ropes of three inches and upwards, have a staff under them, with a truck-wheel at the lower end. An iron bolt goes through the centre of the top, and is fastened down to the staff, on which the tails are put and rounded over the rope, being too heavy to be laid with the collar. A strap is put round the tails, with a wodder for the layer to clothe the rope with.**

**Tops, to lay cables, have a leg to support them, with a truck-wheel at the end to run on, besides the staff which the tails go on.**

**Tops, for laying lines of all sizes, are of box or hard wood, tapered at the after-part, that the line may close sharp. Those for fisht-lines have four grooves, and for runnines eight grooves.**

**Top and Butts, in Ship-Building**, a method of working English plank, so as to make good conversion. As the plank runs very narrow at the top, clear of fap, this is done by dipping the top-end of every plank within six feet of the butt-end of the plank above or below it, letting every plank work as broad as it will hold clear of fap, by which method only can every other beam produce a fair edge.

**Top-Armour, in a Ship of War.** See Top, *jupra*.

**Top-Black.** See *Black*.

**Top-Brim,** a space in the middle of the foot of a top-sail, containing one-fifth of the number of its cloth. It is so called from its situation, being near the fore-part of the top when the sail is extended.

**Top-Chain,** a chain to fling the fail-yards in the time of battle, in order to prevent them from falling down, when the ropes by which they are hung happen to be shot away, or rendered incapable of service. *Falconer*.

**Top-Hamper,** any unnecessary weight aloft, either on the top-side of a ship, or about its tops and rigging.

**Top-Lantern,** a receptacle to hold three or more lights, made of tin and glass, placed in the aft-part of the top, in any ship where an admiral or commodore leads the van of a fleet.
TOP

Top-Lining, the lining sewed on the aft-side of top-falls, to preserve the fail from the chafing of the top.

Top-Maft, the second division of a masts, or that part which stands between the lower mast and the top-gallant mast. See Mast-Making.

By a late order in the navy, the blocks at the heels of top-masts (particularly in line-of-battle ships) are to be discontinued, and the top-masts made from as small blocks as possible; the sheave-hole is to be placed nearer the heel, by which means the several quarters will be brought nearer the butt, and the sizes of the decks for making of top-masts diminished; and as some of the rough blocks will work one way larger than the other in the upper quarters, and thereby increase the circumference of the wood, where strength is so requisite, leave this additional wood, and make the masts oval: a hoop is to be placed below the sheave-hole, and above the fid-plate.

The caps of top-masts, also, are to have a semi-circle cut at the after-part, with an iron clamp to fit, so as to admit of getting a top-gallant-mast up shaft the top-mast, if necessary in chase.

The heels of jib-booms are also to be left square, to serve as substitutes for mizen-top-masts occasionally: and let the hearts be prepared conformable thereto.

Top-Gallant-Masts, are two, viz., main-top-gallant-mast, and fore-top-gallant-mast, which are small round pieces of timber, set on their respective top-masts; on the top of which masts are the top-sheets, on which the colours, as flags, pendant, &c. hang.

Top-Masting is fastened to the rail, shrouds, and top, to preserve the men from falling, &c.

Top-Rope, a rope employed to sway up a top-mast, or top-gallant-mast, in order to fix it in its place, or to lower it in tempestuous weather, or when it is no longer necessary. The rope used on this occasion for the top-masts is furnished with an assemblage of pulleys at its lower end, called the top-tackle; the effort of which in crefting the top-mast is communicated from the head of the lower-mast to the top of the top-mast; and the upper end of the latter is accordingly guided into, and conveyed up through the holes between the treffel-trees and the cap. For this purpose, the top-rope, passing through a block which is hoisted on one side of the cap, and afterwards through the holes, furnished with a shave or pulley, in the lower end of the top-mast, is again brought upwards on the other side of the cap, where it is at length fastened to an eye-bolt in the cap, which is always on the side opposite to the top-block. To the lower end of the top-rope is fixed the top-tackle, the effort of which being transmitted to the top-rope, and thence to the heel of the top-mast, necessarily lifts the latter upward, parallel to the lower-mast. When the top-mast is raised to its proper height, the lower end of it becomes firmly wedged in the square hole, between the treffel-trees. A bar of wood or iron, called the fid, is then thrust through a hole in the heel of it, across the treffel-trees, by which the whole weight of the top-mast is supported. In the same manner the top-gallant-mast is crefted, and fixed at the head of the top-mast.

Falconer.

Top-Sail-Lifts. See LIFTS.

Top-Sails, and Top-gallant-sails, in a Ship, are those belonging to the top-masts, and top-gallant-masts. The former are extended across the top-mast by the top-fall-yard above, and by the yard attached to the lower-mast beneath; being fastened to the former by rebands, and to the latter by means of two blocks fixed on its extremities, through which the top-fall sheets are inferted, passing from thence to two other blocks fixed on the inner part of the yard, close by

the mast; and from these latter the sheets lead downwards to the deck, where they may be fackened or extended at pleasure. The top-gallant-sails are expanded above the top-fall-yard in the same manner. Falconer. See SAILS.

Since the article Sails-making was printed, the following alterations concerning sails have been adopted in the navy; viz. top-sails are to be reduced by deducting four inches for every three feet in length of the top-mast, instead of three inches and an eighth, as at present.

Mizen-top-sails are to be hollowed in the foot a yard and a half, instead of twenty-seven inches, to prevent rubbing over the stay; and top-gallant-sails are to be hollowed two feet in the foot of the sail, for the above-mentioned purpose.

The main-top-mast-day-sail is to have five inches gore in every cloth at the foot of the sail, and long gare at the clue.

Mizen-courtes are not to be supplied to any ships under fifty guns, but two drivers in lieu.

Driver-booms, as used in 1806, are to be reduced two inches in every yard. The length of the gaff to be in proportion to the sail, and then three feet added thereto, to throw signals.

Drivers are to be cut with a deduction in length, to answer the reduction in length of the boom and gaff, as above. Drivers for line-of-battle ships, the leech is to be twice the length of the leaf. For frigates, the length of the leech is to be once and two-thirds the depth of the leaf.

Jib.—The after-leech rope is to be two inches and a half in ships of the line, and in forty-gun frigates two inches and a quarter; other ships above twenty guns two inches, and one inch and three-quarters all under.

White bolt-rope is to be used in making of falls, instead of the tarred rope at present in use.

Single clump-blocks of eight inches in size are to be strap-bound, clue-garnet fashion for reef-tackles in the leech of falls.

Top-Side, a name given to all that part of a ship's side above the main-wales.

Top-Timbers, the timbers which form the top-side of a ship. The first general tier which reach the top of the side are called the long top-timbers, and those the lift above are called the short top-timbers.

Top-Timber Half-breadth, a section containing one-half of the ship, at the height of the top-timber line, perpendicular to the plane of elevation.

Top-Timber Line, is the curve limiting the height of the sheer at the given breadth of the top-timbers.

Top-Timber Sweep, is that which forms the hollow of the top-timber. This hollow is, however, very often formed by a mould, so placed as to touch the upper-breadth sweep, and pass through the point limiting the half-breadth of the top-timber.

Top-a-Starboard, and Top the Yard-arms. See TOPOGRAPHY.

Top-Bank, signifies the level of the top of a canal's bank; as B C K, Plate 1. Canals, fig. 1. &c. This is generally about one foot higher than the surface of the water D K.

Top-Sailing, the art of taking off the vegetable mould or top-soil before a canal is begun, to be returned again upon the bank and new-made ground by the side of it.

Top-Water is the level line of the water's surface, as D H (Plate 1. Canals figs. 14 and 15.) in a canal C F G L.

Top-Draining, in Agriculture, a term sometimes applied to the practice of removing surface-wetnesses from land, either before it is to be prepared for the seed, or after that
Top

has been put into the soil. In the latter of which case, the
wattle, for the water are to be finished with the plough,
so as to terminate in the drains which have been formed, and
take it away. This should be done daily, as the field is
grown over by the harrow. See Superficial Dressing.

"This is an "official" sort of dressing for ploughed lands that
are intended to be sown.

Top-dressing, a term applied to such sorts of reduced
and other manures as is laid upon the surface of land with
out being turned into it; and also to the practice of dress-
ing the surface of great-land, or that of other kinds of land
in crops, with some sorts of highly reduced or powdery
manure, that can be evenly spread out or sown equally over
by the hand.

In the cultivation and management of lands of this
type, a great variety of substances is used for this pur-
puse, such as foot, alfalfa, the dung of rabbits, pigeons, and
other birds, rape-juice, rapeseed, malt-juice, and several
others; the manure, use, and benefits of which are more
particularly noticed under their respective heads, which
follow.

The advantages which the Hertfordshire farmer derive
from the practice of spring or top-dressing their lands and
crops, are fully shown in the statements that have been given
in the original report of the agriculture of that district:
in which it is said, the spring or top-dressings of their
lands are the leading feature of the farming in that county,
and consist of foot, which malt-juice and oil-cake dust, or
possibly powdered oil-cake. The foot is generally sown on
the wheat-crops which have had no previous manure. It is laid
in humps on the crop in winter, and sown over them in the
spring. But the other top dressings are hoed, and kept
dry all used in this way for the period of time. See Super-

It has been observed in some of the early Essex, agricul-
tural reports, that the application of manures upon the sur-
face, or what is generally called top-dressing, ought chiefly
to be regulated by the following considerations, as, first,
whether the soil is of such a nature as to require such an
amendment; secondly, whether it is proper to apply it,
and, thirdly, whether the same is capable of affording nour-
ishment to vegetables, which is brought into the close and
immediate contact with the bottom of the plant or grain,
containing vegetable food in the soil; and, fourthly, whether the plant
supposed to be fed by this manure, draws its nourishment
principally from the ground, or in other ways.

It is said that in the Essex district all these crops it
is plain the manure should only be slightly covered or lightly
ploughed under. But that when the manure is of such a
nature as to apply but highbly to such considerations, when
it is capable of being diffused on the surface, and conveyed
by water downwards to the root of the plant, or by evaporation
into vapour, to be absorbed by their tissues or leaves,
and that the plant is equally prone to receive its nourishment
in both ways, the economy and effective operation of top-
dressing are unprofitably the most highly beneficial and
greatly to be preferred.

These top or spring-dressings are peculiarly applicable to
poor light lands and gravelly lands, and of course to the
production of the specifically heaviest corn; and they put
such lands more on an equality, in point of annual value,
with stronger and richer soils.

And in the Corrected Agricultural Report of the same
district, it is stated that when top-dressing, though they open
and loosen the soil, do not feed a crop. They are sup-
pended to last two crops, and to be of such benefit to wheat,
croppers that when tenants quit farms, they are allowed half
the expense of sowing or top-dressing the clover, which
has been laid out, that the incoming tenants are to sow with
wheat; some few instances too are met with of sowing them
over or on wheats. The usual time is the middle of winter,
if the frost be mild or moist. Moss is destroyed by some
with this sort of top-dressing on park grass-land, who think
they do little good to the wheat that follows the clover
on which they are spread, otherwise than by improving the
clover. They are decidedly of opinion that it is better
undercover to use foot on barley than this kind of top-
dressing; as the farmer will do much good to the following
wheat, whereas the latter are of no more utility to the wheat
than by increasing the quantity of the clover crop. The
farmers in these cases grow from two to sixteen acres on
clovers.

In other parts of the same district, these sorts of top-
dressings are laid to be very beneficial; and that on
being spread out on clover, they do as much good to the
following wheat, as that of a top-dressing of the foot kind
or footing would do. On a comparison of them, as sown
in November and February on clover, over exactly the same
places of land, in the same quantities; there used at the
former period produced the best crop by about a fourth
part of a load of this sort of hay on the acre. Some, how-
ever, in other places, do not much approve of such top-
dressings, except on clay, to harden the soil, as they term
it; they are supposed to do little good on arable chalk
lands.

Top-dressings composed of the dusts of different cakes
are found very useful, but often too expensive for the pur-
pose. Some think those of the hopped cake kind the best
dressing, and have them for wheat in top-folding, even to late
at the month of May, with sheep fed on such cakes as
troughs. The dust of cakes of the rape kind has likewise
been much employed in some places as top-dressings, even
when the expense has been so high as twenty shillings the
quarter. Mills are constructed for grinding it in the above
district, and large quantities are imported from Ireland, and
perhaps other places. Some have houses attached to these
mills for reducing it to dust in a measure, the use of
which is greatly approved of in some cases. By some it has
been found that it answers the best when spread on wheat.
The quantity of this manure as a top-dressing is of from
twelve to sixteen bushels on the acre, as much as to the
richness of the land or soil, already in a tolerable state
of condition. It cannot be made use of for any crop
better than for that of wheat. By having machinery for
breaking and reducing it into a dusty state, the farmer is
said to have the advantage not only of buying it in at
any time of the year when it is the most reasonable, (for as
the two seasons of using it come on, it often increases in price,
and is again cheaper when they are past,) but of readily pre-
paring it and keeping it free from any admixture of other
matters. It is said that this substance is not new to good
farmers, as the manufacturers of oil from the seed of rape
continue to press it twice a year, whereas they for
many years never pressed it more than once; and that, besides,
the only used horses, where they now use life water, wind,
and fires.

The two principal reasons for making use of these sorts
of dressings are, in the very early spring, and in the early
part of the autumn, when the weather is rather
moist.

Top-dressings of the malt-juice kind, which chiefly con-
stitute of the infant sprouts of the grass, and probably contain
facultative matter, from the powerful nature of their effect
in some cafes, should, as in the other dust-top-dressings, be
made ufe of in as dry a condition as poifible, and without
undergoing any degree of fermentation. It is ufed in the
first of the above counties for wheat, in nearly the fame
quantities as other fuch matters, in fome places, at the rate
of twelve fhillings the quarter; and it works much the beft,
it is faid, on lands that are inclined to be rather wet. See
Grass-Land, Gypsum, Salt, &c.

Top-dressings of thefe kinds are often well suited to and
admirably beneficial for recovering and reftoring backward
and funned crops of different sorts, but particularly those
of the grain and grafs kinds.

Top-Folding, a term applied to the practice of feeding
down fome forts of fpring corn-crops with thep, as thofe
of the wheat, and occafionally the barley kinds, when too
rank or luxuriant. It is a method of practice which is
much in ufe in fome parts of Hertfordshire, and which is
faid there to be very beneficial in its effects; it fhould, how-
ever, be employed with caution in moft cafes, and conftantly
in the early stages of growth of the grain, as in the more
advanced ones it muft always be hazardous, and often hurt-
ful and destructive of fuch crops. The feeding down in
the cafes muft, of course, be nicely regulated, fo as never
to fuffer the crops to be too much or too little eaten by the
theep, as in either extreme the confequences will be injurious
to them.

Top-Up, a term ufed to signify the making up or topping
the roofs of hay or corn-flacks or ricks. It is likewife
fometimes made ufe of, in feeding and fattening buillocks,
to imply full feeding, or to finish highly, as with cake,
 oats, &c.

Top-Wood, in Rural Economy, the boughs or branches
which form the tops of timber, or other trees, or the wood
which they contain. See Timber and Trees.

Topan, in Ornithology, a name by which fome have
called the horned-beaked Indian raven, more ufonally known
by the name of the rhinoceros-avis.

Toparchy, formed from topan, place, and qyyn, go-
wermet, a little flate, or signory; confifting only of a few
cities, or towns; or a petty country, governed and poffefed
by a toparch, or lord.

Judza was ancienfly divided into ten toparchies. See
Pliny, lib. v. cap. 14. and Joseph. lib. iii. cap. 2. de Bel.
Jud. & lib. v. &c.

Procopius only gives the quality of toparchy to the king-
dom of Edessa; to Abgarus, the toparch or lord of which,
there is a tradition, that Jesus Chrift fent his picture, with
a letter.

Topayos, in Geography, a river of Brazil, which runs
into the river Amazon, with a fort at its mouth of the fame
name. S. lat. 2° 30' W. Long. 57° 6'.

Topavos, a favage tribe in Brazil, the chief and moft
numerous of the kind. They are anthropophagi; and if
a woman miscarry, will greedily devour the fatus. Strangers
to cultivation, they live upon fruits, and the animals they
kill. The Topayan language is very widely diftributed, and is
divided into feveral dialects. Their nakednefs, ferocity,
vinidive spirit, warfare, and whole mode of exiftence,
have been particularly defcribed by Lessing.

Topaz, in Mineralogy, a gem, called from Topazes,
la small illad in the Red Sea, where the Romans formerly
obtained a stone called by them the topaz, but which is the
cryftolite of the moderons. The topaz is faid to have been
ffirt found by Juba, king of Mauritania; but it was known
to the Hebrews before, as appears from the 118th Pfalm.
The most valued topazes are thofe of Saxon, Siberia, and
Brazil.

Vol. XXXVI.

The principal colour of the topaz inclines to yellow,
called by professor Jameson wine-yellow. The pale wine-
yellow pafles from various shades of yellow and greenish-
white to green. The dark wine-yellow pafles from orange
to cherry-red and even to blue, but the latter colour is very
rare. The topaz fometimes occurs maffe and in rolled
pieces, but more frequently cryftallized. The cryftals are
feldom very large. The primitive form of the cryftal, ac-
cording to Haüys, is a rectangular octahedron. The com-
mon forms of the secondary cryftals are varieties of the
oblique fide-vided prifm, terminated by four planes. The
fides of the prifm are longitudinally freaked, but the termi-
nating planes are smooth. When the edges of the cryftals
are truncated, the truncated planes are also smooth. The
Brazilian and Siberian topazes are more deeply freaked than
the Saxon. The external lufure of the topaz is fplendid,
the internal vitreous. The longitudinal fracture is small,
and imperfectly conchoidal; the cross fracture is ftraight,
and exhibits a lamellar ftructure. The topaz is tranfaent
or transparent, and refracts double: it scratches glafs, but is
refracted by fpinel; it is easily fragile. The specific
gavity varies from 3.434 to 3.641.

The Saxon topaz becomes colourles by a gentle heat,
and in this fate is fometimes fold for the diamond. A
strong heat deprives it of its lufter and transparency. The
Brazilian topaz, by exposure to a strong heat, becomes red;
and in a ftil higher temperature, violet-blue; it is then
fometimes fold for the ruby, or for pale fpinel. The topaz
is infufible by the blowpipe, but melts with the addition of
borax. The topazes of Brazil, Siberia, and Afa Minor,
become electrical by heating. The confluent parts of this
gem appear to vary considerably in different fpecimens.

The topaz is found in various parts of Europe and Afa,
and in South America. It occurs in large quantities in a
rock denominated by Werner the topaz rock, which is an
aggregate of maffe topaz, quartz, and fchoor, in which there
are frequently fmall cavities lined with cryftals of
these three fubfiances, and portions of lithomarge. This
rock is ftuated at Schneckenleit, in Saxony.

It occurs alfo in veins of quartz at St. Michael's mount,
in Cornwall, and with tin-flone at St. Anne's, in the fame
county. The topaz has recently been found, in large crys-
tals and roiled pieces, in alluvial foil in the primitive coun-
y of the upper part of Aberdeenfide; indeed it is ftated,
in the firft volume of the Wernerian Memoirs, that a fpec-
imen of topaz, weighing one pound three ounces eight dracuns
troi weight, has been obtained from that part of Scotland.
The largest fpecimen of Brazilian topaz in the museum of
natural history at Paris, weighs four ounces two gros. In
this museum there is alfo a superb Indian Dacchus engraved
on topaz. Tavernier mentions a topaz, in the poftelion
of the great Mogul, weighing one hundred and fifty-feven
caras, which coft 20,300. Reling; and Boetius de Boot,
in his trelife of precious flones, affirms to have been in
the cabinet of the emperor Rudolphus, whose phyfician he
was, a topaz above three feet long, and six inches broad.
Probable, it might be fome other flone a little tranfparent,
of a topaz colour. This gem was much prized by the
anceint. Yellow-coloured rock-cryftal has not been unfre-
quently impofed on the ignorant for topaz.

The oriental topazes, which have a deep rich orange-
colour, are highly valued at preftent. The Brazilian topaz
has
has not so rich and fine a colour as the former. The Saxon topaz is distinguished by its wine-yellow colour, and when cut, often exhibits a lustrous equal to that of the finest oriental varieties. The mountain-green varieties of topaz, which are found in Siberia, are included under the name of aqua marina. The Brazilian ruby and sapphire include the red and blue Brazilian topaz.

The topaz may generally be distinguished from all other minerals by the rhomboidal base of its crystals, the fracture, and the lamellar structure, and by the longitudinal streaks on its fide planes. It is less hard and heavy than yellow sapphire, and the latter does not become electric by heating. The same characters distinguish it from spinel; it is further distinguished from spinel by its double refraction. Green-coloured topaz is distinguished from beryl by its greater specific gravity, that of topaz being 3.5, and of beryl only 2.7. The latter cleaves in the direction of its lateral planes, which the topaz does not.

The following minerals have been denominated topazes, when colour was considered as affording the most certain character of precious stones.

1. Yellowish-white fapphire
2. Zircon
3. Chrysolite
4. Yellow beryl
5. Yellow rock-cryotal
6. Clove-brown and brown rock-cryotal

Names given to varieties of the topaz.

1. Mountain green topaz
2. Blue topaz
3. Yellow topaz
4. Wine-yellow inclining to red topaz
5. Red topaz
6. Yellowish-green topaz

See SAPPHIRE, RUBY, and GEMS.

A peculiar property of the topaz was discovered by Vauquelin, that the powder of this gem changes the syrup of violets to green if it remain in the liquor two or three hours, and this property is common to all the varieties of the topaz.

Mr. Canton, in 1760, found that the Brazil topaz has the electrical properties of the tourmaline.

Mr. Scott has attempted to counterfeit the topaz in glass, see GLASS resembling Topaz.

Mr. Scott has attempted to counterfeit the topaz in paste: Take crytal prepared, two ounces; ordinary minium, or red lead, seven ounces; put these into a crucible luted, and bake them twenty-four hours in a potter's kiln. If the mass is not sufficiently clear and fine, cover it up again, and give a second baking, and it will come out of a fine topaz colour. See Paste.

If we might believe the ancients, the topaz has very notable virtues; but those are now in discredit. See Gem.

TOPAZOS, or TOPAZUS, in Ancient Geography, an island placed by Pliny in the Red sea, 300 stadia from the continent.

TOPALS, in Geography, a town of Norway, in the province of Christianand; 32 miles N. of Christianand.

TOPE, in Ichthyology, an English name for a species of the fqualus, according to the Artedian system, the fqualus galeus of Linnaeus, distinguished from the other fquali by the nofrils being placed extremely near the mouth, and by certain foramina, or apertures, near the eyes. It is the fish called by the ancients ψαλος κυνος, galeus canis and caniculata. See SQUALUS.

TOPEL, or TAPL, in Geography, a town of Bohemia, in the circle of Pilfen; 56 miles W. of Prague. N. lat. 40° 58'. E. long. 12° 57'.—Alto, a river of Bohemia, which runs into the Egra, near Carlbad.

TOPERS HAT, a small island in a bay on the N. coast of New Guinea. S. lat. 3° 5'. E. long. 135° 33'.

TOPETINA, a town of Mexico, in the province of Mexico, at the mouth of a river near the Pacific ocean; 50 miles N.W. of Zacatula. N. lat. 18° 56'. W. long. 103° 44'.

TOPETRY, a town of Hindoostan, in the Carnatic; 50 miles S.E. of Tanjore.

Tophath, in Ancient Geography, a place in the land of Paradise, near the Dead sea. Josiah destroyed this place on the abolition of idolatry. Also, the fort of concretion found in the joints of gouty persons.

Tophus, in Natural History, is a species of sandstone, called also porus, mostly of a grey colour; but it is also found of other colours, as whitish, brownish, &c. according to the foil in which it is imbedded. It much resembles the pumice in texture, being rough and brittle, and composed of a large angular grit, cemented by a very coarse terreine crystalline substance. It is too soft to strike fire with steel. It is common in Italy and in Germany, where it is used for building, chiefly for cellars and turning arches. Da Costa's Hist. Fossils, p. 136.

TOPI, in Geography, a small island in the Mediterranean, near the N. coast of the island of Elba. N. lat. 42° 51'. E. long. 11° 30'.

TOPIA, a town of Mexico, in the province of Culiacan; 80 miles N. of Culiacan. N. lat. 25° 34'. W. long. 108°.

TOPIA, the chief chain of mountains in Spanish North America, commencing in the neighbourhood of Guadalaxara, and extending north to New Mexico, a distance of 150 leagues, or, according to our maps, more than 700 British miles; while the breadth of all the ridges is, according to Alcedo, sometimes 40 leagues, or 60 miles. This chain is of such a height as to be comparable with the Andes of Peru, and absorbs with precipices of the most profound and terrible aspect. It is almost universally denfely clothed with large and lofty pines, and other trees which afford fufficient to birds of very variegated and beautiful appearance. On the summit the cold is intense, but the temperature on the sides varies according to climate and exposure. It is the source of many rivers flowing into the Atlantic and Pacific, and subject, on the melting of the snow, to very considerable inundations. During the rains, which last from June to September, the rivers become terrible in their devastations to the distance of two or three leagues, and the mo的方向 become intolerable. Among the animals in these regions, are bears, lions, and tigers, as well as squirrels of various kinds. This chain is prolific in silver, yielding about a mark for each quintal of earth. It received its name from a savage tribe, which was converted by the Jesuits in 1550; but the mines, on account of their distance from the capital, have been mostly abandoned. The ridge of Topia is also called the "Sierra Madre," or mother-chain, and embraces the singular province of Nayarit, which remained
remained Pagan till the year 1718. Towards the N. the extent of this chain has not been precisely ascertained; but the Moquis, on the W. of Santa Fe, and under the same parallel, are positively claded among its inhabitants; and it probably forms one chain with that of Nabaja, and the Sierra Azul, or Blue Ridge, of Azlete, and the Rocky mountains of North-west America, sending off a branch called Genes on the W. of New Mexico, while on the E. of that province is the inferior ridge of Nambe. In the vice-
royalty, the general distance of the Topian chain from the western shore is about 140 British miles, but in some parts not above half that space.

Pinkerton.

TOPARI, in Botany, a name by which some authors have called the acanthus, or bear's-breech, a plant common in the gardens of the curious.

TOPIC, in Rhetoric, a probable argument, drawn from the several circumstances and places of a fact, &c. See ARGUMENT and LOCUS.

TOPICE, τόπικα, Topica, expresses the art or manner of inventing and managing all kinds of probable arguments.

The word is formed from the Greek, τόπος, of τόπος, place, its subject being the places, which Aristotle calls the fea of arguments.

Aristotle has written "Topics," and Cicero a kind of comment on them, to his friend Trebatius, who, it seems, did not understand them. But the critics observe, that the "Topica" of Cicero agree to little with those eight books of Topes which pass under the name of Aristotle, that it follows necessarily, either that Cicero was much mistaken, which is not very probable; or that the books of Topes, now attributed to Aristotle, are not wholly his.

Cicero defines topic, or topica, to be the art of finding arguments, "disciplina inveniendorum argumentorum." Rhor is sometimes divided into two parts; judgment, called also dialecitia; and invention, called topica.

TOPICS, formed from τόπος, place, or topical remedies, in Medicine, are commonly used for what we otherwise call external remedies, i.e., such as are applied outwardly to some particular diseased and painful part.

Such are plasters, cataplasms, blisters, unguents, flies, collyriums, &c.

Topes are such medicines, as by the smallness and mobility of their particles, attended for the most part with gentle action, are able to make their way into the surface of the parts to which they are applied, without eroding or wounding any of the foids; and those are justly called penetratin topics.

It may be a question how topics in medicine act. It is commonly said, that this or that medicine penetrates the pores; but the term is annexed to such expressions do not seem very distinct. Writers on the subject have seldom been at the pains to tell us why pores they mean. We have an essay on this subject in the Med. Eff. Edinb. vol. ii. art. 4, by Dr. Armstrong, who thinks that the effects of such medicines are not owing to the particles entering the orifices of the aborbed veins, nor to the opening of the exhalent vessels on the surface of the body by these medicines; nor will he allow the particles of penetrating topics to force their way through the coats of the vessels; but he supposes that subtle medicines are conveyed, by the exhalent vessels of the skin, to the parts of the smaller arteries, where the circulation is checked by obstruction.

The got is never cured by topics; they may afflige the pain for a time; but for a cure, the source of the evil must be attacked with internals.

TOPINAM BANANAS, in Geography, a town of Brazil, in the government of Para, on the river of the Amazons; 80 miles S.W. of Pausis. S. lat. 2° 42'.

TOPINAMBOSS, a considerable tribe of anthropophagi in Brazil.

TOPINO, a river of Italy, which runs into the Tiber, 5 miles S. of Perugia.

TOPIRA, in Ancient Geography, a town situated in the interior of Thrace. Pliny and Ptolemy.

TOPLITZ, in Geography, a town of Bohemia, in the circle of Leitmeritz, near which the Austrians defeated the Prussians in the year 1762; 14 miles W.N.W. of Leit-

meritz. N. lat. 50° 37'. E. long. 13° 51'.

TOPLIWOUDA, a town of Silisia, in the principality of Munsterberg; 7 miles N.W. of Munsterberg.

TOPOCZA, a town of Hungary; 14 miles S.E. of St. Cot.

TOPLUC, a town of Hungary; 20 miles S.S.W. of Podoliz.

TOPOBEA, in Botany, Aubl. Guian. 476. t. 189. N. lat. 32° 9'. Juif. 32° 9', is probably not generically distinct from Melas-
toma; see that article, and the natural order of Melas-
toma.

TOPODURITY, in Geography, a town of Hindoostan, in Myore; 24 miles W. of Tadmorer.

TOPOGRAPHY, formed from τόπος, place, and γράφειν, to write, a description or draught of some particular place, or small tract of land; as that of a city or town, manor or nentment, field, garden, house, cattle, or the like; such as surveyors let out in their plots, or make draughts of, for the information and satisfaction of the proprietors.

Topography differs from ephorography, as a particular from a more general.

TOPOLEVA, in Geography, a fortress of Russia, in the government of Caucasus, on the Urals; 40 miles N. of Grozny.

TOPOLITZA, a town of European Turkey, in Molda-
vania; 12 miles S.W. of Nittoci.

TOPOLITZAN, a town of Hungary; 52 miles N.E.
of Preßburg. N. lat. 48° 34'. E. long. 18° 25'.

TOPOLITZAN, (Kiz), a town and castle of Hungary; 12 miles N.W. of Baranow.

TOPOROW, a town of Austrian Poland, in Galicia; 35 miles N.E. of Lemberg.

TOPPARPOUR, a town of Hindoostan, in Odor; 25 miles E. of Baharatch.

Topping of Trees, in Rural Economy, the practice of cutting or lopping off the heads of them, especially of the different sorts of hedge-row trees, which, in this last cafe, is a disfiguring and disgraceful custom, now on the decline. See POLLARD TREES.

Where, however, this sort of work is to be performed, it should, in all cafes, be executed in the autumn, or very early in the spring months.

In topping fallen trees, the different parts should be cut out and put together into separate lots, as the large arms into one, the smaller branches into another, and the small brush, or faggot-wood, into a third. Thus the whole may be readily disposed of, or converted to its proper use.

Topping the Lifts, aboard a Ship, the same as halting the top-fall-lifts, by slackening one of them, and pulling upon the opposite one, so as to place the yard at a greater or less obliquity with the masts. See Lifts.

Topping-Lifts, a large and strong tackle, employed to suspend or top the outer end of a gaff, or of the boom of a main-fall and fore-fall; such as are used in briggs, schooners, &c.

Falconer.
TOPRACK-KALA, in Geography, a town of Turkish Armenia; 6 miles S. of Kars.

TOPRACK-KALAHII, a town of Asiatic Turkey, in the province of Diarbekir; 60 miles S. of Moufl.

TOPSAIL ISLET, a channel between two small islands off the coast of North Carolina. N. lat. 34° 18'. W. long. 77° 48'.

TOPSFIELD, a township of Massachusetts, in the county of Essex, containing 815 inhabitants; 24 miles N. E. of Boston.

TOPSHAM, a market-town in the hundred of Wonford, and county of Devon, England; situated at the confluence of the rivers Clyd and Exe, 3 miles S. E. from Exeter, and 170 miles W. S. W. from London. Land. speaking of this town, says, "Here is the great trade and rode for shippers that ush this haven, and especially for the shippers and merchant-mannes goodes of Exeter. Men of Exceiter contede to make the haven cum up to Exceeter self; at this time shippes cum not further up but to Apham." The manor was the property of the Courtenays, earls of Exeter, of whom procured for the town the privilege of a market, and an annual fair, which are still held; the market-day being Saturday. The town confisits principally of one long street, of irregular breadth, chiefly extending north and south along the eastern bank of the Exe. Many of the houes are handsome, but the greatest number have but a mean appearance. The southern extremity, called the Strand, is the most pleasant, the river flowing within a short distance of the houes, and is chiefly inhabited by persons of fortune; the view from it is extensive and beautiful. The quay is spacious and convenient, and now belongs to the chamber of Exeter, who purchased it about the year 1778. Most of the inhabitants are employed in the shipping busines; the total number, as returned under the act of the year 1811, was 2871; the number of houes was 620. The church stands near the centre of the town, on a high cliff, which affords an extensive view of a noble river, distant shipping, churches glimmering through groups of trees, a fertile vale, and a fine range of mountains, rising above each other in beautiful perspective, as far as the eye can reach.

In the vicinity of Topsham is Nutwell, the seat of lord Heathfield, nephew and successor to sir Francis Drake. According to Ridlon, the manor-houe was a cafile, till lord Dinham, about the time of Edward IV., converted it into a flatly dwelling-houe. Sir Francis Drake made many alterations, and it has been newly rebuilt by the present poffeflor on a more ample scale, and at a very great expence.

TOPSHAM, a township of the province of Maine, in the county of Lincoln, containing 1271 inhabitants; 156 miles N. E. of Boston.—Allo, a town of Vermont, in the county of Orange, containing 814 inhabitants.

TOR, a sea-port of Arabia, on the coast of the Red sea, formerly a place of confluence, and strong, but at present in a ruinous state and without a garrison. Near it is a ruined cafile, inhabited by the Arabs; the Greeks call this place "Raitho," which might have its name from being inhabited by some of those people called by Ptolemy "Raitheni," towards the mountains of Arabia Felix; it is inhabited by Arabs, and about twenty families of the Greek church. The monks of mount Sinai have a convent here, to which they have sometimes retired when they could not conveniently stay at mount Sinai; only one priest resides in it for the service of the church. About a league north of Tor is a well of very good water, and about it are a great number of date-trees, and several springs of salt-water, especially to the south-east, where the monks have their garden. Near it are several springs, and a bath or two, which are called "the Baths of Mofes;" the Greeks as well as some others are of opinion that this is Elim. The greatest curiosities of Tor are-the productions of the Red sea; the shell-fish of it are different from those of the seas to the north of it; but what are most peculiar to it, are the several flone vegetables, the madrepore, a sort of coral; the fungii, or mushrooms; and the red pipe coral. In 1540, Tor was taken by the Portuguese. N. lat. 28° 10'. E. long. 33° 37'.

TOR, a town of Africa, in the country of the Foulahs. N. lat. 16° 30'.

TOR ALBA, a town of the island of Sardinia; 20 miles N. E. of Algieri.—Allo, a town of the island of Sardinia; 13 miles S. of Orifiganni.

TOR DI CANS, a town of Naples, in the province of Bari; 9 miles S. E. of Monopoli.

TOR Pivot, or Hope's Nofe, a cape of England, on the coast of Devonshire, forming the north point of Torbay. TORA, a town of Egypt, on the Nile; 8 miles S. of Cairo.—Allo, a town of Naples; 9 miles N. E. of Sezza.

TORACA, or BUTUA, a province of Africa, in the empire of Mocaranga.

TORDOS, or BULL-FIGHTING.

TORAITO, in Geography, a town of Thibet; 30 miles N. E. of Tchontori.

TORAL, El, a sea-port of Chili. S. lat. 27° 55'.

TORALLIBA, in Ancient Geography, an island of the Indian sea, near the mouth of the river Indus, and 9 miles from the island of Bybaga. Pliny.

TORAR, in Geography, a town of Hindooflan, in the circur of Surgooga; 30 miles E. S. E. of Surgooga.

TORBAY, is a commodious bay or sea-road, five miles from Dartmouth, on the coast of Devonshire, England. It is formed by two capes, that on the east called Bob's-Nofe, that on the west, Berry-Head. Its general shape is semilunar, enclosing a circumference of about twelve miles. The winding shores on both sides are screened with great ramparts of rock; between which, in the central part, the ground from the country, forming a gentle vale, falls easily to the water's edge. Wood grows all round the bay, even on its rocky sides, where it can get footing and shelter; but in the central part with great luxuriance. This noble bay has often afforded protection to the fleets of England, which, in their full array, ride safely within its ample bosphorus. Beyond the bay is a remarkable place called Kent's-Hole, confisting of many caverns entered by subterraneous passages, but having only one external entrance.

Tor Abbey, the seat of George Cary, esq. is finely situated amidst some ancient and noble trees, and commands an interesting prospect of Torbay, and the rocky tors in the vicinity. The house is mostly modern; though some parts of the old abbey are still preserved. It consists of a centre and two wings; one of which is connected with a cellaret gateway, having octagonal towers and battlements. Beyond this gateway is a large barn, which formerly belonged to the Abbey. It is overgrown with a venerable mantle of ivy, and decorated with loop-holes, and numerous buttresses. The ancient religious house of this place was erected by William, lord Brieure, or Bruer, in the time of king John, and endowed by him with considerable revenues, which were afterwards much augmented by his son. It was appropriated for canons of the Premonstratensian order. After the Bruers, Tor Abbey...
Abbey came into the Mohun family, who were succeeded by the Ridgeways, and then by the Crys, who now enjoy it. At the dissolution, the revenues amounted to 396l. 112.

Gillpin's Observations on the Western Counties, 8vo.

Toreay, a bay of the North Atlantic, on the east coast of Newfoundland. N. lat. 47° 48'. W. long. 52° 20'.—Alto, a town and bay on the south coast of Nova Scotia. N. lat. 45° 38'. W. long. 61° 15'.

Torebek, a town on the south coast of Hispaniola; 9 miles N.W. of Vache island.

Torbia, a town of France, in the department of the Maritime Alps, called by the Romans Trophea Augufi, with an ancient Gothic tower. In the environs are found many remains of monuments erected by the Romans, trophies and fragments of a statue of Augustus; 7 miles E. of Nice.

Torbido, Francesco, called Il More, in Biography, was born, about the year 1500, at Verona, and perhaps rather before it, as he is said to have had, for a short time, the advantage of receiving instruction from Giorgiome. He afterwards became the pupil of Liberale, and his own style is a compound of those of his masters, partaking of the glow of the former, with the elaborate finish of the latter. His principal occupation was in portrait, yet he left several historical pictures of considerable merit. Amongst them are some frescoes, representing the life of the Virgin, in the cathedral at Verona; and a picture in oil of the Transfiguration, in the church of S. Maria Maggiore, at Venice. He died at the age of 81, but the exact date is unknown.

Toribo, in Geography, a river of Naples, which runs into the Crate, near Bifignano.

Toribiscon, a town of Spain, in the province of Granada; 14 miles N.E. of Motril.

Torbole, a town of the Tyrol, on the north-east coast of lake Garda. In 1796, this town was taken by the French; 17 miles N. of Garda.

Torbus. See Tuburbo.

Torc, a mountain of Ireland, in the county of Kerry, on the south side of Lough Lame, whom the southern part is called Lough Torc.

Torcello, a small island in the gulf of Venice, with a town of the same name, the see of a bishop, suffragan of Venice. The town of Torcello is in a flourishing state, which it owes to the inhabitants of Alto, who were driven out of that place by Attila, and fled hither; it has also been the see of the bishop of Alto, in consequence of the bishop Paolo having emigrated to the first-mentioned place. His successor, Mauro, or Maurizio, obtained from pope Severino the confirmation of his new see, and built here several churches, together with the elegant monastery S. Giovanni di Torcello. More churches were built by his successor Giuliano; and Diadato, the fourth bishop, erected finally, in the year 697, the principal church of Santa Maria; which was rebuilt from the ground, in the eleventh century, by the bishop Orso; 3 miles N. of Venice.

Torch, Teda, a sort of luminary, properly a flick of fir, or other resinous and combustible matter, as pine, linden, &c., more or less thick, and long; encompassed at one end with six wax candles, which being lighted, yield a kind of gloomy brightness.

Torches are used in some church ceremonies, particularly at the processions of the holy sacrament in the Romish church, and at the interments of the poorer people.

Formerly they were used at the funerals of those of the first rank; but tapers and flambeaux are now introduced in their stead; and frequently also called by their name.

Torchil-Thistle, in Botany. See CEREUS.

Torchenes, in the Manuge, a long flick with a hole at the end of it, through which a strip of leather is run, the two ends of which being tied together, serve to straighten and closely tie up a horse's nose as long as the flick is fastened upon the halter or bridle. This is done to keep the horse from being unruly when he is drest, or upon any other occasion.

Torchiara Rocca, in Geography, a town of the duchy of Parma; 5 miles S. of Parma.

Torchilli, Jonas, in Biography, the descendant of a respectable family in Iceland, was born in the district of Guldbringe in 1667, and in 1718 he became the bishop of Copenhagen, from whence he proceeded to Holstein, completing his studies at the university of Kiel. In 1728 he returned to Iceland, and became rector of the school of Skalholt, which he resigned in 1736, quitting his country on account of some troubles which ensued from his speaking his sentiments too freely. At Copenhagen, whither he withdrew, he made some unfavourable reports of the clergy in Iceland, and was sent thither as secretary to Harboe, afterwards bishop of Zealand, who was deputed to examine the state of the Iceland Church. Having finished this business, Torchilli retired to Copenhagen, and died there in 1759.

Torre de' Medici, in Anatomy, a name given to one of the sinews of the brain. See Vein.

Toricello, a town of France, in the department of the Lower Seine; 3 miles S. of Arques.

Torda, or Torenburg, a town of Transylvania, famous for its salt-works. The Hungarian language is said to be spoken with the greatest purity in this town; 15 miles W.N.W. of Clujenburgh. N. lat. 46° 42'. E. long. 23° 24'.

Tordesilhas, a town of Spain, in the province of Leon; 5 miles W.S.W. of Rio Seco.

Tordera, a river of Spain, in Catalonia, which runs into the sea, near Blanes.

Tordesillas, a town of Spain, in the province of Leon, on the Duero; 13 miles S.W. of Valladolid.

Tordino, a river of Naples, which so-called Abruzzo Ultra, falls by Teramo, and runs into the Adriatic, N. lat. 42° 40'. E. long. 14°.

Tordino, in Ornithology, a name by which the Venetians call a bird of the dark kind, common in their markets, and called by authors Spinellus.

Tordo Marino, the name of a bird of the flaring kind, called also the cadiglaffo maggiore, or ruticilla major, and by the Austrians the Klein-Ralline. Aldrovandus has named it the merula fasciata, or rock-blackbird. It is of the size of our flaring, and much resembles it in figure; its breast is greyish, and has a black transverse streak, and behind that the whole is of a yellowish hue; its head and back are of a blackish hue, with some light variegations of grey, from the
tip of the feathers being of that colour: the tail is long and of a reddish-orange colour, and the under-feathers of the wings are of the same hue; the females are of a less elegant colour than the males, viz. a mouze-colour, variegated with white on the back, and sih-colour on the belly: what is yellow in the male birds, is also very pale in the females; it is not uncommon in Germany, and may be taught, like the starling, to imitate the human voice.

**TORDYLIUM**, in *Botany*, of the Greeks, probably the very plant of Dioscorides, is supposed by Linnaeus to owe its name to the neat orbicular figure of its seeds, which seem as if artificially wrought, or *turned*. The same idea is hinted by Bodezus a Stapel, in his edition of Theophrastus, 1125; but Linnaeus appears to have been more particularly led by Ambrobinus, to resolve the word into *torn*, a turning *labes*, and *torn* in *tornum*. The latter seems superfluous. De Theis is diffused with this etymology.

*Gen. Ch.* General *Umbel* of many unequal rays; *partial* of many unequal very short ones, flat. General *Involucrum* of several slender undivided leaves, mostly as long as the umbel; *partial* unequal, exceeding the partial umbel in length at its outside. *Perianth* of five teeth. *Cor. Universal* irregular, radiant; all the florets fertile; *partial* of the *life* with five equal petals, whose indented points render them heart-shaped; *of the radius* similar, but its outermost petals are very large, and deeply divided. *Stam.* in all the florets. *Filament* five, capillary; *anthers* simple, roundish. *Pil:* in all the florets. *Germen* roundish, inferior; *styles* two, small, erect; *figmata* obtuse. *Peric.* Fruit nearly orbicular, compressed, crenate at the edge, separate into two parts. *Seed:* two, nearly orbicular, almost flat, with a thickened, finely crenate, margin.

Obs. Linnaeus points out the presence of efficient flaments and pistils in all the florets as the most important difference between this genus and *Caucalis*, see that article. But the seeds of the latter being ovoate, frisiated, and befit with rigid bristles, afford, as he afterwards judiciously thought, a more constant and satisfactory character.

1. *T. syriacum*. Syrian Hart-wort. Linn. Sp. Pl. 345. Willd. n. 4. Ait. n. 4. Jacq. Hort. Vind. v. 1. 21. t. 52. Rivin. Pentap. t. 13. (T. minus syriacum, feminis limbo granulato; Morif. sect. 9. t. 16. f. 5. Gengidiun latifolium; Ger. Em. 1042.)—Partial involucrum many times longer than the nearly feillary flowers.—Native of Syria and Caria. A hardy annual in our botanic gardens, flowering in July. The whole herb is hoary with short close hairs, which render it soft to the touch; *stem* twelve or eighteen inches high, angular, leafy, somewhat branched, zigzag, spreading. *Leaves* stalked, pinnate, of three or five broad, obtuse, rounded, notched leaves; the odd one large, slightly three-lobed, an inch and half long. *Umbel* lateral and terminal, on long, spreading, furrowed stalks. *Flowers* white, few and small; but the leaves of the *partial involucrum* are remarkable for being about an inch in length, obovato-lanceolate, leafy, exceeding those of the *general one in size*. The *seeds* are bristly and viscid, with a crisped margin.

2. *T. officinale*. Official Hart-wort. Linn. Sp. Pl. 345. Willd. n. 2. Fl. Brit. n. 1. Engl. Bot. t. 2442. Ait. n. 2. Sm. Fl. Grac. Sibth. t. 257; unpublished. (*Seefieli criticism minus*; Bauh. Pia. 161; Ger. Em. 1050; Caucaus minor, pulchro feminine, five Belloni; Ban. Hift. v. 3. p. 2. 84. Small Hartwort; Petiv. Herb. Brit. t. 24. f. 6.)—Partial involucrum full as long as the flowers. *Leaflets* ovate, cut, crenate. Radiant petals two together, unequally lobed.—Native of the north of France, Italy, Sicily, and the Levant. Dr. Sibthorp found this plant in various parts of Greece and the neighbouring islands. He judged it, with great probability, to be the identical *T. officinale* of Dioscorides. As a British plant it rests on the authority of Doody, who gathered specimens about Illflworth, and communicated them to Ray. The latter could not mistake the species, but he hints, in his Synopt, ed. 2. 182, that the seeds probably escaped from some garden. This is an annual, more erect than the foregoing, but, like that, downy, not bristly. The *leaflets* are ovate, sometimes rather oblong, sometimes roundish-heartsbaped, from three to nine; stalked and lobed in the larger more luxuriant leaves, but generally unequally crenate only; the upper ones are lanceolate or oblong. *Flowers* large, white or pale flesh coloured, numerous; the two outer petals, especially of the marginal flowers, remarkably radiant, one lobe of each being disproportionately large. General and partial involucrum of narrow awl-shaped leaves, the latter smallest. *Seeds* smooth, with an elegant, broad, thick crenate border. This plant was formerly cultivated for the fake of its seeds, supposed to promote urine and other excretions, but now out of use. The *T. officinale* minimum, Column. Echir. 122. 1. 125. f. 1, seems to us a starred variety, different, as Jacquin well remarks, in Hort. Vind. v. 3. 2, from the following, though he errs in taking it for the true *T. officinale*, which is what he originally so called. See the next species.

3. *T. apulum*. Smaller Hart-wort. Linn. Sp. Pl. 345. Willd. n. 4. Ait. n. 4. Prodr. Fl. Grac. n. 631, excluding the synonyms ofrivin. Pentap. Irr. t. 2. Jacq. Hort. Vind. v. 1. 21. t. 52. Spreng. n. 3. (T. humble; Desfont. Atlant. v. 1. 235.; f. 58.)—Partial involucrum shorter than the flowers. *Leaflets* crenate; the upper ones narrow. Radiant petals solitary, of two equal lobes.—Native of cultivated fields in Italy, Barbary, and Greece. A smaller plant than the foregoing, annual like that, but with several *flaments*, whose lower part, as well as the teeths of each *footsale*, is *thyagar, with long white woolly hairs. The *leaflets* of the lower leaves, about seven, are rounded, variously jagged and notched; those of the upper still more various in figure, narrow, mostly wedge-shaped, often deeply, and very acutely, three-lobed. *Umbel* of usually five rays, sometimes more, four times as long as the *general involucrum*. *Flowers* white, radiant, but not in the manner of the foregoing, they having but one greatly enlarged petal, whose two obovate lobes are nearly equal. The *seeds* have a broader, frisiated, granulated disk, with a thick, but not so broad, border as in *T. officinale*. The synonyms of Bauhin, *Seefieli criticism minimum* are as well those of Tournfort, Ray and Morison, cited in Sp. Pl. and Hort. Clus., all depending on Columba's plant mentioned unter our last species, are to be transferred to that.

Carniola. This appears to be nearly related to the last, nor can we discern why professor Sprengel marks it as a doubtful species. We have seen no specimens. The faithful Scopoli describes it as about a foot high, with uniform leaves, composed of two pair of obliquely ovate, or half-heart-shaped, sely, notched leaves, and a terminal one, broader, deeply three-lobed. The flowers are red, or pink. Fruit oval, compressed, with a thick, bident border, not described as creatal, whence perhaps the doubts of professor Sprengel.

5. T. maximus. Great Hart-wort. Linn. Sp. Pl. 434. Willd. n. 5: Fl. Brit. n. 2. Eng. Bot. t. 1173. Jacq. Auctr. t. 142. Scop. Carn. v. 1. 195. Turn. Inf. 320. (Tordylum; Rivin. Peutap. Irr. t. 1. Sefelii cesticae majus; Bauh. Pin. 161. Ger. Em. 1052. Caecalaiss major; Cluf. Hill. v. 2. 201. Ger. Em. 1021, bad. Heeracleum Tordylum; Spreng. Prodr. 12.)—Umbels dense. Leaflets lanceolate, deeply serrated. Stem rough with deflated bristles; umbels and fruit with creetal ones. Native of wallt ground, banks and hedges, in Italy, Switzerland, Germany, and, though very rarely, England, flowering from June to August. It has long been observed under the hedge on the north side of the parks, at Oxford; and was gathered by Mr. Gotobed near Eton. Dr. Sibthorp met with this plant in Greece and about Constantinople. The root is annual, tapering. Stem three or four feet high, creetal, branched, leafy, furrowed, clothed all over with short, rigid, punctate bristles, which point strongly downward; while the rays of the umbels, the involucral leaves, which are all short and awl-shaped, and the germen, as well as fruit, are equally rough, with creetal bristles. The lower leaves consist of about five broad, ovate leaflets, deeply and irregularly notched; the upper of about three elongated narrow ones, strongly serrated; all rough with clofet-preffed rigid hairs. Flowers small, reddish, with unequal petals, but not strikingly radiant. Calyx-teeth elongated, unequal. Fruit nearly orbicular, bristle, with a thick, pale, rugged border, less crispated than in the first three species, and a slightly tchared ribbed disc. The preference of a general as well as partial involucrum, does not agree with Sprengel’s character of Heeraeleum, nor do the seeds answer to his description of that genus.

6. T. peregrinum. Oriental Hart-wort. Linn. Mant. 55. Willd. n. 3. Ait. n. 3. (Conium dichotomum; Deesfont. Atlant. v. 1. 246. t. 66. Caecaliss Hispanica; Camer. Hart. v. 37. t. 11. Cochryz peregrina; Spreng. Prodr. n. 11, and Cichotoma; Ridl. n. 12.)—Leaves repeatedly compound, smooth, with linear decurrent segments. Fruit elliptical, furrowed, with crispated ribs and margin.—Native of the Levant. Herb annual, smooth, with a branched spreading stem, and very finely divided, three compound leaves. General umbel of scarcely more than three or four flat smooth rays; partial small and dense. General involucrum of one or two small, ovate, pointed, white-edged leaves; partial of several similar unequal ones. Flowers small, scarcely, if at all, radiant, white, or slightly reddish. Fruit thick, almost fessile, more elliptical and acute than in the root of the genus, having a thick, crispated edge, and three greatly elevated, less sharply coriaceous, ribs at each side. The genus of this plant is certainly very ambiguous. It might perhaps be safely referred to Comium, with which its habit more accords, especially as the fruit answers but indifferently to the idea or definition of a Tordylum.

T. latifolium, Anthiricus and nodifolium of Linnaeus are now generally referred to Caecaliss. Sprengel however has restored the genus Torellis of Adanson and Gartner; see that article, to which the latter belong.

We shall have occasion to speak of the difficulties frequent in the generic distribution of this tribe, when we come to the article Umbelliferae.

TORE, TURUS, in Architecture, a large round molding, used in the bays of columns.

Daviler derives the word from the Greek, tore, a cable, to which it bears some resemblance; or from the Latin tornus, a bed, as being supposieto represent the edge of a bed or quilt, swelled out with the weight of the incumbent column.

The tore is also called geno latum, and tomod. It is the bigger that distinguishes the torus from the atlas.

The bafes of Tuscan and Doric columns have but one tore, which is between the plinth and the fillet. In the Attic base there are two; the upper, which is the smaller; and an under, or bigger.

TOREE, in Geography, a cirear of Bengal, bounded on the north by Palamow, Koonda, and Ramgru; on the east by Ramgru; on the south by Chuta and Nagpoon; and on the west by Palamow; about 32 miles long, and 24 broad. Toree is the capital.—Also, a town of Hindostan, and capital of a cirear of the same name, in Bengal; 210 miles W. of Calcutta. N. lat. 22° 37’. E. long. 84° 54’.

TOREK, a town of Hungary, near the Thysfyle; 40 miles W.S.W. of Debreczin.

TORELLI, CELIO, in Biography, a learned jurist, was born at Fano in 1489. Having studied Greek and Latin at Ferrara, he graduated at Perugia, where he studied law. The last respectable office of magistracy, which he occupied, was that of grand chancellor and first secretary to the dukes of Tuscany, Cosmo, and his son Francesco. He was also advanced to the rank of Florentine nobility, and the title of senator, and was consul to the academy of Florence, where he died in 1576, universally esteemed for his mental and moral qualities. He amused himself with polite literature, in which he was a proficient, and with writing Latin and Italian poetry; but the subject of his serious study was jurisprudence. He was the author of several works on the law; but he was principally engaged in preparing a new and correct edition of the Pandects, availing himself of the Pifan or Florentine MS. This magnificent edition appeared from the Torre’tot pref in 1555, in three large volumes folio. His son Francesco was his associate in the labour of this work; but the son died before the father. Gen. Biog.

TORELLI, FUMONTO, a poet and man of letters, and count of Montechiarugola, was educated at Padua, where he resided eleven years. Upon his return to his native place he married, and in 1584 was sent on a mission to Spain; and having succeeded in the object of it, he afterwards employed himself chiefly in literary compositions. His works were numerous, among which we may reckon a treatise, “De Debito de Cavalieero,” 1556; five tragedies, viz. “La Merope,” “Il Tancredi,” “La Galatea,” “La Vittoria,” and “Il Poldoro.” His MSS., which were also numerous, are preserved at Reggio. He died in 1608. Tiraboschi. Gen. Biog.

TORELLI, GIUSEPPE, a native of Verona, member of the Philharmonic society, and principal violon of San Petronio, at Bologna. In 1701 he was concert-master at the court of Anfipach, and his performance on the violin acquired him great reputation. He was a voluminous composer for that instrument. His productions, however, are so superannuated, as almost to cease to be music; for having little original melody, and no uncommon stock of harmony or modulation, there is nothing left to make amends for the want of novelty and elegance. This composer, besides the numerous works which he published for violins during his life,
life, of which the titles are recorded in Walther, left behind him an unedited work, which was published in 1709 by his brother, Felice Torelli, after the author’s decease, under the title of “Concerti grossi con una pantoffale per il santissimo natale,” consisting of twelve concertos in eight parts. These concertos have been thought the best of his productions, and the model of grand concertos for a numerous band. Quantz, Arte de la Flute.

TORELLO, in Geography, a town of Naples, in Principato Ultra; 3 miles W.N.W. of Conza.—Also, a town of Spain, in Catalonia. In the year 1694, a battle was fought near this town between the French and Spaniards, in which the former were victorious; 6 miles N. of Vique.

TORENA, a town of New Navarre; 100 miles S.S.E. of Cafa Grande.

TORENA, in Botany, was so called by Linnæus, after his pupil, the Rev. Olof Torens, or Toreen, chaplain of a ship in the service of the Swedish East India Company, who studied at Upsal, in order the better to qualify himself, as a naturalist, for a voyage to China. He communicated to his great botanical preceptor many scarce plants, and addressed to him a series of letters, descriptive of the voyage, in which, though various other subjects are touched upon, natural history makes a principal figure. These were published at the end of Olbeck’s Voyage (see Osbeckia) and translated with that work into English, by Dr. Forster. Soon after they were written, the author died, apparently at an early age, near Nafinge, in Sweden, Aug. 17, 1753.—Linn. Gen. 311. Schreb. 407. Willd. Sp. Pl. v. 2, 265. Mart. Mill. Dict. v. 4. Brown Prodr. Nov. Holl. v. 1, 440. Juff. 122. Lamarck. Illust. t. 1, 523—Cladis and order, Didynamia Angiosemia. Nat. Ord. Perianate, Linn. Scrophularia, Juff.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, angular, permanent, two-lobed; the lips toothed, unequal. Cor. of one petal, ringlet, twice the length of the calyx; its upper lip nearly entire; lower three-cleft, the middle segment most prominent. Stam. Filaments four; the two uppermost simple; two lowermost longest, with a lateral branch or tooth; anthers of two vertical, oblong, rather distant lobes, converging in pairs, their respective lobes closely contiguous. Petal. Germen superior, elliptico-oblong; style thread-shaped, swelling upwards; stigma of two parallel flat plates. Peric. Capsule elliptico-oblong, of two cells, and two undivided valves, with a parallel unconnected partition. Seeds numerous, roundish, attached to the partition.

Obi. We take our characters of this genus principally from the original Linnæan species, and therefore hesitate to admit, after the example of our learned friend Mr. Brown, any species with a regular five-toothed calyx, such as Capsella crucifera, Linn. and Torenia seabra of Brown. We also omit T. fiaccida of the last-mentioned author, and Anthirrhinum hexandrum of Forster, because we have not seen them. The strange name of the latter probably alludes to the lateral branches of two of the filaments, by which therefore it should seem to be a good Torenia. Yet these appendages appear to be wanting in T. cardifolia of Roxburgh, if we may trust the figure, nor do we find them clearly in our T. obtusifolia. The two-lobed tubular calyx seems to us the most important mark.

1. T. asatica. Smooth Creeping Torenia. Linn. Sp. Pl. 362. Willd. n. 1. Obeck’s Travels, English edition, v. 1, 337. Lamarck f. 1. (T. glabra; Obeck It. 210. "Kaka-pu; Rheedee Hort. Mal. v. 9, 103. t. 53")—Smooth, with a creeping stem. Leaves stalked, ovate, acute, serrated. Native of China, in watery places, flowering in September. The whole herb is smooth, except a few hairs about the joints, and at the insertion of the leaves. Stem a span long, branched, square, leafy, creeping by means of fibrous roots, which seem to be perennial. Leaves hardly an inch long, opposite, smooth, with shallow serrations; on flanks about half their own length. Flowers axillary, solitary, opposite; on long simple stalks, purple, large and handsome, not unlike those of Maurandia; see that article. The small teeth, or points, of the calyx are narrow, close together, and its angles are winged.

2. T. bifurca. Hairy Torenia. Willd. n. 2. Lamarck f. 2. Mart. Mill. Dict. n. 2.—Hairy, with an erect stem. Leaves ovate, serrated, on short stalks.—Native of China. Linnæus thought it a variety of the first species, but it is much more hairy, with smaller flowers; the calyx scarcely winged, except at the very base. The teeth of that part appear to become more deeply separated as the capsule enlarges.

3. T. ciliatis. Fringed Torenia.—Leaves ovate, acute, slightly hairy, serrated, on long stalks. Angles of the calyx broadly winged, fringed.—Native of the Nicobar islands. Communicated by the Right Hon. Sir Joseph Banks. The stem appears to be erect. The leaves are an inch and half long, strongly serrated, slightly beak-shaped with hairs, oblique at the base. Footstalks nearly half the length of the leaves, channelled, hairy. Flowers opposite, about as large as the first species. Calyx remarkable for its broad wings, fringed with short upright hairs; its teeth slender and hairy.

4. T. cordifolia. Heart-leaved Torenia. Roxb. Corom. v. 2, 32. t. 161. Mart. Mill. Dict. n. 3.—Nearly smooth. Stem branched, spreading. Leaves ovate—heart-shaped, serrated. Calyx without wings.—Native of the East Indies. Found by Dr. Roxburgh, in the moist pasture lands about Samulecata, flowering during the cold season. The root is fibrous, simple, apparently annual. Stem erect, six inches high, square, leafy, bushy, with numerous crores branches. Leaves an inch long, paler beneath, on flanks half that length. Flowers about the tops of the branches, axillary, on long flaccid stalks. Calyx rather swelling, angular, but defoliated of wings, two-lobed, with five small teeth. Corolla pale purple, twice the length of the calyx. Staminata, according to Roxburgh, without any lateral branch or tooth.

5. T. obtusifolia. Blunt-leaved Torenia.—Leaves roundish-ovate, obtuse, stalked, wavy, somewhat toothed, smooth. Stem creeping. Lips of the calyx unequal, abrupt.—Sent from Mexico by Mutis to Linnæus. The species were laid into the genus Gratiola, but seem never to have been described. The whole herb is smooth, branched, succulent, creeping; in habit not unlike Veronica Beccabunga, like which plant it seems to grow in swampy places. Leaves ribbed, broad, an inch long. Flowers axillary, stalked, solitary, the five of T. cardifolia. Calyx angular, not winged, oblique at the mouth; its upper lip prominent, obtuse, slightly emarginate; lower much shorter, abrupt, with three small distant teeth. Corolla twice the length of the calyx, white or yellowish; internally somewhat hairy. The insertion of two of the flaments into the upper part of the corolla agrees with T. asatica; we are not sure whether the other pair has any lateral teeth, but there is some appearance of such appendages, conglutinated as it were.
were with the corolla. The authors are roundish, combined in pairs. *Germ in ovate, pointed. Stigma between the authors, of two thin plates. The parts of the flower in our specimen scarcely admit of sufficient examination to determine the genus of this plant with certainty, but it appears to agree with *Triticum better than with any other.

**TOR**

ToRENTO, in Geography. See York.

**Toreumatography**, a Greek term, signifying the knowledge, or rather description, of ancient sculptures, and baso-reliefs.

The invention of toreumatography is owing to Phidias, and its perfection to Polycletus: the Greek gravers have let a great deal of light into the toreumatography.

**TorUJice**, from the Greek *τερόμοιος*, lath, of *τερέμος*, terebro, perforo, that part of sculpture called turning.

**Torfaeus, Thorndus, or Thorod Torsen**, in Biography, an eminent historian, was born in a small island called Engoe, on the southern coast of Iceland; and having laid the foundation of his education at the school of Skalholt, he spent three years, from 1654 to 1677, in the university of Copenhagen. In the spring of 1679 he was captured, in a voyage from Christianland on board a Dutch vessel, by a Swedish cruiser, and carried to Jutland. Upon his release and arrival at Copenhagen, he was appointed the king's interpreter for Icelandic antiquities. In 1662 he visited Iceland, for the purpose of collecting old MSS.; and in the accomplishment of his object was much encouraged and assisted by the bishop of Skalholt. In 1663 he returned to Denmark with a variety of valuable materials; in 1664 he was made secretary to the diocetic of Stavanger; and in the following year he married: but in 1667 he resigned his office, and was appointed antiquary to the king. Upon the death of his father and brother he made a voyage to Iceland, for the purpose of securing his property; and in the same year he went to Amsterdam; but on his return he was shipwrecked at Skagen, and obliged to travel to Aarhus by land. Embarking for Zealand, he encountered a storm near the island of Sanmoe, and landed at Sanas, where he was wantonly attacked by an Icelandar, and in self-defence killed his antagonist. Upon this he was arrested, tried, and condemned to suffer death. Upon an appeal first to a superior court in 1672, and afterwards to the king, it was ultimately determined that he should pay a fine of 100 dollars, and be released. The king, however, was displeased, and deprived him of his salary and office; upon which he retired to Norway, where he lived without any employment till the year 1682, when he was appointed royal historiographer and archivist in the consistory, with a stipend of 600 dollars per annum. Thus circumstanced, he commenced his history of Norway; but in 1706 he was obliged to desist from the prosecution of it by a severe illness, after he had brought it down to the union of Calmar, and to resign the completion of it to professor Richter. Having lost his wife in 1695, he married a second in 1709; and in 1719 died without issue. Torfaeus was a man of considerable learning, and particularly conversant with ancient history and antiquities; and he was much respected by the northern sovereigns, Frederick III., Christian V., and Frederick IV. His works, actually published and left in MS., were very numerous. The collection of his MSS., relating more especially to the history of Iceland, amounts to several volumes folio, and is preserved in the king's library at Copenhagen. Gen. Biog.

In connection with Torfaeus, we shall here mention the learned and eminent Arnar Magnus, the son of an obscure country priest in the western part of Iceland, and more con-

**TO**

**Maecenates** for his devotion to literary pursuits than Torfaeus. Raised from a humble and obscure situation by extraordinary efforts of talent and industry, he attained, in 1694, at the age of 31 years, the honourable situation of professor of philosophy in the university of Copenhagen; and a few years afterwards, he was invited with the offices of professor of northern antiquities and secretary of the royal archives. Luculent in his literary labours, he composed several important works, and collected at great expense a magnificent library, serving to illustrate the literature and antiquities of the North, and more especially the literature of his native island. The greater part of this library was unhappily consumed by the fire which happened at Copenhagen in 1728; and the unfortunate Magnus was witness to the almost total destruction of the fruits of many years' labour. He died two years after this disastrous event, and bequeathed to the library of the university the remnant of his literary treasures. His friend and favourite pupil, Finnur Jenfon, was another of the eminent Icelanders, who, during the last century, have contributed to preserve unimpaired the character and respectability of their country. Created bishop of Skalholt in 1754, he retained this office during the remainder of a long life, wholly devoted to the improvement and happiness of his fellow-citizens. In his admirable work, the "Ecclesiastical History of Iceland," written in elegant Latin, and published at Copenhagen in 2 vols. 4to., he has bequeathed to his countrymen a monument of extensive erudition, genuine piety, and warm patriotic feelings, which will continue as one of the most illustrious monuments of their literature. Mackenzie's Travels in Iceland.

**TORFE, in Geography, a town of Sweden, in West Gothland; 75 miles N.E. of Uddevalla.

**Torga**, a town of the principality of Georgia, in the province of Caket; 85 miles S.E. of Telia.

**Torgau, or Torgaw**, a town of Saxony, in the margrave of Meissen, on the Elbe. It was anciently the head place of a peculiar seigniory, which passed in fief from the electors of Saxony, of the Ascanian line. In the year 1530, the seventeen articles of the Protestant doctrine were presented at this place, to the elector John; and in 1576, the Torgau writing was made here, out of the Swabian Concordat and the Maulbun Formular; from which writing, the year following, the Formular Concordize was drawn up at Kloster Bergen. In the year 1745, the Prussians passed the Elbe here; in the year 1756, they fixed their military office at this place; and in the year 1757, they broke down the bridge thrown over the Elbe. In the year 1760, the Austrians, under marquis Daun, were defeated by the Prussians, commanded by the king in person. The Austrians lost 200 officers, and 7000 men prisoners. Marshal Daun himself was wounded. The Prussians had 2500 men killed, and 4000 wounded; 28 miles E.N.E. of Leipic. N. lat. 51° 32'. E. long. 13° 3'.

**Torgau, Convocation of. See Form of Concord.

**Torgesko, in Geography, a town of Russia, in the government of Irkutsk; 24 miles N.N.W. of Nertilchuk.

**Torgel, a small island in the North Sea, near the coast of Norway. N. lat. 65° 30'.

**Torgelow, a town of Anterior Pomorania, on the Ucker; 9 miles N. of Pafewalk.

**Torgoch, in Ichthyology. See Char.

**Torgots**, in Geography, a tribe of the Mongoles, who formed themselves into a different horde much later than the other Kalmuck branches. Removing at first from the region of the tablet Soongares, they marched westward till they came to the steppes on the Volga, where they finally settled, and
received from the Ruffians the name of the Volgaic Kalmucks. In 1616, this horde is said to have submitted to the Russian empire; and on crossing the Ural in 1662, their number amounted to 50,000 kibitkies. In 1661, the Russian government entered into this agreement with this opulent and powerful horde, which restricted the authority of the khan to narrower bounds, and excited such discontent, that they returned in the winter of 1670 and 1671, to the amount of between 55,000 and 60,000 kibitkies, over the ice of the river Ural, across the Kirghisian steppes, into the Soongary. The greater part of the Soongary took part in this migration; only some few bands of the Torgots remained behind; but the Tartars in subjection to the hordes refused to follow them. The Torgots were pursued by order of the Russian government; but most of them made their escape. Numbers indeed perished on their journey; many were taken prisoners by the Kirghises; and those who reached the place of their destination, put themselves under the protection of the Chinese government, which gave them a kind reception, but afterwards, for political reasons, treated them with great severity. The Torgots, with the Khoschotes and Soongary, who said behind or were brought back from their flight, are distributed among the Derbets; and wander, with their flocks and herds, in the steppes between the Don and Volga, from the line of Tseritzin as far as Caucasus, and between the Volga and the river Ural, from the Irgish quite to the Caspian: consequently in the governments of Saratof and Astrachan, and in the feats of the Cossacks of the Don. Tooke's Ruffia, vol. i.

TORGOWITZA, a town of Ruffian Poland, in the palatinate of Brandaw, 10 miles E. of Human.

TORGSAKER, a town of Sweden, in the province of Angermaandal; 25 miles N. of Hermoland.

TORGHOUT, a town of France, in the department of the Lys; 10 miles S. of Bruges.

TORIES, or Torys, a party or faction in England, opposite to the Whigs.

These two celebrated parties, which have so long divided our country, will make a considerable article in the English history, nothing inferior, in many respects, to that of the Grecis and Gibellines. The division has gone so deep, that it is professed, no Englisman, who has any concern or principles at all, but inclines more to one side than to the other; for which reason, we shall borrow our account of them from the mouths of foreigners, who may be supposed more impartial, and particularly from M. de Cize, a French officer, some time in the service of England, who has written the History of Whigism and Toryism, printed at Leipzic, anno 1717; and M. Rapin, whose Dissertation sur les Weighs & les Torys, printed at the Hague the same year, is well known; and reprinted at the close of the second volume of his History of England, fol. ed.

During the unhappy war which brought king Charles I. to the scaffold, the adherents of that king were first called Cavaliers, and those of the parliament Round-heads; these two names were afterwards changed into those of Tories and Whigs, on the following occasion.

A kind of robbers, or banditti, in Ireland, who kept on the mountains, or in the islands formed by the vast bogs of that country, being called Tories, a name they still bear indifferently with that of Rapparres; the king's enemies seeking him of favouring the rebellion in Ireland, which broke out about that time, gave his partizans the name of Tories; and on the other hand, the Tories, to be even with their enemies, who were closely leagued with the Scots, gave them the name of Whigs, who living in the fields and woods, fed much on milk; whence signifying white. But for a more probable etymology of Whig, see Writs.

The Cavaliers, or Tories, had, in the main, principally in view the political interests of the king, the crown, and the church of England; and the Round-heads, or Whigs, proposed chiefly the maintaining of the rights and interests of the people, and of Protestantism. Nor have the two factions yet lost their first views; though their first names, Cavaliers and Round-head, be now entirely diffused.

This is the most popular account: and yet it is certain that the name Whig and Tory were but little known till about the middle of the reign of Charles II. M. de Cize relates, that it was in the year 1678, that the whole nation was first divided into Whigs and Tories; and that on occasion of the famous deposition of Titus Oates, who accused the Catholics of having conspired against the king and the state,—the appellation Whig was given to such as believed the plot real; and Tory to those who held it fictitious.

When we compare, says Mr. Hume (E. I. I.), the factions of Whig and Tory with those of Round-head and Cavalier, which were merely parties of principle, the most obvious difference that appears between them, consists in the principles of "servile obedience," and "indestructible right," which were but little heard of among the Cavaliers, but became the Universal doctrine, and were esteemed the true characteristics of a Tory. If these principles were pushed into their most obvious consequences, they imply a formal renunciation of all our liberties, and an avowal of absolute monarchy: since nothing can be a greater absurdity than a limited power which must not be refined, even when it exceeds its limitations. But as the most rational principles are often but a weak counterpoise to passion; it is no wonder that these absurd principles were found too weak for that effect. The Tories, as men, were enemies to oppression; and also, as Englishmen, says Hume, they were enemies to arbitrary power. Their zeal for liberty was, perhaps (says this partial writer), less servile than that of their antagonists; but was sufficient to make them forget all their general principles, when they saw themselves openly threatened with a subversion of the ancient government. From these sentiments arose the Revolution; an event of mighty consequence, and the first foundation of British liberty. The conduct of the Tories, during that event, and after it, will afford us a true insight into the nature of that party. In the first place, they appear to have had the genuine sentiments of Britons in their affection for liberty, and in their determined resolution not to sacrifice it to any abstract principle whatever, or to any imaginary rights of princes. This part of their character must justly have been doubted of before the Revolution, from the obvious tendency of their avowed principles, and from their compliance with a court, which seemed to make little secret of its arbitrary designs. The Revolution shewed them to have been, in this respect, nothing but a genuine "court party," such as might be expected in a Britsh government: that is, "lovers of liberty, but greater lovers of monarchy." It must, however, be confessed, that they carried their monarchical principles further, even in practice, but more so in theory, than was in any degree consistent with a limited government. Secondly: Neither their principles nor affections concurred, entirely or basically, with the settlement made at the Revolution, or with that which has since taken place. This part of their character may seem opposite to the former; since any other settlement in those circumstances of the nation, must probably have been dangerous, if not fatal, to liberty. But the
heart of man, says our author, is made to reconcile contradictions; and this contradiction is not greater than that between "passive obedience," and the renunciation employed at the Revolution. A Tory, therefore, since the Revolution, may be defined in a few words to be "a lover of monarchy, though without abandoning liberty; and a partizan of the family of Stuart," as a Whig may be defined to be "a lover of liberty, though without renouncing monarchy; and a friend to the settlement in the Protestant line."

Some, who will not venture to assert, that the real difference between Whig and Tory was lost at the Revolution, seem inclined to think, that the difference is now abolished, and that affairs are so far returned to their natural state, that there are at present no other parties among us but Court and Country; that is, men who, by interest or principle, are attached either to monarchy or liberty. The Tories have been so long obliged to talk in the republican style, that they seem to have made converts of themselves by their hypocrisy, and to have embraced the sentiments, as well as language of their adversaries. There are, however, very considerable remains of that party in England, with all their old prejudices.

The precise difference, says an anonymous writer (Edinb. Rev. No. 1.), between a moderate Tory and a moderate Whig is, "that a Tory is more influenced by loyalty, and a Whig by the love of liberty; that a Tory considers liberty as the second interest of society, while a Whig regards it as the first." Loyalty is denominated by Mr. Hume "that noble and generous principle, inferior only in excellence to the more enlightened affection towards a legal constitution."

We should here confine ourselves to the Tories; and for what regards the Whigs, refer to that article; but since, by comparing and confronting the two parties together, both the one and the other will appear in the stronger light, it would be imprudent to separate them; so that we rather choose to say the less under the word Whigs, and refer thence higher.

The factions we are speaking of, may be considered either with regard to the state, or to religion. The state Tories are either violent or moderate: the first would have the sovereign to be absolute in England, as in other countries, and his will to be a law. This party, which is not very numerous, has yet been considerable. 1. On account of its leaders, who have been lords of the first rank, and generally ministers and favourites. 2. In that, being thus in the ministry, it engaged the church Tories to maintain stiffly the doctrine of passive obedience. 3. Because they have been frequently supported by the crown.

The moderate Tories would not suffer the king to lose any of his prerogatives; but neither would they sacrifice those of the people.

The state Whigs, again, are republican or moderate: the first, according to our author, are the remains of the Long parliament, who took in hand to change the monarchy into a commonwealth: these make for fender a figure, that they only serve to strengthen the party of the other Whigs. The Tories would persuade the world, that all the Whigs are of this kind; as the Whigs would make us believe, that all the Tories are violent.

The moderate state Whigs are much in the same sentiments as the moderate Tories; and desire the government may be maintained on its ancient foundation, and that the king may be reduced to an incapacity of abusing his power, by leaving him the possession of his just rights; all the difference is, that the moderate Tories lean a little more to the side of the king, and the moderate Whigs to that of the parliament and people.

Before we consider our two parties with regard to religion, it must be observed, that the Reformation, as carried on to a greater or less length, divided the English into Episcopalian and Presbyterian or Puritans: the first contend, that the episcopal jurisdiction should be continued on the same footing, and the church in the same form, as before the Reformation: the latter maintained, that all ministers or priests had equal authority; and that the church ought to be governed by presbytery, or consistory of priests and lay-elders. See Puritans.

After long disputes, the more moderate of each party relaxed a little of their stiffness; and thus formed two branches of moderate Whigs, and moderate Tories, with regard to religion; but there were others who kept to their principles with incalculable firmness; and these constituted two branches of rigid Episcopalians and Presbyterians, comprised under the general names of Whigs and Tories; in regard, the first join the Tories, and the latter the Whigs.

The former consisted of rigid churchmen, who were against the least change in the discipline of the church, while the more moderate among the ecclesiastical Tories were less scrupulous and obstinate, and may be called the low or moderate churchmen. See High Church and Non-Jurors.

The latter were the rigid Presbyterians, who would be contented with nothing less than the destruction of the hierarchy, while the more moderate among them would have been satisfied with much less, and put up, says Mr. Rapin, with a bare toleration.

From what has been observed, we may conclude, that as the names Tory and Whig have a regard to two different objects, they are equivocal, and of consequence ought never to be applied without expressing in which sense it is done; for the same person may be, in different respects, both Whig and Tory.

For the rest, the general motives that have formed and kept up the two parties, appear in the main to be no other than the private motives of particular persons: self-interest is the primum mobile of their actions; ever since the rise of these factions, each has struggled earnestly to get the advantage over the other; inasmuch as from such superiority accrue places, and honours, and promotions, &c. which the prevailing party usually distributes among its own members, exclusive of the contrary party.

There are, however, men belonging to each of these parties, though the distinction is almost worn out, who act from conviction; some of whom are for the extension, and others for the limitation of royal prerogative, with a view to the good of the state, as their principles lead them to form different notions of the most effectual method of promoting it. The names, it is true, are almost sunk into oblivion; but the operation of the distinguishing sentiments of Whigs and Tories is discoverable in every period of the English history; and the true interest of a limited monarchy, always inextricably connected with the rights of the people, renders the distinction of importance, and should prevent its ever being disregarded.

It is with the Whigs and Tories on those points, which have discriminated the two parties, says Dr. Gregory Sharpe, as it is with all other sects of men under the agitation of hope and fear, ambition and interest; they tighten or relax their principles as suits their convenience. When the Tories have had the exercise of the powers of the prerogative, they have been eager to extend those powers;
when the edge has been turned against them, they have been as eager in the defence of popular liberty; and in like manner the Whigs, who withstood the storm, have melted in the fun-flower, so that in point of court complaisance, the administrations of the one have differed very little from those of the other. Holberg's Int. to Universal History, by Sharpe, p. 262.

As to the characters commonly attributed to the Whigs and Tories; the Tories, says N. Rapin, appear fierce and haughty: they treat the Whigs with the greatest contempt, and even sometimes with rigour, when they have the advantage over them: they are very hot and vehement, and proceed with a rapidity, which yet is not always the effect of heat and transport, but has its foundation sometimes in good policy: they are very subject to change their principles, as their party prevails or is humbled.

If the rigid Presbyterians prevailed in the Whig party, it would not be less hot and zealous than that of the Tories; but it is said they have not the direction thereof; which gives room to affirm, that those at the head of the Whig party are much more moderate than the chiefs of the Tories; add, that they usually conduct themselves on fixed principles, proceed to their end gradually, and without violence; and their slowness is not less founded on good policy, than the haste and precipitation of the Tories.

Thus much says our author may be said to the advantage of the moderate Whigs, that, in the general, they maintain a good cause, viz. the constitution of the government as by law established.

TORIEDALE, Head, in Geography, a cape on the N. coast of Scotland. N. lat. 58° 30'. W. long. 4° 10'.

TORILIS, in Botany, a genus of Adanson's, whose name perhaps may have been fabricated from τορίλις, to carpe or embois, in allusion to the seeds, which, however, answer not to this idea than those of many neighbouring genera. —A d. Fam. v. 2. 99. Spreng. Prod. Umbellif. 24. Gært. t. 20. —Clas and order, Pentandria Digynia. Nat. Ord. Umbellifera.

Adanson distinguishes this genus from Caucalis, (see that article,) by the want of a general involucre, and the flerones of the leaves which compose the partial ones. These are principles of Artedi and Linnaeus, but not generally reckoned among their bulbs. Gærtner, and more recently Sprengel, distinguish Torilis by the bristles of the fruit being scattered equally on its whole surface; not, as in Caucalis, ranged along its ribs. As one of the species, Anthericus, usually, if not constantly, is furnished with a general involucre, and another, nodosa, is not always destitute of one; and as the inflorescence of the bristles is a very obscure, if not precarious, character; which appears by the disagreement between Gærtner and Sprengel, concerning the species supposed to compose this genus, we prefer leaving our three British ones at least in Caucalis, where they are placed in the Flora Britannica.

TORIM, in Geography, a town of New Mexico, in the province of Hiaqui; 55 miles S.W. of Riochico.

TORIN Rocks, a cluster of rocks near the S.W. coast of the island of Mull. N. lat. 56° 16'. W. long. 6° 28'.

TORISA, a river of European Turkey, which runs into the Mariza, at Adrianople.

TORKESLEY, John, in Biography, author of one of the most important tracts in the MS. of Waltham Holy Cross, at present in the possession of the marquis of Lansdowne. This tract, which is the fifth in the collection, has been already described. See Power, Lionel.

TORLA, in Geography, a town of Spain, in Aragon; 16 miles E. of Jaca.

TORM, Eric Olausii, in Biography, a Danish writer, was born in 1607, and educated in the school of Viborg. Having finished his education, and spent several years in the capacity of private tutor, he set out on his travels in a view to further improvement; and visited Oxford, Leyden, and Paris; and in 1736 he was appointed professor of mathematics in the University of Copenhagen, and afterwards librarian and preacher in one of the churches. He died in 1697. He was the author of many works, chiefly mathematical and historical. Gen. Biog.

TORME, in Geography, a town of Spain, in Old Castile; 15 miles N. of Prias.

TORMENTILLA, in Botany, a diminutive of tormentum, a pain or gripping, supposed to have been chosen to designate this little astringent plant, because it served to alleviate pains of the teeth, or of the bowels, tornina. But it may simply perhaps apply to that astringency, which, considering the primary sense of the above words, the name seems to indicate. —Linn. Gen. Pl. 256. Wild. Sp. Pl. v. 1. 112. Mart. Mill. Diat. v. 4. Sm. Fl. Brit. 552. Jull. 337. Tourn. t. 153. Lamarck Illustr. t. 444. Clas and order, Iosandria Polygyna. Nat. Ord. Senticole, Nat. Raflesi, Jaff.

Gen. Ch. Cal. Periander inferior, of one leaf, flat, cut half way down into eight segments, of which four alternate ones are smaller and more acute. Cor. Petals four, inwardly heart-shaped, flat, spreading, their claws inserted into the calyx. Stem. Filaments fifteen, awl-shaped, half the length of the petals, inserted into the calyx; anthers roundish, simple. Pila. Germs eight, small, collected into a little round head; styles thread-shaped, the length of the flaments, inserted laterally into the gérms; stigma obtuse. Peric. none. Sepals of the seeds, dry, corrugated, bluntly pointed.

Eff. Ch. Calyx inferior, in eight segments. Petals four. Seeds roundish, naked, wrinkled, attached to a small dry receptacle.

Obst. Linnaeus remarks, that this genus differs from Potentilla, (see that article,) in characters founded on number only, and therefore they might be united. Schreber, and recently Dr. Neftler of Strafsburg, have adopted this measure, the latter uniting Comarum allo to Potentilla. As the numerical differences are extended throughout the parts of fructification, though some of them are acknowledgment to vary, and the two species of Tormentilla accord so well in habit, we are induced to follow Linnaeus, Tournefort, and Jussieu, in retaining the genus; for if number were in this case entirely overlooked, we do not perceive how Sibaldia could be supported. (See that article, Comarum, and Rosaceae.) It has been ascertained, that botanists who retain such genera as this, viz. Ray, Tournefort, Linnaeus, and Jussieu, will not gain much fame with posterity; but of this, we humbly presume, posterity will be the judge.

wiry, often procumbent. Leaves ternate, lanceolate, rather hairy, deeply serrated, with a pair of deep cut stipulas. Flowers bright yellow, on long, simple, solitary, lateral flanks. The late Miss Johnes of Hafod found one plant in that romantic spot, whose flowers were double, a rare instance.

2. T. repens. Trailing Tormentil. Linn. Sp. Pl. 716. Wild. n. 2. Fl. Brit. n. 2. Engl. Bot. t. 864. (Pentaphyllum repens alatum, folis profundius ferratis; Plot. Oxford. t. 9. f. 5.)—Stems profuse. Leaves falcate.—Native of banks and shady places, in England and Germany, but not common. We once gathered it in a lane at Brighouse, near Halifax, Yorkshire, in the middle of summer. The root, though perennial, is much smaller and flenser than in the foregoing. Stems few, eighteen or twenty inches long, often simple, entirely profuse, but not creeping. Whole herb finely hairy, of a light green. Radical leaves on long flanks, of five, obovate, deeply serrated leaflets; those on the stem of three only, on shorter flanks; the floral ones falcate, narrow, and often entire. Stipulas united to the base of the footflanks. Flowers twice as large as the foregoing, on very long flanks, opposite to the leaves.

Tormentilla, in the Materia Medica. The root of the common tormentil, or upright seep-toil, tormentilla erecta, is the only part that is used in medicine. It is knotty, externally blackish, and internally reddish. It has a strong styptic tincture, but imparts no peculiar vivid flavour. As a proof of its powerful astringency, it has been sublimated for oak-bark in the tanning of skins for leather. Its active matter is therefore chiefly tannin; the infusion in boiling water being copiously precipitated by solution of sulphate of iron, and striking a deep black with sulphate of iron. This root has been long held in high estimation by physicians, as a very useful astringent; and having little retn, it becomes peculiarly adapted to cases where the heating and stimulating medicines of this class are less proper, as phthisical diarrhoas, diarrrhoea cruenta, &c. Dr. Cullen thinks it has been justly commended for every virtue that is competent to astringents; and he adds, that he has found it, both by itself and as joined with gentian, cure intermittent fevers, when given in substance and in large quantities. It gives out its astringency both to water and rectified spirit, but most perfectly to the latter: the extract, particularly the spirituous, obtained by infusion, are intensely styptic. The root is generally given in powder, from half a drachm to one or more for a dose; but it is more generally given in decoction; an ounce and a half of the powdered root may be boiled in three pints of water to a quart, adding, toward the end of the boiling, a drachm of cinnamon; of the strained liquor, sweetened with an ounce of any agreeable syrup, two ounces or more may be taken four or five times a day. As a local remedy, it may be used with advantage in the form of gargles and lotion in ulcerations of the tongue and mouth, against spongy gums, and as an application to festid ill-conditioned ears; but it is seldom used. Lewis. Woodville.

Tormenting, in Agriculture, a term signifying in tillage cultivation an imperfect sort of horse-hoeing or ploughing, or what is sometimes, in some districts, termed sub-hoeing or sub-ploughing. It is occasionally too used as a term of reproach for bad tillage of any kind.

Tormentor, an implement of the tillage kind, used for breaking down and reducing the parts of stit tills. It is a powerful tool of this fort which is much employed in Devonshire, Cornwall, and some other counties; in the first of which for the purpose of cross-cutting the balks of whole ground, left after the velling and skirring operations for beat-burning, or paring and burning the surface-turf. It is indeed useful in working lands in almost all cases of bringing them into cultivation, and into a fine state of mould. See Skirting, Tillage, and Velling.

This fort of implement is constructed in different modes and forms, as in a kind of long triangular shape, the beam part being lengthened out before, in which is fastened, by a fork of shanks, a small wheel, which is capable of being raised or let down at pleasure, so as to regulate the depth of working of the tool. At or near the extremity of the frame behind are fixed two large wheels, to allow the triangular pointed shares or hoes to work in the ground. The whole is strongly framed together in three pieces; the middle or beam, and the two outside pieces. The number of shares or hoes is usually about nine. The fame tool is sometimes contrived with two wheels in the front, and with a crane neck, being the fame in all other respects.

The spil of iron which passes through the beam in the front, and supports the fore-wheel, has a number of iron rings on it, by which the depth of flaring is regulated. The length of the beam is six feet nine inches. The breadth or width of the back-piece, where the large wheels are placed, is three feet seven inches. The large wheels are three feet in diameter. The small fore-wheel is ten inches in diameter. The side-pieces of wood of which the frame is made, are four inches square, and the beam thereabouts. The shares or hoes, which are fixed upon shanks, with smaller parts to pass through the frame parts and be fastened above, are fifteen inches in length.

The construction of the tool is consequently very simple, and easily accomplished by any common workman, so that the farmer need never be at a loss for so powerful and effective an implement in the cultivation of tillage land.

Tormes, in Geography, a river of Spain, which rises in Old Calchile, and crossing the province of Leon, passes by Alva de Tormes, Salamanca, &c. and enters the Duero a few leagues below Miranda de Duero.

Tornina, in Medicine, a term sometimes used to express pains in the general; but more particularly a species of pain, called tornina ventris, or aevi; in English, the gripe; which see. See also Distention.

Young children are very often troubled with gripes; it is upon this account that nurses, in order to prevent or remedy them, usually mix with their spoon-meats a little brandy, or some carminative feeds, as caraway-seeds, &c.

Some children breed their teeth with violent gripes, which are apt to bring on convulsions of the bowels.

In adults, the dry gripes are usually cured by the exhibition of warm cathartics, such as tincture of hiera pica, elixir faltus, tincture of rubarb, &c. with the addition of opiates.

Tormis, Tornes, in Ancient Geography, a river of Hispания, in Lusitania, which united with the Durius. See Tornes.

Tornia, in Geography, a town of Hungary, and capital of a county; 14 miles S.W. of Cacchan.—Also, a town of Saxony; 3 miles S. of Pirna.

Tornado, or Turnado, a sudden and violent gale of wind rising suddenly from the shore, and afterwards veering round all points of the compass like a hurricane; very frequent on the coast of Guinea. These winds frequently shift suddenly from one quarter of the horizon to another, and then come again to the former point. Before a tornado comes, it calms the const ant easterly winds; and when they are past, the easterly wind gathers force again, and the weather clears up fair. See Hurricane and Whirlwind.
ANCIENT Lucca, Divine Dupin. River was 18 He 1757, parallel Chalcidia. 60 of the 16 valuable 1543, cape 3 yet river 1566. Ancient performed enlarged in 50 the 8 Geography, E. name. 13 N. Biorkhon, But small island from 1600 augmented it, being on the scene in 1566. Ancient Birkin, named its mouth, near the Gulf of Bothnia, and said to be the oldest town in the country, and the farthest towards the north. It has three streets, running in parallel lines from north to south, which are intersected at right angles by fourteen cross-streets or lanes. Torina, though built on an uniform plan, consists mostly of detached cottages, and contains only 600 inhabitants. The streets are very broad, and not being paved, are overgrown with grass, on which the cows regularly pasture. The inhabitants, being a mixture of Finns and Swedes, have the character of being idle, and addicted to drunkenness; yet the adjacent country, chiefly by the industry of the Finnish settlers, is rapidly improving; and the population of the province of Lapland appears to have advanced much faster than that of any other part of Europe. In the year 1750, this, according to baron Hermelin, was 27,000; in 1777, it had increased to 31,000; but in 1801, it amounted to 52,000. The church is built with timber, and stands at a little distance from the other buildings, but within the palisades which inclose the town, and a pretty large piece of arable land. Divine service is performed here in the Swedish language, which is used by the burghers. There is another church, built with stone, on an island called Biorkhon, which lies near the town, in which the service is performed in the Finnish language, for the benefit of the burgher servants, and the inhabitants of the adjacent country. A very considerable trade is carried on here, not only by the Swedes and Laplanders, but the Russians and Norwegians, who also resort to the trading and bartering places of Torina, in order to traffic. In the year 1694, this town was honoured with the presence of king Charles XI, who, being accompanied by several persons of distinction and learning, took a view of the place, at midnight, if it may be called so, from the church tower, at Torina. In this town, and the adjacent country from hence to Kites, observations were made in 1736 by M. Maupertuis, and some other members of the Academy of Sciences at Paris, in order to determine the measure of a degree of, and consequently the figure of the earth, and its ratification and extension by Ivanborg in 1799. N. lat. 65° 48'. E. long. 24° 2'.

Torina Ofvar, a town of Sweden, in West Bothnia. 3 miles N. of Torina. Torina of Var, a town of Sweden, in West Bothnia. 3 miles N. of Torina. Torina Ophav, a town of Sweden, in West Bothnia. 3 miles N. of Torina. Torina Nere, a cape on the coast of the Morea. 3 miles S.S.E. of Chirensa.

Torina Sol. See Torina Sol.

Torina Ness, a cape on the south coast of the island of Stroma. N. lat. 58° 56'. W. long. 2° 29'. Torinelli, Agostino, in Biography, a learned ecclesiastic, was born at Novara in 1543, and having entered into the society of Barnabites, he became general of this society. He undertook to write an ecclesiastical history from the beginning of the world to the time of Christ, in the form of annals, and executed the work with very laudable lauga-

city and correctness, furnishing the reader by his chronological and geographical observations, with a valuable commentary on the books of the Old Testament. It was first printed at Milan in 1610, and afterwards frequently reprinted. Father Negri published an enlarged edition, with valuable notes, in 1577, at Lucca, in four vol. folio. He declined the offer of the bishopric of Mantua, and chose to remain in the Barnabite college at Milan, where he died in 1622. Dupin.

Torino, in Geography, a town of Germany; in the principality of Anhalt Zerbst; 3 miles W. of Zerbst.

Torino, a town of Italy; 18 miles S. of Venice.

Torino, an island in the Baltic, near the coast of Sweden. N. lat. 58° 49'. E. long. 15° 40'.—Alfo, a town of Naples, in the county of Molise; 15 miles S.E. of Molise.—

Alfo, a town of Spain, in the province of Leon, situated on the summit of a hill above the Duero, over which is a bridge of twenty-two arches. It is the seat of a bishop, and one of the most ancient in the kingdom. Here are the remains of an ancient Moorish castle, forming a square of 143 feet, with a round tower at each angle. In the year 1476, a battle was fought here, by which Ferdinand, prince of Aragon, obtained the kingdom of Castile from Alphonso, king of Portugal; 17 miles E. of Zamora. N. lat. 41° 45'. W. long. 5° 37'.—Alfo, a town of New Mexico, in the province of Chalona; 50 miles N. of Chalona.

Tono, 11, a small island in the Mediterranean, near the south coast of Sardinia. N. lat. 39°. E. long. 8° 34'.

Toronca, in Ancient Geography, a town in the interior of European Sarmatia, near the river Careontes. Post.

Torolla, in Geography, a town of Spain, in Aragon; 18 miles N.W. of Jaca.

Torom, a river of Russia, which runs into the Oby; 24 miles E. of Surget.

Toron, a town of European Turkey, in Macedonia, situated on a neck of land which projects into the Archipelago, between the gulf of Monte Santo and the gulf of Cassandra; 60 miles S.E. of Salomiki. N. lat. 40°. E. long. 24° 54'.

Toron, or Toronaicus Sinus, in Ancient Geography, a gulf of the Ægean sea, on the coast of Macedonia, and separated from the Sgotic and Thermaen guls by two large peninsulas. Tacitus. Planys calls this gulf Mcybernus.

Torone, a town of Macedonia, upon the Toronic gulf, to which this gulf owes its name. Ptolemy places it in the Paraxis, and Theudicides fixes it in Chaledia. About three stadia from this town was a temple of Castor and Pollux.—Alfo, a town of Epirus.

Toronto, in Geography, a settlement of Canada, on the N.W. bank of lake Ontario, now called York. See York.

Toronto, a town of Peru; 60 miles S. of Potoxi.

Toronto, a town of Russia, in the government of Pskov; 156 miles S.E. of Pskov. N. lat. 56° 25'. E. long. 32° 24'.

Toronto, a town on the island of Mull. N. lat. 56° 35'. W. long. 6° 5'.

Toronto, a town of Transylvania, in the environs of which are mines of iron and silver; 19 miles N. of Weiffenburg.

Toorus, in Botany, is sometimes used to express an inequality of surface, like the brawny swellings of a molecular limb; as in the capsule of Papaver hybridum.

Torp, in Geography, a town of Sweden, in West Goth-
The torpedo, or Gram-Fish, or Electric Ray, is a sea-fish, famed, both among the ancient and modern naturalists, for a remarkable numbness with which it strikes the arm of such as touch it. See Raja Torpedo.

This species is found in the Mediterranean, on the Atlantic coast of France, and in the English seas, particularly at Torbay, near Waterford, on the coast of Ireland, and in other places. See Anfon's Voyage, p. 266.

It is generally taken with the trawl, but an instance occurs of its taking a bait, which vindicates a fine account which Oppian has left us of this fish. It commonly lies in water about the depth of forty fathoms, in company with the congenerous rays; but its more frequent and favourite situation is the sand, in which it will bury itself by flapping its extremities, and throwing the sand in a light shower over its back. In this situation the torpedo gives its most forcible shock, which throws down the astonished passenger who inadvertently treads upon him. The food of the torpedo is fish, and they probably flupsey their prey by the shock they give them; and yet the sea-leech and common sea-crab will venture to annoy them.

This fish is so far amphibious as to live in air twenty-four hours, and but little longer in fresh water. The best method of preserving them is in well-boats kept in salt water, and not put into much motion.

Road-leas speaks unfavourably of the torpedo as food, and tells us, that at Vepric the prefect of health forbids it to be sold in the market; but in deeming it wholesome food, we have the sanction of Hippocrates and Galen, and it is sold in the markets of France. The electrical organs, indeed, which make one half of the animal, though wholesome, are an impudic mucilage; but its muscular part is, at least, as palatable as the flesh of the other rays: among these, the old and overgrown are always in little request.

The torpedo brings forth its young at the autumnal equinox, as affirmed by Arifotle, though questioned by Lorenzini. In one deposited at La Rochelle, on the 8th of September, were found in the matrices several of the facts quite formed, and nine eggs in no state of forerunners: superfection seems to be, therefore, a property of this fish; the eggs seemed to be defined for the spring brood, as they produce about the vernal as well as the autumnal equinox. There may be also another production at midsummer, but it principally takes place at the two equinoxes.

Upon touching this fish with the fingers, it frequently, though not always, happens, that the person feels an unusual painful numbness, which suddenly seizes the arm up to the elbow, and sometimes to the very shoulder and head.

The pain is of a very particular species, and is not to be described by any words; yet MM. Lorenzini, Borelli, Redi, and Reaumur, who all felt it severely, observe it to bear some resemblance to that painful sensation felt in the arm, upon striking the elbow violently against a hard body: though M. Reaumur affixes us, this gives but a very faint idea of it.

Its chief force is at the instant it begins; it lasts but a few moments, and then vanishes entirely. If a man do not actually touch the torpedo, how near soever he holds his hand, he feels nothing; if he touch it with a flick, he feels a faint effect; if he touch it through the interposition of any pretty thin body, the numbness is felt very considerably; if the hand be pressed very strongly against it, the numbness is the less, but still strong enough to oblige a man speedily to let go.

Oppian affirms, that it will bend the astonished fisherman, even through the whole length of line and rod. See the passage cited and translated by Pennant, Brit. Zool. vol. iii. p. 39.

But great as are the powers of this fish when in vigour, they are impaired as it declines in strength, and totally ceases when it expires. The shocks in water are apprehended to be near a fourth of the force of those at the surface of the water, and not much more than a fourth of those entirely in air. This strange power, with which the torpedo is endowed, and which we shall presently explain, seems to have a double use: the one, when it is exercised as a means of defence against voracious fish, who are by a touch deprived of all power of seizing their prey; the other is well explained by Pliny, who tells us, that by the same powers it attains its end with respect to those fish which it wishes to enframe; for concealing itself in the mud, and bending the fish that are carelessly swimming about, it makes a ready prey of them.

M. Reaumur, having no fishes alive to examine what the torpedo would do to them, shut up a drake in water with it, and after some time it was taken out dead. See Electric Organs of Fishes.

We shall now proceed to give a brief recital of the different theories that have been adopted in order to account for the extraordinary effects of the torpedo. This fish was early known to the Greeks; it is mentioned, as an efeulent fish, by Hippocrates, under the name σπαργα, which flowed that the ancients had some knowledge of its torporic qualities. Plato also was acquainted with them, as appears by the humorous comparison of Socrates to that animal, which he puts into the mouth of Menon. Aristotle likewise treats of the benumbing or stupefying qualities of this fish, though he seems to have no idea of their being communicated by the intervention of a flick, rope, or water.

Theophrastus, according to Athenæus, observed that the torpedo conveyed the benumbing sensation through flicks and spears into the hands of the fishermen that held them. Diphilus, of Laodicea, takes notice that the torpor was occasioned, not by the whole, but by certain parts of the body of this fish; and Hero of Alexandria mentions it as emitting effluvia through brays and iron, and other solid bodies.

Pliny's account, though partly true, is mingled with the marvellous and false. Plutarch is more full and just; for he represents the torpedo as not only benumbing all that touch it, but striking a numbness through the net into the hands of the fishermen, and as even diminishing the feeling of those who poured water upon it, if it happened to be laid on the ground alive. He adds, that whilst the torpedo swims round his prey, he emits certain effluvia like darts, that first affect the water, and then the fishes in it, which are thus disabled from defending themselves or escaping.

Before the days of Galen the torpedo was placed alive to parts affected, and particularly for the cure of an obtirate ache, as appears from Scribonius Largus, who lived under Claudian, and from Dioscorides, who flourished soon after. Galen conceived that the torpedo acted by a frigoricid principle, for as cold occasion a numbness in an animated body, so does the shock given by that animal. Paulus of Egina, one of the Galenic school, recommends the oil of the dead fish for tempering the hot humour of the gout, and for other ailments that required cooling applications.

Such are the unsatisfactory accounts of the philosophers and physicians of antiquity.

The Abyssinians, it is said, use torpedos for the cure of fevers,
fevers, by tying down the patient to a table, and applying the fish successively upon all his members, which puts him to cruel torment, but effectually removes his disease. Bel- 
lonius affurces us, that our own torpedoes applied to the soles of the feet, have proved successful against fevers.

Oppian, like Diphilus, distinguishes the parts where the powers of the fish peculiarly reside; these he calls ʃʃʃʃʃ, the flanks, from which he imagined the animal had a faculty of darting upon other fishes certain substanctes, called by a name ʃʃʃʃʃ, the meaning of which is obscure. In the six- 
teenth century, some members of the Academia del Ci- 
mento availed themselves of their vicinity to the sea to make experiments on the torpedo. Redi began, and was after- 
wards affitled by Borelli, and Steno the Dane; and Lo- 
renzini, his scholar, engaged in the same pursuit, and pub- 
lished a curious treatise upon the subject. Redi, having 
endeavoured to distinguish between the real properties of the torpedo, and those erroneously ascribed to it, proceeded to the anatomy of it; and was the first who with any ac- 
curacy described those crooked substanctes lying on each side of the spine, near the head, which he considered as 
muscles (from thence named ʃʃʃʃʃ) that projected, 

according to him, certain effluvia, occasioning the fen- 
fation of numbnes more or less, as the animal was excited to put 
these organs into action. This hypothesis of the transmis- 
tion of effluvia was immediately embraced by Lorenzini, 
and afterwards by Claude Perrault. Borelli, not admitting 
the emission of benumbing particles, referred the fen- 
fation produced by this fish to a certain brill undulation of the 
parts touched, which the animal could excite at will.

In 1714, M. Reaumur, being on the coast of Poitou, 
took an opportunity of making some experiments on the 
torpedo, which, with the result, he communicated to the 
Royal Academy of Sciences at Paris. His hypothesis, 
which was generally received by the ingenious naturalists 
over all Europe, is not very different from that of Borelli; 
for instead of the undefined vibrating parts of the latter, 
M. Reaumur substituted muscles (the ʃʃʃʃʃ of Redi and Lorenzini) which, by the 

vividness of their action, 

impressed upon the hand, that touched these parts, a sen- 
fation of numbnes, owing to the foppage of the progression 
of the nervous fluid, or a repulsion of the same. But he 
denied that this impression of numbnes could be commu- 
nicated through water, a net, or any other soft and yielding 
substance; nay, through a stick, except a very short one; 
whereas, it is certain, that the shocks of the torpedo are 
not less conducted through such media than those from a 
charged electrical phial.

We have been lately furnished, by the experiments and 
observations of John Walsh, esq. with a theory, much more 
plausible and just than any above recited, which considers 
the electric fluid as the efficient cause of the amazing qua- 
lities of the torpedo. We shall be led to a brief account of 
the facts on which this theory is founded by the follow- 
ing preliminary remarks.

Soon after the discovery of the Leyden phial, the cele- 
brated professor Allemand applied to M. s'Gravefande, go- 
vornor of Exequibo, for an account of a fish in Surinam, 
resembling a conger-eel, and possessing properties similar to 
those of the torpedo; this account was received in 1754, 
and published in the second volume of the Transaotions of 
the society at Haerlem. From this account it appears, 
that the shocks of the fish, which were so violent, when the 
fish was strong and lively, as to throw a person who touched 
it to the ground, were like those of the electrical fire, but 
unaccompanied with sparks of fire; and that the fish was a 
species of the gymnotus of Artedi. In the sixth volume of 
the same work, we have a more ample relation of the exer- 
cises of this animal by M. Vander Lott, dated from Rio 
Exequibo, in 1761. M. Adanson, about the same time 
with the discovery of M. s'Gravefande in America, met 
with the same or a similar fish in the river of Senegal in 
Africa. The earliest account we have of this kind of eel 
is by M. Richer, recorded by M. du Hamel, in his History 
of the Royal Academy of Sciences for 1777. In the if- 
land of Cayenne, says M. du Hamel, there is a fish, not 
unlike a conger-eel, which, touched with the finger, or even 
with the end of a ftick, affects the arm with a numbnes, 
and the head with giddines, and the eyes with a dimness of 
sight, which M. Richer had himself felt upon making the 
experiment. See Gymnotus.

We are indebted to Mr. Walsh for not only the first, but 
for a numerous series of experiments on the torpedo, in order 
to ascertain its electrical nature; together with some correct 
and elegant drawings of the entire animal, and of some of its 
principal organs that appeared upon dissection. These ex- 
periments were made in the year 1772, partly at the ifle of Rhé, 
and partly at Rochelle, in the presence of the members of 
the Royal Academy of Sciences at that place. They were 
conducted in a scientific manner, and properly diversified, 
and the result of them satisfactorily established the torpedo 
in the rank of an electrician, furnished with a power over 
the electric matter; by means of which he can, without 
any foreign machinery, and almost in an instantaneous man- 
ner, collect, condense, and at his will dispence it to neigh- 
bouring bodies, through any of those substanctes that are 
known to be conductors of the electric fluid. The fen- 
fations occasioned by the torpedo and Leyden phial, in the 
human frame, are precisely similar: not only the shock, 
but the numbing senfation sometimes given by the ani- 
mal, may be exactly imitated with the phial, by means of 
Lane's electrometer; the regulating rod of which, to pro- 
duce the latter effect, must be brought almost into con- 
 tact with the prime conductor which joins the phial. The 
first experiment of Mr. Walsh discovered the elec- 
trical quality of the torpedo, by his conveying its effects 
through the same conductors with his electricity, such as 
metals, water, and animal fluids, and by intercepting it 
by the same non-conductors, as glass and sealing-wax. Be- 
sides, one of the most brilliant of his discoveries was, that 
this animal not only could accumulate in one part a large 
quantity of electrical matter, but was furnished with a cer- 
tain organization, disposed in the manner of the Leyden 
phial: thus, while one surface of the electrical part (e.g. 
that on the back) was charged with this matter, in a posi- 
tive state; the other surface (that on the belly) was de- 
prived of it, or in a negative state: so that the equilibrium 
could be restored, by making a communication between 
the two surfaces by water, the fluids of the human body or 
metals, in the same manner as by forming a circuit between 
the inside and outside surfaces of the Leyden phial. A 
living torpedo was laid on a table, upon a wet napkin; 
round another table stood five persons insulated: and two 
brafs wires, each thirteen feet long, were suspended from 
the ceiling by silkens rings. One of the wires rested by 
each end upon the wet napkin, the other end was immered 
in a basin full of water, placed on a second table, on which 
stood four other bacons full of water. The first per- 
son put a finger of one hand into the water in which the 
wire was immered, and a finger of the other hand into the 
second; and so on successively, till all the five persons com- 
municated with one another by the water in the bacons. In 
de the
the last but one end of the second wire was dipped, and with the other end Mr. Walsh touched the back of the torpedo, when the five persons felt a shock, differing in nothing from that of the Leyden experiment, except in being weaker. Mr. Walsh, who was not in the circuit, was not affected. This experiment was successfully repeated several times, even with eight persons. From this experiment it is evident, that the action of the torpedo is communicated through metals and water, or, in general, through the same media that transmit the electrical concussion. It follows, likewise, that the upper and under parts of the animal, like the upper and under surfaces of an electrified plate of glass, are in different states; for a person who touches only the upper or the under surface of the electric organs, will not receive the shock of the torpedo. This action evidently depends on the will of the animal, who, however, scarcely exhibits any other sensible motion or effort at the time of exerting it than a depression or winking of his eyes. The same motion is observed likewise to accompany its fruitless attempts to transmit a shock through non-conductors. The flock of elecrical matter which the torpedo polishes appears to be very considerable: a torpedo, when inflated, has given to Mr. Walsh, insulated likewise, no less than fifty shocks in the space of a minute and a half.

Such are the operations performed by the torpedo in air. When a large fish, very liberal of his shocks, was held in water, with one hand on his breast and another on his back, he gave the operator shocks of the same kind as before, but about one-fourth of the strength of those given in air. At the very instant of raising him out of the water, he constantly gave a very violent shock, and another nearly as violent, when his lower surface first touched the water on dipping him into it. On briskly and alternately plunging him a foot deeper into water, and raising him an equal height into air, besides one or two shocks which he gave during the short time he was wholly in the water, and those which he gave at the surface, he constantly gave at least two when he was wholly in the air: so that Mr. Walsh estimates that he gave above one hundred shocks during the minute in which the experiment was performed. The conclusions drawn from Mr. Walsh's experiments were further confirmed by some experiments made on the torpedo at Leithorn, by Dr. Ingenhousz, in 1773.

Mr. Walsh observes, that the electricity of the torpedo resides in those parts that are called his electric organs: the parts bordering on these acting, more or less, as conductors, either through their substance, or by their superfluities: and of these, the parts which conduct the heat are the two great lateral fins bounding the organs outwardly, and the space lying between the two organs inwardly. All below the double transverse cartilages scarcely conduct at all, unless when the fish is just taken out of water and is still wet, the mucus, with which he is lubricated, shewing itself, as it dries, to be of an insulating nature; and the organs themselves, when uncharged, appeared to be, not interiorly but rather exteriorly, as Mr. Walsh supposes, conductors of a shock. We are indebted to Mr. John Hunter for an accurate anatomical description of the torpedo, accompanied with two excellent drawings, which has thus supplied us with a valuable addition to the anatomical examination of this animal by Redi, Steno, and Lorenzini. For his account, we refer to Electric Organs of Fish.

Although Mr. Walsh's experiments leave little room to doubt, that the shock given by the torpedo is produced by the same agent that gives the shock in an electrical explosion, yet there are some circumstances which it is difficult to reconcile to the supposition that it is produced by the electric fluid. One of these difficulties is, that the fish is able to give a shock when he is in the water, and consequently surrounded by a medium, through which the electric fluid is known to be transmitted with the greatest facility. It has likewise been difficult to conceive why the shock of the torpedo, supposing it to be produced by the electric fluid, should not, like that of an electrified jar, be accompanied with the appearance of light or sparks, or should not exhibit some signs of attraction or repulsion. But from Mr. Walsh's experiments it appears, that no light could possibly accompany the shock of the torpedo, because this shock could never be made to pass through the least sensible space of air, or the smallest interruption made by the circuit; not even through the imperceptible interval between the links of a slender brass chain, apparently in contact with each other, nor over an almost imperceptible interval or slit formed by cutting through a slit of tin-foil pasted on sealing-wax, which constituted part of the circuit; nor are the most delicate pith-balls, or other light bodies, in what manner soever applied, in the least degree affected at the time of the shock. Mr. Walsh observes, that, with respect to the pith-balls, it is not surprizing that no motion could be discovered in them, as all his experiments fully shewed that there was no gradual accumulation of the electric fluid, as in the case of charged glasses; but that it was collected or condensed in the very instant of the explosion, by a sudden energy of the animal. He also explains this and the other differences between the phenomena of the Leyden phial, and of the torpedo, or the absence of light and found, in the experiments made with the ladder, by the following considerations.

In a large fish, the number of columns above mentioned, contained in one electric organ, was found to be no less than eleven hundred and eighty-two. This immense collection of cylinders Mr. Walsh considers as somewhat analogous to a large number of jars in an electrified battery, and as containing a very large area in consequence of the great number and extensive surface of the columns. Now it is known, from experiments made with artificial electricity, that though the electric matter violently condensed, or crowded into a very small phial highly charged, is capable of forcing a passage through an inch of air, and that it will afford, in a very conspicuous manner, the phenomena of light, sound, attraction, and repulsion; yet if the quantity thus condensed be expanded and rarified, by communicating it to, or dividing it amongst a large number of jars, whose coated surfaces constitute a space, e. g. four hundred times larger than that of the phial: this same quantity of electric matter, thus diluted, will now yield only the fainter, or, if they may be so called, the negative phenomena of the torpedo. It will not now be capable of passing over the one hundredth part of that inch of air, which, in its condensed state, before sprung through with ease; it will not now be able to jump over the little gap made in its track by the intercession of the tin-foil; no spark, found, or attraction of light bodies, will now be perceived; and yet this portion of electric matter, in this diluted state, and with its elacitity thus diminished, will, like that of the torpedo, to effect its equilibrium, run through a considerable circuit of different conductors, perfectly continuous, and will communicate a sensible shock.

The Hon. Mr. Cavendish has endeavoured to remove the difficulties above stated, first, by some ingenious reasonings a priori, and afterwards by others drawn from the phenomena presented by an artificial torpedo which he constructed, and by means of which he has imitated the effects produced by the living animal. With respect to the diffi-
faculty of conceiving how the torpedo can give a shock in water, he observes that those electricians are mistaken, who suppose that the electric fluid will only pass along the shortest and best conductors. When different circuits are made (e.g. by means of iron wire, and the human body) between the positive and negative sides of a charged jar, some parts of the electric fluid will pass along each of them; though the greater quantity will pass through those in which it meets with the least resistance. Thus, a person may receive a part of the shock given by the torpedo in water, by holding one hand on the lower surface of an electric organ, and the other on the upper, or by applying his hands to other parts of the fish, or by dipping them into the water, so that one hand is nearer to the upper surface of the electric organs than the other; yet the greater part of the shock or charge may pass at the same time in all directions over the surface of the fish, or through the substance of its body, or through the water contiguous to it. With respect to the other difficulties, he solves them by reasonings similar to those urged by Mr. Wallh, and by concouring experiments. Mr. Cavendish has confirmed these reasonings by means of his artificial torpedo, which is a piece of wood A B C D E (Plate XV. Electricity, fig. 4.) of which the part A B C D E is cut into the shape of the torpedo, and 10 inches long from A to D, and 10 inches broad from B to E: the part C F G D is forty inches long, and serves for a handle. M N m is a glass tube let into a groove cut in the wood: W w is a piece of wire passing through the glass tube, and folded at W to a thin piece of pewter, R r, lying flat on the wood, and intended to represent the upper surface of the electric organs: on the other side of the wood there is placed another glass tube, with a wire passing through it, and folded to another piece of pewter like R r, intended to represent the lower surface of those organs. The whole part A B C D E is covered with a piece of sheep-skin leather. In making experiments with this apparatus, after thoroughly foaming it in water of the salt-tubs of the sea, made by dissolving one part of common salt in thirty parts of water, the end of one of the wires is fastened to the negative side of a large battery, and when it is sufficiently charged, the positive side is touched with the end of the other wire; by which means the battery will be discharged through the torpedo. In experiments with this torpedo under water, Mr. Cavendish țakes a trough, A B C D E (fig. 5.), the length B C of which is nineteen inches, the depth A B fourteen inches, and the breadth thirteen inches. The battery which he used was composed of forty-five jars, of very thin glass, dipped in seven rows, and so contrived, that he could use any number of rows at pleasure. Mr. Cavendish was enabled, by means of this apparatus, when immersed in water, to give shocks much resembling those given by the living animal. He felt similar convulsions likewise when he dipped his hands in the water, at the distance of two or three inches from it; and as it is affirmed, that a person accidentally treading on the living fish, when buried in the sand, is sometimes shocked by it, he imitated this experiment with his artificial torpedo, and received shocks from it. The events, indeed, in the greater part of his experiments, too numerous to be recited in this place, with this artificial fish, relative to the shock, seem to agree sufficiently with those made by Mr. Wallh with the living animal. The experiments which Mr. Cavendish made with this machine, relative to the circumference of the shock of the real torpedo not being able to pass through any sensible space of air, appear likewise to correspond with Mr. Wallh's trials. A piece of sealing-wax covered with tin-foil freely conducted a shock from the artificial torpedo; but on making as small a separation as possible through the metal with a penknife, the shock would not pass. See on the subject of this article for Mr. Wallh's papers, Phil. Trans. vol. lxi. part ii. p. 461. Id. vol. lxiv. part ii. p. 464. For Mr. Hunter's paper, Id. vol. lxii. part ii. p. 481. For Dr. Ingenhouz's, Id. vol. lxv. part i. p. 1. For Mr. Cavendish's, Id. vol. lxvi. part i. p. 169. See also Sir John Pringle's Six Discourses, &c. by Dr. Kippis, p. 45, &c.

TORPEDO, a machine so called, invented by Mr. Fulton of the United States, and defined to blow up the largest ships. It is an apparatus of which the principal piece is a copper-box, including a certain quantity of gunpowder, and prepared with an interior spring which sets fire to the powder, at the same time that the whole is inclosed in a covering of cork, or some other light wood, to make the torpedo float under the surface of the water. It is placed under the keel of the vessel to be destroyed, by means of an harpoon directed against the sides of the ship.

TORPEN, in Geography, a town of Transylvania; 4 miles S.S.W. of Bitiriz.

TORPERLEY, a town of England, in the county of Chelfter; 10 miles S. E. of Chelfter.

TORPETCHIN, a town of Thibet; 100 miles S. of Haratoubé.

TORPHICHEN, a parish in the shire of Linlithgow, Scotland, is situated four miles S. by W. from the shire-town, and extends about nine miles in length, and two and a half in breadth. Its general appearance is hilly, particularly towards the E. end, where the hill called Cairn Naple is situate, which is elevated 1498 feet above the level of the sea. The greater part of the parish is enclosed, and where the land is unfit for cultivation, considerable plantations have been made. Coal is abundant; and here are large quarries of excellent freestone; several seams of ironstone, rich in metal; and a strong chalybeate spring. In the year 1811, the population was returned as 1137, occupying 236 houses. The hospital or preceptory of Torphichen, long the principal residence of the knights of St. John of Jerusalem, was founded, in 1120, by King David I. The choir and a square tower still remain, and are fine specimens of the elegance and beauty of the architecture. There are two wings, one on the S. and the other on the N. side; and evident marks of other two on the E. and W. This preceptory had the privilege of sanctuary, which is supposed to have extended a mile in every direction; there is a tower in the church-yard as a centre, and four others at the distance of a mile, E., W., N., and S., with St. John's crofts upon them, which stand about two feet above the surface. At the Reformation, the wall eftates of that opulent order were converted into a temporal lordship, in favour of Sir James Sandilands, Lord St. John of Jerusalem; in which noble family the title of lord Torphichen still remains. Near Loch-Coat, in this parish, are the ruins of a castle, which still display baronial gloom and grandeur. About a mile to the E. of the village, is an altar of four great unpolished whin-זלones, which is said to have been a druidical place of worship; and about a mile to the N.W., is Boudane Hill, upon which are evident marks of a military station.—Beauty's Scotland, vol. iii. Linlithgow. Carlisle's Topographical Dictionary of Scotland.

TORPON, a town of Little Bucharia; 20 miles S.W. of Acula.

TORQUATA, in Zoology, a name given by many authors to the common or water-snake, from the remarkable ring it has about its neck. See Natrix.

TORQUE, in Heraldry, a round roll of cloth twisted and
and studded: such is the bandage frequently seen in armories about the heads of Moors, favages, &c.

It is always of the two principal colours of the coat. The tórque is the least honourable of all the enrichments worn on the helmet by way of crest.

TORQUEMADA, John de, in Biography, a cardinal, was born at the place in Spain whence he took his name in 1388, and entered at the age of 15 into the Dominican order at Valladolid. He distinguished himself at home, in the univerity of Paris, and in various other places, and at length was promoted to the cardinalate, under the title of St. Sixtus, in 1439. After having been successively translated from one bishops to another, he died in 1468, at the age of 80 years. He published a great number of works on theology, and in defence of the papal authority. Among other prefaces which he enjoyed, he was confessor to Isabella of Castile from her infancy; and such was the intimate zeal that actuated him, he extorted from her a promise, that if the ever came to a throne, she would make the chastisement and destruction of heretics his principal object.

Another person of the same name was provincial in New Spain, and published a Spanish work under the title of “Monarquía Indiana;” or, A History of the Wars, Discoveries, Conquests, &c. in the West Indies, in 22 books, 3 vols. fol. 1615. Dupin. Moreri.

TORQUEMADA, in Geography, a town of Spain, in the province of Leon, on the Arzànna; 12 miles E. of Palencia.

TORQUILLA, in Ornithology, the name of a species of wood-pecker, more commonly known by the name of jynx, and called in English the nory-neck.

TORQUINO, in Geography, a river of Cuba, which runs into the Spanish Main, N. lat. 20°. W. long. 76° 37'.

TÔRR, a town of Arabia, in the province of Yemen; 32 miles E. of Loheia.

TORRALBA, a town of Spain, in New Castile; 7 miles N.E. of Ciudad Real.

TORRALVA, a town of Spain, in Navarre, 15 miles from Leltella.

TORRANO, in Geography, a town of Spain, in Navarre; 15 miles W. of Pamplona.

TORRÉ, Filippo del, in Biography, an eminent antiquary, was born at Ciudad de Friuli in 1657, and having acquired an extensive knowledge of jurisprudence, mathematics, and anatomy at the university of Padua, he fought farther improvement at Rome in 1687, and became an academician of the college of the Propaganda. He was afterwards employed as auditor to cardinal Imperiali, in his legation to Ferrara, and accompanying him on his return to Rome, he devoted his attention to the great work on the antiquities of Antium, which he published in 1700. In 1702 he was nominated by pope Clement XI. to the bishopric of Adria, and there he presided with great reputation till his death, in 1717. Among his writings we may mention as the principal, his "Monumenta Veteris Antii," 4to.; besides which, he published several other dissertations on antiquities, natural history, &c. and left many more in MS. Gen. Bifog.

Torre, John Maria de la, a celebrated Italian philologist, was born at Rome in 1710, studied at the Clementine college, and was elected professor of mathematics and philosophy in the college of Ciudad, in the Frioul; and afterwards removed to Naples, where he taught the same sciences in the archiepiscopal seminary. In 1754 he was appointed librarian to the king of Naples, superintending the royal printing-house, and conservator of the museum. In the construction of microscopes he is said to have made considerable improvements. He was a member of the principal academies in Italy, and a correspondent of those of Paris and Berlin, and of the Royal Society of London. He died in March 1782. His works, besides a Treatise on Arithmetic, are, "The Science of Nature," Naples, 1749, 2 vols. 4to.; "Elementa Physice," Naples, 1767, 8vo.; "History of the Phenomena of Vefuvius," ibid. 1755, 4to.; "Microscopic Observations," ibid. 1776.

Torre, in Geography, a town of Spain, in Catalonia; 6 miles S. of Lerida.

Torre del Acri, or Agri, a town of Naples, in Basilicata, on the coast of the gulf of Tarento; 25 miles S.S.E. of Matera.

Torre del Annuntiata, a town of Naples, in Lavora; 9 miles S.E. of Capua.

Torre Cilenza, a town of the island of Corfica; 15 miles N.E. of Ajazzo.

Torre de Candela, a town of Naples, in Capitanata; 11 miles W.S.W. of Manfredonia.

Torre Capigliola, a town of the island of Corfica; 10 miles N. of Ajazzo.

Torre del Capo di Raffo, a town of Naples, in Calabria Citra; 18 miles N.E. of Cañano.

Torre Carabba, a town of the island of Corfica; 10 miles W.S.W. of Vico.

Torre di Codagni, a town of Spain, in Catalonia; 9 miles N. of Puyerdà.

Torre di Fr anonof, a town of Naples, in Lavora; 8 miles N.W. of Capua.

Torre di Galleria, a town of the island of Corfica; 15 miles S. of Calvi.

Torre la Gattarella, a town of Naples, in Capitanata; 2 miles S. of Viefe.

Torre Girolata, a town of the island of Corfica; 20 miles S. of Calvi.

Torre del Grifo, a town of Naples, in Lavora. This town was destroyed by an eruption of Vefuvius; yet the inhabitants, after the eruption, returned and rebuilt the town on the same spot; 5 miles S.E. of Capua.

Torre Maggiori, a town of Naples, in Capitanata; 5 miles S.W. of St. Serviero.

Torre di Mere, a town of Naples, in Basilicata; 20 miles S.E. of Matera.

Torre di Mezzo, a town of Italy, in the department of the Mincio; 16 miles E.S.E. of Mantua.

Torre Molina, a town of Spain, in Grenada; 12 miles from Antequera.

Torre de Monsuro, a town of Portugal, in the province of Tras os Montes, surrounded with a wall, and defended by a baliffion and a caflle. The number of inhabitants is about 1300; 42 miles S.S.W. of Bragança. N. lat. 41°. W. long. 6° 44'.

Torre di Nespoli, a town of the island of Sardinia; 5 miles N. of Orilltagna.

Torre di Negara, a town of Italy, in the department of the Mincio; 11 miles E. of Mantua.

Torre d'Oglio, a town of Italy, in the department of the Mincio, near its union with the Po; 11 miles S.S.W. of Mantua.

Torre del Penna, a town of Naples, in Abruzzo Citra, on a promontory, near the Adriatic; 15 miles E. of Lanciano.

Torre Rosso, a town of Naples, in the province of Otranto; 10 miles N. of Tarento.

it became dry. The fire, it is thought, would eat along the surface without penetrating deep, when a body of moist watered peat lay below, and not only convert the earth within its reach into brick-dull, but consume many of the incorruptible elastic fibres by which the soil is kept too loose. And by the mixture of incombustible earth checking the rapidity of the combustion, most of the peat would be converted into a sort of charcoal, not ashes. The residue might be mingled with the subsoil, and the field would then be in excellent condition, it is said, for any crop, particularly for turnips; and there is, perhaps, no plant better adapted to such a situation, from its power to refill the autumnal frosts, by which some other cultivated plants are often ruined. See the Paper.

The same writer has, indeed, proved the great disposition of this powdery substance to produce fertility in a variety of experiments, which he has recorded in an elementary work on agriculture, already before the public. See Nisbit's Elements of Agriculture.

**TORRICEILLI, EVANGELISTA,** in Biography,* a very distinguished mathematician and philosopher, was born at Faenza in 1608, and at the age of eighteen he went to Rome to complete his education, and particularly to extend his acquaintance with mathematicians, under the instruction of Benedetto Castelli, who was professor of mathematics in that city. After the perusal of Galileo's "Treatise on Motion," he composed a work of a similar kind, which being shown to Galileo by Castelli, excited his admiration, and induced him to invite the young author to his house. But as Galileo died three months after his arrival, he proposed to return to Rome; he was diverted, however, from his purpose, by being appointed mathematician and philosopher to the grand duke Ferdinand II., who also advanced him to the mathematical chair at Florence. In this honourable situation he affidavously prosecuted his speculations and experiments, till death prematurely deprived the world of the benefit which could not fail to result from them, in the year 1647, at the age of 39 years. His "Treatise on Motion," already mentioned, was published in a "Collection of his Mathematical Works" in 1644. Of his dispute with Roberval concerning the Cycloid, we have already given a short account under that article. But Torricelli's fame is sufficiently established by his discovery of the true principle upon which the barometer is constructed. (See Torricellian.) Torricelli was no less celebrated for his mathematical knowledge, evinced by his improvement of the science of indivisibles discovered by Cavalieri, and for his acquaintance with the principles of optics, by which he was led to improve the construction of telescopes and microscopes. His discoveries, by which his name is immortalized among the promoters of useful sciences, are recorded in his "Lezioni Academiche," published at Florence in 1715, 4to, by Buonaventura, with the life of Torricelli prefixed. The style with which he wrote in his native language was pure and elegant, and his general character was such as to command the respect and esteem of all who knew him.

**TORRICEILLIAN, a term very frequent among physical writers, used in the phrases Torricellian tube, or Torricellian experiment, on account of the inventor, Torricelli, a disciple of the great Galileo.**

**Torricellian Tube,* is a glass tube, open at one end, and hermetically sealed at the other, about three feet long, and one-tenth of an inch in diameter. See Barometer.

**Torricellian Experiment,* is performed by filling the Torricellian tube with mercury, and then stopping the open orifice with the finger, inverting the tube, and plunging that orifice into a vessel of stagnant mercury. This done, the finger is removed, and the tube sustained perpendicular to the surface of the mercury in the vessel.

The consequence is, that part of the mercury falls out of the tube into the vessel, and there remains only enough in the tube to fill from twenty-eight to thirty-one inches of its capacity, above the surface of the stagnant mercury in the vessel.

These twenty-eight, &c. inches of mercury are sustained in the tube by the pressure of the atmosphere on the surface of the stagnant mercury; and according as the atmosphere is more or less heavy, or as the winds, blowing upwards or downwards, heave up or depress the air, and so increase or diminish its weight and spring, more or less mercury is sustained from twenty-eight inches to thirty-one.

There is a cafe, however, first taken notice of by Huygens (Journal de Scav., 1672, p. 111) in which, if a glass tube of a small bore beventy or eighty inches in length, is well cleaned, and filled with mercury well purged of
of air, &c. in the manner described under Barometer, and then carefully inverted into a vessel of flagrant mercury, the mercury, instead of coming down to the height just mentioned, at which the pressure of the atmosphere is able to sustain it, will continue to fill the tube, and stand at the height of seventy-five inches: but by striking the tube, or gently shaking it, the mercury will descend and settle at its proper height, as in the common barometer. This phenomenon is explained on the principles of the attraction of cohesion, which acts most powerfully in contact: for when the tube is clean, and the mercury well purged of air, many parts of the mercury, which, by the interpolation of small air-bubbles, would be kept from touching the tube, are brought into contact with it, and those particles that are in the middle of the column adhere to those that are next to the sides of the tube, and thus form a compact column. Besides, the increase of attracting surface at the arched top of the tube, by means of which a greater number of mercurial particles may come into contact with the glass than those that recede from the contact of one to another, will also give an advantage to the attraction of the glass, and cause the mercury, immediately in contact with it, to adhere to it. That the attraction of cohesion, as already explained, is the cause of this phenomenon is plain, because the experiment will not succeed when the mercury is not well purged of its air, nor even then if the bore of the tube is large.

The Torricellian experiment makes what we now call the barometer.

**Torrcellian Vacuum**, is the vacuum produced by filling a tube with mercury, and allowing it to descend to such a height as is counterbalanced by the pressure of the atmosphere, as in the Torricellian experiment and barometer. For the method of rendering this vacuum luminous by electricity, see Electrical, Exp. 15.

**Torrichelio**, in Geography, a town of the duchy of Parma, on the Po; 12 miles N.N.W. of Parma.

**Torrizone**, See Zone.

**Torrigia**, or Torreglia, in Geography, a town of the Ligurian republic; 15 miles N.N.E. of Genoa.

**Torrilios**, a town of Spain, in New Castile; 15 miles N.W. of Toledo.

**Torrimore Head**, a cape of Scotland, on the E. coast of the island of Skye. N. lat. 57° 42'. W. long. 6° 2'.

**Torrin-Beg**, a rock on the S.W. of the island of Mull. N. lat. 56° 19'. W. long. 6° 20'.

**Torrington**, or Great Torrington, as it is generally called, to distinguish it from a village of the same name, is a market-town in the hundred of Fremington, and county of Devon, England; 36 miles N.W. from Exeter, and 197 miles W. by S. from London. The town is situated, partly on the summit, and partly on the declivity of an eminence which forms the eastern bank of the river Torridge. On the south side are some fine villages of an ancient castle, the origin of which is unknown; though, according to Ridgion, it was the head of a notable barony, which continued from the Conquest to the time of Edward I. Its feite is now used as a bowling-green, and commands a fine prospect. The river is here feen to flow in a graceful current along a narrow valley, inclosed by sloping ridges, and having a beautifully wooded back-ground. Torrington was formerly invested with the privilege of having representatives in parliament; but no return has been made since the reign of Henry VI. Its government is vested in a mayor, eight aldermen, and sixteen burgesses, who act under a charter granted by queen Mary. The town consists chiefly of one long street, "indifferently beautified," says Ridgion, "with buildings very populous, and flourishing with merchants and men of trade." The population return of the year 1811, states the number of houses to be 414; the number of inhabitants 1571: the chief employ of the latter arises from the woollen manufacture. A weekly market is held on Saturdays; and here are four annual fairs. The parish contains two churches, the most ancient of which is furnished with a library. In the town are some ancient almshouses, possessing the right of commonage on an extensive piece of ground given by William Fitz-Robert, baron of Torrington, in the reign of Richard I. Here is likewise a charity-school for thirty-two boys. Margaret, countess of Richmond, mother of Henry VII., resided some time in Torrington, and was a considerable benefactor to it.

At Fritheletoke, a village opposite Torrington, on the W. side of the Torridge, are the ruins of a priory, founded by sir Roger Beauchamp, in the reign of Henry III., for secular Angliine canons. At the dissolution, the annual revenues were valued at 127/. 22. 4d. The feite of the priory is now a farm-yard. The chief remains of the buildings are the walls of two or three apartments, the west window of the conventual church, which still continues perfect, and the great gate.

Near Torrington is Crofs, late the seat of H. Stevens, esq., a handsome mansion, looking down on the romantic scenery which encompasses the bridge and the banks of the Torridge.

A few miles from Crofs, southward, are the ruins of an old manor called Heanton, formerly a seat of the Rolles, afterwards of lord Orford, and lastly of lord Clinton, who, after its late demolition by fire, cut down the oaks which were in the park, forming woods and groups of the noblest trees in the county.—Beauties of England and Wales, vol. iv. Devonshire, by J. Britton and E.W. Brayley, 1805. Polwhele's History, &c. of Devonshire, folio, 1797.

**Torrington**, a town of the rate of Connecticut; 22 miles W.N.W. of Hartford.

**Torrington Bay**, or Bedford's Bay, a bay on the S. coast of Nova Scotia; 3 miles N. of Halifax.

**Toro**, a river of Africa, which runs into the Scherbro.

**Torriff**, a town of Bengal; 70 miles N.E. of Dacca. N. lat. 24° 20'. E. long. 85° 18'.

**Torrum**, a town of Sweden, in the province of Blekingen; 10 miles S.E. of Carlserna.

**Torryburn**, a seaport town of Scotland, in Fifeshire, on the Frith of Forth, with a good harbour, to which belong thirteen vessels, amounting to upwards of 1000 tons.

**Torsaker**, a town of Sweden, in Angermanland; 27 miles N. of Hernosand.—Alfo, a town of Sweden, in the province of Geftricia; 15 miles S.W. of Gelle.

**Torsang**, a town of Sweden, in the province of Dalecarlia; 10 miles S. of Falun.

**Torsas**, a town of Sweden, in the province of Smalandsland; 18 miles S.S.W. of Calmar.—Alfo, a town of Sweden, in the province of Smalands; 16 miles S.W. of Wexlo.

**Torseera**, a town of Hindoostan, in the circus of Sambulpour; 16 miles S. of Sambulpour.

**Torsella**, a town of Sweden, in Sudermanland, on the river which runs into the Mazar lake; 46 miles W. of Stockholm.

**Toshok**, a town of Russia, on the route from Peterburgh to Moscow; 71 versts distant from Vvihyrov-Volokh, remarkable for a spring supernaturally venerated and attracting pilgrims from all parts. This town has no less than 20 churches, some of stone; and is in a thriving condition. See Tonzok.
TORSIANO, a town of the Popedom; 10 miles N. of Perugia.

TÖRSKOG, a town of Sweden, in West Gothland; 53 miles N. of Uddevalla.

TORSO, a small island on the E. side of the gulf of Bothnia. N. lat. 63° 57'. E. long. 22° 14'.

TORSKA, a town of Sweden, in Helsingland, on a river which runs into the gulf of Bothnia; 6 miles W. of Hudickewall.

TORSUTATAS, a town of East Greenland. N. lat. 59° 56'. E. long. 43° 15'.

TORT, in Law, denotes injustice, or injury, as de font trett mene, in his own wrong, &c.

Hence, also, tort-feafor, &c. The word is pure French, and it signifies the same.

Actions upon torts, or wrongs, are all personal actions for trespasses, nuisances, assaults, defamatory words, and the like.

Tort, Executor de font. See Executor.

TORTICOLLIS, from torto, to twist, and collum, the neck; the Wryneck; which see.

TORTO, in Geography, a small river of Spain, which runs into the Orbeaga, in the province of Leon.—Also, a river of Sicily, which runs into the sea, 5 miles E. of Terminii.

TORTOISE, in Zoology. See Testudo.

Dr. Parsons has remarked a singularity in the structure of the wind-pipe of the land-tortoise, which for a few inches from the epiglottis is single, but soon divides into two; and as it descends with the esophagus, forms a folded ring outward on each side, and turns down again to enter the lungs; so that this animal has the advantage of a double apera arteries, with a solution in each; which proves that this provision is intended to contain a greater portion of air than ordinary, while he is under-ground in winter. It has been observed likewise, that the principal use of the lungs in tortoises is to render them specifically lighter or heavier in the water, by their inflation and compression at pleasure, as fishes do by their swimming bladders; and such a power of long inspiration seems to be as necessary in the land-tortoise as in that of the sea; because, in many countries where they breed, they are known to go into the ground, and lie concealed for several months, and several species of land-tortoises go into ponds or canals in gardens, where they are kept, and remain long under water. Phil. Trans. vol. IV. p. 213.

Tortoise-shell, the shell, or rather scales of the testaceous animal, called a tortoise; used in inlaying, and in various other works, as for inlaid boxes, combs, &c. Mr. Catesby observes, that the hard strong covering, which encloses all sorts of tortoises, is very improperly called a shell; being of a perfect bony contexture; but covered on the outside with scales, or rather plates, of an horny substance: which are what the workmen call tortoise-shell. Phil. Trans. No. 438, p. 147.

It is the testudo imbricata of Linnaeus alone, which furnishes that beautiful shell, so much admired in Europe. See Testudo Imbricata.

The lamellae or plates of the shell of this tortoise, called the hawksbill turtle, are much stronger, thicker, and clearer than those of any other kind, and constitute the sole value of the animal. They are semi-transparent, and elegantly variegated with whitish, yellowish, reddish, and dark brown clouds and undulations, so as to imitate, when properly prepared and polished, one of the most elegant articles for ornamental purposes. These laminae form the external coating, and this is raised or separated from the bony part, which it covers, by placing fire beneath the shell; the heat from causing the plates to split, so as to be easily detached from the bone. These plates vary in thickness, according to the age and size of the animal, and measure from an eighth to a quarter of an inch in thickness. A large turtle is said to afford about eight pounds of tortoise-shell; or, according to M. Schoepf, from five to fifteen or twenty pounds; and unless the animal itself be about the weight of 150 pounds, the shell is not worth much.

"In order to bring tortoise-shell into the particular form required on the part of the artist," says Dr. Shaw, "it is steeped in boiling water, till it has acquired a proper degree of softness, and immediately afterwards committed to the pressure of a strong metallic mould of the figure required; and where it is necessary that pieces should be joined together so as to compose a surface of considerable extent, the edges of the respective pieces are first cramped or thinned, and being laid over each other during their heated state, are committed to a strong press, by which means they are effectually joined or agglutinated. These are the methods also by which the various ornaments of gold, silver, &c. are occasionally affixed to the tortoise-shell, which is not capable of being melted, as vulgarly supposed. The Greeks and Romans appear to have been peculiarly partial to this elegant ornamental article, with which it was customary to decorate the doors and pillars of their houses, their beds, &c. In the reign of Augustus, this species of luxury seems to have been at its height in Rome." Shaw's General Zoology, vol. iii. pt. 1.

The Egyptians, says Mr. Bruce in his Abyssinian Travels, dealt very largely with the Romans in this elegant article of commerce. According to Pliny, the cutting of them for fineering or inlaying was first practised by Carvilius Pollio; and this circumstance leads us to presume, that the Romans were not acquainted with the art of separating the laminae by fire placed in the inside of the shell, when the meat is taken out; for these scales, though they appear perfectly distinct and separate, nevertheless adhere, and more frequently break than split, where the mark of separation may be distinctly seen. "Martial says, that beds were inlaid with it. "Juvenal and Apuleius mention, that the Indian bed was all-over inlaid with tortoise-shell on the outside, and swelling with swelling down within. The immense use made of it at Rome may be inferred from what Vellius Paterculus says, who observes, that when Alexandria was taken by Julius Cæsar, the magazines were so full of this article, that he proposed to have made it the principal ornament of his triumph, as he used ivory afterwards, when triumphing for having happily finished the African war. This indulgence has been, in more modern times, a great article in the trade to China.

Tortoise-shell colour may be given to horn, by first preheating the horn, as in proper plates or scales, and tempering two parts of quick-water, and one part of litharge, to the consistence of a soft paste with soap-ley. Let this paste be laid over all the parts of the horn, except such as are proper to be left transparent, and thus let it remain till it be thoroughly dry; when the paste being brushed off, the horn will be found partly opaque and partly transparent, like tortoise-shell. Semi-transparent parts may be added, by mixing whit with some of the paste to weaken its effect in particular places, by which means spots of a reddish-brown will be produced, which will increase the beauty of the work as well as its resemblance of real tortoise-shell. Haudmann to the Arts, vol. i. p. 518.

Tortoise, in the Military Art. See Testudo.

Tortoise, River of, in Geography, a river of North America, in Louisiana and Florida, formed by the Mississippi.
TORTOLA, a town of Spain, in New Castile; 5 miles N.E. of Guadalaxara.—Alfo, a town of Spain, in New Castile; 8 miles S. of Cuenca.—Alfo, one of the Virgin islands in the West Indies, first settled by a party of Dutch Bascueller, who built a fort for their protection; but who, in the year 1666, were driven out by another party of the same adventurers, calling themselves English, and pretending to take possession for the crown of England: and the English monarch, if he did not confirm the enterprise, made no scruple to take the benefit of it; for Tortola and its dependencies were soon afterwards annexed to the Leeward island government, in a commission granted by king Charles II. to sir William Stapleton. The Dutch had done little towards the cultivation of the island, when they were expelled; but the chief merit of its improvements was reserved for some English settlers from the little island of Anguilla, who, about a century and a quarter ago, embarked with their families and settled in the Virgin Islands; which fee. Tortola is not more than 15 miles long and 6 miles broad. Its chief and almost only staple productions are sugar and cotton. N. lat. 18° 20'. E. long. 64° 52'.

TORTOLI, a town of the island of Sardinia, near the E. coast: 50 miles N.N.E. of Cagliari.

TORTONA, a town of France, in the department of Marengo, on the Scrivia; late the fee of a bishop, suffragan of Milan, with a good citadel, situated on an elevation. This place has often been taken and retaken during the different wars in Italy. It gives name to a district called Tortonese; 9 miles E. of Alexandria. N. lat. 44° 35'. E. long. 8° 52'.

TORTORELLA, a town of Naples, in Principato Citera; 5 miles N.E. of Policastro.

TORTORICI, a town of Sicily, in the valley of Demona; 30 miles N.W. of Taormina. N. lat. 38° 9'. E. long. 15'.

TORTOSA, a town of Spain, in the province of Catalonia, situated near the Ebro, about 15 miles from its mouth; the fee of a bishop, suffragan of Saragossa. It is said to have been founded 2000 years before the Christian era, but the proofs of this illustrious origin are unfortunately lost. Scipio gave it the name of "Dordosa," and made it a municipal city. Among the numerous and trifling combats between the Spaniards and the Moors, there was one in which the women of Tortosa signalized themselves. They courageously mounted the ramparts of their city, and performed such prodigies of valour, that Raimond Berenger, the laft count of Barcelona, interested for them, in 1170, the military order of the hacha, or flambeau. They merited and obtained the fame day several honourable privileges, which exit not at present; they have however preserved the right of precedence in matrimonial ceremonies, let the rank of the men be ever so distingushed. The most remarkable buildings are the cathedral and the castle; the latter of which is a mile square, and in a state of decay; and only serves as a place of residence for a governor; 81 miles S.E. of Saragossa. N. lat. 40° 47'. E. long. 0° 26'.

Alfo, a sea-port of Syria, in the pachalic of Tripoli, long called "Antaradus" and "Orthoia." This town appears to have been built about the fifth or sixth century; it is situated on the sea, and may be about three-quarters of a mile in circumference. The ancient walls are of large hewn stone; without them there are other lower walls, with a fosse round them. At the N.W. corner there are great remains of the castle, and the present town is within the walls of it, which are strong, and built of large hewn stone, justificated. They are of a surpising height, being at least fifty feet high, and the whole is near half a mile in circuit. Within the castle there is a church. Towards the E. cor-
TORTULA.

E.F. Ch. Capfule oblong. Fringe simple, of numerous capillary teeth, spirally and repeatedly twisted together.

This is a most natural genus, the character of whose fringe cannot be mistaken. Barbula of Hedwig differs only in having round-headed male flowers, on a separate plant from the female, instead of axillary bud-like ones, on the same individual. This is a difficult and obscure distinction, without any natural difference. Of Barbula Hedwig defines twelve species, of Tortula three. Of the two genera united, nineteen are now enumerated as natives of Britain and Ireland only, exclusive of five of Hedwig's, not as yet discovered among us, so that twenty-four are known in all.

The habit of the genus here described is rather dwarf; the stems erect, sometimes short or nearly wanting; roots fibrous, mostly perennial; leaves entire; fruit-flasks terminal or lateral; capsule nearly erect, generally even, rarely furrowed; lid conical or awl-shaped; fringe long, brown, or deep red, elegantly twisted, its points rather loose and spreading.

The species are, in many cases, difficult to ascertain, and probably some of the smaller ones are too much multiplied. All our native ones are figured in English Botany. We shall here select some of the principal, in order to exhibit, as in other instances, a comprehensive view of the genus.

T. rigida. Rigid Screw-moss. Fl. Brit. n. 1. Engl. Bot. t. 180. (Barbula rigida; Hedw. Crypt. v. 1. 65. t. 25. Bryum rigidum; Huds. 477. B. acaulon, erica tenuifolia Gerardi folio; Dill. Mucf. 388. t. 49. f. 55.) Stem very short. Leaves spreading, rigid, involute, obtuse, riebels. Capsule cylindrical. Lid conical. Found on rocks, walls, chalky banks and cliffs, bearing capsules in the winter and early spring, not only in England, but in various parts of Europe, from Sweden to Greece. The writer of the present article first discovered and distinguished this humble moss, since the time of Dillenius, on a bank on the right hand of the road from Norwich towards Yarmouth, a little beyond Thorpe. It agrees in size with the most common of mosses, T. muralis, hereafter mentioned, but differs in the thickness and dark colour of its almost linear leaves, which have no hair at the point. The fruit-flask is solitary, red, half an inch to an inch high. Capsule inelining, cylindrical, smooth, dark brown, with a slender veil and lid. Fringe brown, of thirty-two fine teeth. The foliage is incurred when dry.

41. Schrad. Spicil. 66.)—Stem much branched. Leaves all ovate, acute, keeled, with a midrib. Sheaths between the branches, imbricated. More common than the last, in England, Sweden, and Germany, bearing capsules in May. The tusks of this are much higher, the branches being longer and more numerous. Leaves more ovate and pointed; those of the frute more numerous, ribbed, imbricated, not rolled together, differing little from the proper foliage. Fruit-flasks tawny, or red. Capsule erect, somewhat ovate, smooth, with a shorter thicker lid than that of T. convoluta, with which the present species has usually been confounded.

T. flarrellata. Starry Furrowed Screw-moss. Fl. Brit. n. 6. Engl. Bot. t. 2384. (Bryum flarrellatum; Dickf. Crypt. f. 2. 6, excluding the synonyms.) Stem none. Leaves ovate, keeled, incurved. Capsule erect, ovate, somewhat cylindrical, furrowed. Lid oblique. Hitherto gathered only by our great English cryptogamist Mr. Dickson, about Banks, and by the sides of rivers, in Scotland. The synonymy he has applied to it are justly pointed out by Hedwig as erroneous, and belong in fact to three different species. But Hedwig himself error far more unaccountably, in affording Mr. Dickson's moss to be merely T. convoluta. The want of a stem, smaller size of the whole plant, and, above all, the strongly furrowed capsule, singular perhaps in the whole genus, afford sufficient distinctions. The fringe and lid are as long as the capsule; the leaf much longer. There appears to be no frute to the solitary fruit-flask, whose height is half an inch.

T. ruralis. Great Hairy Screw-moss. Ehrh. Crypt. n. 184. Fl. Brit. n. 7. Engl. Bot. t. 2070. (Barbula ruralis; Hedw. Sp. Mucf. 121. Bryum ruralfe; Linn. Sp. Pl. 1581. B. ruralae unguiculatum hirutum, elatius et ramofoius; Dill. Mucf. 352. t. 45. f. 12.)—Stem branched. Leaves obtuse, recurved, hair-pointed; the uppermost flatter. Capsule cylindrical, somewhat ovate. Common on walls, roofs, and the trunks of trees, throughout Europe from Sweden to Greece, bearing fruit from January to April. This is much larger than any of the foregoing, the stems, mostly about two inches high, composing broad cushion-like patches, of a dirty hoary aspect in dry weather; dark green in wet; bearing abundance of upright capsules, on long red flasks, in winter and spring. The leaves, recurved in every direction, are very abrupt, with a strong rib, ending in a long, roughish, wavy hair. Capsule slender, the teeth of its fringe united at the bottom into a firm, partly perforated, tube, which lacks character in this, the subfulata, and a few other Tortula, has given occasion to Mohr to establish a genus by the name of Synricha; but it seems to us better avoided.

T. subfulata. Awl-shaped Screw-moss. Hedw. Sp. Mucf. 122. t. 27. Fl. Brit. n. 8. Engl. Bot. t. 1101. (Bryum subfulatum; Linn. Sp. Pl. 1581. Curt. Lond. f. 3. t. 66. B. capulis longis subfulatis; Dill. Mucf. 350. t. 45. f. 10.)—Stem nearly simple, short. Leaves ovato-lanceolate, pointed. Capsule cylindrical. Lid awl-shaped, straight.—Common in damp shady places, in the southern and middle countries of Europe; rare in Sweden, and even in Scotland. It forms dense perennial tufts, of a fine deep green, bearing capsules in March and April. The leaves are broad, nearly obvate, tipped with a point, sometimes elongated into a hair, when it becomes the T. pilosa of Schrad's Spicilgium, 66. The fruit-flasks are terminal, an inch or more in height, rather stout, but seldom straight. Capsule almost erect, long and slender, with a long taper lid and veil. Fringe united into a spiral tube for three quarters of its length.

T. pilosa.
T. muralis. Wall Screw-mosses. Hedw. Sp. Mucf. 126. Fl. Brit. n. 9. Engl. Bot. t. 2035. Bryum murale; Linn. Sp. Pl. 1584. B. tegulare humile, piliferum in incanum. Dill. Mucf. 355. t. 45. f. 14.)—Stem mostly simple, very short. Leaves ovate, acute, hair-pointed. Capsule cylindrical, slightly elliptical. Lid conical.—This is perhaps the most universal of all mosses throughout Europe. Every wall and bank is covered with it, and the abundant capsules, produced in winter and spring, remain in a dry and empty state almost throughout the year. The roots are perennial. Stems very short, though sometimes divided, composing broad dark-green patches, not dense elevated tufts, and rendered hairy by the terminal white hairs of the leaves. These hairs, however, vary in length, and are sometimes scarcely discernible. Fruit-stalk terminal, straight, reddish-brown, near an inch high. Old capsule a little curved when the fringe falls off. The latter is not so much twisted as in most other species, the teeth, all separate and parallel, making hardly more than one turn. Lid red, not half so long as the capsule, slightly oblique. Veil as long as both together, slender, brownish.

T. cumifolia. Wedge-shaped Screw-mosses. Fl. Brit. n. 10. Engl. Bot. t. 1510. (Bryum cumifolium; Dickf. Crypt. falc. 3. 7. B. murale; Hudf. 477. B. humile, pilis carenis, viride et pellicudum; Dill. Mucf. 356. t. 15. f. 15.)—Stem very short, mostly simple. Leaves obovate, reticulated, pellucid, slightly pointed. Capsule cylindrical. Lid conical.—Found on banks and sandy ground, at Streatham, Surrey, and abundantly about Oxford, according to Dillenius. Mr. D. Turner gathered the specimens figured in Engl. Bot. on some old banks at Hopton, near Yarmouth. This moss is said to be biennial, bearing capsules in the early spring, and composing broad indeterminate patches. When carefully examined, it cannot be confounded with any variety of the last. The leaves are of a brighter green, strongly reticulated, pointless. Capsule more oval, with a longer, more awl-shaped, lid; its fringe bright red, or crimson, repeatedly and closely twisted together, which alone would distinguish this species from the preceding.

T. tortuofa. Frizzled Mountain Screw-mosses. Hedw. Sp. Mucf. 124. Fl. Brit. n. 12. Engl. Bot. t. 1708. (Bryum tortuolum; Linn. Sp. Pl. 1583. Dickf. Dr. Pl. 48. B. cirratum, fetis et capulis longioribus; Dill. Mucf. 377. t. 48. f. 40.)—Stem branched, level-topped. Leaves linear inclining to lanceolate, keeled; twisted and undulated when dry. Capsule cylindrical, slightly ovate. Fringe lax.—Plentiful on the mountains of Wales, Scotland, and the north of England, Derbyshire, &c. as well as in Sweden, Switzerland, Germany, Italy, and, according to Dillenius, in Virginia. It bears capsules in summer, but not very constantly. A large and handsome species, whose stems, from two to four inches high, compose broad and soft tufts, of a most beautiful green, the leaves being long and taper, frizzled when dry, especially at the rough, or minutely crenate, edges. Fruit-stalks an inch and a half or two inches high, bright crimson; pale yellow at the summit. Capsule inclining, slender, smooth, light brown, crimson at the mouth; finally erect. Lid taper, half as long as the capsule. Fringe long, crimson, gradually unrolled, and partly spreading or straight, approaching the character of a Trichostomum. See that article hereafter.

T. barbata. Bearded Lateral Screw-mosses. Fl. Brit. n. 14. Engl. Bot. t. 2391. (Bryum barbatum; Curt. Lond. falc. 4. t. 65. B. anguliculatum et barbatum, tenue et rataletum; Dill. Mucf. 384. t. 48. f. 48.)—Stem branched from the base. Leaves elliptic-lanceolate, spreading, somewhat revolute. Fruit-stalks lateral. Capsule ovate.—Native of walls and barren heaths, in the winter and spring, said to be not unfrequent about London, particularly at Charlton, where nevertheless we have many a time sought it in vain. Mr. Hudson is reported to have confounded this species with T. convoluta, or perhaps nerojofa, above described, though certainly none of the genus can be more essentially unlike. The stems are level-topped, branched from the base, clothed with dark-green, single-ribbed, beardless leaves, recurved when dry; the uppermost forming a kind of flar at the top of each branch. The fruit-stalks seem to spring from the base of each branch; yet the flower, to which each owes its origin, perhaps terminated the flow of the preceding season. Capsule small, erect, ovate, polished. Fringe red, not very much twirled, more than half the length of the capsule. The lid is represented by Curtis nearly as long as the capsule, awl-shaped, and oblique. The specific name was meant to contrast this moss with the following, supposed to have no fringe; so that few names can be more exceptional than either.

T. imberius. Deciduous Screw-mosses. Fl. Brit. n. 15. Engl. Bot. t. 2392. (Bryum imberbe; Linn. Mant. 305. B. tenue, imberbe et pallidum, folis erebririosibus; Dill. Mucf. 382. t. 48. f. 46.)—Stem branched. Leaves awl-shaped, spreading; ovate at their base. Stalks about the upper part of the branches. Capsules cylindrical, somewhat elliptical.—Found on dry banks, walls, and amongst grass, perfecting its capsules very early in the spring. This has much the habit of the last, but its leaves are of a paler yellowish-green, more tapering and channelled, turning inward in drying. Fruit-stalks purplish, an inch high. Capsule more cylindrical and longer, while the lid is shorter than in T. barbata. Fringe light brown, very soon deciduous, whence Dillenius thought it to be wanting, and his definition led Linneus to apply the faulty name, which still sticks to this species.

T. arifata. Short-pointed Screw-mosses. Fl. Brit. n. 16. Engl. Bot. t. 2393. (Bryum arifatum; Dickf. Crypt. falc. 4. 12. t. 11. f. 7.)—Stem branched, level-topped. Leaves oblong, obtuse, with a minute point; curved inward and twisted when dry. Capsule cylindrical.—Found on walls at Croydon, Surrey, by Mr. Dickson, who first described this moss, and to whom we are indebted for specimens. The stems are perennial, branched and level-topped, much in the manner of the last. Leaves rather abrupt, with a very small terminal point: by drying they become twisted, enfolding the branch in a spiral order, and are neither recurved nor inflexed. Fruit-stalks terminal, crimson, scarcely an inch high. Capsule cylindrical, of a light shining brown, thin and semi-pellucid. Lid incurved, tapering, tawny, almost equal in length to the capsule. Fringe soon falling off.

TORURA, or TANTUR, in Geography, a town of Palestine, on the coast of the Mediterranean, called in the scripture Dor, Dora, and Nepheh. Josephus took it from the Canaanites, and it fell to the tribe of Manasseh. Tyrophon, tyrant of Syria, after the murder of Antiochus VI. fled to this place for shelter; but he was soon compelled to abandon it, and shortly after lost his life. In the times of Christianity it was erected into a bishopric under the archbishop of Caesarea. It is at present a village only. The environs abound in grain, cotton, and fruit: wheat in particular is abundant, and of a quality superior to the other parts of Palestine and Syria; 15 miles S. of Acre. N. lat. 32° 34'. E. long. 34° 2'.

TORTURA,
TOR

Tortura, a word appropriated by many medical writers, to express only the distortions of the face, and particularly of the mouth, in convulsions.

Torture, a grievous pain inflicted on a criminal, or person accused, to make him confess the truth.

The forms of torture are different in different countries. In some they use water, in others iron, in some the wheel or rack, in some the boot, thumbkins, &c. See Rack, Boot, &c.

Torture, says archdeacon Paley, (Principles of Mor. and Pol. Philos. vol. ii.) is applied, either to obtain confessions of guilt, or to exasperate or prolong the pains of death. No bodily punishment, however exractuating or long continued, receives the name of torture, unless it be designed to kill the criminal by a more lingering death, or to extort from him the discovery of some secret, which is supposed to be concealed in his breast. The question by torture appears to be equivocal in its effects; for since extremity of pain, and not any consciousnes of remorse in the mind, produces those effects, an innocent man may sink under the torture, as soon as the guilty. The latter has as much to fear from yielding as the former. The infant and almost irrefrangible desire of relief may draw from one sufferer false accusations of himself or others, as it may sometimes extract the truth out of another. This ambiguity renders the use of torture, as a means of procuring information in criminal proceedings, liable to the risk of grievous and irreparable injustice. For which reason, though recommended by ancient and general example, it has been properly exploded from the mild and cautious system of penal jurisprudence established in this country. The enlightened and liberal spirit of modern times has excluded torture from most other countries in Europe; and the revival of it in any nation reflects indelible reproach on the government which countenances it.

The torture, says M. Brugere, is a sure expedient to destroy an innocent person of a weak complexon, and to have a criminal of a robust one. It was a noble faying of an ancient, "They who can bear the torture will die, and also they who cannot bear it."

The marquis Beccaria (chap. 16.) with exquisite raillery proposes this problem: the force of the muscles and the sensibility of the nerves of an innocent person being given, it is required to find the degree of pain necessary to make him confess himself guilty of a given crime.

Tortyra, in Ancient Geography, the name of one of the seven towns which Cyrop gave to his favourite Pythæus, supposed to be in the environs of Asia Minor. Athenæus.

Torup, in Geography, a town of Sweden, in the province of Halland; 12 miles N.N.E. of Halmitad.

Torus, in Architecture. See Torre.

Torus, in Botany and Vegetable Physiology, a name applied by Mr. Salibury to what is termed by Linnaeus either the receptacle of the flower, or a glandular nectary surrounding the bafe of the germen. Jullieu and his followers call tidsitus hypergynus, alluding to its form, as well as situation. The word torus is very descriptive, as expressing the frequent resemblance of the part in question to what vulgarly sustains an architectural column, and it is certainly preferable to the compound appellation just mentioned. A very curious lobed and plated torus may be seen in Cobera, but we believe it to be strictly a glandular nectary. Mr. Brown's natural order of Epacridace contains some genera with five separate glands, of a like nature, indubitably (in our opinion) nectariferous; and others with an interrupted annular nectariferous disk, or torus, under the germen. It does not follow, because Linnaeus has sometimes misapplied the term nectarium, that there is no such thing in nature; but his opponents have wished to obscure and invalidate that term, because he has in general, with so much originality and success, employed it for the clear and concise differentiation of genera. This displays a want of candour, unbecoming disinterested students and admirers of Nature.

Torus, in Ancient Geography, a mountain of Sicily, between Heraclæa and Agrigentum.

Toruscula, a word used by some medical writers to express a drop.

Tory. See Tories.

Tory Island, in Geography, an island lying north of Bloody Farland Point, in the county of Donegal, about 67 miles from the main land. It is said to be extremely fertile.

Toryne, in Pharmacy, the name of a kind of spatula intended for flirring up the ingredients of decoctions while boiling.

Torynetos, a name given by some to a mixture of bread and water boiled together, whether meant as a kind of apanade, or for a poultice.

Torza, in Geography, a town of Persia, in the province of Irak; 40 miles E. of Hamadan.

Torsok, a town of Ruffia, in the government of Tver, on the Tverza; 40 miles W.N.W. of Tver. N. lat. 57°. E. long. 35° 14'. See Torosk.

Tosa, a sea-port town of Spain, in the province of Catalonia; 23 miles S.S.E. of Gerona. N. lat. 41° 43'. E. long. 2° 48'.—Also, a river of Italy, which runs into lake Maffone; 4 miles N. E. of Orthez.—Also, a town of Japan, capital of a province of the island of Tsuoke, on the south coast. N. lat. 33° 40'. E. long. 134° 57'.

Tosale, in Ancient Geography, a town of India, on the other side of the Ganges, and near it, which had the title of metropolis. Ptolemy.

Tosanlu, a river of Natalia, which waters the city of Tocat, and afterwards joins the Jekilermak. It was anciently called Lycus.

Tosarcan, a town of Persia, in the province of Irak; 21 miles S. of Hamadan.

Toscanelia, a town of the Papedom, in the Patrimonian, the see of a bishop, suffragan of Viterbo; 9 miles W.S.W. of Viterbo. N. lat. 42° 24'. E. long. 11° 52'.

Toscanni, Paolo, in Biography, an eminent astronomer, was born at Florence in 1397. Declining the profession of his father, who was a physician, he devoted himself to the study of geometry and astronomy, and also of the Latin and Greek languages. He was one of the curators of Niccol's library, and conversant with the folar motions. He corrected the astronomical tables of Alphonso and the Arabsians. Of his astronomical tables he left a memorial in the great dial fixed upon the metropolis church at Florence, erected about the year 1468. He died in 1482, at the age of 85.

Toscolano, in Geography, a town of Italy, in the department of the Benaco, on a small river which runs into lake Garda. Here is a manufacture of cloth, with some paper and iron-mills; 6 miles E.N.E. of Salo.

Tosea, a town of Sweden, in West Gothland; 20 miles W.N.W. of Uddevalla.

Tosi, Giuseppe Felice, of Bologna, in Biography, maestro di capella at Venice the latter end of the 17th century, and composer of five operas for that city between the years 1684 and 1690. (Gloria della Poesia.) Beside these dramas, he composed others for Bologna. His name, however,
however, will be longer remembered by the merit of his son, than by his musical productions, which have been long 
loft and forgotten. See the next article.

Tosi, Pier Francesco, Accademico Filosomico di Bologna, 
and not only an eminent opera singer, in soprano, during 
his youth, but a composer of cantatas, in which the recita-
tives were particularly impassioned, energetic, and impref-
five, and author of an excellent treatise on singing, well 
known in England, by the late Mr. Galliard's admirable 
translation.

The author of this treatise seems to have had no parti-
ality for rapid execution. His own favourite style of sing-
ging was the pathetic, which he describes and recommends by

excellent precepts. Though this elementary treatise has been 
written more than fourscore years, no work of the same 
kind has been produced in Europe since its publication, but 
upon Tosi's model, and in confirmation of his precepts. 
The excellent composer of the old school, Galliard, a pro-
found and experienced judge of every species of musical 
merit, not only recommended its perusal to the first musical 
professors, instrumental as well as vocal, by an admirable 
translation and notes in 1740, but by his encomiums in-
fantly excited it into a classical work.

In 1757, Agricola, opera compose to Frederic II., king 
of Prufia, and the bel Cantor of Rome, published a 
translation of it with useful and instructive notes, which 
made the work well-known in Germany; a knowledge 
which Hilles of Leipzig much increased by frequent ex-
trasts from it, in his musical journals.

And in 1774, Mancini, singing-master to the arch-
duchesses at Vienna, published a treatise on singing of great 
merit, founded on the work, and confirming the principles 
of Tosi, of whom he speaks with the highest respect in his 
chapter on "Intonation." "Giuoro non poco si ò gi-
fare leggera nel libro tanto stimato di Pier Francesco 
Tosi. A carte 12, la spiegazione, che esso fa sopra il 
fenimento maggiore, e minore, appunto per favore la quan-
tità degli intervalli, o fra delle come, che li compone."—"It 
will be of no small service to flouds in singug, if they 
read in the work of P. F. Tosi, (p. 12 of the original,) 
the explanation which he gives of major and minor femi-
tones, that they may know precisely the quantity of the 
several intervals, or rather commas, of which they are com-
posed." See Mancini, for the original title and further 
account of his book.

Of Tosi's life but little is known, except from Galliard's 
prefatory discourse to his translation; who tells us that he 
was a singer of great elocution and reputation. He sung on 
the stage at Venice in 1707, in the opera of "Olimbro," 
written by Apolito Zeno, and set by Galipari, where he 
is styled Virtuoso di S. A. Elettore Polatina. He spent 
the chief part of his time, according to Galliard, in travel-
ning, and by that means heard the most eminent singers in 
Europe; whence, by the help of his refined taste, he made 
the observations which are contained in his book. Among 
many excursions, his curiosity was excited to visit England, 
where he resided for some time in the reigns of king James II., 
king William, George I., and beginning of George II. 
He was very much esteemed by persons of rank wherever 
he went; among whom, in England, was the late earl of 
Petersborough, whom he had often met in his travels on the 
continent, to whom he had dedicated his book, though it 
was printed at Bologna in 1723, some time after he had 
quitted England. The emperor Joseph I. gave him an 
honourable employment in some part of Italy, and the 
archduches, a church retirement in Flanders, where he 
died.

The original title of his book, which is now become 
known, is, "Opinione de' Cantori Antichi e Moderni e 
Sieno Offervazioni sopra il Canto figurato:" 8vo.

The earl of Peterborough, to whom he dedicates his book, 
was one of the best informed judges of dramatic music and 
performance in his time. He married the amiable and ac-
complished Mrs. Annalisa Robinbon, after a very long 
courtship. (See her article.) Tosi used to meet Bonon-
cini, and all the first opera singers of the time, at the earl's 
villa, at Paron's Green; and we remember hearing Monti-
celli, Regimeli, and Munzoli, speaking with great respect of 
the "Trattato di Tosi."

TOSIA, in Geography, a new town of Asia Minor, 
in Natolia, built on the side of a hill, at the foot of which 
was a fertile country; 70 miles S.S.W. of Sinob.

TOSICIA, a town of Naples, in Abruzzo Ultra; 
7 miles S. of Teramo.

TOSINO, a river which crosses the marquise of An-
cona, and runs into the Adriatic, N. lat. 42° 57'; 
E. long. 13° 55'.

TOSMUANASSA, in Ancient Geography, a town of 
Asia, in Bactria. Ptolemy.

TOSNA, in Geography, a river of Russia, which runs 
into the Neva, near Pella, in the government of Pswterburg.

TOSNITZPACH, a river of Austria, which runs 
into the river Erlebach, 2 miles below Scheibs.

TOSOLIC, a town of Styria; 35 miles S. of Tourfan.

TOSON-HOTOC, a town of Chines Tartary; 88 
miles S.S.W. of Haratouche.

TOSPITES, in Ancient Geography, a country of Asia, 
in Greater Armenia, S. of the sources of the Euphrates and 
Tigris. Ptolemy.

TOSQUIATOSSY CREEK, in Geography, one of the 
branches of the Allegany river.

TOS, a river of Switzerland, which runs into the 
Rhine, 2 miles S.E. of Egfland, in the canton of Zurich.

TOSSAQUA, a town of Peru, in the audience of 
Quito; 110 miles W. of Quito.

TOSSE, a town of France, in the department of the 
Landes; 12 miles W. of Dax.

TOSSIAT, a town of France, in the department of the 
Ain; 7 miles S.E. of Bourg-en-Bresse.

TOSSIGNANO, a town of Italy, in the department of 
the Amone; 13 miles W. of Ferrara.

TOSSO, a town of Sweden, in West Gothland; 42 
miles N.E. of Uddevalla.

TOST, or Toschek, a town of Silefla, in the princi-
pality of Oppeln; 26 miles S.E. of Oppeln.

TOSTA, a river of Mexico, which runs into the Pacific 
Ocean, N. lat. 12° 30'.

TOSTAR, or Suster. See SHUS, SHUSTER, and 
SUSU.

TOSTERYD, a town of Sweden, in Smaland; 22 
miles S. of Jonkioping.

TOSTES, a town of France, in the department of the 
Lower Seine; 12 miles S.W. of Arques.

TOSTO, Cape, a cape on the N. coast of Spain. N. 
lat. 43° 15'; W. long. 9° 10'.

TOSUN HOTUN, a town of Thibet; 508 miles W.S.W. 
of Tourfan. N. lat. 41° 55'; E. long. 99° 10'.

TOT VARADIN, a town of Hungary; 24 miles S.E. 
of Boros Jeno.

TOTA ISLAND, or Island of Plantains, an island of 
the Atlantic, near the coast of Africa, at the mouth of the 
Sherbro.

TOTANA, a town of Spain, in the province of Murcia; 
11 miles N.E. of Lorca.
TOTANO, or Totanus, in Ornithology, the name of a bird common in the Italian markets, and more usually
known by the name of *Vetola*; which see.

The totanus of Linnaeus is a species of *Scolopax*, (which see), and the *crex* of other authors. See Rall.

TOTANUS is also used by some for the *Linnaea*; which see.

TOTAQUESTAC, in Ornithology, the name of a beautiful
American bird, described by Nieremberg from Anto-
nius Herrera. It is said to be something smaller than a
pigeon, and all over of a most beautiful green; its tail-feathers
are of a very great length, and are greatly esteemed.

The Indians value the bird so highly, that it is death by their
laws to kill it, so that when it is caught they only fry it and
let it go again. Ray.

TOTEN, in Geography, a town of Norway, in the pro-
vince of Aggerhusen: 47 miles N. of Christiania.

TOTES, a town of France, in the department of the
Lower Seine; 14 miles N. of Rouen.

TOTEZVA, a town of Hungary, on the river Bodrog;
5 miles S.W. of Patak.

TOTFALU, a town of Hungary; 5 miles N. of
Siclos.—Alfo, a town of Hungary; 8 miles W. of
Podolizec.

TOTILA, in Biography, king of the Ostrogoths in
Italy, was a commander of the Gothic garrison at Trévigo,
and upon the deposition and murder of his uncle Eraric, was
chosen to succeed him A.D. 541. After several successful
conflicts with the Romans, and the capture of their chief
cities, he advanced to Tibur, within eighteen miles of the
capital. In every step of his progress his conduct was con-
ciliatory; he restrained his soldiers, in the career of victory,
from all acts of licentiousness; and by the exercise of hu-
morality and liberality, he attached to his service and cau-
sed his vanquished enemies. Upon his approach to the capital,
the emperor Justinian was alarmed, and recalling Belis-
farius from the Persian war, sent him, already renowned for his
character and exploits, to its relief. Failing in his attempts
to throw succours into the city, he withdrew, and abandoned
it to the direst of famine; so that those inhabitants who
could make their escape deserted it, and those that remained
importunately solicited the governor to capitulate. At
length the Roman garrison retired, and one of the gates
was opened to the Gothic troops, by which Totila entered
the city December 17, A.D. 546. Although the con-
queror spared the lives of the inhabitants, he allowed his
soldiers to pillage the city, and by so doing reduced the
wealthy senators and their families to absolute beggary.
Having convened those few of this rank that remained, he
reprehended and threatened them; but pacified by the
intercession of Pelagius, he sent a respectful message to Ju-
tinian, offering to live with him upon amicable terms; and
yet intimating, that on the rejection of his proposal he would
utterly destroy Rome, and remove the seat of war to Illyri-
cum. The emperor referred him for an answer to Belis-
farius, upon which flight he began to demolish the city. As he
was proceeding in the work of destruction, Belis-
farius recon-
municated with him on the barbarity of his conduct, and
so far succeeded as to induce Totila to desist, and to march
off, with his troops and the senators, to Lucania. The remaining
inhabitants were dispersed in exile, and Rome was for
forty days in a state of total depopulation. Belis-
farius seized the opportunity of taking possession of the city, repairing
the fortifications to the utmost of his power, and cau-
sing the inhabitants. Upon receiving this intelligence, the Gothic
sovereign returned, and having made many unsuccessful
attempts for regaining possession of the city, and, sacrificed, in
repeated assaults, the choice of his troops, he was under a
necessity of decamping, and of marching, with degraded
reputation, and a discontented army, to the siege of Pe-
rugia. He contrived, however, to regain the confidence of
his troops, and after obtaining a reinforcement, marched
again for Rome, and by the treachery of some Ifaurian
centinels, became master of the city. Experience had now
taught him wisdom; and he adopted every measure which
found policy dictated for conciliating his enemies. He not
only repaired the walls and edifices which he had demol-
ished, but recalled the senators, and restored them to their
rank, and at the same time invited the citizens to take po-
fession of their property, supplying them in the mean while
with provisions. He also exhibited the Circenian games,
and prefided at them with the dignity of a Roman emperor.

Totila renewed his embassy to Justinian, making an offer
of peace and alliance; but the emperor would not admit the
Gothic ambassadors to an audience. The Gothic sovereign
was incensed by this treatment; and setting out a powerful
fleet, took Rhegium and Tarentum, and passed over to Si-
cily, which he speedily reduced and pillaged; and having
made himself master of Sardinia and Corsica, and ravaged
the whole sea-coast of Greece, whilst his troops were be-
flying Ancona, his fleet was defeated, so that he was obliged to
raise the siege, and soon after he left Sicily. Justinian,
encouraged by these fortunate events, determined to pre
serve Italy from the power of Totila; and having recalled Beli-
farius, devoloped the command of his army on Nares, who
marched directly to Rome, and meeting Totila in his pro-
gress, presented to him the emperor's message, which was
merely an offer of pardon. Totila seemed to regard it as an
inult, and replied, that he would conquer or die. In the
furious combat between the hostile armies that ensued, the
Goths were driven from the field of battle, and Totila fled
with no more than five attendants. In his flight he was
overtaken by Abad, a leader of the Geopides, who pierced
him through the body with a lance. His faithful com-
panions hurried him away seven miles beyond the scene of
action, and had him wound dressed; but he soon after ex-
pired. A private burial terminated the glory of this con-
queror of Rome, whom his eulogists have celebrated for va-
our tempered by humanity and moderation, and for a go-
vernment conducted with a regard to justice and equity.

With this battle, fought in July 552, the 11th year of To-
tila's reign, the triumph and dominion of the Goths in Italy

TOTMA, in Geography, a town of Russia, in the go-
vernment of Vologda. In the environs are several salt-pits;
92 miles N.E. of Vologda. N. lat. 68° 16'; E. long.
42° 34'.

TOTNESS, an ancient borough and market-town in the
hundred of Corderidge, and county of Devon, England; is
situated on the banks of the river Dart, 22 miles S.S.W.
from Exeter, and 105 miles W.S.W. from London. It
ranks among the most ancient towns in the kingdom; and if
credit could be given to Geoffrey of Monmouth, would
assume an origin coeval with the first; for here, according
to this author, Brutus first landed; and the inhabitants,
to corroborate the tale, still point out a dolmen near the
spot where the eait gate stood, as the very one on which he
first set his foot. It is certainly, however, of remote antiquity;
for Leland mentions that the Roman fos-s-way, extending
through Devonshire and Somersetshire, began here; and
Ridgton quotes a passage from Bede, which notices the ar-
ival of Ambrosius and Uther-Pendragon at Totnes, when
they returned from Bretagne to oppose the tyranny of
Vortigern. The feite of the town is peculiarly fine; from the
margin of the Dart it cliines the steep acclivity of a hill, and
stretches itself along its brow; commanding a view of the
winding stream and the country in its vicinity; but sheltered
by
by higher grounds on every side. The piazzas in front of the houses in some parts of the town, and the higher stories projecting over the lower, are manifest proofs of its antiquity; a claim which is strengthened by the keep of its castle, a large circular building, cżsettled, rising from an immense artificial mound. This castle, according to Brown Willis, was erected by Judith de Totnes (to whom the manor was given by the Conqueror), and made the head of his barony. During his residence here, he founded a priory for Benedictines, which continued till the dissolution, when its annual revenues were estimated at 124l. 10s. 3d. The manor was granted in the reign of Henry VII. to Richard Egeecumbbe, whose son, or grandson, in the second year of Elizabeth, conveyed it to the corporation, according to the right of a burgessHIP to his heirs for ever. Totnes was incorporated by charter of king John; and has had its privileges confirmed by several succeeding sovereigns. The corporation is vested in a mayor, recorder, thirteen burgoomasters, and twenty common-councillors. The borough first sent representatives to parliament in the 23d of Edward I. the right of election is in the corporation. At the period of the Norman survey, Totnes had immunity from taxation, excepting at those times when Exeter was rated. The parish-church is a handsome edifice, having a well proportioned tower at the west end. The date of its foundation was unknown till the year 1799, when the south-east pinnacle was struck by lightning, and in its fall bent in the roof of a small room over the porch. In this room were two chests of old records, which became exposed by this accident, among them was found a grant of indulgence from bishop Lacey, "to those people who had or might contribute to the rebuilding of the church at Totnes." This was dated at Chudleigh, where the bishops of Exeter had a residence in 1432. The chancel is separated from the body of the church by an elegant screen of ornamented tracery in stone-work; but the altar-piece, instead of corresponding with the rest of the building, is of Grecian design, having a semi-dome supported by Corinthian pillars. Totnes consists principally of one street, about three-quarters of a mile in length, terminated on the E. by a bridge over the Dart: the town was formerly surrounded by a wall, and had four gates: the east and north gate-houses are now standing. By the population return of the year 1811, the houses were estimated at 3277, the number of inhabitants at 2733. Many of the labouring classes derive employment from the woollen trade, which is rapidly increasing. Five fairs are held annually, and a market weekly, on Saturday.

Edward Lye, the learned author of the Anglo-Saxon and Gothic Dictionary, published in 1772, was a native of Totnes; as was also Dr. Benjamin Kennicott, well known for his collection of Hebrew MSS. The former died in 1769, the latter in 1783.

About two miles below Totnes, on the brow of a thickly wooded declivity which rises from the margin of the Dart, is Sharpam, the seat of Edmund Baillart, Esq. The mansion, an elegant building of freestone, was erected by captain Powall, who lost his life at the moment of victory in a naval engagement during the American war. The daughter of that gentleman married Mr. Baillart.

On the easterm shore is Greenaway, a feast for many generations polished by, and a residence of the family of Gilbert. Of this family, and born here, was Sir Humphrey Gilbert, a celebrated voyager in the reign of Elizabeth: to him this kingdom is indebted for the discovery and settlement of Newfoundland.—Warner's Walk through the Western Counties, 8vo. 1800. Beauties of England and Wales, vol. iv. Devonshire: by J. Britton and E. W. Brayley, 1803. Polwhale's History, &c. of Devonshire, folio, 1797.
part of the last century. The parish-church is built of heav'n stone, flints, and pebbles, and consists of a chancel, nave, two aisles, and a square embattled tower. On the south side of the church is a large brick porch, built, as appears by the architecture, about the beginning of the sixteenth century. At the east end of the north aisle is the vestry, erected in 1606, by Henry, lord Coleraine, and repaired, pursuant to his will, in 1792. The building is semi-circular at the east end; its roof is in the shape of a dome. The font is octagonal, richly ornamented with tracery, and the devices of a mermaid, pelican, &c. Monuments and other sepulchral memorials abound in every part of the church. David, king of Scotland, gave this church, in the twelfth century, to the canons of the Holy Trinity in London; after the dilution of that monastery, the rectory manor and the advowson of the vicarage were granted, in 1544, to the dean and chapter of St. Paul's, in whom they are still vested. There is a considerable Quaker's meeting in this parish, and a chapel belonging to the Methodists. An almshouse for four men and four women was founded and endowed, in 1603, by Balchafir Sanchez, a Spaniard. A similar establishment for six men and six women was built in 1736, pursuant to the will of Nicholas Reynolds, esq.; who also made provision for a school, for twenty poor children. By the bequests of Sarah, duchess dowager of Somerset, the school-house was enlarged, and the benefits extended to all the children of such inhabitants of this parish as were not poor of an estate of 20fl. per annum. A charity-school for girls was established in the year 1735; also a Sunday-school for boys, and a school of industry for girls, in the year 1790. According to the return made to the population act in 1811, the number of houses in this parish was 873; of inhabitants 4571. —Lyfons's Environs of London, vol. iii. quarto, 1792, 1811. Dyfon's History of Tottenham High-Crofs, octavo, 1792.

TOTTIUM, a town of Hindooftan, in the Carnatic; 24 miles W.N.W. of Titchincholly.

TOttWELL, a town of Switzerland, in the county of Baden; 4 miles S.W. of Baden.

TOVALEY, a town of Hindooftan; 16 miles S.E. of Travancore.

TOUCAN, otherwise called anser Americana, in Africology, a modern constellation of the southern hemisphere, consisting of nine small stars. See Constellation.

TOUCAN, in Ornithology. See Ruphaustes.

TOUCH, or Toque, in Costume, the manner of expressing the fineness of gold and silver in China, by dividing it into 100 parts, so called; thus, if it be 93 touch, it contains seven parts of alloy in 100. The Chinese in general take French silver coin at 95 touch (the better informed taking it only at 93), and English silver at 94 ditto; Spanish dollars at about 92; Siam ticals, and Madras rupees, at 98; and Rajamole rupees at 99 ditto.—Also a method of trying the fineness of gold and silver in many places, by means of a stone called touch-stone.

TOUCH, in Mufic. An organ is said to have a good touch, or flop, when the keys clofe, and lie down well, being neither too loofe, nor too fliff.

TOUCH, in Ship-Building, the broadest part of planks worked top and butt, which place is fix feet from the bottom; or, the middle of a plank worked anchor-flock fashion. Also, the angles of the ftern-timbers at the counters, &c.

TOUCH the Wind, in Sea Language, is when the Reafon of the helm is bid to keep the ship as near the wind as may be. See Touching.

TOUCH-Mc-Noh, in Botany. See Impatiens and Mordica.

Touch-Hole, or Vent, in Gunnery, is the small hole at the end of the cylinder of a gun or musket, by which the fire is conveyed to the powder in the chamber.

In a fire-lock, carabine, or piétol, it is called the touch-hole; but in a piece of cannon, it is more properly called the vent.

Touch-Needles, small maffes of gold, silver, and copper, each pure and simple, and in all the different combinations, proportions, and degrees of mixture, prepared for the trying of gold and silver by the touch-stone; by comparison with the mark they leave on it.

The metals usually tried by the touch-stone, are gold, silver, and copper, either pure, or mixed with one another in different degrees and proportions by fusion. In order to find out the purity or quantity of bafier metal in these various admixtures, when they are to be examined, they are compared with these needles, which are mixed in a known proportion, and prepared for this ufe. The metals of these needles, both pure and mixed, are all made into lamina or plates one-twelfth of an inch broad, and of a fourth part of their breadth in thicknes, and an inch and half long; these being thus prepared, you are to engrave on each a mark indicating its purity, or the nature and quantity of the mixture in it.

The manner of making the touch-needles is by the proportions of the mark, a weight of half a pound, or eight ounces, being divided into sixteen half-ounces, the half-ounces each into four drachms, the drachm into four pennyweights, and this into two half-pennyweights.

Touch-Needles, Silver: these must be only tempered with copper, and the proportion determined by the mark divided into half-ounces and grains.

You must therefor for this purpose one mark of such a weight, that it may conftitute a fufficient maff of metal for the making of one needle; let it weigh, for instance, one drachm, then weigh such a mark of the puref silver, wrap it up in a fmall paper, and upon this write sixteen half-ounces, which will signify that the whole mark of this metal is the puref silver, and make the first needle of this mafs.

Next weigh fifteen half-ounces of pure silver, and one half-ounce of pure copper; wrap thefle both in a paper, and write on it fifteen half-ounces, which will signify that there are in that small maff fifteen parts of pure filver, and one part of pure copper; make of this the second needle. In the fame manner go on with the rest, add two half-ounces of copper to fourteen half-ounces of filver, mark it fourteen half-ounces, make the third needle of this; and in the fame manner proportion the small maffes of filver and copper for making the other needles, and put incriptions upon every one in the following manner.

For the needle | half oz. of silver | half oz. copper
When you have the metals in each of their due proportions, each being wrapped up in its separate paper; put each separately into a crucible never used for any operation, and, adding a little borax, melt them together in a very quick fire, which must be well kindled before with bellows; or, what is yet better, throw them suddenly into a hot crucible, and as soon as they melt, stir them with a dry wooden peg, burnt at the end, and pour them immediately into an ingot. When this is done, wrap up each mass, when cold, in its own paper again, and weigh them finely, in a nice balance; if they still weigh a whole mark, they are good; but if there is any considerable deficiency in their weight, it is a sign that your fire, having been too weak, or of too long duration, has consumed as much copper as is wanting in the weight; therefore this mass must be esteemed useless, and another made in its place in the same proportion.

When this is all finished, make with the hammer out of each of these small masses, a needle, making them a little hot; then engrave on each of these needles the number of half-ounces it contains, as before marked on its paper; that is, upon the first sixteen, upon the second fifteen, and so on; and then pierce them at one end, and running a silver wire through their eyes, collect them in order according to their different numbers. These are the silver touch-needles, made of the different alloys of silver and copper.

In Holland they make use of the mint mark, divided into grains, for the making of their needles. The first needle made of pure silver is said to be of twelve pennyweights. The second is made of eleven pennyweights, and eighteen grains, by the addition of six grains of copper. The third is made of eleven pennyweights and twelve grains, by the addition of twelve grains of copper; and so on, the proportion of silver decreasing always six grains, that is, one quarter of a pennyweight at a time, and that of the copper being always increased in the same proportion, till at last the weight of the silver is reduced to one pennyweight, and that of the copper increased to eleven pennyweights, which proportion constitutes the last needle.

It is needles, however, to go through the whole series of the needles, by so small progressions to the very last, for very delicate proportions cannot be very accurately distinguished in the operation.

**Touch-Needles, Gold.** These must be mixed either with silver alone, or with silver and copper variously intermixed. This mixture is called allowing or carating, and is determined by a mark divided into twenty-four carats, or weights of two-sixth parts of an ounce. There is nothing to be observed about the making of these needles, beside what has already been said in regard to the silver needles; except that the proportions of the weights are determined in another manner. These needles are made according to the following division and order; and they all weigh one mark.

The first is totally of pure gold, or of 24 carats.

| 2 | 23 car. 6 gr. | 6 gr. | 1 car. |
| 3 | 23 car. | 1 car. |
| 4 | 22 car. | 1 car. | 6 gr. |
| 5 | 22 car. | 2 car. |
| 6 | 21 car. | 2 car. | 6 gr. |
| 7 | 21 car. | 3 car. |
| 8 | 20 car. | 3 car. | 6 gr. |
| 9 | 20 car. | 4 car. |
| 10 | 19 car. | 5 car. |
| 11 | 18 car. | 6 car. |

The decrease goes on thus, by whole carats, till the weight of the gold is arrived at one carat, and that of the silver at twenty-three; for after the ninth needle, you cannot make so exact a distinction of the half-carats.

**N.B.** The carat is divided into twelve grains.

This mixture of the gold and silver is called the white alloy; but when copper together with silver enters into the mixture of the gold, then it is called a mixed alloy. The needles for trial of pieces thus debased, are made of mixtures analogous to the former, except only that those portions, which in the first case were pure silver, here consist of copper and silver mixt. Therefore you have a double series: for the mixture is either of two parts of silver and one of copper, or of two parts of copper and one of silver. For instance,

The first is of pure gold.

If in this table you take pure copper instead of pure silver, and silver instead of copper, this gives you a third series of golden needles. And you may have a fourth by mixing with gold equal quantities of silver and copper in the same proportion. These alloys of gold are much in use, but workmen may easily employ a number of other variations, which, compared with those already mentioned, will be distinguished into a thousand different ways by an experienced person, so that it is neither possible, nor necessary to imitate them all.

But that these golden needles may not be too expensive, they may be made much shorter than those of silver, and afterwards folded to plates of copper, that may be sufficiently strong for use.

The use of these needles is by means of the touch-flone; and arises hence, that every metal when pure must have its specific colour, that distinguishes it from the rest: but metals being the most opaque of all known bodies, the specific colour of every one appears most distinctly when you rub it against a very black hard stone; and if the colours of two or more metals are expressed by large lively spots, made near each other on the same plane, by rubbing them against the surface of the stone, you will by that means easily discern their difference, or their likeness.

The stone adapted to this use, and called from its office the touch-flone, must have the following qualities. It must be of the deepest black, left the tincture of the metal should be altered by spurious rays of light shining among it: it must be capable of being pretty well polished, for when too rough, the colours of the metals rubbed against it cannot be nearly or regularly distinguished; and if it is too smooth, the metals are but faintly, and too slowly abraded or erased by it, especially when gold is tried. It must also be neither too hard nor too soft. Tripoli, coal-dust, and tin-ashes, are used in rubbing off the thin metalline cruts, and in a short time the flone when very hard is apt to acquire too smooth a surface; and when it is too soft it easily wears, throws off a dust, and contracts furrows.

The stone is made in the form of a quadrangular prism, about an inch thick, and two or three inches long.

If the proper stone cannot be procured, moderately smooth pieces of flint are the best substitutes; and the more they approach in colour to the other the better.
The method of using your needles and the stone is this: the piece of gold to be examined, being well cleaned in some convenient part of its surface, a stroke is to be made with it on the stone; and another, close by it, with such of the touch-needles as appear to come the nearest to it in colour. If the colour of both, upon the stone, is exactly the same, it is judged that the given mass is of the same fineness with the needle: if different, another and another needle must be tried, till such a one is found as exactly corresponds to it. To do this readily, practice only can teach.

In making the strokes, both the given piece, and the needle of comparison, are to be rubbed several times backwards and forwards upon the stone, that the marks may be strong and full, not less than a quarter of an inch long, and about a tenth or an eighth of an inch broad: both marks are to be wetted before the examination of them, their colours being thus rendered more distinct. A stroke, which has been drawn some days, is never to be compared with a fresh one, as the colour may have suffered an alteration from the air; the fine atoms, left upon the touch-stone, being much more susceptible of such alterations than the metal in the mass. If the piece is supposed to be superficially heightened by art in its colour, that part of it, which the stroke is designed to be made with, should be previously rubbed on another part of the stone, or rather on a rougher kind of stone than the common touch-stones, that a fresh surface of the metal may be exposed. If it is suspected to be gilt with a thick coat of metal finer than the internal part, it should be raised with a graver, to some depth, that the exterior coat may be broken through: cutting the piece in two is a less certain way of discovering this abuse; the outer coat being frequently drawn along by the fingers, or chisel, so as to cover the divided parts.

The metallic compositions, made to resemble gold in colour, are readily known by means of a drop or two of aqua fortis, which has no effect upon gold, but dissolves or discharges the marks made by all its known imitations. If gold is debauched by an admixture of any considerable quantity of these compositions, aqua fortis will, in this case, also discharge so much of the mark as was made by the bafe metal, and leave only that of the gold, which will now appear discontinued or in specks. Silver and copper are in like manner eaten out from gold on the touch-stone, and hence some judgment may be formed of the fineness of the metal from the proportion of the remaining gold to the vacancies.

Ecker observes, that hard gold appears on the touch-stone less fine than it really is. It may be presumed that this difference does not proceed from the simple hardenss; but from the hardenss being occasioned by an admixture of such metallic bodies, as debase the colour in a greater degree than an equal quantity of the common alloy. Silver and copper are the only metals usually found mixed with gold, whether in bullion or in coins; and the only ones, whose quantity is attempted to be judged of by this method of trial.

The Chinefe are said to be extremely expert in the use of the touch-stone, fo as to distinguish by it the small difference in the fineness as half a touch, or a two hundredth part of the mixt. The touch-stone, says Dr. Lewis, is the only test by which they regulate the value of their gold to the European merchants; and in those countries it is subjeed to fewer difficulties than among us, on account of the uniformity of the alloy, where there is almost always silver; the least appearance of copper being used in the alloy gives a suspicion of fraud. As an alloy of the gold is rarely permitted in that commerce, it behoves the European trader to be well prac-

tified in this way of examination; by carefully attending to the above directions, and by accustoming himself to compare the colours of a good set of touch-needles, it is presumed he will be able to avoid being imposed on, either in the touch itself, or by the abusés laid to be sometimes committed, of covering the bar or ingot with a thick coat of finer metal than the interior part, or of including maffes of base metal within it. A set of needles may be prepared, for this use, with silver alloy, in the series of the Chinefe touches; or the needles of the European account may be easily accommodated to the Chinefe, by means of a table formed for that purpose on the principles already explained. It may be observed, that the gold shotes of China have a depression in the middle, from the shrinking of the metal in its cooling, with a number of circular rings, like those on the balls of the fingers, but larger: Dr. Lewis says, that when any other metallic mass is included within the fraud, is discoverable at sight, by the middle being elevated instead of depressed, and the fides being uneven and knobby; but that the same kind of fraud is sometimes practifed in the gold bars, where it is not discoverable by any external mark. See Cramer’s Art of Assaying, p. 116, &c. Lewis’s Com. of Arts, p. 122, &c. See also Assaying.

TOUCH-Stone, a black, smooth, glossy stone, used to try metals upon.

The ancients called it lapis Lydus, the Lydian stone, from Lydia, a country of Asia Minor, whence it was brought. See Touch-Needles.

TOUCH-Stone, Iris, called bafanum Hibernicum by Molyneux and some others, is a black stone, found in the county of Antrim, in that kingdom, in angular columns, forming that amazing pile called by the vulgar the Giant’s Causeway. See BAFALTES and MARMARO-PROSERA.

The bafaltes being an excellent touch-stone, authors have confounded it with the touch-stone of the ancient Greeks, called by them bafanum, bafanites, lapis Lydus or Heracles, &c. which were, probably, only black jaspers; and they have derived bafanum and bafaltes from the same Greek word, βάσαλτης to try or prove; but the bafaltes was not known to the Greeks, and Pliny expressly tells us, that it is an Ethnic or Egyptian name; whence it is probable that bafaltes is a corruption of the Hebrew word בַּזָּל, basel, which signifies iron, a very proper name for a stone, which they describe to be of the colour and hardines of iron. Many authors affirm, that the touch-stone is a kind of black marble, or that most black marbles may serve for touch-stones: black marbles, it is true, take the colours of metals, and may be used as touch-stones in the ancient manner mentioned by Theophratis and Pliny; i.e. by touching them with needles of different alloys; which manner is still practisfed in Germany and other countries: but in the manner of trying them with aqua fortis, it is ascertained by any calcareous substanacs, as the acid will immediately destroy the substanaces of the stone, and consequently affect and somewhat deface the strokes of the metals. For a good touch-stone, choice should be made of a black stone of the genus of marmaro-proséra, or of the Jasper genus, on which the aqua fortis will only dissolve the copper, silver, &c. without touching the gold, or affecting the stone. The first genus should be preferred, as a nice touch-stone should only have a certain degree of polish, and should be of a compact fine texture, and neither too hard nor too soft; whereas the jaspers are too hard, and do not shew with sufficient exactness the different degrees of alloy; for the touches of the metal give them a higher lustre than their natural polish, and that lustre injures the distinctness of the strokes made upon it. Coiia’s Hist. Fuff. p. 264. See Touch-Needles.
TOUCHWOOD, in Botany, a name given to spunk or agane of the oak, on account of its readily taking fire.

TOU-CHAN, in Geography, a city of China, of the second rank, in Koo-e-techen; 987 miles S.S.W. of Peking. N. lat. 25° 40'. E. long. 105° 3'.—Also, a lake of China, in Chien-tong, 52 miles in circumference; 15 miles S. of Tei-ang.

TOU-CHANG-TAO, a small island near the coast of China. N. lat. 35° 55'. E. long. 121°.

TOUCHE, CLAUDE GUYMONDE DE LA, in Biography, a French poet, was born in 1670, and entered among the Jefuits; but a comedy, acted in 1748, occasioned his alienation from their fraternity. The flight of this body was resented by him in a poetical epiflet published in 1766, and entitled "Les Soupirs du Cloître, ou le Triomphe du Fauconifer," in which he has exhibited the Jefuits in the blackest colours. Upon abandoning their society, he attached himself to the theatre; and in 1757 introduced on the stage his tragedy "Iphigenie en Tauride," the subject of which he borrowed from Euripides. This play, though chargeable with many defects, was well received, and has retained its reputation. Whilst he was preparing another tragedy on the story of Regulus, he fell a victim to a pulmonic disorder in 1762. Among his MSS. was found his "Epître à l'Amicie," which has been read with pleasure. Noui. Dic. Hift.

TOUCHE, in Geography, a town of France, in the department of the Saône and Loire; 7 miles N.W. of Chalon sur Saône.

TOUCHING is sometimes used for the sense of feeling. This sense may be injured by any thing that obstructs the nervous influence, or prevents its being regularly conveyed to the organs of touching, as preffure, extreme cold, &c., also by too great a degree of sensibility, when the nerve is not sufficiently covered with the skin, or there is too great tension, or it is too delicate. Whatever disorders the functions of the brain and nerves, hurts the sense of touching; and as it proceeds from the same general causes, as palsy and apoplexy, it requires nearly the same method of treatment. In a defect of touching, which arises from an obftruction of the cutaneous nerves, the patient must be first purged, and then such medicines as excite the action of the nerves or stimulate the fystmy may be used; for which purpose spirit of hartshorn, fad volatile oliveum, horfe-radifh, &c. may be taken inwardly; and the fufpended parts often rubbed with fresh nettles or spirit of fal ammoniac.

Blistering plasters and fcinapfis applied to the parts will likewise be of use, as also warm bathing, especially in the natural hot baths.

TOUCHING, in Geometry. See TANGENT.

TOUCHING, in Sea Language, denotes the fate of a ship's falls when they first begin to fliver, with their edges in the direction of the wind. It is either occasioned by a sudden alteration of the ship's course, or by a change of the wind, in which it blows more obliquely along the surface of the falls, instead of falling into their cavities from behind, according to its usual direction. Falconer. See FULL-AND-BY.

TOUCHING-AF, denotes the circumstance of stopping, or anchoring occasionally, at some intermediate port, in the course of a voyage.

TOUCHIROA, in Botany, formed by Aublet, out of the Caribbean appellation Moutenbirine, which belongs to an aromatic tree of Guiana. See CRUDA.

TOUQUES, in Geography, a sea-port town of France, in the department of the Calvados, taken by the English in 1427; 6 miles S.W. of Honfleur.

TOUQUES, a river of France, which runs into the sea, about 8 miles N. from the town of Touques.

TOUCY, a town of France, in the department of the Yonne; 12 miles W.S.W. of Auxerre.

TOUFRAGA, a town of Affric Turkey, in Natalia; 26 miles W.S.W. of Boli.

TOUSSONG, a town of Thibet; 92 miles S.S.W. of Laffa. N. lat. 29° 6'. E. long. 90° 42'.

TOUKEY, a town of Hindoostan, in the cirque of Nagore; 20 miles S.W. of Nagore.

TOVET, in Rural Economy, a term used provincially in some districts to signify a measure of half a hufel. It is sometimes written toef in books on agriculture and rural economy.

TOU-FANS, in Geography. See SI-FANS.

TOUGITO-HOTOC, a town of China. N. lat. 44° 40'. E. long. 116° 54'.

TOURING, a town of Croatia; 24 miles S.S.W. of Carlifth.

TOUINCHOSE, a Tartarian standard of China. N. lat. 41° 40'. E. long. 111° 14'.

TOU-JOO, a small island near the W. coast of Sumatra. S. lat. 6° 38'. E. long. 99° 24'.

TOU-LOYEN, a town of Corea; 50 miles N.E. of King-ki-tao.

TOU-KIE, a city of China, of the second rank, in Quang-foo; 1137 miles S.S.W. of Peking. N. lat. 25° 10'. E. long. 106° 49'.

TOUL, a town of France, and principal place of a district, in the department of the Meurthe, on the Moselle, which is a lime bridge, and regularly fortified. Before the revolution it was the principal town of a government, and the seat of a bishop. It was formerly imperial, and the bishop a prince of the empire, and suffragan of Treves. The Toulois, with the town of Toul, and the two bishoprics of Mertz and Verdin, in the year 1552, put themselves under the protection of France; and, in 1648, became a part of that country; 12 miles W. of Nancy. N. lat. 45° 41'. E. long. 5° 59'.

TOULA, a river of Tartary, in that part inhabited by the Kalkas, and called Kalka-pira, which takes its source from E. to W., and is often broader, deeper, and more rapid than the Kerlon, another river of the same country, which runs from W. to E., and discharges itself into the lake Koulon-nor, the waters of which again flow into the river Saghalien by that of Ergone; and the banks of which afford the best pastures in Tartary. The banks of the Toula are covered with woods and beautiful meadows. The mountains which hang over it on the northern side are covered with forests of aged firs, and present to the view a kind of amphitheatere. This river, after receiving the waters of the Selingeu, loses itself in the lake of Paj-cal, which is the largest lake in Tartary, and lies in the territories of the Mufcovites. The Russiains are also masters of the lower part of the Selingeu, where they have built a small city called the Selingeufikoi.

TOULICIA, in Botany, from the Caribbean name of the same plant Toulou. See PONAZA.

TOULOMBA, in Geography, a town and fortress of Hindoostan, in the fubah of Moultan, on the Ravee. This town was taken and plundered by Timur Bec; 50 miles N.E. of Moultan. N. lat. 30° 59'. E. long. 73° 25'.

TOULON, a city and sea-port of France, and capital of the department of the Var, strongly fortified. Before the revolution, it was the seat of a bishop, and, besides the cathedral
cathedral and other parish-churches, contained nine convents, a seminary, and a college. The old and new harbour lie contiguous, and, by means of a canal, communicate with one another, both having an outlet into the spacious outer harbour, which is naturally almost of a circular figure, and very large, being surrounded with hills. The entrance on both sides is defended by a fort, with strong batteries. The new harbour, which is a work of Louis XIV., is well defended by batteries, and round it stands the arsenal, where every man-of-war has its own particular florehouse, but the guns and ordnance are laid up separately. In it are spacious working houses for blacksmiths, joiners, carpenters, lock-smiths, curvers, &c. The rope-house is built wholly of freestone, being 320 toises in length, with three arched walks, in which as many parties of rope-makers may work at the same time. The general magazine here, which supplies whatever may be wanting in the particular florehouses for single ships, contains an immense quantity of all kinds of stores, dispensed in the greatest order and convenience. In the month of August, 1793, the people of Toulon, and the French vice-admiral Tragoff, entered into a negociation with the English admiral lord Hood, who was then cruising in the Mediterranean, and he took possession both of the town and of the shipping, in the name of Louis XV., and, under the express and positive stipulation, that he was to affit in restoring the constitution of 1789. Great expectations were formed on this occasion; and general O'Hara was sent with troops from Gibraltar, being appointed, under the king of England's commission, governor and commander-in-chief: the republicans were not negligent in attempting to recover a place of so much consequence, and soon succeeded. General O'Hara was wounded, and taken prisoner, and the city and port abandoned. On the 19th of December, the town was bombarded from noon till ten o'clock in the evening; when the allies, and part of the inhabitants, having set fire to the town and shipping, precipitated their flight. Two chaloupes, filled with fugitives, were sunk to the bottom by the batteries. The precipitation with which the evacuation was effected, caused a great part of the ships and property to fall into the hands of the French, and was attended with the most melancholy consequences to the wretched inhabitants. Of thirty-one ships of the line, which the English found at Toulon, thirteen were left behind, nine were burned at Toulon, and one at Leghorn, and four lord Hood had previously sent away to the French ports, Brest and Rochefort, with 5000 republican feamen, whom he was afraid to trust; 7½ ports E. of Marseilles. N. lat. 43° 7'. E. long. 6°.

TOULON, a township of New York, near lake Ontario. TOULON en Charolais, a town of France, in the department of the Saône and Loire, near the Arroux river; 16 miles N.W. of Charolles. N. lat. 46° 41'. E. long. 4° 13'.

TOULOUSE, a town of France, and capital of the department of the Upper Garonne, on the Garonne. In the sixth century, it was the capital of the kingdom of the Goths. Before the revolution, it was the capital of Languedoc, fee of an archbishop, and second parliament of France: it is recognized for size next to Paris; the streets are mostly broad, and the houses are built of brick. The number of inhabitants, by a late enumeration, is said to be 50,171. Though so finely situated, its trade is inconsiderable, the principal article being Spanish wool. The university here was founded in 1228. The town-house is a spacious building, and called the capitole, whence the aldermen are termed capitouls; and amongst other curiosities preferred here, are fifteen large parchment folios, delicately written and illuminated, being annals of the city, commencing from the year 1288, and annually continued by the eldest capitoul. These were drawn up originally in Latin, but under Francis 1. were altered to French. The three first volumes are principally filled with the portraits and names of the capitouls, and the following contain all the memorable events and transactions throughout the whole kingdom. Here is also an academy of the sciences and liberal arts. At half an hour's distance below the city, the celebrated canal of Languedoc joins the Garonne, which here becomes navigable. In this city are made carpets, but of little value; together with some light silk and woollen stuffs; 34 ports S.E. of Bourdeaux. N. lat. 43° 35'. E. long. 1° 51'.

TOUM, a town of Syria; 6 miles N.E. of Damascas. TOUMANDI, a town of Aflatic Turkey, in Natolia; 32 miles W. of Kintaja. TOUMANDI Daghi, a mountain of Natolia, part of the ancient Olympus; 20 miles S.E. of Burja. TOUMANUGREE, a town of Hindooftan, in the ancient Kutchwaj; 12 miles S. of Budawar. TOUMEN, a town of Chinefe Tartary; 608 miles E.N.E. of Peking. N. lat. 42° 27'. E. long. 128° 51'.— Also, a river of Corea, which rises lat. 42° 8', long. 127° 34', and runs into the sea of Japan. N. lat. 42° 30'. E. long. 130° 34'.

TOUMET, a Tartarian standard of Chinefe Tartary. N. lat. 41° 7'. E. long. 110° 49'.

TOUN, a town of Peruia, in the province of Khorrassan; 90 miles N.W. of Herat.

TOUNA, or Shiek Abdullab, a small island of Egypt, in lake Menzaheh, where are the ruins of an ancient town; 3 miles W. of Tennis.

TOUNATEA, in Botany, one of the generia name Tounan. See SWARTZIA.

TOUNSE, in Geography, a river of Hindooftan, which rises about 20 miles S.W. of Mahur, in the circuit of Gurrah, and runs into the Ganges, about 20 miles below Allahabad.

TOVOMITA, in Botany, an unenamed name, altered by Aublet, from the Caribbean Fotonite. Juiffien has, we presume, according to his declared intention, afforded it merely a temporary adoption, till the genus is fully understood. With the same view we here admit this name, for the present only.—Juff. Gen. 256. Aubl. Guian. 956. Point in Lamarck's Dict. v. 7. 717. —Clafs and order, Palyandria Monogynia. Nat. Ord. Guttiferes, Juff.

Gen. Ch. Cal. Periathan inferior, of two roundish, concave leaves. Cor. Petals four, rather longer, ovate, acute, concave, equal, inferted into the receptacle of the flower. Stam. Filaments numerous, twenty to twenty-five, inferted into the fame receptacle, erect, linear, shorter than the corolla; anthers of two distinct ovate cells. Pfl. German superior, fefile, ovate, with four furrows; style none; stigma cruciform, in four depressed, rounded lobes. Fruit unknown.

1. T. guianensis. Aubl. t. 364.—The only species, found in the inland forests of Guiana, flowering in September. This is a tree, whose trunk rises to the height of ten feet, and is a foot in diameter, with a branching head. The wood is compact and hard. Bark reddish, exuding drops of a yellow transparent resin. Leaves on the young branches only, opposite, stalked, smooth, three inches long, elliptical, pointed, entire; green above; whitish, with red parallel veins, beneath. Flowers in little terminal three-forked panicules,
TOUP, Jonathan, in Biography, a learned critic, was born at St. Ives, in Cornwall, in the year 1713, and entered at Exeter college, Oxford, where he took a bachelor's degree. After being presented to the rectory of St. Martin, Cornwall, he took the degree of M. A. at Cambridge, in 1756. His "Emendationes in Suidam" introduced him to the learned world: it was published successively in three parts, the first in 1760, the second in 1764, and the third in 1766. The learning of this writer recommended him to the notice and patronage of bishop Warburton, whose positive and contemptuous manner he too much resembles; and for which he received merited censure. In 1769 he published "Epitola Critica ad Virum celeberrimum G.W. Glocet-

TOUP, in Geography, a lake of Thibet, 27 miles in circumference; 10 miles N. of Soue. TOUR, in Geography, a French term, often used among English writers for a journey. Thus we say the tour of Paris, or Rome, &c.

TOUPON, in Geography, a town of France, in the department of the Calvados; 3 miles W.N.W. of Bayeux. TOUR, La, a town of France, in the department of the Puy-de-Dôme; 12 miles W. of Besse. TOUE &c.

TOUPOUR, in Geography, a lake of Thibet, 27 miles in circumference; 10 miles N. of Soue. TOUR, a French term, often used among English writers for a journey. Thus we say the tour of Paris, or Rome, &c.

The edges of the prism are frequently truncated, and thus form prisms with nine or twelve sides. The primitive form of the crystal, according to Hauy, is an obtuse rhomb. The fracture of tourmaline is perfectly conchoidal; the internal lustre is vitreous. It is harder than hornblende, but softer than quartz; it scratches glass, and is brittle. The principal colours are dark green and brown, but it occurs also red and blue, of various shades and degrees of intensity. It is sometimes nearly opaque, but more frequently translucent or transparent. The crystals of tourmaline possess the peculiar property of being transparent when the light passes perpendicular to the axis of the prism, and opaque when it passes in the direction of the axis. It is always opaque when the height of the prism is less than its breadth. The principal form of the crystal has been before stated; but the most common of the fourteen or fifteen different varieties, is the prism with nine sides terminated by six planes at one end, and by three at the other; or by seven planes at one end, and three at the other. The end which has the smallest number of planes exhibits negative electricity, and that which has the greatest number, positive. This difference in the form of the electric poles is a general law of all crystallized minerals that are electric by heat. Before the blowpipe, the tourmaline melts into a greyish-white porous enamel, but the red Siberian tourmaline is infusible. The constituent parts of tourmaline are given by Vauquelin and Klaproth as under.

According to Vauquelin:

The tourmaline is a name given, as Dr. Watson has evinced, to the lyncium of the ancients. See Lyncium Lapis.

This stone is very common in several parts of the East Indies, particularly in the island of Ceylon, where it is called tourmaline. Pliny mentions a red or purple stone which attracted light bodies. This is supposed to be the tourmaline. The first account of this stone, that occurs of late years, is in the History of the Royal Academy of Sciences at Paris for 1717, where we are told that M. Lemerex exhibited an uncommon stone brought from Ceylon, which attracted and repelled small light bodies. Linneus, in his Flora Zeylanica, calls this stone lapis electricus, and takes notice of Lemerex's experiments. M. Epsinus, having been informed of the attractive power of the tourmaline by Mr. Lechman, and furnished by him with two stones, made many experiments, the result of which was published in the History of the Academy of Sciences and Belles Lettres at Berlin, for 1756. The substance of his memoir is as follows: the tourmaline has always, at the same time, a positive and a negative electricity; the one of its sides being in one plane, and the other in the opposite; and this does not depend on the external form of the stone. These electricities could excite in the strongest degree by plunging the stone in boiling water.

The proper degree of heat for manifesting the electricity of the tourmaline, is from 100° Fahrenheit to 212°. If we raise the temperature above 212°, it loses its electricity, but regains it in cooling; but if we continue to raise the temperature, we arrive at a point in which the mineral again becomes electric, but has its poles reversed to what they were before. Hauy observed, that we may also change the position of the poles, by heating it unequally in the focus of a lens or mirror. If an electrified tourmaline be broken, the fragments immediately present electric poles, situated in the same direction as that of the large crystal.

If one side of the tourmaline be heated more than the other (as if it had lain upon a hot cake of metal), each of the sides acquires an electricity opposite to that which is natural to it; but if left to itself, it will return to its natural state.

If one of the sides of the tourmaline be rubbed, while the other is in contact with some conductor communicating with the ground; the rubbed side is always positive, and the other negative. If neither side be in contact with a conductor, both become positive. If, in the former of these cases, the tourmaline be rubbed so as to acquire a sensible heat, and the side which is naturally positive be made negative, it will, upon standing to cool, return to its natural state; but if it has acquired no sensible heat, it will not return to its natural state while any kind of electricity remains. If it be heated, even when it is rubbed and insulated (in which case both sides become positive), it will still return to its natural state upon cooling.

The Duc de Nova, who, in 1758, procured two of these stones in Holland, and made a number of experiments with them, an account of which he published, mentions the experiments of M. Epsinus, but does not admit of a plus and minus electricity belonging to the tourmaline when heated. On the contrary, he says that both the sides are electrified plus, but one of them more than the other. The tourmaline was introduced to the notice of the English philosophers by Dr. Hetherden, who procured one (and, indeed, the only one known in England at that time) for Mr. Willson; whole experiments confirmed the opinion of its positive and negative power, advanced by M. Epsinus. Dr. Franklin, likewise, in a letter to Dr. Hetherden, in 1759, informs him of experiments on one of these stones, sufficient for establishing the same theory. About this time Dr. Hetherden procured one of these stones from Holland, and put them into the hands of Mr. Willson and Mr. Cottam, gentlemen particularly conversant with the subject of electricity, and capable of using them with the greatest advantage to this branch of science. Mr. Willson's experiments and observations are very numerous; the result of which was, in the main, the same with that of M. Epsinus, establishing the opinion of the two different powers of this stone; but he differs from him in ascertaining, that when the sides of the tourmaline are unequally heated, it exhibits that species of electricity which is natural to the hotter side; i.e. the tourmaline is plus on both sides, when the plus side is the hottest; and minus on both sides, when the minus side is the hottest. Both these gentlemen repeated their experiments, and each retained his own opinion; but Mr. Willson's apparatus was better calculated for the purpose of accurate experiments than that of M. Epsinus, and he used a greater variety of methods.
methods for communicating heat to his tourmaline. Mr. Wilfon imagined that this stone, as well as glafs, was permeable to the electric fluid, and that the refiftance to its entering the subftance of it was lefs on what he calls the negative than on the positive fide; for rubbing the positive fide of the ftone strongly, he found both fides electrified plus; by rubbing the negative fide in the fame manner, both fides were electrified plus, more strongly than before. Several experiments led Mr. Wilfon to conclude, that the tourmaline refifted the exit and entrance of the electric fluid conliderably lefs than glafs, or even than amber; and he infers, upon the whole, that this ftone differs in nothing from other elec- tric bodies but in acquiring electricity by heat. Mr. Wilfon also conceived, that the tourmaline fuffered the electric fluid to pass through it only in one direction, bearing in this respect fome analogy to the lod-stone, and having as it were two electric poles, which are not eafily destroyed or altered. He also apprehended, that the electric fluid, flowing through all the ftones and gems which re- femble the tourmaline in their electrical properties, moves in that direction in which the grain happens to lie; the refiftance, as he fuppofes, which the fluid meets with, being lefs in that direction than in any other.

Notwithstanding the attention given to this subjeft by M. Åpinus and Mr. Wilfon, the moft important discovery relating to the electricity of the tourmaline was referred for Mr. Canton, who, in a paper read before the Royal Society in December 1759, observes, that the tourmaline emits and aborbs the electric fluid only by the increafe or diminution of its heat; for if the tourmaline, he fays, be placed on a plain piece of heated glafs or metal, fo that one fide of it, by being perpendicular to the surface of the heated body, may be equally heated; it will while heating have the electricity of one of its fides positive, and that of the other negative. This will likewise be the cafe, when it is taken out of boiling water, and fuffered to cool; but the fide which was positive while it was heating, will be negative while it is cooling; and the fide which was negative will be positive. In the Gentleman's Magazine for September 1759, (vol. xxix. p. 424.) he published the reft of fome experiments which he had made on a tourmaline procured from Holland, in a series of propositions, comprising the principal part of what is known on this fubjeft. They are as follow: 1. When the tourmaline is not electrical or attractive, heating it, without friction, will make it fo; and the electricity of one fide of it (diftinguifhed by A) will be positive, and that of the other fide (B) will be negative. 2. The tourmaline not being electrical, will become fo by cooling; but with this difference, that the fide A will be negative, and the fide B positive. 3. If the tourmaline, in a non-electrical flate, be heated, and fuffered to cool again, without either of its fides being touched; A will be positive and B negative, during the whole time of the increafe and decreafe of its heat. 4. Either fide of the tourmaline will be positive by friction, and both may be fo made at the fame time. He fuppofes that, if air be endued with similar properties, or be capable of becoming electrical by the increafe or diminution of its heat (as is probable by attending to its flate before and after a thunder-form), thunder-clouds, both positive and negative, as well as thunder-gulfis, may be easily accounted for. Mr. Canton, with the tour- maline which he received from Dr. Heberden, made other new and curious experiments, firft published by Dr. Prieftley. He put one of them, which was of the common colour, into the flame from a blowpipe, and burnt it white; when he found that its electrical property was entirely destroyed. The electricity of another was only in part destroyed by fire.

He joined two others, made foft by fire, without destroying their electrical property. The virtue of another was improved by being melted at one end; and he found (con- trary to what Mr. Wilfon had obferved of another tour- maline, heated in the fame manner) that one tourmaline re- tained its electrical property, after it had been frequently made red-hot, and in that flate put into cold water. But the moft curious experiment was made on a large irregular tourmaline, about half an inch long, which he cut into three pieces; taking one part from the positive and another from the negative end. Trying these pieces separately, he found the outer fide of the piece cut from the end that was nega- tive when cooling, was likewise negative when cooling; and that the outer fide of that piece which was cut from the end that was positive when cooling, was likewise positive when cooling; the opposite fides of both pieces being, ac- cording to the general law of the electricity of the tour- maline, in a contrary flate. The middle part of the fame ftone was affected as it had been when it was entire; the positive end remaining positive, and the negative end negative.

Dr. Prieftley, about the clofe of the year 1766, directed his attention to the tourmaline: being in pofteffion of Dr. Heberden's large polished one, which weighed one hundred and twenty grains, of an oval form, plane on one fide and convex on the other, and which had paffed through the hands of Mr. Wilfon and Mr. Canton, he purfued his inves- tigation of the properties of this ftone in a variety of experiments. Several of them were undertaken with a view of determining, whether the tourmaline collected its electricity from the neighbouring air; he was led to this conclu- sion from the confideration of Mr. Wicke's experiments on the production of spontaneous electricity, by melting one fubftance within another; and his experiments feem to prove that his conjecture was juft. He also discovered a method of reversing all the experiments made upon the tourmaline, making that fide which is positive in heating or cooling to be negative; and that which is negative to be positive: so that the kind of electricity fhall be juft what the operator fhall direct, by the application of proper fub- ftances to the ftone. Dr. Prieftley not only tried how the tourmaline would be affected by being heated or cooled in contact with various fubftances, to which only one of its fides was expofed at once, but he also made other experiments, in which the ftone was entirely furronded by them. Having covered the ftone to the thickness of about a crown-piece with feeling-wax, he found it to act nearly, if not quite as well, through this coating of wax, as if it had been ex- pofed to the air: hence, if a tourmaline be concealed in a ftick of feeling-wax, the wax feem to have acquired the properties of the tourmaline. See on this article Phil. Trans. vol. li. p. 368, &c. p. 394, &c. vol. liii. p. 436, &c. Franklin's Letters, &c. p. 376. Prieftley's Elec- tricity, vol. i. p. 347, &c. vol. ii. p. 308, &c. 8vo. ed.

The tourmaline, according to Mr. Kirwan, is a fliceous earth, imperfectly united with from 1.05 to 1.47 of its weight of argill, from 0.3 to 0.4 of its weight of mild cal- careous earth, and from 0.15 to 0.243 of its weight of iron. This ftone has been found in Ceylon, Brazil, and the Tyrol: a fpecimen of each has been examined by Mr. Bergman; that of Ceylon is of a dark-brown or yellowwith colour; its specific gravity 3.05 or 3.205: that of Brazil is green, blue, red, or yellow, and its specific gravity 3.07 or 3.18: that of the Tyrol, by re- flected light, is of a blackifh-brown, but by refracted light, yellowish, or in thin pieces, green; its specific gravity 3.05. In fire, none of them deccipitate: but thoie of Ceylon
The red-coloured tourmaline from Siberia is regarded by some mineralogists as a distinct species; it differs from other tourmalines in being infusible: it has been denominated rubellite, (which see.) The indigo-blue variety of tourmaline has been called by Karsten and Dendrada indigolite.

The tourmaline occurs imbedded in gneiss, mica-flate, talcose flate, and talc. It is sometimes found in granite. It is found in rolled pieces in alluvial ground: it was first discovered in the island of Ceylon in the 15th century. It has since been found in various alpine districts of Europe and Asia, in the island of Madagascar, and in North and South America.

The tourmaline may be distinguished from common fchorl by its colour; the latter is always black. The fracture in common fchorl is small-grained and uneven, that of tourmaline conchoidal. The opacity of common fchorl is always greater than that of tourmaline. It differs from common and bafatic hornblende in its fracture, that of the latter being distinctly foliated. The following names have been given to different varieties of tourmaline.

Green tourmaline — Brefilian emerald
Berlin blue — Brefilian fapphir
Indigo-blue — Indicolite
Honey-yellow — Peridot of Ceylon.
Red — Rubellite, fherite, and

TOURNAY, a town of France, in the department of the Pyrenees; 9 miles S.E. of Tarbes.

TOURNE-COUPE-EN-BIGORRE, a town of France, in the department of the Gers; 9 miles S.E. of Lectoure.

TOURNEFORT, Joseph Pitton de, in Biography, the great leader of the French school of botany, of whom we have spoken (see RIVIUS) as one of the three most distinguished systematic writers of the age preceding LINNAEUS, was born of a gentleman’s family at Aix, in Provence, June 5th, 1656. His mother, Ademara Fagoué, was of a Parifian family, likewifc, in the French fcent, noble. Being defined by his parents for the church, he was educated at the Jesuits’ college of his native town; but he soon imbibed a taffe for natural knowledge, which led him at the age of 21, on the death of his father, to change his original defination, for the profeflion of phyfic. This latter indeed was but infubfervent to a moft ardent devotion for botanic science, which ever after made the object and the happiness of his life. Not that his education, in other refpects, was neglected; for he proved a good fcholar, well grounded in the studies necefary to his medical profeflion, particularly anatomy and chemistry, and no lefs verfed in historical and critical knowledge; infomuch that he became an elegant writer and lecturer, as happy in his powers of communicating, as of acquiring, information. His per- fonal character, manners, and addresses were alfo such as to prove a general recommendation in his favour through life.

Having soon exhausted the botanical riches of a phyfic-garden at Aix, and of the circumjacent fields, he extended his researches to the neighbouring Alps, and afterwards to the Pyrenees, where his hardy frame of body, and his ob- serving enterprising mind, rendered easy to him the acquisi- tion of the principal vegetable flores of those romantic and fertile regions. Even the thievifh and lawlefs hordes, which fo often infet the borders of kingdoms, and which then abounded in the Pyrenean fastnesses, were fearcly formidable to a traveller, whose only riches were dried plants, and whose onlyfible provifion for his journey con- fisted of a little black bread, in which he concealed his money. The intermediate winters between his feveral visits to Dauphiny, Savoy, Catalonia, the Pyrenees, &c.
were spent in the university of Montpellier, where he first entered in 1679; but he is said to have taken his doctor's degree at Orange. At Montpellier he enjoyed the intimacy of the excellent Magnol, of whom we have given an account in his proper place, and to whom the long-established botanical fame of that university is chiefly owing. Yet this able man narrowly escaped being hunted from his seat; as his holy name evinced successor, professor Decandolle, has lately, in 1876, been, because he was a Protestant; nor could the appointment of his king peremptorily the latter from that king's worst enemies. Tournefort was in no danger of this kind. He was nevertheless a liberal Catholic, whose subsequent am NSDataions on the depraved superstitions that occurred in his travels, prove him to have been by no means the slave of any church or priesthood.

The merits of Tournefort, as a botanist, soon became conspicuous at Paris, and, aided by a fortunate introduction, procured him the especial favour of professor Fagon, then chief physician to the queen, (see Fagónia,) who resigned in his favor the superintendence of the royal garden. In this school he was soon attended by a numerous throng of students, eager to follow him in his herborizations round Paris, and to profit by his practical remarks. We have already, in our account of William Sherard, mentioned that illustrious botanist as among his affidious pupils. The subject of our memoir now became desirous of further examining the productions of other countries than his own, in their native situations. For this purpose he travelled in 1688 to Spain and Portugal, afterwards into Holland and England; enriching by these means his own collection of dried plants, as well as the living collections of the Parisian garden, and procuring the acquaintance and correspondence of all the most eminent cultivators of the science in which he excelled. Hence the great herbarium of Sherard became supplied with all Tournefort's acquisitions, not only at that time, but after his subsequent voyage to the East, the fruits of which were transmitted to England with more particular care and exactness, than perhaps to any other country, as appears by what are still preserved at Oxford. The studies and labours of Tournefort were facilitated and encouraged by a royal pension, which could certainly not come under the opprobrious denomination of a sinecure. In 1692 he became a member of the Academy of Sciences, and in 1694 published in French his Elements de Botanique, making three octavo volumes, dedicated to Louis XIV.—This was but a prelude to his immortal work, the Institutiones Rei Herbariae, of which the first edition, in three quarto volumes, with 476 plates, appeared in 1700. The second, which, with a reference to the "Elements," is called the third, was published by Anthony de Jussieu, at Lyons, in 1719, with the Corollarium, composed of the author's Oriental discoveries. In 1698, when he was admitted a member of the Medical Faculty at Paris, he published a little duo-decimo volume, Histoire des Plantes qui naissent aux Environs de Paris, afterwards translated by professor Martyn into English. The reputed virtues of the plants are subjoined to their synonyms and descriptions. The arrangement is alphabetical, the style defuljory, nor is this one of the best books of its kind.

We know not at what period Tournefort received the order of St. Michael, but that he was decorated therewith appears by his portrait, published by Dr. Thornton, from an original picture; and the circulation is alluded to by Haller, Bibl. Bot. v. 2. 3.

At the earnest recommendation of his friend Fagon, Tournefort was dispatched, under royal patronage, on a voyage to the Levant, the avowed object of which was to investigate the plants of ancient writers, as well as to make new discoveries. He was accompanied by a German physician, named Andrew Gundelfscheimer, (see Gundelia,) and by Claude Aubriet, one of the most exquisite botanical painters that the world ever saw. These travellers left Paris on the 9th of March, 1700, and embarking at Marfelles the 23rd of April, anchored nine days afterwards in Crete. The investigation of the Archipelago, Greece, the shores of the Euxine, the countries of Bithynia, Cappadocia, Iberia, Armenia, Georgia, Galatia, Lydia, &c. occupied two years, and our adventurers returned in safety to Marfelles, on the 3d of June, 1702. Tournefort's account of this expedition, written in French, and published soon after his decease, is one of the most agreeable, intelligent, and valuable books of travels extant. De Thésys justly refutes the cenfure of the Abbé Sellami, that it is written with the furia francese, or rage for every thing French. To the mode of its composition indeed something may be objected. The work is addressed, in the form of letters, to the comte de Pontchartrain, secretary of state, &c. &c.; and as the etiquette of the French court required that so illustrious a personage should of course be endowed with all human erudition and knowledge, the writer is obliged to treat him accordingly. We are therefore told nothing without the impertinence of "vous favez Monseigneur!" except perhaps the harmless description of a new plant, in writing which the author's love of science made him flip, for a moment, the collar of patronage. The reader indeed soon forgets every thing but the delightful company of the narrator, who takes us along with him to every spot; details with equal intelligence the manners, dress, and information of the people he visits; or carries us into the profoundest researches of ancient history and geography; tracing the fate of empires, countries, and cities, with the same grace and facility with which he makes us enamoured with a new plant, or exposes the impositions or the ignorance of emperors of the soul or body. This work is illustrated with a very large number of plates, of which the botanical ones are particularly excellent. We have a good English edition, and Haller mentions one in Dutch. The curious grotto of Antiparos afforded the author an opportunity of detailing his favourite theory of the vegetation of stones, which is now refuted by more accurate chemical enquiries. (See Stones.) His travels were to have extended into Africa, but the plague raging in Egypt, he returned home directly from Smyrna. On arriving at Paris, it was his design to have turned to advantage the connections and reputation he had acquired, by devoting himself to the practice of physic. But whatever prospect he might formerly have had of successes in this line, was defeated by his long absence; nor did the duties of his botanical appointments leave him sufficient leisure to court or to pursue his more lucrative profession. His time however was incessantly occupied; and the preparation of his Voyage du Levant for publication, which, confederating the books necessary to be consulted, was not light or speedy task, led him too often to encroach on the night, after the superabundant labours of the day. His health became impaired, but this could not relax his ardour. His fate however was precipitated by the accident of a carriage in the street, which crushed his breast, and even threatened him with instant death, from which he was rescued by the exertions of a friend near at hand. He languished for a few months only after this event, and died December 28, 1708, in the fifty-third year of his age. We find no mention of his place of burial, nor of any monument erected to his memory. He was never married. He left his collection of plants to the king, who bestowed a pension of a thousand
thousand livres on his nephew, as an avowed return for this legacy, and a testimony of royal esteem for the deceased. The first volume only of his *Voyage* was printed at the time of its author's death. A second edition appeared at Amsterdam in 1718, to which are prefixed the *Éloge de Tournefort*, delivered by Fontenelle to the Academy of Sciences, April 10, 1709; and a more ample composition of the same kind by Lauthier, in a letter to M. Bégon, the patron of Plumer, and the friend of Tournefort. This last account, in particular, is written with the affektion and respect of a person intimately acquainted with the private character, as well as public merits, of the subject of his narrative. Tournefort is described by him as of the most simple though engaging manners, devoid alike of ostentation and of jealousy, as amiable and exemplary in private life, as he was zealous and exact to fulfill his public duties. Besides his knowledge of Latin and Greek, he was versed in the Italian and Spanish languages. The abundant riches of his mind were readily communicated, with clearness and facility, but without parade, in his conversation as well as in his lectures.

Of the principal works of this eminent man, we have already spoken; and it chiefly remains for us to offer some remarks upon his merits as a systematic botanist. He is said to have left several works in manuscript. One of these was entitled *Topographie Botanique*, containing the precise places of growth of the plants collected by himself in the south of France, as well as in Spain and Portugal, between the years 1676 and 1690. He also composed an universal critical history of plants, in alphabetical order, under the title of *Plantarum Adversaria*, in which the remarks of preceding writers were collected and compared, and his own opinions subjoined. The *Schola Botanica* a catalogue of the Paris garden, we have already mentioned in the biographical article of William Sherard. M. Lauthier removes all doubt respecting the real author of that little volume, by informing us he had seen a copy, with manuscript additions and corrections in Tournefort's own hand, where Sherard was named as the writer of the book.

Tournefort was led, by the philosophy of his time, to search for the medical qualities of plants by a chemical analysis. On this subject he is recorded to have left a volume of manuscripts. That it has never been published is no loss to the world; the work of Geoffroy, undertaken, and laboriously accomplished, with the same view, having proved that no real knowledge is to be acquired by this means, and having therefore put the question for ever at rest. Our readers will find the principles of Tournefort's system of botanical arrangement, under the article *Classification*. According to this, his *Institutiones Rerum Herbarum* are divided; and the same subject was adopted by several compilers of local *Floras*, or of garden Catalogues, in the early part of the eighteenth century. Even Linnaeus's earliest work, entitled *Sphaera Botanica*, five *Planta Rariores Qua Smolandiac, Scandian et Refugianae observata et enumerates*, the unpublished manuscript of which, dated Upfal, 1729, and illustrated with drawings, is now before us, is clasped after Tournefort's method. Nor did any great difficulties attend the application of that method to any tribes of plants with which its author had been conversant. But when the productions of new continents came to be examined, it necessarily fell short; as we have remarked in the biographical article of Dr. Alexander Garden. No system of botanical classification, except the artificial sexual one of Linnaeus, has ever proved universally applicable to the vegetables of all countries, because no other depends on parts essential to the very being of every plant.

Tournefort's method, however, by its apparent facility, the elegance of the parts on which it chiefly rested, and its great conformity, in many respects, to the evident order of nature, though in others it as remarkably infringes on that order; became, by all these attractions, very popular. If the more abstruse and philosophical principles of Cæcilius, Ray, Hermann, &c. educated founder theoretical botanists; the method of Tournefort made a great number of practical ones. Yet it is not upon his system of classification that the fame of this great naturalist depends. His discrimination of the genera of plants must alone immortalize his memory. His labours in this department of the science are the principal foundation of all that has been done since his time, and of all that can ever be attempted in future. If he did not, like Linnaeus, invent a clear mode of defining each genus by words, no one can deny that he had a most comprehensive, and, for the chief part, distinct idea of the whole subject. He has caused each genus to be figured in a able manner, that his exquisitely plates supply, as much as possible, all verbal deficiencies. Haller indeed complains, not unjustly, that Tournefort's figures are more instructive than his definitions, as exhibiting characters respecting the flanes, styles, and other parts of flowers, which, though affording the best generic distinctions, are not taken into his descriptions. Such defects seem to have arisen from his disapprobation, bordering on contempt, of the doctrine of the lex of plants. He thought the authors served merely to discharge an extraordinary matter, or to separate iniquities from the eminence; though it could not escape him that these two parts were often very distant from each other; and he was therefore not much satisfied with his own hypothesis. Such dissatisfaction would naturally lead him further from dwelling with pleasure on the parts in question, for any purposes of arrangement. He rather delighted to perfect in the disgraceful blunder of the old authors, who spoke of the male and female plants of Nettle, Mercury, Hemp, &c., as distinct species, and called the female the male, because of the form of the seed-vessel. It is indeed one of the most remarkable facts in the philosophy of botany, if it may here deserve to be honoured with an appellation, that when the most ancient writers, as well as their early followers among the moderns, distinguished plants by the names of male and female, they meant to designate them in general, as different species. Tournefort, from inadvertency falsely, followed them in this error, as well as in every other, relating to the species of plants. To that subject he never gave any philosophical attention. The plan of his work was to dispose all the known plants, under genera, whose leading principles of distinction were, with some exceptions, taken from the fructification. This great undertaking he accomplished in a masterly manner, as well as the arrangement of these genera, according to a philosophical system. But he was content to collect under each genus all the reputed species of Calypso Bœhn and others, judging of their generic character only, and not taking into the leaf consideration their specific differences. Hence double flowers, varieties of colour, flavour, &c. stand as species in Tournefort's *Institutiones*. It is unfair to blame him for imperfections in what he never undertook to amend; but if genuine specific distinctions be, as Linnaeus declared, the perfection of botanical science, as they are, in fact, the only permanent and indisputable ground of the whole; we cannot claim for Tournefort the highest rank as a practical botanical philosopher. That he was deeply and learnedly versed in the theory of the science, appears from all parts of his writings, and from none more than his masterly *Syngoge in Rerum Herbariwm*, where the subject is treated historically as well as systematically. Whatever this illustrious botanist has done, or whatever he has...
left undone, he is the father of the French school of botany, and the traces of his principles, either confirmed, improved, or superseded by the labours of other teachers, are conspicuous in the works of his distinguished followers Vaillant, Lamarck, and the Jullieux. With the feelings of the first of these, as Vaillant could not but be sensible that, in some important points, he had the advantage of his great predecessor, somewhat of conscious superioriety, not inconsistent with jealousy, was often intermixed, and too often betrayed. But the others, living at too remote a period from their idol to consider him otherwise than as the glory of their country, have made him ample amends in identifying his fame with that of France itself. The most valuable improvements, not only in classification, but in nomenclature, were, for a long time, not permitted to encroach even on thenegligences or errors of Tournefort. The national spirit of the French still renders this illiberal principle sanctified. The homage long given to Tournefort is now transferred to Jullieux. The term of *læve-nature* is applied to the Linnaean system, as if his own were entirely a natural one, and as if what the great Swedish botanist modestly called fragments of a natural scheme of arrangement, were not, in fact, the basis of the best part of Jullieux's. The mischief of these exclusive partialities is, that the really valuable improvements in science, which originate in other schools, are too much neglected by the pupils of the Parian one. In clear discrimination, and concise definition, in lucid order, elegant and classical terminology and nomenclature, in judicious combination, as opposed to faidious and indiscriminate dilution, they generally, and sometimes very remarkably, fail. If any of them should design to peruse this criticism, may they disarm it by correcting the imperfections to which it alludes! Rivalship in science or philosophy ought only to lead to mutual improvement; for he who will learn nothing from an adversary, does but render apparent one inextricable cause of his own imperfections. Tournefort's Works. Hall. Bibl. Bot. S.

TOURNEFORTIA, in Botany, bears that name in commemoration of the great French botanist, of whom we have given an account in the preceding article. This genus, founded by Plumier, was called by him *Pittonia*, after the family name of the person commemorated. Linnaeus altered it, according to his own rule, of retaining the appellation by which that person was most known. So he preferred *Hippocratea* to the Coa of Plumier, and *Theophrastia* to his *Erythea*. French writers have subsequently acceded to this decision.—Linn. Gen. 78. Schreb. 104. Willd. Sp. Pl. v. 1. 791. Mart. Mill. Dicht. v. 4. Ait. Hort. Kew. v. 1. 303. Brown Prod. Nov. Holl. v. 1. 496. Jull. 129. Lamarck Illust. t. 95. Poiret in Lam. Dict. v. 5. 355. Gärtn. t. 76. (Pittonia; Plum. Gen. 5. t. 3.) —Clas and order, *Pentandra Monogyna*. Nat. Ord. *Asterifolii*. Linn. *Borrageae*, Jull.

Gen. Ch. Cal. Perianth inferior, of one leaf, small, in five deep, awl-shaped, persistent segments. *Cor.* of one petal, funnel-shaped; tube cylindrical, globose at the bottom; limb spreading, divided half way down into five pointed, horizontal segments. *Stam.* Filaments five, awl-shaped, in the throat of the corolla; anthers simple, within the orifice of the tube, converging, pointed. *Pil.* Germen superior, globose; style simple, the length of the stamens, club-shaped; stigma bare, umbonate. *Peric.* Berry globose, of two cells, perforated by two pores at the summit. *Seeds* four, nearly ovate, lepaped by pulp.

TOU

A tropical genus of erect or twining shrubs, with simple, undivided, alternate, rough, hairy, or silky, rarely smooth, leaves. The flowers are numerous, mostly white or bluish, in dense, recurved, unilateral, often cymose, spikes, without bracteas. Berries white, bluish or black. In habit, this genus comes nearest to *Heliotropium*. *Messerchmidia* is united to it by Mr. Brown. (See those articles.) In the true *Tournefortia*, according to that learned botanist, the berry has only two seeds, or nuts, each with two cells. To these belong the *Messerchmide* and *Heliotropium gaephalodes* of Linnaeus. In *T. hisrtissiflora*, the berry has four simple, or single-kerneled, seeds, and a straight embryo. In *T. volubilis* of Linnaeus, and *scander* of Solander, to which we may add *serica* of Vahl, the segments of the corolla are awl-shaped, the berry with four simple seeds, of which two or three are often abortive, and a curved embryo. Mr. Brown would separate all these from *Tournefortia*, but whether the *hisrtissiflora* should form a distinct genus from the species with awl-shaped segments of the corolla, he is doubtful. A confederation of the genera *Onagia* and *Ceratke*, to say nothing of others of this same order, makes us doubt if the number of parts, or cells, in the fruit, or rather the greater or less union of those parts, can here make a general distinction. We submit it to the re-consideration of our learned friend; and in the meanwhile we shall attempt a display of all the species of *Tournefortia*, of which Linnaeus and Willdenow have given but a very incomplete list. Poiret in Lamarck's Dict. has added several to the number, but we polishes some, even from Commerson's collection, which are not to be referred to any of his. Some of the described ones have not come under our inspection, and the history of others is much confused, but we hope to leave the subject, if not fully elucidated, at least in a clearer state than we find it.—*T. bunida*, Linn. Sp. Pl. 202, belongs, according to Mr. Brown, to *Heliotropium*. See that article.

1. *T. ferrata*. Greater Serrated Tournefortia. Linn. Sp. Pl. 201. Willd. n. 1. (Pittonia arborescens, chamadricolia major; Plum. l. 224. t. 228 f. 1.) Varronia mirabiloides; Poiret in Lam. Dict. v. 4. 262.)—Leaves ovate, serrated, on pinnate footstalks. Spikes recurved, on axillary stalks, longer than the leaves.—Native of the West Indies, where it was found by Plumier, from whose figure alone it is known to us. The flower is said to be arbo-rectile, with round zigzag branches. Leaves about two inches long, strongly serrated, on stalks nearly an inch in length, each with a joint about the middle, where the stalks seem finally to separate, the lower part hardening into a spine. Flowers: stalks axillary, solitary, each bearing three recurved spikes, of numerous, large self flowers, the limb of whole corolla is undulated, an inch in diameter. Berry the size of a pea, globose, undivided. Poiret says it is red. If his plant from Hispaniola be the same, this species must be removed to *Varronia*, which is rendered probable by the aspect of its corolla.

2. *T. chamadricolia*. Lesser Serrated Tournefortia. (T. ferrata var.; Linn. Sp. Pl. 201. Willd. n. 1. Pittonia arborescens, chamadricolia minor; Plum. l. 224. t. 228 f. 2.)—Leaves oblong, serrated, on recurved pinnate footstalks. Spikes capital, terminal.—For this also our only authority is Plumier, who gathered it in some part of the West Indies. It appears to differ essentially from the former, in the characters above given, as well as its much smaller size. The flowers however are nearly as large, but much fewer, with partial stalks, which become very conspicuous as the fruit ripens. Their corolla is represented very regularly crenate, rather than undulated, but indicates a *Varronia*, as well as that of the foregoing.

3. *T.*
3. *T. hirsutiflora.* Hairy Tournefortia. Linn. Sp. Pl. 201. Willd. n. 2. Poiret n. 1. Swartz Obs. 56. (Pittonia hirsutiflora et lamosiflora, baccis albis; Plum. Ic. 226. t. 228. Heliotropi flore, brutex baccifer racemosi, folio rugoso footi maximo subrotundo hirsuto, fructu albo; Sloane Jam. v. 2. 108. t. 212. f. 1.)—Native of bushy places in Jamaica, and other West Indian islands, as well as of Mexico, from whence it was sent by Mutis to Linnaeus. This is a *frub*, three or four feet high, somewhat twining, its branches, filals, foliage, and calyx clothed with rufly down. The *corolla* is still more densely covered externally with silky hairs. *Leaves* foetid, filaked, elliptical, entire, pointed at each end, tranfversely ribbed, three inches long, and an inch and half broad; molt hairy, and rather filaky, at the back. *Spikes* aggregate, on long, hairy, axillary and terminal filals, about the ends of the branches. *Flowers*, as well as *berries*, white; the latter rough and hairy, Swartz fays of two cells, with two *seeds* in each, which does not agree with Mr. Brown’s account, given above.

4. *T. multiflora.* Tobacco-leaved Tournefortia. Linn. Sp. Pl. 201. Willd. n. 5. Ait. n. 2. Swartz Obs. 58. (Pittonia racemosa, nicotiana folis, faticiflora; Plum. Ic. 226. t. 230.)—Leaves ovato-lanceolate, rough; downy and pearly beneath. *Flower-flanks* branched. *Spikes* pendulous. *Calyx* shorter than the *style*.—Native of Jamaica. Dr. Wright. The *leaves* vary in size; but are not unlike thole of *T. hirsutiflora* in shape. Their upper surface is more minutely rough than in that species, and their under one more softly and densely downy. The *spikes* are very remarkable for their extremely long linear form, and pendulous position. They measure frequently eight or ten inches, and are from six to eight on each axillary forked filal. The *flowers* are small, fepulchre, in a fimple unilateral line. *Calyx* hairy, with lanceolate upright figures. *Tubes* of the *corolla* hairy upwards, about thrice as long as the *calyx*; its limb in five ovate, obtuse, keeled, refexed figures. *Style* projecting beyond the permanent *calyx*, after the *corolla* is fallen, with a very large pulley-shaped pointed /hifma/. This is united, by Lamarck and Poiret, to the following, under the name of *macrophylla*; Poiret n. 2.

5. *T. cymofo.* Drooping Cymofo Tournefortia. Linn. Sp. Pl. 202. Willd. n. 8. Ait. n. 4. Jacq. Coll. v. 1. 96. Ic. Rar. t. 31. (Heliotropi flore, brutex, folio maximo oblongo acuminate glabo; Sloane Jam. v. 2. 109. t. 212. f. 2.)—Leaves elliptic-lanceolate, pointed, smooth. *Flower-flanks* much branched. Spikes drooping. *Calyx* as long as the *style*.—Native of the Weft Indies. This is certainly, as Linnaeus observes, nearly related to the foregoing, but differs in the smoothness, and more elongated points, of the *leaves*, as well as in its more numerous, shorter, and less definitely pendulous, *spikes*. The *flowers* are similar, but the *style* in our fpecimens does not project beyond the *calyx*. The *corolla*, at first white, turns tawny, and dark red, before it falls. *Berry* the size of a small pea, white, with black dots.

6. *T. fringeloida.* Lilac-leaved Tournefortia. Vahl. Symb. v. 3. 23. Willd. n. 4. Poiret n. 17. —Leaves ovate, somewhat heart-shaped, pointed, smooth. *Spikes* terminal, divaricatet, hairy, as well as the *filals*.—Native of Cayenne, and, if we mistake not, of Jamaica, where our fpecimen, precifely anfwering to Vahl’s description, was gathered by Dr. Wright. The *young branches*, as well as the *flower-flanks*, the main rib of the *leaves* on both fides, and the tranverse ribs underneath, are all more or less hairy, like the *flower-flanks*, *spikes*, *calyx*, and outside of the *corolla*. *Leaves* two inches long, deftitute of fine intermediaf veins, quite smooth, except the ribs. *Flower-flalk terminal, erect, forked, with spreading *spikes* above an inch long. *Flowers* alternate. Segments of the *corolla* with long taper points.

7. *T. bicolor.* Pale-backed Tournefortia. Swartz Ind. Occ. v. 1. 344. Willd. n. 7. (T. levigata; Poiret n. 37.)—Leaves elliptical, pointed, smooth; slightly rufky on the upper side. *Spikes* terminal, cymofo, crowded, erect, recurved, somewhat hairy.—Native of bushy places in Jamaica. A *frub* fix feet high, with smooth branches. *Leaves* three or four inches long, elliptical rather than ovate, acute at each end, finely reticulated with veins between the ribs, occasionally minutely hairy, as well as the branches and *foot-flanks*; pelar beneath. *Flower-flanks* several, terminal, alternate, rather hairy, erect, each bearing fix or eight sub-divided, cymofo, dense *spikes*. Segments of the *calyx* ovate, scarcely hairy, except when the leaves are fo. *Corolla* greenish-white, externally covered with fily hairs. *T. glabra*, Linn. Sp. Pl. cd. 1. 141, is perhaps a variety of this.

10. *T. farnentofo.* Trailing Tournefortia. Poiret n. 5.—“Leaves ovato-oblong, acute. *Spikes* branched, very short, two-ranked. Stem twining.”—Native of the Mauritius. Sonnerat. A fpecimen gathered by Commerfon in the Philippine iflands, anfwers very nearly to the following defcription of Poiret. The *flams* are climbing, with long, diant, trailing *shoots*, flirated, nearly cylindrical, clothed with short whitifh hairs. *Leaves* alternate; downy, and whitifh bencath, especially when young; rounded and di- lated at the base; almost smooth on the upper surface; three or four inches long, and an inch and half wide. *Foot-flanks* short, very downy. *Flowers* terminal, in short, close, branched, downy *spikes*, and difpofed in two rows, felfife. *Calyx* short, with blunt segments.

11. *T. braflinfis.* Braflial Tournefortia. Poiret n. 6.—“Leaves ovato-lanceolate, harfh, somewhat finuated; whitifh beneath. Stem round, acutely flirated.”—Sent to Lamarek from Braflial. Allied to the laft, but the *leaves* are of a different shape, and the whole plant nearly deftitute of pubfeence. *Leaves* two or three inches long, an inch or more in breadth, confracted at their base, harfh on both fides, whitifh and downy beneath when young. *Flowers* in short, refexed, downy, hoary, branched *spikes*, compofing a terminal *cyme*. Segments of the *calyx* downy, very acute, flightly recurved. Poiret.

12. *T. arboreofen*. Arboreofen Tournefortia. Poiret n. 7.—“Leaves ovato-lanceolate; somewhat downy when young. *Spikes* branched, very short. Stem arboreofen.”—Gathered by Sonnerat, in the East Indies. *Branches* woody, angular, rough and rugged, particularly the young *shoots*. *Leaves* ovato-lanceolate, confracted at each end, veiny, ribbed, harfh, four or five inches long, an inch and half broad; white and downy beneath when young. We have nothing
TOURENFORTIA.

anwering to this description, nor is the specific character such as to afford much affinity in determining the plant.

13. **T. velutina.** Velvet-leaved Tournefortia. — Leaves elliptic-lanceolate, acute, silky on both sides. Spikes dense, aggregate, cymose, from the forks of the branches, silky. Stigma slightly two-lobed. — Gathered by *Collonson* in mountainous woods of the isle of Bourbon. The branches, *flasks*, *leaves*, *calyx* and *corolla* are entirely clothed with fine silky pubescence, the glabose base, and obtuse limb of the latter, on its upper side, being the only smooth parts, except the *berries*, which are snow-white. The *leaves* are four or five inches long, somewhat undulated, various in breadth. We have from the Mauritius what may possibly be a variety, with very narrow, and nearly smooth, *leaves*. Its *inflorescence* betrays no difference.

14. **T. argentea.** Blunt-leaved Silver Tournefortia. *Linn. Suppl. 133. Willd. n. 9. Poiret n. 8. Brown n. 2.* *(Buglossium lanuginosum;* Rumph. Amboin. v. 4. 119. t. 55.) — Leaves obovate, bluntish, silky on both sides. Spikes in repeatedly compound cymes. Tube of the corolla very short. — Native of the sea-coast, in Ceylon, Amboyna, Banda, and other parts of the East Indies. This *flora* is hardly so tall as a man; its main stem very short, the bark full of deep fissures; the branches widely spreading, hairy. *Leaves* crowded about the ends of the branches, alternate, stalked, about three inches long, entire; tapering at the base; rather flabby, beautifully clothed all over with the finest silky pubescence, which appears to vary in degree, and in one of our specimens, from the isle of Bourbon, excels in splendour every plant of our acquaintance. The *flowers*, *flasks*, longer than the leaves, are at first terminal, but the branch is soon protruded at each side beyond them. They are subdivided into tufts of dense recurved *spikes*, above an inch in length. All the *flasks*, like the broad oblate *calyx*, are silky. *Corolla* white, with a short tube, and a recurved limb, altogether not extending beyond the calyx. Mr. Brown describes the *ligula* as fleshy and two-lobed. Rumphius says the *leaves* are eatable, and much esteemed in Amboyna for their saltish flavour.

15. **T. gnaphaloides.** Cud-weed Tournefortia. See Brown 496. *(Hedcotropium gnaphaloides;* Linn. Sp. Pl. 188. Willd. Pl. Pl. v. 1. 745. H. gnaphaloides litoreum frutescens americana;* Phip. Phys. v. 183. f. 5.) — Leaves linear, obtuse, densely downy on both sides. Spikes dense, downy, recurved, on cymose *flanks*. — Native of the sea-coast in the West Indies. We follow Mr. Brown in removing to the present genus this elegant *flora*, whose snow-white downy covering is rather more cotonny than silky, and yet partakes of the silvery beauty of the leaf described. The *leaves* are crowded, thick, about two or three inches long, and hardly a quarter of an inch wide. *Flowers* small, white, in short, thick, woolly, solitary, twin, recurved *spikes*. *Berries* smooth, the size of a currant.

16. **T. suffruticoso.** Hoary-leaved Tournefortia. *Linn. Sp. Pl. 272. Willd. n. 11. Ait. n. 5.* *(T. subfruticosa, folium frutex an oblongis, fronde composita;* Browne Jam. 170, excluding the fynonym of Sloane, which belongs to *Suriana maritima. T. incana;* Poiret n. 92. Lamark Illutr. n. 1880. t. 95. f. 3.) — Leaves nearly lanceolate, hoary. Stem somewhat hairy. — Native of Jamaica, by the sea-fide, near the porch of St. James's. Seldom rides above three or four feet from the ground. *Brown*. This is a very uncertain species, for which Dr. Browne seems the only authority, nor is there any specimen to represent it in the Linnaean herbarium. The *Tymnete satue fruteti, Sloane Jam. v. 2. 291. t. 106. f. 4,* is certainly *Suriana maritima*, for which it was subsequently quoted by Linnaeus. Conferently Wildedenow cites it under both. It is sufficient to read Sloane, to see that his plant can be no *Tournefortia*. Possibly it may, nevertheless, have been what Browne intended. If so, the plant of Lamarck and Poiret has nothing to do with it, and may perhaps be the *fruits* of Vahl, hereafter described. Miller is recorded as having cultivated the *T. suffruticoso*, whence it has found a place in Mr. Aiton's work, but apparently without being known at the present day.

17. **T. volubilis.** Climbing Rough Tournefortia. *Linn. Sp. Pl. 201. Willd. n. 3. Ait. n. 1. Poiret n. 10. Lamark Illutr. n. 1884. t. 95. f. 2.* *(Bryonia nigra fruticosa, racemi ramulis varii implicitis, acutae, angustissimi inflar in fe contortis, baccis albis una vel altera nigra maculata;* Sloane Jam. v. 1. 234. t. 143. f. 2.) — Virga aurea americana frutecens glabra, foliis subtris catatis, &c.; *Phil. Phyto. t. 235. f. 6.*) — Leaves deflexed, ovate, acute, rough with minute points on both sides. Stem twining. Segments of the corolla awl-shaped. — Native of South America and the West Indies. It flowered with Linnaeus in the Upal garden, and is preserved occasionally in our English flowers. Sloane says the *trunk* near the ground is as thick as one's arm, twining round any thing it comes near, rising to the height of seven or eight feet. The *branches* are slender, round, somewhat zigzag, repeatedly subdivided, minutely downy, or rather silky, with close-preffed hairs. *Leaves* scatterd, an inch or inch and half long, on slender, downy, deflexed *flasks*, about half an inch in length, fingle-ribbed, entire, flat and even, clothed on both sides with very minute, white, callous prickles, but no hairines. *Flowers* numerous, small, greenish, in lateral, or somewhat terminal, slender, divaricated, downy, cymose *panicles* of lax spikes, or rather *cliffers*. *Calyx* in five deep, hairy, narrow segments. Tube of the *corolla* silky, hardly thrice the length of the *calyx*; limb in five narrow, awl-shaped, spreading segments, above half the length of the tube. *Style* slender, with a large long-beaked *ligula*. *Berry* half the size of a pea, glabrous, often two-lobed, white, with black dots.

18. **T. leucogaster.** Climbing Smooth Tournefortia. — Leaves spreading, ovate, acute; smooth above; rough with minute points beneath. Stem twining. Segments of the corolla awl-shaped. — Native of Jamaica. *Dr. Wright*. This has altogether the habit of the *calyx*, of which it may possibly be a variety. The chief difference discoverable in the dried specimens is the upper surface of the *leaves* being perfectly delitute of the innumerable callous points which cover their backs, and which are found on both sides of the foliage of the foregoing. The *leaves* of the present are also perhaps left deflexed. The *influence* and *flowers* afford no marks of distinction. The *berries* are most frequently of three globular lobes.

19. **T. ferricola.** Climbing Hoary Tournefortia. *Vahl. Eclog. fasc. 1. 17. Willd. n. 10. Poiret n. 11.* *(T. incana;* Poiret n. 9. Lamark Illutr. n. 1880. t. 95. f. 3.* Frutes;* Meregr. Brafil. 78, excellent as to the leaves, but though cited by Vahl, without any exception, the description shews it to be a Tynggenous *plant.)* — *Leaves* spreading, ovate, acute; rough with minute points above; *downy* and hoary beneath. Stem twining. Segments of the corolla awl-shaped. — Native of Hispaniola, and other parts of the West Indies. Like the two last in size and general habit; but the *inflans* are rather shorter; *leaves* more rounded, and often somewhat heart-shaped, at the base; their upper surface covered with much more numerous and minute, hair-pointed, white, callous tubercles, which produce somewhat of a hoary appearance; while the under
20. T. somenotos. Climbing Downy Tournefortia. Mill. Dict. ed. 8. n. 5. Poiret n. 12. — Leaves heart-shaped; downy beneath. Stem twining. Segments of the corolla awl-shaped.—Discovered by Mr. Robert Millar, near Cartagena, in South America. The twining stems reach to the height of ten or twelve feet. Leaves two inches long, and one and a quarter broad near their base, very downy beneath, on very short footstalks. Inflorescence apparently like the leaf. Flowers small, dirty-white. Berries juicy, with two, three, or four seeds. We gather from Miller's account, our only authority, that this plant comes very near our idea, of which it may possibly be a variety; yet the leaves seem to be of a broader figure, and their footstalks shorter.

21. T. ferruginea. Climbing Rlinky Tournefortia. Lamarck Illistr. n. 1882. Poiret n. 13. — "Leaves somewhat heart-shaped, acute; villous beneath. Stem somewhat climbing. Young branches very hairy."—Native of Hispaniola, where it is known by the name of Kellakoa. Allied to T. volubilis, but its branches are less elongated and trailing; its leaves and young shoots very much more hairy, or shaggy, with stiff, straight, ruddy-coloured hairs, equally remarkable on the footstalks, and ribs at the backs of the leaves. The latter are pointed, thick, harsh above, downy beneath, a little fringed at the margin, dark green, two or three inches long and one broad. Their footstalks straight, very short. Flower-footstalks much branched, hairy, divided into short spikes. Flowers small, unilateral, with a rough hairy calyx, and a short tubular corolla. Poiret.

22. T. feabra. Rough Small-leaved Tournefortia. Lamarck Illistr. n. 1883. Poiret n. 14. — "Leaves reflexed, oblong, obtuse; very rough above; wrinkled and downy beneath. Flower-footstalks branched, terminal. Berries conical." — Gathered in Hispaniola, by Joseph Martin. Branches slender and flexible, filleted, somewhat downy. Leaves stiff, slightly toothed, an inch long and four lines broad, rounded at the base, blunted at the extremity. Calyx hairy, rough, widely spreading, acute. Berry reddish, oval, almost conical. Poiret, whole description is our only guide, mentions a suffused variety, with leaves twice as long, but narrower, of which, however, he had seen neither flowers nor fruit.

23. T. feandens. Climbing Brown-flowered Tournefortia. Mill. Dict. ed. 8. n. 4. Poiret n. 18. — "Leaves heart-shaped, hairy. Spikes branched, reflexed. Stem twining. Segments of the corolla awl-shaped." — Found in Jamaica by Houon, who sent seeds to Miller. We preclude its being the same with that Mr. Brown mentions as T. feandens of Solander's manuscripts, and therefore we adopt from him the character of the corolla; though our Levigata was marked by Dr. Wright, with doubt indeed, as the plant of Solander; but it does not at all answer to the description. The prehensile shrubbery branches stems, ten or twelve feet high. Leaves near three inches long, one and a half broad near the base, acutely pointed, on short footstalks. Flowers in very slender, branching, terminal spikes, small, unilateral, of a dirty brown. Berries pulpy, with four seeds. Miller.

24. T. bifida. Self-levy Tournefortia. Poiret n. 19. — "Leaves soft, linear-lanceolate, villous. Flowers in roundish dense terminal spikes. Stem bifid." — Gathered by Comberfons at Buenos Ayres. Branches shrubby, round, clothed with stiff hairs. Leaves obtuse at each end, though a little contracted at the base, half clasping the stem, an inch and a half long, three lines broad, downy on both sides. Flowers at the ends of the branches, on a common footstalk, which divides into two parts, each bearing several very dense crowded spikes. Limbs of the corolla dilated, with five short blunt segments. Stalks and calyx clothed with numerous, stiff, glandular hairs. Poiret.

Besides all the above species, Poiret has a T. bifida, n. 16. Of this we find a specimen, gathered by Comberfons in the island of Mauritius; but it appears to be totally foreign to this genus. The stem is shrubby, with opposite, bluntly quadrangular, rugged branches. Leaves like opposite, though Poiret says alternate, on downy channelled footstalks, ovate, about two inches long, entire, even, smooth, pale green, with a yellow mid-rib, slender lateral ribs hairy at their origin, and innumerably, exceptionally minute, reticulated veins. Stipulae opposite, between the footstalks, and half as long, broad at the base, pointed, silky, deciduous. Flower-footstalks axillary, solitary, opposite, round, downy, longer than the footstalks, each bearing two, horizontally divaricated, simple, unilateral spikes, of numerous, small, fleshy flowers, in two rows. Germin inferior, oblong, silky, crowned with a calyx of five deep, round, silky segments. Corolla funnel-shaped, white, or yellowish, twice as long as the calyx and stems together, a little silky externally. Stamens within the tube; anthers large, oblong, obtuse. Of the style, stigma, or fruit, we can give no account. This shrub appears to belong to the natural order of Rubiaceae, but we have not sufficient materials to determine its genus.

Tournefortia, in Gardening, contains plants of the shrubby exotic kind, among which the species cultivated are, the hairy Tournefortia (T. hirsutissima); the climbing Tournefortia (T. volubilis); the fettid Tournefortia (T. factidissima); the dwarf Tournefortia (T. humillis); the broad-leaved Tournefortia (T. cymosa); the silvery Tournefortia (T. argentea); and the hoary-leaved Tournefortia (T. fulvifolius). Method of Culture.—These plants may all be increased by seeds, which should be procured from the countries where they grow naturally, and be sown in small pots filled with light earth, and plunged into a hot-bed of tanners' bark. They sometimes grow the first year, but often remain in the ground a whole year; therefore, when the plants do not come up the same season, the pots should be plunged in autumn into a tan-bed in the iwoe, where they should remain all the winter, and in the spring be removed and plunged into a fresh tan-bed, which will soon bring up the plants, if the seeds were good. When these are fit to remove, they should be each planted in a small pot, and plunged into a tan-bed, where they must be shaded from the sun till they have taken new root, and then be treated in the same way as other tender plants from the same countries, which require to be kept constantly in the bark-iwoe. They may also sometimes be increased by cuttings, which should be planted in pots, and plunged into the bark-bed.

These
These are all plants of the tender kind, which constantly stand in need of the heat of the stove in this climate.

They afford variety in stove collections, among others in pots, mostly retaining their leaves the year round.

**TOURNEHEM**, in Geography, a town of France, in the department of the Straits of Calais; 9 miles N.W. of Soissons.

**TOURMEME, REUJVSEPH DE**, in Biography, a learned Jesuit, was born at Reuses in 1661, entered among the Jesuits in 1683, and took all the vows of their order in 1693. In 1701 he reigned in the Jesuits college at Paris, for the convenience of conducting and superintending the journal of Treviso, or “Memories pour servir à l’Histoire des Sciences et des beaux Arts,” printed at Treviso, and periodically published from 1701 to 1767, when it fell with the society. In 1718, Tourmemoine was made librarian of the Jesuits library, in the protected house of the society, where he died in 1739, at the age of seventy-eights years. Tourmemoine published some other works of not less Merici.

**TOUENR, PETER LE, born at Alque, in Normandy, in 1556, gained prizes at Montauban and Besançon for his literary pieces, which were reprinted at Paris, and admired on account of their philosophic spirit and eloquence. But he was brought more into notice by his free translation of Young’s “Night Thoughts,” which were favourably received, was followed with translations of “Hervey’s Meditations”; “The Life of Savage”; “Ollan and other Gaelic Poems”; a great part of the “Universal History”; “Shakespeare”; “Clarissa”; and other works. These translations are introduced by prefaces, absid, according to poems and interesting ideas. His praises of Shakespeare provoked various attacks, and particularly from Voltaire. Le Touneur, who died in 1788, is represented as one of the mildest and most amiable of men. Nouv. Dict. Hist.

**TOURQUET**, Fr. from tourner, to turn, a machine, or instrument, employed in the practice of Surgery, in order to stop bleeding. It is only applicable, however, to the limbs, and its use is merely intended to be temporary, that is to say, until a more permanent method of checking the hemorrhage can be practiced. Thus, in the operation of amputation, the touriquet is applied with a view of preventing the loss of blood, which would otherwise happen before the surgeon had done with the knife and the saw, and before he could possibly devote his attention to the ligature of the arteries. But it is never put on tightly with the design of being left any considerable time in this way, as the constriction produced would inevitably bring on mortification. Sometimes, after amputations, operations for aneurisms, and in cases of wounds, it is left loosely upon the limb, so that, in the event of a sudden hemorrhage, it may be tightened in an instant. Here, however, the surgeon does not regard it as the principal means by which the bleeding is to be stopped; but simply as a temporary attendance, until an opportunity has been afforded of securing the bleeding vessels in another way.

When hemorrhage takes place from a large artery in one of the limbs, where the vessel can be conveniently compressed above the wound is it, a touriquet, judiciously applied, never fails in putting an immediate stop to the bleeding.

Before the invention of this instrument, which did not take place till the latter part of the seventeenth century, surgery was really a very defective art. No important operation could be undertaken on the extremities without placing the patient in the most imminent peril; and the want of the aid afforded by the touriquet made many wounds mortal which otherwise would not have been attended with the least danger.

Perhaps we are not justified in stating that the touriquet was not invented till the late period above specified; and it might be more correct to say, that it has been used in a rude and imperfect manner ever since surgeons have known that the flow of blood through a limb may be commanded by pressure. For when a simple band was tightly applied round a limb, in order to stop bleeding, it was, in fact, a kind of touriquet. The records of surgery, indeed, inform us, that the old surgeons used to surround the limb with a band, with which they made such a degree of constriction, that the circulation was quite stopped. These practitioners also believed, that the pressure of the band was advantageous in blemishing the limb, and moderating the pain of operations.

The violent pain and confusion, however, which this sort of touriquet occasioned, were frequently followed by knocking and abscesses, and therefore surgeons endeavored to devise some other method of checking hemorrhage. The application of the circular band was first improved, so that it caused less pain and less mischief to the skin. The limb was surrounded with a very thick compress, over which the band was placed. Two small sticks were next put under the band, one on the inside, the other on the outside of the limb; and they were twisted till the band was rendered sufficiently tight. It is in this manner, says Dionis, in his Treatise on the Operations of Surgery, that carriers tighten the cords which fatten the bales of goods in their carts. A French surgeon named Morel is said to have made this first improvement in the application of touriquets.

Although in the Armamentarium Chirurgicum of Scultetus, there is an engraving of a machine invented by this author for compressing the radial artery by means of a screw, M. Petit is universally allowed to be the first who brought the touriquet to perfection, by combining the circular band with a ferre, in such a manner, that the greatest pressure operates on the principal artery. It was in 1718 that he presented his improved instrument to the Academy of Sciences. It consists of two pieces of wood, one of which is superior, the other inferior. The inferior piece is about four inches and a half long, and nearly two broad. Its under surface is somewhat concave, while its upper one is a little convex; and the ends are hollowed out. From its middle part rises a round eminence, about seven lines high, and eight and a half broad. The superior piece is almost the same as the inferior, but rather shorter. The eminence which descends from its middle part is six lines high, and an inch and a half in diameter. This eminence is hollow within, and calculated to receive a wooden screw, the top of which is a fort of button for turning the ferre. The grooves of Petit’s screw were about four or five, and each of them four lines in diameter, in order that a half-turn might produce the necessary effect. Lastly, all the pieces of the instrument were fastened together with an iron pin, which went through the middle of the two pieces of wood, and through the whole length of the ferre. This iron pin was riveted under the inferior piece, and at the top of the button; in such a manner, however, that the ferre was capable of turning on it as on a pivot.

In order to apply this touriquet, the limb is to be surrounded with a double strap, about four finger-breaths wide, and made of chamois leather, which is the softest material that can be used. To one end of the strap a small double cushion is fastened, of the same length and breadth as the lower piece of the touriquet. A narrow compress, or cylindrical pad, is also requisite, for the purpose of compressing
prelling the track of the vessels. This comprefls a
very firm roll of linen, covered with chamois leather. The
ends of a piece of tape are fewed to the outer part of the
pad, and thus the tape leaves a passage for the leather flap.
By this artifice, the pad can be moved to any situation on
the flap which may be most convenient, according to the bulk
of the limb. The middle of the tape is to be felled to the
outside of the leather flap. The cylindrical comprefs, or
pad, is to be put over the courfe of the vessels. The double
cufion is to be placed on the opposite fide of the member,
while the leather flap is to furrond the limb in a circular
manner. All the different pieces of the apparatus are next
to be retained by the tape, which is to be tied at the fide of
the cuflion.

The tourniquet is now to be put over the cuflion, on that
fide of the limb which is furthest from the track of the large
veffels, and is to be felled in this situation by a double
band, with a hole in it for the reception of the upper part of
the fcrew.

In order to make proper compreffion, the fcrew is to be
half turned round from the right to the left. The upper
piece of the tourniquet becoming now further from the lower
one, the double band draws the pad, and preffes it againft
the veffels, fo as to make the dege degree of compreffion
for ftopping the flow of blood through the main arteries.

The following are the advantages attending the ufe of
Petit’s tourniquet. 1. It compreffes the lateral parts of the
limb lefs than the tourniquet previously in ufe. 2. It requires
the aid of no affilant either to hold, tighten, or loofen it.
3. The operator is able of himfelf to flop the flow of blood
through the artery by means of the fcrew. 4. When there
is any danger of hemorrhage after an operation, this kind of
tourniquet may be left on the limb; and in cafe of bleeding
coming on, the patient, if no one be at hand, can tighten
the inftrument himfelf as much as neceffary. 5. The con-
ftruction which this tourniquet produces may be continued
longer than that of the old method, without hazard of flopping
becaufe it does not altogether ftop the flow of blood
through the collateral arteries.

The tourniquet juft defcribed is certainly very complex,
when compared with what is now ufed by the belt modern
practitioners; but flill it is the original of the latter, and
both are confequently on the fame prinples. The feveral
pieces of a modern tourniquet are always kept connected
in felf, and, instead of two pieces of wood, ufed by Petit,
there is contrived a brafs bridge, which is capable of being
elevated or defpresse by means of a screw of the fame metal.
Over this bridge a very strong band proceeds, and by paffing
under two little rollers at the ends of the bridge, it always
remains connected with the inftrument. A convex firm pad is
fewed to the band, and put immediately over the artery when
the inftrument is applied. There are no cuflions for the op-
posite fide of the limb under the fcrew; but a thick piece of
leather, through which the band proceeds in two places, is
sometimes put under the lower furface of the brafs, and
ferves to prevent any bad effects of its prifure on the skin.
It is ufual, alfo, for the surgeon to fold fome rag, and put
it in this situation at the time of applying the inftrument.

Cooper’s Dict. of Prac. Surgery.

In the army, surgeons are provided with what are named
field tourniquets, in addition to fuch as are always found in
cafes of amputating inftruments. A field tourniquet is made
fimple in its conftuction, and is particularly intended for
ufe on the field of battle, where numerous foldiers frequently
fland in need of temporary compreffion of their bleeding
limbs, until the surgeon has time to pay their accidents fur-
ther attention. It confifts merely of a strong band, a pad
fixed to this band, and a buckle. It admits of being applied
in an infant. Every military furgeon is commonly furnifhed
with two or three dozen field tourniquets, and the plan is
undoubtedly good, as the prefervation of many lives by it
has confirmed.

The reader will have a better idea of the nature of a tour-
niquet, by referring to engravings of the inftrument; but
a fight of the thing itself will be still more ufeful.

Some tourniquets of different conftuctions are repre-
fented in Plate I. of the Surgical Infruments, where fig. 1. fews a
tourniquet of the molt fimple kind, which is tightened by
flipping the band D with the piece of wood B. C is the
pad which is to be placed upon the main artery, and A is a
fort of metallic or wooden guard, for preventing the twifled
part of the band from hurting the skin. Fig. 2. a tour-
niquet of a more modern and improved make. D the fcrew.
C, C, the two pieces of the frame or bridge of the tour-
niquet, which tighten the band B, when the upper piece
is raised by turning the fcrew. A is the pad. Fig. 3. repre-
sents another kind of tourniquet, which is tightened by a
convenience ftrewing a windfals in principle; C the handle
by which it is turned; E a ftee1 branch, which ferves to
prevent the handle from turning back again; B a fhort bit
of chain, which fixes itfelf in the notchcs of the circle, and
by carrying the band with it when moved round, tightens
the band D; A the basis of the tourniquet. Fig. 4. another
kind of fcrew-tourniquet.

TOUROIS, in Coinage, the name applied to French
money in the old frytem, as fterling is to English money.

TOURNON, in Geography, a town of France, in the
department of the Lozé and Garonne; 12 miles E. of Vil-
leuene d’Agen.—Allo, a town of France, fited on the
river Creufe, one part in the department of the Indre, and
the other in the department of the Indre and Loire; 7 miles
S. of Prouilly.—Allo, a town of France, in the depart-
ment of the Ardeche, on the Rhone; 22 miles N.N.E. of
Privas. N. lat. 45° 4’. E. long. 4° 54’.—Allo, a town of
France, in the department of Mont Blanc; 15 miles
E. of Chambery.

TOURNUS, a town of France, in the department of the
Saone and Loire, on the Saone; 3 pofts S. of Chalons
fur Saone. N. lat. 46° 34’. E. long. 5° 0’.

TOURO, a town of Portugal, in the province of Beira;
13 miles W.S.W. of Alfayates.

TOUROULNE, a town of Persia, in the province of Co-
lefi-an; 80 miles S.W. of Neifabur.

TOUROULINE, in Botany, a Caribbean name, ufed by
Aublet, but absolutely inadmissible into any classical work.
t. 424. Poiret in Lam. Dict. v. 7. 718.—Schreber and
Wildenow, after Scopoli, have called this genus ROB-
SONIA, which may be found in its proper place.

TOUROUMANG, in Geography, a town on the west
coast of Sumatra. N. lat. 2° 50’. E. long. 95° 0’.

TOUROUVRE, a town of France, in the department of
the Orne; 6 miles N.E. of Mortagne.

TOURRETTE, MARK-ANTHONY-LEWIS-CLARET DE
LA, in Biography, was born at Lyons in 1729, and having
studied at the college de Harcourt, at Paris, settled in his
native place, where for twenty years he occupied an impor-
tant poft in the magiftracy. Strongly attached to the
study of natural history, he formed, in 1763, a large collection
of infects, and a feries of specimens in mineralogy. In 1766
he introduced into a large park near the town of Arbrelle
all the foreign trees and shrubs that could bear that climate,
and in his own garden at Lyons, he cultivated more than 3000
species of rare plants. He was a companion of J. J. Rouf-
feau,
A moveable tower was constructed by the
royalties to late as the troubles under king Charles I., which
was surprised and taken by the parliamentary forces. It
was mistimed about; which fee.
Towers are also built to enable people, by their elevation,
to view a great distance. There are of all figures, as
square, round, pentagonal, &c. (See PHAROS.) In China
is a famous tower of porcelain, of which the Dutch relate
wonders.
Towers are also built for fortresses, prisons, &c., as the
Tower of London, the towers of the late Battle, &c.
The Tower of London is not only a citadel to defend and
command the city, river, &c.; but also a royal palace, where
our kings, with their courts, have sometimes lodged.
It contains a royal arsenal, in which are arms and ammunition
for 20,000 soldiers; the office of ordnance; a treasury
for the jewels and ornaments of the crown; formerly a mint
for coined money; the great archive, in which are preserved
all the ancient records of the courts of Westminster, &c.
and is the chief prison for state criminals.
In the midst of it is the great square white tower, built by
William the Conqueror, about the year 1079. Within the
Tower is a parochial church, founded by king Edward III.
and dedicated it the name of St. Peter in Chains, exempt
from all jurisdiction of the archbishop, and a royal chapel,
now defaced.
The chief officer of the Tower is a constable, or chief
governor, under whom is the lieutenant-governor, who acts
by his direction, and in his absence. He has, by grant of
several of our kings, seven apartments, two galleries and a pint
of wine before, and as much behind the main of all wine
ships that come to London; and a certain quantity out of
every boat laden with lobster, oysters, and other fish, and
double the quantity out of every alien's boat passing by the
Tower. Under the constable, besides the lieutenant are
deputy-lieutenants, a major, a chaplain, a physician;
gentleman-porter, gentleman-gaoler, slopman, and forty
warders. The gentleman-porter has charge of the gates to
lock and unlock them, and deliver the keys every night to the
constable or lieutenant, and receive them of him the next
morning; he commands the warders in waiting, and at
the entrance of a prisoner has for his use regiments of period
or else a composition for the same.
For the forenoon warders of the Tower, see WARDEN.
In the Tower is likewise kept a court of record by
prescription for the liberty of the Tower of East, West, South,
and all other actions of any kind.
The Tower liberty, subject to no jurisdiction but that of
the Tower itself, includes both the Tower-hills, part of East
Smithfield, Rotherhithe-town, Wellow-fleet, Little Mores.
Ailesbury-street, French-alley, Dock-street, Steward-
street, Green-street, Forst-street, and the other courts and
alleys within their compass, in Smithfield.
Tower, in Glass-making. See LIME.
Towers, Glass, in Parochial are small towers, made
in the form of buildings by M. Vassy, in his second and
third method, with rooms of cellars underneath, for accom-
modating men and guns. See FORTIFICATION.
Tower, Hollow. See HOLLOW TOWER.
Towers, Island, are those whose tops hang so far over,
as to appear in danger to people walking below. Such is
that of Philadelphia, 150 feet high, whose top overhangs the base
13 feet; and that of Belem, 150 feet high, whose top
overhangs the base 9 feet; and the reason why they do not
fall in, that their centres of gravity are supposed, or the
lines of direction in these fall within their base. But if
towers of this kind, that incline, were to be elevated in
height by any additional weight on their tops; in that case
the centres of gravity would be raised, and their lines of
direction fall without the base, so that the towers themselves
must fall.
Tower Mustard, and Buffard Tower Mustard, in Bosam.
See MUSTARD.
Tower Pond, an old English weight for coins. This
tower or moneyers' pond, with which gold and silver
were weighed in England before the reign of Henry VIII.
and which is still occasionally referred to on the subject of
coins, was lighter than the pound troy by fifteen penny-
weights troy.
Tower-Island, in Geography, a town of the state of Rhode
island, with a post-office; 17 miles S. of Providence.— Also,
a town of North Carolina, on the Neuse; 30 miles W. of Newbern.
Tower Island, a small island in the East Indian sea,
near the S. coast of the island of Flores. S. lat. 9° 7'. E.
long. 124° 37'.
TOWACHES, called Passi by the French, a tribe of
Indians in Louisiana, who live on the S. bank of the
Red river, by the course of the river upward of 500 miles
above Natchitoches, and by the nearest land distance about
340 miles. They have two towns near one another, the
lower town, where the chief lives, is called Natchez, and the
other is called Towahach. Their present chief is
designated the Great Bear. They are at war with the Spaniards,
but friendly to those French and American hunters who have
lately been among them, according to the statement of Mr.
Jefferson in the year 1805. They are likewise at war with the
Olges, as is every other nation. For many hundreds
of miles round them, the country is a rich prairie, covered
with luxuriant grass; which is green summer and winter,
with skirts of wood on the river bank, by the springs
and creeks. They have many hawks and owls. They raise
more corn, pumpkins, beans, and tobacco than they want
for their own consumption, so that some of these commodities
furnish articles of trade. They have but few guns,
and very little ammunition, which they keep for war, and
hunt with the bow. Their meat is principally buffalo, and
they seldom kill a deer, though plentiful. They have also
eagles, bears, wolves, antelopes, and wild hogs in abundance,
and white rabbits and hares, as well as the common rabbits.
The men are generally altogether naked, and the women
nearly so, with the exception of a small flap of a piece of
skin. They have many Spaniards among them, taken from
the settlement of Santa Fé, when they were children. Their
language differs from that of every other nation, the Tow-
achines excepted. Mr. Jefferson states the number of men
at about 500; a great number of them having been swept
away about four years before, by the small-pox.
TOWING-PATH, the road or path which is formed
along the borders of navigable rivers and canals, for the
purpose of drawing different sorts of materials for farm and
other uses, in some kind of small vessels, on them, either
by men or horses. (See E.C. fig. 16. Plate I. Canal, and fig. 1c.
Plate V.) These paths constitute one of the great
improvements in this art of navigation, by removing the
inconvenience and danger afforded by the mode of loading
the barges by means of men instead of horses, where they are
formed with that intention.
In speaking of the inland navigation of the river Severn,
and the county, in the Shropshire agricultural report, Mr.
Telford observes, that with regard to adopting the mode
of loading barges by means of horses, instead of the present
backwards and expensive custom of performing this service
by men. it is only necessary that a good towing-path for
horses should be formed along the banks of the river,
and which will no doubt take place, if any scheme of gen-
ral
TOW

ral improvements should ever be adopted. That in the mean time, a laudable example has been shown by Mr. W. Reynolds, of Ketley, who has formed a towing-path for horses near to the new manufactories at Coalport, and has carried it on through his father’s property to the iron bridge, a distance of about two miles: this being along some rugged banks, and over some of the worst fords which are on the river, proves, beyond contradiction, it is thought, that this sort of towing-path is practicable at no very extravagant expense, and besides, that it completely destroys the common objection of horse towing-paths where many rapid or fords intervene.

In constructing all sorts of towing-paths, they should be formed as much on the level as possible, and be well and firmly laid with some convenient sort of hard materials. Where they are for men or small animals, they need not be of such breadth or depths of hard substanences, as where large and many horses are in use. In carrying them over fords or runs of water, an experienced workman will mostly be necessary.

Towing-Path Wall, is a wall under the bridges, A B C D, (Plate V. Canals, fig. 40.) for keeping up the towing-path. TOWLGAW, in Geography, a town of Hindoostan, in Dowlatabad; 6 miles W. of Toolapour.

TOWN, a place inhabited by a considerable number of people, of an intermediate magnitude and degree between a city and a village, &c.

It is hard to give a tolerable definition of a town, because the idea is a little arbitrary and unfixed. A town is generally without walls, which is the character which usually distinguishes it from a city; but this does not hold universally.

Tithings, towns, and villages, have the same signification in law; and are said to have had, each of them, originally a church, and celebration of divine service, sacraments, and burials; though that seems to be rather an ecclesiastical than a civil distinction. The word town or vill is, indeed, by the alteration of times and language, now become a general term, comprehending under it the several species of cities, boroughs, and common towns. A city is a town incorporated, which is or hath been the see of a bishop: a borough is now understood to be a town, either corporate or not, that sends burgesses to parliament: other towns there are, to the number, according to Sir Edward Coke, of 8803, which are neither cities nor boroughs; some of which have the privileges of markets, and others not; but both are equally towns in law. To several of these towns there are small appendages belonging, called hamlets.

Entire vills, fir H. Spelman conjectures, consisted of ten freemen, or frank-pledges, demi-vills of five, and hamlets of less than five. These little collections of homes are sometimes under the same administration as the town itself, sometimes governed by separate officers; in which last case they are, to some purposes in law, looked upon as distinct townships. These towns contained each originally but one parish and one tithing, though many of them now, by the increase of inhabitants, are divided into several parishes and tithings; and sometimes there is but one parish where there are two or more vills or tithings. Blacklt. Com. b. 1.

We have several kinds of towns; borough-towns, market-towns, county-towns, &c. See Borough, &c.

Towns, Hanse. See Hanse.

Town-Clerk, or Common Clerk, an officer in the city of London, who keeps the original charters of the city, the books, rolls, and other records, wherein are registered the acts and proceedings of the city. He is to attend the lord-mayor and aldermen at their courts.

Towns-Dung or Manure, in Agriculture, that sort which is scraped up and collected from the streets and other places of large towns. This kind of manure is used in large quantities in some districts near the metropolis, as in Essex and some others, with great success and advantage, though at very considerable expense. Mr. Hardy, near Bradfield, in the above county, uses to the amount, it is said, of one waggon-load to every acre of summer fallow, at the expense, for the charge of the dung or manure only, of one guinea the load; it is then mixed with his own yard-dung in heaps for the purpose of exciting fermentation, from a notion that it has this effect, and that having it, the benefit will be in proportion. In several other parts of the same district, the usual mode of manuring per acre, is one waggon-load of town-muck with about five times the quantity of fresh foil collected from road-fides and hedge-greens.

Town-House. See House.

Town-Adjutant, in Military Language, is an assistant to the town-major.

Town-Major. See Major.

Town, Cape, in Geography, a town agreeably situated somewhat above 30 miles from the Cape of Good Hope, in a valley, between the Table and Lion mountains. It contains about 200 houses, many of which are magnificent; its streets are broad, but ill-paved. Provisions of every kind are very reasonable, and the town is well supplied with springs of excellent water, sufficient for the ships which recr to this port. S. lat. 34° 49’. E. long. 18° 23’.

TOWNSEND, a town of the state of Massachusetts; 36 miles N.W. of Boston.

TOWNSEND, a township of the state of Vermont, in the county of Windham, containing 1115 inhabitants; 25 miles S. of Windor.

TOWNSEND, Cape, a cape on the N.E. coast of New Holland. S. lat. 22° 15’. W. long. 209° 43’. See also Vermilion Point.

TOWPAAL, a town of Meckley; 12 miles S.E. of Munympour.

TOWRIDGE, a river of England, which paffes by Biddesford, and joins the Tow near Appledore, in Devonshire.

TOWY, a river of Wales, which rises in the county of Cardigan, and runs into the bay of Caermarneth, 6 miles below Caermarneth.

TOWYN, or TWYN, a small town in the hundred of Yrumaner, and county of Merioneth, North Wales, is 12 miles W. by S. from Machynlleth, and 223 miles W.N.W. from London. It is built of coarse schisto-fine stone, commands an unbounded view of the ocean, and is backed by a range of high mountains. During the bathing season, it is frequented by several genteel families. The town is surrounded by several populous hamlets, and respectable farm-houses. In the population return of the year 1811, the parish is stated to contain 1941 inhabitants, occupying 482 houses. Though the soil is rocky, and exposed to the influence of the western gales, yet industry has surmounted these obstacles; the marsh is converted into meadows and pastures; and corn overtops the sterile rock and bleak shore. The church contains several ancient monuments. Gwenddydd, daughter of Brychan, and wife of Cadell, prince of Powys, about the middle of the fifth century, was buried here. In the cemetery are two rude pillars: one of them, called St. Cadfan’s stone, is shaped like a wedge, about seven feet in height, with a crofs, and an inscription on each side in old British characters. St. Cadfan is supposed to have been interred in this church about the year
TOX

TOZ

tember, as well as in the east of Tankerville's collection. Mr. Lambert was informed by Mr. Moilson, that a farmer who lived near the native place of this shrub, named about May a year by the gathering of the fruit, which being beaten to powder, is used to poison the carrioles of lambs, &c. By feeding on these, the lambs are infallibly destroyed. This is a shrub, or small tree, fix or seven feet high, with spreading branches, which appear joints, from the scars where the footstalks have been inserted. Leaves three to four in a whorl, stalked, spreading, about three inches in length, oblong or oblong, entire, emarginate, ciliate, smooth, obtuse, with one red rib, and many branching lateral veins. Finely thick, channelled, about half an inch long. Male flowers in axillary, branched, yellowish panicles, shorter than the leaves; female ones on a separate plant, in simple, axillary, green tufts. Fruit smooth, about the size and shape of a Hickory-nut.

It has been debated between Mr. Miller and Mr. Ellis, whether our poison-apple, or wrenched-back American toxicodendron, be the true Japan varnish-tree: Mr. Miller maintains the affirmative, and Mr. Ellis the negative: for the arguments on both sides, see Phil. Trans. vol. xlii. p. 180, p. 366. vol. l. p. 252, p. 241. See VARNISH.

TOXICUM, a word particularly used to express a sort of poison, said to be used by the Indians to their arrows, in order to render wounds made by them incurable.

The wood, in a more general sense, signifies any poison.

The Indians are supposed to poison their arrows, daggers, &c. with the virtue of vapors, the metinerary of which continues a long time after the master is quite dried up.

TOXICUS, in Botany, a name by which some authors have called the arnica jurtina, of which walking-canes are made.

TOXILLI, TOZ,

in Ancient Geography, a people of India, in the number of three who inhabited territories near the rivers Ganges, Indus, Hydaspes and Amaili.

TOXOTAE, a name, among the Athenians, bowmen, a sort of inferior officers, or rather servants, who attended the lesvians.

They were much like the Roman velites; there were a thousand of them in the court of Athens, that lived in tents, erected both in the forum and afterwards in the acropolis.

See LEVIES.

TOZER, in Geography, a town of Africa, in the country of Sahara; 52 miles S.S.W. of Gafsa. N. lat. 35° 52' E. long. 8° 15'.

TOZZETTIA, in Botany, was so called by professor Savv of Pisa, in honour of his learned friend Dr. Guiseppe Tiziano Tizzetti, the present professor of the history and manners of the celebrated Michelis, at Florence, and son of the botanist after whom. Tizzetti was named, who afterwards took the name of Tizzetti; see the characters just indicated. Savv in U.S. Ann. v. 24. 52. Unfortunately the plant thus denominated is a genuine species of Clarygus; as proved, for Schreber has made it, in Phil. Genn. v. i. 1742, and at the writer of the present article has long ago shown, in Te. of Linn. Soc. v. i. 1747, as well as in Prodr. Phil. Genn. v. i. 1742 it being not only the Phaleric aucuparia of Linnaeus, but his wife's. Coccinia aucuparia. We find it difficult to account for the mistake of Linnaeus in referring this grass to Phaleric, of which genus it has neither the habit nor characters.

TOZZI, ANDREAS, in Botany, a member of the Philharmonic Society at Bologna, where he was born, and where he was a disciple of Padre Mattioli. In 1543 he was appointed
appointed maestro di capella to the duke of Brunswick, for whole court he first composed "Andromacher," and in 1775 "Rinaldo." His subsequent productions were unknown to Gerber. In Italy, Tozzi has two operas recorded; "Tigrane" in 1762, and "L'Innocenza vindicata" in 1763.

TOZZIA, in Botany, received its name from Micheli, in honour of the reverend father Bruno Tozzi, abbot of Vallombrosa, who found this rare and curious plant, on the alpine heights of Tuscany, above the celebrated and romantic solitude, where his abbey is situated. This learned ecclesiastic, unlike many of his monkish brethren, delighted to adorn his Creator through his works, and was the cheerful and welcome companion of Micheli, in many of his botanical excursions, over the Italian alps, as well as along the shores of the Mediterranean. He was a fellow of the Royal Society of London, and of the Botanical Society of Florence. A number of figures of rare Tuscan Orchideæ, drawn by him, may be seen in Petiver's Works, vol. 1. t. 128.—Linn. Gen. 306. Schreb. 403. Wild. Sp. Pl. v. 3. 202. Mart. Mill. Diet. v. 4. Mich. Gen. 19. t. 16. Jul. 97. Lamarck Illutr. t. 522.—Chafers and Order, Díí-dííaímía Angioípífíraí. Nat. Ord. Perfíóñá, Linn. Ly-íí-,íímántíis ofíí, Juff.

Gen. Ch. Gal. Períthífer inferior, of one leaf, tubular, very short, five-toothed, permanent. Cor. of one petal, ringent; tube cylindrical, longer than the calyx; limb spreading; its upper lip in two, lower in three, segments, all nearly equal and roundish. Stam. Filaments four, concealed beneath the upper lip, unequal; anthers roundish, of two lobes, each with a spur at the base. Ptál. Germen superior, ovate; blue thread-shaped, agreeing with the filaments in length and situation; Rígma capitáte. Peric. Capules globose, of one cell and two valves. Seed solitary, ovate.

Efl. Ch. Calyংx tubular, five-toothed. Corolla ringent, with five rounded segments. Capsule globose, of one cell, and two valves. Seed solitary.

Obf. Surely the affinity of this genus to Euphrofía, Lathrea, &c. is apparently, even without the character of the spurred anthers, indicated by Jacquin. The fruit, which in this tribe affords such admirable distincions, is here peculiarly marked. Melamýripum alone approaches it, by the fewness, size and shape of its seeds. Tozízia is erroneously described by Linkus, with a single-valved capsule. We would premise to remove this genus to the Pediciulares of Jussieu.

1. T. alpina. Alpine Tozzia. Linn. Sp. Pl. 844. Wild. n. 1. Savi Etrusc. v. 2. 164. Jacq. Alfr. t. 165. (T. alpina lutea, alfinæ folio, radice fquamata; Mich. Gen. 20. t. 16. Euphrofía luteá alfinæfolia, radice squamata; Bauh. Pin. 234. Prodr. 111. Anonyma fratriis Gregoriis, radice dentaria; Column. Ecpl. v. 2. 49. t. 50. Dentaria buguloides, &c.; Meuntz. Pugli. t. 9. f. 3. 4.)—Native of moll fttbilly alpine places, in Austria, Switzerland, Dauphinie, Italy, and the Pyrenees, flowering in May. Mentzelius gives an interesting account of his gathering it among the melting snows, on a lofty precipitous mountain, near the source of the Iper, in 1654. The perennial root consists of numerous, fleathy, imbricated scales, and bears a solitary, herbaceous, erect, branched, square, juicy ftem, about a foot high, lightly downy at the angles only. Leaves opposite, ffeille, ovate, ribbed, succulent, smooth, lightly but coarsely notched, an inch long at most; the numerous floral ones much smaller. Flowers axillary, solitary, on simple slender stalks, shorter than the leaves, bright yellow, a little drooping, perfectly two-lipped, and rather more irregular than Micheli represents them. Calyx oblique, smooth, brownish. We know of no attempt to cultivate this plant, nor would it perhaps be possible.

TRAABURG, in Geography. See DRAABURG.

TRAABACH, a town of France, in the department of the Sarre. Its neighbourhood is a fine wine country. Opposite the town, on the other side of the Moselle, France, after the treaty of Nimeguen, erected a fort, called Mont Royal; but the demolition of it was made an article of the peace of Rywick: 34 miles S.W. of Coblenz. N. lat. 50° 0′. E. long. 7° 5′.

TRABAY, a river of Spain, in the province of Granada, which runs into the sea near Mixcura.

TRABEATION, TRABRATIO, in the Ancient Architecture, the same with entablature; which see.

TRABENKA, in Geography, a town of Sweden, in the island of Aland.

TRABIA, a town of Sicily, in the valley of Mazara; 2 miles W. of Termini.

TRABUNACTUM, in Ancient Geography, a town of Africa Propria, on the route from Tácapae to Leptis Major, between Adanmadun and Tramufdius. Anton. Tín.

TRACANA, a town in the interior of European Sarcenia, in the vicinity of the river Carcinius. Poletomy.

TRACE, a mark or impression which any thing leaves behind it in palling over another.

Traces of the Brain, among the Cartesian philosophers, are those impressions, more or less deep, which, they say, fenible objects make on the fine fibres of the brain, by means of the organs of sense.

These impressions are also called traces of the object; the corule of the animal spirits, they say, serves to keep them up, and to renew them.

The vivacity of the imagination, they say, arises from the prodigious quantity of traces of different objects in the brain; which are fo linked together, that the spirits cannot be sent into one of them, but they run into all the rest; by which means the ideas occasioned by the application of the spirits to those several traces, are all excited, as it were, at once.

Memory, according to the same, consists in the traces which the animal spirits have impressed.

Trace of a Hare, among Hunters, is her footing in the snow; distinct from other treading, called doubling and pricking, &c.

Traces also denote the tracks of ravenous beasts, as wolves, wild beasts, &c.

Traces, Lady's, in Botany. See OPHRYS.

Trachea, in Ancient Geography, a name which Ovid gives to Aixur.

TRACHEA, in Anatomy, the wind-pipe, (from αυτύκερας, a rough tube containing air, (rough from its cartilaginous rings) whence the Latin astera arteria.) It is the tube conveying air into the lungs, and commencing at the root of the tongue. See Lungs.

Trachea, Wounds of. See Wounds.

TRACHE, in Vegetable Physiology, is the appellation given by Malpighi, Grew, &c. to the large spiral-coated vessels of plants; which, being generally found filled with air only, are likewise termed air-vessels. The discoveries of Dr. Darwin, Mr. Knight, and others, have shewn them rather to be sap-vessels, and that the empty state in which they are usually found, is owing to their contents having been expelled on deflection, by the elasticity and irritability of their coats. Such is known to be the fact with regard to the arteries of animals. We have explained the nature of these vessels, and their functions, under the articles Circula-
Circulation of Sept. Leaf, and Spiral Vessels, the latter being now their most usual denomination. It is preferable to any of the above, as not involving any theoretical opinion.

TRACHEAL ARTERY, in Anatomy, a branch of the right subclavian, running up from it in a winding course, along the aorta, to the glandular thymus and larynx, detachling small arteries to both sides; one of which runs to the upper part of the saccula. The tracheal artery may likewise be called utricular inferior. See Artery, and Lung.

TRACHELAGRA, formed of trachea, novil, and ongo, fexure, a term used by some medical writers, to express the gout in the neck.

Gen. Ch. Cal. Persant superior, very small, in five deep segments, permanent. Cor. of one petal, funnel-shaped; tube cylindrical, very long and slender; limb small, spreading, in five deep, ovate, concave segments. Stam. Filaments five, capitellate, nearly the length of the corolla; anthers simple, oblong. P. Germen inferior, roundish, with three angles; style thread-shaped, twice as long as the corolla, rather swelling upward: stigma capititate, glabrous, slightly three-lobed. Peric. Capsule roundish, bluntly three-lobed angular, of three cells, curling by pores at the base. Seed numerous, minute.

Obs. Linnamhus himself corrected in his Sylbus Nature the error in his Genera, of the single-celled capsule. The remark subjoined in the last-named work, of some bicellular species, properly belongs to the preceding genus, Petustemis.

1. T. ceruleum. Blue Throatwort. Linn. Sp. Pl. 243. Supp. 145. Willd. n. 1. Ait. n. 1. (Trachelis azurea umbellifera; Pern. Bald. 44. Valeriana cerulea, urtica folio; Brot. f. c. 683, 684.)—Leaves ovate, serrated. Corolys compound.—Native of shady rocky places, in Italy, Spain, and Barbary. Frequent on the ancient walls of Rome, flowering in the spring and summer. It may be kept for many years, with us in a greenhouse, though usually considered as a hardy biennial. The root is tawny, white, with many fibres. Herbages smooth, dark green, about two feet high. Stem roundish, often branched, leafy. Leaves alternate, ovate, acute, entire, an inch or two long, and half as broad, sharply, and sometimes very deeply, serrated. Footstalks linear; the upper ones half the length of the leaves; lower longer. Flowers very numerous, of a fine

blue, in a terminal, corymbose, level-topped, tufted, or panicled, with awl-shaped bracteas, in aspect, though not, in colour, resembling a Valerian.

2. T. diffusum. Slender Shaggy Throatwort. Linn. Suppl. 145. Willid. n. 2. Thumb. Prodr. 38.—Leaves awl-shaped, erect. Stem panicled, with divaricating branches. Found by Thunberg, at the Cape of Good Hope. Mr. Masson sent it in 1787 to Kew, where it is a greenhouse plant, flowering in August. Stem a foot or more in height, woody, much branched in the lower part, the branches erect, straight, round, leafy, smooth, or very minutely downy. Leaves scattered, slender, an inch long, very narrow, revolute, entire, awl-pointed, nearly or quite smooth. Flowers blue, with a pale tube, small, foliary at the ends of the numerous, widely spreading or deflexed, branches of the slender, rigid, smooth panicled.

3. T. trilobatum. Slender Fringed Throatwort. Linn. Suppl. 145. Willd. n. 3. Thumb. Prodr. 38.—Leaves linear, flat, recurved, fringed. Stem branches. Flowers lateral.—Brought by Thunberg likewise from the Cape, but as yet a stranger to our gardens. The long woody root bears a bushy woody firm, a few inches high, divided from the bottom into many branches, clothed with crowded, narrow, recurved, frill-pointed leaves, half as long; strongly fringed at the margin; flat above; keeled beneath; often somewhat downy. Flowers numerous, axillary, foliary, felilile, slender, apparently white or yellowish, except the tips of the corolla. We must rely on the authors cited for the determination of the genus. The style does not project out of the flower. The flower is inferior. TRACHEUM, in Gardening, contains a hardy herbaceous plant of the perennial kind, of which the species cultivated is the blue throatwort (T. caruleum). It is a plant that is perennial in its nature, being very lasting in culture which are dry and not of a rich quality, but not in the contrary fort.

Method of Culture.—It is raised from seeds, which should be sown in the autumn when well ripened, or in the spring, in a bed or border of light mould. And when the plants are two or three inches in height, they should be set out in nursery-rows six inches apart, to remain till the following autumn, when they should be planted out where they are to remain.

These are flowering perennials which may have their seeds sown in the crevices of old walls, runs, and rockeries with much effort and advantage, as the plants continue several years, and display many flowers. They afford ornament in the above sort of works, and other situations where the earth is poor.

TRACHELO-MASTOIDEUS, in Anatomy, complexus minor; a small narrow muscle, situated at the posterior and lateral part of the neck, and extending from the mastoid process to the transverser process of the vertebrae. Behind, it is covered by the splenius, and the transversus falls, to which it is connected: in front, it covers the complexus, the obliquus capitis, the posterior extremity of the digastricus, and the occipital artery. Its inner edge is close to the complexus, and is sometimes united by a muscular flap to the longissimus dorsi. The outer edge is fixed by small tendinous and fibrous slips to the transverser process of the fourth and fifth cervical vertebrae: and is unattached above. The inferior extremity of the tracheolo-mastoideus is fleshy and pointed, and fixed to the transverser process of the seventh cervical vertebrae, or sometimes of the first dorsal bone. Thence it ascends perpendicularly, growing thicker and broader to its upper end, which is fixed to the back of the mastoid process in front of the splenius. It is attached to
the vertebral processes by small tendons, which produce muscular slips united in the body of the muscle: a flattened tendon is the medium of infection in the head. When the right and left muscles act together, they relieve the head, after it has been bent forwards, and they carry it backwards. The muscle of one side inclines the head and neck laterally.

**TRACHELOPHYMA**, a swelling of the thyroid gland. See Bronchocele, and Thyroid Gland.

**TRACHELOS**, a word used by some anatomical authors to express the neck.

**TRACHENBERG**, or Drachenberg, in Geography, a principality of Silezia, bounded on the N. by Poland; on the E. and S. by the principality of Oels, and on the W. by Wohlan. It was formerly a part of Oels, but erected into a distinct principality, in the year 1741, by the king of Prussia, in favour of the count of Hafeld and Gleichen, who was made a prince of the empire, by the emperor Francis, in 1748.

**TRACHENBERG, or Straburck, a town of Silezia, and capital of the principality of the same name; 14 miles W.S.W. of Militch. N. lat. 51° 28'. E. long. 16° 50'**

**TRACHEOCELE**, an enlargement of the thyroid gland. See Bronchocele, and Thyroid Gland.

**TRACHEOTOMY**, (from *τραχηλός*, the wind-pipe, and *κόπω*, to cut) in Surgery, denotes the operation of making an opening into the wind-pipe.

When a foreign body has entered the trachea, the only means of relief consists in making a longitudinal incision through the skin and cellular substanee of the neck, in order to expose the wind-pipe, and fit it open in the same direction. Several of the old practitioners conceived the propriety of this operation, which Junkers, in his "Confpectus Medicinæ Chirurgicæ," profcribed in the most polite terms. How, indeed, would it be otherwise possible to put an end to the suffocation and convulsiv cough, which the extraneous substance produces? Few practitioners, however, have ventured to do the operation. In the year 1650, the performance of it was recommended by Bonnet, upon a child seven years of age, who, in eating some rice-foup, swallowed a small bone, which passed into the trachea. The young patient pointed out with his finger the place where the foreign body had stopped, and which was exactly opposite the middle of the throat. A physician, who was consulted, gave it as his opinion, that the operation was improper, either because he was not convinced of the presence of the bone in the trachea, or because he thought that it could not be taken out without exposing the child to a certain death. At the end of five days the boy died, and the trachea having been opened, the extraneous substance was taken out of it with the greatest ease. Raw and Heifter also successfully extracted foreign bodies from the trachea; the former, a piece of mushroom, which had been swallowed with some soup; the latter, a bean, which had fallen into the wind-pipe.

Louis was not equally fortunate, in a cafe where the operation would have infallibly saved the patient's life. A child seven years old, like that of Bonnet, was amusing herself with throwing up small dry beans, and catching them in her mouth. She supposed she had swallowed one of them; but was instantly seized with a difficulty of breathing, and a most fatiguing convulsive cough. It was suspected that the bean had stopped in the throat, and every thing was tried, which was thought to be likely to make it descend into the stomach, or cause it to be ejected from the mouth. The symptoms, however, recurred from time to time, with the addition of convulsions of the limbs. The cafe had gone on in this manner two days, when Louis was consulted. He found the child sitting up in bed, leaning upon her two arms, and breathing with difficulty. When he asked her where she felt any thing the matter, she placed her left fore-finger upon the trachea, betwixt the larynx and the sternum. The consideration of the various circumstances of the cafe made him conclude, that the bean had passed into the wind-pipe, and that the practice of bronchotomy was indispensably necessary for its extraction. Others, who were called into consultation, entertained a different sentiment. M. Louis could not bring them over to his opinion. The opposition which they made even increased, as the child appeared for a time a little better. But at length a new symptom occurred, which no one had yet observed, and which two hours previously did not exist. The child was evidently affected with an emphysematous swelling on each side of the neck above the clavicle. She took an emetic, which only had the effect of disturbing her. The third day she seemed more tranquil, though her respiration was always difficult. In the evening she died. When the trachea was opened, the bean was seen lodged at the upper part of this tube, whence it admitted of being most easily extracted with a pair of forceps.

The long intervals of cafe which the patient had, contributed particularly to throw doubts on the presence of the extraneous body in the trachea. It was suppos'd, that it would necessarily have kept up there a continual irritation, which could not have allowed of the alternations of suffuring and cafe which took place. But the fact is, the body was smooth, and it had defended below the glottis, the sensibility of which is double less than that of the trachea, so that it only produced urgent symptoms, when it was forced by the action of respiration against the lower part of the glottis, whose ligaments it hurt, and whose aperture it closed in such a manner, that the air was no longer capable of passing through it with its wonted freedom. It is to this cause that the emphysema, which has been spoken of, must be imputed; for the air being urged back into the lungs, must have ruptured some of the bronchial cells, infiltrating itself into the cellular texture of this viscus, and extending from below upward to the lower part of the neck, the integuments of which were elevated by it. This symptom is truly pathognomonic. It was also imagined, that if the extraneous substance had been in the trachea, it would have caused more quickly a fatal suffocation; but there are many cafes on record, proving that patients have survived the accident a long while. Bonnet's child, and another mentioned by Marcellus Donatus, did not die until the fifth day. The only symptom which the last experienced, was a slight cough, with a little irritation. The cough which occurred before death was attended with efforts, in which the child turned livid, as if it had been strangled with a rope. Other children also, who have swallowed beans, and whose cafes are related by Louis, died; one on the eighth or ninth day after the accident; the other at the end of three weeks, and after having in the interim followed the amusements of their age.

Perhaps it may be apprehended, that a foreign body, after its entrance into the trachea, will descend by its weight to the bottom of this tube; or, that after the proper incisions are made, its extraction will be attended with too much difficulty; but to these two objections, experience gives the most decisive answer. In almost all cafes of this sort, the foreign body has been found opposite that part of the trachea which would have been opened, if tracheotomy had been performed; and the experiments relating to this operation which have been made upon living animals, for the purpose
purposo of judging the facility or difficulty of extracting foreign bodies from the trachea, have drawn, not only that they remain at the upper part of the trachea, (whence they are forced by the air which endeavours to find a way out from the lungs,) but that they even of themselves come out of this tube, and are thrown out to a distance by the same cause, immediately a sufficient opening for their escape has been procured by the surgeon. We are indebted for such experiments to M. Favre, from a student in surgery at the Hotel des Invalides, and since member of the college of surgery at Paris. A large dog, which was muzzled, had an incision made under his jaw, spacious enough to let the tongue be drawn out through it. M. Favre took an opportunity, when the animal was in the act of inspiration, of introducing into the glottis an extremely substance of an irregularly spherical shape. The dog was wheezed with convulsive motions, which gave reason for apprehending immediate suffocation; but symptoms abated sufficiently, to allow the operation of tracheotomy to be deferred six hours. The wind-pipe was then opened by a longitudinal incision, which divided three of its cartilaginous rings. Scuriosity was the bukhoury withdrawn, when a strong respiration expelled the foreign body out of the wound; and as soon as it was a second time introduced, it was expelled again.

The experiment was repeated ten times with the same result. M. Saintiaux informs us, that he had seen M. Favre introduce into the wind-pipes of other dogs, extraneous substances of every description and figure, and amongst other things nails and small leaden bullets. These were even pushed very far down with instruments; but notwithstanding this, they were thrown out with force as soon as they were left to themselves.

The difficulty of finding and extracting foreign bodies which are lodged in the trachea, must therefore be no longer urged as a pretext for omitting the performance of tracheotomy in all cases in which there is imminent danger of suffocation, in consequence of the presence of those bodies. If, after the instruments and trachea have been divided, they should neither make their ascent nor protrude themselves at the opening, the surgeon should at once endeavour to find them with a pair of forceps, or any other instrument calculated to facilitate their extraction. All that now remains to be done, is to check the wound in the most simple manner, and to promote its cicatrization by the usual means. The operation which we have been speaking of, may be successfully conducted in some other cases. When the function of expiration is but slightly impaired in inflammatory conditions, or by the presence of a foreign body in the cleft of trachea, which foreign body cannot possibly be extricated, we pushed down into the stomach, the patient’s life may be saved by making an opening into the trachea or larynx. The necessity for such an operation was recognized in the very infancy of the art. With the same view, Hippocrates advised the introduction of a tube into the trachea. This had practice prevailed until Achates, who proposed the method of making an incision into the larynx of patients who were in danger of suffocation. This operation however, met with opposition. Celsus Alcidemus considered it as ridiculous and absurd. But it met with advocates in several other celebrated physicians, such as Aretaeus, Oribasius, Erasistratus, and especially Paulus Magens, who defended it in the following terms.

"If the patient be not made into the trachea, under the larynx, about the third or fourth ring. This incision is the most proper, because it is not covered with flesh, and the vessels are not seen in it. The patient’s head is to be carried backward, so that the wind-pipe may project more forward. We make a transverse section between two rings, so that the cartilages may not be wounded, but only the membrane which joins them together."

The Athenians, who succeeded the Greeks, were also advocates for tracheotomy. It does not appear, however, that they often practised the operation, on account of the dangers by which it was liable to be followed. Since the revival of learning, the possibility of doing it has been more generally admitted. The subsequent frequent examples of wounds of the throat, where the trachea has likewise been divided, have now produced a conviction, that this canal may be successfully opened in such cases as require it.

Fabricius ab Aquapendente was the first who proposed the operation in strong terms. He judiciously examined and considered every part of it, and was fully aware of its advantages.

The cannula which has been employed for placing in the opening made in the wind-pipe, seems to have been invented by him. He recommends it to be introduced between two of the rings; to have a straight shape; and to be furnished with wings, by means of which it may be fastened in its place. Its length should not be great, lest it should reach too far, and hurt the back part of the wind-pipe. Lastly; Fabricius advises it to be worn only during the impediment to respiration, since as a foreign body it may do harm, and cause pain and coughing.

Caffieri, his pupil, also carefully treats of bronchoeotomy. He describes the manner of performing it. By the first incision, the skin is to be opened longitudinally over the trachea. By the second, which is to be made between the muscles going up to the larynx, the wind-pipe itself is to be brought into view. A transverse opening is then to be made in it below the thyroid gland. Mompagni gives much credit to this author for having first noticed this gland, which in its enlarged state may materially increase the difficulty of the operation. Caffieri approves of the cannula recommended by Fabricius, which he thinks ought to be made of silver, of a flat form, curved, every where pierced with small holes, and fastened to the neck with a ribbon. He was quite apprised of all the inconveniences, which Fabricius pointed out as being liable to attend the employment of this instrument.

While these two Italian practitioners professed themselves to be in favour of bronchoeotomy in cases where the necessity for it exists, a French surgeon, M. Habibott, endeavoured to bring the operation into requisites. The method which he has published upon this subject, is entitled, "Questions Chirurgicales, par lequel il a été démontré que le Chirurgien doit suffisamment pratiquer l'Opérature de la Bronchoeotomie, volgarément dite Laryngotomie, ou Perforation de la Plate, ou Tyranne." This treatise made its appearance in 1669. Besides the reasons upon which this author supports his observations, he relates several cases in which bronchoeotomy saved the patients’ lives. The first is that of a young girl, who was shot in the throat. The bullet, after breaking the larynx, and particularly the left side of the thyroid cartilage, made its exit below the superior angle of the jugala. So considerable a degree of swelling followed, that the patient was almost suffocated. Habibott introduced into the trachea a leaden tube, which was worn three weeks, until the inflammation had subsided. The patient got well. The second person upon whom he performed bronchoeotomy was a young man, who had received twenty-two wounds in the head, face, throat, hands, arms, chest, back, wort, and thighs. There were done with a sword, knife, and pincers. In the evening of the same day, Habibott perceived that the patient was nearly suffocated in consequence of the inflammation and swelling of the throat. He was therefore de-
TRACHEOTOMY.

terminated to make an opening in the trachea, below the wound, opposite the upper part of the larynx. The respiration was immediately established again, and the wound was kept open with a grooved tent, until the tumefaction of the larynx was diminished. The cure was complete in three months. M. Louis was of opinion, that, in these two cases, the cannula only served to keep the lips of the wound in the skin apart, because, in the first, the thyroid cartilage was broken so extensively, that it could hardly be supposed to form an obstacle to the passage of the air; and because, in the second, the wound of the trachea had allowed the air to enter and come out again with ease, without the assistance of any tube.

We find in Habicot's essay a third instance in which tracheotomy was successfully performed. "A lad, fourteen years of age, who had heard that gold, when swallowed, did no harm, having sold some merchandise at Paris, for which he had received about nine pittloos, wrapped them up in a piece of cloth and swallowed them, for fear of being robbed. But as they could not pass through the narrow part of the pharynx or oesophagus, his face became so frightful and deformed with swellings and blackness, that his companions could not recollect him. Hence, having caused him to be brought to my house, and not being able to make him void, nor get the obstacle into his funnel, so closely was it fixed by the swelling of the throat; and considering that he would be suffocated, I first made a favourable prognosis, and then performed bronchotomy, which being finished, he revived so rapidly from the violence of the air, that the bystanders were alarmed; but the tumour and unfavourable colour of the face having disappeared, I assured them that he would recover," &c. The foreign bodies were then pushed down into the funnel with a leaden probe, and these were discharged about a week afterwards at different times with the stools. As the patient was so promptly relieved, probably Habicot never thought of keeping the wound open with a cannula, but endeavoured to heal it as expeditiously as possible. In the two other cases, he employed this instrument, which he has described in the last chapter of his treatise.

Since Habicot, and before the end of the seventeenth century, the testimonies to be found in favour of tracheotomy are very numerous; but no one did any thing to perfect the operation until Decker, who, in 1675, proposed to practise it with a small trocar, armed with a cannula. The method is more simple, more easy, and subject, as some have conceived, to fewer inconveniences, if the trachea be not pierced until this tube is exposed by an incision made in the anterior and inferior part of the neck, betwixt the muscles defined to depress the os hyoideum and larynx. Paulus, in his notes on Van Horne, imputes the preceding method to Sanctorius, who recommends the trachea to be pierced in the operation of tracheotomy, with the same instrument which he had invented for the paracentesis of the abdomen. By this means the trachea is opened, and the cannula placed, at the same time, a circumstance which prevents the bleeding, which might otherwise escape from the edges of the wound, and occasion an inconvenient and perhaps fatal cough. Dionis, who only proposes bronchotomy in the case of inflammatory quinsy, thinks that it may be done in a more expeditious manner, with less pain, and in a way more calculated to procure a speedy cure, than the mode which was previously in use. This plan consists in performing the operation by one puncture, so that the lancet at once opens the integuments and the interstice of the cartilages of the trachea, and the instrument is not withdrawn before the introduction of the probe, which is to serve as a conductor for the cannula. The advantages which Dionis ascribes to this method would merit the greatest attention, were they not counter-balanced by the inconveniences which result from it. There are not many subjects, whose necks are so entirely destitute of fat, that the interstice of the rings of the trachea can be felt. This tube, whose figure is cylindrical, easily slips under the fingers, and the change of position may render Dionis's manner of operating extremely difficult. The operation is not without danger of wounding the posterior parietes of the trachea, because one cannot penetrate into its cavity, through the thickness of the integuments and cellular substance, without using a degree of force which it is difficult to regulate with precision. Lastly, when the cannula is put into the wind-pipe, this canal closes, and defends so considerably in various circumstances, and especially in the action of deglutition, that the instrument must be liable to flip out of it. Verduc, before Dionis, had made some remarks on the poffure of the patient during the operation. His head was extended back, and the integuments were pinched up into a transverse fold before being divided. Verduc observed, that by inclining the head back, the difficulty of breathing would probably be increased, and that when this position was adopted, the integuments of the neck could not easily be pinched up into a fold. For such reasons, he thinks that posture best, in which the patient breathes with most freedom.

Tracheotomy had been practised only with a view of relieving the suffocation arising from the quinsy, and that which is produced by the pressure of a foreign body in the oesophagus upon the trachea. Detharding, professor of medicine at Rollock, published in 1714 a dissertation, entitled "De Methodo subvencendi submeretis per Laryngotomyum," the object of which was to prove, that this operation is necessary in order to restore drowned persons. The principle with which he vets out is, that drowned persons cannot breathe when taken out of the water, because the epiglottis is in contact with the glottis, and closes this opening so closely, as to leave no passage at all for the air. But some observations, carefully drawn up by M. Louis, have proved that the glottis is open and free in drowned persons, as well as in persons who have perished of any other kind of death, and that their death is caused by the water which they have forcibly inspired, and which mixing with the air and mucus with which the bronchial and bronchiolar cells are naturally filled, obstructs and blocks up these organs, so that the air can no longer enter them. But if Detharding has been mistaken in this point, he has not been deceived in regard to the advantages of tracheotomy in every other circumstance, and the little risk that is in practising it. He states, that the integuments, and the membrane which unites the rings of the trachea, being the only parts which ought to be cut, no vessels nor nerves of importance need be wounded.

Though there are no nerves of considerable size in the track through which the incision must necessarily follow, the same observation cannot be made in respect to the blood-vessels. The thyroid gland sends down, to the left subclavian, veins which, after having ramified on its anterior surface, unite into two trunks, the left of which most commonly paffes in front of the trachea, at the lower part of the interstice, which lies between the sternum-hyoidi muscles. In the greater number of subjects, these trunks only form one at the place of their intermission. Sometimes they continue separate. Sometimes, also, one of them terminates in the left subclavian vein, and the other in the right. The left may be injured in dividing the cellular substance which covers the trachea. This canal itself has likewise its own vessels, which may be cut, and bleed a good deal. This was what
what happened in a cafe infected by Hevin, in his memoir on foreign bodies lodged in the œsophagus and trachea, in the first volume of the Mémoires of l’Acad. de Chirurgie. A Spanish soldier, twenty-three years of age, was nearly dying of suffocation from quinsey. Tracheotomy was deemed the only means by which his life could be saved. The wind-pipe having been exposed by a longitudinal incision, an opening was made between two of its cartilaginous rings; but the patient derived no benefit from it, because the blood entered it, and occasioned a convulsive cough, which hindered the cannula from keeping in its place. The cafe appeared fo urgent, that M. Virgili determined to divide the trachea longitudinally down to the sixth ring; and he then made the patient lean forward. The blood soon ceased, and the surgeon was enabled to place in the wound a plate of lead, pierced with several holes, and provided with two shoulders, very much like what Bellotto employed in the treatment of the wound after trepanning. The next day the fever was diminished, and deglutition easer. M. Virgili suspected that the patient would be able to breathe without the affistance of the plate, and he therefore removed it. His hopes were not deceived. The only thing which remained to be done, was to bring the edges of the wound together, and endeavour to heal it, which was accomplished in a few days.

Garengeot states, that in separating the flerno-thyroidei muscles, the thyroid glands are separated, a circumstance which produces a risk of cutting them in the centre, and of wounding a great many of the vessels which are either distributed upon them or the adjacent parts, so that the blood running into the trachea, the operation must be useless. He allows that it is necessary to operate thus upon persons who are inclined to be fat; but in order to avoid so great an inconvenience, when the patients are thin, and the interface betwixt the third and fourth ring of the trachea has been felt with the index-finger of the left hand, and the place marked, Garengeot recommends introducing a lancet into the trachea at once, before the finger has been removed. The lancet is then to be moved gently towards each side, fo as to enlarge the opening. A flat tube is afterwards to be introduced, the fides of which are furnished with narrow ribbands. In this manner, the vessels of the trachea are alone cut, and these are small and of no consequence, so that there is less danger of blood flowing into the wind-pipe: Garengeot adds, that tracheotomy was in his days accounted a dangerous operation, and that there were few who had practised it, or who mentioned their having done it with success. This want of success appeared to him to be less ascribable to the operation itself, than to its having been undertaken too late. Such was also the sentiment of M. Louis, who infists upon the necessity of having recourse to it as soon as the suffocation appears at all urgent, so as to prevent the effusions in the lungs and brain, always brought on by an extreme difficulty of respiration.

Garengeot’s method was not original, since it had been described by Dionis. It has also some resemblance to Decker’s mode of operating, which consisted in opening the trachea through the integuments, without exposing this canal by a longitudinal incision, in the usual way. Sharp records a cafe, which confirms the inconveniences which have been attributed to it. A patient, who was in great danger of dying suffocated, was operated upon in the preceding manner. The motion of the wind-pipe in respiration soon separated the opening in the trachea from that in the skin, and occasioned the utmost difficulty in introducing the cannula, and keeping it in its place. Sharp rightly infers from this fact, that it is absolutely necessary to produce a longitudinal incision, and make it of sufficient size. Platner likewise recommends this incision of the skin, after which, he says, the trachea may be opened with a lancet, or with an instrument analogous to what is employed for tapping. But though this method seemed to him the most expeditious, he deemed it too late.

It does not appear to Sabatier, however, in what it is more objectionable than the other. On the contrary, he thinks that it has the advantage of preventing bleeding into the trachea, because the cannula immediately fills the opening made in this tube. Platner cites a cafe, which is recorded in the Philosophical Tracts, and which the celebrated commentator upon Boerhaave has also quoted. Authors who had mentioned the cannula which was to be introduced into the trachea, had contented themselves with stating, that it ought not to be too long, lest it should injure the posterior side of that canal. Garengeot conceived, that the dimensions of the instrument might be determined with more precision, and he calculated that its length should be about twenty-seven millimetres. Dr. G. Martin, the author of the cafe to which we have alluded, found this length insufficient, and he was even obliged to use the cannula of a trocar for the paracentesis of the abdomen, instead of what he was first about to employ; but as it was too long, he was under the necessity of making it pass through an aperture made in a thick linen compres.

It has been apprehended, that the extraneous substanccs in the air may pafs through the cannula into the lungs, and, consequentle, it has been recommended to cover the mouth of the instrument with a bit of sponge, cotton, or gauze. But Dr. Martin did not find this precaution necessary. He thinks it more useful to warm the air which the patient breathes, so that the lungs may not be hurt by it. There is one serious inconvenience which experience taught him, and which arises from the mucus discharged from the lungs. By this the cannula becomes fo obstrueted, that its presence affords no assistance. Dr. Martin was several times compelled to take out the tube in order to clean it. He received a suggestion, that he might employ a double cannula, that is to say, two cannules, one within the other, fo that the internal one might be withdrawn as often as necessary, without disturbing the outer one, into which it could be easily put again. In this manner, a free respiration would be assured; but Sabatier conceives, that a thick tube would be difficult of introduction. He also doubts whether the tube, of which all practitioners have spoken, is indispensably requisite. When the trachea, or larynx, is opened in wounds of the neck, the air makes its escape with force, and the circumstance needs to be checked by inclining the patient’s head forward, and confining it in this posture with bandages. Meyfionnier, who wrote towards the conclusion of the seventeenth century, and who practised tracheotomy three times, put no leaden cannula in the wound. He contented himself with applying dry lint, a pledge, and bandage. Sabatier notices, that these cafes are detailed too briefly. They prove, however, that the cannula may be dispensed with, and that the making of an opening in the trachea will enable the patient to breathe.

Van Swieten, as well as Platner, rejects the plan of opening the trachea with a trocar. His reason was, because the point of this instrument being thick and short, it was difficult to make it penetrate without using a great deal of force, especially in consequence of the great meseableness of the part on which it has to act. The trials which he made of this method, both on the dead subject and on living animals, convinced him that it was difficult, and that there was danger
in the event of the trocar slipping. This risk may be avoided by fixing the trachea well, and particularly by using some instruments, which were invented by Bauchot, an old surgeon-major of the French navy. They consist of a cutting blade mounted on a handle, to which is adapted a flat cannula, the opening of which has a rim furnished with two small rings, and of a kind of steel crescent, which served to fix the trachea, and as a conductor to the first instrument, which was called the bronchotome. Bauchot employed these instruments successfully upon two persons attacked with quinsey, and threatened with suffocation.

It may be concluded from all which has been said, that the operation of tracheotomy, which is also named bronchothomy, and laryngotomy, may be successfully practised, when patients are in danger of suffocation in cases of inflammatory quinsey; when respiration is obstructed by the lodgment of a foreign body in the oesophagus, which body can neither be extracted, nor pulled down into the stomach; and when an extraneous substance has fallen into the wind-pipe. In quinsey, and in cases of foreign bodies lodged in the oesophagus, the operation consists in making an opening, through which the air can enter to the lungs. In the case of a foreign body in the trachea, an incision is required, which divides longitudinally several of the cartilaginous rings of this tube, which is of a size proportioned to that of the substance to be extracted.

When merely an opening is required for the passage of the air, the surgeon may proceed in several different ways. In the oldest method, the patient was placed in the recumbent posture, with his head supported on pillows, so that the skin of the front and lower part of the neck could be pinched up into a transverse fold, of which one end was held by an attendant, the other by the surgeon himself with his left hand. This fold was divided from above downwards, and the incision was continued from the lower part of the larynx to the front of the upper edge of the sternum. The cellular substance between the sternothyroid and sternothyroidei muscles, was next divided down to the fore-part of the thyroid gland and trachea. This canal being exposed, the surgeon puts his left-hand index-finger between two of the cartilaginous rings, and then passing along his nail the instrument of which he has made choice, he makes a transverse incision in it. When he judges a cannula indispensible, Bauchot's instrument is the belt, the perforating part of which should be taken out immediately the trachea is divided, so as to leave only the tube, which is to be fixed in its place with suitable ribbons passed through the little rings.

In this manner, there is no risk of blood falling into the trachea, because the wound is filled by the instrument with which it is made. If, on the contrary, the tube be consider'd useless, the surgeon should use a lancet with rather a long point.

Instead of practising tracheotomy, or bronchotomy, surgeons have been recommended to perform the operation of laryngotomy, as more safe and easy. The lower edge of the thyroid cartilage, and the upper edge of the cricoid cartilage, are connected together by a thick ligamentous membrane, covered in front merely by the integuments. This anterior part of the crico-thyroid membrane is also immediately opposite the highest and broadest portion of the cavity of the larynx, directly below the glottis, so that it is not only easy to bring it into view by a superficial small cut through the skin and cellular substance, but the incision may be made longitudinally, by which its union will be facilitated, and there can be no risk of hurting the opposite side of the larynx. In France, this mode of operating has had several distinguished advocates, and the celebrated Vie-d'Azyr com-

TRACHICHTHYS, in Ichthyology, a genus of fishes, first described by Dr. Shaw in the "Naturalist's Miscellany," the characters of which are as follow: head rounded in front; eye large, mouth wide, toothless, deciduous. Gill-membrane furnished with eight rays, of which the four lowermost are rough on the edges. Scales rough; abdomen mailed with large carinated scales. There is one species: viz.

T. AUSTRALIS, or Southern Tr. With mailed abdomen; a native of the coast of New Holland. Its colour is a bright pink-ferruginous, or fair reddish-brown. The middle part of all the fins of a deeper colour than the rest of the animal, and the edges lighter, or of a yellowish tinge.

TRACHIDNA, a name given by Jovius and some others to the draco marinus of the old authors, called by us the "scarecrow." TRACHINIA, in Ancient Geography, a canton of Thessaly, in the Phthiotides, near mount Oeta. It is also called Melide. In this country was the town of Heraclea, first called Heraclea Trachiniae. Thyctides.

TRACHINÆ PETRÆ, high and inaccessible rocks which bordered a plain near the Malia gulf. They surrounded the Melide. Between these rocks and the sea flowed the river Melas, whence the territory had its name.

TRACHINUS, in the Linnean system of Ichthyology, the name of a genus of fish of the order of the Juguilares: the characters are, that the head is compressed and not smooth: the membrane of the gills has five rays, and the lower lamina of the operculum is serrated; and the anus is near the head. Linneus mentions one species, viz. the Draco. Artedi refers the Uranopterus also to this genus.

The name is originally Greek, the word τραχίνως signifying rough, sharp, or prickly. It was given to this fish from the
the rays of its back-fin being remarkably rigid, and sharp like prickles.

Trachinus Lapis, in Natural History, a fish mentioned by the writers of the middle ages, as possessing many great medicinal virtues. It seems to have been a kind of lapis nepriliteus, being described as bright, but not transparent, and being of two kinds, the one blackish, and the other green.

Trachis, in Ancient Geography, a town of Thessaly, said to have been built by Hercules at the foot of Mount Oeta, towards the mouth of the river Alorus. It derived its name from its mountainous and rugged situation. On the site of this town, which is mentioned by Homer, the Lacedaemonians built another, to which they gave the name of Hercules.

Trachoma, (from τραχύς, rough), a roughness of the inner surface of the eyelids, caused by hardened mucus and scabs. It implies the same sort of disease as the Pteroplasm, which see.

Trachon, in Ancient Geography, a plain which bounded the territory of the king of the Cimmerian Bosporus, on the side of Scythia.

Trachones, the name of two hills situated beyond the town of Damascus, in Syria. Strabo.

Trachonitès Arabes, Arabs who inhabited Succa, at the foot of Mount Alphadamus. Ptolemy.

Tracht, or Tractin, in Geography, a town of Moravia, in the circle of Brunn; 21 miles S. of Brunn.

Trachurus, in Ichthyology, the name of a fish of the Scimber kind, called in English a sword, and by several authors, furca, furus, and acius marinus. See Scomber.

Trachurus Chalcodon, a fish given by Mr. Ray to a fish of the scimber kind, the scimber cordylus of Linnaeus, known among writers on these subjects by its Brabian name gavalaroéa.

Trachynotia, in Botany, a genus of grasses, so named by Michaux, from τραχύς, rough, and νοτία, the back, because the glumes are rough in that part. — Michaux Bot.-Amer. v. 1. 63. — This is the same with Limnetis of Richard and Perfoon, adopted by Pursh, v. 1. 25 and 59, referred to Triandra Monogynia, and thus defined.

E. Ch. Spike lateral-flowered; flowers imbricated in two ranks. Calyx of two valves; one smaller than the other. Corolla of two valves, pointless, compressed, keeled. Style elongated.—Three species are described.

These are very coarse harsh grasses; the last is laid by Clayton to have a rancid smell. We mention them here, because Linnetis is accidentally omitted in its proper alphabetical order. Which of the two above names is to be preferred, might require consideration; but we have already declared under Dactylis that we do not fee the necessity of dividing that genus. If otherwise, our British D. stricta, Fl. Brit. 110. Engl. Bot. t. 380. Knapp. Gram. t. 63, must be associated with the above three American species.

Trachys Mons, in Ancient Geography, a mountain of the Peloponnesus, in Arcadia. Paulyanias.

Tracing, in Husbandry, a term used by our planters for the method of preferring the maize, or Indian corn. This being a large grain, is apt to spoil, if not carefully preferred.

Some thrall out the corn as soon as the ears are gathered, and lay it up in holes of the earth, which are their granaries: but those who have not opportunities of doing this, trace it, that is, they leave it in the ear, and weave, or fallen together a great number of ears by the ends of the hufks: these traces of corn they hang up within doors, on such supports as will keep them from one another; and they will, in this manner, keep good the whole winter.

This is a method of our introducing; but their own, of burying the clean corn, was at least as good, and was the same practised by the Egyptians of old, and by all the wiflett nations of the East at this time. But whether we have improved their husbandry in this particular, or not, it is certain that we have greatly affihed them in the planting of this corn, which we do by the plough, instead of the troublesome method they had of doing it with the hoe. The manner of our planting it is this: we plough single furrows the whole length of the field, and at about six feet distance one from another; we then plough others across at the same distance, and then, wherever the furrows meet, the corn is thrown in; it is then covered either by the hoe, or by running another furrow behind it with the plough; and when the weeds begin to overtop the corn, they plough the spaces again, and by this means destroy and turn in all the weeds, and give the earth a flitting, that greatly affihes vegetation.

The famous method of horse-hoeing husbandry, so celebrated by Mr. Tull, in a book written on that subject, is no other than the bringing home this method of our American planters, on the culture of the maize, and applying it to our European corn. The Indians, and our planters, join in the method of raising a hill of earth round every stalk of the maize; and when the ground is poor, or out of heart, they bury two or three hufks, of a kind called by them the ailes, under every hill, and by this means they have a crop double to what would otherwise have been produced. The English have learned this manure from the Indians; and in New England, where they are near the fishing-stages, they bury the heads and garbage of the cods, which fucceed as well as the ailes, and colt nothing but the carriage.

The lands on which the maize or Indian corn has grown, are as well fatted for our European corn as if they had been laid fallow. The reason of this is, that the plants of the Indian corn standing at fix feet distance from each other, the far greater part of the ground has remained unoccupied, and at the same time has had the advantage of often ploughing to kill the weeds, which is a benefit equal to that of dung and reft. All this, though it tends to prove the doctrine of horse-hoeing husbandry not new, yet it strengthens the system greatly. Phil. Trans. No. 142.
TRACTIONS, Drawing, the act of a moving power, by which the moveable is brought nearer to the mover, called also attraction.

Traction, Line of, in Mechanics. See Wheels.

Tractoriæ, among the Romans, were diplomas or tickets given by the emperor to such as he sent into, or called out of, the provinces; by which they were entitled to the use of the public post, and to be maintained at the expense of the government.

Tractrix, in Geometry, a curve line, called catenary; which see.

Trade, Traffic, Commerce, the act, or, art, of dealing, buying, selling, exchanging, &c. of commodities, bills, money, &c.

For the origin, progress, &c. of trade, see Commerce and Navigation.

It is observed by Dr. Smith, that all wholesale trade, all buying in order to sell again by wholesale, may be reduced to three different sorts: viz. the home trade, the foreign trade of consumption, and the carrying trade. The home trade is employed in purchasing in one part of the same country, and selling in another, the produce of the industry of that country; and it comprehends both the inland and the coasting trade. The foreign trade of consumption is employed in purchasing foreign goods for home consumption. The carrying trade is employed in transacting the commerce of foreign countries, or in carrying the surplus produce of one to another.

The capital that is employed in the first kind of trade generally replaces, by every such operation, two distinct capitals, that had both been employed in the agriculture or manufactures of that country, and thereby enables them to continue that employment. When it sends out from the residence of the merchant a certain value of commodities, it generally brings back in return at least an equal value of other commodities. When both are the produce of domestic industry, it necessarily replaces, by every such operation, two distinct capitals, which had both been employed in supporting productive labour, and thereby enables them to continue that support.

The capital employed in purchasing foreign goods for home consumption, when this purchase is made with the produce of domestic industry, replaces, too, by every such operation, two distinct capitals; one of which only is employed in supporting domestic industry. Though the returns of the foreign trade should be as quick as those of the home trade, the capital employed in it will give but one-half the encouragement to the industry or productive labour of the country. But, in fact, the returns of the foreign trade are very seldom so quick as those of the home trade; the former coming in before the end of the year, and sometimes three or four times in the year; and the latter seldom coming in before the end of the year, and sometimes not till after two or three years. The capital, therefore, in the home trade will sometimes make twelve operations, before a capital employed in the foreign trade of consumption has made one. If the capitals are equal, therefore, the one will give twenty-four times more encouragement and support to the industry of the country than the other.

That part of the capital of any country which is employed in the carrying trade, is altogether withdrawn from supporting the productive labour of that particular country, to support that of some foreign countries. And though it may replace, by every operation, two distinct capitals, yet neither of them belongs to that particular country. See the illustration of these principles in Smith's Wealth of Nations, vol. ii. p. 60, &c. See Capital.

The offences against trade, considered in a legal view, are smuggling, or the offence of transporting wool or sheep out of this kingdom, to the detriment of its staple manufacture, (see OWLER,) fraudulently importing, &c. of commodities, bills, &c. See Trade. See also the two following articles.

Trade, Balance of. See Balance.

Trade, Board of. See Board.

Trading Society. See Society.

Trade-Winds, denote certain regular winds at sea, blowing either constantly the same way, or alternately this way and that; thus called from their great use in navigation, and the Indian commerce.

The trade-winds are of different kinds, some blowing three or six months of the year one way, and then the like space of time the opposite way; these are very common in the Indian seas, and are called monsoons; which see.

Others blow constantly the same way; such is that general wind between the tropics, which off at sea is found to blow all day long from east to west. For the phenomena of each, with their physical causers, see Wind.

Dr. Lifier has a conjecture in the Philosophical Transactions, No. 156, that the tropical or trade-winds arise, in great part, from the daily and constant exhalations of a salt plant, called the farfosa, or lanica marina, which grows in vast quantities from $36^\circ$ to $18^\circ$ north latitude, and else-where upon the deep-sea isles. For the matter of wind, coming
coming from the breadth of one only plant, must needs be constant and uniform; whereas the great variety of trees and plants at land furnishes a confused mixture of winds. Hence, he adds, it is, that these winds are briskest about noon; the sun quickening the plant, and making it to breathe faster, and more vigorously. Lastly, the direction of this wind of east to west, he attributes to the general current of the sea; for a gentle air is observed to be constantly led along with the stream of the river: not much it is omitted, that every plant is, in some manner, an heliotrope, and bends itself, and moves after the sun, and consequently emits its vapour thitherward: so that the direction of the trade-wind is, in some measure, also owing to the course of the sun.

Dr. Georden has another hypothesis: the atmosphere, which surrounds the earth, and moves along with it in its diurnal motion, he supposes to keep pace with it; that part of it, at least, which is near the earth, if the remotest part should be judged to lost ground.

If then, there were no changes in the atmosphere's gravity, it would always go along with the earth from west to east in an uniform motion, altogether unsensible to us; but the portion of the atmosphere under the line being extremely rarified, its force expanded, and so to its gravity; and pressure much less than the neighbouring parts of the atmosphere, it is incapable of the uniform motion towards the east, and must, therefore, be pressed westwards, and make the continual breeze from east to west, between the tropics.

TRADESCANT, John, in Biography, one of the fathers of natural history in England, having been the first who made any considerable collection of natural productions, (see Museum,) as well as one of the earliest cultivators of exotic plants in this country, is represented by Lathbury Wood to have been a Dutchman. His name interchanged appears to be English, and was originally of two syllables, Tradescant, though it subsequently became Trasdescant, as appears by a line in his family epitaph,

"__

Lae John Tradescant, grandiflora, iun.

Dr. Pulteney thinks he was not settled in England during the life of Graves, though often mentioned in the second edition of that author's Herbal, by its editor Johnston, as well as in Parkinson's Works. He is recorded to have been for a considerable time in the service of the lord-treasurer Sackville, and Lord Wooten. He travelled into various parts of Europe, even as far Russia, and was on board a fleet against the Algerines in 1622. He brought home plants and other curiosities from those various excursions, but it does not appear what was his primary object. About the year 1635, he obtained the title of gardener to King Charles. About that time, or before, was settled at Lambeth, where his own garden was situated. Some remains of this were traced out by Mr. William Wotton 120 years afterwards. Tradescant's Ark, or Museum, became very famous as a collection of natural rarities. It was much visited by the great, and even by the royal family, all of whom took pleasure in examining it, as in later times their descendants have done to other such collections. A catalogue of the Museum Tradescantianum, in 1697, appeared. It contains the portraits of the owner and his son, engraved by Rys eldest; of which however most of the copies are diminished by mere print collectors, curshing the value of any thing beyond their own object. By this catalogue, the museum appears to have been furnished, not only with herbs, quadrupeds, fishes, shells, insects, minerals, fruits, &c., but also with warlike instruments, haberd, utensils, coins, and medals. There is annexed a catalogue in English and Latin of the plants cultivated in the author's garden. His portrait represents him as greatly advanced in age at this period; but the time of his death is not known. His son, of the same name, visited Virginia, and returned with several new plants; amongst others the original Tradescantia, hereafter mentioned. This son inherited his father's collections, and dying in 1662, bequeathed them to Mr. Elias Ashmole, so that they may be said to have laid the foundation of the Ashmolean Museum at Oxford, in which they, like the name of their original owner, are now sunk. The widow of the younger Tradescant, the mother probably of the grandson mentioned in the epitaph, is said to have carried the curious and rather splendid taste, remarkable for its allusive decorations, which still exist in Lambeth church-yard. See Dr. Dunciarell's account of this monument, in the thirty-third volume of the Philosophical Transactions. Pulteney's Sketches of Botany.

Obl. Mr. Brown, by whose and Gartn. our observations we have endeavoured to improve the above generic characters, has most judiciously established a natural order of Compositae, as distinct from Jaffuret's Juncis, from which they are, as he says, very different in habit as well as structure. Indeed we were never able to conceive how any professed naturalist (who could allow of so strange an alliance, of plants that have so little in common, as the above-named order of the great French teachers. Now are we left surprised at the extraordinary assumption which will still call the beautiful delicate and transient corolla of their plants, a calyx, though as different and distinct from the real external pericarp, as in any flower whatever. But it is deemed that monococcous plants can have but one arrangement to their flowers, and that this one must be a calyx; though here they have manifestly two, of which the external one is, as usual, a flat-veined corolla. Mr. Brown indeed feels the necessity of calling their internal parts petals with Linnæus, though such phytology overtops the Jaffuret hypotheses. The genus before us consists of various species of herbs.
TRADESCANTIA.

aceous plants, some annual, others perennial, none of them natives of Europe. Their leaves are alternate, theathing, simple, entire, with parallel ribs. Flowers clustered, short-lived, usually purplish, differing from those of Commelina, (see that article,) in being regular, with almost universally six perfect anthers. Mr. Brown proposes to separate, into a distinct genus, certain species, the claws of whose petals are united, and whose two seeds, in each cell, are directed in a contrary manner, one upward, the other downward. The fear of these seeds, moreover, is said to be at the base, their embryo at the opposite extremity. In this predicable are T. axillaris, crista, and some unpublishe species.

We proceed to augment Willdenow's list with some new species, most of which recently published by Mr. Kunth, among the discoveries of those illustrious travellers Baron Humboldt and M. Boupland.

1. T. virginica. Common Virginian Spider-wort. Linna. Sp. Pl. 411. Willd. n. 1. Ait. n. 1. Pursh n. 1. Curt. Mag. t. 12. Sowerb. Drawing-book t. 6. Redout. Liliac. t. 95. (Phalanquium euphemicum virginianum; Park. Parad. 152. t. 151. f. 4.) — Stem erect. Leaves lanceolate, smooth. Flowers numerous, in a sort of terminal sessile umbel. Calyx hairy. — This, the original species of its genus, was brought from Virginia by the younger Tradescant, (see that article,) before the year 1629, as appears by Parkinson's Paradisus; and is now one of the most common hardy perennials of every country garden, blossoming copiously throughout summer and autumn. Pursh says it occurs in flathy woods, from Pennsylvania to Carolina, flowering in May and June. The plant is readily increased, by parting its long fibrous roots, and thrives particularly well in shade and moisture. The petals are eighteen inches long, round, leafy, scarcely branched. Leaves sheathing, concave, taper-pointed, of a dark shining green. Flowers large, of a rich violet blue, each lasting but a day, or rather a few hours in the early part of a day, after which they roll up into a liquefying pulp mass; but there being a great number in each umbel, or tuft, there is a long succession. The fix golden anthers are brilliantly contrasted with the dark purple shaggy filaments.

3. T. flabesera. Roughish Spider-wort. Curt. Mag. t. 1597. Ait. Epit. 375. (T. cirrata; Walt. Carol. 119.) — Stem erect. Leaves ovato-lanceolate, recurved, rough-edged. Umbels lateral and terminal, many-flowered. Calyx hairy. — Native of North America, from whence it is reported to have been brought by Mr. Lyon in 1812. The plant is a hardy perennial with us, flowering from June to September, but has little superiority to claim over T. virginica, except what arises from novelty. The foliage is broader, and more divaricated, than that of this species, as well as wavy and roughish, especially at the edge. Flower-flanks reddish or purple, becoming wrinkled as the flowers fade.

4. T. crassifolia. Thick-leaved Spider-wort. Cavan. Ic. v. 1. 54. t. 75. Willd. n. 2. Kunth n. 5. Curt. Mag. t. 1598. — Stem erect, woolly. Leaves ovate, coriaceous; silky at the margin and under side; with very short teeth. Umbels terminal, hairy. — Native of New Spain, flowering in September. A flowe plant in England, introduced by the late marchioness of Bute. The root is tuberous, perennial. Mr. Ker Bellenden describes the stem as procumbent, but by every other account it is erect. The broad thick ovate leaves, densely silky with white hairs at the margin, as well as beneath, distinguishes this species from all the foregoing. The flowers are of a pale violet, expanded but for three or four hours in a morning; their size equal to our first and third species. Calyx hairy.

— Native of the elevated plains of Mexico, near Chapotepec, flowering in May. Perennial. Stem fruticat, sparingly clothed with white woolly pubescence. Leaves lanceolate-oblong, membranous, somewhat channelled, three inches long, hardly one broad. Stalks short, lax, fruticat, woolly at the edge. Umbels of about twenty flowers, whose flanks are divaricated, round, hairy, near an inch long. Calyx tipped with purple. Petals thrice its length, purple, combined at the base. Germin woolly. Style purplish, smooth. Kunth.

7. T. undata. Wavy Racemose Spider-wort. Kunth n. 7. Willd. Emm. 347. — Stem erect, with a hairy lateral line. Leaves oblong, acute at each end, wavy, rough on the upper side and margin, with fringed teeth. Clusters terminal, in pairs. — Native of the sloping sides of hills in Cumania, flowering in September. An annual plant, very nearly related to the last, but more tender, and with reddish-purple flowers.

8. T. Zanonia. Gentian-leaved Spider-wort. Swartz Ind. Occ. v. 1. 624. Willd. n. 4. Ait. n. 5. (Commelina Zanonia; Linna. Sp. Pl. 62. Redout. Liliac. t. 192. Campell Zanonia; Kunth 264. Zanonia graminea perioliata; Plum. Gen. 38. t. 38. Periclymenum rectum herbaceum, gentiane fioho, foli pediculo caulem ambi ente; Swayne Jam. v. 1. 243. t. 147. f. 1.) — Stem erect. Leaves elliptical, tapering at each end. Flowers capitate, on long, lateral, foliary flanks, jointed in the middle, with a pair of bracteae. Capsule clothed with the permanent pulpy corolla. — Native of woods in the West Indies and South America, flowering in autumn. A not unfrequent floweplant in Europe, though less remarkable for the beauty of its flowers, which are small and white, than for the peculiarity of its dark-purple juicy fruits, formed of the thickened and enlarged corolla, which completely invets the capsule. The root is perennial. Stem two or three feet high, mostly branched, smooth, juicy, leafy in the upper part. Leaves near a foot long, downy beneath, fringed at the base; often red at the edges; their stipules tumid, densely fringed. Flower-flanks opposite to each leaf, and nearly as long, with a sheath in the middle, and two ovate, spreading, leafy bracteas at the top, accompanying a head of eight or ten flowers.

9. T.
10. T. malabarica. Grafted-Leaved Spider-wort. Linn. Sp. Pl. 412. Willd. t. 6. Apt. n. 7. (Tali pullu; Rheedea Hor. Mal. v. 9. 125. t. 63.)—Stems erect, angular; hairy at one side. Leaves linear, channelled, recurved, clasping the stem. Flowers lateral and terminal, hairy, two or three together.—Native of the East Indies. Perennial, flowering in our flowers in June and July. About a foot high, with many slender, slightly branched, dense, moss leafy in their lower part, and small flowers. The calyx is hairy. Capsule exquisitely polined, as if varnished.

11. T. diversa. Spreading Spider-wort. "Vahl Edag. v. 1. § 54." Willd. n. 8. (Commelina hexandra; Aubl. Guin. 35. t. 12.)—Stems branched, trailing. Leaves ovate, somewhat flaked, smooth, with bearded sheaths. Panicles terminal. Filaments naked.—Found by Aublet about rivers in Cayenne and Guiana, flowering almost all the year. Root perennial. Stems rising to the height of ten feet, supporting themselves upon the neighbouring bushes. Leaves two or three inches long. Flowers blue, in compound clusters, or panicles. Their filaments are said to be smooth, white, and yellow.

12. T. pendula. Knotted Spider-wort. Linn. Sp. Pl. 412. Willd. n. 9. Apt. n. 8. Jacq. Amer. t. 64. (Ranunculus ran Dimensionum repens, parvifolia folia villosa; Plum. 1c. 156. t. 116. f. 2.)—Stem decumbent, with a hairy lateral line. Leaves ovate, flanked at the base and sheath. Panicles terminal, compound, capillary, nearly smooth.—Native of the West Indies, in shady moist places, flowering in our flowers about July and August. Root perennial. Stems slender; decumbent and creeping at the bottom; branched and leafy above. Leaves either above an inch in length, pointed, hairy, especially at the margin and base; their sheaths terminal, membranous, densely flanged at the border. Flowers small, white, in loose diversified panicles. Calyx smooth. Capsule pellucid, polished.

13. T. monandra. Small Monandrous Spider-wort. Swartz Ind. Occ. v. 1. 597. Willd. n. 10.—Stems diffuse, with a hairy lateral line. Leaves ovate-heart-shaped, smooth. Stalks axillary, many-flowered. Stamen foliary. —Discovered by the scrutinizing eyes of Dr. Swartz in bushy places on hills in the western part of Hispaniola, flowering from June to March. A delicate perennial herb, creeping by means of long fibrous radicles. The leaves are not an inch long, very smooth, pointed, finely renculated when dry, with pale fringed flowers. Flowers minute, white, in little axillary umbels. Calyx hairy. Stamen but one, slender, smooth.

16. T. procumbens. Procumbent White Spider-wort. Willd. n. 13. (T. multiflora; Jacq. Coll. v. 2. 266. T. Rac. t. 555.)—Stem procumbent, creeping. Leaves ovate, fringed at the base. Stalks axillary, many-flowered. Three of the filaments short and bearded.—Found in moist situations at the Curaccas. Flowers in the flower from August to December, and is perennial. Jacqui. This appears to be a much larger and floret plant than the preceding, the fringes being four feet long; their numerous flowering branches ascending. Leaves an inch and half or two inches in length, dark green, with ribbed sheaths. Flowers in many axillary, as well as terminal, many-flowered tufts, small and white; their three longer filaments only beard at the summit.

17. T. axillaris. Grafted-Leaved Axillary Spider-wort. Linn. Syn. Vég. ed. 15. 260. Willd. n. 14. (Commelina axillaris; Linn. Sp. Pl. 61. Euphorbe phalangoides madagascariensis minimum, secundum cranium quoddam utraque floridam Plak. Phys. t. 174. f. 9. Nit-pulli; Rheedea Hor. Mal. v. 12. t. 28. f. 15.)—Stem branched, decumbent. Leaves linear, acute; with short, fringed, tufted sheaths, which are longer than the axillary filaments.—Native of the East Indies. Root small, fibrous, annual. Stem much branched, decumbent, taking root at the joints, leafy, smooth, a foot long or more. Leaves graceful, smooth, from three to five inches in length, and one-third of an inch in breadth; their sheaths coloured, smooth, but strongly fringed. Flowers rather small, blue, slightly flaked, scarcely projecting beyond the sheaths of the leaves, not always solitary in our specimens. Calyx-ovaries lanceolate, but half as long as the tube formed by the united bases of the petals. Stamen according to Koch, six, with jointed hairs.

18. T. crenata. Crenated Spider-wort. Willd. n. 15. Apt. n. 9. Jacq. Hort. Vind. v. 2. 64. t. 157. (Commelina crenata; Linn. Sp. Pl. 62. Barm. Ind. 18. t. 7. f. 2. Euphorbe crenata procumbens crenata; Herri. Parad. 128.)—Stem branched, decumbent. Leaves lanceolate, reflexed. Spikes terminal, recurved, with imbricated crenate-shaped bractea.—Native of Ceylon; introduced to Kew in 1770 by M. Richard. It is annual, flowering in the dove from July to September, and is remarkable for its long-stalked bearded recurved spikes, of pretty little bright blue flowers, whose five filaments are all bearded at the summit. The habit of the herb is like the last, but with shorter, broader, and blunt, deflexed leaves.

Spikes terminal, with three clasping bracteae.—Native of the East Indies. Burmann’s figure indicates a very distinct species from the leaf, with longer and linear leaves. Each spike moreover seems completely enfolded in one large external bractea. Yet the Linnean specimen, from the Upal garden, appears scarcely different from T. crista, as Linneus himself suspected. He says the flowers are violet, not sky-blue. Those who poetros both plants, in a living state, can alone clear up the uncertainty which envelops these species.

20. T. gracilis. Slender Purple-veined Spider-wort. Kunth n. 1.—“Stem branched, procumbent. Leaves ovate, acute, fringed as well as their lax sheaths. Umbels terminal, aggregate, on downy stalks. Calyx coloured, rather downy.”—Native of the cooler regions of Quito, near Tarqui and Chillo; perennial, flowering in February. Stems smooth, a foot long. Leaves thickish, eight or nine lines in length. Umbels three or four together, with about seven flowers in each, whose corolla is white, veined with purple. Stamens hairy at the base. Cells of the anthers widely separated.

21. T. albula. Weak White Spider-wort. Kunth n. 2.—“Stem erect, weak, nearly simple. Leaves ovate-oblong, acute, fringed as well as their lax sheaths. Umbels solitary or in pairs, on smooth stalks. Calyx hairy at the summit.”—Found with the last, to which it is confusedly nearly akin; but the leaves differ somewhat in shape, and the umbels consist of ten or twelve flowers, whose calyx is green, and their petals pure white.

22. T. pulchella. Dwarf Purple Spider-wort. Kunth n. 3.—“Stem procumbent, branched. Leaves ovate-oblong, pointed, smooth; rough with minute ferratures at the margin. Sheaths lax. Umbels in pairs, on smooth stalks. Calyx gibbous at the base, smooth.”—Native of a temperate climate, on the Mexican mountains, between Guanacuato and Santa Rosa de la Sierra, flowering in September. — Root perennial. Stem six inches or more in length, round, smooth, sometimes simple. Leaves an inch and a half long, membranous, with about thirteen ribs. Umbels terminal, of about nine purple flowers. Calyx-leaves linear-lanceolate, blunt, gibbous at the base. Capsule oblong, smooth, of only two cells, with solitary seeds, rough with dots.

23. T. biflora. Hairy Procumbent Spider-wort. Kunth n. 4.—“Stem procumbent, branched. Leaves oblong-lanceolate, pointed, rough-edged, waved, beneath hairy, as well as their lax sheaths. Stalks three or four-flowered, terminal, in pairs, hairy like the slightly coloured calyx.”—Native of the cooler mountains of New Granada, near San Miguel on the banks of the river Putes, Teindala, and the village of La Cruz, flowering in November. The root is perennial. Stem two or three feet long, round, fringed, smooth. Leaves rounded at the base, flat, with about nine ribs, an inch and a half or more in length, four lines broad; their upper surface nearly smooth. Sheaths pellucid, fringed, half an inch long. Calyx-leaves lanceolate, acute, purplish-green. Petals twice as long, purple. Filaments red, hairy at the base.

24. T. formosa. Tall Cape Spider-wort. Willd. n. 15. (T. formosa; Linn. Suppl. 192. Lamarck n. 9. T. no- diolora; Lamarck n. 6, according to Willdenow. Commelinia formosa; Thunb. Prodr. 88.)—Stem erect, zigzag. Leaves opposite, combined at the base.—Found by Thunberg at the Cape of Good Hope. The stem is two feet, or more, in height, round, smooth, except a little woolly line at each side, running down from the joints. Stem-leaves opposite, awl-shaped, keeled, from two to four inches long, rather woolly at the margin, inserted in pairs to a tumid, entire, woolly or hairy sheath, about half an inch in length. Flowers in dense, axillary, aggregate heads, with lanceolate bracteae; the lower heads stalked. Leaves of the calyx lanceolate, keeled, combined at the base. Filaments very hairy. Style bearded at the upper part. Willdenow seems, in transferring from the Supplementum, to have written the name formosum by mistake for speciosa. The latter being now applied to a different species, see n. 5, we retain the former here. Lamarck might possibly have inferred the same plant twice, once after Linnaeus, without seeing a specimen.

The most singular circumstance in the botanical history of Tradescantia relates to what Linnaeus has named T. nervosa, Mant. 223. Willd. n. 7. This proves, by the original specimen from Mutis, accompanied with a drawing, to be a very curious plant of the Orchis family. Mutis justly remodelled with Linnaeus against making it a Tradescantia, and called it an Epidendrum. Mr. Kunth, who has seen our specimen, informs us it belongs to a new genus, and is named by him Thylochiton aquifolius. The style, or column, is excessively hairy, or rather bristly. The lip is very little broader than the two petals, all of them being marked with numerous parallel ribs. The whole flower is above an inch wide, and seems to be very handsome.

Tradescantia, in Gardening, furnishes a plant of the hardy herbaceous perennial kind, the species of which that is chiefly cultivated, is the common Virginian spider-wort, or flower of a day; but there are other species that may be cultivated. And there are varieties with pale blue flowers, with deep blue flowers, with white flowers, with red flowers, and with purple flowers.

Method of Culture.—They are readily increased by parting the roots, and planting them out in the autumn, or early in the spring, in a bed or border of common earth. And also by seeds sown at the same seasons in similar situations, the plants being pricked out into other beds in the summer, and removed in the autumn to the places where they are to grow. These plants are durable in the roots, but the stalks decay annually: they mostly breed forth a new flower every day, hence the common name, during some weeks in the summer season, and are proper for planting out in various places in pleasure-grounds.

They afford ornament in the common borders among other flower-plants.

Trade-water, in Geography, a river of Kentucky, which runs into the Ohio, N. lat. 37° 17'. W. long. 88° 30'.

Tradita Nexu. See Abalination. Tradition, Tradition, the act of delivering a thing into the hands of another. The sale of a moveable is completed by a simple tradition.

Tradition, in Matters of Religion, is applied to those laws, doctrines, relations, &c. which have been handed down to us from our forefathers, without being written.

Taking tradition in this sense, for every thing relating to faith, or the rites and ceremonies of religion thus derived down to us from the primitive church, there are two kinds, viz. apostolical and ecclesiastical tradition.

Tradition, Apostolical, which is what we properly call tradition, is defined by the Romanists to be the unwritten word of God, descended from the apostles to us, through a continual succession of the faithful.

By this tradition, say they, it is, that the Holy Scriptures have been kept entire, both as to the letter, i.e. the text, and as to the spirit or sense thereof. This tradition the council
council of Trent declares to have the same authority with the Holy Scripture itself, and pronounces every one who rejects it an heretic.

It is a question of some difficulty, when the church of Rome began to derogate from the authority of the Scriptures, and to raise these traditions to an equality with them. It is generally supposed, that pope Nicholas ordained, that the declaral epistles of the popes should be of the same authority as the Scriptures, about the year 835. Du Plessis (Myth. Inq. Progr. 31.), indeed says, that pope Agatho had, 170 years before, pronounced openly, that all decrees made by the bee apostolic, ought to be received as if they had proceeded from St. Peter's own mouth. But as this doctrine had gained no canonical authority in the pontificate of Nicholas, it ought not at so early a period be placed to the account of the church. Nor did that diligent inquirer find any formal decree to such effect till the year 1415, when the council of Constance, in the condemnation of the 38th article of Wickliffe's heresy, ordained, that such of the declaral epistles as should be found upon examination to be rightly ascribed to the popes whose names they bore, should be of equal authority with the epistles of the apostles. (L'Enfant's Hist. Council of Constance, vol. i. p. 229.)

From this period, the sufficiency of the Scriptures alone to salvation became a formal heresy, as appears by the 12th of the interrogatories exhibited to Lambert with Fox's Martyrology in the year 1538. Hitherto, however, the Scriptures stood upon even ground with papal constitutions; and the inconformities between them were kept sufficiently out of sight, by depriving the people of the ordinary means of studying the sacred oracles, and entertaining them only with the ignorant and mystical comments of the monks upon them. When these would no longer pass upon mankind, it then became necessary to degrade the Scriptures to an inferior class.

Traditions, Ecclesiastical, are certain statutes and regulations regarding the rites, customs, and circumstances of religion, introduced since the time of the apostles, by councils, popes, &c. and continued to our time through a constant observance of the church.

The Romanists make another division of tradition, viz. into written and unwritten.

Tradition, Written, is that of which we find some traces in the ancient fathers and doctors.

Tradition, Unwritten, is that of which there appear no signs or specks in any of the fathers extant.

The church of Rome pretends to be the depositary of each kind; tradition the holds to be absolutely necessary in the church, grounding this necessity on the promise of inaffilibility which Jesus Christ is pretended to have made her.

Yet others of that communion deny tradition, how excellent forever it may be for the reclaiming of heretics, to be absolutely necessary; maintaining, that the church would not be less inaffilible, nor less the rule of doctrine, &c. if the fathers had never written at all.

Traditionary, Traditionaries, a name given among the Jews to such of them as acknowledge tradition, follow it, and explain the Scriptures by it: in opposition to the Caraites, who refuse any thing but the pure Scriptures themselves.

The traditionaries are what we more usually call rabbis, and rabbinitis, or talmudists. Hillel shone among the traditionaries, and Shimma among the texturaries.

Traditors, a name given in the first ages of the church to such Christians as, in times of persecution, to avoid death and martyrdom, delivered up the sacred writings to the persecutors.

"The enemies of religion, even under the old law, made their utmost efforts to deprive the world of the Holy Scriptures; in that cruel persecution which Antiochus raised against the Jews, the books of the law were very licentiously sought after, torn, and burnt, and such as kept them were put to death; as we read in the first book of Maccab. ch. i. vs. 56, 57.

Diocletian reversed the same impolicy, by an edict published in the nineteenth year of his empire, commanding all the sacred books to be brought to the magistrates, and burnt.

Many weak Christians, and even some bishops, overcome with the fear of punishment, carried in their books to the persecutors, which the church detesting, made very severe laws against them, and gave them the infamous names of traditores, from tradere, I deliver, betray.

As the great pretence of the feichism of the Donatists was, that the Catholics tolerated the traditores, it was decreed in the council of Arles, held in 314, that such as should be found guilty of having delivered up any of the holy books, or vesels, should be deposed from the order of the clergy, &c.

Traducian, Traducianum, a name which the Pelagians anciently gave the Catholics, because of their teaching that original sin was transmitted from father to children, or that it was communicated to the children by the father in the way of generation.

The word is formed of the Latin tradus, which was made use of to express that communication; and which comes from traduo, I transmit, or propagate from one to another.

At present, some give the appellation traducianum, to such as hold, that the souls are transmitted to the children by the father.

Traduction, formed of trans, beyond, and ducere, I lead, draw; the act of translating, or turning out of one language into another. See Translation.

Traeth Buchan, in Geography, a bay of the Irish sea, on the west coast of Wales, in the county of Merioneth; 2 miles N. of Harlech.

Traeth Cwb. See Redwhare Bay.

Traeth Mucor, a bay of the Irish sea, on the west coast of Wales, between the counties of Merioneth and Caernavon; 4 miles N. of Harlech.

Traetta, Tomaso, in Biography, a Neapolitan composer of the first class during the last century. We have a very spirited and accurate account of the rapid progress of this master to the temple of Fame. in M. Laborde's "Effai sur la Musique," drawn up, we believe, by the animated and discriminative pen of count Benincasa; who says that, "Traetta, one of the last disciples of Durante, quitted the conservatorio at the age of twenty-one, and two years after he was chosen to compose an opera for the great theatre royal of San Carlo, at Naples, entitled "Farmace." His successes in this first attempt was so great, that he was employed in the same city to compose fix other operas, serious and comic, succissively.

"The reputation of this young composer soon reached Rome, whither he was invited, and composed for the Albartii theatre "Ezio;" which, though it had been previously set by so many great matters, that of Traetta was, and is still, the most esteemed. All the great theatres of Italy now wished to engage him, and he composed for them all more than once, till he was fixed in the service of the court of Parma, in the splendid reign of Don Philip, where he had the honour of instructing in music the late archduchess, consof of the emperor Joseph II., and the princeps of Austria.
The operas which he then composed at Parma were entirely in the French taste, which was that of the court. The choruses and the ballets are not yet forgotten. It is this totality that unites the charms of all the fine arts together.

The Italians have long known and applauded such splendid spectacles, and often exhibited them successfully in the last and preceding century; but with them the occasions cannot be frequent. A great capital, like Paris, is necessary, which constantly furnishes an audience and spectators able to pay for their amusements all the year round; or magnificent courts, such as those of the princes of the house of Este, Medici, Parma, and Florence, in former times.

"The first of the six operas which Traetta composed in this style, was 'l'opitoto e Aricia,' written by the famous poet, the abate Frugoni, in 1759. At this period Traetta was twice called to Vienna to compose 'Arminia' and 'Ingenia,' two grand operas with choruses and ballets, which were crowned with the greatest succcess. (This was five years previous to the performance of Gluck's "Orfeo" at Vienna.)"

"These two operas were afterwards represented at Milan, Florence, Mantua, and Naples. After the decease of the infant Don Philip, Traetta was called to Venice, where he was appointed maestro to the conservatorio of l'Opipidetto; but he could not there refit the proposals made to him from all parts of Europe. After two years' residence at Venice, he suffered himself to be attracted to Petersburg, where he was engaged for five years; at the end of which period he was detained two years longer, during which periods he composed many operas, and many cantatas."

England wished to have him in its turn; but he arrived too late; his health was so impaired, that it seemed never to have enjoyed a day's ease and comfort while he was there. And Sacchini, who was still in London, had taken such possession of our hearts, and so firmly established himself in the favour of the public, that he was not to be supphanted by a composer in the same style, neither so young, so graceful, nor so fanciful as himself.

Sacchini's person and address had contributed towards endearing him to the English; but, on the contrary, Traetta's countenance and general appearance were so chilling as to be almost frightful. A skin extremely adult, a settled gravity, discontent and gloom covered his visage so contently, as to make a beholder shrink at the sight of him, and imagine it impossible that anything pleasing, even to capture, should flow from its matter. But all this only proves that Horace, who says, "Fronti nulla sines," was a much better phylognomist than Lataver.

Though many excellent songs and scenes of his composition had been introduced in pafficino operas on our stage, yet we can remember but two entire dramas of this matter that were executed here, "Germando," a serious opera; and "La Serva rivala," a burleque. But the dramas which he composed in and for different parts of Europe, much amount to more than fifty.

On quitting England, he returned to Italy in an alarming state of health; however, we find that, in 1778, he produced two operas there: "La Disfatta di Dario," and "Il Cavaliere Mante;" but 1779 was the last year of this admirable musician's existence.

TRAFAGNOL, in Geography, a river of Germany, in the county of Tyrol, which runs into the Lavis, 4 miles N. of Caifersier.

TRAFALGAR, Cape, a cape of Spain, on the coast of Andalusia; about 60 miles E. of Cadiz. N. lat. 36° 10'. W. long. 6° 8'. This cape has been rendered famous by the complete victory obtained October 21, 1805, by the British fleet, commanded by lord Nelson, over the combined fleets of France and Spain off this cape. (See the biographical article of Nelson.) Among the Arabsians there is a tradition, that the province of El Garb, in Morocco (see Garb), was originally united to Trafalgar and Gibraltar, shut up the Mediterranean sea, from whichapsed into the Western ocean by a subterraneous passage: and at this day they call Trafalgar Trafel-garb, i.e. the piece or part of El Gar; and Gibraltar, Jibbel-taf, i.e. the mountain of the piece, or part of El Garb.

TRAFARIA, a fort of Portugal, in the province of Estremadura, on the south side of the Tagus; 6 miles S.W. of Lisbon.

TRAFFICK. See Trade and Commerce.

The word is formed from the French, trafic, and that from the Italian, traffico, which is again borrowed from the Arabic.

The principal traffic in Muscovy and the North is in furs and skins: the great traffic of the Dutch in the East is in spices: the traffic of money is mostly carried on at the Exchange.

TRAFINE. See Thepan.

TRAGACANTHA, in Botany, γκωκαςαδο of Dioscorides, book 3, chap. 23, is so called from τραγακας, a goat, and ακαςαδο, a thorn, probably because of its growing in mountainous situations, frequented by goats; or perhaps from being the food of those animals, to whom its thorny footstalks may fearfully prove any impediment. There are several species, allmost all confounded by Linneus under his Aftragalus Tragacanthus, but distinguish'd by Tournefort, as well as more recently by Willdenow, Lamarck and others. Three of them are deffined to appear in the Flora Graca. They all produce more or less of the mucilaginous substan-cce called Gum-Tragacanth, or Gum-Dragon, and are remarkable for their dense bulbous thorny habit, and copious, not inelegant, flowers. Tournefort, in his Corolla, p. 29, 35, has added nineteen Oriental species to the four mentioned in his Instituciones, p. 4.17; but these, though for the most part truly distinct, are some of them probably mere varieties, and are so considered by Lamarck; see his Dic-tionnaire de Botanique, v. 1. 1. 320; where these plants compose a secon of the genus Aftragalus, characterised by the permanent, Trident spinous, common footstalks of the leaves.

TRAGACANTHA, in the Materia Medica. The naked hillocks of mount Idæa, in Cadià, M. Tournefort tells us, produce much of the plant tragacantha, or goat's thorn, which gives the gum spontaneously towards the end of June, and in the following month; when the nutritious juice of the plant, thickened by the heat, hurst's most of the vessels in which it is contained.

This juice coagulates in threads, which make their way into the pores of the bark, where being pushed forward by new juice, they get through the bark, and are at length hardened in the air, either into little lumps, or into twisted pieces in form of little worms, more or less long, according to the quantity of the matter of which they are formed.

It should seem, too, that the contraction of the fibres contributes to the expresssion of the gum; those fine fibres, like the fibres of hemp, laid bare and tramped under foot by men and horoses, contract themselves, and facilitate the expression of the extravasated juice. The plant grows also in several places of the Levant, particularly about Aleppo.
M. de la Billardiere's account of the manner in which this gum is produced, differs in some respects from that of Tournefort. Having visited mount Lebanon in August, 1766, the season when this gum is collected, he found the species which afforded it to be different from that figured and described by Tournefort; and consequently not the tragacanth of Linnaeus. The stem of the Grecian *tragacanth* is blackish, that of Lebanon is yellow: the leaves of the first are downy, of the second smooth: the flowers of one are red, those of the other are of a pale yellow. Hence he infers that there are several species of *tragacanth* which produce gum-tragacanth. He also considers the situation of Tournefort, who attributes the flowing of the gum to the contraction of the thorns of the bark, occasioned by the intensity of the solar heat; observing, that it is only during the night, or when the sun is obscured by clouds, that the gum issues from the plant, and that the same has been remarked at Crete.

The gum is of different colours and qualities, some being white, some greyish, some reddish, and some almost black. The white is the best: it must be chosen clear, smooth, and twirled, or vermilion. It is dry, and yet somewhat soft to the touch.

Gum-tragacanth differs from all the other known gums in giving a thick consistence to a much larger quantity of water; and in being much more difficultly soluble, or rather dissolving only imperfectly. Ruty affirms, that in five or six hours it will disolve in cold water. Put into water, it slowly imbibes a great quantity of the liquid, swells to a large volume, and forms a soft but not fluid mucilage; with the addition of more water, a fluid solution may be obtained by agitation, but the liquor appears turbid and whity, and on standing the mucilage turbidizes.

It is smooth and softening, and is therefore good to obviate the acrimony of any humours; which makes it of service in such coughs as proceed from catarrh, and other defluxions of rheum. It is also very strengthening in some retaliation weaknesses, and is prevalent against the whites in women.

Tragacanth is usually preferred to the other gums for making up troches, and other such purporses, and is supposed likewise to be the most effectual as a medicine; but on account of its imperfect solubility, it is unfit for liquid forms. The dose is grs. x to 5j., or more. It is commonly given in powder, with the addition of other materials of similar intention.

The mucilage of tragacanth of the Edinb. Ph. is prepared by macerating one ounce of gum-tragacanth in powder, in eight ounces of boiling water for 24 hours, and filtering the gum so that it may be disolved, and straining the mucilage through linen. The mucilage of gum-tragacanth of the Dubl. Ph. is obtained by macerating two drachms of gum-tragacanth in powder, in eight fluid-ounces of water, in a covered vessel, until the gum is disolved, and straining the mucilage through linen. The compound powder of tragacanth of the Lond. Ph. is formed by taking of tragacanth powdered, acacia gum powdered, and starch of each an ounce and a half; and of refined sugar three ounces. Rub the starch and sugar together to a powder; then add the tragacanth and the acacia gum, and mix the whole together. This powder is used with effect as a demulcent in hectic fever, and to allay the tickling cough of catarrh; in gonorrhoea and strangury it is given combined with nitre, and in dyestery with ipecacuanha powder. The dose is from 5s. to 5j., mixed in water or any bland fluid.

**TRAGACANTHUM** *Plantagen Indicus*, in *Natural History*, a name given by some writers to the bird's-nets, which are famous in soups in China, and in some parts of Europe, for their cordial, restorative, and provocative virtues. They are the seeds of a kind of Indian sea-swallow, and are made up of a substance resembling gum-tragacanth, and, like it, melting in a jelly in any warm liquor.

**TRAGAEA**, in *Antiquary Geography*, a town of the island of Naxos, in which particular worship was paid to Apollo Trias.

**TRAGAN**, in *Geography*, a town of Africa, in Fezziu; 100 miles N. of Murrabook.

**TRAGARCH**, a river of Wales, in the county of Brecknock, which runs into the North Sea.

**TRAGASIAN SALT**, a term used among the ancients for a sort of sea-salt, very little different from the common kind, being made by the evaporation of the water of some salt-ponds near the sea-shores.

**TRAGAEA**, in *Pharmacy*, an aromatic powder grossly beaten and mixed with sugar; taken by way of carminative.

**TRAGAE, or TRAGUS**, in *Ancient Geography*, an island situated in the vicinity of the Cyclades.

**TRAGEE**, islands situated on the coast of Ionia, but they were joined to the continent by the depredations of the Meander. They served as a retreat for pirates, according to Strabo, and lay N. of the promontory Phocis.' E. of that of Troy, and W. of the town of Myrurus.

**TRAGEDY**, a dramatic poem, representing some signal action performed by illustrious persons, and which has generally a moral issue or end.

Accordingly, it has been always reckoned a more dignified entertainment than comedy. The former directs our attention to the high passions, the virtues, crimes, and sufferings of mankind; the latter to their humours, follies, and pleasures. Terror and pity are the great instruments of tragedy; and ridicule is the sole instrument of comedy.

Tragedy exhibits the characters and actions of men, says Dr. Blair, in some of the most trying and critical situations of life, and serves as a direct imitation of human manners and actions. It differs from the epic poem, in which the poet narrates and describes characters, by excluding the poet, and setting before us the personages themselves, acting and speaking what is suitable to their characters. As no kind of writing affords in great a trial of the author's profound knowledge of the human heart, none, when duly executed, has so much power to raise the strongest emotions. It is, or ought to be, a mirror, in which we behold ourselves, and the evils to which we are exposed; a faithful copy of the human passions, with all their direful effects, when they are suffered to become extravagant.

Arifito scientifically defines tragedy, the imitation of one grave and entire action, of a just length, and which, without the assistance of narration, by raising of terror and compassion, refines and purges our passions.

This definition has given the critics some perplexity; and Corneille declares he cannot reconcile Arifito with himself; the instances Arifito cites, he thinks, defeat his own definition. He even denies the purging of our passions to be the end of tragedy.

Our English authors are more favourable to the definition; by the purging of our passions, they understand not the extinguishing of them, but the reducing them to just bounds; for by drawing the sufferings that attend a subject to us, we are taught to examine them more narrowly; and by seeing the great misfortunes of others, it2 minimizes the fate of our own.
The ingenious writer already cited, disapproving the statement of Aristotle with regard to the design of tragedy as somewhat obscure, thinks its intention may be more shortly and clearly defined, "to improve our virtuous sensibility." If an author interests us in behalf of virtue, forms us to compassion for the distresses, inspires us with proper sentiments, on beholding the vicissitudes of life, and by means of the concern which he raises for the misfortunes of others, leads us to guard against errors in our own conduct, he accomplishes all the purposes of tragedy. Tragedy is, therefore, a moral species of composition; and the impressions left by it on the mind are, upon the whole, favourable to virtue and good dispositions. In order to produce this beneficial effect, it is necessary that the author should choose some interesting and moving story, and then conduct it in a natural and probable manner. The end of tragedy is not like that of epic poetry, to elevate the imagination by the marvellous; but to affect the heart by a stricter imitation of the life and actions of men. This principle, duly regarded, excludes from tragedy all machinery, or fabulous intervention of the gods; and, therefore, the mixture of machinery with the tragic action, is a blemish in the ancient theatre. Hence some critics have required, that in order to produce and maintain the impression of probability upon which the success of tragedy depends, the subject should not be a pure fiction, but founded on real history, or known facts. This, however, seems to be an extreme; as a fictitious tale may affect the heart as much as a true history, provided that the events related be such as might easily have happened in the ordinary course of nature. Some of the most pathetic tragedies are altogether fictitious as to their subject; such as Voltaire's Zaire and Alzire, the Orphan, Douglas, the Fair Penitent, &c. For the regulation of the conduct of a tragedy, critics have established the famous rule of the three unities, to which we shall presently advert.

Tragedy, in its original, M. Hedin obseves, was only an hymn sung in honour of Bacchus by several persons, who, together, made a chorus of music with dances and instruments. A goat was the sacrifice offered to that god; and from ἄριας, a goat, and οὖν, a song, was formed the appellation tragedy.

As this was long, and might fatigue the singers, as well as tire the audience, they betought themselves to divide the singing of the chorus into several parts, and to have certain recitations in the intervals. Accordingly, Thespis (see his article) first introduced a person to speak upon the stage with this view. Phrynichus, the disciple of Thespis, selected that kind of verse which is most suitable to the drama; and introduced some other changes, but left tragedy in its infancy. He, it is said, introduced women's parts on the stage. 

Aeschylus, the father of tragedy, as he has been called, finding one person insufficient, introduced a second to entertain the audience more agreeably by a kind of dialogue; he also clothed his persons more decently, and first put them on the bulkin. For his other improvements in this species of drama, see his article ÆSCHYLUS.

The persons who made their recitations on the scene, were called αἰτῶν; so that tragedy at first was without many actors. And what they thus rehearsed, being things added to the singing of the chorus, of which they were not necessary part, were called ἐπιτόξευσ. 

Sophocles found that two persons were not enough for the variety of incidents; and accordingly he introduced a third; and here the Greeks seem to have stopped; at least, it is very rare that they introduce four speakers in the same scene.

The progress of the art under the culture of Æschylus, and his immediate successors, was extremely rapid. He had for contemporaries and competitors, Clerides, Pratinus, and Phrynichus already mentioned, whose glory he eclipsed; and Sophocles, who rivalled his own. Sophocles cenured in Æschylus three defects: the excessive elevation of his ideas, the gigantic style of his expressions, and the difficult conduct of his plots; and these faults he flattered himself for having avoided. By reducing heroism to its just standard, Sophocles lowered the style of tragedy, and banished those expressions which a wild imagination had dictated to Æschylus, and which diffused terror through the souls of his spectators. His style, like that of Homer, is full of strength, magnificence, sublimity, and mildness. Even in depicting the most violent passions, he happily fuits his style to the dignity of his personages. See the article SOPHOCLES.

Euripides, at an early age, emulated the fame of Sophocles, and aspired to the sovereignty of the stage. See the biographical article EURIPIDES.

Notwithstanding the prejudices and hatred of Aritophanes against Euripides, his decision in affigning the first place to Æschylus, the second to Sophocles, and the third to Euripides, was conformable to the opinion of the greater part of the Athenians. Æschylus, it is faid, painted men greater than they can be, Sophocles as they ought to be, and Euripides as they are. The two former had neglected passions and situations, which the latter thought capable of producing great effects. He sometimes represented princes inflamed with love, and refrining only adultery and crime; and sometimes kings debated by calamy to such poverty, as to be covered with rags, and solicit a wretched alms. These scenes, in which no resemblnce was discernible of the manner of Æschylus or Sophocles, at first disturbed the spectators. It was faid, that under no pretext ought the character and rank of the heroes of the stage to be so degraded; that it was highly reprehensible to portray with so much art images so shameful, and dangerous to supply vice with the authority of great examples. But at this time the Athenians in general were less offended at the attacks which the pieces of Euripides made on received ideas, than hurried away by the sentiments with which he had animated them; for this great poet, capable of managing at pleasure all the passions of the soul, is especially admirable when he paints the frays of love, or excites the emotions of pity; thus, surpassing himfelf, he sometimes attains the sublime, for which he seems not to have been intended by nature. While he was accused of enervating tragedy, he had proposed to render it the school of wisdom. Euripides, whose eloquence sometimes degenerated into a redundant profusition of words, and whose rhetorical phrases, learned digressions, and idle disputes reduced him much below Sophocles, who has said nothing which has not its utility, is nevertheless faid to have fixed the language of tragedy. He retained scarcely any expressions that are especially appropriated to poetry; but he so judiciously selected and employed those of ordinary language, that, under their happy combination, the feelings of the thought seemed to disapper, and the most common word to become ennobleed. Such was the magic of that enchanting style, which, preferring a just medium between fees and inflation, is almost always eloquent, clear, harmonious, flowing, and flexible, that it seems to adapt itself without effort to every feeling of the soul. Wliilst Sophocles admitted into his choruses the Phrygian
TRAGEDY.

Purposed harmony, the object of which was to moderate and temper the passions, and which was adopted to the worship of the gods; Europeans, favouing the innovations made by Thucydides in the ancient music, employed almost all the modes, and especially those, the sweetest and finest of which accorded with the genius of his poetry. Accordingly the audience were attracted to hear in the theatre entertainments, and sometimes division on a single syllable. Hence the author represented as a feeble art, with incapable of raising himself to the habitat of tragedy, had dispelled tragedy to the level of his own inferior abilities.

Europeans rarely succeeded in the enjoyment of his subjects; sometimes he offends against probability, sometimes the incidents are forced, and sometimes the action wastes away; almost always the complications and developments of his plots are not in some respect imperfect; and his characters have frequently only an indirect relation to the actions.

He invented the art of explaining his subjects in a prologue, or long prologue, almost entirely detached from the piece, in which usually one of the persons of the drama comes forward, and finally details all the events that forewent or related to the action, gives his own generation, or that of one of the principal characters, informs us of the occasion of his return, from whence he is a deity, or who has called him forth from the tomb, a mortal: and announces himself to the spectators by declaring his name.

It is hardly necessary in this connection to mention Derrylus the elder, king of Syracuse, who was adored in the composition of his tragedy by some men of genius, but was modeled to their admiration: for the victory he obtained in this species of literature. Aeschylus, Sophocles, and Euripides were, and ever will be, placed in the head of those who in ancient times rendered the stage illustrious. Nevertheless, though the number of pieces that performed in the theatrical compositions was very great, the best obtained the crown only thirteen times, the second but eighteen, and the last only five times; because the victory was decided by the multitude, which had powers which pattern in expression, and favourites whose interests are supported. It is remarkable, in how short a space of time tragedy grew up among the Greeks, from the modest beginning to the most perfect state. For Sophocles, the greatest and most correct of all the tragic poets, flourished only twenty-two years after Aeschylus, and was but little more than seventy years predecessor to Euripides. The obscure was the birth of the ancient tragedy, and the dramatic dialogue was superseded almost in a very few years. In proceeding to the chorus, the chorus, being the principal, became only the accessory in tragedy; all at last, in modern tragedy, it has disappeared altogether, which forms the chief distinction between the ancient and the modern stage.

Each tragedy required those actors for the three leading parts: and the same action sometimes performed both in tragedy and comedy; but persons very rarely excelled in both. Actors who had acquired great celebrity received considerable part; not less than a talent per annum in two days. The kind of verse generally employed in tragedy was the trochaic, a species of measure that frequently occurred in conversation. The actors had masks and symbols fixed to their several parts; and tragedy showed from its earliest invention employed the mask, which was completed under the hands of Aeschylus. In tragedy the number of the actors was frequently increased to four cubits (six English feet and nearly half an inch); which was effected by buffoons, that raised them four or five inches;
Unity of the action should not be confounded with the
simplicity of the plot. The plot is simple, when a small
number of incidents are introduced into it; but it may be
complex, in the language of critics, or include a considera-
able number of persons and events, and yet not be deficient
in unity, if all the incidents tend towards the principal
object of the play, and be properly connected with it.
Congreve's "Mourning Bride" is added as an instance
which stands in perfect opposition to the simplicity of the
ancient plots. The incidents succeed one another too rap-
idly, and the play is too full of cafes. Unity of action
must not only be regarded in the construction of the fable,
or plot, but it must also regulate the fcveral acts and scenes
into which the play is divided. The division of the play
into five acts is altogether arbitrary, and rests merely on
common practice, and the authority of Horace, De Art.
Poet. (See Acts, in Poetry.) The pauses between the
acts shou'd be duly adjusted; fo that there are correspond-
ating pauses in the action. The fifth act is the feat of the
Catastrophe; which fee. For the fcveral parts of tragedy,
see Act, Action, Character, Fable, Plot, Manners,
and Scene.

It has been a question much agitated among philo-
osophical critics, how it comes to pass that those emotions
of sorrow which tragedy exaites afford any gratification to
the mind? Sorrow, it is faid, is a painful fation: fcnes of
nilery exhibited in tragedies excite a degree of sympa-
thy and agitation that occasions anguish and diftrefs.
The fpeculators cannot fuppref their feelings; they are indicated
by their tears: and yet they applaud fuch exhibitions, and
recur to them with fatisfaction and pleaure. That fuch
exhibitions should draw fuch crowds of fpeculators, and that
they fhould be fo highly gratified by them, appears to be
fomewhat miffcrifious. The fect is acknowledged, and many
hypothefes have been propofed for the fatisfactory expi-
cation of it. In order to account for it, we can by no
means recur to an innate principle of malice, which prompts
us to extract delight from the fufferings of others, and as
it were to enjoy their calamities. Dr. Campbell, in his
"Philofophy of Rhetoric," (vol. i. chap. 11.) has detailed
and examined the various hypothefes that have been devisd
by ingenious men for the solutlon of this difficulty. The
theory of the abbe du Bos, in his "Reflections on Poetry
and Painting," is as follows. Few things, according to him,
are more difagreeable to the mind, than that littlefaccs into
which it falls, when it has nothing to occupy it, or
to awake the passions. In order to get rid of this most painful
situation, it feeks with avidity every amufement and
pufh: buffeins, gaming, news, showes, public executions,
romances; in fhort, whatever will rufe the passions, and take
off the mind's attention from itfelf. It matters not what
the emotion be, only the stronger it is, fo much the better.
And for this reafon, fuch passions, which, confidered in
themselves, are the moft afflicting and difagreeable, are pref-
erable to the pleafant, in a manner as they most effectually
relieve the foul from that oppressive languor which preys
upon it in a flate of inactivity. They afford it ample occu-
pation, and by giving play to its latent movements and fprings
of action, convey a pleaure which more than counter-
balances the pain.

Mr. Hume, in reference to this theory, obferves, that
the fame object of disaftris which pleafes in a tragedy, were
it really fet before us, would, without doubt, give the moft
unfeigned uneafiness, though it fhould be the moft effectual
cause of languor and indolence; and Dr. Campbell fays,
that the moft which can be concluded from the abbe's pre-
mife is, the utility of exciting passion of fome kind or other,
what moves them, and their experiences to be convinced that
it is a fiction. This can result only from the consciousness
that, in ordinary cases, disbelief, by weakening their pity,
would diminish, instead of increasing, their pleasure. They
must be very far then from entertaining Fontenelle's notion,
that it is necessary to the production of that pleasure; for
we cannot well suspect them of a plot against their own
enjoyment: thirdly, and lastly, from the delight which we
take in reading or hearing the most tragic narratives of
orators and historians, of the reality of which we entertain
no doubt; I might add, in revolting in our own minds,
and in relating to others, frightful incidents, which have
fallen within the compass of our own knowledge, and as
to which, consequently, we have an absolute assurance of the
fact."

The third hypothesis produced and examined by Dr.
Campbell is Mr. Hume's, which he proposes as a supple-
ment to the former two, in the doctrine of both which he,
in a great measure, acquiesces. "What is it then," says
Mr. Hume, "which in this case (that is, when the sorrow
is not softened by fiction) raises a pleasure from the bofon
of uneasiness, so to speak; and a pleasure, which still re-
tains all the features and outward symptoms of distress and
sorrow? I answer: This extraordinary effect proceeds
from that very eloquence, with which the melancholy scene
is represented. The genius required to paint objects in a
lively manner, the art employed in collecting all the pathetic
circumstances, the judgment displayed in disposing them:
the exercise, I say, of these noble talents, together with
the force of expression, and beauty of oratorical numbers, diffuse
the highest satisfaction on the audience, and excite the most
delightful movements. By this means, the uneasiness of
the melancholy passions is not only overpowered and effaced
by something stronger of an opposite kind, but the whole
movement of those passions is converted into pleasure, and
swells the delight which the eloquence raises in us. The
fame force of oratory employed on an uninteresting subject,
would not please half so much, or rather would appear
altogether ridiculous; and the mind, being left in absolute
calmness and indifference, would relish none of those beauties
of imagination or expression, which, if joined to
pain, give it such exquisite entertainment. The impulse
or vehemence arising from sorrow, compassion, indignation,
receives a new direction from the sentiments of beauty.
The latter being the predominant emotion, seizes the whole
mind, and converts the former into themselves, or at least
triumphs them so strongly, as totally to alter their nature;
and the soul, being at the same time roused by passion,
and charmed by eloquence, feels on the whole a strong
movement, which is altogether delightful."

The insufficiency of this hypothesis is very satisfactorily
evaded by Dr. Campbell; and he has shown, that instead
of being supplementary to M. Fontenelle's, as he intended it
to be, it is subversive of the principles on which the French
critic's theory is founded. The effect, according to the
latter, results from moderating, weakening, softening, and
diminishing the passion; according to the former, it results
from what is directly opposite, from the arts employed by
the orator for the purpose of exaggerating, strengthening,
heightening, and inflaming the passion. Indeed, neither of
these writers seems to have attended sufficiently to one par-
cular, which of itself might have shown the insufficiency
of their systems. The particular alluded to is, that pity, if
it exceed not a certain degree, gives pleasure to the mind,
when excited by the original objects in distress, as well as
by the representations made by poets, painters, and orators:
and, on the contrary, if it exceed a certain degree, it is on the
whole painful, whether awakened by the real objects of pity,
or roused by the exhibitions of the historian or of the poet.
Indeed, as fierce operates much more strongly on the mind
than imagination does, the excess is much more frequent in
the former case than in the latter. But our limits will not
allow our enlarging.

A fourth hypothesis is that of those who maintain that
compasion is "an example of unmixed selfishness and ma-
lignity," and may be "resolved into that power of ima-
gination, by which we apply the misfortunes of others to
ourselves," that we are said "to pity no longer than we
fancy ourselves to suffer, and to be pleased only by re-
lecting that our sufferings are not real; this indulging
a dream of distress, from which we can awake whenever we
please, to exult in our security, and enjoy the comparison
of the fiction with truth."

This is no other, as Dr. Campbell observes, than the
antiquated doctrine of the philosopher of Malmesbury
refused from oblivion, to which it had been fast declining,
and republished with improvements. Hobbes, indeed,
thought it a sufficient stretch, in order to render the sym-
pathetic sorrow purely selfish, to define it "imagina tion or
fiction of future calamity to ourselves, proceeding from
the same of another man's calamity." This paradoxical con-
ext, as our author has denominated it, has been adopted by
Hawkesworth in the "Adventurer." In the selfish system
it appears to be a great objection, that in pity we are
affected with a real sorrow for the sufferings of others, or
at least that men have universally understood this to be the
case, as appears from the very words and phrases expressive
of this emotion to be found in all known languages. But
to one who has thoroughly imbibed the principles and
spirit of a philosophic nature, who hath commonly as violent
an appetite for mystery (though under a different name, for
with the philosopher it is paradox) as any religious sect
however, women must an objection appear, which
hath nothing to support it but the conviction of all mankind,
those only excepted whose minds have been perverted by
scholastic sophistry?

It is remarkable, that though it has been contended by a
number of persons, that some fiction of the imagination
is absolutely necessary to the production of pity, and
though the examples of this emotion are so frequent, as to
give ample scope for examination, they disagree with re-
gard to their fiction. Some contend only, that in witt-
ening tragedy, one is under a sort of momentary deception,
which a very little reflection can correct, and imagines that
he is actually witnessing those distresses and miseries which
are only represented in borrowed characters, and that the
actors are the very persons whom they exhibit.

Others, who refer every thing to self-maintenance, that by
a fiction of the mind, we instantly conceive some future and
similar calamity as coming upon ourselves; and that it is
fondly this conception, and this dread, which call forth all
our sorrow and our tears. Others, not satisfied with this,
maintain boldly, that we conceive ourselves to be the
persons suffering the miseries related or represented, at the very
instant that our pity is raised. When nature is deferred by
us, it is no wonder that we should lose our way in the
devious tracks of imagination, and not know where to
foster.

Dr. Campbell's hypothesis is illustrated by the following
general observations, of which the following detail is an
abstract. He observes, it, that almost all the simple
passions, of which the mind is susceptible, may be divided into
two classes, viz. the pleasant and the painful, differing
considerably both in kind and degree: 2dly. Among the
passions,
TRAGEDY.

passions, as well as among the ideas of the mind, there is an attraction or affection. 3dly. Pain of every kind generally makes a stronger impression on the imagination than pleasure does, and is longer retained by the memory. 4thly. From a group of passions associated together, and having the same object, some of them pleasurable, and others painful; if the pleasurable predominate, there arises often a greater and a more durable pleasure to the mind, than would result from these, if alone and unmixed. 5thly. Under the name pity may be included all the emotions excited by tragedy. It has been usual, however, to comprehend pity and terror under the class of passions that are moved by tragedy; but our author observes, that this enumeration is more popular than philosophical, though adopted by the Stagyrite himself. For what is pity but a participation by sympathy in the woes of others, and the feelings naturally consequent upon them, of whatever kind they be, their fears as well as forrovs: whereas, this way of contradicting nothing from pity, would make one, who knew nothing of tragedy but from the definition, imagine, that it was intended to make us compassionate others in trouble, and dread mischief to ourselves. If this were really the case, Dr. Campbell thinks there are few or none who would find any pleasure in this species of entertainment. If all the sympathetic affections excited by theatrical representations were enumerated, our author cannot see why hope, indignation, love and hatred, gratitude and resentment, should not be included as well as fear. 6thly. Pity is not a single passion, but a group of passions distinctly united by affection, and as it were blended, by centering in the same object. Of these, some are pleasurable, some painful, but commonly the pleasurable preponderate.

In pity there are three different emotions: firstly, commiseration, purely painful; secondly, benevolence, or a desire of the relief and happiness of the object pitied, a passion, as was already observed, of the intermediate kind; thirdly, love, in which is always implied one of the noblest and most exquisitely pleasures whereas the soul is susceptible, and which is itself, in most cases, sufficient to give a counterpoise of pleasure to the whole.

The principal pleasure in pity arises from its own nature, or from the nature of those passions of which it is compounded, and not from any thing extrinsic or adventitious. Nevertheless, certain adventitious circumstances may contribute to heighten the effect; but they cannot be regarded as essential to the passion. Of this fort is the satisfaction which ariseth from a sense of our own ease and security, compared with the calamity and the danger of another.

"Tis pleant, safely to behold from shore
The rolling ship, and hear the tempest roar:
Not that another's pain is our delight;
But pangs unfelt produce the pleasing light.
"Tis pleant also to behold from far
The moving legions mingled in the war."

Another adventitious source of pleasure is, the satisfaction that results from the concious exercise of the humane affections, which it is our duty to cherish and improve. Sensc, as we have frequent occasion to observe, invariably makes a stronger impression than memory, and memory a stronger than imagination; yet there are particular circumstances which appear to form an exception, and to give an efficacy to the ideas of imagination, beyond what either memory or sense can boast. So great is the anomaly which sometimes displays itself in human characters, that it is not impossible to find persons who are quickly made to cry at seeing a tragedy, or reading a romance, which they know to be fictitious, and yet are both inattentive and unfeeling in respect of the actual objects of compassion who live in their neighbourhood, and are daily under their eye.

Men, says our author, may be of a selfish, contracted, and even avaricious disposition, who are not what we should denominate hard-hearted, or inflexible of sympathetic feeling. Such will gladly enjoy the luxury of pity, (as Hawkeford terms it,) when it nowise interferes with their more powerful passions; that is, when it comes unaccompanied with a demand upon their pockets. With the tragic or the romantic hero or heroine they most cordially sympathize, because the only tribute which wretches of their dignity exact from them is sighs and tears. And of these their confidences inform them, to their inexplicable consolation, that they are no niggards. But the cafe is totally different with living objects. Barren tears and sighs will not satisfy theie. Hence it is that people's avarice, a most formidable adversary to the unhappy, is interested to prevent their being moved by such, and to make them avoid, as much as possible, every opportunity of knowing or seeing them. See this observation admirably exemplified in the parable of the compassionate Samaritan, Luke, x. 30. Our author concludes with observing, that compassion alone, especially that displayed on occasion of witnessing public spectacles, is at best but a very weak evidence of philanthropy.

Dr. Blair, agreeing in the main with the hypothesis of Dr. Campbell, introduces the following observations on this subject, which we cannot forbear transcribing. "By the wife and gracious constitution of our nature, the exercise of all the social passions is attended with pleasure. Nothing is more pleasing and gratifying than love and friendship. Wherever man takes a strong interest in the concerns of his fellow-creatures, an internal satisfaction is made to accompany the feeling. Pity, or compassion, in particular, is, for wife ends, appointed to be one of the strongest instincts of our frame, and is attended with a peculiar attractive power. It is an affection which cannot but be productive of some distresses, on account of the sympathy with the sufferers, which it necessarily involves. But, as it includes benevolence and friendship, it partakes, at the same time, of the agreeable and pleasing nature of those affections. The heart is warmed by kindreds and humanity, at the same moment at which it is afflicted by the disaffections of those with whom it sympathizes: and the pleasure arising from those kind emotions prevails so much in the mixture, and so far counterbalances the pain, as to render the state of the mind, upon the whole, agreeable. At the same time, the immediate pleasure, which always goes along with the operation of the benevolent and sympathetic affections, derives an addition from the approbation of our own minds. We are pleased with ourselves for feeling as we ought, and for entering, with proper sorrow, into the concerns of the afflicted. In tragedy, besides, other adventitious circumstances concur to diminish the painful part of sympathy, and to increase the satisfaction attending it. We are, in some measure, relieved, by thinking that the cause of our distress is feigned, not real; and we are also gratified by the charms of poetry, the propriety of sentiment and language, and the beauty of action. From the concurrence of these causes, the pleasure which we receive from tragedy, notwithstanding the distress it occasion, seems to me to be accounted for in a satisfactory manner. At the same time, it is to be observed, that, as there is always a mixture of pain in the pleasure, that pain is capable of being so much heightened, by the representation of incidents extremely direful, as to shackle our feelings, and to render us averse, either to the reading of such tragedies, or to the beholding of them upon the stage."

Under the general head of the unity of action, to which
after a long digression we now return, it may not be improper to make a few remarks on the conduct of the several scenes which make up the acts of a play. See Scene.

The contrast of a new passage with the stage form, what is called, a new scene. These forms, or successive conversations, should be closely linked and connected with each other. For this purpose, two rules should be observed. The first, that, during the course of one act, the stage should never be left vacant; for whenever the stage is vacated, the act is closed. This rule is generally observed by the French dramatists; but the English writers, both of comedy and tragedy, seldom pay any regard to it. The second rule, better observed by English writers than the former, is, that no person should come upon the stage or leave it, without a reason appearing to us, both for the one and the other.

In order to render the unity of action more complete, critics have added the other two articles of time and place. The unity of place requires, that the scene should never be changed, but that the action of the play should be continued in the same scene, in the same place, as it is supposed to begin. The unity of time, hardly taken, requires, that the time of the action be no longer than the time that is allowed for the representation of the play; though Aristophanes seems to have given the poet a little more liberty, and permitted the action to comprehend the whole time of one day. During the course of each act, the states of time and place ought to be distinctly observed, that is, during each act the scene should continue the same, and no more time should be supposed to pass than is employed in the representation of that act. This is a rule which the French dramatists regularly observe. To violate this rule, is to too often allow the English to change the place, and shift the scenes in the midst of one act, these great contradictions, and destroy the whole intention of the division of a play into acts. Mr. Addison's "Cato" is remarkable beyond most English tragedies for the regularity of conduct. The author has limited himself in time, to a single day; and in place, has maintained a most rigorous unity. The scene is never changed; and the whole action takes place in the hall of Cato's house, in Utica.

The characters must appear to be exhibited in tragedy as have been usually considered by writers on this subject. (See Character.) Several critics require that the principal persons should be of high or princely rank, because their qualifications and actions interest in the imagination, and impress the heart more forcibly than those of persons in humbler condition or more private life. But this observation is more specious than sound, and is refuted by facts. The histories of Dido, Constance, and Belvedere, all as much as if they had been princes or princes. The moral characters of the persons represented are much more important than the external circumstances in which they are exhibited. The passions presented to view, and the incidents relating to them, should be so described, as to leave upon the spectator impressions favourable to virtue, and to the administration of Providence. Mix of characters, such as occur in the world, afford the most proper field for displaying, without any bad effect, on morals, the weaknesses of life; and they interest us the more deeply, as they display emotions and passions, of which we have all been conscious. The subjects of the ancient Greek tragedies were too often founded on more daring, and incredible misfortunes; and though the court of the drama, many moral sentiments occurred, the instruction conveyed by the fable of the play was seldom any more than that revenge was owing to the gods, and submission to the decrees of destiny. Besides, their tales about fables, and the vengeance of the gods, led to many incidents more melodiously and tragically than moral and useful. Modern tragedy has aimed at a higher object. An Othello, hurried by jealousy to murder his innocent wife: a Jaffar, embarrassed by repentance and want to engage in a conspiracy, and then flight with remorse, and involved in ruin: a Siiffred, through the deceit which he employs for public purposes, with bribery, distortion on whom he loved: a Caius, induced into a criminal intrigue, which overthrows his wife, his father, and all his friends in misery: these, and such as these, are the examples which tragedy now displays to public view: and by means of which, it incites or men the proper government of their passions.

The events of a tragedy should be suited to the characters of the persons to whom they are attributed, and to the situations in which they are placed. Moral sentiments and reflections would not occur too often, because they would thus lose their effect, and they would render the play ponderous and declamatory. This is the character, in a great degree, of Seneca's tragedies. Nevertheless, moral reflections, properly introduced, give dignity to a composition, and on many occasions, are extremely natural. Much of the merit of Addison's Cato depends upon that moral turn of thoughts which distinguishes it. The style and composition of tragedy should be free, easy, and varied. Our blank verse is happily suited to this purpose. The style of tragedy ought always to possess force and dignity, but at the same time that ease and brilliancy, which are adapted to the freedom of dialogue, and the expressions of passion.

Of the Greek tragedy and tragedies we have already given some account, in the composition of some of the French dramatic writers, particularly Corneille, Racine, and Voltaire, tragedy has appeared with much latitude and dignity. But though they have improved upon the ancients, though they are attentive to all the units, and to all the decorums of sentiment and morality; and though their style is generally very poetical and elegant: yet they want fervour, strength, and the natural language of passion too declamatory, when they should be passionate; and too refined, when they should be simple. These defects of the French theatre are freely acknowledged by Voltaire. See their respective biographical articles. The general characteristics of tragedy in Great Britain, is, that it is more sublime and passionate than French tragedy, but more irregular and incorrect, and less attentive to decorum and to elegance. See the biographical articles of Shakespear, Dryden, Otway, Rowe, Young, Congreve, Thomson.

We shall close this account of tragic compositions with the following extract from Dr. Blair's Lectures, vol. i.

"A Greek tragedy is the relation of any disastrous or melancholy incident: sometimes the effect of passion or crime; sometimes of the decree of the gods, simply expected: without much variety of parts or events, but naturally and beautifully set before us, heightened by the poetry of the chorus. A French tragedy is a variety of artless and refined conversations, founded upon a variety of tragic and interesting situations: carried on with little action and vagueness; but with much poetical beauty, and high propriety and decorum. An English tragedy is the counterfeit of solemn pageantry; it begins in us all their violence; producing deep emotions; often irregularly constructed;1 involving no action; and filling the spectator with grief. The ancient tragedies were more natural and simple: the modern are more artificial and complex. Among the French, there is more correctness; among the English, more fire. Andromaque and Zare, written by Othello and Venier Preserved, round the heart. It deserves remark, that three of the greatest masterpieces of the French tragic stage, are wholly upon religious subjects: the Atheist of Racine, the Polyburnes of Corneille, and the Zare of Voltaire. The first is founded upon an
ADANON always called him Le Bouc, as if we were to say in English Mr. He-goat; and would not retain the Linnean name of the present genus, preferring that used in the Hortus Malabaricus, Schorgeram, etc., by a fatality incident in orthography to many of his countrymen, Schorgeram, which blunder he seems to have copied from Linneas. Nobody has attended to this erudite alteration.

Gen. Ch. Male, Cal. Perianth in three deep, ovate, acute, flat, spreading segments. Cor. none. Stamen three, the length of the calyx; anthers roundish.

Obf. Linneas remarks, that Plumer took this calyx for a funnel-shaped monopetalous corolla.

Female, on the same plant, Cal. Perianth inferior, in five, sometimes six, deep, ovate, concave, acute, permanent segments. Cor. none. Pest. German superior, roundish, with three furrows; style one, erect, longer than the calyx; stigma in three spreading segments. Peric. Capsule of three globular lobes and three cells, bristly, each cell marked at the base externally with a pair of dots. Seeds solitary, globose.

Obf. Some species have the style more or less deeply split into three parts.

TRAGIA is an unfigurative genus, with the aspect of a nettle, or a Croton. The flowers are green and inconspicuous; the herbage moliy lapidary or hairy; the stem either twining, often shurby and perennial; or erect, herbaceous, with an annual root.

Sect. 1. Stem climbing.
Lamark f. 1. (T. ala scandens, urtica folio; Plun. Lc. 251. t. 252. f. 2.)—Leaves ovate, somewhat heart-shaped, pointed, strongly serrated, rather hairy. Foot-flaks bristly above. Segments of the female calyx undivided. Stem twining.—Native of dry, calcareous situations in the West Indies, blooming in our stove in June and July, provided it be admitted there. The stem is round, hairy, leafy, branched, twining from well to call. Leaves alternate, about two inches long; paler beneath. Flowers axillary; the males in long bracteated clusters; the females solitary, on a long flalk at the base of each cluster. Capsule the size of a large pea. Browne's specimen has the leaves more soft and downy beneath than in the original one from the Upal garden. Whether the S of Linneas, Plun. Lc. t. 252. f. 1, be a variety, or a distinct species, we have no means of determining.

2. T. cordata. Heart-leaved Tragia. Vahl Symb. v. 1. 76. Illusr. n. 2. (Jatropha pungens; Forsk. Ægypt.-Arab. 163.) — "Leaves heart-shaped, pointed, serrated; bristly beneath. Segments of the female calyx pinnatifid, hairy. Stem twinning."—Gathered by Forskall near Yemen, in Arabia Felix, where it is called Hörnek, Meherkaka, or Humija. Vahl says the stem is shrubby, twining, and, like the whole plant, bristly. Leaves paler beneath. Spikes terminal.

3. T. biflora. Brittle Tragia. Plun. illusr. n. 3. "Leaves lanceolate,
TRAGIA.

laccolate, pointed, bifid, nearly entire; heart-shaped at the base. Segments of the female calyx pinnatisected, rough with bristles. Stem climbing. - Native of the East Indies. Leaves on very short, very hirsute stalks, more or less branched, two inches long, occasionally furnished with an oblong tooth at the base, or near the point. Spike axillary, filiform. Calyx densely covered with white bristles.

2. T. macrorhiza. Large-stemmed Tragia. Willd. n. 2. Parch n. 3. (T. exorticata ; Michaux Borel.- Amer. v. 2. 1815.) — Leaves obovate, sharply toothed, hispid; deeply heart-shaped at the base. Stem twining. - Found by Michaux in Kentucky. Annual, flowering in July. Parch. Each lobe of the capsule is said to be the size of a large pea.

3. T. colletia. Shaggy Tragia. Thumb. Prodr. 12. Willd. n. 3. - "Leaves heart-shaped, entire; hairy beneath. Stem climbing." - Gathered at the Cape of Good Hope by Thouburn, who alone appears to have seen this or the next species.

From the same country.

Clasper; lateral, afiliform, short and simple, each of several very small green male flowers, with a solitary female one at the base. Capsule woody, hairy, enveloped in the large, very bristly, strongly pinnatifid, or pinnate, permanent calyx.

22. T. sphaerocarpa. Horned Tragia. Linne. Sp. Pl. 1821. Willd. n. 12. Art. n. 3. Parch n. 1. Lamark n. 12. (Ricinocarpus pumus, folius esculentus, virginianus; Plunk. Phyt. t. 107. f. 5.) - Leaves oblong-laccolate, obtuse, edentate, more or less toothed towards the extremity, downy, as well as the upright; branched stem. - In cultivated and waste ground, and by road-sides, from Virginia to Carolina; annual, flowering from June to August. Parch.

The name of these seems to have remained with this species on the authority of Plukkenet. Its pubescence appears to be of a very fine kind; nor has any recent botanist attributed to it any fuming property. The habit of the herb is like a Mercurialis. The leaves are from one to two inches long, very variable in breadth; usually deeply toothed, or almost fringed; rarely linear and entire. Clasper axillary, longer than the leaves. Capsule: slightly hairy.

14. T. cernua. Lance-leaved Tragia. Linne. Suppl. 1845. Willd. n. 14. Art. n. 2. Lamark n. 12. (Croton hystosterus; Linne. Sp. Pl. 1821. Bemm. Ind. 1825. t. 63. f. 1. Ricinus laevius, alceae venus folium hystesterum acceperat; Plunk. Phyt. t. 202. f. 2.) - Croton urceae; Linne. Sp. Pl. 1821. (Ricinus urceae, canthus folium triphylloides; Plunk. Phyt. t. 202. f. 2.) - Leaves deeply three-toothed, or serrate, toothed; the middle lobe longest; ribs more bristly beneath. Stem erect. - Native of the coast of Mahobah, in gravelly places. A perennial herb, whose foliage bears a considerable resemblance to the Venetian Mallow, Hibiscus Tenstrum. The lobes of the leaves are obtuse, jagged and toothed, bristly on both sides, but particularly along the ribs and veins beneath. The leaflets and tendrils are also bristly. Clasper: on long, lamina, very bristly, thick. Calyx of the fruit pinnatifid, thickly covered, as well as the capsule, with pale yellow bristles. When the lobes of the leaves are quite separate to the very base, the plant becomes Croton urceae of Linne; but this affects no permanent specific distinction. Plukkenet's figures of both varieties are ineffectively preferable to Bremsius's plate.

TRAGI-COMEDY. See Emmelia.

TRAGI-COMEDY, a kind of dramatic piece, repre-}

senting fome action paffed among eminent persons, the

event of which is not unhappy or bloody, and in which is

sometimes admitted a mixture of fels serious characters.

The ancients, M. Dacier observes, knew nothing of fuch

compositions, in which the serious and comic are blended;

nor does the epithet M. Cornelle gives them, of heroic

comedies, excuse their irregularity.

Their foundation is certainly bad; for, endeavou ring

both to make us laugh and cry in their turns, they endea-

vour at contrary emotions, which the heart can never

undergo; every thing that disposes for the one, indispofing

for the other.

The tragi-comedy was formerly very common on the

Englifh stage; there was fearcely fuch a thing in the seven-

tenfenth century as a pure tragedy, without a fpic of comedy

or farce to make the people laugh. Now that the stage

and our tafe are brought nearer to the model of nature and

the ancients, the tragi-comedy is difflufed.

Tragi-comedy is the only cafe wherein comedy is allowed
to introduce kings and heroes. 

See EAR.

TRAGILUS, in Ancient Geography, a town of Thrace,
between the Cheronica and Macedon. Steph. Byz.

TRAGIUM, in Botany, a new umbelliferous genus of

Sprengel's, feparated by him from Pimpinella; fee that

article. The name is borrowed from Dioscorides, whose

appears to belong to our Pimpinella, and to have been

denominated from spina, a goat; because when the wild

goats fed upon it, the arrows with which they were

wounded would drop ou t; as Aelian relates of the Cretan

Dittany.—Sprengel Prodrt. Umbellif. 26—Clafs and order,

fruits armata, Sprengel.

The learned author whom we have juft quoted, in his new

mode of arranging the Umbellifera, of which, as well as

of other attempts of the fame kind, we propofe to treat here-

after in its proper place, lays confiderable frefs on the hairy

or briskly clothing of the feeds in fome fpecies. Such are

all feparated by him from thole with smooth feeds, and dif-

eposed in different genera, compofing by themfelves a par-

ricular fection characterized "fruits armatis." Among them is

Tragium, diftinguifhed from Pimpinella chiefly by the

furnucjhad juft mentioned, and the almost total ab-

de of ribs to the feeds.

Ef. Ch. Fruit ovate-oblong, downy, with scarcely any

ribs. Scan flatifis. Skin rather hoole. No general or

partial infolurcnce.

Obf The feam, commiffura, is the line by which the two

feeds touch each other.

The fpecies enumerated by professor Sprengel are

1. T. Columna. (Pimpinella Tragium of Villars. See

our Pimpinella, fp. 4, where notice is taken of the

importance of the downiefs of the feeds, as a fpecific diffic-

tion; and where for Columbia read Columna.)

Marich. a Bieberit. Taur.-Caucal. V. 1. 241; fee fp. 7.)

3. T. aromaticum. (P. aromatica; Marich. a Bieberit.

Taur.-Caucal. V. 1. 241.)—"Hoary with down. Leaves

pinate; leaflets all wedge-shaped, lined; with deep fer-

creations at the extremity."—Native of the borders of woods,

and banks of torrents, on the eaf side of mount Caucaus,

flowering in July. Root biennial. Akin to Pimpinella

Anisafum, with which it exactly agrees in the tafe and infell

of its feeds. But the preffent plant has all the leaves pinate

and glaucous, more flightly flirated, or ribbed, and the

feeds are downy.

4. T. villosum. (Pimpinella villosa of Schoubee; un-

known to us.)

5. T.
5. T. Broteri. (P. bubonoides; n. 5.)

The fruit of this last is much more hairy than that of the first species. On a review of the whole genus of Pimpinella, there appears to us not the slightest difference in the form of the seeds, nor in the thickness of the ribs in the several species, except that the latter are concealed by the hairs in P. bubonoides, though this is by no means the case in P. Tragium, whose ribs are more prominent than in any other under our inspection. There seems to be no reason for changing the specific name bubonoides; which is singularly expressive of the habit of the plant.

TRAGONISI, or DRAGONISI, in Geography, an island in the Greek Archipelago, so called from the number of goats, which are almost its only inhabitants; 2 miles W. of Myconos. N. lat. 38° 27'. E. long. 25° 30'.

TRAGOPON, in Botany, Goat's-beard, from 2ae2ae, a goat, and a beard; a name adopted from Dioscorides, whose authority may well belong to the genus which now bears it. His description answers in every particular to our T. perfoliatus, except the shortness of the stem. He says it is "an erect herb, with leaves like Garlic or Saffron, a short stem, a long sweet root, with a large flower-cup on the top of the stalk, and a black, or dark, seed," according to some readings, "from whence, its name is derived." But Sibthorp, the best commentator on this ancient author, instead of 2ae2ae myconos, and 2ae2ae monos, would read 2ae2ae myconos, and 2ae2ae monos; for he justly remarks, that a black seal could never have given rise to the name of Goats-beard. With this explanation, the dark calyx, and the large papita, or seed-head, are intelligible enough, as describing the deep purple florets lining the calyx, and the feathery seed-head, of T. perfoliatus. So Matthiolus likewise understands the matter.

Dr. Sibthorp indeed did not meet with this plant in Greece, and it is found a place in his Prod. F. Grec. merely as having been observed by the abbe Sessini, near Constantiopolis; but it might have been cultivated in Greece, as well as elsewhere.

Obs. Vaillant distinguished his Tragopogon by having straight seeds, and a calyx longer than the corolla; while his Tragopogonidz. has incurved seeds, and a calyx shorter than the corolla. Linnaeus makes no such distinction. Jussieu, and after him Willdenow, have adopted the latter genus of Vaillant, though by a different character and name, referring thereto such species as have a turbinate simple-leaved calyx, in eight segments only, not eight leaves. Of this we shall treat at the end of the present article, describing first the genuine species of Tragopogon, all首席, from which are to be removed what constitute the Tragopogon of Gartnert, to be described in its proper place.

Ed. Ch. Receptacle naked. Calyx of several leaves in a simple series. Seed-down stalked, feathery.

2. T. pratensis. Changeable Goat's-beard. Jacq. Mus. v. 2. 315. L. Rar. t. 357. Willd. n. 2. - Calyx as long as the corolla. Leaves lanceolate, rough-edged; recurved at the point; somewhat ovate at the base. - Supposed to be a native of Siberia, the seeds having been sent to Jacqueline by Pallas. We have seen no specimen. The leaves appear to be broader at the base, and less sheathing, than in the foregoing, and their points rather revolute than flat. The flowers, which open at sun-rise, and close about on the Island in the morning, for three successive days, are usually white in some individuals roseline, and red in others, having the edge much waved, revolute at the point. - Found in the lowlands of Austria, along with T. pratensis, of which some think it a variety; but the flowers are much smaller and paler, and the undulated leaves are remarkable. 

2. T. pratensis. Oriental Goat's-beard. Linn. Sp. Pl. 1129. Willd. n. 4. Alt. n. 3. (Bakhtiar hirti; Camer. Epit. 212.) - Calyx shorter than the corolla. Leaves tapering, somewhat wavy, with spired points. - Found by Tournefort in the Levant, and by Cameron, as it seems, in Germany. M. Thouain sends seeds to Kew garden in 1787. It is a hardy biennial, flowering, like all the foregoing, in June and July, and not the plant seem to differ much from the first, or most common kind, except in the greater size of its golden flowers, whose marginal florets extend far beyond the calyx.

6. T. major. Great Goat's-beard. Jacq. Autr. v. 19. t. 29. Willd. n. 6. Ait. n. 4. Marsh. von Bieberlit. Taur.-Caucuf. v. 2. 233. — Calyx longer than the corolla. Leaves tapering, straight. Flower-flats swelling upward. Flores rounded at the tip. — Native of meadows, vineyards, &c. in Germany and Austria, as well as near Branfon, in Switzerland, where it was found flowering in Auguft, by the late Mr. Davall, who fed its seeds to Kew in 1788, and whose own specimen is now before us. The gradual dilatation of the flower-flats upward, the great size of the flowers, at leaf of their calyx, which extends much beyond the corolla, and confails of a greater number of leaves than the generic character requires, even as many as twelve or thirteen; these circumstances led Jacquin to consider the present plant as a diftinct species from T. pratensis, or at leaft as a remarkable variety. We believe it remains conffant from seed. Some of the preceding are but too nearly akin, this to oad next to the pratensis.

7. T. porrifolius. Purple Goat's-beard, or Saffafle. Linn. Sp. Pl. 1110. Willd. n. 7. Fl. Brit. n. 2. Engl. Bot. t. 58. Jacq. Ic. Rur. t. 159. Fl. Dan. t. 707. (T. purpureum; Ger. Em. 735. T. alterum; Matth. Valgr. t. 491.) — Calyx almpt twice as long as the corolla. Flores tapering, abrupt. Leaves ftraight. Flower-flats swelling upwards. — Native of meadows in Switzerland, Germany, England, and about Constantinople, flowering in May and June. Cultivated in the kitchen gardens of the more opulent, the roots being esteemed a delicacy, and known by the name of Saffafle. They refeemble Scorasera bifanica, and have a feewett delicately flavoured, when defreen with cream, but are esteemed chiefly for the fake of variety. This plant having been perhaps more cultivated when efulent vegetables were fewer in England, has become naturalized in various situations, chiefly of a low and moist defcription. We have alluded to it above as the true πραγμήνη of the Greeks. The herb is biennial, erect, glaouos, smooth, four or five feet high. Leaves feightly, or not all, wavy. Flowers of a violet-purple, with black anthers; they close before noon. Linnaeus, in his Difler-ufion on the Sexes of Plants, Englih ed. 54, relates that he obtained a mule plant, by fprinking the fligma of T. pratensis with the pollen of the present species. The progeny of the feds had purple flowers, yellow at the bafe, evidently of an intermediate nature between the two parents; nor can any thing, as Linnaeus observes, more decidedly evince the generation of plants.

8. T. anguifolius. Narrow-leaved Goat's-beard. "Beldari MSS." Willd. n. 8. — "Calyx of eight leaves, longer than the corolla. Leaves ftraight, smooth." — Found near Niece. Biennial. Like T. crolfolius, but the calyx consists of eight leaves, and the foliage is entirely smooth at the bafe. The stem is but four inches high. Wildenow. We are not fure whether one of our fpecimens from Dauphiny be referrible to this species. It is hardly three inches high; the foliage quite smooth and naked throughout; but the calyx has only five fexes. Another from the fame country fseems intermediate between it and crolfolius. The fpecies of few genera are lefs fatisfactorily defined than thofe of Tragopogon.

9. T. crolfolius. Crocus-leaved Goat's-beard. Linn. Sp. Pl. 1110. Willd. n. 9. Ait. n. 6. Sm. Fl. Grec. Sibth. t. 779. unpublished. (T. crocololium montanum, flore negro-purpureo; Column. Ecpr. v. 1. t. 320.) — Calyx longer than the corolla. Leaves tapering; loofely woolly at the bafe on the upper fide. — Native of Italy, the fouth of France, and the ifle of Cyprus. Miller is faid to have cultivated this fpecies, but we do not remember to have met with it in gardens. The root is tapering and biennial, like all the reft of this fection. The flena is fearely above a foot high, branched, nearly or quite fmoother, clothed with numerous, narrow, spreading, drooping, white-ribbed leaves, very remarkable for a quanity of loft, flagggy, cottony wool, about their bafe on the upper fide, which is fometimes found also on the branches and flower-flats. Flowers of a violet-purple, with yellow fligma and blackifh anthers; their florets more spreading than in T. porrifolius, and their calyx greatly deflexed, twice as long as the corolla, conflufing of from five to eight acute leaves. Columna reprefents five broad ones only; Dr. Sibthorp found eight, which are narrower. The humble fature of the plant, and its woolly leaves, afford its moft striking diftinctions. The feds are beautifully adorned with advancing fcales, which prevent their efcaping, when once lodged in the earth, the agitation of their feathery wings, by the wind, ferving only to force them further down, till each wing shrivels at its bafe, and early breaks off. The fame economy is apparent in other fpecies of this and fimilar genera, but peculiarly admirable in that before us. It is analogouf to what has been obferved in the firt fpecies of Stipa; fee that article.

10. T. villifolius. Hairy-Goat's-beard. Linn. Sp. Pl. 1110. Willd. n. 10. Ait. n. 433. — Calyx longer than the corolla. Stem much branched, corymbose, clothed, like the bafes of the ovato-lanceolate leaves, with flagggy wool. — Native of Spain and Siberia; introduced at Kew, in 1794, by Mr. Hurnemann. Herb biennial. Herb as tall as T. porrifolius, but the flmen is very much more branched, and more flender, clothed with fiole, flattered, cottony wool, as well as with numerous, fhort, ovato-lanceolate, pointed leaves, those about the corymbose upper part of the flmen measuring from one and a half to two inches in length. Flowers a little drooping, pale yellow, rather smaller than thofe of porrifolius, on cylindrical ftriata flats. Calyx of about nine leaves, nearly half as long again as the corolla. Anthers brown. Rays of the feed-down rough, very woolly, with long, naked, taper points. This, at leaft, is an unquestionably diftinct species.

For Tragopogon virginicum, Linn. Sp. Pl. 1111. (Hyacinth praecox of Wild. Sp. Pl. v. 3. 1615.), as well as the two iftems of Linnaeus and Wildenow, fee TROXIMON.

Other Linnaean fpecies are feperated, as we have already faid, into a no fels diftinct and natural genus, for which we here retain Wildenow's name.

Gen. Ch. Common Calyx fimo, of one leaf, ovate, tu med at the bafe, deeply divided into eight equal, lanceolate segments. Cor. compound, imbricated, uniform. Flores numerous, all perfect, one petal, ligulate, abrupt, with five teeth; their tubes about the length of the calyx. Stam. Filaments,
Filaments, in each floret, five, capillary, short: anthers united into a cylindrical tube, projecting out of the tube of the floret. 

Pet. Germen in each floret: obsolete: style tumid and oblique at the base, with a kind of joint, then thread-shaped, straight, the length of the filaments; stigmas two, revolute. Peric. none, except the permanent closed turbinate calyx, shorter than the seed-down, finely reflexed. Seed: solitary, obsolete, oblique, angular, rough, each crowned: at an obtuse angle, with a flax, various in length, tumid and inflated at the base, bearing the foregoing feathery seed-down. Roots: naked, flat, roughish.

1. A. Dalechampii. Green-flowered Shrop's-beard. Willd. t. 1. Ait. n. 1. Sm. Fl. Græc. Sibth. t. 738, unpublished. (Tragopogon Dalechampii; Linn. Sp. Pl. 1113. Hieracium magnum; Dalechamp. Hist. 329, bad. H. purpureum, incis. foliis, montanum; Barcel. P. t. 109.)—Calyx finely downy, without bristles. Leaves rudimentary, toothed.—Native of Spain, the south of France, Italy, and the Levant. We have seen it, adorning sunny hills about Genoa, in the early part of a summer's day, when its copious large flowers, of a delicate sulphur-colour, purple underneath, make a fine appearance, intersected with the blue Catananche, and other handsome plants, while the great Myosotis sinuata is seen boldly fluttering over their blossoms. Miller appears to have cultivated this plant, which is a remarkably hardy perennial in warm dry situations, flowering from June to October, but not often seen in gardens. The stem is from two inches to a foot high, purpling at the base, leafy, roughish, as well as the alternate, clasping, rudimentary leaves, of which the upper ones are oblong, and nearly entire. Flowers: two inches wide, solitary, on very long, simple, terminal, round, rough, hollow stalk. Calyx green, covered with peculiarly felted-down. Flowers: hairy at the back. Stalk of the seed-down tapering, hollow throughout, nearly vertical, about three the length of the seed.

2. A. plicatus. Prockly-cupped Shrop's-beard. Willd. n. 2. Ait. n. 2. Sm. Fl. Græc. Sibth. t. 731, unpublished. (Tragopogon plicatus; Linn. Sp. Pl. 1111. Sonchus alpe; jugas cretaceus; Bubh. Prodr. 62.)—Calyx hispid, with prominent bristles. Leaves: toothed: the upper ones jagged; dilated at the base, clasping the stem.—Native of the south of France, and the shores of Italy, Sicily, Crete, &c. Dr. Sibthorp found it frequent in Greece and the Archipelago, especially among rubbish near the sea. He suspected it might be the Greater Hawkweed, Tragopogon pratensis, of Dioscorides. Curious cultivators: have often raised the plant in England, where it proves a hardy annual, but is too like a common Sow-thistle to be much cherished. The bark varies in luxuriance and roughness, but is not at all hairy. Lower leaves: ovate, tapering much at the base, where they clasp the stem: upper-greatly dilated in the same part, and furnished throughout with many sharp segments and teeth; their midrib prickly beneath. Flowers: several; bright yellow, not half the size of the former, on long, terminal, solitary, bristly stalks. Calyx: thin, covered with towy, rigid, projecting bristles. Seeds: dark brown, depressed, flat; as is the thin base of the otherwise slender, longish, and white stalk which sustains the snow-white feathery down.

3. A. ater. Rough Shrop's-beard. Willd. n. 3. Ait. n. 3. Sm. Fl. Græc. Sibth. t. 732, unpublished. (Tragopogon ater; Linn. Sp. Pl. 1111. Sonchus ater; subperundum fici; Bubh. Prodr. 62, no figure.)—Calyx hispid, with prominent bristles. Leaves undivided, toothed: those of the stem oblong, contracted towards the rounded clasping base.—Found on the shores of Montpellier, Italy, and Alizé Minor. Seen to. Kew by Mr. Richard in 1754. Annual, with the habit and flowers of the last, but the leaves are very different, at least those of the stem, which, instead of being dilated and deeply jagged, are merely oblong and toothed. The stalk of the seed-down more or less contains much more, though equally tumid at the base.

4. A. scoparius. Cape Shrop's-beard. Willd. n. 4. (Tragopogon capensis; Jacq. Col. v. 2. 420. Ic. Rar. 347.)—Calyx hispid, with prominent bristles, and deeply channelled. Leaves rudimentary, toothed: the upper ones arrow-shaped at the base, nearly entire. The seeds were received by Jacquin from the Cape of Good Hope, and produced biennial plants, three or four feet high, branched, having much of the appearance of a Sow-thistle, like our second species. But the leaves are much less dilated at the base, and the calyx is more deeply channelled, having eight tumid ribs, or angles. The slender and elongated stalk of the seed-down is very like that species, of which it is possible the parent may be but a variety. We know it only from Jacquin's work.

Tragopogon, in Gardening, contains plants of the hardy, herbaceous, biennial, and perennial kinds, among which the species mostly cultivated are, the purple goat's-beard, or Wildpea (T. porrafolius); the common yellow goat's-beard (T. pratensis); the crocus-leaved goat's-beard (T. croci folius); and the great-flowered goat's-beard (T. Dalechampii).

Tragopogon is cultivated in gardens under the name of tallage principally for the use of the root parts of the plant and the young shoots. The roots, when boiled or stewed, have a mild sweetsavour. The stalks are also cut in the spring, when they are four or five inches high, and drooped like alspargis, in which way they eat very tender and well.

Method of Culture.—The first is only raised from seed, which should be sown in the spring, in an open situation to remain, either broadcast and raked in, or in shallow drills eight or nine inches asunder, scattering the seeds thinly, and covering them half an inch deep: and when the plants are come up two or three inches high, they should be thinned and weeded by hand or the hoe, leaving them eight or ten inches asunder, repeating the weeding as required during the summer, which is all the culture they require, and they will have large roots by the autumn, as September or October, when they may be begun taking up for use; and in November, when the leaves begin to decay, a quantity be preserved in sand for use in time of severe frost, when those in the ground cannot be got up.

In the spring, when those remaining in the ground begin to shoot, the shoots, when a few inches high, may be cut for use, which, when quite young and tender, on being boiled, are excellent eating. A few plants should be suffered to run up to stalk every spring, to produce seeds. The shoots are brought to market in bunches during the autumn and winter seasons.

The two following sorts may also be raised from seeds in the same way, and the plants, when a little advanced in growth, may be pulled out if they are required for any variety in a particular part.

The third sort may also be propagated by parting the roots in autumn and spring, and planting them where they are to remain.

The first is cultivated wholly as a culinary plant, but the others afford variety in the borders of pleasure grounds, &c.
TRAGORCHIS, in Botany, from πεταλος, a goat, and Orchis, see that article, has been used by several old authors to designate certain species of that beautiful and curious tribe, whose flowers were thought to have a goat-like scent. Two in particular have thus been called; the Satyrium hircinum of Linnaeus, now Orchis hircina, and his Orchis coriophora.

TRAGORIGANUM, from πεταλος, a goat, and ὁργυνος, marjoram, a name applied by the older botanists to several plants, mostly belonging to our present genus Origania, which may be found in its proper place, or to some aromatic plants allied thereto. The original meaning of the word was founded in the idea of Marjoram being agreeable to goats, and especially of the Cretan Marjoram, or Dittany, being a sovereign remedy for such as were wounded by arrows. Tragoriganum notatum, Barford Goat-marjoram, Dalechamp Hif. 889, has indeed no connexion or affinity with other plants that bear this name, being the Libithum marianum, whose leaves only possess a flight resemblance to the ringent plants, without any of their flavour or qualities.

TRAGOSELIMUM, from πεταλος, a goat, and σελεως, parley, a name first used by Tabernaemontanus for the Pim- pinella saxifraga of Linnaeus, which some have called Tra- gium; see this article and Tragus.

TRAGULA, among the Romans, a strong kind of jelin, with a barb' head. Tragum, in Ichthyology, the name given by Aristotle, and others of the old Greek writers, to the trigum of Aelian, Athenæus, and Oppian. Both names are used to express the fish called by authors the poifinachs marina, and by us the fire-fish, or fire-faire.

TRAGURNIUM, in Ancient Geography, a town of Dal- matia, famous for its marble. Ptolkmy.

TRAGUS, a river of the Peloponnesus, in Arcadia. Pausanias.

TRAGUS, in Anatomy, an eminence of the external car. See EAR.

TRAGUS, in Botany, a name which has been variously applied. One πεταλος of Dioscorides, book 2. chap. 119, appears to be a kind of meal or flour. Hence perhaps Haller was led to use this name for a genus of grasses, now denominated Lappago; see that article. Such an application is like the old derivation of luca, "a non lucendo," of few of the tribe being likely to yield foa meal. Another πεταλος of the above Greek author, book 4. chap. 51, is described by him as "a maritime shrub, of humble growth, without leaves, whose branches are betel with a kind of reddish berries, the size of grains of wheat, pointed, and very aromatic." Whether this may be the Ephebra, or any thing else, it is difficult to determine. Valerius Cordus thought it Sedum album, which is a common Greek plant. We might rather indicate S. anglicum, were that found in Greece, the leaves, in both cases, being taken for berries. Camerarius gives Salsola Kali for the plant of Dioscorides, annexing an ab- stract of his description of its form and qualities, the former of which, at least, does not agree with this Salsola; any more than with S. Tragus, so called by Linnaeus, apparently because the name was at hand when he was intent on dislin- guishing it from S. Kali; see Amoen. Acad. v. 4. 310. We collect these particulars to shew the difficulty of the enquiry, as well as its mutility. Dioscorides is amusing enough, as a botanical riddle-book, because, while some of his descrip- tions are elaborate and precise, others are jull sufficiently vague to afford room for conjecture. Theophrastus, though far more philosophical, is in but a few instances clearly intelligible. The greater number of his plants are merely named, as being suppos’d well-known to his readers, and therefore he scarcely affords matter to found any conjectures upon.

TRAHINA, in Geography, a town of Sicily, in the valley of Demonas; 28 miles N.W. of Catania. Lat. 37° 40'. E. long. 14° 40'.

TRAHONA, a town of Italy, in the Valteline, on a small river which runs into the Adda, 2 miles N. of Morbegno.

TRAJAN, M. ULPNIUS TRAJANUS, in Biography, a Roman emperor, the fon of a distinguished commander under Vespasian in the Jewish wars, was born at Italica in the Spanish province of Boetica, entered into the army, and accompanied his father in several military expeditions; acquiring the hardihood, submitting to the discipline, and uniformly practising the duties of a soldier. In the career of public honour, he was first made praetor A.D. 86, con- skull A.D. 97, and raised by Nerva to the rank of Cæsar A.D. 97, being at this time in the 42d or 43d year of his age, according to the statements of different writers, and polishing a majestic stature, manly features, and dignified aspect. Upon the death of Nerva in the following year, Trajan succeeded, without opposition, to the imperial throne. He was at this time at Cologne, and remained for some time in Germany. In 99 he set out for Rome, and entered the city on foot, preceded by the lictors as an ordi- nary magistrate, and followed by a few soldiers exhibiting the demeanour of citizens. Affable in his manners, bountifull in his largesses to the Roman people, and anxious to procure a suppley of corn by allowing free importation from the colonies, Trajan acquired and maintained a very great degree of popularity. He likewise very much contributed to the tranquility and good order of the city, by removing to exile the infamous tribe of delators, who had been encour- aged by the tyranny of Domitian, and not sufficiently re- pressed by the lenity of Nerva, and by infusing an edict with some penalties against all false accusers. He also reduced the tax of the twentieth upon collateral successeions, imposed by Augustus, and formed a fund for the exercise of liberality by his own economy and frugality. He encouraged merit, and advanced to polts of true men distinguished by their in- tegrity and talents. He associated on the most condescending terms with perfons of various rank and condition, and treated the citizens of Rome in general more as friends than as subjects. Although his military education and employ- ments allowed him no leisure for acquiring the accomplish- ments of literature, he was the patron of learned men, and by founding libraries and other methods, he promoted the diffusion of learning. As he was moderate and frugal in his own habits, and in the entertainments he provided for his guests, he checked and restrained the prevalence of luxury and extravagant expenditure in others. By pursuing various methods for rendering the people happy, he obtained, by the unanimous voice of the senate, the title of "Optimus," which glorious distinction he retained through life and trans- mitted to posterity. In the third year of his reign he was honoured with a third consulat; and during his exercise of this office, Pliny pronounced that panegyric which is still extant, and which pretends to view a finished portrait of a perfect prince. In the following year, when he was again consul, he was engaged in a war with Decebals, king of the Dacians, from which he returned victorious, and obtained a triumph with the surname of "Dacius." Having spent the two following years in an attention to objects that contrib- uted to the improvement of the empire, one of which was the establishment of a port at Centuncelae, now Civita- Vecchia, the clofe of the latter of these years was ren- dered
dered important and interesting, by the appointment of Pliny, A.D. 103, as governor of Pontus and Britain, and by the correspondence to which this appointment gave occasion, and which pourtrays in the most pleasing characters the enlightened and benignant spirit by which he was actuated.

(See Christian Religion and Pliny.) In the following
year the war with Decebalus was reviewed, and on this occa-
sion Trajan constructed a bridge over the Danube, which
was long admired as one of the most considerable relics of
antiquity. When Decebalus had dispatched himself after
the loss of his capital, Dacia was constituted a Roman pro-
vince, and colonized from other parts of the empire. (See
Dacia.) Upon his return to Rome, he employed himself in
carrying on some works of public magnificence and util-
y; but success in his military expeditions unfortunately
clarified the innate propensity of war, which seems to have
been his most consummate felicity; and accordingly the sub-
sequent period of his reign was too ardently devoted to the
gratification of his ambition, in extending the boundaries of
the Roman empire. In the year 107, he reduced Armenia
into a Roman province; the whole of Mesopotamia was also
subdued; Arabi Petraea was likewise made a Roman pro-
vince; and all the barbarous tribes situated north of Armenia,
between the Euxine and Caspian seas, were reduced to sub-
mission. After the lapse of some years, of which no regu-
lar account remains, we find Trajan A.D. 114, dedicating
the magnificent forum, which he had constructed at Rome,
and erecting the columns on which his exploits are sculptured
(See Trajan and Forum); and also renewing the war with the Parthians.
In 114 he crossed the Tigris in a bridge of boats, and subdued Adiabene and the whole of Assyria; and having captured Cedigaph and Sura, he de-
defated the Tigris with his fleet, and had the honour of
being the first and last Roman general who navigated the
Indian ocean, ravaging the coast of Arabia Felix. He even
indulged the ambition of visiting India. On his return he
laid siege to Atra, the capital of an Arabian tribe, which
he was obliged to relive and to withdraw to Syria. In
the year 117 he was attacked with a paralytic disorder, attended
with Euphory, and he therefore hastened his return to Italy.
At Seleucia in Cilicia he had another attack, which proved
fatal. In his last moments, the emperor's Plutina secured
the adoption of Adrian for his successor. Trajan died in
the sixty-fourth year of his age, after a reign of nineteen
years and a half, and his remains were deposited under his own
column. This emperor's virtues were shaded by weakness
and vice. His passion for war has been already mentioned;
he was also addicted to sexual indulgences, of which inter-
course in drinking was the least scandalous. Notwithstanding
the blemishes of his character, his memory was long
held in veneration, inasmuch that 250 years after his death,
the senators, in their acclamations on the choice of a new
emperor, vociferated the wish that he might be "more fortu-
none than Augustus, and better than Trajan." Anc.

**TRAJAN COLUMN, a famous historical column, erected
in Rome, in honour of the emperor Trajan. See COLUMN, Cilica.**

**TRAJAN, in Geography, a town of European Turkey, in
Moldavia, on the Pruth; 16 miles N. of Galatz.**

**TRAJANA, or TREA, in Ancient Geography, a town of
Italy, in the province of Picenum. Pol. and Hist. Anton.**

**TRAJANOPOLIS, in Geography, a town of European
Turkey, in the province of Romania, on the Mariza. This
is an ancient town, and took its name from the emperor
Trajan, who repaired and adorned it: it afterwards became
very considerable, and now, though much reduced from its
ancient splendour, is still the seat of a Greek archbishop; 40
miles S. of Adrianople.**

**TRAJANOPOLIS, in Ancient Geography, a town in the
interior of Thrace, upon the banks of the river Hebrus.
In the Ist. Anton. this town is placed between Bresesc
and Cephal.—Also, a town of Lydia, near the sea, between
Antandrus and Aradus.—Also, a town of Asia, in Cilicia
Trachea, where the emperor Trajan died: the same
with Seleucia.**

**TRAJANOPOLIS, or Transpolis, a town of Asia, in Phrygia
Pacatiae.**

**TRAJANUS PORTUS, a port of Italy, on the coast
of Etruria, at the mouth of the Tiber; constructed by the
emperor Claudius, and repaired by Trajan, who rendered it
more secure and commodious, and gave it its name.**

**TRAJECTORIA OF A COMET, is its path or orbit, or the
line it describes in its motion.**

This, Hevelius, in his Compendia, will have to be
written nearly a right line; but Dr. Halley concludes it to be
a very eccentric ellipse.

Sir Isaac Newton, in prop. all. of his third book, shews
how to determine the trajectory of a comet from three
observations; and, in his last proposition, how to correct a
trajectory graphically described. See Comet.

This term is often used, in general, for the path of any
body moving either in a void, or in a medium that resists
its motion; or even for any curve passing through a given
number of points. Thus Newton, Princip. lib. 1 prop. 22,
proposes to describe a trajectory that shall pass through five
given points.

**TRAJECTUM, in Ancient Geography, a town of the
Batavii upon the Rhine. Trajectum is thought to be one of
the fifty main cities erected by Drusus in this country, to
fortify the course of its rivers. This town contained a
variety of vicissitudes, till at length it was established by the
Romans. It had the name of Trajectum Oppidum, in honour
of Ulpius Trajan. In its environs are found many ancient
remains. See Utrecht.**

**TRAJECTUS, a place in the isle of Albion, upon the
route from Collevia to Lice, between Abooe and Aquae
Salis. Anton. Ist. Antiquities are generally of opinion,
that Trajectus should have been placed before Abooe,
and that it was situated at Oldbury, where, as they suppose,
was a ferry over the Severn: but Mr. Horsley imagines
that Trajectus was situated at the passaghe over the Avon,
near Ilmham, 9 miles from Bath.**

**TRAJETO, in Geography, a town of Naples, in
Lavosa, near the mouth of the Garigliano, the seat of a
bishop, built on the ruins of the ancient Metternum; 6 miles
S.W. of Sezza.**

**TRAIGUERA, a town of Spain, in Valencia; 12
miles N.W. of Peniopolis.**

**TRAIR-BOARDS, in Ship-Building, a term for the carved
work between the cheeks of the head, at the heel of the
figure.**

**TRAILING ARBUTUS, in Gardening, the common
name of a curious ornamental plant. See Eugene.**

**TRAIN, the attendance of a great person, or the trail of
a town, or route of state.**

In Flanders, it denotes the tail of a hawk.

**Train is likewise used for the number of beasts which a
watch makes in an hour, or any other certain time. See
Watch-word, &c.**

**Train is also used for a line of gunpowder laid to give
fire to a quantity thereof, in order to do execution, by
blowing up earth, works, buildings, &c.**

**TRAIN or TRAIL of ARTILLERY. See Artillery.**

**TRAIN-
TRAIN-Band, or Trained-Band, a name given to the militia of England, particularly to those of the city of London.

Train-Oil, the oil procured from the blubber of whales, by boiling. See Whale and Whale-Fishery.

Train-Roads, a flight kind of rail-ways for small wagons, used in mines.

Train-Scout, in the Manege, a method of trying the speed and goodness of the horses defined to the sport of hunting, so denominated because the scent which the hounds hunted, proceeded from some animal which had previously been trained along the fields and over hedges and ditches, according to the pleasure of the person who trained or dragged it after him. The rival horses were to follow the hounds which hunted this scent, and give proofs of their speed and merit, in competition with one another. Of all chaces this was reckoned the swiftest and most trying, because the scent lies the hottest; so that the hounds run all the time at the utmost stretch, and the horses must have been exerted to their utmost powers to keep pace with them. Besides, in this manner of hunting, the sport was always ready when a fox or hare might not easily be found; and this mode of matching and running hunters, in order to try their speed against one another, while they followed the dogs, was thought to be more cheerful both to the riders and horses, than to make them run simply against one another, or against time, as the present practice is. When neither the hunting of the hare, nor the running of train-scents, could not decide which horse is the best, recourse was had to another kind of chase, called by horsemen the _wild-game chase or chale. See Chase._

Train, in Geography, a river of France, which runs into the Dyle, about 9 miles S. of Lovain.—Also, a town of Bavaria, on the Ambs; 5 miles S. of Ahensperg.

Traina, a town of Sicily, in the valley of Demona, on a river of the same name; 56 miles S.E. of Cefalu.

Trained Trees, in Gardening, such young fruit-trees as are designed for walls and espaliers, being trained in the nursery to the intended form, by planting them against any kind of walls, pales, reed-hedges, or other close fences; when a year old from the grafting or budding, training them in the manner of wall or espalier trees, for two, three, or more years, till they obtain a good spread of branches, and are arrived to a fruitful state, in order that those who are in haste to have their walls or espaliers covered at once with bearing trees, may have it accomplished in one season. The trees thus trained in the nursery, &c. on being planted out in autumn or spring to the places intended, cover the wall or espalier in some manner at once, and often bear fruit the ensuing summer, when the feaon proves favourable for the purpose.

In the public nurseries, large quantities of these sorts of trees are always kept ready trained for sale, particularly peaches, nectarines, and apricots for walls; in many places also, cherries and plums, &c. like-wise apples, pears, and other fruit-trees, for espaliers; and are proper to furnish the walls and espaliers of new gardens, and occasionally those of old ones, to bear fruit till younger trees, planted untrained, become fruitful, or for supplying the places of old trees that fail, or bear bad fruit. In all cases of this sort, this mode of planting may often be adopted with great propriety and benefit, and besides much time and trouble be saved by it, in waiting for the trees to become in a bearing state, as well as the expense which is constantly incurred in carrying on the operations and processes of preparing young fruit-trees. The difference in the prices of trained trees over those of untrained ones is a mere trifle, and of no consideration in such undertakings. Therefore, in all nurseries some of the belt sorts of these trained fruit-trees, both for walls and espaliers, may be kept ready for these purposes with great utility and advantage.

When, of course, it is intended to raise trained fruit-trees for walls and espaliers, a quantity of the best young plants of the respective sorts, dwarf and half-standard, of one year old, with the first shoots from the budding and grafting entire, should be planted out in autumn against some kind of fence in a free open situation, not less than four or five feet high, placing them from five to six to eight or ten feet distant, to remain for training. These in the spring following, just as they begin to make an effort for shooting, should be headed down, with a clean sloping cut upward, to within four, five, or six eyes or buds of their origin, or place of insertion in the stock, especially those intended for dwarfs, and the half-standards, if worked on tall flocks; which prevents their running up too high with a single naked item, andcauses them to throw out lateral shoots from the lower part to fill the wall or espalier regularly with branches quite from the bottom upward; as they soon after push forth strong shoots from all the remaining lower buds, sufficient to give the tree its first proper formation as a wall-tree, &c.; which shoots, when advanced in length in summer, should be trained along to the fence equally to the right and left, in a somewhat slanting or inclined present at full length till next spring, when these shoots may also be cut down to the length of six or eight inches, to force out a further supply of more branches near the bottom, as it is proper that they should be well furnished with branches below, in order to cover the wall, &c. at the bottom part, that none of it may be lost or left in an uncovered slate.

The summer's shoots should be shortened in this manner; more or less the two or three first springs, as may be necessary, in order to obtain a proper spread of lower branches to give the tree its intended form; though this work of cutting in short to obtain laterals, may also be performed occasionally in summer, in May or early in June, on the strong young shoots of the year, cutting or pinching them down to a few eyes; but the first is the bell mode. This last mode, by forcing out lateral shoots the same year, often saves time.

As the supply of branches thus obtained arrive at proper lengths, in the summer they should be all trained in along close to the wall, and if any fore-right or back shoots come out, they should be rubbed off close, leaving all the well-placed side and terminal shoots in every part, and letting the whole, or as many as possible, be trained in during this season, to have a plenty to choose from in the general pruning. Feasions of winter and spring, laying them in close to the wall, &c. equally to the right and left, on each side of the tree, in a spreading somewhat horizontal or fan-like manner, no where crossing one another but at parallel distances, and mostly all at full length during the summer's growth, to remain till the general winter or spring pruning.

In the winter pruning, where more wood was trained up in summer than appears necessary, or that can be trained in with due regularity, it should be retrenched, as well as any remaining fore-right or back shoots and other irregular growths omitted in the summer, be now all pruned out, cutting them quite close to their origin. The whole should then be close-nailed to the wall, in somewhat the fan manner, removing in the first place all the irregular side and other shoots of the different branches before they are laid in and nailed. See Pruning.

Having thus procured proper heads, they should afterwards be pruned or cut in according to the method peculiar to
to each respective fort, as directed under the culture, some requiring the branches to be shortened annually, others to be mostly trained at full length. See Dwarf and Espalier Trees, Pruning, &c.

The training of espalier trees is effected exactly in the same manner, only these may be trained as they stand in the nursery lines, in the open quarters or borders, &c. by ranging some stout flakes in the ground along one side of each tree, not in a continued straight range immediately the way of the row, but those of each tree ranged separate and obliquely, somewhat crosways the row as it were, that the branches of the different trees may range beside one another, and thereby have more room to extend the branches both ways, than the common distance in the nursery lines would admit, if ranged directly the way of the row.

It may be noticed, that occasionally it may happen that some particular trained trees of both the wall and espalier kinds may assume in the course of their training a state of extremism vigorous and luxuriant flowering and growth either in the whole of them, or in some particular parts, by which very strong rampant, rude shoots that have a peculiar unfruitful-like nature and appearance are sent forth, which in all such cases and circumstances should be ordered and directed in a particular manner, according to their nature and situation, until they have in a great measure exhausted their too great abundance or redundancy of sap which caused their excessive luxuriance, and they begin to take on a more moderate state of flowering and growth. In consequence of which, therefore, wherever there appears to prevail a general luxuriance and excess of growth in the whole trees, or parts of them, while under the course of training, or afterwards, it will be advisable to use proper and necessary caution in the way of pruning, employing the knife in rather a moderate manner in the way of thinning out and shortening the branches, and in some degree humouring, as it were, the trees in their natural tendency of flowering and growth, by leaving the young shoots and branches thicker and closer together than what is the common rule in all such cafes, the whole being left at their full lengths particularly during their summer’s growth: and to all those which are usually shortened in their winter pruning, as in the peach, nectarine, and other similar sorts of trees, it should be shortened much less in proportion than the other kinds; but those of the apple, pear, plum, cherry, and others of the same sorts, should always be continued at their whole lengths; that, on the whole, by thus dividing the sap-juice among a greater number, as well as larger extent of branches, that luxuriance may be checked which would take place in the cafes of a smaller number and less extent of growth. As, in general, the more wood can be cut out of a vigorous flowering tree, and the more the shoots are shortened, practices which are erroneously too frequently had recourse to, the more vigorously it will continue to shoot, without ever becoming properly fruitful; and if severe cutting-in be repeatedly practised and continued, the tree will often exhaust itself so greatly by its luxuriant flowering, that it suddenly becomes in a weak, imperfect, and decayed state of growth. But, on the contrary, if the natural inclination of the very vigorous-flowering young trees be somewhat confuted and indulged, in the first instance, by training in as many branches as can be conveniently had for the purpose, and those which require shortening, be cut in moderately only, or some which are very luxuriant hardly at all, and these methods continued to be practised for two or three years with proper direction, the trees will be gradually reduced to a moderate state of growth, and good condition of bearing, after which they may be managed and directed in the common way which is proper for each of the different sorts.

And, on the other hand, such trees as are only vigorous in particular shoots, may, in some cafes, have such shoots radically retrenched, but in others reserved; and if a very vigorous shoot runs considerably stronger than all the rest, and seems to support its vigour at the expense of the others in its vicinity, it should be retrenched to its very origin as early in the summer as it is perceived: in other cafes, if a luxuriant shoot arises in any vacant space, especially towards the bottom part, where a supply of more wood is wanted, it may be retained, and pinched off or topped down to a few eyes in the late spring or beginning summer months, when it will send out several lateral shoots below, the same season, and instead of one rude luxuriant shoot, there will probably be four, five, or more of a moderate growth to fill the vacancy in a more effectual manner, and which will much sooner attain the state of fruitfulness.

The trees having been thus in training in the nurseries for the space of three, four, or five years, they will have obtained a handsome spread of fruitful branches fanned in the regular proper and necessary forms for the different purposes which are intended, so as that when planted out, they may at once cover a large space, and become quickly fruitful and productive. The particular method of culture which is proper for each of the forts, is more fully given in speaking of them individually under their several heads.

But it may be remarked that, in general, unless good trained trees can be readily obtained, of from three or four to five or six years old, of a clean free growth, it will be better to plant entire young untrained trees of one or two years old, immediately from the nursery, putting them at once where they are to remain, managing them afterwards as the trained trees, to give them the proper form of head.

Some, in order to have as great a chance as possible, plant young untrained trees to remain, and trained trees of a bearing flat, dwarfs and half standards between, to cover the wall more effectually at once, and furnish a supply of fruit, until the young ones are trained and arrive at the bearing flat; then, according as the trees of both sorts advance in that state of growth, those which appear the most prosperous are retained, and the others are gradually cut away, leaving the most thriving trees to occupy the wall wholly at last.

In most of the public nurseries, they raise trained trees for sale, which occupy all their close fences of walls, pales, &c. where they may be procured of almost any size, differing in price from three to five or ten shillings or more per trees, according to the sorts, age, and goodness of growth. See Trainer, in Geography, a town of France, in the department of the Aube; 6 miles S. of Nogent fur Seine.

TRAINING, in Planting and Gardening, the practice of regulating the forms and growth of forest and fruit trees, by the proper topping and retrenching of their side or other branches in the first kind, and by the cutting-in and distribution of their shoots and branches in the latter. What is principally necessary in the management of the former of these sorts of trees, in this respect, has been already pointed out under the heads to which it properly belongs. See Pruning and Timber.

And in regard to the latter, or garden kinds of trees, it has been remarked, that when by mixtures it is properly a practice much connected with that of pruning, and which is employed, either for the purposes of protecting exotics of the tender fruit-tree kinds from the wind, for improving their climate by spreading them in a regular manner upon a wall or fence, or for supporting climbing or training
trailing plants. In the first case, it is performed in a great variety of modes and manners, according to the nature and kind of support which is made use of for the purpose. In the second intention too, it is done differently, as the circumstances may be, and mostly against walls, as in the fan and horizontal modes; the former of which is said to be calculated for fonnet covering the walls, and to be likewise the most proper for such kinds of trees as do not abound in superfluous wood, as the cherry, peach, and apricot. The latter mode, however, is said to fill the walls more completely, though longer in accomplishing the business; and to be the best suited for such trees as run much to wood, as is the case with many apple and pear trees. See these different sorts of trees.

In the work of training for the support of climbing plants, nature fhould, it is suppos'd, be imitated as nearly as possible. That with the kinds which twine round other trees or supports, or that fallen themselves to walls, nothing more is thought necessary, than to put them on similar objects which are within their reach; but that with others, which support themselves by claspers or tendrils, it is requisite to fallen them by art when these claspers fail; which, in nature, is commonly the second year; when the whole twining shrub or climber falls down, or hangs by its last formed tendrils in such a manner, as that its shoots are bent, twisted, or inclined in almost every direction. This is the case with many sorts of tree plants, such as vines, passion-flowers, and others, and strongly suggests the advantage of training such kinds in a twirled or a pergament manner; as nothing can be more unnatural than to train them in an upright mode, as is too commonly done with the firft of these sorts, where set against the back walls of hot-houses, &c. In training them along a trellis, under the sloping glafs of such houses, they are said to be in a more natural sitution, and are more likely to send out shoots, or to break, as it is often termed, at every joint; but full experience has, it is thought, proved the vaft advantage of training in a pergament or twisting direction in every situation. In a great many houses of the above sort in all parts of the country, nearly two-thirds of the crops which might annually be produced, are, it is suppos'd, lost for want of attention to this circumstance. And, that as the practice is natural, uniformly successful, so far as it has been yet tried, and without injury, it ought to be more generally had recourse to in the buildings.

Great ufs and benefits are capable of being taken of the fame principle in the training of other sorts of trees; as whenever the sap is constrained by twilling a shoot or branch, it is sure at such places as are most bent, or which have most of the angle of the curve, to send out a shoot, as has been well noticed, illustrated, and taken advantage of by both ancient and modern writers on horticulture. See Hitt's and Forbyth's Treatises on Fruit-Trees, &c.

In the training of fruit-trees, few who have been engaged in the work have, it is suppos'd, fully understood or sufficiently availed themselves of the advantages which might be taken of this general law in vegetable economy, that the extreme branches bent downward, or the extreme roots turned upward and exposed to the air, throw the tree more or less into a fruiting state. It has lately, however, been done by turning the branches of such trees over the tops of walls, or in other modes, with astonishing effects in the production of fruit. The great effects of this sort of training are evident too in many other inftances, where bends, twills, and downward directions are given to shoots and branches by different circumstances in the objects to which they are trained. The powerful and excellent effects of cutting the roots of trees either at some distance from or near to the chief item, as well as those of cutting the item itself, in order to throw them into a fruiting condition, have, it is said, been fully recorded by former writers on gardening, and been recently practifed with complete success. See Espalier Trees, Pruning, Trained Trees, and Wall-Trees.

TRAINING, or Tracing, in Mineralogy, a term used by our miners to express the tracing up of the mineral appearances on the surface of the earth to their head or original place, and there finding a mine of the metal they contain: or, training or tracing a lode, denotes the same with backing of it; that is, laying open the bryle, and discovering the back of the lode, by many pits for several fathoms in length, eait and west. The bryle of a lode, is that mineralized subsidence which lies loosely upon the top of it under the loose mould and rubbish of the earth.

The principle on which this practice depends, is the change wrought in the face of the earth by the deluge, of the effects of which these remains are a very great proof. The superficial or upper part of veins, or lodes of ore, is always the poorest, the richer ores lying deeper down, the poor ones only serving to lead the way. These poor ores, or lodes impregnated with the metallic matter of the mine, and called by our workmen fford-lodes, were, probably, at the creation of the earth, brought regularly up to the surface, and shewed the place of the metals below. But at the time of the covering of the earth by the waters of the deluge, they were, with the ref of the surface, washed off, and carried with the defcent of the water down into the plains, or into the beds of rivers, and there carried many miles down the stream. This being an allowed truth, the art of training a mine is easy; for though this carrying of the fford-lodes and poor ore was done so many ages ago, yet all the way that fome pieces were carried on, others would be deposited by the way, and the heaviest and richest falling first, the lighteft would always be carried farthest, and there would be always left a fream of the matter all the way from the place where it was first produced, that is, where the mine now is: for the breaking of the furface of the earth at this great catastrophe was not fo deep as to reach that, and this fream or train of matter will be found richer and richer as it approaches the mine, and finally will flop at the place where it is.

Where there is suppos'd to be a mine of any metal, the hills and country all about are diligently searched; the situations and defcent of the lands, and the earth, lones, and other soluble bodies, are examin'd, particularly the colour and nature of the various forts of earths and lones which are found on the hills where the mine is suspefted to lie, that they may be readily known again if any of them are found in the neighbouring valleys. The lones which denote the lodes, and are called fford-lones, are found two, three, four, or even five miles from the hills where they originally lay; but if the fame fort of lones are remembered on the hills, the train is to be made out. After any great land-flood, in which it is suppos'd there are usually some new frets made in the banks of the rivers, these are carefully examin'd, to see whether any metallic lones may be found in their sides and bottoms, all being then so clean, that the smallest fford-lone may usually be seen. If no lones of this kind are found, it sometimes is of ufe, in order to farther researches, to examine whether any pieces of earth, of a different colour and nature from that of the rest of the bank, be found; for these being, if any such are found, washed also from the neighbouring hills, afford a great direction which side of the hill to search into.
If no shoad-stone or grews of a different nature from the
several be found in thee frets or newly worn banks, the miners
leave the place for the present. For though the bed of the
river afford many metalline stones, they never regard them,
the continual change of place they receive from the current
of the water rendering them only tokens that there is metal
somewhere in the country; but they confound and perplex
rather than instruct in the search after the places where
it is.

If there be found indeed stones of the shoad-kind, full of
protuberances, or having sharp angles, as if newly broken,
it may be worth while to see whether they are not washed
out of some part of the neighbouring banks by the late floods;
as this fort of appearance is a token of their having been
newly taken into the bed of the river. But if they are
rounded and smooth, it may be concluded they have been
long subject to the action of the water, and brought, per-
haps, many miles from the places where they were; origin-
ally lodged in the earth, and where only they could have
been of any use to the tracers of the mine.

When the frets in the sides of rivers have been traced in
vein, the searcher after a mine goes up to the sides of the
hills most suspected to have mines in them, and there seeks
for a convenience of bringing a little stream of water to run
down. When this is found, he cuts a trench about two feet
over, and as deep as the shelf. The water is turned into
this cut, and after two or three days running in it, all the
sink will be washed away, and the looe part of the earth
cleared off; and if any shoad-stones are lodged within the
whole course of this cut, they will be found. If any such
are found, it is an unquestionable proof that there is ore in
the higher parts of the hill; this encourages the work, and
there is always a found, or at least a split, which will,
without much danger, repay the expense and trouble. The
fquets are flat parcels of the ore, lying in different and dif-
tinct places of the hills, and not communicating with one
another.

Sometimes a great deal of this labour is saved, and the
shoad-stones are found on the surface of the ground, either
turned up by the plough, or thrown up in small quantities
in mole-hills, or raised by some other accident, for they are
f seldom found naturally lying on the very surface of the
earth; for the putrid remains of vegetable and animal sub-
stances, and other adventitious matter, has raised the
surface of the earth in all places, since the time of the
flood, and made indeed a sort of new surface. These
stones were certainly laid bare on the surface of the ground,
at the time of their being carried down from the mines; but this adventitious matter has buried them in
this long tract of time, and they are generally found under
about a foot or a foot of vegetable mould. If, by any of
these searches, a shoad is found, the miners have nothing to
do but to follow it to its head, and there make the opening;
but if no such direction can be had, nor any shoad found,
and there is yet suspicion that there is a mine in the hill,
the method is to make an effay-hatch, as it is called; this is
funk near the foot or bottom of the hill, and is an opening
of about six feet long, and four feet broad, made in search
of a vein as deep as the shelf; this is a caution that must
be always carefully observed, for if they are made less
than this, they may mislead of the vein, though there is one.

And the sinking thus deep is always attended with certainty,
for if no shoad is found on this, it may be concluded there
is none there; except that sometimes it is found that the
shoad has been washed clean away, within two or three feet
from the land; and then the lode or vein is two feet farther
or thereabouts up in the hill. If any shoad is found in the
effay-hatch, there is a certainty of a vein of ore; neither
doth it add a little toward the making of a conjecture how
high up the hill, or how far off the vein-diring, or bonny, is,
carefully to mark how deep from the surface of the earth
the shoad lies, for this is held an infallible rule, that the
nearer the shoad lies to the shelf, or flat ground, the nearer
the vein itself is, and vice versa.

When there is no shoad or appearance of a mine found in
the first effay-hatch, if the conjecture of a mine being in the
hill has any tolerable foundation, the tracing it does not end
here; but they go ten or twelve fathoms up the hill, and
there open a second effay-hatch, and if no ore or shoad-stone
is found in this, they go as many fathoms on each hand at the
same height with the second hatch, and there open a third
and a fourth hatch, of the same depth and dimensions with
the first; if in neither of these there is found any shoad-
stones, they ascend proportionally with three more hatches,
if the space of ground require, at every ten or twelve fathoms,
and in this manner open them three abreast, at twelve fathoms
distance up to the top of the hill. If no shoad is found in
any of these, it is concluded then that there is no tracing of
a mine there, and the hill is left.

If any shoad is found in any of these hatches or openings,
the ascending hatches from this are kept on in a direct line,
and the deeper the shoad lies the nearer the vein is. The
shoad grows gradually deeper from the surface, but higher the shelf
as they approach the mine: as suppose it to be but half a
foot from the shelf, and fewer feet from the surface, the vein
is then concluded to be within a fathom or two; and on this
the first proportion of twelve fathoms between every hatch is
leffened to fix, four, two, one, or even less than that, as the
vein is conjectured to be more and more near.

It often happens, for want of a good guide in this matter,
that the diggers over-shoot the lode; that is, they open their
next hatch too high up the hill, or above the lode or vein: this
is a mistake easily discovered, and easily rectified. If a
shoad is found lying near the shelf in one hatch, and in the
hatch above there is no shoad at all, it is a proof that the
hatch is too high, and the remedy is only to sink a hatch at
a middle distance between the last two, which will probably
fall upon the very point of the lode, and finish the work of
tracing.

Sometimes it happens, that in continuing the tracing of
the first shoad, a second or new one is found: it is not
uncommon for two hoads to be thus found in one hatch, and
this is easily discovered without any danger of mistake; for
suppose in the last hatch the shoad which they trace lay at
eight feet deep, and in this it lies at ten feet, and besides
this there is a shoad found at two feet depth: it is very certain
that the shoad at ten feet deep is the same they were before
tracing, and this is a new one pointing to another vein or lode,
which is now first discovered to near the surface of the earth.
This has generally gravel or earth mixed with it, and is to be
carefully examined: when the higher hatches are opened, this
is continually found as well as the old lode: and when the
shoad is traced to the point of the vein, this second is to be con-
tinued in the same manner, by other hatches opened at the
same distances above: it often happens, that in tracing this
second lode, the hatches dug for it discover another new
one, or a third shoad; all these are to be traced over the
other by the same hatches, and will all be found worth
the seeking after.

The old writers on mineralogy agree with us in this ob-
servation, and tell us, it is not uncommon in some places
to find as far as seven lodes lying parallel to one another
in the same hill. In these cases, however, there is usually one
master-lode, or a grand vein; the other six, that is, three on
each.
each side, being the lesser or concomitant veins. Five in the same manner sometimes lie in this order, the grand lode in the middle and two on each side; but the more common method is three, a large one, and two smaller.

Every lode has a peculiar coloured earth or gravel about it, which is found also with the shoad, and this always in a greater quantity the nearer the shoad lies to the lode, and becomes lessened by degrees to the distance of about a quarter of a mile, farther than which that peculiar gravel is never found in any quantity with the shoad; so that this is a proof that the lode or vein is near, when it is found in any quantity.

A valley may chance to lie at the foot of three several hills, in such a manner as to contain three several greats, or that earth which was moved with the shoad in the conclosure of the irata at the deluge, with as many different shoads or trains of shoad-lomes in the midst of each; in this case it will be very necessary to know the call of the country, and of each hill in respect to its grewt, for the furter training of them one after another as they lie in order; according to the foregoing rules of efflay-hatching, the uppermost in this cafe always directs which hill to begin with first.

It sometimes happens, that after having trained the shoad found in a valley up to the upper parts of a hill, there is only a squash, or bonny, found instead of a right vein of ore; for these detached parcels of ore have their shoads as well as the right veins. These are usually about two or three fathom long, and a fathom broad, few of them are larger, most least, and they never communicate with any other lode or vein, nor ever fend forth any of their own. The extenuations of these beds of ore terminate without sending out any frings, not lying within walls as the lodes; but though they are in the shelf or fall ground, not moved by the shoad, their surface is equal every where with that of the imaginary shelfy one, and they go down five or six fathoms deep, and there terminate at once. The ore contained in these is rich, and they are always wrought out to the considerable advantage of the owners.

These are the general rules of tracing mines, and though somewhat tedious and expensive, they are certain, and never subject to the error and disappointment the other shorter ways, as they are called, are liable to. These short ways are by the virgula divinatoria, or the hazel-wood, whose bending in certain places without any external visible force, is to point out where the place the vein of ore lies; the waters thought to infuse from the particular lodes, are also used by fome as a short means of finding the veins; other of these ways are also by mineral streams and effluvia, by the barrens of the foil, and the pitching of nocturnal lights on the fupposed orifices of mines. But these methods are too extravagant or too uncertain to be used in cafes of fo much consequence.

Another way of discovering lodes, is by working drifts across the country, as it is called, that is, from north and south, and vice versa.

When the mine is found by the more certain rules of tracing, the digging of it is a matter of less difficulty. Phil. Trans. No. 69. See Mineralogy, and Pryce's Mineral. Cornub. book i. cap. 1.

Training of Cattle, in Agriculture, the practice of taming and breaking in oxen and other neat cattle for the purpose of team-labour. It is performed in many different ways in different districts and places; but principally by first gradually accustoming them to be led by means of a halter or rope, and then usinf them to travel in other forts of teams after the yoke or harnets has been put on and rendered familiar to them; when afterwards they may be wrought in the plough-teams with the old labouring oxen, being placed between them both before and behind, and with such as are not too free workers. See Team, Yoke, and Yoking.

TRAISENDORF, in Geography, a town of Germany, in the principality of Culmbach; 5 miles N.E. of Baveuth.

TRAIT, Fr. Trattus, is the name of an ancient musical character, called likewise in old Latin treatises, plia; which fee.

TRAIT, or Tedia, in Geography, a town of Romania, on the Mariza; 12 miles S.W. of Filippepol.

TRAITOR. See TRAYTOR.

TRAITOR'S Cove, in Geography, a harbour on the west coast of the island of Revilla Gigedo, in the North Pacific ocean; so called by captain Vancouver, from the circumstance of being attacked, and two of his men wounded, by the natives of this place. N. lat. 55° 40'. E. long. 228° 31'.

TRAITOR'S Head, the north-east point of Erromango, one of the New Hebrides, so called by captain Cook in 1774, from the treacherous conduct of its inhabitants. S. lat. 18° 43'. E. long. 160° 28'.

TRAITOR'S Islands, a cluster of small islands, in a bay of the Pacific ocean, on the coast of New Guinea. S. lat. 10' 12'. E. long. 137°.

TRAITOR'S Island, an island in the Pacific ocean, discovered by Le Maire and Schouten in 1616, and so called from an attempt made by the natives to seize the vessel. M. Peroufe discovered this island to be divided into two parts, by a channel about 150 toises wide. It belongs to the Friendly islands, and is called by the natives Neocota-boatboo; 16 miles from mount Cocos. N. lat. 15° 55'. W. long. 173° 48'.

TRAITOR'S Island. See Keppel's Island.

TRAITTE. See Foreign Traitte.

TRALEE, in Geography, a post-town in the county of Kerry, Ireland, pleasantly situated at the bottom of Tralee bay, on the banks of the river Lee. It is the shire and assizes town of the county; was incorporated in 1612 by James 1; and fends one member to the imperial parliament. There were formerly four strong cells erected in this town, of which only one remains, which was the chief residence of the Desmond family, in which they exercised their jurisdiction during the continuance of the Palatinate. Tralee bay is shallow and unsafe, and therefore not much frequented. Near the town is a chalybeate spring, which is drunk medicinally with fascets. Tralee is 144 ½ miles S.W. by W. from Dublin, and 48 S.W. from Limerick.

TRALLEBOURG, a sea-port town of Sweden, in the province of Skone, near the Baltic; 19 miles S. of Lund. N. lat. 55° 20'. E. long. 12° 54'.

TRALLES, Balthasar-Lewis, in Biography, an eminent physician, was born at Brielau in 1708, and having studied medicine at Hall under Frederic Hoffman, settled in his native city, where he gained great reputation. His works were numerous and valuable, and caused him to be admitted into the Imperial Academy at Vienna, and the Royal Society of Berlin. But his most celebrated work was that on opium, entitled "Uetus Opif fiaburis et noxius in Morborum Medela, solidis et certis principiis superfructus," 1757-1762, 2 vols. 4to. He also published a treatise against the materialism of La Mettrie. He declined, in 1767, accepting the offer of first physician at Warsaw to Stanifans, king of Poland, partly on account of his advanced age, and principally from his attachment to the reformed religion. Haller. Eloy.

TRALLIA, called also Troadoidea, in Ancient Geography, a country of Illyria.
TRALLIANUS, in Botany, was so named by Loureiro, from whom alone we have any knowledge of this genus, in memory of Alexander Trallianus, a celebrated physician and naturalist, whose works are said to have been published at Paris in 1543, and republished by Haller in 1743. He wrote a letter on intestinal worms, which is mentioned in Dryander's Bibl. Banks. v. 2. 356; but we find no traces of his botanical information. Loure. Cochin. 157.—Cliffs and order, Pentandria Monogynia. Nat. Ord. Monadelphia. Juff.

Gen. Ch. Cal. Perianth inferior, of five short, rounded, permanent leaves. Cor. Petals five, oblong, spreading, reflexed, longer than the calyx. Nectary large, erect, with ten notches. Stam. Filaments five, short, inserted into the receptacle; anthers roundish, of two cells. Plum. Germ. superior, roundish; style the length of the stamens; stigma (simple?) Pericarp. Berry roundish, of two cells, with two seeds, which are angular on the inside, rounded externally.

1. T. leadiens. Cic. râe of the Cochinchine.—Found running up all kinds of trees in Cochinchina. Stems numerous, thrubby, long, climbing, without thorns or prickles; their branches copious, jointed. Leaves alternate, roundish-heart-shaped, pointed, crenate, smooth. Clusters lateral, forked, each on a long common stalk. Flowers of a whitish green.

TRALLIANUS, in Biography. See Alexander Trallianus.

TRALLICON, in Ancient Geography, a town of Aria Minor, in the vicinity of Caria, watered by the river Harpasus.

TRALLIS, or Tralles, a town of Asia Minor, in the interior of Lydia, which, according to Strabo, was rich and populous, and strongly fortified by nature. According to Plutarch, here was a temple of Victory. The town had been denominated Anthéia, Eunapia, Selicula, and Antiochia.

TRAMOS-MONTES, in Geography. See Tramos-Montes.

TRAM, in the Silk Trade. See Silk.

TRAM-ROAD, the same with Rail-ROAD; which see.

TRAMACASTRE, in Geography, a town of Spain, in Aragon; 12 miles S.S.E. of Albarazin.

TRAMANDI, a town of Brazil, on a river of the same name, which runs into the Atlantic, S. lat. 27° 15'.

TRAMARICUM, in Ancient Geography, a place of Africa Propria, upon the route from Carthage to Alexandria, between Scina and Abydorm. Ant. Itin.

TRAMAYE, in Geography, a town of France, in the department of the Saone and Loire; 9 miles W. of Micon.

TRAMAZA, a town of Sardinia; 8 miles from Oristagui.

TRAMLING of Tin-Ore, among Miners, is the washing of it very clean, which is done with a thovel, and in a frame of boards. See Tin.

TRAMIN, in Geography, a town of the county of Tyrol, on a small river which runs into the Adige, 8 miles S.S.W. of Bolzano.

TRAMIS, a word used by some medical writers, to express the line running along the middle of the scrotum from the penis to the anus.

TRAMMEL, an instrument or device, sometimes of leather, more usually of rope, fitted to a horse's legs, to regulate his motion, and form him to an amble.

It is also taken in many places for an iron moveable instrument in chimneys, to hang pots over the fire.

TRAMMEL-Net, or Tramel, is a long net with which to take fowl by night in champaign countries, much like the net used for the low-bell both in shape, size, and meshes.

The word comes from the French tremail, formed of the Latin tremalum or tremalus; of trees and macula, because it is composed of three rows of meshes.

To use it, they spread it on the ground, to the north or farther end, fitted with small plumbets, may lie loofs thereon; then the other part being borne up by men placed at the fore-ends, it is thus trained along the ground. At each nine are carried great blazing lights, by which the birds are raised; and as they rise under the net, they are taken. See Lark.

TRAMMELLED, in the Muses. A horse is said to be trammelled, that has blazes or white marks upon the fore and hind-foot of one side; as the far foot before and behind. He is so called, from the resemblance the white feet bears to a half-trammel.

TRAMMELLED, Horse, Crest, is one that has white marks in two of his feet that stand crofs-ways, like St. Andrew's cross; as in the far fore-foot and the near hind-foot, or in the near-foot before and the far-foot behind.

TRAMMELS, in Mechanics, an instrument so called by the joiners, and used by them for drawing oval upon boards. One part of it consists of a crofs with two grooves at right angles: the other is a beam carrying two pins which ride in those grooves, and also the describing pencil. All the engines for turning ovals are constructed upon the same principles with the trammels: the only difference is, that in the trammels the board is at rest, and the pencil moves upon it: in the turning engine, the tool, which supplies the place of the pencil, is at rest, and the board moves against it. See a Demonstration of the principal properties of these instruments, by Mr. Ludlam, in Phil. Trans. vol. lxx. part ii. p. 178, &c.

TRAMONNEL, in Geography, a town of France, in the department of Mont Blanc; 14 miles W. of Chambery.

TRAMONTANE, or Tramontane, formed from the Italian trae, of the Latin trans, which signifies beyond; and mons or mont, mountain; something beyond, or on the farther side, the mountains.

The term is particularly applied, by the Italian painters, to all such as live on the other side the Alps, i.e. all out of Italy; as the Germans, Flemish, French, &c.

The French lawyers give the same title of tramontane, or ultramontane doctors, to the Italian canonists, Gomez, Holleinits, Panorm, &c. who go upon rules and maxims too favourable to the court of Rome, and contrary to those of France, &c. On the Mediterranean, and in Italy, a north wind is called tramontane, a tramontane wind.

Some also call the pole-star, tramontana. Hence the proverb, to lost the tramontane; that is, to be out of one's aim, to be disconnected.

TRAMORE, in Geography, a small post-town of the county of Waterford, on a bay of the same name, where there is a very fine ilrand, from which it takes its appellation. It has a handforde market-houfe and assembly-room, and is much frequented for sea-bathing. It is 82 miles S.S.W. from Dublin, and about 6 S. from Waterford.

TRAMUTUL, a town of Naples, in Basilicata; 13 miles S.S.E. of Potenza.

TRANADUCA, in Ancient Geography, a town of Hifpamia, in Bactria, in the country of the Butili, between Mesalia and Barbebola. Ptolemy.

TRANCAULT, in Geography, a town of France, in the department of the Aube; 9 miles S. of Nogent fur Seine.

TRANCHE,
TRANCE, or Trenché, is used by the French armorists, to express that manner of partition called among us, party per bend dexter.

A cantil on is said to be trenched, cut, when it is divided in two diagonally, the division coming from the dexter angle of the chief to the sinister angle of the point. When it is divided contrariwise, it is said to be tailé, or party per bend sinister.

TRANCEFILARE, in the Manze, the cross chain of a bridge, that runs along the bit branch, from one branch to the other.

TRANCOSO, in Geography, a town of Portugal, in the province of Tra-os-Montes. In the beginning of the 12th century, Abacoan, a Moorish king of Badajoz, laid siege to this town, and persevered with great obstinacy, till the inhabitants were driven to the last extremity, but were relieved by King Alphonso Henriques, who defeated the Moors with great slaughter; 9 miles W. of Pinhel.

TRAME, a town of Sweden, in the province of Skone; 9 miles W. of Christianfladt.

TRANEKIAR, an ancient fortress of Denmark, in the island of Langeland.

TRANEMO, a town of Sweden, in the West Gothland; 46 miles E.S.E. of Gothenburg.

TRANENT, a market-town in the presbytery and thire of Haddington, Scotland, is situated on the eastern side of a narrow valley, 10 miles E. from Edinburgh, and 380 miles N. by W. from London. It was anciently called Tree-arnet and Travenent, signifying the habitation in the vale. The church is an ancient incommodeous fabric, of a very peculiar form. On the outside, it appears to consist of three separate oblong houses; but when entered, is found to be only one building. A square tower rises from the centre, supported by the side-walls of the middle building, and by crofs arches. Two weekly markets are well supplied with butcher's meat. The parih of Tranent extends about six miles in length, and three miles in breadth, and is divided by the great east road into two nearly equal parts. It comprizes the villages of Cockenzie, Port Seaton, Seaton, St. Clement's Wells, and Wetter Falside. The surface is level and well cultivated. The coast abounds with oyster-beds, but they are nearly exhausted by over-dredging. Coal is abundant, and is worked at three collieries to a great extent. At Cockenzie is a great manufactory of common salt; and at St. Clement's Wells is the most considerable distillery in Scotland. According to the population return of the year 1811, the inhabitants of this parish were 2036, occupying 640 houses. Here is a parochial school, with a salary to the master of 300 merks and perquisites; here are also seven other schools. After the reformation, the parish of Seaton was annexed to that of Tranent; but it was reduced in 1686, by making the baronies of Preston-Grange and Preston-Pans a new parish, under the name of Preston.

In 1695, the parish of Tranent was further diminished, by the north-east corner of it being annexed to the new parish of Glades-Muir. In 1493, a collegiate church was founded in the village of Seaton, by George, lord Seaton, which is still nearly entire. The most ancient edifice in the parish is that of St. Germans, now the seat of David Anderson, esq., where an hospital was founded previous to the year 1296. It was afterwards poffessed by the Knights Templars; and after its suppression, was granted in 1494, with most of its revenues, by king James IV., to the King's College of Aberdeen. The battle of Preston, in 1745, was fought partly in this parish.—Beauties of Scotland, vol. i. 1805.

Vol. XXXVI.

TRANFRANT, a town of Algiers, near the coast; 30 miles S.W. of Oran.

TRANG, a river of Lower Siam, which runs into the Indian sea, N. lat. 7°. E. long. 9° 33'.

TRANGANO, a town of Asia, in the kingdom of Jore, near the sea, on the side of a river, which has a shallow bar and several rocks scattered about. There are about 1000 houses; 110 miles N. of Pahang. N. lat. 5° 30'. E. long. 103° 5'.

TRANGOAR, a town of Hindooftan, in the county of Cullcut; 8 miles N.E. of Panniary.

TRANGLE, in Heraldry, the diminutive of a felle, commonly called a bar.

TRANI, in Geography, a city of Naples, and capital of the province of Bari; the see of an archbishop, and residence of the governor; 21 miles W. of Bari. N. lat. 41° 19'. E. long. 16° 28'.

TRANKEY, a name given in the island of Carrick, near the Perian shore, to a vessel about the size of a Peter-boat, sharp at both ends. It is built of very rough pieces of wood, rudely put together, and covered over with a thick coat of bitumen, with which the country abounds. These vessels sail with great speed with either end foremost, having no direction of head from stern. The island of Carrick is about twelve miles long and seven broad, and contains between 600 and 700 inhabitants. It abounds with goats, but has very few cows, and no beasts of prey; nor are there any fowls, tame or wild, except fowk and turtle doves. It produces few vegetables, but has wheat, rice, and barley, though not in sufficient quantity for the inhabitants, whose food is fish, with which they are plentifully supplied from the vicinity of the island. Here is also very fine turtle, but not eaten by the natives.

TRANQUEBAR, in Geography, a sea-port town of Hindooftan, in the country of Tanjore, situated on the coast of Coromandel, with a harbour, at the mouth of one of the branches of the Cauvery, defended by a fort, erected by the Danes in the year 1621, who had obtained a grant of the town, and a fertile territory, from the rajah of Tanjore, for an annual rent of about 7201. In the beginning of the present century, the prince of Tanjore attempted to seize on Tranquebar, and began a regular siege; but by the assistance of the English, he was compelled to give over the attempt, and make peace. The town is between two and three miles in circumference, and surrounded with a wall and several bastions, well provided with artillery; within the walls are three Christian churches, one of which is for Roman Catholics, descendants of Portuguese in possession of the town before the Danes; a large mosque for the Mahometans, and several pagodas for the Gentoos. The territory belonging to the town is considerable, and is full of populous villages; 56 miles S. of Pondicherry. N. lat. 11° 1'. E. long. 79° 54'.

TRANQUILLITY, a town of New Jersey; 8 miles S. of Newtown.

TRANQUILLO, a cape at the south end of the island of Rhodes. N. lat. 38° 2'. E. long. 27° 28'.

TRANS, a town of France, in the department of the Ille and Vilaine; 6 miles S.E. of Dole.

TRANSECO, a town of Naples, in Abruzzo Ultra; 8 miles S. of Celano.

TRANSACTION, Transaction, in the Civil Law, an accommodation of some business or dispute between two parties, by a mutual and voluntary agreement or contract between them.

Transactions, Philosophical, are a kind of journal of the
the principal things that come before the Royal Society of London. The Translations contain the several discoveries and histories of nature and art, made by the members of the Society, or communicated by them from their correspondents, with the several experiments, observations, &c. made by them, or transmitted to them, &c.

They were first set on foot in 1663, by Mr. Oldenburg, secretary of the Society, and were continued by him till the year 1674. Upon his death, they were discontinued till January 1678, when Dr. Grew resumed the publication of them, and continued it for the months of December 1678, and January and February 1679, after which they were intermittent till January 1683. During this last interval, they were suppled in some measure by Dr. Hook's Philosophical Collections. They were also interrupted for three years, from December 1687 to January 1691, besides other smaller interruptions amounting to near one year and a half more, before October 1693, since which time the Translations have been regularly carried on.

They were for many years published in numbers, and the printing of them was always, from time to time, the single acts of the respective secretaries, till the year 1732, when the Society thought fit that a committee should be appointed to reconsider the papers read before them, and to select out of them such as they should judge most proper for publication in the future Translations. The members of the council continue a standing committee for this purpose. They meet on the first Thursday of every month, and no less than seven members of the committee (of which number the president, or, in his absence, a vice-president, is always to be one) are allowed to be a quorum, capable of acting in relation to such papers. The question, with regard to the publication of any paper, is always decided by the majority of votes taken by ballot.

They are published annually in two parts, at the expense of the Society, and each fellow is entitled to receive one copy gratis, of every volume published after his admission into the Society.

The Philosophical Translations, to the end of the year 1700, were abridged in three volumes, by Mr. John Lowthorp; those from the year 1700 to 1720 were abridged in two volumes, by Mr. Henry Jones; those from 1719 to 1733 were abridged in two volumes, by Mr. John Eames and Mr. John Martyn. Mr. Martyn continued the abridgment of them from 1732 to 1744, in two volumes; and those from 1743 to 1752, in two volumes.

**Transcellsensis Mons.** In *Ancient Geography*, a mountain of Africa, near the municipality; called by Ammianus Marcellinus, Sugabiraritamus. This town was situated in Mauritania Ccesarea, south of the town of Zucchabari, and near the river Chnalam.

**Transcendent.** Or Transcendental, something raised or elevated beyond other things; or which passes or transcends the nature and circumstances of other inferior beings, so as not to be intimately and essentially included under them.

The term is particularly applied to the object of metaphysics, which considers beings in general, or transcendental beings, as God and angels, and truths consisting in pure speculation.

Logicians and metaphysicians give the name of transcendental to those which are so general, and of a signification so extensive and universal, that they pass through all the categories, and agree to all kinds of things. Such are the terms *re*, *vom*, *verum*, *bonum*, *etc.* See **Ens**, &c.

**Transcendental Art.** See **Art.**

**Transcendental Perfection.** See **Perfection.**

**Transcendental Quantities, among Schoolmen.** See **Quantity.**

**Transcendental Quantities, among Geometrical.** are indeterminate ones; or such as cannot be expressed or fixed to any constant equation. Such is a transcendental curve, or the like.

M. Leibnitz has a dissertation in the *Acta Erud.* Lii. in which he endeavours to shew the origin of such quantities; *viz.* why some problems are neither plain, solid, nor transfigured, nor of any certain degree, but do transcend all algebraical equations.

He also shews how it may be demonstrated without calculation, that an algebraic quadratrix for the circle or hyperbola is impossible: for if such a quadratrix could be found, it would follow, that, by means of it, any angle, ratio, or logarithm, might be divided in a given proportion of one right line to another, and this by one universal construction; and consequently the problem of the section of an angle, or the invention of any number of mean proportional, would be of a certain finite degree.

Whereas the different degrees of algebraical equations, and therefore the problems, understood in general of any number of parts of an angle, or mean proportions, is of an indefinite degree, and transcend all algebraical equations.

**Transcendental Curve.** In the Higher Geometry, is such a one as cannot be defined by any algebraical equation; or of which, when it is expressed by an equation, one of the terms is a variable quantity. See **Curve.**

These curves are the same with what Declarers, and, after his example, several others, call mechanical curves, and which they would have excluded out of geometry; but for Isaac Newton and M. Leibnitz are of another sentiment. For, in effect, in the construction of geometrical problems, one curve is not to be preferred to another, as it is defined by a more simple equation, but as it is more easily described than that other. See **Geometrical Line.**

And some of these transcendental or mechanical curves are found of greater use than all the algebraical ones together, except the circle.

Add, that M. Leibnitz, in the *Acta Erud.* Lii. gives us a kind of transcendental equations, by which these transcendental curves are actually defined, and which are of an indefinite degree; that is, are not always the same in all the points of the curve.

Whereas algebraists use to assume some general letters or numbers of the quantities sought, in these transcendental problems; M. Leibnitz assumes general or indefinite equations for the lines sought; +, +, putting x and y for the absciss and ordinates, the equation he uses for a line sought is

\[ a = b x + c y + d x y + e x + f y, \]

where c = 0. By the help of which indefinite equation, which in reality is finite, for it may always be determined how far farer it is necessary to raise it, he seeks the tangents; and comparing that which results, with the given properties of tangents, he finds the value of the assumed letters a, b, c, and thus defines the equations of the line sought.

If the comparison above mentioned do not proceed, he pronounces the line sought not to be an algebraical, but a transcendental one.

This supposed, he goes on to find the species of transcendence; for some transcendental depend on the general division or section of a ratio, or upon the logarithms, others upon the arcs of a circle, and others on more indefinite and compound inquiries.

Here, therefore, besides the symbols x and y, he assumes a third, as v, which denotes the transcendental quantity; and
and of these three forms a general equation of the line
found, from which he finds the tangent according to the
differential method, which succeeds even in transcendental
quantiies. What he finds he compares with the given prop-
erties of the tangent, and so discovers not only the value of
\(a, b, c, \text{ &c.} \) but also the particular nature of the trans-
cendental quantity.

And though it may sometimes happen that the several
transcendentals are so to be made use of, and thefe of dif-
terent natures, too, one from another; alfo, though there
be transcendentals, or transcendentalts, and a propagation
of these in infinitum; yet we may be fatisfied with the moft
eafy and useful one, and for the moft part may have re-
course to fome peculiar artifices for shortening the calculus,
and reducing the problem to as fimple terms as may be.

This method being applied to the funfines of quadratures,
or to the invention of quadratrices, in which the property
of the tangent is always given, it is manifest not only how
it may be discovered, whether the indefinite quadrature may
be algebraically impossible, but alfo how, when this impos-
fibility is discovered, a transcendental quadratrix may be
found; which is a thing which had not before been known.
So that it fems that geometry is by this method carried in-
finitely beyond the bounds to which Vieta and Descartes
brought it; hence, by this means, a certain and general
analysis is established, which extends to all the problems
which are of no certain degree, and confequently not com-
prehended within algebraical equations.

Again, in order to manage transcendental problems
(wherever the funfines of tangents or quadratures occurs)
by a calculus, there is hardly any that can be imagined
shorter, more advantageous or univerfal, than the differential
calculus, or analysis of indivifibles and infinites.

By this method we may explain the nature of trancen-
dental lines by an equation; e. g. Let \( a \) be the arc of
a circle, and \( x \) the vefted line; then will \( a = \frac{\int f \, dx}{\sqrt{2x - xx}} \):
and if the ordinate of the cycloid be \( y \), then will \( y = \sqrt{2x}
- xx + \frac{\int f \, dx}{\sqrt{2x - xx}} \), which equation perfectly ex-
prefes the relation between the ordinate \( y \) and the abscifs \( x \);
and from it all the properties of the cycloid may be demont-
rated.

Thus is the analytical calculus extended to thofe lines
which have hitherto been excluded, for no other caufe but
that they were thought incapable of it.

TRANSTATION, in Pharmacy, the fame with filtration, or percolation.

TRANSCRIPT, a copy of any original writing, par-
ticularly that of an act, or instrumcnt, inferted in the body
of another.

In this fenfe we fay, transcript of a fine, &c. See Fine
and Duplicate.

TRANSCRIPTIO recognitionis faepe coram judiciaribus
existenatis, &c. in Law, is a writ for certifying a re-
gnizance into chancery, taken before the justice in eyre.

TRANSCRIPTUS pedis finis levati intentandi in cancellarium, is
a writ for certifying the foot of a line leved before juflices
in eyre, &c. into chancery.

TRANSEAT, in the Schools, &c. a term purely Latin,
figurifying, let it pafe, or fuppofe a proportion to be true,
without granting it.

Hence the proverb, tranfeat, Gracum est, non legitur: the
phrase is faid to have taken its rife from fome ancient com-
mentators, or glosfographers of the civil law, who, not
understanding Greek, pafted over all the words that oc-
curred in that language, without explaining them.

In the Roman chancery, a nil tranfeat is a kind of oppo-
mation made to the felling of a bull, or to the delivery of
fome other instrument, till the parties, againft whom it is
directed, have been heard againft it.

TRANSEMENTATION, a change of the ele-
ments or principles of one body into thofe of another.
Such is that which Roman Catholics contend for in the
eucharif, where the elements of bread and wine, they fay,
are changed into thofe of flefh and blood. See Trans-
substantiation.

TRANSEMENTATION, wherever it happens, is always allowed
miraculous, or an effect beyond the ordinary powers of
nature.

TRANSEPT, the crofs aisle, extending from north to
south across the nave and main ailes of our ancient churches.
In foine churches, as in the cathedral of Salifiury, there is
a double tranfept, which makes it refeemble an archiepisco-
pal crofs in its ichnography.

TRANSFER, in Commerce, &c. an act by which a
perfon surrenders his right, interefl, or property, in any
thing moveable or immoveable, to another.

The fafe or donation of an inheritance, &c. transfers the
property, rights, &c. of it.

The term is principally used, in the commerce of flocks,
for the affigning and making over of fubfcriptions or shares
therein to fuch as purcafe them of the proprietors. In the
South Sea Company, the Bank, East India, &c. transfers
are made by entering the flock under the name of the pur-
cafer under his proper letter of the alphabet.

A counterfeit, in this cafe, is by act of parliament made
a capital crime.

TRANSFIGURATION, among Diviners, that mira-
culous change wrought by Jefus Chrift, in prefence of St.
Peter, St. James, and St. John, on mount Thabor,
where he appeared in his glory, in company with Mofes
and Elias. See the defcription of it in St. Matthew,
chap. xvii.

The term is also applied to a fect held in the Romifh
church on the 6th of August, in commemoration of that
miracle.

TRANSFORMATION, a metamorphofis, or change
of form.

The chemifs have been a long time feeking the trans-
formation of metals, that is, their tranformation, or the
manner of changing them into gold.

Among the myafics, by transformation is understood
a change of the contemplative fou\( \text{f, by which it is in some
meafure defignified, or converted into the
fubftance of God, and in which it is, as it were, lost and
swallowed up in the divinity, fo as not to perceive its own
diffinition from God.

The word transformation is very liable to be abused;
but many of the myafics ufe it innocently enough; meaning
no other by it than what St. Paul did, \( \text{Vivo ego, jam non
ego, vivit vero in me Chriftus}. \)

Transformation is also fometimes used for what we
more properly call transubfiantiation.

TRANSFORMATION of Equations, in Algebra, is a method
of changing equations into others of a different form,
but of equal value. This operation is neceffary in order
to prepare equations for a more easy folution. We fafl-fub-
join fome examples of the moft common and ufeful kind
under this head. The affirmative roots of an equation are
changed into negative roots of the fame value, and \( vise
versa \), by only changing the figns of the terms alternately,
beginning with the second.
Thus, the roots of the equation $x^3 - x^3 - 19x^2 + 49x - 30 = 0$, are $-1, +2, +3, -5$; whereas the roots of the same equation having only the signs of the second and fourth terms changed, viz. $x^3 + x^3 - 19x^2 - 49x - 30 = 0$, are $-1, -2, -3, +5$.

If it be required to transform an equation into another that shall have its roots greater or less than the roots of the proposed equation by some given difference, the method is as follows. Let the proposed equation be the cubic $x^3 - p x^2 + q x - r = 0$; and let it be required to transform it into another, whose roots shall be less than the roots of this equation by some given difference ($e$), i.e., suppose $y = x - e$, and consequently $x = y + e$; then, instead of $x$ and its powers, substitute $y + e$ and its powers, there will arise this new equation.

$$(A) y^3 + 3ey^2 + 3e^2y + e^3$$

$${-py^2} - 2pey - pe^2$$

$$+ qy + qe$$

$$= 0;$$

whose roots are less than the roots of the preceding equation by the difference ($e$).

To find an equation whose roots shall be greater than those of the proposed equation by the quantity ($e$), suppose $y = x + e$, and $x = y - e$, and the equation will have this form.

$$(B) y^3 - 3ey^2 + 3e^2y - e^3$$

$$-py^2 + 2pey - pe^2$$

$$+ qy - qe$$

$$= 0.$$  

If the proposed equation be in this form, $x^3 + px^2 + qx + r = 0$, then by supposing $x + e = y$, there will arise an equation agreeing in all respects with the equation (A), but that the second and fourth terms will have contrary signs.

$$(C) y^3 - 3ey^2 + 3e^2y - e^3$$

$$+ py^2 - 2pey + pe^2$$

$$+ qy - qe$$

$$= 0.$$  

By supposing $x - e = y$, there will arise an equation agreeing with (B) in all respects, but that the second and fourth terms will have contrary signs to what they have in (B) as

$$(D) y^3 + 3ey^2 + 3e^2y + e^3$$

$$+ py^2 + 2pey + pe^2$$

$$+ qy + qe$$

$$= 0.$$  

Hence we see how the second or other intermediate term may be taken away out of an equation; for, in the equation (A), whose second term is $3e - p \times y^2$, if we suppose $e = \frac{1}{3}p$, and consequently $3e - e = 0$, the second term will vanish. In the equation (C), whose second term is $-3e + p \times y^2$, supposing $e = \frac{1}{3}p$, the second term also vanishes. But the equation (A) was deduced from $x^3 - px^2 + qx + r = 0$, by supposing $y = x - e$; and the equation (C) was deduced from $x^3 + px^2 + qx + r = 0$, by supposing $y = x + e$; whence may be deduced the following rule for exterminating the second term out of any cubic equation; viz. add to the unknown quantity of the given equation the third part of the coefficient of the second term with its proper signs, viz. $\pm \frac{1}{3}p$, and suppose this aggregate equal to a new unknown quantity $y$. From this value of $y$ find a value of $x$ by transposition, and substitute the value of $x$ and its powers in the given equation, and there will arise a new equation wanting the second term. E.g. Let the equation be $x^3 - 9x^2 + 26x - 34 = 0$; suppose $x - 3 = y$, or $y + 3 = x$, and substituting according to the rule, we shall have,

$$y^3 + 9y^2 + 27y + 27$$

$$- 9y^2 - 54y - 81$$

$$+ 26y + 78$$

$$= 0.$$  

$y^3 - y - 10 = 0 = 0$, an equation wanting the second term.

If the equation proposed be of any number of dimensions ($n$), and the co-efficient of the second term with its sign prefixed be $-p$, then supposing $x - \frac{p}{n} = y$, and $x = y + \frac{p}{n}$, and substituting this value for $x$ in the given equation, there will arise a new equation that shall want the second term; whence the second term may be exterminated out of any given equation by the following rule. Divide the co-efficient of the second term of the proposed equation by the number of dimensions of the equation; and assuming a new unknown quantity $y$, add to it the quotient having its sign changed; then suppose this aggregate equal to $x$, the unknown quantity in the proposed equation; and for $x$ and its powers, substitute the aggregate and its powers, and the new equation will want its second term.

Let the proposed equation be a quadratic, as $x^2 - px + q = 0$, then suppose $u + \frac{p}{2} = y$, and $x = y - \frac{p}{2}$, and substituting this value for $x$, we shall have,

$$y^2 - \frac{p}{2}y + \frac{p^2}{4}$$

$$- py - \frac{p^2}{4}$$

$$+ q.$$  

Having found the value of $y$, that of $x$ may be had by means of $y + \frac{p}{2} = x$; e.g., since $y^2 - q - \frac{p^2}{4} = 0$, $y^2 = \frac{p^2}{4} - q$, and $y = \pm \sqrt{\frac{p^2}{4} - q}$, and therefore $x = y + \frac{p}{2} = \frac{p}{2} + \sqrt{\frac{p^2}{4} - q}$.

If the proposed equation is a biquadratic, as $x^4 - px^3 + qx^2 - rx + s = 0$, then by supposing $x - \frac{1}{2}p = y$, or $x = y + \frac{1}{2}p$, an equation shall arise having no second term. And if the proposed equation is of five dimensions, we must suppose $x = y + \frac{1}{3}p$, &c. It is plain, that in a quadratic equation wanting the second term, there must be one root affirmative and one negative, and these must be equal to one another. In a cubic equation wanting the second term, there must be either two affirmative roots equal, taken together, to a third root which must be positive.

Let an equation $x^2 - px + q x - r = 0$ be proposed, and let it be required to exterminate the third term. By supposing $y = x - e$, the co-efficient of the third term in the equation of $y$ is found (see equation A supra) to be $3e - 2pe + q$. Suppose that co-efficient equal to nothing, and by resolvable the quadratic equation $3e - 2pe + q = 0$, you will find the value of $e$, which substituted for it in the equation $y = x - e$, will shew how to transform the proposed equation into one that shall want the third term.

The quadratic $3e - 2pe + q = 0$, gives $e = p \pm \sqrt{p^2 - 3q}$; so that the proposed cubic will be transformed into an equation
equation wanting the third term, by supposing \( y = x - \frac{\sqrt{p^3 - 3q}}{3} \), or \( y = x - \frac{\sqrt{p^3} - 3q}{3} \).

If the proposed equation is of \( n \) dimensions, the value of \( y \), by which the third term may be taken away, is had by resolving the quadratic equation 
\[
\frac{2b}{n(n-1)} = c, \text{ supposing } p \text{ and } q \text{ to be the co-efficients of the second and third terms of the proposed equation.}
\]
The fourth term of any equation may be taken away by solving a cubic equation, which is the co-efficient of the fourth term in the equation when transformed. The fifth term may be taken away by solving a biquadratic, &c.

There are other transformations of equations that on some occasions are useful. An equation, as \( x^3 - px^2 + qx - r = c \), may be transformed into another that shall have its roots equal to the roots of this equation multiplied by a given quantity, as \( f \), by supposing \( y = fx \), and \( x = \frac{y}{f} \); and substituting this value for \( x \) in the proposed equation, there will arise 
\[
\frac{y^3}{f^3} - \frac{p y^2}{f^2} + \frac{q y}{f} - r = c,
\]
and multiplying all by \( f^3 \), \( y^3 - px^2 + qx - r = f^3 c \), where the co-efficient of the second term of the second proposed equation, multiplied into \( f \), makes the co-efficient of the second term of the transformed equation; and the following co-efficients are produced by the following co-efficients of the proposed equation (as \( a, p, r, &c. \)) multiplied into \( f \) (\( f^3, f^2, f, &c. \)). Therefore, to transform any equation into another whose roots shall be equal to the roots of the proposed equation multiplied by a given quantity \( f \), you need only multiply the terms of the proposed equation, beginning at the second term, by \( f, f^2, f^3, &c. \) and putting \( y \) instead of \( x \), there will arise an equation having its roots equal to the roots of the proposed equation multiplied by \( f \) as required. Let it be required to transform an equation, the highest term of which has a co-efficient different from unity, into one that shall have the co-efficient of the highest term unit. If the equation proposed is \( ax^3 - px^2 + qx - r = c \), then transform it into one whose roots are equal to the roots of the proposed equation, multiplied by \( a \): 
\[
i. e. \text{ supposing } y = ax, \text{ or } x = \frac{y}{a}, \text{ and there will arise } \frac{y^3}{a^3} - \frac{p y^2}{a^2} + \frac{q y}{a} - r = c; \text{ so that } y^3 - px^2 + qx - r a^2 = c; \text{ whence we deduce the following rule; change the unknown quantity } x \text{ into another } y, \text{ prefix no co-efficient to the highest term, pass the second, multiply the following terms, beginning with the third, by } a, a^2, a^3, &c. \text{ the powers of the co-efficient of the highest term of the proposed equation, respectively. Thus, the equation } 3x^3 - 13x^2 + 14x + 16 = c, \text{ is transformed into the equation } y^3 - 13y^2 + 14y + 16 = c, \text{ or } y^3 - 13y^2 + 42x^2 + 144 = c. \text{ Then finding the roots of this equation, it will easily be discovered what are the roots of the proposed equation; since } 3x = y, \text{ or } x = \frac{y}{3}; \text{ and therefore, since one of the values of } y \text{ is } 2, \text{ it follows that one of the values of } x \text{ is } \frac{2}{3}. \text{ By this rule an equation is easily cleared of fractions.}

Suppose the equation proposed is \( \frac{p}{m} x^3 + \frac{q}{m} x - r = c \). Multiply all the terms by the product of the denominator, you find \( mn s x^3 - np x^2 + mbe x - mn r = 0 \). Then transforming the equation into one that shall have unit for the co-efficient of the highest term, you find \( y - n e p x^2 + m^2 n q x - y - m^2 n r = c \). Or, neglecting the denominator of the last term \( c \), you need only multiply all the equation by \( mn, \) which will give 
\[
m s x^3 - np x^2 + m q x - \frac{m n r}{c} = 0, \text{ and then, } y^3
\]
\[
- np x^2 + m^2 n q x - y - \frac{m^2 n r}{c} = 0.
\]
After the values of \( y \) are found, it will be easy to discover the values of \( x \); since, in the first case, \( x = \frac{y}{m n e} \); in the second, \( x = \frac{y}{m n} \).

Sometimes, by these transformations, surds are taken away. E. g. The equation \( x^3 - \frac{x}{2} - \frac{146}{27} = 0 \) is first reduced to this form \( 3x^3 - 4x - \frac{146}{9} = 0 \), and then transformed into \( y^3 - 12y - 146 = 0 \).

An equation, as \( x^3 - px^2 + qx - r = c \), may be transformed into one whose roots shall be the quantities reciprocals of \( x \), by supposing \( y = \frac{1}{x} \), and \( y = \frac{a}{x} \), or by one supposition \( x = \frac{r}{a} \), becomes \( x^3 - q x^2 + p r z - r = c \). By this transformation, the greatest root in the one is transformed into the least root in the other: for since \( x = \frac{1}{y} \), and \( y = \frac{1}{x} \), it is plain that when the value of \( x \) is greatest, the value of \( y \) is least, and conversely. See on this subject Maclaurin's Algebra part ii. chap. iii. iv. Saunderson's Algebra vol. ii. p. 687, &c. See Reduction of Equations.

TRANSFFUGA, in Antiquity, a defector. Among the Romans, defectors were commonly punished by cutting off their hands, it being thought that living in such a miserable truncated condition would strike more terror than death itself. We find, however, that defectors were likewise crucified, burnt alive, thrown from the Tarpeian rock, or exposed to wild beasts at public shows.

TRANSFUSION, TRANSFUSIO, compounded of the preposition trans, beyond, farther, and fundo, pour, the act of pouring a liquor out of one vessel into another.

In the preparations of chemistry and pharmacy there are frequent transfusions of liquors, syrups, &c.
Transfusion of the Blood, in Physiology, the transfer of the blood of one animal into the vascular system of another, by means of a tube connected with a vein of the receiving animal, and an artery of the other. A vein is first opened, to allow the efflux of the animal's own blood, and thus to make room for the fresh supply. This preliminary evacuation produces syncope; the animal ceases to move, and appears dead; but when the end of the tube connected with the artery of the other animal is introduced into the vein, and the stop-cock is turned, the current of arterial blood produces reanimation; the power of motion and the former strength are restored.

The experiments on this subject were first tried in England, where T. Clarke failed in his attempts in the year 1657; Phil. Trans. N° 35. Lower succeeded in 1665, and communicated his success to the Royal Society; Phil. Trans. N° 30. This was on dogs: Th. Coxe did it on pigeons; Birch, vol. ii. p. 50. Coxe and King exhibited the experiment on dogs before the Society, transfusing the blood from vein to vein; ibid. p. 123; Phil. Trans. N° 19, 20. 25. 27. It was again performed from a sheep to a dog; Birch, p. 153; and the experiment was afterwards frequently repeated; Birch, vol. ii. pp. 162. 179. 190. 191. It was also performed in France and other countries.

The first proceedings in this matter seem to have been intrigued merely by curiosity, or at least by a disposition to inquire into the powers of the animal economy. But higher views soon opened themselves: it was conceived that invertebrate diseasés, such as epilepsy, gout, and others, supposing to revive in the blood, might be expelled with that fluid, while, with the blood of a sheep or calf, the health and strength of the animal might be transferred to the patient. The most singular anticipations were indulged on the occasion, and the new process was almost expected to realize the alchemical reveries of an elixir of life and immortality. The experiment was first tried in France, where the blood of a sheep was transfused into the veins of a stupid youth, with the effect, as was asserted, of sharpening his wits. (Phil. Trans. 27. 32.) And a similar experiment was made without injury in a healthy man. (Ibid.) Lower and King transfused blood from a sheep into the siftem of a literary man, who had offered himself for the experiment, at first without inconvenience, but afterwards with a less favourable result; the Royal Society still recommending perseverence in the trials. Birch, vol. ii. pp. 216. 225. 227. 312. Phil. Trans. N° 30.

These events were not calculated to keep up the expectations that had been raised, of brilliant results; and other occurrences produced full more severe disappointment. The French youth first mentioned died languishing soon after the second transfusion: the physicians incurred great disgrace, and were judiciously prosecuted by the relations. (Phil. Trans. 28. 32. 56. 37. 54.) Not however discouraged by this unlucky case, they soon after transfused the blood of a calf into a youth related to the royal family, who died soon after with the intestines inflamed. (Phil. Trans. 28. 30.) The parliament of Paris now interfered, and proscribed the practice. (Du Hamel, Hist. Acad. Reg. Societ. p. 21, 22.) Two persons having died after transfusion at Rome, the pope also issued a prohibitory edict. (Eph. Nat. Cur. Dec. I., ann. 1, ofb. 149. Mercelin de Transfus. San- guinum, p. 253. 83.) From this time the practice has not been repeated in the human subject; although it has been repeatedly done, as a matter of philosophical curiosity, on animals who have suffered no interruption of their health and strength. Haller, Elementa Physeologiae, lib. iii. sect. 3. § 15—29.

Transgression, Transgression, compounded of trans, beyond, and gradire, to go, an offence against some law, or a breach or violation of it. The term is chiefly used in respect of the laws of God. In the doctrine of original sin, all mankind are supposed to share with Adam in the guilt of his first transgression. See Original Sin. Mofes threatens the transgressors of his law with a variety of temporal punishments.

Transgression, in our Law, a writ, usually called a writ, or action of trespass.

Of this Fitzherbert has two sorts; one vicountial, thus called because directed to the sheriff, and not returnable, but to be determined in the country. Its form differs from that of the other, as wanting the words quare et et armis, &c. See Vicountiel.

The other is termed a writ of trespass, and to be filed in the common pleas and king's bench. See Trespass.

Transitory Action. See Action.

Transitory Air. See Air.

Transitory, in lat. 14 Car. II. c. 11. is used for a custom-house warrant, or let pa.s; from the verb transire, I pass forth.

Transit, Transitus, from transire, to pass over, formed of trans and oe, I go beyond, in Astronomy, signifies the passage of any heavenly body over the meridian, or of one body over another having the same apparent declination. When the smaller body is behind the larger, it is said to suffer an occultation; but when it passes before, it is said to transit the other. Thus a star behind the moon suffers an occultation, but a planet passing over the sun's disc is said to transit him.

Mercury and Venus, &c, in their transits over the sun, appear like dark specks. See Meridian and Parallax.

Transit-Instrument, or Transit-Telescope, is an astronomical instrument, by which the transit or meridian passages of the heavenly bodies are taken. Before telescopic sights were introduced into the practice of astronomy, the instruments for finding a meridian line, and for observing meridian passages, were very different from what they are at the present day. So early as about the year 1570, Sir Christopher Wren, Mr. Gray, and Dr. Derham (see Phil. Trans.) had con- trived instruments for this purpose; the last and best of which we shall briefly notice, by way of contrast with the modern transit-instrument, to shew the improvements that have taken place within the last century. In fig. 11. Plate XXXII. of Astronomical Instruments, A B is a horizontal bar of hard wood or metal, turning stifly on the central stem of a tripod, and carrying two upright bars, C D and E F, which are bent a little near the lower extremity, and turned to a right angle at top; where there is a horizontal joint, as seen in the figure. From each of these upright bars is fastened a plumb-line, so as to come close to the ends of the horizontal bar A B respectively. At the ends A and B are two vases, or light-holes, from the former of which the sun, or may be seen through a smoked glass, and from the latter the pole-star, P, with the plumb-line interposed. The portions of the horizontal bar A C and B E are moveable round the joints at C and E, and the plumb-lines are long enough to be tangent to the angles of elevation required to the radius A B, which therefore will be proportional in any given latitude, whatever the dimensions may be. The use of this meridian instrument may be thus explained: when P is the pole-star, the whole instrument must be turned round till the eye at A sees the pole-star very
very nearly in contact with the suspended line; and the con-
tact or biflection may then more conveniently be effected by
turning the vane a little round the joint E: in this situation,
if the bar be at the moment on the true meridian by cal-
culation, the direction of light will be in the meridian line,
and bodies falling to the north, may be seen falling the
plumb-line BF at any altitude below the pole. Suspend
now the plumb-line AD from D, and turn the horizontal
part on its joint, till this line biflects the vane at A, and
move the vane at B gently round its joint E, till it is also
interfected by the other plumb-line DA, and the two lines
will be both suspended in the meridian line; consequently,
and eye looking through the vane at B, will see any body to
the fourth transit the line DA, provided it be below the
ecliptic.

The condition to be attended to in the construction of
a modern transit-instrument is, that while the telescope,
through which the object is viewed, undergoes a change of
elevation, its line of collimation shall move exactly in the
plane of the meridian circle of the place of observation,
after it has been once adjusted accurately into a line that
lies truly parallel with the north and south line. To effect
this purpose, it was found necessary that the axis of motion
should lie exactly horizontal, in the direction of a line that
joins the east and west points; that it should not bend by
the superincumbent weight in any position whatever; and
that the line of collimation should always cut the line of
the axis at right angles, without the least perceptible devia-
tion; for it is only while these conditions are fulfilled, that
the line of collimation will ascend from the horizon in a
true vertical line, during an increase of altitude; and that
this vertical line will continue also in the meridian. The
first perfon, we believe, who used an astronomical instrument
polishing the essential properties which we have described,
was Dr. Halley at Greenwich Observatory, soon after the
year 1719, which was the year in which he succeeded Flam-
stead as astronomer-royal. According to Dr. Smith, the
tube of Halley's telescope was five feet and a half long,
and its axis of motion about an el: it had also cross-hairs
with the requisite adjustments in the piece-eye, with Y sup-
ports for the pivots of the axis, likewise adjustable, and
the axis was levell'd by a spirit-level, so that but little room
remained for subsequent improvement, except in what re-
lates to the achromatic object-glasses, and the method of illu-
minating the hairs, and of limiting the quantity of light
necessary for particular observations. In the older instru-
ments, the reflected light of a lamp or candle was received
at the aperture of the telescope, as shown in fig. 15.
Plate XXIX. of Astronomical Instruments; but this mode
of illuminating the hairs was found inconvenient, on account
of the change of elevation of the telescope in successive
observations, which required as many new adjustments of the
lamp; and it was not till about the year 1787, that Dr.
Uffler of Dublin contrived the new method of transmitting
light through one end of the horizontal axis to a diagonal
perforated reflector, in the body of the tube, which brings
it to the hairs after reflection, whatever the altitude
may be to which the telescope is pointed. In our descrip-
tion of the different transit-instruments, it will not be nec-
ffary to repeat what we have already said of the theory
and construction of either object-glasses or eye-pieces, under our
article Telescope, to which therefore our readers are re-
ferred on these essential points.

Transit-instruments, as they are now constructed, may be
considered either as stationery or portable; the form of which was the original construction, and con-
tinues to be used in fixed observatories, for the purpose of
determining, in conjunction with a good astronomical clock,
the right ascensions of the heavenly bodies; but the latter
may be used in any place, for ascertaining the rate of a
clock or chronometer, and when nicely brought into the
meridian, for determining also the right ascensions with con-
fiderable accuracy.

Fig. 1. Plate XXXII. of Astronomical Instruments, repres-
ents a transit-instrument of the most approved stationery
construction, which may be made of any dimensions that
the aperture and focal length of the object-glasses will allow;
but is usually made with a tube of from 30 to 120 inches
long, and of proportional thicknesses, according to the degree
of accuracy that is required. A and B are either a pair of
solid plates firmly fixed in the ground, or a pair of pillars of
firm masonry, sufficiently high to allow the eye of the ob-
server to reach the eye-piece when the angle of elevation is
about 45°. Fig. 2. exhibits a lateral view of the same,
except that only one of the pillars is seen, in the direction of its
breadth; while fig. 3. is an enlarged representation of the
eye-end of the telescope; and figs. 4. and 5. are appendages
attached to the superior end of the pillars, all which we
shall describe in due succession. The tube of the telescope
ab is usuall'y of bras, of which the eye-end is at a, and the
object-end at b: in the instrument before us it is five feet
long; c and d, which appear to be two cones, are united to
the central part of the tube, and form the axis of motion
about three feet long: they are of bras also, and hollow,
but are rendered very strong by circular pieces of metal,
different diameters, that are forced into the hollow space one
after another at equal intervals: so that this axis has all the
strength without the weight of solid metal. The pivots at
the extreme ends of the axis are of bell-metal, and turned in
the lathe to precisely the same dimensions, so that they may
at any time have their positions reversed without affecting
the horizontal line. The pieces, shown by figs. 4 and 5, are
made fast to the upper extremities of the pillars, and receive
the pivots of the axis, each having an angular notch, called a
Y, which are adjusable by proper screws, one in a vertical,
and the other in a horizontal direction. The situation of
each of these screws is seen by the handle inferred on the
axis of the screw to which it belongs; and the manner
in which the moving parts are made to slide by the action
of the screws, between the parallel checks of the small frames,
requires no particular description. When the weight of the
telecope and of its axis is considerable, some part of this
weight is supported by a loaded lever, as seen in
fig. 1, which, by acting on the ponderous matter at some distance
from the pivots, relieves them from a portion of the stress
that would otherwise be laid on them by the whole weight.
Hence the pivots have their friction diminished; and conse-
quentlv their dimensions, as well as those of the Ys, remain
unaltered. When the weight is small, such appendage may
be dispensed with, provided the Ys and pivots be rectified
occasionally, when they are a little altered by attrition.
At a small distance from one end of the axis a graduated
circle is made fall, which moving with the axis, shows the
degree and minute of elevation, that the telescope has in any
position, on two opposite adjustable verniers, which carry a
spirit-level, and are clamped in a horizontal position, as seen
in fig. 2. The extreme end of the axis, which is remote
from the graduated circle, has a lens screwed into it, through
which the light of a lamp is made to pass in its way to the
diagonal reflector, contained between the two conical por-
tions of the axis, within the tube; and by the light thus
transmitted and reflected, the spider's lines, substituted for
hairs or wires, are illuminated; without which illumination
they would be invisible by night, except when the Moon or
Venus
VENUS is observed. The spirit-level, which hangs on two
vertical rods over the axis, is capable of being reversed in
position, and is used, in the first place, for placing the axis
of the telescope perfectly horizontal, and in the next, for
watching the permanence of such position by the situation
of its bubble. As the ends of the brass tube that contains
the level revolve on two opposite pins, projecting from the
rods of suspension respectively, the bubble will always oc-
cupy the upper part of the glass tube every state of the
telescope’s elevation; but in the reversed position of the
axis \( \varepsilon \), the level will be underneath it, though the bubble
will retain its place. The inside of the tube is ground to such
a long radius, that single seconds of deviation from a true
horizontal position may be read on an ivory scale by the
end of the bubble. When, however, the telescope is large,
and the axis consequently bulky, a spirit-level cannot be so
well applied, as with telescopes of ordinary size; and when
this is the case, a bason of pure mercury may be substituted
with great advantage: for when the pole-star is on the mer-
idian, and shines brightly, its reflected image, and also the
star itself, will both pass together over the central vertical
axis of the spider’s line, at corresponding degrees of elevation
and depression of the telescope, provided the axis be truly hori-
zontal, and as little time as possible be suffered to elapse
between the superior and inferior observations: but to render
this operation easy, stops may be clamped to the
graduated circle, to limit the space that is necessary to be
described by the object-end of the telescope. There is in
the instrument before us, moreover, a plumb-line apparatus
for levelling the axis, which is seen in fig. 2, and partially
on a larger scale in fig. 3. At \( a \) is a pin, from which a fine
silver wire may be suspended: and at \( e \) is a horizontal screw,
between two threads of which the wire rests, so as to be
able of adjustment in a latitudinal direction: the long narrow
tube, which lies parallel with the main tube of the tele-
scope, then receives the wire, and is put into a perpendicular
direction, so that the suspended plummet may be immersed
in a vessel of water; the microscope at \( j \) next the eye-piece,
now uppermost, views the image of a transparent dot, as a
point to which the wire is referred, and to cover which it is
brought by the screw \( e \); at the opposite end of the main tube,
are \( \delta \), is a similar microscope with a point of suspension
and adjusting screw; so that when the object-end of the tele-
scope is placed uppermost, the same adjustment is required
to bring the stretched wire over its luminous image; and when
this is done, the wire will bifurcate the lower luminous image
also, if the axis be perfectly level, but not otherwise. To
produce this coincidence, it will usually be necessary to ad-
just partly by the vertical screw of the proper \( Y \), and partly
by the screws of the plumb-line apparatus after each inver-
tion of the tube.

When the achromatic object-glasses does not produce a
round and well-defined point, as the image of a large star,
in any observation, it will be advantageous to diminish
the aperture till this appearance takes place, which will gen-
erally be the case when the central part of the object-glass
only transmits the light of such a star; but for small stars,
it will always be better to allow the whole aperture to be
open; not only because more light is thus admitted, but
also because the image of a small star is always a point free
from luminous irradiations, even in inferior achromatic tele-
scopes. Is the ten-feet telescope which Mr. Troughton has
 lately converted into a magnificent transit-instrument at
Greenwich (vis. in 1816), he has ingeniously contrived a
species of iris, that will contract or enlarge the effective part
of the aperture by the simple turning of a milled out, within
reach of the hand, while the eye is at its place for making
the observation; so that the proper quantity of light can
at any time be proportioned to what the nature of the ob-
ervation may require. There are fatal screws of adjust-
ment of the spider’s lines in the eye-piece both for horizontal
and vertical motion, and, in the best instruments, the eye-piece
itself has a sliding horizontal motion, which enables the ob-
server to keep the celestial body, though in motion, at the centre
of the field of view during the whole passage over the five
lines.

The best construction of a portable transit-instrument which
we have yet seen, is that represented by figs. 6 and 7, which
exhibit all the parts that are necessary for description,
and which was one of the numerous inventions which we have
had occasion to notice as the offspring of Troughton’s in-
genuity. The telescope of this instrument is 20 inches
long, and magnifies from 20 to 35 times, according to the
eye-pieces that are used; two of which are usually of the
prismatic or diagonal kind, to be used in high altitudes;
the aperture is 1.75 inch, and the power is competent to
see the pole-star by clear day-light. The construction of
the tube and axis is similar to that of the stationary instru-
ment, except that the graduated circle and double vernier,
with the level, lie beyond the \( Y \) of the support, and the iris
is wanting: otherwise it has all the adjustments for levelling
the axis, and bringing the line of collimation to a meridian
mark that the larger instrument possesses, as well as those
that rectify the position of the spider’s lines in the focus of
the negative eye-piece. The base of the stand is a thick
ring or rim of brass, that receives three equi-distant screws
for feet, besides the four screws that fix the two vertical
frames thereto, which constitute the supports of the axis;
one of which is seen entire in fig. 7. These supports are
kept perpendicular by the interior brassing-bars, of which
two are discoverable in fig. 6, attached by thumb-screws
at both ends to the ring and upright frames respectively.
The circular figure of the base is not only firm, but preserves
its shape in all degrees of temperature; and when the parts
are detached by loosening the thumb-screws, they will all pack
into a box that is of a convenient size for carriage. The
diameter of the circular base, and the consequent length
of the axis, is a foot within, and the height of the supports
thirteen inches. The graduated circle being of six inches dia-
meter, admits of readings by each of the two opposite verniers
to the accuracy of one minute, which is sufficient for finding
the meridian altitude of any celestial body, of which the de-
cision is known when the latitude is given; or for deter-
mining the latitude, when unknown, to the accuracy of one
minute. If the circle were made a little larger, and three
verniers substituted for two, a larger level might be used,
and the readings might be accurate to 20" or 25"; but as the
instrument was never meant to be used as an altitude-instru-
mament, the inventor considered only what dimensions are re-
quisite for constituting an useful transit-instrument in a port-
able form. The level of this instrument is entirely detached,
and equal in length to the axis itself; its shape is delineated
in the upper part of fig. 9, and the notches of its end-pieces
stand upon the pivots of the axis, so that the revolution of
the ends is performed without the least impediment. It is
however necessary to remove the level from the axis, when
the horizontal adjustment is finished, to avoid its being dis-
placed and broken by an alteration in the elevation of the
telecope. There are usually three studs of brass included
with the darkening-glasses, lantern, and other appendages;
two of which studs have conical holes, to receive the points
of the screws, or feet of the circular base: and for this pur-
pose, all the studs must be made fast to the slab or pillar
which supports the instrument, by plaster of Paris or putty
inferred into as many holes in the plate of the marble or
flour,
TRANSIT-INSTRUMENT.

None, care being taken that the line which joins the two conical points be in the direction of the meridian, or fo nearly so, that the adjufting screw of one of the Y's will bring it into that situation.

Mr. Thomas Jones, of Charing-Crofts, has made several 30 and 42-inch transit-instruments of the portable fort, supported by oblong frames of cast-iron, which look very neat, and

answer the purpose very well, a drawing of which construction we should have introduced into our plate, if it would have admitted of such addition. These instruments have all the properties of the instrument we last described, and have of course greater powers in their telescopes, and are also cheaper in proportion to their size. He has also made some of them with telescopes of only twenty inches, for the sake of greater portability.

Before any useful observation can be made with a transit-instrument of either the stationary or portable construction, it is necessary that all the adjustments be nicely made, and also that they be examined occasionally after a few observations are finished, in order to prevent errors which cannot be detected, or at least appreciated, at a subflece period. These adjustments are nearly the same for all the common transit-instruments, and may be explained under eight heads, as follow: viz.

1. To adjust the Spirit-Level.—When the level hangs on, or is made fast to the axis, put the telescope in its place, and see to which end of the level the bubble runs, which will always be the more elevated end; bring it back to the middle by the Y screw for vertical motion, or by the foot-screw under the end of the axis, if it be a portable instrument, and then invert the axis, end for end; then, if the bubble is again found in the middle, the level is already parallel to the axis; but if not, adjust one half of the error by the adjufting-screw of the level, and the other half by the Y screw, or foot of the support, as the case may be; and let the operation of reversing and adjusting by halves be repeated, until the bubble will remain stationary in either position of the axis, in which case the level will be right. When the detached level is used, that notch must be made a little deeper, by scraping with a penknife, which has the bubble refting over it, instead of wing an adjufting-screw, with which it is not usually provided; and when the notches that rest on the pivots are once made right, they will seldom require a second rectification. In the hanging level there are five-screws also, which adjust for parallelism of the level, as it regards a line joining the pivots of the telescope's axis; and this adjustment is known to be truly made, when the bubble does not run to one end, when the level is moved some degrees by a rotatory motion round its pivots, or central pins of suspension.

2. To place the Axis of the Telescope truly horizontal.—If the spirit-level is made use of, which is generally the cafe in instruments of ordinary dimensions, the fame operation which we have juft described will put the axis level, at the fame time that it puts the level parallel to the axis; for unless both these conditions are fulfilled, the adjuftment of the level will be deranged by reversion, and when this is not the case, it is a proof that both the level and the axis are truly horizontal. Hence, when the level is previously adjufted, it will be sufficient to bring the bubble to the middle of the level by the Y screw, or foot-screw alone, as the conftuction may require.

This adjuftment may also be made, in the larger instruments particularly, by means of a plumb-line, either applied to a frame, suspended by the pivots of the axis, that will reverse in position according to Ramfden's method; or hang-

ing on the tube of the telescope parallel to the line of collimation, as we have described Troughton's in figs. 2 and 3: in either cafe, a dot is bifected by the plumb-line near the point of suspension, and another near the lower end of the line, in both the reversed positions of the axis, when the adjuftment is truly made by the proper screws, as above directed.

But the moft accurate, as well as probably the moft convenient method of levelling the axis of a large instrument, is by reflection, by the aid of a bafon of pure quicksilver, as we have already intimated; and the pole-flar, being flow in its apparent motion, particularly at the time of its greatest elongation, is the moft proper object by which to make the adjuftment in question; for when the axis is level, and the flar is made to cover any one of the spiders' lines, its image reflected from the surface of the mercury will cover the same line, provided the depression of the telescope is effected instantaneously; and if this is not the cafe, the proper screws must be used for effecting this purpose without any reversion of the axis; for by this experiment, the line of flight of the telescope is proved to have a motion truly vertical, which is what the horizontal position of the axis is intended to produce.

Hence, if the exact coincidence of the places of the star and of its reflected image takes place in an instrument both before and after the reversion of its axis, this is a proof that both the pivots and Y's are respectively similar. This method of adjufting the axis of the large transit-instrument at Greenwich has been lately adopted, after a trial had been made by the astronomer-royal, of the application of a plumb-line, suspended in a detached flate from a point of considerable elevation.

3. To produce distinct Vision.—Before the subsequent adjustments can be made, it is necessary that the telescope should be put into a state of perfect vision; viz. that the object fixed upon should be seen well defined. This may be accomplished by sliding either the object-glafs or the eye-piece within the tube, till the desired effect is produced; but when wires, hairs, or lines of any kind are made fast in the common focus of these glafses, a motion given to the eye-piece will make those lines disappear, and a motion given to the object-glafs is in danger of deranging its best position; therefore, when a meridian mark is necessarily at so short a distance, that the same adjuftment of the eye-piece will not suit it that has been made for a celestial object, by which the parallel lines have been fixed in the focus, an auxiliary object-glafs, or glafs of long focus to be added to the proper object-glafs, is provided to remedy these inconveniences, whenever the meridian mark is the object viewed. The method of determining the focus of such additional glaftes, as shall shorten the compound focus of the object-glafs agreeably to what is requisite for a given distance, is explained under our article Telescope.

4. To put the Wires, Hairs, or Spider's Lines perpendicular to the Axis.—The parallel lines in the eye-piece of the telescope are usually attached to a circular piece of brass that turns tight within the interior end of the tube, and if, when the telescope changes its elevation, a point in the meridian, or other mark, travels along one of these lines, so as to be bifoected by it through the whole field of view, the said line will be perpendicular to the axis of motion; or if a long plumb-line be suspended at a distance, and a vertical line in the eye-piece is found to coincide with it while the telescope alters its angle of elevation, this will not only be a proof of the same thing, but will moreover, show that the axis is level; and when this is not the case, the piece holding the lines must be turned till they are found by trial to be truly vertical. The similarity of the intervals between the lines, and
also the angle measured by each, may be ascertained by a graduated staff, and the tables which we published under Telescope.

5. To make the Line of Collimation perpendicular to the Axis. — After having adjusted for distinct vision to some distant known object, make the middle line in the eye-piece biflect some well-defined point in it, and, having reversed the ends of the axis, observe if the same line again biflects the same point exactly; if it does, the line of collimation is right; but if not, the error may arise either from the situation of the point observed, or of the centre of the object-glass, as they respectively regard the vertical line in the eye-piece; that is, one or other of those lines may deviate a little from a true perpendicular to the line of the axis of motion, or both may be erroneous in their respective degrees; therefore, when revision has taken place, bring the vertical line one half way towards coincidence with the observed point, by the horizontal screw at the end of the axis, which alters the azimuth, and the other half by the side-screws of the eye-piece, which move the plate of the parallel lines, releasing one screw and tightening the other, so as to leave the said plate flat; then reverse again, and repeat the operation, till the same point is biflected in both positions of the axis.

6. To illumine the Wires, Hair, or Spider's Lines. — Before an observation of a star or planet can be taken, the parallel lines must be rendered visible to the eye of the observer, and the quantity of light to be admitted will depend on the magnitude of the body to be observed. A lantern containing a lamp must be fixed opposite that end of the axis which has its aperture closed by a lens, and so much of the light must be excluded as is superfluous for the observation; for when a small star is the object, much light will render it invisible, and yet it is necessary to have light enough to render the parallel lines visible; hence observations on very small stars require management of the quantity, and sometimes of the quality too of the extraneous light; on which account prisms of different coloured glass have been interposed between the lamp and the end of the axis, with sliding motions, to produce various modifications in the illumination, according to the exigencies of the moment.

7. To adjust the horizontal Wire or Hair for taking Altitudes. — When the altitude of an object is to be accurately taken, bring the bubble of the double vernier to the middle of the level, and turn the telescope on its axis of motion, till vernier 1 has its zero at 0 in the circle, or at 90°, if the circle is graduated for zenithal distances, as is mostly the case; then notice what distant point is cut by the horizontal wire; reverse then the axis, and biflect the same point again, and in this situation see what quantity is read by the same vernier; or, which will be still better, half the sum of the readings of both verniers; and may be read at both times, and the difference of the two average readings may be considerable; then one half of this difference, + or —, is the real error of each observation, accordingly as the axis is situated in position; and if this error is not obviated by a proper adjustment, it must be allowed for in the reading of every observation. But this error may be owing partly to the unadjusted state of the vernier level, and partly to the situation which the horizontal wire occupies in the eye-piece; therefore the screws which elevate and depress the horizontal wire, which, however, are not in all instruments, may correct one half of the error, and the screws of the vernier level the other, in each reversed position till the error disappears; i. e. till there is no difference perceived in altitudes of the same object taken in reversed positions of the axis of the telescope’s motion. But it is usual with astronomers, who take altitudes in reversed positions of a circle, to ascertain the error arising from want of true collimation in altitude, from a repetition of observations, and to apply it to each observation as a correction, rather than attempt an exact adjustment in this respect, when the error is incon siderable.

8. To make the Line of Collimation move in the Plane of the Meridian. — In order to fix a transit-instrument well in the meridian of any given place, it is necessary that the polar star be exposed to its view; as the polar point is situated in the centre of its diurnal circle, this circle must be biflected by the middle wire, or spider’s line, that passes through the zenith, before it will move in the plane of the true meridian. Formerly it was usual to place the instrument, by double altitudes of the sun, or by a knowledge of the solar time gained by observation of its altitude on a given day, nearly in the meridian of the place, and then to observe which of the two semicircles, to the right and left of the approximate meridian line, were passed through in the shorter time, by means of taking both the upper and lower transits of the pole-star successively; after which an allowance was made for the deviation from the meridian, and the observations were repeated till both semicircles were performed in the same time. But by this method of finding the centre of the circle surrounding the pole, the accuracy of the result depended on the rate of the clock that was used, during the whole time that the successive observations were employed; consequently some uncertainty remained as to the comparative times intervening between the successive transits, and the true polar point was, therefore, not easily ascertained: but this difficulty has recently been obviated by fixing on two stars nearly at opposite sides of the circle, so that their difference of right ascension may be very nearly 18°; for, when the two semicircles are alike, the time that elapses between the superior transit of one, and the inferior one of the other, will not be altered by a change of situation; the difference of the times will remain the same, whichever of the two stars makes the upper transit; but if the semicircles are unequal, the intervals of time will differ accordingly; so that if one star precede the other two minutes at its upper transit, and only one at its lower, half of this quantity will be the time corresponding to the deviation in position from the true meridian, which may be rectified by repeated observations of the short intervals, according to which the two stars follow one another, in transiting first above and then below the pole respectively; and all that the clock has to do, according to this method, is to count the seconds in each of those short intervals. When an instrument that is adjusted to have its line of collimation pass through the zenith by means of the horizontal position of its axis of motion, is thus made to biflect a polar circle, it will also pass through the pole, and will consequently move in the plane of the true meridian of the place. Various other methods of placing a common transit-instrument truly in the meridian have been recommended, but this is not only the easiest, but the best; and if the right ascensions of Dr. Maskelyne’s or Mr. Pond’s stars come right, when observed after the final verification, it may safely be concluded that the position of the instrument is in the true meridian.

When a transit-instrument is well constructed, and properly adjusted in all respects, it is one of the most useful instruments in astronomy; for without it the right ascensions of the heavenly bodies would not be accurately taken by direct observation, neither could the time, either solar or sidereal, be ascertained with that degree of precision which
TRANSIT-INSTRUMENT.

may be done by its aid. Indeed a perfect transit-instrument and a good sidereal clock are the indispensible furniture of every fixed observatory, and as companions, that mutually assist each other, they ought never to be separated.

We might now proceed to illustrate the use of the transit-instrument by real examples in practice, if we had not anticipated this part of our article under the heads ASCENSION and CHRONOMETER; in one or other of which articles we have explained both the method of determining the right ascension of any body, and also of ascertaining, without much calculation, the rate of a chronometer or astronomical clock. See the respective problems under CHRONOMETER.

The transit-instruments which we have above described are necessarily expensive, even in the portable form; and encouragement has been held out, by the Adelphi Society, for further improvements in the portable kind, so that they may become more common. And the frequent enquiries that have been made for a cheap portable instrument, induced Mr. H. C. Englefield, bart. to contrive a very simple one, which was first made by Mr. Thomas Jones, mathematical instrument-maker in London, and is now sold at his house at Charing-Cross. A description of this instrument, called a side transit-instrument, written by the contriver, is fold along with it, from which it appears, that it is not to be considered an original instrument, but an improvement on an old transit-instrument formerly belonging to Mr. Aubert, and purchased at his sale by the late Mr. W. Walker. We propose to copy the description nearly as it has been published, "It is well known," says the ingenious author, "that the transit-instrument, in its usual form, is liable to great injuries from blows, or other violence affecting the perpendicularity of the telescope to the axis; that it necessarily takes up much room in package; that, unless of a very small size, it is not easily fixed in a window or other opening in a common dwelling-house; and that it is quite impossible, except in fixed observations, to make it sweep the entire arc between the southern and northern points of the horizon. In windy weather its use is also very difficult and inconvenient. In the instrument now offered, all these inconveniences are avoided. It may be fixed almost anywhere; in many places it may be made to describe the entire semicircle of the meridian; the observer is put to no difficulties by change of place, as he always looks directly along the axis; it is packed in one-eighth of the space requisite to pack a common transit-instrument of the same real size; its weight is not more than a sixth of the other; from its simplicity it will be afforded at half the price; and its vernier and adjustments are easy and simple. It has also another advantage, that the mark by which it is placed in the meridian may be either in the meridian or at right angles to it; or, if convenient, two marks may be erected, one to the fourth or north, the other east or west; and if so fixed, it will be always seen, by inspection only, whether the mirror needs adjustment or not. In many confined situations, such as occur in cities, the power of having a mark at right angles to the meridian may be eminently useful. The general description of the instrument is as follows: The telescope is included in a brass cylinder, having a small cylinder at each end, turned true in the usual manner, and resting in Ys of the usual construction. These smaller cylinders are both pierced. In one is the eye-piece of the telescope, with its wires, &c. The other is open, for the purpose of seeing through it, if necessary, the eastern or western mark; and for adjusting by direct vision the line of collimation of the instrument. It also serves for the illumination of the wires. The object-glass of the telescope is placed to near this cylinder, as only to allow room for an unsilvered plane glass mirror to be placed before it at an angle of 45°. It is obvious, that as the telescope revolves on its axis in the Ys, every celestial object at right angles to it may successively be seen by reflection from the mirror; and of course, if the axis be placed due east and west, the transits of all celestial bodies over the meridian will be observed with the utmost accuracy and convenience. The aperture in the axis beyond the object-glass is not only of use for the adjustment of the instrument to an eastern or western mark, or for the illumination of the wires, but affords a means of seeing the mark at the same time with the body whole meridian passage is to be observed, and of thereby being certain of the true adjustments of the instrument at the very moment of observation; which is impossible in any other construction of the transit-instrument, and feems to be a very material advantage. I am convinced that transit-instruments of the largest size might, with very great advantage, be constructed on this principle. It is true, that where very much light is wanted, as in observations of stars in the day-time, the losses by reflection will be some disadvantage; but the losses of light from an unsilvered mirror is very small: and the convenient and simple form of the instrument; by its lightness less subject to flexure; by its position much less liable to errors from unequal change of temperature; and fo extremely commodious in its use; present advantages of a very important nature, and such as might introduce it into the most extensive observatories with profit. The advantages may perhaps be even greater than in small transit-instruments. When in the present construction the telescope is long, as its whole weight rests on the most disadvantageous part of the axis, this is of necessity made very large towards its centre, to avoid flexure; and the whole instrument is so heavy, that an additional apparatus of counterpoise must be added to the pivots, lest they should wear away the Ys, and the reverting the instrument becomes a work of some difficulty and danger: whereas in the construction propounded, the small comparative weight of the object-glasses and eye-glasses lies very near the pivots, and the middle of the tube is the lightest part of it. The operation of reverting is performed with great ease, both from the form and lightness of the instrument; and it may be added, that the comparative facility of observations is of greater advantage the larger the instrument. Having so far explained the general principles of this transit-telescope, which was executed very much to my satisfaction by Mr. Thomas Jones, it will be proper to describe more particularly its construction. The transit-stand is represented by either the upper or lower part of fig. 10.

The first is constructed for being placed or fixed on a vertical surface; the second for a horizontal one, A B; in both are the Ys, or supports for receiving the axis of the telescope. The end A, intended to be always next the eye, is furnished with both the horizontal and vertical adjustments, such as are usual to transit-instruments. The telescope's axis is represented by the lower part of fig. 9. The eye-end being at C, the object-end at D turns round in the Ys; A B upon its cyliners n, n: the screw-head r, at the object-end D, is for the purpose of adjusting the parallel glafs. The telescope is adjusted to distinct vision by means of the head or knob at P. The wires of the telescope are adjusted by means of the four capstan head-screws at the eye-end t t. The circle R is divided on the surface next to the eye. The eye-tube has a sliding motion for viewing the wires distinctly; the short piece of tube at the object-end turns round on the telescope's tube, and serves as a cover for the object-glafs. The upper part of fig. 9 is the riding level, and is placed upon the axis in the Ys, and ad-
justed by means of the screw S. Fig. 8. represents the stand, telescope, and level, displaying the position in which they are used; fig. 12, for placing the transit in the meridian. Of the verifications of this instrument, two are common to every construction; one only is peculiar to this. The line of collimation is adjusted by looking directly at some distant small point (the cover being turned over the lateral aperture), and turning the telescope gradually round on its axis, and moving the screw of the wires, if necessary, till the spot is in every position covered by the intersection of the wires. The axis is brought to a horizontal position, and the level is in the same mode adjusted by reversing the telescope or level, and correcting half the error by the level-screw, and half by the vertical screw of the Y, in the usual mode. The verification peculiar to this instrument is that of the mirror, and perhaps the best mode of doing this is by the pole-star, when nearly in an eastern or western position from the pole; its motion in azimuth is then so slow as to give ample time for the adjustment. Bring the pole-star to the vertical wire (the line of collimation having been previously adjusted); then reverse the telescope in its Y's; and if the star is still on the wire, the mirror is in adjustment: if not, correct half the difference by the mirror-screw, and half by the horizontal of the Y, till the error vanishes. This adjustment may also be performed, by setting up a board with two parallel perpendicular lines drawn on it, distant from each other exactly the space between the positions of the mirror when the telescope is reversed in its Y's. If the vertical wire be brought to cover one of the marks, and on being reversed, the wire covers the other mark, it is right: if not, the error must be made to vanish by correcting it half and half, as before directed, for the adjustment by the pole-star. The following method of placing the instrument correctly in the meridian, is equal if not superior to any that has yet been devised. Let Z (fig. 12,) be the zenith; P, the pole; H O, the horizon; Z P I, the meridian circle; Z K, a circle of altitude, distant from the meridian by a small quantity I K (suppose a degree); 1, 2, 3, 4, the diurnal circle of the pole-star, whose radius is 1° 45' nearly; and let the altitude of the pole be 51° 30'. Then when the pole-star is on the northern meridian, its altitude 3 I will be 49° 43', and its zenith distance Z 3 = 40° 15'; and A C D be a part of the diurnal arc of a star whose polar distance is 46° 30', and N. meridian altitude 50°. Now suppose the transit-instrument, whose axis is accurately levelled, and of course in the meridian at Z, to point at the horizon to K (it is obvious from its construction the telescope's axis will be at right angles to the meridian line) instead of I, the true meridian; then at 3 (the altitude of the pole-star under the pole) it will point at B, and the arc 3 B will be to I K, as the cosine of the altitude 3 I to radius; but 3 B, measured on the diurnal circle of the pole-star, will be the line of its distance from the meridian to the radius P 3 or P B: and, as in small arcs, the arc of a great circle, or of a small circle, or of their lines, are nearly coincident, we shall have very nearly, as Z 3 (the zenith distance) is to P 3 (the polar distance), so is the value of 3 B, in degrees of the pole-circle, to its value in degrees of a circle whose radius is Z 3. As and the radius Z 3 is to P 3 very nearly as 23 to I, the error of the transt telecope at the altitude 3 I, will be measured by a scale (if it may be so called) 23 times as great as itself. Now, let there be another star A, whose northern meridian altitude is as small as it conveniently can be, for example 3°, whose polar distance is, therefore, 46° 30', and whose right ascension is the same as that of the polar star; then, if the transit-telecope be in the meridian, both these stars will pass through it at the same time; but if it be out of the meridian by the quantity I K, the star A will pass through it when it comes to C, but the polar star not till it comes to B, when the star A has got to D, in its diurnal circle. The value of A C being therefore found, by multiplying I K by the cosine of its altitude A I, that value, being reduced to the angular value from the radius P A, will give the time of the star A passing through the transit telescope, after the time of its passing the meridian; and the fame operation being performed for the pole-star as before directed, the difference of these times will be the error in time of the transt, answering to the given deviation I K of the transit-telescope. And tables having been previously constructed for such stars as shall be thought convenient, the transit-telecope may, in a very short space of time, be let to the meridian, with a degree of precision unattainable by any other method. If the star A precedes the pole-star in its passage under the pole, no tables are requisite, nor any thing necessary to be known but the exact difference of the right ascension between the two stars; for having observed the transt of the star A, (the instrument being previously brought near the meridian, suppose half a degree,) then elevate the telescope to the pole-star, by moving the horizontal adjustment of the axis; keep the pole-star on the middle wire, till the due interval of time between their transit is elapsed; the instrument will then be extremely near its true position; and, by repeating the observation once more, will be brought to a perfect exactness. Or, if another star, following the pole-star in its passage, be observed on the fame evening, if the times elapsed between their transits are equal to the tabular difference or their right ascensions, which will probably be the case, the accuracy of the first placing the instrument will be immediately ascertained. Other stars near the pole may be made use of in the same manner as is here described for the pole-star, but with proportionately less advantage as the polar distance is increased. It is also obvious from the figure, that the transit of the pole-star above the pole may be also used, and that with nearly, though not quite, the same advantage as the transt below the pole. The same method may also be applied with equal ease, if the second star A pafs the southern meridian instead of the northern.

"The flaws of the pole-star's motion, though it renders its transit uncertain to a few seconds, cannot materially affect the accuracy of this method, as an error of ten seconds in time, in the elimation of its passage, which is certainly more than can be committed, would not cause an error of a third of a second of time in the passage of stars near the equator.

"Example of the computation with the numbers given above.

"The error of a degree, therefore, in the position of the transit-telecope at the horizon, causes the star A to pass through it 5° 29' in time later than it ought; whereas the same error causes the transit of the pole-star to be 1° 26' 40" later than it ought; and the difference between the
these two times, viz. 1st 21st 114, will be the difference of the observed time of their transits, owing to the error of the position of the transit-telescope, their real right ascension being supposed the same." After having thus given Sir H. Englefield's own words, we shall only add on this subject, that on enquiry of Mr. Thomas Jones, we learn that several of these instruments have been made and fold, and one on an enlarged scale; but that stars smaller than those of the third magnitude cannot be seen by a telescope in which the reflection precedes the refraction.

Transit-Circle, is an astronomical instrument, by which, with the aid of an astronomical clock, both the right ascension and declination of a heavenly body are determined at the same time. This instrument is of modern date, and differs from a transit-instrument of the best construction, only as it has a graduated circle of larger dimensions than the latter, and, by means of microscopes, reads the angle observed to the accuracy of a single second; whoever, therefore, has a good transit-circle, and a superior astronomical clock, has an observatory for determining the exact place of any heavenly body. Under our article Circle, we have described the mural transit-circle by Troughton, which has been usefully employed by Mr. S. Groombridge at Blackheath, and which has proved itself to be an instrument of the first class; and we have flated a report, that a large one was in contemplation for Greenwich, which we said we might possibly have occasion to describe. That instrument has been finifhed by Troughton in his best manner, and though the plan of the construction is unique, and the mode of using it novel, its application to the purposes for which it was intended answers the most sanguine expectation of the maker, and in the hands of the present astronomer-royal, affords the means of making more accurate and at the same time more numerous observations in a given time, than ever were effected by any other instrument. Though this instrument has a long axis passing through a fold pier of masonry, and is capable of being used for transits, it has hitherto been principally used for determining polar distances, by actual measurement from the polar point; according to which mode, the uncertainty in the results, which commonly arises from variable refraction in ordinary measurements, is almost entirely obviated, and a repetition of any series of observations may be made on any part of the circle ad libitum, and with any number of readings to the number of fix at the same time; so that a single observation is made with as much accuracy, as can be obtained from an average of several successive observations taken with a repeating-circle of the same dimensions; and yet there is the power of repeating any observation in various positions. Mr. Pond has already published one volume of observations taken with this instrument, which completely verifies our affections, and in this first volume he has given a plan and section of this instrument, the circle of which is six feet two inches in diameter; but as Mr. Troughton intends to give a complete description thereof himself, as a paper suitable for the Philosophical Transactions, which, to be published therein, must be an original communication, Mr. Pond was not at liberty to describe the drawing which he has given as a frontispiece to his first volume; and as the description in question is not yet finifhed, we are in the same predicament with the astronomer-royal, and must consequently for the present forego the pleasure we had promised ourselves, of introducing this magnificent instrument to the notice of the public.

Transit, in Music, is nearly synonymous with modulation; it implies little more, in its technical use, than a change; and, in general, a change of key, from major to minor, or the contrary; or, indeed, from any one genus or key to another. Luckily no laws were laid down by our forefathers for transition, as for modulation, which we so long feared to violate.

Transition, in Rhetoric, a kind of connection in discourse, by which the several different parts and members of it are joined, so as to constitute one regular whole; or, as Voltaire defines it, it is a form of speech, by which the speaker, in a few words, tells his hearers both what he has said already, and what he next designs to say. Sometimes, however, in passing from one thing to another, a general hint of it is thought sufficient to prepare the hearers, without particularly specifying what has been said, or is next to follow.

Some place transition in the number of figures; others, with Quintilian, exclude it from that rank.

F. de Colonia makes two kinds of transitions, the one perfect, and the other imperfect.

Transition, Perfect, is that in which we briefly intimate what is said, and what remains to be said. As, Now that we have spoken of earth, there remains something to be said of peace. Satis multa de turpitudine: dicam delicatis, quod propofuit, de periculis. Uni epiflo reponsi: venio ad alteram: Sed hac uenem: illud recens: Cofarum meo confilio interfecimus.

Transition, Imperfect, is that in which only one of these is expressed. As, Let us now consider the consequences of... Populare hic locus, ut dicerent de—sed finis finit; nec enim pra laetitiam jam loqui possum; et hic laetitiam deferendi negat.

Transitions, in Geology, a name introduced by Werner to designate those rocks which, on account of their containing few organic remains, and lying immediately over other rocks which contain none, are supposed by him to have been formed when the world was passing from an uninhabitable to a habitable state. According to the fame geologist, transition rocks are of more recent formation than the lower or primary rocks, and older than the flinty flate, or stratified rocks, and are intermediate between both, being mostly of mechanical and partly of chemical formation. The rocks which are enumerated in this class by Werner, are transition lime-flone, transition trap, greywacke, and flinty flate. It is now, however, admitted, that the division made between transition rocks and the lower stratified or flinty rocks, has little or no foundation in nature, as these rocks are not unfrequently observed to alternate with each other. (See Rocks.) Nor is the absence of organic remains in the lower rocks, called primary, a decisive proof that they were formed previously to the existence of organic life upon our planet; for in a series of stratified rocks containing organic remains, we frequently meet with other beds interposed, in which no vestige whatever of such remains can be traced. Hence we may infer, that the processes by which the latter was consolidated, has destroyed the organic matter which they may have once contained. The absence of organic remains in silicious beds that have a crystalline granitic structure, is, we conceive, owing to the peculiar mode by which they were crystallized, as such beds sometimes repose on other beds abounding in marine shells. Nor can we be certain, that the lowest rocks of granite were formed before the existence of animal life on our planet. The more extensively modern geologists have carried their observations, the more numerous are the indications found of marine shells or vegetables occurring in alpine districts formerly regarded as primary; and if granitic rocks, wherever they occur, are invariably defiluete of extraneous fossils, we must attribute it to the peculiar mode of their formation, rather than to their priority of age.

The
The only circumstance which makes it probable, that the rocks classed as transition rocks, are the lowest in which the remains of organic substancess have ever been imbedded, is, that the fossils found in such rocks belong almost exclusively to different species of zoophytes and stell-fish, which may be regarded as the first or lowest links in the chain of animated beings. It is only in the upper strata that we meet with remains of animals poisselling the facultics of vision and locomotion, and a more complex organization. See Rock, Stratification, and Systems of Geology.

**TRANSLATION**, in Grammar, an epithet given to those verbs as figuratively an action which passes from the subject that does it, to, or upon, another subject which receives it. Under the head of verbs transitive, come what we usually call verbs active and passive: other verbs, whose action does not pass out of themselves, are called **intransitives**, and by some grammarians **intranebrates**.

In the Hebrew, the verb יָדַע, yada', in the Greek ἔρωμα, and in the Latin amare, are verbs purely neuter, or intransitive; or, as the Latin and Greek grammarians more usually express it, verbs subtransitive, signifying the mere existence of the thing, without the active or transitive conjugations.

**TRANSTORY**. in Common Law, stands opposite to local. See Action.

**TRANSTORY CHEF**. See CHEF.

**TRANSTORY TRASPASS**. See TRESPASS.

**TRANSLATION**, formed of trans, beyond, and latus, of foot, to carry: the act of transferring or removing a thing from one place to another.

We say, the translation of a bishop's see, a council, a seat of judicature, a parliament; the translation of the relics of a saint, the translation of the empire, &c.

The translations of bishops from one see to another are prohibited by the council of Nice, which declares them null, and appoints the translated bishop to return to his former church. The council of Sardica excludes translated bishops from communion. It has been observed, that no bishop was ever removed from a greater church to a lesser; and that those who thus quitted their churches, only did it out of ambition or avarice.

This discipline was generally observed for nine hundred years; and the first instance of any violation of note, was that of Pope Formosus, who was bishop of Porto. One of his successors took hold of this pretence to have him dug out of his grave; and a council, held soon after, forbid this translation to be made a precedent.

However, the same church allowed of some legitimate causes of translations, as the apparent advantage of the church; under which pretence, translations soon became so frequent, that for 500 or 600 years last past, they have been allowed a kind of common law.

The translation of a religious from one order to another cannot be effected without the consent of the pope; it is added, that it is not allowed to translate from a feverer rule to a laxer one.

**TRANSLATION** is also used for the version of a book or writing out of one language into another. See Version.

**TRANSMARINE, TRANSMARINUS**, something that comes from, or belongs to, the parts beyond sea.

**TRANSMARISCA**, in Ancient Geography, a town of Lower or Second Media, upon the route from Viminacium to Nicaea; between Apulia and Candidia. Anton. Itin.

**TRANSMIGRATION**, the removal or translation of a whole people into another country, by the power of a conqueror. See Migration.

**Transmigation** is particularly used for the passage of a soul out of one body into another; the same with what we otherwise call metempsychosis; which fee.

The Siamese, F. Tachard informs us, from a belief of the transmigration of souls into other bodies, forbear killing any beasts; left, by that means, they should dispossess the souls of their deceased relations.

**Transmigration**, Ionia. See Ionic.

**TRANSMISSION**, in Optics, &c. denotes the property of a transparent body, by which it suffuses the rays of light to pass through its substance; in which virtue, the word hands opposed to reflection.

Transmation is also frequently used in the same sense with refraction, because most bodies, in transmitting the rays, do also refract them.

For the cause of transmition, or the reason why some bodies transmit, and others reflect, the rays, see transparency and opacity.

The rays of light, as Isaac Newton observeth, are subject to fits of easy transmission and reflection. See Light and Reflection.

**TRANSMUTATION**, the act of transforming or changing one nature into another.

The term is chiefly used in chemistry and medicine. It has been greatly questioned, whether the transmutation of silver into gold, and of tin into silver, so much sought by the chemists, be possible or not.

The purest and subtlest parts of the food are transmuted or assimilated into the proper substance of the body. See Nutrition.

Nature, as Isaac Newton observeth, seems delighted with transmutations; he goes on to enumerate several kinds of natural transmutions; gross bodies and light, he supposes, may be mutually transmuted into each other; and adds, that all bodies receive their active force from the particles of light which enter their competition.

For all fixed bodies, when well heated, emit light as long as they continue so; and, again, light intermingles itself and inheres in bodies as often as its rays fall on the solid particles of those bodies.

Again, water, which is a fluid, volatile, tasteless salt, is by heat transmuted into vapour, which is a kind of air; and by cold into ice, which is a cold, transparent, brittle stone, easily divisible; and this stone is convertible again into water by heat, as vapour is by cold.

Earth by heat becomes fire, and by cold is turned into earth again: dense bodies are vapposed into various kinds of air, and that air reverts into gross bodies.

Quicksilver sometimes puts on the form of a fluid metal; sometimes it appears in the shape of a bell-metal, fragile salt, called sublimes; sometimes of a bell-metal, volatile, white, tasteless earth, called mercurius dulcis; by distillation, it becomes Lynceum; and by agitation in vacuo, it shines like fire, &c.

All bodies, beasts, fishes, insects, plants, &c., with all their various parts, grow and increase out of water, and aqueous and saline tinctures; and, by putrefaction, all of them revert into water, or an aqueous liquor, again.

Further, water exposed awhile to the open air, puts on a tincture, which, in process of time, has a sediment and a spirit; and, before putrefaction, yields nourishment both for animals and vegetables.

**Transmutation**, in Alchemy, denotes the act of changing or exalting imperfect metals into gold or silver.

This is also called the grand operation; and, they say, it is to be effected with the philosopher's stone.

The trick of transmuting cinnabar into silver is thus: the
the cinnabar, being bruised grossly, is stratified in a crucible with granulated silver, and the crucible placed in a great fire; and, after a due time for calcination, taken off; then the matter being poured out, is found to be cinnabar turned into real silver, though the silver grains appear in the same number and form as when they were put into the crucible; but the mischief is, coming to handle the grains of silver, you find them nothing but light friable bladders, which will crumble to pieces between the fingers.

Mr. Boyle, in his Sceptical Chemist, tells us, that two friends of his did, by urging mercury in a skillfully managed fire, turn it, almost weight for weight, into water; but he does not say what was the specific gravity of the produced water, nor of the remaining untransmutated mafs of mercury. He likewise assures us, that rain-water, being distilled and re-distilled, by a friend of his, nearly two hundred times, did, after distillation, leave at the bottom of the glafs body, a considerable quantity of a white earth; and that more plentifully in the latter distillations, than the former.

This he believed to be a certain quantity of water actually transmutated into earth, adding, that it was above twice as heavy specifically as common water, and of so fixed a nature, that it lay a considerable time, in a red-hot crucible, without losing any thing of its weight, or even permitting any smoke.

For the transmutation of iron into copper, see Copper and Vitriol.

Transmutation, in Geometry, denotes the reduction or change of one figure or body into another of the same area or solidity, but of a different form; as a triangle into a square, a pyramid into a parallelepiped, &c.

Transmutation, in the Higher Geometry, is used for the converting of a figure into another of the same kind and order, whose respective parts rise to the same dimensions in an equation, admit the same tangents, &c.

If a rectilinear figure be to be transmuted into another, it is sufficient that the intersections of the lines which compose it be transferred, and lines drawn through the same in the new figure.

If the figure to be transmuted be curvilinear, the points, tangents, and other right lines, by means of which the curved line is to be defined, must be transferred.

Transmutation of Colours. The change of colour of a decocction of the nephritic wood, according to the different lights it was viewed in, long perplexed those who attempted to account for it; but Wolfius has carried the experiments on this decocction much farther, and found a way of giving it its colours again, after taking them wholly away. If this decocction be held between the eye and the light, it appears of a blue colour; but if the eye be placed between it and the light, it appears then of a yellow or a red colour. If a few drops of oil of vitriol be dropped into it, it will appear of a gold yellow in whatever light it is viewed; but if too much of this oil be added, the whole becomes foul and obscure; and if a few drops do not produce the effect, it is a sign that the decocction is too strong, and that it must be diluted with water. See Colours.

Oil of vitriol has the same effect upon many other decocctions of the woods, particularly on that of Brazil wood, which is of a fine red, but immediately becomes yellow on dropping a small quantity of this acid into it. And as in the other instance, so in this, it is necessary to the success of the experiment, that the tincture be not over strong. A few drops of oil of tartar added to this yellow liquor turn it red again as at first; and if more oil of tartar be added, the colour becomes blueish, with a tinge of red, much stronger than the colour of the nephritic wood at first, when held between the eye and the light. In all experiments of this kind, the weakness of the tincture produces the greatest beauty; and therefore it is best, instead of making a decoction, to make only a cold infusion, by putting a small quantity of the chips of the wood into water, and letting this stand cold for some time.

A tincture of red roses, made with common water and oil of vitriol, is well known to be of a very beautiful red colour, yet when the water has stood ever so long on the roses alone, it has factly any colour; if it be strained off in this colourless state, and the oil of vitriol then added, the red colour is produced as strongly as if this acid had been dropped into the water, while the roses were yet in it. When the liquor is of this fine red colour, a small quantity ofoil of tartar makes it immediately green; and if more oil of vitriol be added to this green liquor, it becomes red again, but is muddy, and not so well coloured as before.

If a few drops of a solution of corrosive sublimate be added to this, it does not at all change colour; and on adding more water, with salt of tartar dissolved in it, the liquor became red again, but of a very different red from what it was before in its muddy state, being now clear and deeper. When the tincture of roses has scarcely any colour, a small quantity of salt of tartar makes it green, but a large quantity makes it yellow. A few drops of oil of vitriol added to this yellow liquor, turned it to a pale red, and this could never be made green again by oil of tartar. Alum-water, added to a solution of salt of tartar, makes a white and opaque fluid, though they are both separately pellucid.

What is most observable in these experiments on the infusion of woods, is, that oil of tartar, and a solution of salt of tartar in water, have a very different effect. Thus an infusion of Brazil wood is red, and on dropping into it a few drops of oil of vitriol, it becomes yellow. If oil of tartar be added to this liquor, it only makes it yet more yellow; but if a solution of salt of tartar in water be added to this, it makes it red again. Act. Erudit. ann. 1718. p. 322.

The solution of verdigris, which is green, becomes colourless by the affusion of spirit of nitre or spirit of vitriol, and by the affusion of the oil of tartar it becomes green again. The spirit of falc ammoniac gives it a purple colour, and oil of vitriol makes it pellucid. The solution of galls with vitriol gives black, the affusion of oil of vitriol destroys the blackness, and it becomes pellucid as before.

M. Mufchenbroeck thought it to be universally true, that yellow vegetables, dissolved in spirit of wine, gave yellow tinctures, which are either not at all, or very little changed by acid, alkaline, or any other salts; but he thought there were some exceptions, and says, that when oil of vitriol is put to yellow paint, called anceton, it becomes of a beautiful blue, which is destroyed by water or any salt. A small quantity of an astringent substance, with iron, gives a black colour; a greater quantity of the astringent produces blue, more of it makes a violet, and more still produces purple.

There are some tinctures, the colours of which depend upon the external air: such is the red tincture made of Canarian lichen, called orfelle, and water, a diluted spirit of wine, with lime and an urinous salt. For, if this tincture be put into a glass tube, hermetically sealed, in a few days it becomes colourless; and when the tube is opened the colour returns. The abbé Nollet made a variety of experiments with this tincture. To the same clafs may be referred the sympathetic inks.

Colours may be produced in liquours which originally have no colour: thus, spirit of wine with red roses, upon which, whilst it is yet white, any saline acid spirit is poured, in so small a quantity that the acid can hardly be perceived, produces...
produces a florid red. Many other red flowers hardly give any
colour to spirit of wine in a short time, yet give a red colour
by the addition of any of the acids. A solution of mercury
and oil of tartar gives orange; a solution of sublimate and
lime-water produces yellow. The tincture of red roses
with oil of tartar per deliquium, or with spirit of salt amno-
niac, gives green. In like manner, the tincture of many
red flowers it changes into green by an alkali. The tincture
of red roses and spirit of wine gives blue. The solution of
copper and spirit of salt ammoniac gives purple. The solu-
tion of sublimate and spirit of salt ammoniac gives white.
The solution of sal ammoniac, and that of vitriol, also the
tincture of red roses, or many other red flowers, and the
solution of copperas in water, and likewise the solution of
galls and copperas, produce black. The following table
exhibits the colours arising from different mixtures.

The result of a variety of mixtures to produce colours,
was recited before the Royal Society by Dr. Goddard in
1661, and may be seen in Birch's History, vol. i. p. 11.
Mr. Melville has made many observations on the tran-
sformation of colours by the light of different
burning bodies. Bodies of all the principal colours, e.g.
red, yellow, green, and blue, are very little altered, he
observes, when they are seen by the light of burning spirits;
but if salts be continually mixed with them, during the
burning, different changes ensue. When sal ammoniac,
potash, or alum, is infused, the colour of red bodies appears
somewhat faded and dirty. Green and blue appear much
the same as in candle-light, both being faint, and hardly dis-
tinguishable. White and yellow are hardly at all affected.

When nitre, or salpetre, is plentifully mixed with the
burning spirits, and the whole is stirred about briskly, the
brightest red bodies, seen by the light then emitted, are re-
duced to a dirty tawny brown, which seems to have nothing
of redness in it. Green is transformed into another sort of
brown, only distinguishable from the former by a certain in-
nclination to a livid olive colour. When nitre is mixed with
the spirits, one may still see some remains of greenish colour,
unless it be poured in very plentifully. Dark blue is hardly
to be known from black, except that it appears the deeper
black of the two. Light blue is changed into a very light
brown, of a peculiar kind. White assumes a livid yellow-
ish cast; and yellow alone appears unaltered, and extremely
luminous.

These experiments he made with different sorts of richly
coloured bodies, as silks, cloths, and paints. Polished cop-
pers, which had contracted from the air a high flaming
colour, was reduced, by the same light, to the appearance of
yellow before. The faces and hands of the spectaturs
appeared like those of a dead corpse; and other mixed co-
lours, which had red or green in their composition, undergo
the like changes.

Having placed a pasteboard, with a circular hole in it,
between his eyes and the flame of the spirits, in order to
diminish and circumscribe this object, he examined the con-
titution of those different lights with a prism, holding the
refracting angle upwards; and found that, in the first case,
when sal ammoniac, alum, or potash fell into the spirits,
rays of all kinds were emitted, but not in equal quantities,
the yellow being much more copious than all the rest put
at one time, and the red being more faint than the green and
blue.

In the light of spirits mixed with nitre, or salpetre, he
observed some blue, though exceedingly weak and elu-
dated. With the latter the green was equally faint, but
with the former pretty copious. But when either of these
salts was used, he could hardly perceive any trace of red,
especially when they were mixed in great plenty, and the
spirits constantly agitated. At every little intermission, in-
deed, the red rays would shew themselves very manifestly
below the hole, and red bodies seen by that light refumed
somewhat of their ordinary colour; and it was entertaining
to observe how both would vanish again at once, when the
fading and rivals were renewed.

The proportion in which the bright yellow exceeded the
other colours in this light, was still more extraordinary than
in the former: insomuch that the hole, seen through the
prism, appeared uniformly of that yellow, and as distinctly
terminated as through a plane glass; except that there was
adjoining to it, on the upper side, a very faint streak of
green and blue. White bodies illuminated with it, appeared
also through the prism perfectly well defined, both which,
he says, are very surprising phenomena to those who have
been accustomed to the use of the prism in heterogeneous
lights, where it never fails to throw confusion on the ex-
tremities of all visible objects.

Upon examining bubbles of soap and water in the same
light, he could only observe luminous streaks, separated by
dark ones, the green and blue being too weak to affect his

Transmutation of Plants. See Seeds and Degeneration.

Transom, among Builders, the piece that is framed
across a double light window.

Transom, among Mathematicians, denotes the vane of a
cross-raft; or a wooden member fixed across it, with a square
whereon it slides, &c.

Transoms, in a Ship, are beams and timbers extended
across the stern-post of a ship, to fortify her after-part, and
give it the figure most suitable to the service for which she
is calculated. See Ship-building.

The general figure or curve given to the ship by the dis-
position of the arms of the transoms, which are generally
closer in proportion to their distance from the wing-transom
downwards, in consequence of which it becomes extremely
narrow from the counter towards the keel, is called the fig-
ure of the transoms. Although these pieces are extremely dif-
fierent in their figures, according to the extent of the angles
formed by their branches or horns, each of them has never-theless a double curve, which is partly vertical, and partly horizontal, with regard to its situation in the ship. The former of these is called, by the artificers, the round-up, and the latter the round-off.

As the transoms fill up the whole space comprehended between the head of the stern-post above, and the aft-most floor-timbers below, it is necessary to distinguish them by particular names. Thus, the highest is called the swing-tranfom; the next, the deck-tranfom; and afterward follows the firft, second, and third tranfoms, together with the intermediate ones.

The highest tranfoms are connected to the ship's quarter by knees, which are bolted to those pieces, and to the floor-timbers. See SLEEPERS, Falconer.

TRANSPARENCY, Diaphaneity, in Physic, a quality in certain bodies, by which they give passage to the rays of light.

The transparency of natural bodies, as glafs, water, air, &c, have imputed to the great number and size of the pores or interstices between the particles of those bodies; but this account is exceedingly defective; for the most solid and opaque body in nature, we know, contains a great deal more pores than it does matter; a great deal more, fully, than is necessary for the passage of fo infinitely fine and subtile a body as light.

Aristotle, Defcartes, &c. place transparency in the rectitude or straightsnefs of the pores; by means of which, say they, the rays are enabled to make their way through without striking againft the solid parts, and being refracted back again: but this account, fay Isaac Newton fays, is imperfect; the quantity of pores, in all bodies, being sufficient to tranfmit all the rays that fall on them, however those pores be situated with refpeét to each other.

The cause, then, why all bodies are not transparent, muft not be ascribed to their wanting rectilinear pores; but either to the unequal density of the parts, or to the pores being filled with fome foreign matters, or to their being quite empty, by means of which the rays, in paffing through, undergoing a great variety of reflections and refractions, are perpetually diverted this way and that, till, at length, falling on some of the solid parts of the body, they are extinguished and absorbed.

Thus cork, paper, wood, &c. are opaque; whereas glafs, diamonds, &c. are transparent: the reafon is, that in the neighbourhood of parts equal in densi ty, fuch as thofe of glafs, water, diamonds, &c. are with refpeét to each other, the attraction being equal on every fide, no refLECTION or refraction ensues; but the rays, which entered the firft face of the bodies, proceed, without interruption; quite through the body, thofe few only excepted which chance to meet with the solid parts; but in the neighbourhood of parts that differ much in density, fuch as the parts of wood and paper are, both in refpeét of themselves, and of the air, or the empty fpaces in their pores; as the attraction will be very unequal, the reflections and refractions muft be very great; and therefore the rays will not be able to make their way through fuch bodies, but will be properly deflected, and at falk quite flop ped. See OPACITY.

TRANSPARENT; we think, would be as ufeful a term in muic, as in painting. We know that visibility and audibility are objects of two different fenses; but cleaners, chiarezza, is a favourite excellence with muicains, in speaking of counterpoint; and in comnodations of many different parts carrying on different deigns, that cleaners in their texture and arrangement, which enables the hearer to dif-entangle them, and to diftinguish the several parts through each other, but particularly in vocal muic, and to hear the principal melody through all the accompaniments, we think might with some degree of propriety be termed transparent.

TRANSPARENT Column. See COLUMN.

TRANSPIRATION, in Phyfology, an expreffion derived from the French, for the cutaneous exhalation. See INTEGRUMENTS.

TRANSPLANTATION, in Natural Magic, was used for a ridiculous sup posed method of curing difeafes by transferring them from one fubjeét to another; and was much in vogue among certain chemical, or rather sympa thetical physicians, fome ages ago.

This tranfplantation was effected, either by the ufe of a certain medium, called on that account a magnet; or, without that, only by fimple contact.

Transplantation, by means of the magnet, was of five kinds, viz. infusion, implantation, infipication, irration, and insemination; but the whole practice is now defervedly exploded.

TRANSPLANTATION, or Transplanting, in Agriculture and Gardening, the operation of removing plants and trees of various kinds from the situations and places in which they were originally fown, fet, or railed, and replanting them in others which are more convenient and fittable. It is practiced with a great number of each of these different sorts of vegetable productions.

With the former, for field crops, it is had recourse to with many of the cabbage tribe, and some other fuch sorts of plants, for wheat, and lately for potatoes. The transplanting of all the different sorts of plants of the firft of these kinds, should always be performed, as much as poffible, when the weather is in rather a moif flate, the ground hav ing previously been put into a fuitable state of preparation, by proper ploughing and other means. The plants are placed out, in fuch cafes, at different dilances, as from two to three feet or more, as the nature of the land and circumstances may direct.

In transplanting wheat plants, which is sometimes the cafe, it has been noticed to be a practice which is not likely to become general for whole fields, but that circumstances may not unfrequently occur where it may be attended with much benefit when employed in a partial manner; as in fuch cafes where fome accidental failures may have happened to the parts of fields, which on a careful examination may be found to have wholly failed, or to be thinner than the others. In all fuch infances, whatever may have been the cafe of the deficiency,—whether from the wheat plants having been destroyed by wetnefs during the winter, or any other cafe,—fome parts of the fame fields will moftly be found, from which plants may be drawn for this purpose, without injury; and if attention be paid to good and neat cultivation, the vacancies may be usefully filled up by transplanting from fuch spots, where it may sometimes happen that the plants are fo thick as to do harm to each other, and, of course, service be done to the crops in fuch parts, while the vacant land is filling with them in other places, and by fuch means the whole will be rendered more perfect, uniform, and regular, improving the appearance as well as the abundance of the crops.

The practice of transplanting wheat in the early spring months, in fhef and other cafes, has long been advised by different writers, and lately had recourse to, with great succces, in the parih of Bocking in Essex, to fome considerable extent. It was there performed with the common dibble at the dilance of twelve inches, but nine would have been pre-
ferred, had it not been apprehended that the plants which could be collected would be insufficient.

It is thought capable of being more generally introduced with great advantage not only in the abundance of the crops and the saving of feed, but in the vast increase of employment which it furnishes for the labouring poor of different descriptions, as well as in some other respects, as may be seen in the first volume of the Corrected Agricultural Survey of the above county.

In regard to the transplanting of potatoes, it has been shewn by the trials of the Rev. Mr. Cartwright, which are described in a paper in the fifth volume of Communications to the Board of Agriculture, that there is no plant which admits of being transplanted with more complete success. It is suggested as a practice which, besides affording hints to the farmer for the improvement of the field-crops of this fort, may throw in the way of the cottager some useful information, as it may teach him, that after he has had crops of spring and early summer vegetables in his garden, he may procure from it, by being provided with a small bed of the nursery kind for potato plants, a valuable supply of useful food for his winter consumption and advantage.

The crops in these transplantings were after tares of the winter kind, and only top-dressed for, which is a considerable saving of manure.

In garden culture, transplanting is essentially necessary for a great variety of different plants of the eculent and other kinds, as has been seen under their different heads. And it has lately been found to be a considerable improvement in the culture of the onion, both in the garden and the field. When transplanted in moist weather into small shallow drills, eight or nine inches apart on beds, having the whole roots first well dipped in a thick puddle liquid, composed of one part foot, and three parts earth, with a sufficient quantity of water to form the mixture, they are said to succeed perfectly. It is a method too which has the advantage of being less expensive, and of course more profitable, than the common one, as the work can be cheaply done by boys or girls; it admits of clearing the plants of weeds better, which is highly beneficial to their growth; a few small beds thickly sown will furnish plants for as many acres; the ground which is to be planted may be under winter or spring crops, it being sufficient to clear it of them by the end of April, or the beginning of the following month, when the transplanting of the onions is to take place, and those contained in the feed-beds will, in the mean time, afford the necessary supplies for family use or the market. It has besides the benefit of having the onions better in quality and larger in size, and the crops wholly free from worms and the rot. See a paper on this subject in the first volume of the Memoirs of the Caledonian Horticultural Society.

With the latter, or plants of the tree-kind, transplanting is performed both for thofe of the foreif and fruit kinds in a great number of cafes. It is a practice which is much had recourse to in nursery-gardens for raising the different kinds while in their early growths, as the first two or three years. But for providing timber-wood, especially with some sorts of trees, as the oak and a few others, it is probably better not to transplant at all, as the produce is said to be firmer, more durable, and better for many uses, where it is not done. See Timber.

Though the work of transplanting be Molly practised while the trees are in this young state, it is capable of being effected, by proper management and attention, with perfect success, when they are of considerably larger growth. Mr. Amos, in his work on "Agriculture and Planting," has observed that, as in forming various sorts of ornamental undertakings with trees, as those of extensive lawns and fields intersected with large collections of such as are of the forest kind, and flowering shrubs placed out in the wilderness manner, with serpentine walks and paths running through the whole, the designs often become defective and unsatisfactory, from the want of various sorts of proper large-sized trees: to supply the defect in such cases, plenty of different proper-sized trees should always be at command, for the purpose of transplanting into bare fields, parks, and about naked new buildings, or into other situations where they may be most capable of imitating that charming tasteful negligence of nature which is so ravishingly pleasing to the senses. And that, in order to prepare the young trees for being thus transplanted when large, they should, if it is said, be continued in the feed-beds for the space of two years and a half, and then be set out at greater distances, reducing the tap-roots considerably, but those of the lateral kind only sparingly. That as in such young trees the root grows faster than the stem, (as an oak-plant a foot and a half in height has sometimes a root four feet in length,) the necessity of muting the root, especially the tap one, in such cases, is clearly shewn, the plants then emitting radicles in every direction, grow faster than if the roots had remained perfect. And that if a plant, or tree, be transplanted in this state, it succeeds with greater certainty the more abundant radicles are preferred to the root. When such trees have remained two years in the nursery-beds, they should be again removed, dressing their roots as before, and increasing the distance between them, when they may continue three or four years more. After which they may be put out in collections, where they are to remain for good, or until wanted for transplanting. That as in transplanting large trees, some large fibres of the roots are unavoidably broken and mutilated, and consequently the absorption of nutriment in the plant diminished, it is necessary that boughs answer ing to the defroyed roots should be cut away, in order to lessen the transpiration in proportion to the quantity of food that may be taken up.

The most proper and desirable sorts of trees for transplanting in this large state, are, it is conceived, the different sorts of elms, of which the English is the best, as it is more airy, and soonest recovers its wounds. The lime, too, will bear to be removed at a great size, as its wounds soon heal, and it may be formed into any shape desired. The oak, the beech, and the ash, will likewise bear to be removed when rather large, but they require more care in the work than the former: on the whole, those trees, the bark of which is the thinnest and smoothest, will be the most proper for this purpose. The hornbeam, the fycamore, the large-leaved maple, the sweet and horse-chestnut, and the laburnum, will all bear transplanting and removing, if they do not exceed fifteen or sixteen years' growth, and from twenty to twenty-five feet in height: if they are older and larger when this is done, they do not recover their wounds so perfectly as to become handorne trees. The larch and mountain-ash also bear transplanting and removing when large, but they should not exceed twelve years' growth. The balsam poplar of Canada, too, is a fine plant of the tree-kind, which is railed with much ease, is hardly, quick in its growth, and will bear to be transplanted and removed at a great size. And the crab-tree and white-thorn will suffer themselves to be transplanted at a large growth, when in a healthy and growing state; and that as few trees exceed them in beauty or fragrance in the spring season, or their

rich
TRANSLANTATION.

Rich glow of fruit in the autumn, they may be transplanted out singly into lawns, fields, and parks, where, when judiciously intermixed with other trees, they may highly decorate such situations. The elevation of flatly trees in clumps, parks, lawns, or fields, is considered, on the whole, as having a most agreeable effect, but that in new designs they cannot often be had without waiting many years, and incurring much labour, difficulty, and expense. However, by means of the directions which have been given above, and the use of the transplanter for large trees, it is thought the difficulty may be greatly removed, and a figure be soon made, even in bare fields, parks, and about new-built houses, without suffering such inconveniences, which must be a great inducement to such persons as are advanced in life to have recourse to the practice. See Transplanter, Tree.

In the work of preparing for the removal and transplanting of large tall forest-trees, it is recommended as proper to dig a circular trench all round them two or three feet deep, as early as possible in the spring; by which many new roots will shoot from those which have their ends cut off, and by which the balls of earth will be better held together, when the trees are removed in the succeeding autumn; and, by their having previously produced so many more fine radicles of the absorptive kind, be more certain of growing in their new situations. After which, the first step to be taken in the following autumn, is to mark out the places where the trees are to be removed and transplanted to, and there to dig pits three, four, five, or six feet wide, having the depth of from twenty-four to thirty-fix inches, as the size of the roots and balls of earth which hang about them may be. The top-soil in these diggings is to be thrown to the sides of the pits where the trees are to come, and the bottom or poor soil to the other sides. It this flate the pits are to remain until the trees are nearly ready for removal, which is to be effected in this manner, and is the next step in the busines. It is carefully to raise the trees which are to be the most healthy, and such as are of the pyramidal form, with as many roots, and thick fibres, and as much earth about them as possible. This is to be accomplished by digging trenches round about them, two, three, or four feet from the bodies of the trees, as their sizes may be, and about three or four feet deep, sloping them on the sides where the transplanter is to receive the trees. Then to bend the trees so far to one side, by the assistance of ropes, that the bottom roots may be easily got at, when they may be cut across with a sharp hatchet, and the extremities smoothed, which have been scattered, by a sharp hedging-hill, when rearing them upright again, bend them to the contrary side, and dres the roots in the same way, then raise them up a second time, when they will be ready for transplanting. In which case, it is directed that one set of hands, as one, two, or three men, should fill the pits half full of water, the top-soil and other fresh mould being mixed with it to the confluence of a thin puddle. That another set of men, as two, four, six, or eight hands, as the sizes of the trees may be, should rear up the transplanter of the trees against them by means of the rope for the purpose, balancing them properly by the machine, and leaving the fore-carriage part of it upon the ground, taking care to surround the places well with straw, where they rest upon the bars and bolts, in order to prevent the bark from being galled and rubbed off, which would greatly injure the trees. The whole should then be pulled and brought down together, in a gentle manner, by the rope for the purpose; three or four men and a horse being employed in the busines, where necessary, readying well the motion downwards, and at the same time a man or two are to guide the bolt of the machine into the fore-carriage, into which the horses are then to be put, and the trees conveyed to the pits, which by this time will be ready for their reception. The carriage is then to be drawn up along that side of the pits on which the top-soil was laid, backing it until it gets into such a position, that by rearing the machine and trees upright, as in loading, the root parts with the balls of earth about them, may be dropped exactly into the centres of the pits, amidst the puddle, which will soon run among and into the cavities of the balls hanging to the roots, as to surround and cover every fibre. The pits are then to be filled completely up, and a mound of earth raised about a foot higher than the surface all round each of the trees to two or three feet distant from the centres, hollowing it towards the trees, for the better reception and retention of moisiture. After this, it is supposed the trees will be able to brave and defy the rudest assaults of the winds, without any supports, even at the first transplanting out. In this manner, the whole busines of transplanting large forest-trees is to be proceeded in, and which has been found very successful in a variety of trials.

In garden management, too, large old fruit-trees of both the wall, espalier and standard kinds have lately been found capable of being transplanted with great success and advantage, when performed somewhat in this simple manner. When for large wall-trees, it is to be done by forming a half-circle for each in extent equal to the size of the trees, as seven or eight feet for such as cover a large space, measuring from the trunks of them; digging a trench round that three feet in width, and fix inches below the roots, carefully preferring the whole, and working out the earth from among them with a blunt tool, and caiming out the loose mould by the spade. Proceeding thus until got fully under the trees to be raised. The roots are then to be tied loosely together, and the branches freed from the walls, and put in parcels to prevent their being injured. The trees are now to be conveyed to the places into which they are to be transplanted; where proper-sized pits, for allowing the roots to be spread out and extended, are to be provided, placing them upright in them, using fresh earth alone or mixed with dung, and disposing them, so as that the surface roots may be equal to the top of the border in which they are put; then packing in the well-broken earth underneath, and for about a foot round the bottoms of the trunks, to fill all vacancies where the roots proceed from. After which, the whole of the perfect roots are to be attentively spread out at full length, cutting off any dead, bruised, or knotty parts; the ends of the remaining ones being smoothed and preferred at different lengths, keeping some at full length, others at five, four, and three feet, and a few even at one foot long, taking care to fave as many of the small fibres attached to the leading roots as possible; beginning by laying the whole out in sets or layers from the bottom at the wall-side of the half-circle, in the usual manner, until the top be reached, arranging the small fibres in regular order, and covering the different layers of roots with two or three inches in thicknesses of mould, packing it in well by the hand, and never setting the foot on the roots which have been covered. Proceeding in this way with each side of the half-circle, until they meet in the middle part of it, raising the whole with earth to the height of two inches above the level of the border; and above all applying three inches thick of good rotten dung. A full watering is then to be given, to settle the earth about the roots. Boards are to be laid to prevent the roots being trodden upon in nai-
ing the trees, the principal branches being only first secured, the whole being completed when the ground has fully settled.

The transplanting of espalier and standard trees only differs in this, that a full circle is to be dug round them.

The most proper seasons for transplanting large fruit-trees, are either in the beginning of the autumn, or just before the spring, in mild weather.

A great number of such large trees have been transplanted in this manner with complete success, some of which have borne half crops the first year afterwards, and others more, the fruit in most cases being greatly improved, as may be fully seen by consultating different papers on the subject in the volume of Horticultural Transactions already noticed.

For fruit-grounds, the young flocks for apple-tree plants are mostly in a proper state for transplanting out the second or third year of their growth. See Stocks, Apple, &c.

The transplantation of the blossom-buds of fruit and other trees has lately also been tried, by transferring the abundant buds of this fruit, of one tree to the barren branches of others, which is said to be capable of being performed with facility, and perhaps considerable advantage, in some cases. Such buds of pear-trees, when inserted into the strong young shoots of old ones, may afford abundant crops of very fine pears, and be gained with little trouble. The buds of those pear-trees are the best which have been formed upon the bases of the abortive bunches of blossoms of the preceding year; and that, instead of taking out the wood of the bud wholly, as is usual, it is most advantageous to let it remain in small quantities, only paring it very thin. See a Paper in the London Horticultural Transactions, vol. ii.

Transplantation of Flower-Plants, among Florists, the means of putting out and managing the different sorts of young plants of this kind. Work of this sort should always be performed according to the particular nature and habits of growth of the several kinds of these plants. In the auricula, the polyanthus, and different other similar kinds, the transplanting is often done early in the spring season by some; while others perform it annually about the beginning of the autumn. Especially for the first of these sorts; but probably the most suitable period is that about the beginning of the first of the above seasons, when the weather is rather flowery, though it may often be performed later with good success. Those plants designed for very strong blooming, should, however, never be transplanted, either early in the spring or too late in the summer, as they always require to get well-rooted before the winter season sets in. But notwithstanding the young offsets and other plants are to be transplanted in the above manner into their small pots, the large strong-blowing roots are not to be transplanted or removed more frequently than once in every two or three years, as the risk of losing fine strong flowers is otherwise very great, as plants of this sort never thrive in a right manner, until their roots have reached the sides of the pots, which rarely happens in so short a time as twelve months; but a difference is to be made, in performing this sort of work, between the plants which throw out suckers or offsets in great abundance, and such as do not; as the former require more frequent transplanting, all or most of such parts being carefully pared off and removed at the time; while in the latter it need not be so often. Where plants of strong superior bloom for increase are wanted, it is of material consequence to keep all such suckers and offsets from growing on the flocks of the old plants without fibres, they being kept constantly well rubbed off while of very small sizes, but those that rise from below the surface of the earth need not be so much regarded.

It is thought by some, that the large healthy strong blooming plants of this sort need not be removed or transplanted, and have the earth shaken wholly from their roots every year, as is the usual practice; as they have been found to do better without, by having occasional fresh earthings without removing them from the pots in fowne late trials. They should not, however, remain longer in this way than the third year. Florists in general have, it is supposed, been too fond of frequently transplanting or removing the large blooming plants of this sort, as once in two, or not more than three years, will be found sufficient, and more beneficial. The plants of this large blooming kind are not by any means to be transplanted or removed in dry hot times, as by shaking the mould cleanly from the roots of the plants, fresh fibres will not be freely drawn, unless the leaf be inclined to be flowery, and there be what is termed a cool moist state of the air. Fine young maiden plants may, however, sometimes be transplanted into small pots in such dry weather, being slipped out of the pots with the whole balls of earth about them, and then immediately replanted in full-sized blooming pots for the ensuing season.

In short, in transplanting these as well as many other sorts of flower-plants, much must always depend upon the state and condition in which the plants are found.

Where the plants of this kind have not been transplanted for some length of time, as two or three years, the small roots having filled the pots, the large, the tap, or the carrot root, as it is often termed, may have become so long as to stand in need of shortening by taking it out of the pot, shaking the earth away from it, and doing what is necessary, as by remaining too long it either gets rotten at the end, and constantly keeps the plant weak, or becomes too long for a common pot; besides, it wants shifting or transplanting every year, and never produces fine strong flowers. The small roots are to be reduced to about a dozen, those nearest the leaves being left for supporting the plants. Where there is any canker or rottenness in the root, it is to be cut off the quick or quite found parts, and the wounded part secured by the use of a composition made of bees-wax, turpentine, and white resin, and be made to crust over by exposure to the sun. Where large blooming or other plants of this sort to be removed have been in the pots only one year since the last transplanting, they are to be slipped out of the pots, with all the earth about them; and as the roots will be small and but little matted, it need not be shaken from them, only cutting it and the fibres of the roots down to a small ball in each plant, according to their ages and sizes. Some, however, do not like this method, but remove all the earth in transplanting them.

Different other fine flower-plants are to be managed somewhat in the manner which has been thus laid down in transplanting them, as the differences of their nature and habits may direct, only they will, for the most part, seldom require so many transplantations; indeed once or twice will almost always be as many as are necessary for them.

Transplanted or Ground Onion, in Gardening, a new sort of root of this kind lately brought from Egypt, and introduced into the northern parts of this island by Mr. J. Burn, captain in the royal navy, whence it is sometimes called by that name.

The manner of its cultivation, uses, and advantages, are thus described in a paper in the Scotch Horticultural Memoirs. The roots, being separated from the branches in which they grow, should be put out or transplanted into
any ground that is considered suitable for the common root of this fort, the soil being firft well prepared and enriched by the use of horse-dung in a reduced state; the plants or roots are then to be covered with only about one inch in depth of earth. The bell and most proper time for the putting them out or transplanting them is during the month of April. They should be put about a foot or eighteen inches afunder. They grow and are produced in clusters, some what in the manner of the bunches of grapes or currants; some growing in a round, others in a conical form or shape; those on the surface being the largest, while those in the centre are usually the soonest ripe. It is necessary that they should be taken up as they ripen, and when they are intended for keeping, they may be taken up rather before they are completely ripe.

It was found that two roots, the tops of which had begun to decay in the beginning of August, and which had been raised from the ground in the beginning of the following month, produced, in one cafe, nine onions, and in the other twelve. The onions in these cafes were of very different sizes, but the whole, when taken together, weighed more than a pound. Twenty-three onions of this fort, when planted out, are however said, in another instance, to have produced upwards of six hundred fine plants at the same time.

The circumstance in which this fort chiefly differs from the common Deptford and Stratford feed-kinds is, that it is larger, as in taste the quality is much the same. But it has, it is said, a material advantage over the feed-onion in this particular, that if planted about the middle of April, it will be fully ripe about the same time in the following September. Besides, it is not liable to accidents from any badness, imperfection, or too moist or too dry season, as is often the case in the common feed-onion. Another great advantage the transplanted or ground onion has over the feed fort is, that no infestation has yet occurred where it has been injured by vermin or insects, which is frequently the case with the feed-kind.

This fort of onion would seem on several accounts to deserve further attention to its cultivation and growth in this very uncertain climate for the common crops of such fruits.

TRANSPANTER, TRE, in Agriculture and Gardening, a machine or contrivance constructed for the purpose of affisting and facilitating the means of transplanting and removing trees of large growths and fizes.

A very simple and useful contrivance or machine of this kind has been given by Mr. Amos in his practical work on "Agriculture and Planting," with a correct representation of the same. It is simply composed of the two hind and the two fore-wheels and carriage part of a farm-waggon, with a platform, and diagonal frame raised and erected upon them so as to be capable of receiving the tree, and of retaining it in firm, steady position, until it be conveyed to the place where it is wanted to be replanted, when it can be let down with great care and readiness into the hole where it is to be set and grow.

Much facility and dispatch are given in replanting large trees by machinery of this kind for ornament or other uses. See Transplantation.

TRANSPORT, Ship, is a vessel used to convey provisions, warlike flores, folders, &c. from one place to another; also convicts over the seas.

TRANSPORTATION, the act of conveying or carrying a thing from one place or country to another. In matters of commerce, transportation is of equal import with re-exportation, viz. the taking up of commodities in one foreign state or kingdom, bringing them hither, and paying duties for them; and then conveying them into some other foreign state; by which it is distinguished from importation and exportation; where the commodities are either carried originally out of, or brought finally into, our own kingdom.

TRANSPORTATION, in Law, is also a kind of punishment, or, more properly, an alleviation or commutation of punishment, for criminals convicted of felony; who, for the first offence, unless it be an extraordinary one, are ordinarily transported to some foreign country for a term of years, or for life; within which, if they return, they are executed without farther trial than ascertaining their identity.

This is made felony without benefit of clergy by statutes 4 Geo. I. cap. 11. 6 Geo. I. cap. 23. 16 Geo. II. cap. 15. and 8 Geo. III. cap. 15. as is also the affiling transports to escape from such as are conveying them to the port of transportation.

Exile and transportation are punishments at present unknown to the common law; and whenever the latter is now inflicted, it is either by the choice of the criminal himself, to escape a capital punishment, or else by the express direction of some modern act of parliament. Accordingly, it was enacted by the statutes 4 Geo. I. cap. 11. and 6 Geo. I. cap. 23, that when any persons shall be convicted of any larceny or felony, who by the law shall be entitled to the benefit of clergy, and liable only to the penalties of burning in the hand or whipping, the court in their discretion, instead of such burning in the hand or whipping, may direct such offenders to be transported to America (or, by statute 19 Geo. III. cap. 74, to any other parts beyond the seas) for seven years. And by the subsequent statutes 16 Geo. II. cap. 15. and 8 Geo. III. cap. 15. many wife provisions are made for the more speedy and effectual execution of the laws relating to transportation, and the conviction of such as transgress them. But now, by the statute 19 Geo. III. cap. 74, all offenders liable to transportation may, in lieu thereof, at the discretion of the judges, be employed, if males (except in the case of petty larceny) in hard labour for the benefit of some public Navigation; or, whether males or females, may, in all cases, be confined to hard labour in certain penitentiary houses, to be erected by virtue of the said act, for the several terms therein specified, but in no case exceeding seven years; with a power of subsequent mitigation, and even of reward, in case of their good behaviour; but if they escape and are retaken, for the first time an addition of three years is made to the term of their confinement; and a second escape is felony without benefit of clergy.

Transportation is said to have been first inflicted as a punishment by 39 Eliz. cap. 4. Blacki. Com. vol. iv.

TRANSPORTATION OF PLANTS, is the removal of them from one country to another: with respect to which great caution is necessary. The plants sent from a hotter country to a colder should be transported in the spring of the year, that the heat of the season may be advancing as they approach the colder climates; and, on the contrary, those which are sent from a colder country to a hotter should be sent in the beginning of winter.

The best way of packing up plants for a voyage, if they be such as will not bear keeping out of the earth, is to have boxes with handles, and holes bored in their bottoms to let out the moisture, filling them with earth, and planting the roots as close together as may be; the plants should be set in these boxes a fortnight or three weeks before they are to be put on board, and in good weather they
they should be set upon the deck, and in bad removed or covered with a tarpaulin. If they are going from a hotter country to a colder one, they must have very little moisture; if, on the contrary, they are going from a colder to a warmer, they may be allowed water more largely, and being shaded from the heat of the sun, they will come safe. Very many plants, however, will live out of the earth a great while; as the fuchias, euphorbias, ficoids, and other succulent ones. These need no other care than the packing them up with moss in a clofet-box; and there should be a little hay put between them, to prevent them from wounding or bruising one another, and holes bored in the boxes, to keep them from heating and putreying. In this manner they will come safe from a voyage of two or three, or even four or five months. Several trees also will come safely in the same manner, taking them up at a season when they have done growing, and packing them up with moss. Of this sort are oranges, olives, capers, jasmines, and pomegranate-trees. These, and many others, are annually brought over thus from Italy; and though they are three or four months in the passage, seldom miscarry. And the best way of sending over seeds, is in their natural husks, in a bag, or packed up in a gourd-shell, keeping them dry, and out of the way of vermin. Miller. See SEED.

Those who are desirous of particular instructions with regard to the best means of collecting both seeds and plants in different countries, and of preferring them during a voyage hither in a vegetating state, may consult Mr. Ellis's Directions for bringing over Seeds and Plants from the East Indies, and other different Countries, in a State of Vegetation, &c. 4to. 1770.

TRANSPORTING, in Sea Language, the act of removing a ship from one place to another, by the help of anchors and ropes. See WARP.

TRANPOSITION, in Algebra, the bringing any term of an equation over to the other side. Thus, if \( a + b = c \), and you may make \( a = c - b \); \( b \) is said to be transposed. See REDUCTION OF EQUATIONS.

TRANPOSITION, in Grammar, a disturbing or dislocating of the words in a discourse; or a changing of their natural order of construction, to please the ear, by rendering the contexture more easy, smooth, and harmonious. A transposition, which renders the sense perplexed, is vicious. The construction of the ancient languages, being much more artful than that of the modern ones, allowed of much greater, and more frequent transpositions. The English, French, &c. scarcely ever allow of them but in oratory and poetry; in which cases, they serve to give a force and energy to the discourse, or the verse, and to prevent their languishing.

TRANPOSITION, in Music. We will venture to say, from long experience, that no musician can transpose at Sight, with certainty and firmness, but by a perfect knowledge of all the clefs necessary to change any one of the seven notes in music to any other we please. (See CLEFS.) This was Dr. Pepusch's method of teaching transposition, though not very clearly explained in his treatise; and Mr. Galliard's method, which he has made perfectly intelligible by a plate, in his translation of Tofii Cerone, in 1614, seems to have been the inventor of this method. See CERONE.

The transposer, besides changing the notes higher or lower by imaginary clefs, without changing their original places on the staff, must likewise know what sharps and flats belong to every key. If, for instance, we wanted to transpose our national supplication of "God save great George our King!" from G natural to Eb, a major third lower, we have only to imagine a clef that will make the second line E, which is the soprano, or tenor clef, on the first line. If, again, a finger wished to have this favourite air a third higher than G, which is Bb, the base clef with two flats will render all the notes, which with the treble clefs were in G, a minor third higher.

Now to render G on the fourth space in the base Eb, we have only to suppose the treble clef in the accompaniments, instead of the base. And to render the fourth space Bb, instead of G natural, we have only to imagine the base clef on the third line with two flats, instead of the fourth with one sharp.

TRAN-S-ART, in Geography, a town of Algiers, near the coast of the Mediterranean, on a gulf called the Immisfe; 30 miles S.W. of Oran.

TRAN-STRAND, a town of Sweden, in Dalecarlia; 50 miles N.W. of Falun.

TRANSTRUM, in the Naval Architecture of the Ancients, a term used to express a sort of cros or transverse seats that were placed in the polycracy galleries of those times, and served for the places of several of the rows of men, who could move and work their oars under the seats of the other or lateral rowers of the next tire.

Meibomius, who has written expressly on the naval architecture of the ancients, has better understood the places and use of these transtra, than any other author of late times; by a proper arrangement of these seats, and the lateral ones above and below each, he has taken off greatly from the height allowed by Scaliger, and others, to the polycracy vesels.

TRAN-SUBSTANTIATION, TRANSUBSTANTIATION, in the Roman Theology, the suppos'd conversion or change of the substance of the bread and wine, in the eucharist, into the body and blood of Jesus Christ.

Transubstantiation, taken in its general and literal sense, implies any change of one substance into another. Thus, the change of Moses's rod into a serpent; of the waters of the Nile into blood; of Lot's wife into a pillar of salt; were preternatural transubstantiations: and the change of the food we eat into the substance of our bodies, is a natural transubstantiation.

But the word, in its proper and technical sense, is restrained to the miraculous change which the Romish church holds is wrought in the sacrament, by the consecration of the priest.

One of the great articles of that church, rejected by the reformed, is that of transubstantiation; the latter maintaining the transubstantiation to be only figurative, and the former affirming it to be real.

The reformed interpreters, is, in the text Hoc est corpus mecum, This is my body, by signification, q. d. This signifies my body.
body: but the council of Trent stand up strenuously for the literal sense of the verb. Thus, in can. 1.fell. 15. of that council, it is expressly decreed, that, in transubstantiation, the body and blood of our Lord Jesus Christ are truly, really, and substantially, under the species of bread and wine.

It is added, that by truly, we mean properly; and not only by signification, as if the eucharist were no more than a sign of the body and blood of Jesus Christ: that by really, we mean in fact, and not only in figure, as if the eucharist were only a figure and representation of the body and blood of the Saviour of the world; and that by substantially, we mean in substance, and not only in virtue and energy. Thus is truly opposed to a simple sign, really to a figure, and substantially to energy or virtue.

This doctrine was established in the fourth general Lateran council, under pope Innocent III., in 1215, who is said to have introduced and established the use of the term transubstantiation, which was hitherto absolutely unknown; though some say that Stephen, bishop of Autun, first used this term. Burnet on the Articles, p. 312.

It was principally owing to the authority of Lanfranc, the principal champion of this new doctrine against Berengarius, supported by Rome, that so strange a tenet was established in the eleventh century, both in England and France. At the beginning of this century it was unknown to the church of England, as is incontestably proved by the epistles and canons of Elfric, archbishop of Canterbury, and by the prayers and homilies used at that time.

It seems difficult, at first sight, to account for the zeal of Rome in advancing and propagating a doctrine fo full of absurdity as that of transubstantiation. What use it may be said, could there be in understanding a figurative expression (with which manner of speaking the Scripture so much abounds) according to the letter, which makes it nonsense; when that nonsense does not appear to be productive either of power or profit to the church? The supremacy and infallibility of the bishops of Rome; the doctrine of purgatory, masses, and prayers for the dead; the worship of saints and images; the celibacy of the clergy; the merit of monastic vows; the necessity of confession to, and abolution by a priest, for the remission of sins; the power of the pope to grant indulgences, and apply to the benefit of other men the works of supererogation done by saints, and therefore belonging to the treasury of the church: all these opinions have a clear and evident tendency to raise and support the dominion and wealth of the Roman see and the clergy: whereas the multiplied contradictions and impossibilities contained in the notion of transubstantiation, seem to serve no purpose, but to expose the Christian faith to the ridicule and contempt of the Jews and Mahometans, or other unbelievers. Nevertheless, the solution of this difficulty may be found in the words of pope Pechal II., viz. "That it was a most execrable thing, that these hands, which had received such eminent power above what had been granted to the angels themselves, as, by their ministry to create God the creator of all, and offer up the fame God, before the face of God the Father, for the redemption and salvation of the whole world, should defecde to such ignominy, as, to be put, in sign of subjection, in the hands of princes, &c."

The same words were also used by pope Urban II. at the council of Bari. And certainly nothing could so raze the idea of the priesthood, or produce such veneration for them in the minds of the people, as their being suppofed to possess this more than angelical power. Lyttelton's Hist. of King Henry II., vol. 1.

Transubstantiation, Declaration against. See Declaration.

Transversalis colli, transversaire grels, in Anatomy, a small narrow muscle, placed at the lower and lateral part of the neck, and upper part of the back, where it extends from the transverse processes of the five or fix lower cervical vertebrae, to the corresponding processes of four or five dorsal vertebrae after the second. The splenius, levator scapulae, fa-

crowlumbaris, and longissimus dorfi, cover it behind, where it is inseparably connected to the two latter: it lies upon the tracheo-maloidens, to which it is also intimately connected, the complexus, and multifidus spinae. The front edge of the muscle is attached to the cervical transverse processes already mentioned: it passes over the first of these two first dorsal vertebrae, and is then attached to the transverse processes of the four or five following ones. These attachments are effected by slender tendons, connected with those of the splenius, levator scapulae, and multifidus spinae. It will extend the neck on the back; or, if the muscle of one side acts separately, it will incline the neck to its own side. Transverse, something that goes across another from corner to corner.

Thus heads and bars, in heraldry, are transverse pieces, or bearings: the diagonals of a parallelogram, or a square, are transverse lines.

Lines which make intersections with perpendiculars, are also called oblique or transverse lines.

Transverse Axis, or Diameter, called also the first or principal axis. See Axis, Diameter, and Latus-Transversum.

The transverse axis of an ellipse is the longer axis, or that which transverses it lengthwise, in contradistinction from the conjugate one. See Conic Sections, and Ellipses.

For the transverse axis of the hyperbola, see Conic Sections, and Hyperbola.

Transverso-spinalis, in Anatomy, a name sometimes given to the multifidus spinae. See Multipidus.

Transversus abdominis, a broad muscle of the abdomen. See Obliquus.

Transversus nasi, a synonyme of the constrictor narium. See Nose.

Transversus peclis, transversalis des ortis, a small muscle lying across the foot, immediately under the heads of the metatarsal bones, and extending from the four last of these bones to the first phalanx of the great toe. It is thin and fleasy; covered above by the metatarsal bones and interossei muscles, and covering below the flexor tendons, arteries and nerves of the toes. It arises from the heads of the four last metatarsal bones, and is inserted, together with the tendon of the adductor pollicis pedis, in the outside of the basis of the first phalanx of the great toe. It will approximate the great toe to the others; and by drawing the toes together, from side to side, will render the foot concave. Transversus perinei, two muscles of the penis.

Transversus perinei alter, rimus, of which the former is connected to the end of the large intestine. See Intestine.

Transum, in Gunner, is a piece of wood which goes across the cheeks of a gun-carriage, or of a gun, to keep them fixed together; each transum in a carriage is strengthened by a bolt of iron. See Carriage.

Transumption, Transumption, in the Schools, a syllagism by concession or agreement, used where a question proposed is transferred to another, with this condition, that the proof of this latter shall be admitted for a proof of the former.

Thus
Thus Aristotle, in his book De Caelo, undertaking to shew, that all the stars are round, transfers the quætion to the moon, and proves her rotundity from her increasing and waning; supposing it a thing admitted by his opponents, that the stars are all alike.

**Transylvania, Principality of**, in Geography, a country of Europe, bounded on the N. by Hungary, Poland, and Moldavia; on the E. by Moldavia; on the S. by Walachia and the bannat of Temeswar; and on the W. by Hungary. The form is nearly oval, about 400 miles in circumference. It is surrounded on all sides by lofty mountains, and is itself mountainous and woody; the mountains run from N. to S., and branch off likewise E. and W., and terminate at the centre, in hills covered with vineyards, and abundant in minerals. The air is generally warm, but more wholesome than that of Hungary; the soil is fertile, abounding in corn; flax of a very good quality, which is manufactured into linen; wine, cattle, and rich pastures: among the minerals are gold, silver, copper, iron, quicksilver, cinabrar, antimoniy, sulphur, vitriol, rock-falt, silt-petre, ochre, &c. The principal quadrupeds are buffaloes, horses, wild affes, elks, bears, wild boars, lynxes, chamois, martens, ermines, and beavers. The inhabitants are composed of different nations: Hungarians, Sikli or Sceythian Huns, Saxons, Walachians, Armenians, Rascians, Bulgarians, and Greeks; to which may be added Jews and Cingars, who live in tents, and lead a vagabond life like gypsies. This country is by the Germans called Siebenbergen, and by the Hungarians Erdely. It was anciently a part of Dacia; and, conquered by Trajan, it became a Roman province. It afterwards fell into the hands of the Goths, Huns, and afterwards the Hungarians. In the year 1004, it was first made a province of Hungary, and continued under the government of a waivode to the year 1526, when two rival princes contended for this principality; one of them was supported by the German emperor, and the other by the Turks; whereupon this country became the seat of war for many years. The princes of the house of Râgotzki were at the head of the Protestant faction, and supported by the Turks, but being at length obliged to quit Transylvania by the Austrians, Râgotzki fled for refuge into Turkey; and at the treaty of Carlowitz in 1669, this country was confirmed to the house of Austria by the Turks. The government of Transylvania is wholly different from that of Hungary; and, by the joint consent of prince and people, formed into an arithocratical government; and, since the year 1722, rendered hereditary to the princes and princeses of the house of Austria. Formerly the prince of Transylvania succeeded to the government by free election, but since the year 1722 by inheritance; and though his power is connected with that of the king of Hungary, and archduke of Austria, yet his government and privileges differ from both. The states of Transylvania, with respect to the number of its nations, are divided into Hungarians, Siculi, and Saxons; with respect to its different religions, into Catholics, Calvinists, and Lutherans; and formerly, also, into Unitarians; but, politically, after the example of Hungary, into prelates, nobility, gentry, and royal towns. The magnates confift of the great officers of state, the counts and barons. The gentry are Hungarians and Siculi, but the royal towns Saxons only. The nobility are generally very proud, and keep their peafantry in a state of slavery; four out of six days in the week the peafant is obliged to labour for his master, having only the remaining two days for himself. The principality of Transylvania is governed in the name of the prince and nobility, by the diet, the office of state, the royal government, the exchequer, the assembly of Hungarian counts, the tribunals of justice, and the magistrates of the Siculi and Saxons. The diets meet by summons from the prince at Hermanstadt. The revenue arises from the contributions, cullions, metals, minerals, rock-falt, royal demefnes, echevets, and confiscations; and are levied by the treasury. This province pays to the emperor in taxes of all kinds 1,500,000 florins annually, which is chiefly imposed upon the land, for the payment of the citizens is very trifing. Transylvania formerly could bring from 80,000 to 90,000 soldiers into the field; but at present the whole force of that principality consists of six regiments, under a commander-in-chief, for the defence of the country.

**Trantery, in some Cystoms**, denotes the money arising by amencements of ale-fellers and victualers for breaking the alhife of bread and ale; particularly at Lufton, and other manors in Herefordhire.

**Traper,** in Geography, a town of Maryland; 7 miles S.E. of Oxford.—Alfo, a town of Maryland; 7 miles S.W. of Salisbury.

**Traper,** in Geology, a class or family of rocks, characterized by the tendency to assume a columnar shape, or to divide into steps forming natural terraces. The name is originally derived from the Swedifh word trappo, a step. It was called by Wallerius corneus trapaezins.

Rocks of the trap family are very extensively spread over the globe, and no quætion in geology has excited greater attention than that respecting the mode of their formation. The near resemblance which many of these rocks bear to compact lava, the remarkable position in which they frequently occur, the regularity of their structure, and the changes which the rocks in their vicinity have evidently undergone, induce many geologists to ascribe to them an igneous origin; other geologists strenuously contend, that all trap-rocks have been originally formed by depositions from an aqueous fluid. Before detailing the facts in favour of these different hypotheses, it will be proper to describe the rocks which are comprised in the trap-formation. The earlier geologists have frequently applied the term trap indefinitely to a great variety of rocks, and the distinction made between trap and the rocks which the French mineralogists have denominated corneâne, is extremely vague.

The roche de corne, so frequently mentioned by Sauvagine, according to Bronniart is a trap-rock in the Wernerian acceptance of the term. Werner, according to Mr. Jameson, restricts the term trap to rocks principally characterized by the presence of hornblende and black iron-clay; yet the same author informs us, in the following paragraph, that in the oldest or primitive trap, no iron-clay whatever occurs. Jameson’s Mineralogy, vol. ii. p. 129.

The presence of hornblende and feldspar, or augite and feldspar, would have formed a more accurate and comprehensive definition of the constituents of trap-rocks, or of those rocks which are comprised by Werner in the trap-formation.

M. le Cordier, in an interesting memoir presented to the National Institute in 1815, alters that in the trap-rocks which are supposed to be of igneous origin, and in volcanic rocks, hornblende is extremely rare, but its place is supplied by augite, which has been mistaken for hornblende. The constituent parts of these two minerals are the same, and the proportions in which they combine do not greatly vary, so that considerable doubt has existed whether they should not be classed as the same species, notwith-
TRAP.

notwithstanding the difference of their crystallization. Be
this as it may; we consider it to be a question yet undecided,
whether augite (pyroxene of Häüy) is confined to rocks of
undoubted igneous origin, though Cordier, in the memoir
before alluded to, has proved that this mineral is a con-
taminant part of a considerable number of lavas, and of many
rocks denominated trap; and we know that this opinion is
further confirmed by the extensive observations of that emi-
tinent geologist Von Buch.
The classification of trap-rocks adopted by Werner having
been extensively admitted, we shall endeavour to state it as
concisely as is consistent with peripatetic. He divides trap-
rocks into three formations: primitive trap, transition trap,
and the new flëzzx trap.

Primitive trap is almost always distinguished by a great
predominance of hornblende, so that some of these rocks are
entirely composed of this mineral, or nearly so. There are
three principal species of primitive trap; common hornblende-
rock, hornblende mixed with felspar, and hornblende mixed
with mica.

Common hornblende-rock is principally composed of
hornblende; it contains two subordinate kinds, granular
hornblende-rock and hornblende-flate; the latter differs
from the frite in having a flaty structure. Hornblende-
flate pass sometimes into gnéifs, and sometimes into talcose
flate. (See GEITSS, and TALCOSI Flates.) These two
kinds of hornblende-rock occur in gnéifs and mica-flate,
forming beds which are but few in number, and of incom-
considerable magnitude; but in clay-flate they occur fre-
quently, and in very thick beds.

Hornblende mixed with felspar. This species Werner
divides into two subordinate kinds; greenstone and green-
stone-flate. The term greenstone (grünstein, German) is
used by Werner to denote a rock composed of crys-
tals of felspar and hornblende, and nearly resembling fiente (see SiENITE); but in greenstone the hornblende generally
predominates, and the felspar is commonly white, whereas
in fiente it is red. When the greenstone includes large
crystals of felspar, it is denominated porphyritic greenstone.
When the granular basis is very fine, it is called greenstone
porphyry. According to Mr. Jameson, this is the black
porphyry of the ancients. When the granular nature of the
base is no longer visible to the naked eye, it has a blackish
green colour, and includes crystals of compact felspar. It
is the porphyre verre, or antique green porphyry of sculptors.

Greenstone-flate is composed of hornblende and compact
felspar, and has a distinct flaty structure. The felspar is gen-
erally more abundant than the hornblende, and it some-
times contains scales of mica. It occurs in great beds and
masses in clay-flate.

Hornblende mixed with mica is the third species of pri-
mitive trap; it is composed of an intimate mixture of
hornblende and felspar, and includes scales of mica. It oc-
vol. iii.

Transition trap is divided into transition greenstone and
transition amygdaloid; but it does not appear that these
rocks have any very distinct character to distinguish them
from the greenstone and amygdaloid of the other trap-for-
maions. According to Mr. Jameson, transition greenstone is
a fine granular mixture of hornblende and felspar; but some
of the primitive and flëzzx greenstones are also described by
the same geologist as being finely granular. Transition
amygdaloid is slated to have a base of wacke, (see WACKE),
and approaches more or less to the nature of greenstone,
sometimes inclining to bafalt, and sometimes to iron-clay.

The vehicles are filled with clay, or with chalcedony and
agate: it alternates with transition lime-flate.
The new flëzzx trap-rocks of Werner comprise green-
stone, bafalt, wacke, porphyry-flate or clink-flone porphyry,
trap-fluff, greyflone, amygdaloid, with compact felspar and
clay-flone. He also includes pearl-flone, pitch-flone, obsidian,
and pumice in this formation of trap. (See the various ar-
ticles here enumerated.) It is these rocks, which Werner
calls the new flëzzx trap, that present the strongest indica-
tions of their igneous origin; and some of the substances
here enumerated, such as obsidian and pumice, are now gen-
erally classed with volcanic products.

Some geologists are of opinion, that there is no foundation
in nature for the division of trap-rocks into three distinct
formations, introduced by Werner.

There are, however, certain peculiarities of position, which
seem to indicate a difference in the mode of formation
between the trap-rocks that occur imbedded in other rocks,
and those which cover the secondary strata. To form a
more distinct idea of this, we must refer to the general
structure of the surface of the globe. The beds of rock
which form the crust of the globe, are commonly arranged
over each other in what is denominated a conformable po-
tion, as represented Plate II. Geology, fig. 6, where G is
the foundation, or lowest rock, on which the different beds a, b, c,
d and d are laid, and may be supposed to cover the mountain
with a general conformity to the shape of the lower rock.
This is more distinctly seen in the same plate (fig. 3.), where
the upper beds have the same elevations, depressions, and
undulations as those of the lower. The other position in
which rocks occur, is called unconformable. “If a thick
stream of lava, as frequently happens, were to flow over a
range of conformable rocks, filling up the cavities and
inqualities of the surface, when it hardens by cooling, it
would form a bed of superimposed unconformable rock.
Such infusions are common in volcanic countries. Very
extensive ranges of rocks occur in this position in various
parts of the world, covering not only the primary, but the
secondary rocks. These unconformable rocks, composed of
different kinds of trap, porphyry, and fiente, frequently
assume the columnar structure, and form vast ranges of
natural pillars, as at Staffa and many of the Hebrides, on
the northern coast of Ireland, and in Iceland, Sicily, and
various volcanic countries. Now whatever theory we adopt
respecting the formation of unconformable rocks in this
position, we must admit that they are of more recent origin
than the rocks which they cover; the lower rocks must have
been hard and unyielding, when the upper were thrown
upon them.” Bakewell’s Introduction to Geology.
The unconformable position of bafaltic rocks, or rocks of
the trap-formation, is represented Plate IV. Geology, fig. 2
a, a, a, a, being a series of regularly stratified rocks, covered
by a mass of unconformable bafalt, b b. The trap in this
position is often divided into distinct beds, some of which
are columnar, as represented at e e, and these columnar beds
are frequently separated by beds of compact trap.

Masses of trap also occur, forming perpendicular walls
(called dykes in the northern part of England): these in-
tersect the strata and frequently change their position, as
represented Plate II. Geology, fig. 8. Where a series of
strata a, b, c, d, e, f, g, which were once continuous,
are broken by a dyke of bafalt. The familiar letters on each
side of the dyke represent the same stratum, as d d, e e, broken
by the intervention of the bafalt. In such instances, the
strata in the immediate vicinity of the bafalt have under-
gone a considerable degree of change; and where the
stratum e e is coal, it is frequently found converted into
coak,
coak, or charred for some distance on each side of the basalt. These walls or dykes of trap are sometimes twenty, thirty, or even a hundred yards or more in thickness, and sometimes range along through very extensive districts; indeed there is reason to believe that many mountains of trap which are arranged in one line along a country, have been originally dykes of enormous magnitude, through which vales have been excavated by diluvial currents, by partial subsidence, and by other agents which have in former ages changed the surface of our present continents. See Veins, Mineral.

Independently of theoretical opinions respecting the formation of trap-rocks, it is obvious that the masses of un-conformable overlying trap, and also the trap or whin-lime in dyke, must be of posterior date to the rocks which they cover or underlie; whereas the hornblende-rock or primitive trap which is imbedded in gneiss, mica-flake, or clay-flake, must be coeval with the rocks in which it occurs; and the same is equally obvious with respect to trap-rocks alternating with secondary strata. Trap or basalt sometimes occurs in globular masses composed of concentric spheres, or of prisms of basalt in a radiated diverging form. The spheroidal basalt with concentric layers, frequently includes in its centre a mass of basalt similar to that which envelops it; but sometimes the central maf is of a harder kind, or is a fragment of some other rock, as of shelly lime-lime. Many trap-rocks, in decomposing, present a spheroidal structure which was not before visible in the maf; and it is observed, that the balls of basalt which fall out or remain when the rock is decomposed, are harder than the main body of the rock. This is the case with the basalt at Rowley in Staffordshire, called Rowley Rag. See Rowley Rag.

The spheroidal structure is however not peculiar to basaltic rocks. Rocks of granite, in decomposing, sometimes present globular masses of harder granite imbedded in the maf.

In columnar trap we find the columns of all sizes, from a few inches to two hundred and fifty feet in length. The form of the prifm or column is also various, and more or less regular, having generally three, four, or five sides: the latter or pentagonal form is the most common. The diameter of the larger columns is frequently four or five feet, or more, and sometimes is nearly equal to the height.

Rocks of the trap-formation are also frequently observed to form conical mountains, or to occur as detached masses on caps on the summits of other hills, and to occur at nearly the same level as represented Plate IV. Geology, fig. 3. c, d, and e. In such instances, it seems probable that the different caps have originally formed parts of one continuous bed, which has been broken either by the excavation of currents, by subsidence of the intermediate parts, or by the elevation of the hills from their primeval position.

The columnar structure and the overlying position so remarkable in trap-rocks, are also common to some kinds of porphyry, and to syenite, which are not included by geologists among trap-rocks, but to which they bear a near affinity. To take a just and enlarged view of this class of rocks, we must leave the minute subdivisions and classifications of cabinet philosophers, and contemplate the natural relations which these rocks have to each other, and the gradations which may be traced between mountain mafes pafsing great difference in their external appearance. Hornblende or augite forms an essential part of almost all trap-rocks, as well as rocks of undoubted volcanic origin. Now these minerals, though classified by mineralogists as two distinct species, are so nearly alike in their constituent parts, that we may consider them as identical, when they existed in a fluid state in the matter of the rocks of which they form a part. Circumstances of minor import may easily be conceived to have changed the form of their crystals, as we know by experiment the slight causes which occasion varieties of form in the crystallization of the same constituent ingredients in our laboratories. The constituents of hornblende and of augite, are felsy, alumine, lime, magnesia, iron, manganese, and a trace of potash: the proportions of each, which exist in the two minerals, do not vary more than the proportions which exist in substances clafied by Haüy with hornblende, or between varieties of the same species in many other minerals.

We may regard then, in a geological view, the constituents of hornblende and augite as forming the same mineral, under whatever crystalline forms they may present themselves in rocks. It is this substance which forms the connecting link between granite, trap-rocks, and lava. Hornblende enters as a constituent part into many rocks of granite. According to Patric, mafes and veins of granite occur in hornblende-rocks, and mafes and veins of hornblende in granite-rocks, in the Alpina mountains. Hornblende is found in some of the granites of the Higher Alps: it exists abundantly in most rocks of gneiss, which is only a laminated granite. When the hornblende in granite increases in quantity, so as to form a considerable part of the maf, the rock is denominated syenite. When the hornblende gives its colour to the rock, it forms greenstone. When the parts are more intimately mixed, it becomes a compact trap or basalt; and basalt and compact lava bear in many instances so near a resemblance, as not to be distinguished. According to the account of Sir George Mackenzie, beds and even columns of basalt frequently occur in Iceland, the lower parts of which are a porous and vitreous lava or flag. The close resemblance between the compact lavas, and the columnar basalt in the vicinity of Etna, and other active volcanoes, is so great, that we believe it is extremely difficult, if not impossible, to distinguish them from each other by any well-defined characters. The currents of lava which have recently flowed, differ indeed from beds of basalt or trap by their porosity; but Cordier has well observed, in the memoir before alluded to, that it is only the superficial part of modern currents of lava that are exposed to our observation; and to judge of their real nature from the external features, would be like judging of the contents of a vat of wine, from the froth floating on its surface. The ancient currents of lava are some of them of immense fize, and have frequently been excavated or broken, by which the internal parts are discovered, and these, as before remarked, bear a near resemblance to many of the regular rock-formation, and particularly to varieties of trap-rock.

Such being the leading characters in the composition, structure, and position of trap-rocks, we need not be surprised that the earlier geologists were disposed to class them all with volcanic products, and to asssert that they had been formed by eruptions from ancient volcanoes, in a manner similar to the formation of modern currents of lava. This hypothesis, advanced before many phenomena attending volcanic eruptions were known, and when the effects of heat combined with pressure had not been investigated, was exposed to many weighty objections. Another theory, which ascribed the formation of trap-rocks to aqueous depositions, was warmly supported by many geologists on the continent, and particularly by M. Werner. He supposes, that after all the primitive and conformable rocks had been deposited, the primeval waters which covered the highest mountains sunk slowly to their present level.
TRAP.

From some unknown cause, a sudden rising of the water took place in a turbid and agitated state, and covered the whole globe: it then became calm, and during the period of its settling, deposited the different rocks of overlying trap, and again retired to its former level with considerable rapidity. The broken stratification, so characteristic of this formation, was caused partly by the rapid retreating of the water. The heaps of trees, the beds of clay, sand, and gravel, and their confluent occurrence in the lower parts of this formation, are evident proofs (says Mr. Janson) of the rapid and tumultuous rising of the water. The subaqueous calcareous of the water is proved by the fineness of the mechanical and the increasing fineness of the chemical solutions, as we approach the upper part of the formation. Janson's Mineralogy, vol. iii. p. 85.

According to this theory, the regular ranges of columns so frequent in trap-rocks, were produced by the shrinking in or drying of the mafs. As the inundation was general, the rocks of this family must be spread universally over the globe. Indeed the fame geologist supposes there were two inundations, the first, which deposited the overlying porphyry and fientite, the second, which deposited the basaltic or flow trap-rocks. On this theory, Mr. Bakewell remarks in his Introduction to Geology, "it is scarcely possible for the human mind to invent a system more repugnant to existing facts. Were basaltic rocks, as Werner supposes, deposited from an aqueous fluid, that covered the whole globe after the formation of the secondary strata, every part of the dry land and every valley must have been incrusted or filled with basalt; it would be the prevailing rock of every district: on the contrary, overlying trap or basalt exults only in detached mafs, in particular situations, nor do fragments of basalt occur in any quantity sufficient to warrant the belief that it was ever formed universally over the globe."

Though the mode of aqueous formation, suggested by Werner, is utterly inadmissible, we do not think it improbable that many basaltic rocks may have been formed in the humid way, by eruptions of mud of limited extent, like those which fluce at present from the volcanoes in South America. The opinion that all basalt or trap-rocks have originally flowed in the form of lavas, we do not seem authorized, from existing facts, to maintain; and the great latitude given to this mode of formation, has induced other geologists to reject it altogether. But it has been well observed, that there is a wide difference between ascertaining the agency by which a rock has been formed, and the manner in which that agent has been applied. Numerous observations, which have been recently made on trap-rocks in volcanic countries, have led to the opinion that many of these rocks have been softend, and even fused, in their original position, without ever having flowed as currents of lava.

The principal objections against the agency of fire in the formation of these rocks are enumerated by Brochant. (Min. tom. ii.) Many of these objections, we think, can be satisfactorily answered.

1. "Basalts are extremely rare among the products of burning volcanoes, and modern eruptions have not produced any."—This objection is founded on an assumption of facts, which are not admitted by other geologists. The observations of Daubuisson in Auvergne, of Sir George Mackenzie in Iceland and the Færoe islands, and of Humboldt in South America, prove that trap-rocks are extensively spread among volcanic products; though, in many instances, they appear to have been formed by the agency of subterranean heat acting on beds of schist, which have been melted or softened in their original position, and been subsequently elevated, without ever having flowed as lava. If modern eruptions have produced no basalt, we may collect that it is only the external parts or fociis that are exposed to our view; and we have no opportunity of examining the currents of submolar lavas, formed at great depths under the ocean, in circumstances similar to those which may have attended the formation of basalts. That many basaltic rocks were formed under the sea, is evident from their alternating with beds of lime-stone containing marine shells.

2. "Whatever origin may be attributed to the columnar or tabular structure of basalt, it is not peculiar to trap-rocks; there are gypseums, marls, and sand-stones, which frequently form this structure."—The columnar and globular structure may be formed by the slow refrigeration of a melted mass of basalt, as was proved in the experiments of Mr. Gregory Watt. (See Rowe? Rag.) The columnar structure has been observed by Colonel Imrie in a current of lava which had flowed from a volcano in Feli-cuda, one of the Lipari islands. This current could be traced from the mouth of the volcano to the sea. That the columnar structure may also exist in some rocks of aqueous origin, cannot invalidate the above facts. The particular forms which the columns of basalt sometimes present, which will be subsequtently noticed, appear to be the effects of partial fusion.

3. "Basalts often repose immediately on coal, as at Melfiner, near Caffel. Now, if this basalt were volcanic, it must necessarily have produced the combustion of the beds of coal."—To this objection it will be sufficient to reply, that numerous instances may be cited of basaltic dykes and beds of basalt having charred the coal in their vicinity, and reduced it to a flate of coke or cinder. (See Veins, Mineral.) And from the experiments of Dr. Maccullock on powdered jet and wood-coal, inclosed in gun-barrels under pressure, so as to confine a considerable part of the volatile products, it appears that they were converted into true mineral coal by a red heat; and had the confinence, fracture, and every property of pit-coal. Where basalt in contact with coal has reduced it to a coke, it appears highly probable that the volatile parts have been driven off by heat; and where the coal prefers its true character, the volatile parts have been retained by compresion.

4. "The remains of animals and vegetables which are found in some trap-rocks, could not have filled the action of volcanic heat without being destroyed. It is the fame with many very fusible minerals. Some such fusible minerals are also found in volcanic rocks; but these infusions are rare, and cannot serve as a basis for a general rule."—In the experiments of Sir James Hall on lime-stone exposed to heat under compresion, it was found that chalk, which contained shells, might be melted and reduced to a crystalline flate by cooling, without destroying the organic structure of the shells. Most of the organic remains in basaltic rocks are in a softer amygdaloid, or in wacke, which may probably have been formed from eruptions of volcanic mud, like that called naya, from the South American volcanoes. The fusible minerals found in basalt and some volcanic products, there is every reason to believe, assumed a distinct crystalline form when the mafs was conglobating.

5. "Cavities filled with water in secondary trap-mountains, oppose the supposition of their igneous origin."—That these cavities have been filled by infiltration is rendered almost certain, from the circumstance that the water may be expelled by a gentle heat; and if the water can find a passage through the stone from the cavity to the surface, it may also find a passage from the surface to the centre of the mafs.

U 2

6. "There
6. "There are not observed in trap-rocks either that black colour, or those indications of vitrification, that are apparent at least in certain portions of the products of burning volcanoes: real craters have never been observed. All those which have been cited were hollows, chafms filled with water, so common in some mountains."—This is an assumption of facts which recent observations disprove. The basalt in the Ferro islands, and in Iceland, have, in some instances, the black appearance which is here denied: the columns and beds of basalt contain also in their lower, and sometimes in their upper parts, ferorie, and those indications of vitrification that are apparent in burning volcanoes; and the sides of the basaltic dykes are generally vitrified. That many of the hollows, supposed to have been craters, were hollows formed by defruption, is probable; but what other appearance could the crater of an ancient volcano be expected to present, than a hollow or chasm which might be filled with water?

7. "Mandeltine (or porous amygdaloid) has certainly some resemblance to porous lava; but there are mandeltines evidently not volcanic. Besides, the cavities in the mandeltines of trap-mountains contain very different minerals, and such as could not have undergone the action of fire, without being changed."—The remarks made previously on very fusible minerals inclosed in basalts, and some lava, apply equally to this objection. It is also probable that soft and amygdaloidal basalts may have been formed from eruptions of mud, as before stated.

8. "Although from experiments made on basalts and lava, and from observations made on burning volcanoes, it is known that fomy substances may, after perfect fusion, resume their fomy character; but when this takes place in burning volcanoes, there are always found in the vicinity substances which are fcorified or vitrified, and denote the action of fire."—It has before been remarked, that fcorie and vitrified substances occur in the basalts of Iceland and Ferro; they accompany the basalts in Auvergne, and the vicinity of Etta. In almost all basaltic countries, some of the rocks present so striking a similarity to volcanic products, that the resemblance has often struck the most common observer. If other basaltic rocks do not present the same appearances, it may be owing to their having been formed by submarine eruptions, under circumstances very different from those which take place on land; and it is not contended that all basalts have originally flowed as lava.

9. "In various countries, beds of basalt are observed to alternate with sandstone and stratified lime-stone."—It is observed in many parts of England and Scotland, and is probably general, that where beds of trap are interposed between sandstone or lime-stone, they are generally very irregular both with respect to thickness and extent, and have seldom the same uniform arrangement as the stratified rocks with which they alternate. That the lime-stone was formed under the sea, is proved by its containing marine shells: and there is no improbability in the supposition, that currents of submarine lava may have flowed at different periods over beds of shells or sand, and converted the one into lime-stone and the other into sandstone.

10. "In many basaltic districts, basalt is only found on the summits of hills; and it is evidently perceptible, by the correspondence of the beds, that all these summits were parts of one and the same bed, which spread over all the district. This is not the form of volcanic deposits: they take a certain direction, and no similar instances of such vast volcanic deposits are known."—The frequent occurrence of detached caps of basalt forming the summits of hills, in an extensive district at nearly the same level, constitutes one of the most remarkable peculiarities of the trap or basaltic formation, and defers particular attention, as marking some of the latest revolutions that have changed the surface of the globe. To form a more distinct idea of the situation of these caps, we refer to Plate IV. Geology, fig, 3, where a mass of unconformable trap, a, lies upon the stratified rocks, and may be seen on the summits of other stratified hills at b, d and c. In some instances, as in the Isle of Skye, as described by Dr. Macculloch (Geological Transactions, vol. iii.), the mass at a appears to be connected with the lower rock, and to form a part of it, as if it had broken through the strata, and been thrown over the surface in a flat or fusion. The strata consist of grey lime-stone containing shells; but where the lime-stone is in the vicinity of the trap, it is converted into white crystalline flinty marble. A similar change is produced on chalk, or earthy lime-stone, when subjected to heat under pressure, as was proved in a series of experiments made by Sir James Hall; and as we are unacquainted with any other cause which could produce this change, it appears probable that the lime-stone has been converted into marble by subterranean heat, and that the trap has flowed over the surface like lava, but under the pressure of the ocean; the existence of marine shells in the lime-stone proving that such must have been its original situation. The cafes which have changed the relative level of the lime-stone, with respect to the sea, may have broken the continuity of the strata, and of the basalt which lies upon them. The basaltic mountains of Auvergne, in the departments of Puy-de-Dôme and Cantal, in France, have excited much attention from the existence of ancient volcanic craters in their vicinity. According to Daubrun, the fundamental rock of that district is granite, covered in some places with a marly lime-stone. Nearly all the foil is covered with volcanic or igneous productions; they are of three kinds, and appear to have been formed at three distinct epochs. The most recent are currents of lava, which lead to craters still extant, though dormant. The second formation consists of masses or tables of basalt, separated by openings or valleys. The third consists of mountains composed of a kind of volcanic porphyry. The currents of lava are observed to have run from the bottom of a number of conical hills, from two hundred to four hundred yards in height. These hills, of which there are about one hundred, are formed of heaps of scoriaceous fragments of lava, and papillo or tufa. Their summit often presents a hollow in the form of a crater: they rest immediately upon granite. The lava at the bottom is of a basaltic nature: it is of a greyish-black colour, with a fine compact grain; it contains grains of augite, olivine, and felspar. The superfiacies is blistered and fluided with aperities, which sometimes exceed a yard in height. The interior is more compact. The currents are spread in the adjacent plain; they have sometimes reached the bottom of certain valleys, and have followed their course for three or four leagues. In advancing progressively, they always defected to lower elevations; they follow the inequalities of the soil; and separate on meeting with any obstrucing eminences in their path. The history of these currents of lava, says M. Daubrun, is complete, and there is nothing left for the imagination to supply. We behold the orifice from whence they issued, the course they pursued, and the country they occupy. As for the period when these lavas flowed, though anterior to the history of man, it is nevertheless recent, compared with those vast changes which the surface of the globe presents, and was posterior to the excavation of the valleys, since it flowed through them, and occupied their bottoms.
TRAP.

The igneous productions of the second kind are basalts, which in the form of beds, tabular masses, or peaks, cover the elevated parts of the ancient surface of the country, or occur on the summits of some mountains and isolated eminences. They are also observed on the flanks round the sides of Mont Dor and Cantal. They are, says M. Daubuisson, evidently only the remains and patches of different currents which have spread over the country; they present the same mineralogical characters as the basalts of Saxony, and other districts; they contain the same fusions, and have the same tendency to form regular prisms or columns; they cover, without distinction, all kinds of rocks, and are never covered by them. An igneous origin cannot be denied to these basalts; the perfect resemblance between their pacts and that of some of the currents of lava in their vicinity, which can be traced to existing craters, affords a strong presumption of this; but they present other invariable marks of their origin. In following step by step certain masses of basalt, which are near Mont Dor and Cantal, and supplying by imagination what has been taken away, where their continuity is broken, you arrive at the sides of these two enormous volcanic mountains, and we come to masses of felspar or of bifurcated rocks, where beyond doubt we are near the current: all the basalts which have been traced upwards made part of that current. A great number of these large basaltic platforms, which cover isolated mountains, display on their surface blisters, fongy felspar or droplets, like those which cover the belt preferred lavas; nor can we refute them a similar origin. Some of these platforms repose on volcanic ashes. It is true, some isolated eminences have summits of compact prismatic basalt of a black colour, and definite of those unequivocal signs of the action of fire which are seen elsewhere; but these eminences of compact basalt most frequently find by the side of those platforms with scoriaceous surfaces, before deferebrated: they once formed with them a continued whole, and have evidently been divided from them by the excavation of the ravines and valleys which now separate them. They cannot have had a different origin. The convulsive action of time and the elements must have destroyed the scoriaceous crust; only the compact nucleus remains, deprived of the marks of the action of fire, like the interior parts of most currents of lava, which are equally deficient of such marks. Thus, says M. Daubuisson, all the basalts of Auvergne present proofs either direct or indirect of an igneous origin; though the disintegration of the surface, and the hardening that the currents have suffered, prevent us from retracing them to the crater from whence they flowed, and from seeing the number, form, and extent of the different currents; but we are certain that their existence was anterior to the excavation of the valleys.

The porphyroidal trap is the third kind of igneous rock-formation in Auvergne. It forms eight or ten distinctly mountains: the most considerable are Mont Dor, Cantal, and Puy-de-Dôme. The habit of these mountains, from the account of Daubuisson, appears to be a kind of felspar or clinilite porphyry: their pacts, direct or indirect, into basalt, and, above all, the volcanic felspar imbedded in their mafs, prove that they owe their existence to fire. These porphyries are the most ancient of the igneous productions of Auvergne; they are covered with basalt, and contain veins of that substance.

In the opinion of some geologists, these mountains and masses of porphyry have never flowed as lava, but have been fished in their native beds, and subsequently elevated. The homogeneity of their pacts shews how complete the fusion has been. The crystals of felspar were, in all probability, formed during the igneous fluidity of the mafs. However different the currents of lava, the basalt, and the porphyryic trap may be, and however various the periods of their formation, they appear, says M. Daubuisson, to be united in a certain degree. Cantal, Mont Dor, Puy-de-Dôme, and the other porphyry mountains, are ranged in a direct line running nearly from north to south. Almost all the basalts of these regions, that can be, in some manner, retraced to their origin, seem to have taken their direction in the same line. It is also in this direction, and among the ancient products, that the greater part of the craters have been opened whose vestiges are still visible. When, at two leagues to the westward of Clermont, we see near sixty volcanic mountains ranged in a straight line, it can scarcely be believed to be the effect of chance. A cause has certainly existed, which has produced this effect. Perhaps, says Daubuisson, there was in this direction a vein of matter that contained the germ of volcanic fire, which burst forth and was renewed at different periods.

Perhaps this range of mountains may be regarded as an enormous basaltic dyke, which has broken through the crust of the globe along the line where they are now ranged, their continuity having been broken by partial subsidence, and by diluvial currents. Daubuisson's account of the trap-rocks or basalt of Auvergne is particularly interesting, as establishing the intimate connection between trap-rocks and those of undoubted igneous origin. It is further remarkable, as M. Daubuisson had previously published an account of the basalts of Saxony, in which he endeavoured to prove the aqueous formation of basaltic rocks.

The most remarkable trap-formation in Europe, and perhaps in the world, extends from the county of Antrim, in Ireland, through part of the Scotch Hebrides, and is probably the fame which occurs in the Faroe islands, and the island of Iceland. An account of the columnar basalt of this formation will be found under the articles Giant's Causeway, and Staffa. The geological relations of the trap-rocks of Antrim with the regular strata in that country, have been recently traced by the Rev. J. Connibear and Dr. Berger. The basalt of this district generally covers chalk, similar to the chalk on the eastern side of England, and like it resting upon beds of sand, and the grey frutified lime-stone called lias. In England we have no instance of basalt occurring above the chalk, or any of the strata over the lias, or in the lias itself, though it occurs in the coal-formation under the lias. A fine fection of the beds of basalt with the chalk, sand-stone, lias, and coal-strata, may be seen for many miles along the coast, presenting numerous dykes and fractures of the strata, which have sometimes brought the basalt to the fame level with the chalk, and in other situations with the coal-strata. The basalt in the interior, and in some parts of the coast, forms isolated caps on the summits of detached conical hills. The existence of these isolated caps has been attributed to diluvial currents, which have cut through the once continuous beds of basalt. Though such currents have doubtless existed in various situations, and have excavated valleys, another agent has obviously been employed in the formation of the valleys of Antrim. We have only to examine the coast to convince ourselves of this fact, where we may see the strata suddenly thrown down or elevated several hundred feet, by mineral veins or dykes filled with basalt. If we trace in imagination the fame displacement into the interior, where it obviously extends, we shall see a sufficient cause for the existence of isolated caps or beds of basalt, separated from each other by valleys, or lower grounds, that have been formed by subsidence. Through these veins or dykes the basalt itself was probably
probably thrown up, and splayed over the surface in a fluid state. Wherever these dykes pass through the chalk, they have converted it into crystalline lime-stone to a certain distance on each side, and produced various appearances, which tend further to prove that the matter of the basalt has been in a state of igneous fusion. See Vikes, Mineral.

That the basalt has been forced through the chalk and the other strata on which it now rests, is rendered almost certain, by the occurrence of broken strata of chalk enveloped in the basalt, and contorted in a manner which proves the violence of the dislocation, the upheaving of the basalt, and the lateral pressure to which the chalk-strata have been subjected. See Plate IV. Geology, fig. 4.

One remarkable feature in the arrangement of the basaltic columns in Antrim must not be overlooked. The great ranges of columns are nearly vertical, but the columns of basalt in the mineral dykes are arranged horizontally. This difference of position may admit of a probable solution, if we allow that the basalt, in both instances, had been in a state of igneous fusion. The beds of columnar basalt being thrown over the surface of the ground that formed the bed of the ocean, would begin to refrigerate at the upper and under side in a vertical direction. On the contrary, in mineral dykes intersecting rocks already formed, the basalt would suffer refrigeration most rapidly where it was in contact with them, which would be on the fides, and this refrigeration would gradually extend to the interior, in a horizontal direction: and to this difference in the mode of their consolidation, we may ascribe the horizontal or vertical position of the columns in the beds and dykes of basalt. For an account of the experiments of M. G. Watt and Sir James Hall on the fusion of basalt and lava, see Rowley Rag, and Volcano.

Trap-Hole, in Rural Economy, a term applied to a round hole, which is cut out and prepared in the floors of the flowage-rooms, where hobs are deposited after being dried, for the purpose and convenience of bagging them. It is formed exactly equal in size to the mouth or opening of the bag, around which a wooden frame is securely placed and fixed, to the edge of which, the border of the mouth of the bag is firmly attached all round. By this means the hobs are readily forced into the bags in a close compact manner.

The term is also occasionally applied to other holes cut and formed in the floors of farm-buildings.

Traps, Gardens, such as are contrived for the purpose of destroying mice and other vermin; which are often conveyed into such places with the flax, litter, and other materials that are made use of in them; and which are extremely hurtful and troublesome in the spring season, in destroying peas and beans, as well as lettuce, melons, and cucumbers in frames.

Traps for this purpose are contrived in a great many ways; but as field vermin are very shy, and will rarely enter traps which are close, the following simple cheap form has been advised by Mr. Forth, though it has nothing of novelty in it. These traps may be made by fringing garden-beans on a piece of fine pack-thread, in the manner of beads, and then driving two small flake-like pieces of wood into the ground at the breadth of a brick from each other, and setting up a brick, flat stone, or board with a weight on it, inclining to an angle of about forty-five degrees; tying the flaring, with the beans on it, round the brick or other substances and flakes, to support them in their inclining position, being careful to place all the beans on the under sides of the bricks or other matters. The mice in eating the beans, in such cafes, will also destroy the pack-thread, and by such means diluge the brick or other weighty body, which by falling on them readily destroys them.

Mice are always the first got rid of by some sort of simple open traps of this nature.

TRAPA, in Botany, a Linnean name, whose idea is certainly taken from the warlike instrument called Caltrop, the Tribulus of the ancients, which consisted of four iron radiating spikes, so placed that one of them must always stand upwards, in order to wound the feet of passengers. Such is the figure of the singular fruit of this genus, hence named by Tournefort Tribuloides. Callicarpa, an old botanical word of similar meaning to Tribulus, is compounded perhaps of calco, to tread, or kick, and Tribu, to turn, because the Caltrops are continually kicked over if they fail of their intended mischief. Here we have the immediate origin of Trapa.—Linn. Gen. 62. Schreb. 84. Willd. Sp. Pl. v. t. 681. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. t. 267. Sm. Prodr. Fl. Grac. Sibth. v. t. 104. Juss. 95. Lamarck Illust. t. 75. Genrtn. t. 26. and 95. (Tribuloides; Tourn. t. 431.)—Clasf and order, Tetrandria Monogynia. Nat. Ord. Inundata, Linn.? Hydrocharidce. Juss. or rather, as that author himself indicates, his Onagre.

Gen. Ch. Cal. Perianth superior, of four acute, equal, permanent leaves, firmly united to the sides of the germ. Cor. Petals four, obovate, larger than the calyx. Stam. Filaments four, the length of the calyx; anthers simple. Fift. Germin turbinate, crowned by the calyx, of two cells; style fimbie, as long as the calyx; stigma capitate, emarginate. Peric. none. Seed. Nut turbinate, more or less compressed, of one cell, armed with two or four horn-like protuberances, originating in the persistent calyx, thickened, either spiny or blunt. Kernel foliary.

Eff. Ch. Corolla of four petals. Calyx of four leaves. Nut armed with two or four opposite horns, originating in the leaves of the calyx.

1. T. natans. European Water-caltrops. Linn. Sp. Pl. 175. Suppl. 128. Willd. n. t. Ait. n. t. Prodr. Fl. Grac. n. t. Genrtn. t. 26. (T. aquaticus; Camer. Epit. 715. Matth. Valgr. v. 2. 324. Ger. Em. 324.)—Nuts with four spiny ascending horns.—Native of ponds and muddy ditches in the south of Europe, flowering in summer. The plant is annual, and has several times been brought into England; but whether its seeds are not perfected here, or from any other cause, it has never yet been naturalized. The plants at Verfaiabes abound with this Trapca. The foliary fimbie roots send up a long, cylindrical, floating flarn, varying in length according to the depth of the water, furnished with numerous, oppositely, pectinated tufts of fibrous radicles, gradually diminishing to simple fibres, and at the top of the flem, which is thickened, these fibres are replaced by alternate flattened leaves, which are crowded at the summit into a large spreading flarn, floating on the surface of the pool, and often ten or twelve inches in diameter. Each leaf is rhomboid, fusculent, an inch or more in breadth, vein; strongly toothed in front; entire at the base; the veins rather hairy underneath. Footstalks three or four times as long as the leaves, smooth, swelling beyond the middle into an elliptical cellular body, rendering the plant more buoyant. Flowers small, white, on short, club-shaped, axillary, simple, partly hairy stalks, scarcely half an inch long. Nuts turbinate, about an inch in diameter, angular, smooth, with four, by accident only two or three, prominent ascending pointed horns, becoming lateral by the increase of the summit of the germen, two of them situated at the angles of the nut, two lower down at the sides. The kernel is edible, somewhat like a chestnut. This plant is doubtless the Bryophyta natans of Dioscorides, found by Mr. Sibthorp in countries bordering
on the north of Greece, though not in that country itself, nor the neighbouring islands. The wooden cut of Camerarius, executed, we believe, under Conrad Gessner's inspection, is one of the best representations of any known plant. — Linnaeus mildook the radicles for submerfed foliage, like that of Myriophyllum.

2. T. bicoloris. Chinefe Water-caltrops. Linn. Suppl. 128. Willd. n. 2. Alt. n. 2. Gertr. t. 95. Olbeck's Voyage, Engl. ed. v. 1. 305. (Bucephalon; Burm. in Plunt. Ic. 55. t. 57. at the bottom. Linkaia, Lang-kamm, or Leng-kla, of the Chinefe.) — Nuts compressed, with two oppo- difed defexed horns. — Native of ponds in China. Some of its nuts were procured by fr. Joseph Banks, in bottles of water, from China. These being immersed in mud at the bottom of some tubs of water at Kew, as well as in Mr. Lodges' flove at Hackney, vegefated, and produced plants hardly diftinguishable, in any refept, from the foregoing, of which we obtained fpeimens, from the fifters at Kew, in October 1790. These had the shell of the parent nut at their root, fo that no deception could take place. This nut is very different from the former, being twice as large, much compressed, with two large, diverficated, recurved, oppofite horns, more or lefs pointed, which could hardly be fuppoled to have originated from the calyx. We know nothing of the flowers of this species, nor are we perfuaded of its exiftence at prezent in the English gardens. Mr. Aiton indeed marks it as a perennial greenhouse plant, but not as having flowered; and we perfume, with deference to his well-known accuracy, that it perfumed as an annual, without flowing, we having never heard of it since the feafon. One of our fpeimens has feveral ftons from a fingle root, which may pofibly be the cafe with $T$. natans occafionally. Gard- ter's figure is different from Burmann's, and from our Kew fpeimens, in the bluntefs of its horns. We have a fpecimen like it, from China or the East Indies, and are not without a fufpicion that it may belong to a third species, whose herbage is, as yet, unknown to botanifs.

TRAPANI, in Geography, a fea-port town of Sicily, in the valley of Mazarra, situated on a peninsula, with a good harbour, defended by a fort, which flands on a small island, called Colombara. This town was anciently called Drepanum, from the fimilitude its haven is thought to have borne to a fickle. It is ancient, and, according to Virgil, existed in the time of Æneas. According to Diidorus, it was fortified in the first Punic war by Hamilcar, the father of Hannibal. The Carthaginians were always defirous of poffefling this city on account of its harbour. Here is a good pearl-fisfery on the coaft, and in the neighbourhood a confiderable falt-work. The number of inhabitants is about 20,000; 43 miles W.S.W. of Palermo. N. lat. 3° 10'. E. long. 12° 20'.

TRAPESO, in Commerce, a weight in Malta, Sicily, and Naples. At Malta, gold and filver are weighed by the libra or pound of 12 ounces. The ounce is divided into 16 parts, or into 32 trapezi, and the trapеzo into 18 grani. This pound weighs 4888 English grains; and thus 270 lbs. or ounces of Malta = 615 lbs. or ounces Troy. At Naples, gold and filver are weighed by the libra of 12 ounces, the ounce being subdivided into 30 trapezi, and the trapеzo into 20 achili. The pound of Naples weighs 4950 Troy grains; hence 64 lbs. or ounces = 55 lbs. or ounces Troy weight.

TRAPEZA, in Ancient Geography, a promontory of Afa Minor, in the Troade, at the entrance of the Hellespont, and 18 miles from the small town of Dardanum. Pliny.

TRAPEZIUM in Anatomy, a plane figure contained under four unequal lines.

TRAPEZIUS, in Anatomy, (circularis, dorso-fus-acro- mien,) a broad and flattened muscle, of triangular shape, describing with that of the oppofite side the lozenge figure, whence its name is derived, situated on the posterior surface of the neck and back, and reaching from the head and vertebral column to the scapula and clavicle. Its line of origin is very long. It arises, by a thin aponeurofis, from the occipital tuberofity, and the external tranferve ridge of the bone; from the ligamentum nuchae in its whole length; from the spinous procefs of the last cervical vertebra; from the fipnes of all the dorsal vertebrae, and the intervening interfipnal ligaments, by means of fhort aponeurotic fibres, except from the fixth cervical to the third dorsal vertebrae inelusive, where these fibres are much longer, and form a broad feni Maiaponeurofis. At the lower part too, the origin of the trapеzius presents an aponeurofis of fome breadth. The muscular fibres pursue various directions: the superior, which are the thifteft, defend; the middle ones pass horizontally; and the inferior ones ascend; the two latter portions are much thicker than the upper. The middle fibres are the fhortefl, the upper and lower confiderably longer. The fibres converge towards the shoulder, and form a flat aponeurofis, which, having pafled over the smooth triangular fpace at the root of the fpine of the fcapula, is fixed to the inferior margin of that procefs in its whole length, to the inferior margin of the acromion, to the ligaments of the fcapulo-clavicular joint, and to one third of the posterior edge of the clavicle. Numerous fleshy fibres are infiltrated, with aponeurotic ones, in the acromion and clavicle.

The posterior flat furface of the trapеzius is every where subcutaneous; the cellular fubfance between it and the skin does not contain much fat, particularly about the neck. Its anterior furface covers the complexus, splenii, levator fcapula, ferratus superior pollicis, suprascapulatus, rhomboideus, the triangular furface at the root of the fcapular fpine, the infraspinatus, latissimus dorsi, and a fmall portion of the longifimus dorsi and facrombularis. The upper and lower edges of the muscle are oblique: the former from the occiput to the clavicle, the latter from the last dorsal vertebra to the fcapula.

The trapеzius carries the shoulder backwards, at the fame time making the fcapula rotate, fo as to turn its inferior angle forwards, and the inferior backwards. In this way the shoulder is elevated, as in supporting a burden. If the levator fcapula acts with it, the fcapula is moved direcfly upwards: if the rhomboideus, direcfly backwards. When the shoulder is fixed, it will extend the head, and incline it, with the trunk, to one fide.

TRAPEZOID, in Geometry, a plane irregular figure, having four fides, no two of which are parallel to each other.

TRAPEZOPOLIS, in Ancient Geography, a town of Afa Minor, in the interior of Caria. Ptolemy.

TRAPEZUNTINA LAURUS, a name used by some botanical authors for the laurens, or common laurel.

TRAPEZIUS, in Biography. See George of Trebizond.

TRAPEZUS, TERRISONDE, in Ancient Geography, a populous town of Greece, E. of Pontus, and on the coaft of the Euxine Sea. It was a colony of Sinope. In the retreat
retreat of the 10,000 Greeks, they sojourned about a month near this town; and as they had a great number of cattle, they offered sacrifices to Jupiter the Saviour, to Hercules, and to other deities. They celebrated also the Gymnic games on the mountain where they encamped. The inhabitants of Trebifonde furnished the Greeks with two vessels, one of 50 and another of 30 oars. Trapezus was the boundary of the ancient kingdom of Pontus, and the commencement of the Colchide. - Alto, a town of Arcadia, S. of the river Alpheus and near it, towards the W. and not far from Megalopolis. It was abandoned by its inhabitants, and fink into ruin upon the establishment of Megalopolis. On the left of the Alpheus is a place named "Bathos," where were triennially celebrated the mysteries of the gods. See TREMISI. 

**Trapezus Mons**, mountains of the Tauric Cheroneus, W.S.W. of mount Cimmerus. M. de Peyronel says that the Trapezus comprehended the mountains now called Jacbelow, Biskhefarai, and Katchi.

**TRAPEZUSA**, a town of Aifa, in the interior of the Cappodocien Pontus. Ptolemy.

**TRAPOLIZA**, in Geography, a town of European Turkey, in the Morea; 30 miles N. of Mystra. N. lat. 37° 40'. E. long. 22° 26'.

**TRAPP, Joseph, D.D.** in Biography, a divine and poet, was born in 1679, probably at Cherrington, in Gloucestershire, where his father was rector, educated at Wadham college, Oxford, of which he was a fellow, and in 1702 commenced M.A. and took orders. As a specimen of his talents for poetry, he wrote a tragedy, entitled "Aramule, or Love and Empire," which was acted in 1704. In 1708 he was chosen professor of poetry at Oxford, the duties of which office he performed by delivering lectures in elegant Latin; which lectures were published under the title of "Prælectiones Poetice," and an English translation was printed by Bowyer in 1742. In 1711 Trapp was chaplain to the lord chancellor of Ireland, and published in the same year "A Character of the present Set of Whigs," of which, as well as of the author, Swift, who sent it to the presses, speaks contemptuously in his letters to Stella. He recommended him, however, to be chaplain to Lord Bolingbroke, who gave him the rectory of Harlington in Middlex. He was also appointed lecturer of St. Martin's-in-the-Fields; and afterwards obtained the vicarage of the united parishes of Chrift-church, Newgate-Greet, and St. Leonard's, Fother-lane. At this time he was deemed a popular preacher. As a poet, he published a flat and prosaic translation of Virgil in blank verse, Latin versions of Anacreon, and Milton's Paradise Lost. He also wrote several English poems, one of which was "On the Four Last Things." In 1721 he married. His subsequent publications were "Sermons at Lady Moyer's Lecture," various other "Sermons," and "A Defence of the Church of England against the Church of Rome." In 1727 he was created D.D. at Oxford by diploma. He died at the parfonage-house in Chrift-church, in 1747, with the character of an excellent scholar, an instructive preacher, and a worthy man. Biog. Brit.

**TRAPPE, Monks of La**, in Ecclesiastical History, monks of the Cistercian order, belonging to an abbey beautifully situated on a large valley in the province of Le Perche, on the confines of Normandy, in France. The abbey was founded in 1140 by Rotrou, count of Perche, and dedicated under the name of the Blessed Virgin, in 1214, by Robert, archbishop of Rouen. This abbey was subjected to a very rigorous discipline by the abbé d'Rance, in 1654. Encyclop.

**TRAPPINGS.** Among the ancients, some will have the horse-trappings to have been placed on their breasts; others, on their forehead; and others, again, on their cheeks; that on the breast was a small kind of shield, finely polished.

**TRAPRAIN LAW, in Geography,** a mountain of Scotland, in the county of Haddington; 4 miles E. of Haddington.

**TRAPS, The,** a town of Pennsylvania; 26 miles N.W. of Philadelphia.

**TRAPSALO,** in Zoology, a name given by the Greeks in the Levant to a species or variety of Calamary, or Sepia Loligo (which fee), called by the Provençais Arqui. It resembles the common calamary, but differs from it by the extraordinary size of its eyes, by a less extent of fins, by its feet having a greater number of small bony points to their cardilaginous tubercles, by a less length of back-bone, by the fin's having a smaller quantity of black liquor, and by its becoming very large. The Greeks are of opinion, that their trapalo is only the calamary changed by age. The arqui approaches the coast more frequently than the calamary; it often comes on the sand of the shore, and there deposits its eggs, whereas the calamary never goes on land. The flesh is better and less difficult of digestion; but their eggs have a flight purgative property, from which no bad effects are felt. It is considered as a preface of a tempest, when the calamaries dart out of the water. Sonnini's Greece, p. 128.

**TRAPTOWN, in Geography,** a town of Maryland; 7 miles S.W. of Fredericktown.

**TRAQUAIR,** or TRE-QUAIR, a parish in the shire of Peebles, Scotland, on the southern bank of the Tweed, is watered by the river Quair, which has its rise and its whole course in the parish to which it communicated its name; Tre-Quair signifying a dwelling on the Quair. The present parish is comprised of the old parish of Traquir, with that half of the ancient parish of Kailzie, which lies on the south side of the Tweed, and to which it was annexed in the year 1674. Its greatest length from E. to W. is about nine miles; its greatest breadth, from the Tweed to the source of the Quair, is from four to five miles: the whole contains 17,290 acres, of which about 4000 are arable. The surface is rocky and mountainous. Minchoor, one of the hills, is upwards of 2000 feet above the level of the sea; and Gumsfleugh and some other heights are elevated above 2000 feet more. The hills, in general, afford excellent pasture for sheep, of which there are above 10,000 in the parish. The soil in the low grounds is shallow and fliny, but tolerably fertile; and the air fabulous. In the population return of the year 1811, the number of inhabitants was stated to be 621, occupying 102 houses. The church was rebuilt in the year 1785. A parochial school is established, with a salary of 300 marks and perquisites, a free house and garden. Traquir House, the residence of that branch of the Stewart family who derive the title of earl from this parish, is seated on the bank of the Tweed; and on the side of a hill, which overlooks the lawn, are the remains of "The Bush aboon Traquir," celebrated in ancient melodies, and probably in former times a considerable thicket, but now reduced to five solitary thorn-trees. Part of the mansion is of very remote antiquity;
TRATOW, a town of the duchy of Holstein; 6 miles S. of Segeborg.

TRATTINICKIA, in Botany, is so called by Willdenow, in honour of a Vienna botanist named Trattinnick. The name of Leopold Trattinnick occurs in Mr. Dryander's Bibl. Bankf. v. 3. 646, 648, and 654, as the author of some botanical treatises in German. Persoon, it appears from Pursh 519, has a Trattinickia, which is Marshallia of Pursh, after Schreber. (See that article.) We must presume Willdenow to be most correct in the above orthography. — Wildl. Sp. Pl. v. 4. 975. — Clas and order, Polygania Monococ, Wildl.; rather Pentandria Monogynia, Nat. Ord. Terebinthaceae, Jull.

Gen. Ch. Cal. Perianth inferior, of one leaf, hairy, bell-shaped, with three teeth. Cor. of one petal, bell-shaped, longer than the calyx, with three flight, somewhat hairy at its outside. Stam. Filaments five, awl-shaped, very short, inserted into the receptacle; anthers oblong, erect. Ptl. Germin ovate, superior; style awl-shaped, the length of the stamens; stigma simple. Fruit unknown.

Obf. There are some flowers male only, having merely a short style, without any germ. But we cannot for that reason admit the genus into Polygania, there appearing to be no difference of structure in the other parts of the flowers.

1. T. rheiifolia. Sumach-leaved Trattinnickia. Wildl. n. 1.—Found in the province of Para, in Brazil, by count Hoffmannsegg, who communicated a dried specimen to professor Willdenow. — A large and very handsome tree, whose ultimate branches are striated and smooth, as thick as the little finger. Leaves alternate, a longer, pinnate, two feet long, composed of even pair of opposite leaflets, with an odd one, which are corded, four or five inches in length, oblong, pointed, entire, rigid, rough on both sides, very strongly heart-shaped at the base. The common footstalk is cylindrical and striated; partial one half an inch long, corrugated. Stipulas lanceolat, an inch long, rough with hairs, deciduous. Panicle terminal, spreading, compound, five inches in length. Flowers white, feathery, in little round tufts. The panicle ends in a pointed bud, expanding into a branch after the flowering is over, so that the branches of the panicle subsequeintly become lateral. The habit of this plant most resembles Cannarium, though the genus is unquestionably distinct. Willd.

TRATUZ, a town of European Turkey, in Moldavia; 49 miles S. of Niemecz.

TRAU, or Trochila, a town of Dalmatia, pleasanly situated on a piece of land, which was formerly a peninsula, but now separated from the continent by a canal cut through. It is divided into the New and Old; the latter of which has a double, the former only a single wall, and defended by three towers. The harbour, which is formed by a bay, has depth of water enough for the largest ships, which ride there sheltered by two capes. It abounds also in fish, particularly fine fardines. It was an ancient Roman colony of the emperor Claudius; and so early as the year 997, put itself under the protection of Venice; on which it has been continually dependent ever since the year 1420, though not without many changes and disfavour revolutions. Vines, olives, figs, and almonds are cultivated here, and some corn, which however is not the richest produce of these parts. The internal part of the territory of Trau, which
is about 100 miles in circuit, on the continent, produces very little wine, and scarcely any oil. The flocks that feed there, together with those on the island under the same jurifdiction, yield about 400,000 pounds of cheese, and wool in proportion. The number of inhabitants in this territory is about 20,000; 12 miles W. of Spalatro. N. lat. 43° 30'. E. long. 16° 30'.

Trau Vecchia, a town of Dalmatia; 12 miles S.W. of Trau.

TRAVAIATO, a town of Italy, in the department of the Mela; 6 miles W.S.W. of Brescia.

Travail, (from the French verb, travailler,) labour, toil, fatigue; but it is more generally applied to the pains of labour, or child-birth. See Labour.

Travail, in the Manoe. See Travice.

TRAVAILLER, Fr., in Music, to labour, work. In English music, a fuge is said to be well-worked, if the subject is frequently and ingeniously brought in, with new accompaniments and modulation: and an inward part of a Polyphonic composition is said to be well-worked, if some particular design is carried on in a spirited manner, while the other parts are fulfilling flow notes in pure and pleasing harmony. The Italians express much the same at present by the term tirato. A subject or theme well treated, is said to be ben tirato. The old Italian masters used to call any series of notes ascending or descending, regularly tirata, in the same sense as the French tirade; which fee.

TRAVANCORE, in Geography, a city of Hindoostan, and capital of a country of the same name; 108 miles S.S.W. of Madura. N. lat. 8° 22'. E. long. 77° 14'.

Travancore, a country of Hindoostan, situated in the S. part of the coast of Malabar, and southward of the Carnatic; about 90 miles in extent from N. to S.; governed by a rajah. This country began to rise into importance about the year 1730, by the abilities of the king, or rajah. Around the capital and chief province, he suffered the woods to grow for a number of years, till they formed an impenetrable belt of great depth. This, cut into labyrinths, afforded easy egress to his people, and rendered all attacks from without impracticable. Immured within these natural fortifications, he encouraged the cultivation of the arts and sciences; he invited the approach of men of genius and knowledge; he cultivated the friendship of the Brahmins, and was himself admitted into their society, by the ceremony of paffing (as Raynal says) through a golden cow, which became the property of the Brahmins, the cow being sacred in India, as formerly in Egypt; and by preparing his own military stores, calling iron, making gunpowder, &c., he rendered himself independent of foreign aid. The subjects of his remote provinces, who, to avoid the ravages of war, had taken refuge within the woody circle, now returned with their families and effects to their former habitations.

Even the approach to this difficult retreat was impeded by the famous lines of Travancore, which extended from the southern banks of the river Cranganore, close to the sea, to the foot of the Ghauts, strongly fortified in their whole extent. These proved the first check to the ambition of Tippoo Sultan. Tippoo, from the outside of the lines, was a spectator of the horrid carnage of his followers. The Nairs, pressed on him on all sides, and being repulsed with disgrace, and himself thrown over from his horse in the retreat, he is said to have made an oath, that he never would wear his turban again, till he had taken the rajah's lines; and accordingly he prepared to attack them by regular approach. On April 12th, 1799, he completely executed his menaces, and laid Cranganore in ruins, carried defilement through the country, and put every opponent to flight.

TRAVAY BAY, a bay on the S.W. coast of Tiree, one of the Western islands of Scotland. N. lat. 56° 31'. W. long. 6° 48'.

TRAUCHBURG, or Trauenburg, a town and castle of Germany, in the circle of Swabia, which gives name to a small county situated to the S.W. of the territory of Kempten; 12 miles E. of Wangen.

Trave, a river of Germany, which rises from a lake in the duchy of Holstein, 2 miles W. of Arensbok, passes by Oldeslohe, Lubeck, &c. and runs into the Baltic, about 10 miles N.E. of Lubeck. N. lat. 54°. E. long. 10° 55'.

Trave, in Agriculture, a term applied, in some districts, as Effex, to a large fort of louk of the wheat kind. In the work of traving, fourteen sheaves are fet in a flanting position, head to head, across a furrow, and pressed together as close as may be; a single sheaf being then firmly placed in the furrow against each end of the trave. The traves are by this means made quite secure, solid, and compact, and may defy almost any force and violence of the wind. In some cafes, instead of placing sheaves at the ends in this way, they are laid along the top or ridge of the trave; which, without doubt, at once better preserves the trave from the rain and wet, and gives a freer passage to the air between the sheaves, and sooner dries them, in case of their having been thoroughly soaked with rain; but then they are not nearly so strong to withstand powerful storms and blasts of wind as in the other mode of constructing them. See Harvesting.

Trave, among Farriers, the fame with travice.

TRAVELLER, in a Ship, a port of thimble, whole diameter is much longer, in proportion to the breadth of its surface, than the common ones. It is furnished with a tail formed of a piece of rope, about three feet in length, one end of which encircles the ring to which it is fixed. These machines are principally intended to facilitate the hoisting or lowering of the top-gallant-yards at sea; for which purpose, two of them are fixed on each back-sail, whereon they slide upwards and downwards, like the ring of a curtain upon its rod; being thus attached to the extremities of the top-gallant-yard, they prevent it from swaying backwards and forwards, by the agitation of the ship, whilst the yard is hoisting or lowering at sea. Falconer.

TRAVELLER'S Joy, in Botany. See Clematis.

TRAUMENDEN, in Geography, a sea-port of the duchy of Holstein, on the Baltic, at the mouth of the Trave, belonging to the city of Lubeck, which appoints a governor or commandant. The harbour is capable of containing 60 vessels, and deep enough for those of 200 tons. Men of war ride at anchor in the road. Travemunden is defended by a small fortress, mounting 40 guns, and a garrison of 50 men; 8 miles N.E. of Lubeck. N. lat. 54°. E. long. 10° 51'.

TRAVE, a town of Holstein, on the Trave; 2 miles S.W. of Segeborg.

TRAVERON, a town of France, in the department of the Meuse; 10 miles E. of Gondrecourt.

TRAVES, John, in Biography, a musician brought up in St. George's chapel at Windsor, and afterwards bound apprentice to Dr. Greene, about the year 1730, was elected organist of St. Paul's Covent-Garden; and in 1737, on the death of Jonathan Martin, was appointed one of the organists of the king's chapel. He afterwards attached himself to Dr. Pepusch, and composed his studies solely to the correct, dry, and fanciful style of that master. His compositions, however pure the harmony, can only be ranked with pieces of mechanism, which labour alone may produce, without the assistance of genius.
His passion for fugues, resembled that of an inveterate punter, who never hears a phrase or sentence uttered in conversation, without considering what quibble or pun it will furnish: so Travers seems never to have seen or heard any ferries of sounds, without trying to form them into a fugue, and meditating when and where the answer might be brought in.

Travers, in Geography, a town of the county of Neufchâtel; 11 miles W. of Neufchâtel.

Traverse, or Transverse, something that goes athwart another, i.e. that croffes and cuts it obliquely.

Traverse is particularly used for a piece of wood or iron placed transversely, to strengthen and fortify another: such are those used in gates, windows, &c.

To plane a board against the grain, is also called, among joiners, &c. to traverse it.

Traverse, in Gunner, signifies to turn or point a piece of ordnance, which way one pleases, upon her platform.

The laying or removing of a piece of ordnance, or a great gun, in order to bring it to bear, or lie level with the mark, is also called traversing the piece. See Gunner.

Traverse, in Fortification, denotes a trench with a little parapet, sometimes two, one on each side, to serve as a cover from the enemy that might come in flank. See Glacis, and Plate V. Fortification, fig. 6, in which w, w, represent traverses, constructed at the extremities of the places of arms, which serve to enclose them: these traverses are three toises thick, and as long as the covert-way is broad; and a palisade is cut in the glacis round them of about six or eight, in order to have a free communication with the rest of the covert-way. There are also traverses of the same dimensions before every salient angle of the bastion and outworks, and in the same direction of the faces of those works produced; and the thickets lies at the same side as the parapets. The palisades round these last traverses are from six to eight feet wide. The second covert-way has also traverses every where, in the same manner as the first.

Traverses are sometimes covered over-head with planks, and loaded with earth. Each traverse is furnished with a foot-bank, and a row of palisades planted on the foot-bank; and the palisade round its end should be furnished with klinets, or doors, to shut them up when necessary. They are very commodious for flapping an enemy's way, and to prevent being enfiladed: they likewise make a good defence, in a dry fos, in making the parapet on the side next the opposite flank.

Traverse, in a sout foss, is a fort of gallery, made by throwing fauciens, joists, fascines, flanes, earth, and other things, into the fos, over-against the place where the miner is to be put to the foot, or the wall, in order to fill up the ditch, and make a palisade over it.

Traverse also denotes a wall of earth, or stone, raised across a work which is commanded, in order to cover the men.

Traverse also signifies any intrenchment, or line fortified with fascines, barrels, or bags of earth, or gabions.

Traverse, in Navigation, is the variation or alteration of a ship's course, occasioned by the shifting of the winds, currents, &c.; or a traverse is a compound course, in which several different courses and distances are known.

Traverse failing is used when a ship, having set sail from one port towards another, whose course and distance from the port failed from are given or known, is, by reason of contrary winds, or other accidents, forced to shift and fail on several courses, which are to be brought into one course, to learn, after so many turnings and windings, the true course and distance made from the place failed from, and the true point or place where the ship is; that is, the wind coming fair, it may be known how, afterwards, to shape a course for the place intended.

This may be performed geometrically two ways: the first by drawing new meridians, through the extremity of every course, parallel to the first meridian, or north and south line at first made, and setting off every course with a sweep of sixty, as if it were a question in plain failing: you may also let fall perpendiculars to every new meridian, from the point that the ship failed upon that course; by which you have the course, distance, direction of latitude, and departure, to every course.

To illustrate this by an example: a ship, being bound for a port distant 120 miles N.E. ½ E. fails S.S.E. 30 miles, then N.E. by N. 40, then E. by N. 25, then N.N.E. 44; it is required to find the course and distance made good, and also the course and distance to the port bound for?

Draw the line H K (Plate VI. Navigation, fig. 1.) at pleasure, for a meridian, or north and south line, and therein assume a point, as A, for the port failed from; then, with 60 of the chords, and one foot in A, draw the arc L M, upon which set off two points (because the course is S.S.E.) from L to m, and draw the line A m, upon which set off the distance 30 from A to B; then is the ship at B: thus letting fall the perpendicular B K, A K 25° 7' is the difference of latitude, and B K 11° 5', the departure of the first course.

For the second course: with the distance K B draw the parallel B N, and thereby with the chord of 60, as before, set off the second course and distance, N.E. by N. 40, from B to C, and set fall the perpendicular C L; then is the ship at C, the difference of latitude upon the course is B L 33° 3; and departure C L 22° 2.

Proceed in the same manner for the third course: with the parallel C O, set off E. by N. 25, from C to D, and draw the line D P, from which set off the last course, N.N.E. 44; then is your ship at E.

Since, then, the ship came from A, and is now at E, the line A E, measured on the same equal parts upon which all the other distances were taken, will be found 91 miles; and the arc R Q, measured on the rhumbs, five points; viz. N.E. by E; so that the ship is now 91 miles N.E. by E, from the port failed from.

To find her course and distance to the port bound for, set off four half-points upon the arc R Q, from R to S, and from A through S draw the line A S F; upon which set off 120, the distance from the port failed from, to the port bound for, from A to F; then is F the port bound for: now the port bound for being at F, and the ship being but at E, the line E F, measured on the same equal parts that the rect was taken from, will be found to be 31°; and the arc T V, measured on the chords, is 35° 12', or N.E. by N. somewhat easterly, &c. This method is useful where the courses tend generally one way, without interchanging one another; but if they often cross, it is best to have recourse to the second method, which is without new meridians.

In order to this, observe how many points are between the point next to be laid down, and the point opposite to the course laid down; for that is the point for laying down: then when the chord of 60, and one foot in the point the ship is last come to, describe an arc; upon which set off the points found by the aboveaid rule, and through that draw the line for the next course, &c. For an example:

Draw a north and south line, as in the former, as the line R M (fig. 2.), in which assume a point, as at A, for the port
port failed from; then from A set off the first course and distance, viz. N.N.W. 68, from A to B; and for the second course, with the chord of 62, and one foot in B, draw the arc T W, upon which to set off the next course S.S.W. 70: observe the rule above delivered; viz. to take the number of points between the point next to fail on. The reason of which rule is this; if from A to B your course be N.N.W., then back from B to A must needs be S.S.E. the opposite point; and then if you were to fail S. by E. it must be one point to the southward of that S.S.E. line, if S. is two points; and consequentially the next course being S.S.W., you are to set off four points, upon which set off 70 miles, from B to C, and then is your ship at C: for the third course, if from B to C be S.S.W., then from C to B is N.N.E.; but the next course being E. ½ N. the points between N.N.E. and E. ½ N. are five points and a half; and therefore, with the chord of 62, and one foot in C, draw the arc X Y, upon which set off five points and a half from X to Y; and through Y draw the line C D, upon which set off 90 miles from C D: then is your ship at D.

After the same manner lay down all the rest, as D E, which is W.N.W. ½ N. 70; then E F, S. 25; then F G, E. ½ S. 45; then lastly G H, S. 30, which is the last course.

Thus your ship being at H, and the port failed from at A, the line A H, 28 miles, is the distance made good; and the angle at A is four points, viz. S.E.; but the port intended for being S.W. 55, set it from A to K; and the ship being at H, the line H K, 62 miles, is the distance from the ship to the port bound for; and the course is found by measuring the angle at H 71° 45', or W.S.W. more than a quarter westerly, &c.

To work a Traverse by the Tables of Difference of Latitude and Departure.—This is the principal use to which these tables are intended for; and the way of working a traverse by them is equal to the best for exactness, and superior in point of expedition.

Make a little table with six columns, the first for the course, the second for the distance, the third for the northing, the fourth for the southing, the fifth for the easterly, the sixth for the westerly. Then find the difference of the latitude and the departure to every course, and set them in their proper columns; as, where the course is northerly, set the difference of the latitude under northing, or in the north column; and where the course is southerly, set the difference of latitude in the south column.

Again, where the course is easterly, set the departure in the east column; and when westerly, set it in the west column: then, adding up each column by itself, subtract the north and south columns, the less from the greater, the remainder is the northing or southing made good. Also subtract the east and west columns, the less from the greater, the remainder is the easterly or westerly made good; then you have the difference of latitude and departure given to find the course and distance.

In the first example above specified, the first course is S.S.E. 30 miles, or two points 30 miles; for which I find the difference of latitude 27° 7. Now the course being between south and easter, I place my difference of latitude in the south column, and my departure, 11° 5, in the east column, leaving the north and west columns blank.

Then for the second course N.E. by N. or three points 40 miles, my difference of latitude, 33° 3, is to be placed in the north column, and the departure, 22° 2, in the east column: because the course is between the north and east.

Then the third course being E. by N. or seven points 25 miles, I place my difference of latitude, 4° 9, in the north column; and departure, 24° 5, in the east column.

And so for the fourth course N.E. or two points 44 miles, I place my difference of latitude, 40° 6, in the north column; and my departure, 16° 8, in the east column: then adding up each column, the sum of the northing column is 78° 8, and the sum of the southing column is 27° 7; which subtracted from the northing, 78° 8, the remainder, 51° 1, is the difference of latitude made good, which is northing, because the northing was the greater number.

Again, the sum of the easterly column is 75° 0, which, because there is no equivalent to subtract from it, is the easterly made good. Thus you have the northing 51° 1, and the easterly 75° 0 given, to find course and distance; and though you cannot find in the table the exact number of 51° 1 and 75° 0 together, yet find the nearest you can, which is 75° 4; and 50° 9, over which, at the top, you find 34 degrees for the course, which is N.E. by N. 0° 15' easterly, and the distance is 91 miles.

To resolve a Traverse by the Scales on Gunter's Scale, improved by Mr. Robertson. — E.g. A ship in 40° N. lat. and 5° 14' W. long., sails the S.E. by S. 68 min. then S.W. by W. 55 min. and then W.N.W. 75 min. What is her difference of latitude and departure in this general run?

The proportions are, for the

First Course.
As rad. : Diff. :: S. Co. cour. : Diff. lat. :: S. co :
Depart. S. 8 pts. : 68' :: S. 5 pts. : 57' S. :: S. 3 pts. : 38' E.

Second Course.
S. 8 pts. : 55' :: S. 3 pts. : 30' S. 6 S. :: S. 5 pts. : 40' W.

Third Course.
S. 8 pts. : 75' :: S. 2 pts. : 28' S. N. :: S. 6 pts. : 69' 5 W.

General diff. Lat. 58.8
Departure 77.5

The departure made good in this day's run.

To work the above on the Sliding Gunter. — Set fine of 8 points on the fixed piece, by the help of the brass index against 68 num. on the slide; then draw the fixed index to S. 5 points, you will find 57 num. on the slide for the difference of latitude; and (without any alteration) against S. 3 points, on the fixed piece, you will have 38 num. on the slide for the departure.

With the compasses, take the extent from 8 points on the fine rhumbs to 68 on the numbers; the said extent laid the same way from fine 5 points will reach to 57 on the num.
If a matter be expressly pleaded in the affirmative, which is expressly answered in the negative, no traverse is necessary, there being a sufficient issue joined: also where the defendant hath given a particular answer in his plea to all the material points contained in the declaration, he need not take a traverse: because when the thing is answered, there needs no further denial.

**Traverse of an Indictment or Presentment** is the contradicting or denying some chief point of it, and taking issue thereon. See Indictment, and Presentment.

Thus, in a presentment against a person for a highway overflowed with water, for default of securing a ditch, &c. he may either traverse the matter, by alleging that there is no highway, or that the ditch is sufficiently secured; or he may traverse the cause, viz. by alleging that he hath not the land, or that he and they were in estate, &c. have not used to clean the ditch.

It is not customary, nor agreeable to the general course of proceedings, unless by consent of parties, to try persons indicted of smaller misdemeanors at the same court in which they have pleaded not guilty, or traversed the indictment. But they usually give security to the court, to appear at the next assizes or sefions, and then and there to try the traverse, giving notice to the prosecutor of the same.

**Traverse of an Office.** is the proving that an inquisition made of lands or goods is defective, and untruly made. See Office.

No person shall traverse an office, unless he can make to himself a good right and title: and if one be admitted to traverse an office, this admission of the party to the traverse supposes the title to be in him, or else he could have no cause to traverse.

**Traverse** is sometimes used in Heraldry, for a partition of an escutcheon, which they blazon parti per pale, traverse, argent and gules.

**Traverse, in the Mangn.** A horfe is said to traverse, when he cuts his tred crofs-wife; throwing his croupe to one fide, and his head to another.

**Traverse, in Tyle.** See Tyle.

**Traverse Bay, Grand, in Geography,** a bay on the caft fide of lake Michigan. N. lat. 45° 45'. W. long. 85°.

**Traverse Islands, a chain of islands at the caft end of Noquet's bay, in lake Michigan:** on one of the larges is a town of the Ottowa Indians.

**Traverse River,** a river of Louisiana, which runs into the Milfouri, N. lat. 38° 36'. W. long. 92° 5'.

**TRAVERSIERE, FLUTE, commonly the German-flute, being supposèd of German invention. But it has its title of flute traversiere in France, from the different manner of holding it from that of la flute à bec, or common flute.**

Its original compass was from the lowest D in the treble, to a in altiflorno.

Such was the extent of the scale in 1752, when Quantz published his "Methode de la Flute," who was the late Frederic king of Prufiia's maître on that instrument, and the firft who added keys to correct and clear the bad notes.

In the folio Encyclopédie, tom. vi. there is a scale of all the tones, femi-tones, and shades poftible on the instrument, with an additional half-note, C ∑ or D♭, below the usual lowest note of its compass, and three notes above A in altiflorno, the highest note of Quantz's scale. See Music Flutes.

For the history of the flute traversiere, Quantz tells us that in the year 1620 it had no key to make D♭ or E♭, and was called the Swifi flute. It was the French who added the firft key; but it was not known by whom or when.
when. Quantz himself added a second key in the year 1726, and about 1732, a third. Two more keys have since been added by frequent performers on the instrument; but it has been thought more for parade than use: as, the management of five keys in rapid performance, would be as difficult as running divisions on an organ with all the five short keys set into quarter-tones. See TACTET.

TRAVESTY, or TRAVESTI, a term which some late authors have introduced into poetry: it is originally French, being a participle of the word traverter, to disguise one's self, or to appear in maleface. Hence travesty comes to be applied to the disfiguring of an author, or the translating him into a fyle and manner different from his own; and is generally applied to pieces of humour.

Travesty, or parody, may be divided into two classes:—that which is intended to ridicule absurdity, and that the purpose of which is to extract gaiety and laughter from compositions in their own nature grave and admirable. The Rehearsal by the duke of Buckingham is the belt specimen of the former. At a period when falfe taste seems to have prevailed in an eminent degree, which would be most likely to happen when a man of splendid talents like Dryden con-
defends to sacrifice his better judgment for the fpecious allurement of a temporary popularity, an author of wit has the appearance of doing the public a service, who shall call them to fobriety and good fense by the force of ridicule. The second kind of travesty has still fels that can be alleged in its favour. Its direct operation is to pollute our better feelings, and tarniffh with a putrefying film of ridicule all the noblest and most expreflive effufions of the human mind. Here unfortunately ridicule most fally takes hold. We cannot laugh at nothing: the prattle of inanity bids defiance to the ludicrous. There muft be fomething of what we have been accustomed to view with honour in the com-
pofition we are successively invited to contemplate again and again with bursts of laughter against the author. But that which is molt easily turned into burlefque, and affords the molt permanent hold of an attack of this fort, is the language and sentiments that had before excited in us the deepref and molt facred emotions. The very contrari-
ty between the folemn feelings with which these things had been formerly regarded, and the unexpected colour of abstraction which is given them now, makes the temptation to laughter the more violent and irrefiflible.

G. Battifa Lalli has travelted Virgil, or turned him into Italian burleque verse. Scarron has done the fame in French; and Cotton and Philips in English verfe.

Caltalio is, by fome, charged with having travelted the facred text, by reafon of the difference of air and fyle between his verfion and the original.

TRAVICE, in the Mange, is a small inclosure or ob-
long quadrangle placed before a farrier's shop, and conflit-
ing of four pillars or posts, kept close together by crofs poles. This inclosure is designed for holding and keeping in a horfe that is apt to be unruly or disorderly in the time of fhoeling, or of any operation.

This, in fome of the remoter parts of England, goes by the name of a break; and is called in French, travail.

TRAUMATICS, Treparatures, Vulneraries, or medi-
cines good for the healing of wounds. See Vulnerary
and Agglutinant, Healing, and Consolidation.

TRAUMATICUM, Balsamin. See Balsamin

Traumaticum.

TRAUN, in Geography, a river of Auffria, which rifies in the Hallatter See, forms a confiderable lake, called Traun See, and runs into the Danube, about three miles below Steyrefig.—Also, a river of Bavaria, which rifies from two lakes, Forchenee and Daubenree, and enters the Alza, 4 miles N. of Chiemfeet.

TRAVNIKOVA, a town of Russia, on the Lena; 6 miles S.S.E. of Orlenga.

TRAUERKIRCHEN, a town of Auffria; 10 miles S.S.E. of Voglinbruck.

TRAUNSTAIN, a town of Auffria; 4 miles S.W. of Zwettl.

TRAUNSTEIN, a town of Bavaria, on the Traun, where are some confiderable falt-works; 18 miles W. of Salzburg. N. lat. 47° 51'. E. long. 13° 55'.

TRAUSL, in Ancient Geography, a people of Thrace, in the environs of mount Hannus, whose manners, defcribed by Herodotus, resembled thefe of the other Thracians.

TRAUSTADT, or Wschova, in Geography, a town of the duchy of Warflaw; 40 miles S.S.W. of Pofen.

TRAUTENAU, a town of Bohemia, in the circle of Konigingritz; 21 miles N. of Konigingritz. N. lat. 50° 27'. E. long. 15° 48'.

TRAUTENFELS, a town of the duchy of Stiria; 7 miles E.N.E. of Groming.

TRAUTMANSDORF, a citadel in the county of Tyrol; 2 miles N.E. of Tyrol.

TRAUTMANSTORFF, a town of Auffria; 6 miles W.N.W. of Brugg.

TRAVUS, in Ancient Geography, a river of Thrace, which discharged its waters into the lake of Bitonis.

TRAYAGUERA, in Geography, a town of Spain, in Valencia, surrounded by a wall flanked with towers. Here is a Manufacture of fine earthenware; 30 miles N.E. of Valencia.

TRAYL-BASTON, or TRAIL-BASTON. Edward I. in his 32d year, sent out a new writ of inquisition, under this denomination, against the intrudors on other men's lands, who, to opprefs the right owner, would make over their lands to great men; against batters hired to beat men, breakers of peace, ravilers, incendiaries, fitters, false affizors, and other malefactors: which inquisition was fo strictly executed, and fuch fines taken, that it brought in much treafure to the king.

Hence, alfo, juftices of trayl-bafon, a denomination given to the juftices appointed to execute this commiffion, either by reafon of their fervor and fummary way of proceeding, or becaufe a staff was delivered them as the badge of their office, and the offendars were dragged before this jurif-
diction.

TRAYTOR, TRAITOR, Traditior, a betrayer of his
king and country, or one guilty of high-trefon. See TREATON.

TRAYTOROUS or TRAITEROUS Posiion, is parti-
cularly underftood of a tenet, which fome formerly held, of the legality of taking arms, by the king's authority, againft his perfon, and thofe commiffioned by him: which is con-
demned by statute 14 Car. II. c. 3.

TRAZA, in Geography, a town of Arabia, in the country of Yemen; 70 miles N. of Loheia.

TREACLE, in Pharmacy, &c. See Theriac.

The word treacle is alfo popularly ufed for melafes; and in this fenfe it is that Dr. Shaw, in his "Effay on Diffillery," has endeavoured to bring into ufe fcveral forts of treacales, which might be made at home, and would ferve very con-
veniently for the diffillation of spirits, or the making of potable liquors. Thefe are the infpiffated juices or deco-
cions of vegetables: fuch as the fweet juice of the birch, or fycamore, procured by tapping or piercing the trees in spring, and the common Wort made from malt, or from other vegetable fubftances treated in the fame manner. Thefe
liquors
liquors are severally to be boiled down in a copper till they begin to infipitate, and then to be poured into a balene, where the remainder of the evaporation may be finifhed without burning the infipitated juices; thus prepared, it may be at any time reduced to the rate of wort, only by adding a sufficient quantity of warm water.

Treceale is employed for the more quickly fattening some forts of domestic animals, such as sheep and neat cattle, when properly mixed and united with different sorts of dry materials, such as pollard, bruited grain, cut hay, and many other matters of the same nature, as they mollify soon become very fond of it, and it is well known to be of a very nutritious quality. Trials have been made with it in this view, with great success. See Stall-Feeding.

Treceale-Malgard, or Mitridate, in Botany. See Thlaspi.

The feed enters into the composition of the theriaca, and externally used, cleanses all sorts of ulcers, and is also a purgative, but not very common. It is reckoned an enemy to pregnant women, because it kills the fetus. James. See Thlaspeos Semen.

Treceale-Malgard, is also a name given to the clypeola.

Treceale-Water, Aqua Theriacalis, a compound cordial, or spirituous water, distilled with a spirituous menstruum, from any cordial and sudorific drugs and herbs, with a mixture of some of the theriaca Andromachi, or Venice treacle; whence its name.

TREAD, in the Measure. See Piste.

The tread of a horse is considered to be good, when firm, and without the animal resting upon one side of the foot more than upon the other, or setting down the toe or heel one before the other. Where the heels are first set down to the ground, it is often supposed to be a sign that the animal is unfeated in its feet. And where the toes are first put to the ground, it is considered as shewing that the horse has been of the team or draught kind. Consequently, in a good going horse of the caddie foot, the whole foot should be set down equally, at the same instant of time, and neither turned out nor in, in any perceptible degree.

Tread upon the Coronet, is a term applied to any injury which is done to it by the treading of the other horses or animals on it. See Coronet.

TREADHAVEN Creek, in Geography, a branch of the river Choptank.

Treading in Wheat, in Agriculture, the practice of making such land as is light, sandy, and friable, hard and firm by such means after the seed has been put into it, in order to secure its vegetation and growth in a more perfect manner. It has been suggested as useful on different kinds of soil, but it is evidently the most proper for those that are light and open, either from their particular nature and quality, or the sorts of crops by which they have been occupied, as those of the potatoe, turnip, or other simular kinds. In all such cafes, it will be found of great utility and advantage in promoting the establishment of the roots of the plants, by forcing the wheat to strike more strongly into the soil, and by keeping the fronds from injuring and throwing them out while in the early state of their growth. But in stronger lands it may be injurious and hurtful in many circumstances, and mostly unnecessary.

The best mode of effecting it is probably by the use of sheep immediately after the land has been tilled and harrowed, by turning them upon it in sufficient quantities, as they do it in a very effectual manner. Some have, however, recourse to other sorts of animals, as neat cattle and horfes, and to rolling; but this hill seldom answers well, as it is liable to increase the friability below in such soils. The cattle and horses, when in sufficient number, often produce much benefit in this way; and in some places, where the land is of a soft abraded loamy quality, teams of fix or eight oxen are used in covering the seed, in drawing a light pair of harrows, in this intention. Wherever treading is necessary in this view, it should constantly be performed in an effectual manner, with whatever sort of live-stock it is done, whether sheep, oxen, or horfes. Sometimes treading is found beneficial for wheat, on such soils, so late as March, even more so than at the time of putting in the seed, as tending to destroy weeds, such as the corn-poppy, &c.

The practice of treading in the wheats is, of course, mostly to be adopted, in all these cafes, as tending to secure and increace the quantity of the produce whenever such sorts of land are found with that kind of crop. See Wheat.

TREASON, Treachery, the act or crime of infidelity to one's lawful sovereign.

Treason is a general appellation made use by the law, to denote not only offences against the king and government, but also that accumulation of guilt which arises whenever a superior reposes a confidence in a subject or inferior, between whom and himself there subsists a natural, civil, or even spiritual relation; and the inferior so abuses that confidence, and so forgets the obligation of duty, subjection, and allegiance, as to destroy the life of any such superior or lord. Whence

Treason, in our laws, is of two sorts, high and petty.

Treason, High, or Treason Paramount, which is equivalent to the crimen lese majestatis of the Romans, (as Glanvil denominates it also in our English law,) is an offence committed against the security of the king or kingdom, whether by imagination, word, or deed.

In order to prevent the inconveniences which arose in England from a multitude of constructive trefonors, the statute 25 Edw. III. c. 2. was made; which defines what offences only for the future should be held to be trefon; and this statute comprehends all kinds of high-trefon under seven distinct branches.

1. "When a man doth compass or imagine the death of our lord the king, of our lady his queen, or of their eldest son and heir." A queen pregnant is also within the words of the act, though it does not extend to the husband of such a queen. And the king here intended is the king in possession, without any respect to his title: consequently, a king who has reneged his crown, such renunciation being admitted and ratified in parliament, is no longer the object of high-trefon; and the same reason holds in case the king abdicates the government; or, by actions subversive of the constitution, virtually renounces the authority which he claims by that very constitution. As the compalling or imagination, expressed by this statute, is an act of the mind, it cannot possibly fall under any judicial cognizance, unless it be demonstrated by some open or overt act. The statute expressly requires, that the accused be thereof upon sufficient proof attainted of some open act by men of his own condition. Thus to provide weapons or ammunition for the purpose of killing the king, is held to be a palpable overt act of trefon in imagining his death; to conspire to imprison the king by force, and move towards it by assembling company, is an overt act of compassing the king's death; and taking any measures to render treasonable purposes effectual, as assembling and consulting on the means to kill the king, is a sufficient overt act of high-trefon. It now seems clearly to be agreed, that, by the common law and the statute of Edw. III., words spoken amount only to a high misdemeanor, and no treason. If the words be set down
TREASON.

down in writing, it argues more deliberate intention; and it
has been held, that writing is an overt act of treason; for
scribere est ager.

But even in this case, the bare words are not the treason, but the deliberate act of writing them. It
was formerly held, that the publication of a treasonable
writing was a sufficient overt act of treason at the common
law; though of late even that has been questioned.

2. The second species of treason is, “if a man do violate
the king’s companion, or the king’s eldest daughter un-
married, or the wife of the king’s eldest son and heir.” By
the king’s companion is meant his wife, and by violation is
understood carnal knowledge, as well without force, as with
it; and this is high-treason in both parties, if both be con-
senting.

3. The third species of treason is, “if a man do levy
war against our lord the king in his realm.” And this may
be done by taking arms, not only to dethrone the king, but
under pretence to reform religion, or the laws; or to remove
evil counsellors, or their grievances, whether real or pre-
tended; and by intimidation and violence to force the re-
peal of law.

4. “If a man be adherent to the king’s enemies in his
realm, giving to them aid and comfort in the realm, or else-
where,” he is also declared guilty of high-treason. This
must likewise be proved by some overt act, as by giving
them intelligence, by sending them provisions, by selling
them arms, by treacherously surrendering a fortress, or the
like.

5. “If a man counterfeit the king’s great or privy-seal,”
this is also high-treason.

6. The sixth species of treason under this statute is, “if a
man counterfeit the king’s money; and if a man bring
false money into the realm counterfeit to the money of
England, knowing the money to be false, to merchandise
and make payment withal.” Counterfeiting the king’s
money is treason, whether the false money be uttered in
payment, or not. Also if the king’s own minters alter the
standard or alloy established by law, it is treason. But
gold and silver money only are held to be within this
statute. With regard, likewise, to importing foreign coun-
terfeit money, in order to utter it here; it is held that
uttering it, without importing it, is not within the statute.

7. The last species of treason ascertained by this statute
is, “if a man slay the chancellor, treasurer, or the king’s
justices of the one bench or the other, justices in eyre, or
justices of assize, and all other justices assigned to hear and
determine, being in their places doing their offices.” This
statute extends only to the actual killing of them, and not
to a wounding, or bare attempt to kill them. The barons
of the exchequer are not within the protection of this act;
but the lord keeper or commissaries of the great seal now
seem to be within it, by virtue of the statute 5 Eliz. c. 18.
and 1 W. & M. c. 21.

The new treasons created since the statute 1 M. c. 1.
and not comprehended under the description of statute
25 Edw. III. may be comprised under three heads. The
first species relates to Papists; the second, to falsifying the
coin (see British Coins) or other royal signatures; as falsely
forging the sign manual, privy siget or privy seal, which
shall be deemed high-treason. (1 M. l. ii. c. 6.) The third
new species of high-treason, is such as was created for the
security of the Protestant succession in the house of Ha-
over. For this purpose, after the Act of Settlement was
made, it was enacted by statute 25 Edw. III. c. 3, that
the pretended prince of Wales, assuming the title of king
James III., should be attainted of high-treason; and it was
made high-treason for any of the king’s subjects to hold cor-
respondence with him or any person employed by him, or to
remit money for his use. And by 17 Geo. II. c. 39, it is
enacted, that if any of the sons of the Pretender shall land
or attempt to land in this kingdom, or be found in the king-
don or any of its dominions, he shall be adjudged attainted
of high-treason; and corresponding with them or remitting
money to their use, is made high-treason. By 1 Ann. flt. 2.
c. 17, the offence of hindering the next in succession from suc-
cessing to the crown is high-treason; and by 6 Ann. c. 7, if
any person shall maliciously, advisedly, and directly, by writing
or printing, maintain, that any other person hath any right to
the crown of this realm, either without according to the
Act of Settlement, or that the kings of this realm, with the
authority of parliament, are not able to make laws to bind
the crown and its defective; such person shall be guilty of
high-treason.

The punishment of high-treason in general is very solemn
and terrible. 1. That the offender be drawn to the gallows,
and not be carried or walk; though usually (by connivance,
at length ripened by humanity into law) a fledge or hurdle
is allowed, to preserve the offender from the extreme tor-
ment of being dragged on the ground or pavement. 2. That
he be hanged by the neck, and then cut down alive. 3. That
his entrails be taken out, and burned, while he is yet alive.
4. That his head be cut off. 5. That his body be divided
into four parts. 6. That his head and quarters be at the
king’s dispofal.

The king may, and often doth, discharge all the punish-
ment, except beheading, especially where any of noble blood
are attainted. For beheading being part of the judgment,
that may be executed, though all the rest be omitted by the
king’s command. But where beheading is no part of the
judgment, as in murder or other felonies, it hath been said
that the king cannot change the judgment, although at the
request of the party, from one species of death to another.
See Execution.

In the case of coining, the punishment is milder for male
offenders; being only to be drawn, and hanged by the neck
till dead. But in treasons of every kind, the punishment
of women is the same, and different from that of men: for,
as the decency due to the sex forbids the exposing and publicly
mangling of their bodies, their sentence is to be drawn to the
gallows, and there to be burnt alive.

The confessions of the judgment pronounced upon a
traitor are attainted, for forfeiture, and corruption of blood.
See ATTAINDER, &c.

It is a maxim, that, in majori probitione, omnes sunt princi-
pales, there are no accusers in high-treason, all are accounted
principals.

Also, that voluntas non reputabitur pro facto, nisi in causa
proditionis, the will is never taken for the deed in any one,
but in that of high-treason. See INDICTMENT.

TREASON, Petit or Petit, according to the fl. 25 Edw. III.
c. 2, may happen three ways: by a servant killing his
master, a wife her husband, or an ecclesiastical person (either
peculiar or regular) his superior, to whom he owes faith and
obedience. A servant, who kills his master whom he has
left, upon a grudge conceived against him during his service,
is guilty of petit treason: so if a wife be divorced a mensa et
thoro, fill the vinculum matrimonii subfatis; and if the kill
such divorced husband, she’s a traitress; and if a clergyman
is underoath to owe canonical obedience to the bishop who
ordained him, to him in whose diocese he is benefited, and
also to the metropolitam of such suffragan or diocesan bishop;
and therefore to kill any of these is petit treason.

A person indicted of petit treason may be acquitted thereof,
and found guilty of manslaughter or murder; and in such case,
it should seem that two witnesses are not necessary, as in the
case of petit treason they are. See Indictment.

The punishment of petit treason, in a man, is to be drawn
and hanged; and in a woman, to be drawn and burnt: the
idea of which latter punishment, says judge Blackstone, seems
to have been handed down to us by the laws of the ancient
Druids, which condemned a woman to be burnt for murder-
ing her husband; and it is now the usual punishment for all
forts of treasons committed by those of the female sex. Per-
fous guilty of petit treason, were first debared the benefit of
clergy by stat. 12 Hen. VIII. c. 7. which has been since
extended to their aiders, abettors, and counsellors, by stat.
23 Hen. VIII. c. 1. 4. and 5 P. & M. c. 4.

This kind gives forfeiture of lands by sequestration to the lord
of the fee. See Forfeiture and Sequestration.

TREASON, Accumulative. See Accumulation. Blackl.
Comm. vol. iv. &c.

TREASON, Appeal of High. It was anciently permitted,
that any subject might appeal another subject of high-treason,
either in the courts of common law, or in parliament, or
(for treasons committed beyond the seas) in the court of the
high constable and marshal. The cognizance of appeals in
the latter still continues in force; and so late as 1651, there
was a trial by battle awarded in the court of chivalry, on
such an appeal of treason; but that in the first was virtually
abolished by the first stat. 5 Edw. III. c. 9. and 25 Edw. III.
c. 24. and in the second expressly by stat. 1 Hen. IV. c. 14.
So that the only appeals now in force, for things done within
the realm, are appeals of felony and mayhem. Blackl.
Comm. vol. iv.

TREASON, Constructive, an offence raised, by forced and
arbitrary construetion, into the crime and punishment of
treason, which never was suspected to be such: a multitude
of these excited before the inconvenience was remedied by
25 Edw. III. c. 2. Constructive treasons were also nu-
merous in the reign of Richard II. and afterwards between
the reign of Henry IV. and queen Mary, and particularly
in the bloody reign of Henry VIII., all which were abro-
gated by the stat. 1 Mary, c. 1. which once more reduced all
treasons to the standard of the stat. 25 Edw. III.

TREASON, Misprision of. See Misprision.

TREASURE, Thesaurus, strong box, a store, or flock
of money, in reserve.

TREASURE, q.d. treasure found, thesaurus inventus,
in Law, is when money, gold, silver, plate, or bullion, is
found in the ground, in any place, and none knows to whom
it belongs.

This should naturally fall to the finder, to whom it for-
merly belonged, as was the rule of the civil law; but par-
cular nations have made particular provisions for it. The
Jews give it to the proprietor of the place where it was
found: the Roman jurisprudence was various with regard to
it; sometimes it was given to the master of the grounds,
sometimes to the finder, and sometimes it was adjudged to the
public treasury.

In England, and also in Germany, France, Spain, and
Denmark, the general usage is, to have such treasure seque-
tered to the king, unleas where the benefit of it is expressly
granted or made over by the king to some other, as the lord
of the manor; and that the prince shall be intitled to this
hidden treasure, is now become, according to Grotius, jus
commune et gentium. If, indeed, he that hid it be known, or
afterwards found out, the owner, and not the king, is intitled
to it. Also, if it be found in the sea, or upon the earth, it
doeth not belong to the king, but the finder, if no owner
appears. So that it feems it is the hiding, not the abandon-
ing of it, that gives the king a property.

Vol. XXXVI.

In some places in France it is divided into three parts,
one for the king, one for the proprietor of the land, and one
for the finder.

Briton says, it is every subject's part, as soon as he hath
found any treasure in the earth, to make it known to the
coroner of the county, &c.

The punishment for concealing treasure found in England,
was formerly no less than death; but now it is only imprison-
ment and fine; but if any mine of metal be found in any
ground, it always appertains to the lord of the soil, except
it be a mine of gold or silver, which anciently always be-
longed to the king, in whose ground forever it was found;
but, by an act of parliament, the king hath now only the
pre-emption.

TREASURER, an officer to whom the treasure of the
prince, or corporation, is committed to be kept, and duly
dispersed, in payment of officers, and other expenses. See
TREASURE.

Of these there is a great variety. His majesty of Great
Britain, in quality of elector of Brunswick, was formerly
arch-treasurer of the Roman empire. In the states of Po-
land are two grand-treasurers; that of the kingdom of
Poland, and that of the duchy of Lithuania.

In England, the principal officers under this denomination
are, the lord high-treasurer, the treasurer of the house-
hold, treasurer of the navy, the king's chamber, &c. &c.
Anciently, we had likewise a treasurer of the exchequer, trea-
urer of war, &c. In the Roman countries, the title of treasurer is also
given, somewhat abusively, to an ecclesiastical, who has the
keeping of the relics, and of the charters and archives of a
church or monastery. This dignity succeeds, in some mea-
sure, to that of the ancient deacons, who had the like charge
in the primitive church.

TREASURER of England, Lord High, is the principal
officer of the crown; under whose charge and government is
all the king's revenue kept in the exchequer.

He receives the office by delivery of a white staff to him
from the king, and holds it during the king's pleasure: an-
ciently he received it by delivery of the golden keys of the
treasury.

He has the cheque of all the officers any way em-
ployed in collecting imposts, customs, tributes, or other
revenues of the crown. He has the gift of all the customs,
comptrollers, and searchers' places, in all the ports of
London; and the nomination of the escheators in every
county.

He alone (or others in commissione with him) lets leaves of
crown-lands, gives warrants to certain persons of quality
to have their wine custom-free, &c.

Killing, the lord-treasurer in the execution of his office, is
trea-treson.

The office of lord-treasurer is now in commision.

The number of lords-commissioners is five.

TREASURER of the Household, is an officer who, in the
absence of the lord-warden, has power, with the comptroller
and other officers of the Green-cloth, and the steward of the
Marhalls, to hear and determine treasons, felonies, and
other crimes committed within the king's palace. See
HOUShOLD.

There is also a treasurer belonging to the establishment of
her majesty's household, &c.

TREASURER of the Navy, is an officer who receives money
of the exchequer, by warrant from the lord high-treasurer,
or the lords-commissioners executing that place; and pays all
charges of the navy, by warrant from the principal officers
of the navy. See NAVY.
TRE

Treasurer of the County, he that keeps the county flock.

There are two of them in each county, chosen by the major part of the justices of the peace, &c. at their general quarterly seissen; under previous security given for the money entrusted with them, and the faithful execution of the trust repose on them.

The justices may continue or remove these treasurers at pleasure, and allow each of them a salary of 20l. a year.

The county fock, of which this officer hath the keeping, is raised by rating every parish yearly; and is disposed of to charitable uses, for the relief of maimed foldiers and mariners, prisoners in the county-gaols, paying the salaries of governors of houses of correction, and relieving poor almshouses, &c. And the duty of these treasurers, with the manner of raising the fock, and how it shall be disposed of, is set forth particularly in the statutes of 43 Eliz. cap. 2. Jac. I. cap. 4. 11 & 12 W. III. cap. 18. 5 Ann. cap. 32. 6 Geo. I. cap. 23. See particularly 11 Geo. II. cap. 20, and 12 Geo. II. cap. 29.

Treasurer, in Cathedral Churches, an officer whose buffets was to take charge of the vestments, plate, jewels, relics, and other treasuries belonging to the said churches. At the time of the Reformation, the office was extinguished as needless in most cathedral churches; but it is still remaining in those of Salisbury, London, &c.

TREASURY, the place in which the revenues of a prince are received, preferred, and disbursed.

In England, the treasury is a part of the exchequer; by some called the lower exchequer.

The officers of his majesty's treasury, or the lower exchequer, are the lords-commissioners, one of whom is chancellor, two joint secretaries, private secretary to the first lord, two chamberlains, an auditor, four tellers, a clerk of the seals, officers of the receipt, a tally-cutter, &c. See each officer under his proper article, CHANCELLOR, TELLER, TALLY, &c.

At Rome, under the emperors, there were two kinds of treasuries, the one called ararium, wherein the monies defined to support the charges of the government were kept; the other fiscus, wherein were preferred those intended for the particular subsistence of the emperor and his court. In effect, the ararium belonged to the people, and the fiscus to the prince. See ARARIUM and FISCUS.

We have still a remembrance of this difference among us; but it is confounded in France, &c. where the king disposes absolutely of the public treasuries, &c.

The Athenian treasury was sacred to Jupiter SOUTAR, or the Saviour, and to Pallas the god of riches. Besides the public monies, there were always a thousand talents kept in it, which it was capital to touch, unless on the most pressing occasions. See OPISIODOMUS.

The funds, among the Athenians, which supplied their treasury, were four; viz. the Athenians, the tele, telis; the phori, fagula; the eisbore, eisfogra; and the timematia, tynamata.

The public treasury was divided into three parts, according to the use it was applied to: as 1. The chremata of the diocese, or that expended in civil uses. 2. The chremata for the war, or money designed to defray the charges of war. 3. The chremata, or money intended for pious uses, in which they included the expenses at plays, public shows, and festivals, &c. Potter Archirol. Græc. tom. 1. p. 82.

To each of these branches of the public revenue there was a treasurer appointed, as την την την την την την την, and την την. So we see:

TREASURY, Lords of the. In lieu of one single director and administrator of his majesty's revenues, under the title of lord high-treasurer, it is frequently thought proper to put that office in commission, i.e. to appoint several persons to discharge it, with equal authority, under the title of lords-commissioners of the treasury. See Lord-high-Treasurer.

TREASURY Islands, in Geography, a cluster of islands among Solomon's islands. S. lat. 6° 38' to 7° 30'. E. long. 155° 34' to 156°.

TREAT, in our old Law-Books, signifies as much as taken out, or withheld. Thus a juror was challenged, because he could not dispense 40l. and therefore was treated by the statute, or discharged.

TREATISE, Tractus, a set discourse in writing, on any subject.

A treatise is supposed more express, formal, and methodical, than an essay; but else so than a system.

TREATY, Lat. Fidus, a covenant between several nations; or the several articles or conditions stipulated and agreed upon between sovereign powers.

Sovereigns treat with each other by their proxies, who are invested with sufficient power, and who are commonly called plenipotentiaries. The rights of the proxy are expressed in the instructions that are given him; but every thing he promises within the terms of his commission, and the extent of his powers, bind his constituent. At present, in order to avoid all danger and difficulty, princes refer to themselves the ratification of what has been concluded upon in their name by their ministers. A treaty is valid, if there be no fault in the manner in which it was concluded; and for this purpose nothing more can be required than a sufficient power in the contracting parties, and their mutual consent, sufficiently declared. If, however, a treaty has been honestly concluded by a sovereign without his perceiving any iniquity in it, and turns at length to the detriment of an ally, nothing can be more amiable, more laudable, more conformable to the reciprocal duties of nations, than to yield as much as possible, without being wanting to himself, without putting himself in danger, or without suffering a considerable loss. Since every treaty ought to be made with a sufficient power, a treaty pernicious to the state is null, and not at all obligatory; no conductor of the nation having the power to enter into engagements to do such things as are capable of destroying the state, for the safety of which the empire is entrusted to him. Moreover, a treaty made for an unjust and dishonest intention is absolutely null; nobody having a right to engage to do things contrary to the law of nature. Nations and their conductors ought to keep their promises and their treaties inviolable. This great truth, though too often neglected in practice, is generally acknowledged by all nations: the reproach of perfidy is esteemed by sovereigns a most atrocious injury; and he who does not observe a treaty is certainly perfidious, since he violates his faith. On the contrary, nothing adds so great a glory to a prince, and the nation he governs, as the reputation of an inviolable fidelity to his promise. To violate a treaty, is to violate the perfect right of him with whom we have contracted, and this is to do him an injury. No subsequent treaty can be made contrary to those that actually subsist. Nothing hinders a sovereign from entering into engagements of the same nature with two or more nations, if he is at the same time able to fulfill them with respect to all his allies. But in cases of competition or difference, the most ancient ally ought to be preferred; and, besides, the justice of the cause is another reason of preference between two allies; nor ought we to afflict him whose cause is unjust, whether he be at war with one of our allies, or with another state.

Grotius (De Jure Belli et Prin. I. c. 15. § 5.) divides treaties into two general classes: viz. 1. Those which turn merely
merely on things to which we were already bound by the law of nature; and 2. Those by which we engage something more. Of the first clafs are all the simple treaties of peace and friendship, when the engagements contracted in them add nothing to what men owe each other as brethren, and as members of the human society; as those that permit commerce, paflage, &c. Treaties of the second clafs, in which sovereigns engage to do what they are not obliged to perform by the law of nature, are either equal or unequal. Equal treaties are those in which the contracting parties promise the fame things, or things that are equivalent, or, in short, that are equitably proportioned, fo that their condition is equal; such, e.gr. is a defensive alliance, in which they reciprocally fipulate for the fame fuccors: such is an offensive alliance, in which it is agreed that each of the allies fhall furnish the fame number of veffels, the fame number of troops, of caPafy and infantry, or an equivalent in veffels, in troops, in artillery, or in money. Such is also a league, in which the contingent of each of the allies is regulated in proportion to the interest he takes or may have in the design of the league. Equal treaties may be subdivided into as many kinds as the sovereigns have different transactions between them. Thus they treat of the conditions of commerce, of their mutual defence, of affocations in war, of the paflage they fhall reciprocally grant to each other, or refused to the enemies of their ally, &c.

Nations ought as much as possible to preserve equality in their treaties.

Equal treaties are distinguished from equal alliances. The former are those where equality is kept in promifes; and the latter are those where equal treaties with equal, forming no difference in the contracting parties, or, at leaft, admitting no superiority too plainly pointed out; but only some pre-eminence of honours and rank. Unequal treaties are those in which the allies do not promise the fame things; and the alliance is unequal when it makes a difference in the dignity of the contracting parties. Those unequal treaties that are at the fame time unequal alliances, are divided into two kinds: the first, where the inequality is found on the side of the moft confiderable power, and the second comprehending treaties where the inequality is on the side of the inferior power. Unequal alliances are subdivided into two kinds, fuch as degrade the sovereignty, and fuch as do not.

By another general division of treaties or alliances, they are distinguished into personal and real; the former are those that relate to the person of the contracting parties, and are confined and in a manner attached to them. Real alliances relate only to the things of which they treat, without any dependence on the person of the contracting parties. The personal alliance expires with him who contracted it; but the real alliance is allied to the body of the state, and subsists as long as the state, if the time of its duration is not limited. The alliance terminates as soon as the term of it is expired; but a treaty made for a time may be renewed by the common consent of the allies, and the renewal is manifested either expressly or tacitly.

Treaties between nations are sacred; and he who violates his treaties, violates at the fame time the law of nations; for he defpies the faith of treaties, that faith which the law of nations declares sacred, and he does all in his power to render it vain. But unhappy experience having too fully convinced mankind, that the faith of treaties is not always a sufficient warrant for their being observed, securities have been fought for against perjury; and hence is derived the origin of a guaranty, and hostage, which fee. The interpretation of treaties is fubjecf to certain rules or maxims, of which writers on this fubjecf have enumerated the following. It is not allowable to interpret what has no need of interpretation: if he who can and ought to explain himself has not done it, it is to his own damage: neither of the contracting parties has a right to interpret the treaty at his pleasure: what a perfon has sufficiently declared, ought to be taken for true against him: the interpretation ought to be made according to certain rules previously understood and allowed. For these and other particulars, we refer to Vattel's Law of Nations, b. ii.

For the folemn manner in which the Romans used to conclude treaties, fee Livy, lib. i. cap. 24. The ceremonies observed by the Greeks in making treaties may be seen in Pot-ter, Archæol. Græc. lib. ii. cap. 6. tom. i. p. 525, &c.

In general, it appears that the ancients were very religious, grave and folemn in making treaties; which were always confirmed by sacrifices and mutual oaths, with horrid impreca-tions on the party that should break the terms of agreement.

There are treaties of war, of peace, of marriage, of con-federacy, of neutrality, of capitulation, and of commerce and navigation.

Treaties relating to war are of several kinds. Some of these are connected with alliances, defensive and offensive. In judging of the morality of these several treaties or alliances, or of the lawfulnefs of them, according to the law of nations, the following is an incontestable principle: It is lawful and commendable to succour and affift, in any way, a nation making a juft war; and this affiftance is the duty of every nation, which can give it without being wanting to itself. But he who makes an unjust war is not to be affifted in any manner. Other treaties relating to war include those of neutrality. Sometimes necessity renders a treaty of this fort justifiable; at other times this kind of treaty is the best method of securing peace, and preventing alteration. Some treaties relate to the paflage of troops through a neutral country; and others to the search of neutral ships, &c.

When the powers at war have agreed to lay down their arms, the agreement or contract in which they fipulate the conditions of peace, with the manner in which it is to be restored and supported, is called the "treaty of peace." The effect of this treaty is to put an end to the war, and to abolish the fubjed of it. It leaves the contracting parties without any rights of committing hostility, either for the very fubjed which kindled the war, or for what has passed in the course of it; it is therefore no longer permitted to take up arms again for the fame caufe. Accordingly, in these treaties, the parties reciprocally obligle themselves to a perpetual peace, which is not to be understood as if the contracting parties promised never to make war on each other for any caufe whatever. Peace relates to the war which it terminates; and as it forbids the revival of the fame war by taking arms for the caufe which at first kindled it, is in reality perpetual. As it is the end of peace to extinguish all fubjeds of difcord, animosity, or a perfect oblivion of what is past, should be the leading article of the treaty; and though the treaty should be silent on this head, it is necessarily understood. This treaty binds the contracting parties from the moment of its conclusion, as soon as it has paflèd through all its forms. From this time all hostilities ceafe, unless a day is specified when the peace shall take place; but this treaty becomes obligatory on fubjeds only from the time of its being notified to them. When no term is assigned for the accomplishment of the treaty, and the execution of the several articles, common fenee dialects that every point should be executed as soon as possible. The faith of treaties equally excludes from the execution of them all neglect, all dilator-iness, and deliberate delays. A treaty of peace is a public treaty,
Tre, a town of Spain, in the province of Leon; 46 miles S. of Civid Rodrigo.

TREBELLIANICA, or TREBELLIAN Fourth, in the Roman Jurisprudence, a right belonging to an heir instituted by testament. If the testator, after appointing a full and general heir, spent and disposed of all his effects in legacies; or if he went ultra dictatam, beyond three-fourths thereof; in that case, the heir was allowed to retrench and retain one fourth part of the legacies to his own use. This was called the trebelfiana.

In like manner, if the testator charges his heir with a feoffment of trust, and to restore the inheritance to another; in that case, the heir might likewise retain a fourth of the whole succession, that the quality of heir might not be rendered wholly vain and fruitless.

TREBELLUS-POLlio, in Biography, a Latin historian, flourished about the year 298 of the vulgar era. According to Vopiscus, he wrote the lives of the Roman emperors from the two Philips to Claudius; but we have extant only the latter part of the reign of the elder Valerian, that of his son, the lives of the two Gallici, those of the thirty tyrants, and that of Claudius. He is reckoned one of the "Historia Augusta Scriptores," and praised by Vopiscus for his exactness, which applies only to some dates, as in other points he is very incorrect. His style is somewhat superior to that of the other historians. Volusi.

TREBENDA, in Ancient Geography, a town of Asia Minor, in the interior of Lycia. Ptol.

TREBENITZ, in Geography, a town of Bohemia, in the circle of Leitmeritz; 70 miles S.W. of Leitmeritz. N. lat. 50° 27'; E. long. 14° 5'.

TREBENTSHIKOV, a forteress of Ruffia, in the government of Caucalbus, on the Ural; 64 miles N. of Guryev.

TREBERK, a town of Germany, in the duchy of Anhalt-Cotten; 4 miles N. of Cothen.

TREBES, a town of France, in the department of the Aude; 6 miles E. of Carcassonne.

TREBIA, in Ancient Geography, a river which ran from south to north, commencing in Liguria, south of the valley inhabited by the Prinates, and palling into Gallia Cipadana, across the territory of the Aramines, watered the town of Placentia, and discharged itself into the Padus. The Trebia was famous for the victory obtained by Hannibal, near its mouth, over the preeminent and impudent Sempronius, in the year of Rome 435; on which occasion the Romans lost 26,000 men.

TREBIA, in Geography, a river of Italy, which runs into the Po, 2 miles W. of Piacenza.

TREBIGNO, a town of European Turkey, in Dalmatia; the seat of a bishop; 60 miles S. of Mollar.

TREBINA, a town of Naples, in Bafllicata; 5 miles S.S.W. of Turri.

TREBISACCIA, a town of Naples, in the province of Calabria Circa, on the coast; 10 miles N.E. of Caffano.

TREBISOND, or TARABOSAN, a city of Asiatic Turkey, with a harbour, on the Black Sea, in the country of the Colchians; founded by a Greek colony of Sinope, defended from the Miletians. It derives its historical fame more from the circumstance of its hospitable reception of the 10,000 Greeks after their celebrated retreat, than for having been the capital of that portion of the Lower Empire. From the Romans it was taken by the Scythians, or Tarars, in the time of Valerian. The Greek emperors became afterwards masters of Trebizond, and erected it into a principality; Alexis Comnenes took possession of it in the year 1204. When the French and Venetians made themselves masters
masters of Constantinople, this principality, or, as it is
f sometines called, empire, continued till the year 1462,
when it was taken by Mahomet II., who carried David
Commences and all his family prisoners to Constantinople,
where they were mostly put to death. The town of Tre-
bifond is built on the sea-side, at the foot of a little hill,
pretty steep; its walls are almost square, high embawed,
and, though they are not of the first ages, yet it is very
probable they stand upon the foundations of the ancient in-
closure, which got this town the name of “Trapezium,”
or “Trapezus.” The present walls are built of the ruins
of the ancient edifices, as appears by old pieces of marble
fet in several parts, and whose inscriptions are not legible,
becaus they are too high. The town is large, and not well
peopled; there are more woods and gardens in it than
houfes; and those houfes that are there, though well built,
are but one florly high. The caftle, which is pretty large,
but very much neglected, is situated upon a flat rock, and
its ditchs are cut in the rock. The inferption that is on
the gate of this caftle, the arch whereof is a femi-circle,
shows that the emperor Jullian repaired the edifices of the
town. The port of Trebifond, called “Platana,” is to the
geft of the town. The emperor Adrian caufed it to be re-
paired, as we are informed by Arrian. This port is now
proper for nothing but trajiques. The mole which the
Genoese are faid to have built there is almost defroyed, and
the Turks give themselves very little trouble about repairing
fuch works; 170 miles N.N.E. of Sivas. N. lat. 41° 1'.
E. long. 50° 40'.
TREBITSCH, or Trebitz, a town of Moravia, in the
circle of Iglau, on the Iglawa, with confiderable manu-
factures of cloth, iron, glafs, &c.; 20 miles S.E. of Iglau.
N. lat. 49° 14'. E. long. 15° 50'.
TREBITZ, a town of Saxony; 3 miles N.W. of
Schmeidberg.
TREBIUS, in Lythology, a name given by Joannes
Cuba, and some other writers, to the fish called pliycis by
Aritotle, Aelian, and Pliny.
TREBLE, in Musick, the highest of the four
parts in fymphony, or that which is heard the cleareft and
shrieff of in a concert.
In the like fenfe we fay, a treble violin, treble hautboy,
&c.
In vocal musick, the treble is usually commiffed to boys
and girls. Their part is the treble.
The treble is divided into firt or highest treble, and
second or beft treble. The half treble is the fame with the
counter-tener.
TREBLIZ, in Geography, a town of Bohemia, in the
circle of Leitemitz; 10 miles S.W. of Leitemitz.
TRENBITZ, a town of Silefia, in the principality of
Oels; 12 miles N. of Breclaw. N. lat. 51° 18'. E. long.
17° 2'.
TREBNIZ, a town of Bohemia, in the circle of Leitem-
itz; 6 miles S.W. of Leitemitz.
TREDOWE. See Tribat.
TREBSCHEN, a town of Brandenburg, in the New
Mark; 6 miles S.E. of Zulichau.
TREBSEN, a town of Saxony, in the circle of Leipic,
on the Muldan; 26 miles W. of Meiffen. N. lat. 51° 16'.
E. long. 13° 42'.
TREBUCHET, Trebucquet, or Trebucquetum, a
tumbler, ducking, or eucking-flood. See Cucking-Stool
and Scolds.
Trebucquet, in Artillery, a machine for throwing ftones,
for which purpose a fling was fometimes fixed to it: it
acted by means of a great weight fattened to the fhort arm
of a lever, which being let fall, raised the end of the long
arm with a great velocity.
TREBULAZ MUTUSCA, in Ancient Geography, a town
placed by Strabo and Pliny among the Sabines, the exiftence
of which is testified by many infcriptions. Virgil recog-
nizes it for its olives, which perhaps might have occafioned
its being called “Oliveto.”
TREBULAZ SUFFENATA, a town of Italy, in the
Sabine territory. It is fuppofed to have been fittuated in
the valley of Tura eo, probably at the place called Rocca
Sinibaldi.
TREBURG, in Geography, a town of Heife-Darmfaald;
10 miles W. of Darmfaald.
TREBUXENA, a town of Spain, in the kingdom of
Seville; 12 miles from Xeres de la Frontera.
TRECASE, a town of Naples, in the province of
Otranto; 5 miles E.N.E. of Aeifeano.
TRECASSIS, or Trecasit, in Ancient Geography, a
people of Celtic or Lyonnefe Gaul, according to Pliny and
Ptolemy; fubjeft, in the time of Cefar, to the city of Sens
(civitas Senonum), which was very powerful.
TRECASTE, in Geography, a town of Italy, in the
department of the Olona; 5 miles E. of Novara.
TRECCHINA, a town of Naples, in Basilicata; 36
miles S. of Potenza.
TRECENTA, a town of Italy, in the department of
the Mineco; 25 miles E.S.E. of Mantu,a.— Alfo, a town of
Italy, in the department of the Lower Po; 12 miles
N.N.W. of Ferrara.
TRECHEDIPNA, zevEcj, a formed of qjo, I run,
and inftex, a fugger, in Antiquity, a kind of lively, or dif-
tinguishing habits worn by paraflites; the wearing of which
was a fufficient passport to the tables of their patrons whose-
lively it was.
TRECHINIA, or Trachinia, in Ancient Geography,
a fmall country of Thrify, occupying the whole moun-
tainous part well of the Malici gulf, between the river
Spencerius to the north and mount Oeta to the south. Near
it was Hercules Trachinia.
TRECHIS. See Trachis.
TRECHANT, one of the many names by which the
chemical writers have called quickfiver.
TRECOTHIC, in Geography, a township of New
Hampshire; 65 miles N.W. of Portmouth.
TREDREDE, or Treddle, Chafna, in Natural His-
tory, a part of an egg. See Chalaza.
TREDDECLE. See Aspect.
TREE, Arboz, the first and largift of the vegetable
kind, confifing of a fingle trunk, out of which spring forth
branches and leaves.
Mr. Ray distinguishes the trees and shrubs of our native
growth of England into, 1. Such as have their fower dis-
jointed and remote from the fruit: which are
1. The nufciferous trees, or fuch as bear nuts: as the
walnut-tree, the hazel-nut-tree, the beech, the chefun, and
the common oak.
2. Coniferous trees, or fuch as bear a fquamous or fcaly
fruit, of a conical figure, and a woody or hard ftuff, in
which are many feeds, which, when they are ripe, the
cone opens or grapes in all its ferveral cells or partifions,
and lets drop out; of this kind are the Scotch fir, male and
female; the pine, which, in our gardens, is called the Scotch
fir; the common alder-tree, and the birch-tree.
Thefe trees are also called elfinerous, by reafon that
coniferous trees are generally covered with a burr that
abounds in refin.
3. Bacciferous trees, are such as bear berries, as the juniper and yew-tree.

4. Lamiforous, or fuch as bear a woolly, downy

5. Trees which bear their seeds (having an imperfect

II. Such as have their fruits and flowers coniious;

The latter kinds are either such as have their fruit moist and soft when ripe: as, 1. Pruniferous ones, whose fruit is pretty large and soft, with a stone in the middle; as the black-thorn, or fuc-tree, the black and white bullace-tree, the common wild cherry, the black cherry, &c.

2. Bacciferous, as the strawberry-tree common in

Of such as have their fruit dry when ripe: as the bladdernut-tree, the box-tree, the common elm and ash, the maple, the gaule, or sweet willow, common heath-broom, dyer's-weed, furze or gorse, and the lime-tree.

TREES in full Air, or Standards, are such as naturally rise a great height, and are not topped. See Standards, Standard-Trees, and Timber.

TREES, Dwarf, are fuch as are kept low, and never suffered to have above half a foot of stem. These are used to be kept vacant, or hollow in the middle, that the branches, spreading round about the fides, may form a kind of round bowl, or buhl. See Dwarf-Trees.

TREES, Fortified. See Forest-Trees and Planting.

TREES, Wall, are fuch whose branches are stretched out, and nailed against walls.

For dwarf and wall-trees, fuch are to be chosen out of the nursery for transplantation as are straight, and confift of a single item, and a fingle graft, rather than two or three grafts in several branches: their thickens at bottom, when removed, should be two or three inches.

TREES, Fruits, are fuch as bear fruit. See Fruit-Trees.

TREES, Timber, are fuch whose trunks are tall and straight, of which beams, masts, &c. are used to be made.

TREES, that are nine inches girt about a yard from the ground, are commonly reckoned timber-trees, but none under this fize. See Timber and Planting.

The growth of trees is a curious and interesting subject; but few experiments have been made in order satisfactorily to ascertain the annual accifions that are made to the bulk of trees at different periods of their age. Mr. Barker has furished a table exhibiting the increafe of three kinds of trees, viz. the oak, ash, and elm, in the Phil. Tranf. for 1788. He fates the refult as follows:

"I find (fays he) the growth of oak and ash to be nearly the fame. I have fome of both forts planted at the fame time, and in the fame hedges, of which the oaks are the largest; but there is no certain rule as to that. The common growth of an oak or an ash is about an inch in girth in a year; fome thriving ones will grow an inch and a half; the unthriving ones not fo much. Great trees grow more

timber in a year than small ones; for if the annual growth be an inch, a coat of one-fifth of an inch is laid on all round, and the timber added to the body every year is its length multiplied into the thickens of the coat and into the girth, and therefore the thicker the tree is, the more timber is added."

We will prefent our readers with a table, fhewing the growth of 17 kinds of trees for two years. The trees grew at Cavenham in Suffolk.

Heat is so efential to the growth of trees, that we fee them grow larger and smaller in a fort of gradation as the climates in which they stand are more or lefs hot. The hottest countries yield, in general, the largest and taller trees, and those also in much greater beauty and variety than the colder do; and even thofe plants which are common to both, arrive at much a greater bulk in the fouthern than in the northern climates; nay, there are fome regions fo bleak and chill, that they raife no vegetables at all to any confiderable height. Greenland, Iceland, and the like places, afford no trees at all; and what shrubs grow in them are always little and low.

In the warmer climates, where trees grow to a moderate fize, any accidental diminution of the common heat is found very greatly to impede vegetation; and even in England, the cold fummers we fometimes have, give us an evident proof of this; for though the corn and low plants have fucceeded well enough, and goofeberries, currants, rafberries, or other low shrubs, have brought forth fruit in fufficient plenty, yet the production of taller trees has been found very much hurt; and walnuts, apples, and pears, have been very fcarce among us.

Heat, whatever be the producing caufe, acts as well upon vegetation one way as another. Thus the heat of dung, and the artificial heat of coal-fires in floves, is found to supply the place of the fun.

Great numbers of the Indian trees, in their native foil, flower twice in a year, and fome flower and bear ripe fruit all the year round; and it is observed of thefe latt, that they are at once the moft frequent and the moft ufeful to the inhabitants; their fruits, which always hang on them in readnefs, containing cool juices, which are good in fevers, and other of the common difeafes of hot countries.

Plantations of ufeful trees might be made to very great advantage in many places in every country, and the country
greatly enriched by it, while the public would be also benefited by it, since it would raise a continual supply of timber used in ship-building, and on other public as well as private occasions.

We have in many places heaths, and other barren and uncultivated lands, of very great extent; and how great an advantage would it be to the public to bring these to be truly valuable. Many, if not all of these heaths, would be found on trial capable of producing trees; and some of them are truly the remains of destroyed forests; and though the profit to be reaped from the planting of them would come late, yet the expense of doing this would be very trifling in comparison of that profit, and the means easy. See **Timber and Plantation**.

The authors who have given rules for planting, having employed themselves only about small spots of ground, the establishing of orchards or parks, are by no means to be supposed proper guides in attempts of this kind; and Monf. de Buffon, who had a great opinion of the knowledge of our Evelyn and Miller, who seem to speak of every thing from their own experience, found, when he felt about large plantations, that their opinions and rules were erroneous; and was obliged to have recourse to experience only, which he varied a thousand ways; and though many of them proved unsuccessful, yet they all gave hints towards others, by which the attempt might afterwards be brought to succeed.

This sagacious inquirer into the operations of nature in the growth of vegetables, having set apart a considerable quantity of land for the trial, and procured a number of young trees, first divided the whole quantity into a number of small squares, and having made a plan of it, examined the nature, depth, and other circumstances of the soil in each, and minutely the whole down on a proper part of the plan; that himself, or whoever succeeded him, might judge from the different growths of a number of trees planted in the same flat in these different soils, the different advantages and disadvantages of every circumstance in the depth and nature of the ground, in regard to the growth of useful trees. Different numbers of labourers were employed upon different spots of this ground, and the acorns for the young growth planted at different seasons: but the result in general was, that what should seem the best methods succeeded the worst; and those pieces where many labourers had been employed, and the acorns planted before winter, were much thinner of young oaks than those where the leaf labour had been belted upon the ground, and where the acorns had been planted in the spring: but those places which succeeded best from the fowing, were those which had the acorns planted in holes made by a pick-axe, without any preceding culture of the ground. And those where the acorns had only been laid upon the earth, under the graps, afforded a great number of vigorous young trees, though the greater part had been carried away by birds and other devouring animals. Those spots of ground where the acorns were set at six inches depth were much worse furnished with young shoots, than those where they had been buried but an inch deep; and in some places where they were buried at a foot deep not one shoot appeared, though in others, where they had been buried at nine inches, there were many.

Those acorns which had been slooped for eight or nine days in wine lees, and in the water of the common feverows, appeared out of the ground much earlier than those which were put in without this previous management.

But the most successful of all the trials, was that of planting in the spring such acorns as had been sown toge-

ther in another place, and had time to root there; of these scarcely any one failed, and the plantation was perfectly flourishing, though the growth of these young shoots was not so quick or vigorous as those of the acorns which had remained when first sown; which was probably owing to the injury the tender radicles received in transplanting.

Thus succeeded the experiments by sowing, while of those made by planting young trees, such as had been brought out of woods and places under covert, succeeded much worse than those which had grown in more exposed places.

The young trees of the several parts of the plantation kept on their growth in the manner they had begun to shoot, those of more laboured parts continuing more weak, and lower than those of the less laboured.

Thus were a number of necessary experiments carefully tried, and the result of the whole was, that to make a plantation of oaks, on a foil of the common clayey or loamy kind, the most successful method is this: the acorns must be preferred during the winter in the earth in this manner; let there be made a bed of earth of fix inches deep; on this place a layer of acorns, two inches deep; and then lay a bed of another half foot of earth, over that another layer of acorns, and so on successively, till as many are employed as there will be occasion for: the whole is then to be covered with a foot depth of earth to preserve all from the frost. In the beginning of March these beds are to be opened, and the acorns, which will by that time have shot out, and are then in reality so many young oaks, are to be planted out a foot distance each, and the success of a plantation of this kind need not be feared. This is a manner of planting that is done at a small expense, and even that might be in a great measure spared, were it not for the birds and other devouring animals; since, could the acorns be defended from these, they might be only laid on the surface of the ground under the grapes in autumn, and they would infallibly shew themselves in so many young oaks the succeeding spring.

It is easy to continue the carrying of the acorns, when taken out of their winter's bed, to the place where they are to be planted, without doing them much injury; and the small sloop the transplanting puts to their growth is in reality rather an advantage than an injury, since it only retards the young shoots for about three weeks, or less than that; and by that means secures them from the few cold mornings that may be expected about the time of their natural appearance. Mem. Acad. Scienc. Paris, 1739. See **Timber**.

An experiment to determine the comparative durability of different kinds of timber, when exposed to the weather, was made by a nobleman in Norfolk; of which an account is given by Sir Thomas Beevor. This nobleman, the year 1774, ordered three polls, forming two sides of a quadrangle, to be fixed in the earth on a rising ground in his park. Into these polls were mortified planks, an inch and a half thick, cut out of trees from 30 to 45 years' growth. These, after standing ten years, were examined, and found in the following state and condition:

The cedar was perfectly found; larch, the heart found, but the sap quite decayed; spruce fir, found; silver fir, in decay; Scotch fir, much decayed; pinafore, quite rotten; chestnut, perfectly found; beale, found; beech, found; walnut, in decay; sycamore, much decayed; birch, quite rotten.

Sir Thomas Beevor jubily remarks, that the trees ought to have been of the same age; and Mr. Arthur Young adds, they ought to have been cut out of the same plantation.
The immense quantity of timber consumed of late years in ship-building and other purposes, has diminished in a very great degree the quantity produced in this country. On this account, many gentlemen who with well to their country, alarmed with the fear of a scarcity, have strongly recommended it to government to pay some attention to the cultivation and preservation of timber.

It appears, on the authority of Mr. Irving, inspector-general of imports and exports, that the shipping of England in 1760 amounted to 6107 in number, the tonnage being 433,921; and the shipping in Scotland amounted to 976 in number, the tonnage being 52,818. In 1788, the whole shipping of Britain and Ireland and their colonies amounted to 13,800, being 1,359,752 tons burden, and employing 177,925 men. The tonnage of the royal navy in the same year was 413,667. It also appears, from the report of the commissioners of the land revenue, that the quantity of oak-timber of English growth, delivered into the dock-yards from 1760 to 1788, was no less than 768,676 loads, and that the quantity used in the merchants' yards in the same time was 516,630 loads; in all 1,285,306 loads. The foreign oak used in the same period was only 137,766 loads. So that after deducting the quantity remaining in the dock-yards in 1760 and 1788, and the foreign oak, there will remain about 1,054,284 loads of English oak, consumed in 28 years, which is at an average 31,653 loads per annum, besides from 8,300 to 10,000 loads expended annually by the East India Company within the same period.

A writer in the Bath Transactions, cited in the Encyclopædia Britannica, article Trees, says, that the aggregate of oaks felled in England and Wales for 30 years past, has amounted to 320,000 loads in a year; and as this statement seems to differ from that above given, under the authority of the commissioners of land revenue, we think it necessary to point out the reason of this difference. This we are enabled to do, by the liberal communication of the ingenious Samuel Purkis, esq: whole diligence of research and accuracy in making the necessary calculations, and fidelity in reporting the result of his inquiries, must be admitted by all who knew him without hesitation. He informs us, that the calculation was made by himself and a friend at the request of Mr. Pitt, then prime-minister, in order to ascertain whether there was a sufficient quantity of oak-timber in this country to supply the probable demand for many years.

The calculations were made from documents furnished by government, and upon principles which could not fail to afford an accurate result. This result was communicated by Mr. Purkis to Mr. South, a man of fortune and respectability in Hampshire, and was published by him in the Bath Transactions. The discrepancy above-mentioned is merely apparent, and not real. For the commissioners of the land revenue only stated the annual consumption in the royal navy, and by the East India Company; whereas Mr. Purkis’s statement comprehended the annual consumption of the whole kingdom; nor had they the means which he possessed of making the latter estimate.

The building of a 70-gun ship, it is said, would take 40 acres of timber; and though this may seem to be an exaggerated estimate, it should be considered, that, according to the prevailing opinion of experienced surveyors, it will require a good soil and good management to produce 40 trees on an acre, which, in 100 years, may, at an average, be computed at two loads each. Reckoning, therefore, two loads at 8l. 16s., one acre will be worth 350L. and consequently 40 acres will be only worth 14,200L. The building of a 70-gun ship is generally supposed to cost 70,000L.; and as ships do not last many years, the navy continually requires new ships, so that the forests must be stripped in a century or two, unless young trees are planted to supply their place.

As the consumption of oak-timber is so considerable, methods should be devised and diligently practised for procuring a fresh supply.

Trees are liable to a variety of diseases and injuries, for the prevention or cure of which various means have been proposed.

The chevalier de Bienenberg of Prague, we are told, has discovered a method of effectually preserving trees from the fatal effects of those frosts which sometimes in the spring destroy the most promising hopes of a plentiful crop of fruit. His method is extremely simple. He surrounds the trunk of the tree in blossom with a wip of straw or hemp. The end of this he links, by means of a float tied to it, in a vessel of spring-water, at a little distance from the tree. One vessel will conveniently serve two trees; or the cord may be lengthened so as to surround several, before its end is plunged into the water. It is necessary that the vessel be placed in an open situation, and by no means shaded by the branches of the neighbouring trees, that the frost may produce all its effects on the water, by means of the cord communicating with it.—This precaution is particularly necessary for those trees, the flowers of which appear nearly at the same time as the leaves; which trees are peculiarly exposed to the ravages of the frost. The proofs of its efficacy, which he had an opportunity of observing in the spring of 1787, were remarkably striking. Seven apricot espaliers in his garden began to blossom in the month of March. Fearing that they would suffer from the late frosts, he surrounded them with cords as above directed. In effect, pretty sharp frosts took place five or eight nights; the apricot-trees in the neighbouring gardens were all frozen, and none of them produced any fruit, whilst each of the chevalier’s produced fruit in abundance, which came to the greatest perfection. See frost.

For Mr. Forysth’s remedy, we refer to the article Composition for Trees. See also Grafting.

Mr. Ray, and other authors, speak of several trees of prodigious bulk.

The jeufet d’Acofla, in his History of the Indies, lib. iv. cap. 3, mentions a hollow tree at Tiacocharaya, three leagues from Guaxa, in New Spain, nine fathoms within side the ground, and sixteen without side. He adds, that it is under this tree the barbarians assembled to perform their religious ceremonies, dance round their idols, &c. Herrera mentions another, which sixteen men, joining hands, could not fathom. And F. Kircher, in his Latium, p. 50, affirms that he has seen a tree, near Gonzano, which would lodge a whole family of twenty-five persons in its cavity. The common people had a tradition, that this tree was planted by Augustus.

There are forests of very large chestnut-trees, growing out of the mount Ætna, in Sicily. One of these, called the Castaggio di Cento Cavalli, is much the most celebrated. It measures 204 feet round, and though said to be united below in one stem, it is a bush of five large trees growing together. The hollow of one of these chestnut-trees is said to contain a hundred sheep, and it is also related, that thirty people have been in it on horseback.

In the Indies there are very large forests formed from a single tree, whose branches bending to the ground, take root, and put forth new trees: the Indian fig-tree and patavciel are of this kind.

M. Lonvillers mentions trees in Peru, one part of whose branches produce fruit one half the year, and the other part
TREES.

part the other half. In China there is a tree which bears tallow, of which that nation make their candles. See SELLER AND TALLOW.

Mr. Marham saw spruce and silver fir in the dock-yard at Venice above forty yards long, and one of thirty-nine yards was eighteen inches in diameter at the smallest end. It was said that they were brought from Switzerland. Some pews have been found in British sixty feet round. Palms in Jamaica attain the height of 200 feet, and some of the pines in Norfolk Island are 280 feet high.

At Tortworth, in Gloucestershire, it is said by the writer of the report on agriculture for that district, that a chefmon-tree was measured in 1791, which was found to be forty-four feet and four inches in circumference.

The great Bodham oak, belonging to the manor-farm of the same name in the same district, before it was burnt down in 1790, either by accident or design, was not less remarkable. It grew in an old orchard-ground, and the following account was given of it by Marshall, in his work on planting, as it appeared in 1783. The stem was remarkably coloured and snug at the root; the fence of its trunk more upright than those of large trees in general; its circumference at the ground somewhat more than eighteen yards, and at its smallest dimensions twelve. The greatest extent of arm, eight yards from the stem; and the greatest height of the branches, forty-five feet. The stem quite hollow, forming a capacious well-sized room, measuring on the floor, one way, more than sixteen feet in diameter. At that time it was perfectly alive and fruitful, with a large fine crop of acorns upon it. Part of the trunk, it is said, escaped the fire, and still remains.

In Needwood forest, the oak-tree called the Swilcar lawn oak contains, as Mr. Pitt supposes, in his account of the agriculture of Staffordshire, at least a thousand feet of timber. The Rev. Mr. Snow says, this oak, the father of the forest, girts at five feet high twenty-one feet; the lowest stem is ten feet clear; the whole height about sixty-five; the extent of the arms about forty-five feet. It is of great antiquity, but still fruitful in acorns.

In the first volume of the Agricultural Survey for the County of Essex, it is stated, that in Hatfield forest sir John Barrington has a very beautiful oak, for which a timber dealer offered one hundred guineas. And that near it is the ruin of a most venerable tree of the same kind, which gave the name of Broad-Oak to Hatfield.

There is a Lombardy poplar in this district which is a very fine and beautiful tree, guessed to be above seventy feet high, and which at five feet from the ground measures seven feet three inches in circumference. It is one of the three original trees of this kind which were brought by lord Rochfort from Italy, and planted at St. Oysth above forty years ago, and from which much the greater part of these which are now scattered through the kingdom originated.

Very near to it is the largest and most beautiful laurel of the Portuguese kind that is almost any where to be seen; it is nearly of a semi-globular form; feathered all round to the crown it grows in, and is fifty-two yards in circumference.

At a small distance from these prodigies of vegetation is, it is said, a new variety of almond, which would be no inconceivable figure at Killarney. They are in the grounds of Mr. Naffau, in which the fruit is a fine rich found loam. See the Report.

There are now growing about Donway Hall, in Lancaster, beside many large fine oak timber-trees, an alder-tree, called the wain-house ash, which measures fourteen feet in circumference; a hazel-tree, which is three feet in girth; an yew-tree, which has six feet two inches of girth; and a white-thorn, in New Copy field, which measures seven feet in circumference.

There are two or three very remarkable phenomena in the growth of trees, which have escaped the observation of the naturalists of all ages, except those of our own: these are the perpendicularity of their trunks or stems to the horizon, and the parallelism of their twigs to the spot of earth they grow on. See PARALLELISM AND PERPENDICULARITY.

For the planting, transplantaing, femonation, pruning, fell-ling, grafting, thridding, &c. of trees. See PLANTATION, PLANTING, &c.

On felling of trees, letters have sometimes been found in the midst of them. We have instances of this kind mentioned in the Philos. Trans. No. 1441, sect. 16. where the trunk of a beech being fawed, discovered several letters in the wood, about an inch and a half from the bark, and near the fame distance from the centre of the trunk. It seems these letters had been formerly cut into the bark, and in process of time these might be covered.

In the same Transactions, we have an account of the horn of a deer found in the heart of an oak. Crucifixes have also been found in trees, and were of course shewn as miraculous to the ignorant. See p. 236. of the said Transactions in the Remarks.

Trees are often found buried in the earth. See MORASS, FOSSIL WOOD, and BOG WOOD.

For the punishment of stealing trees, see LARCENY.

By lat. 1 Geo. I. e. 48. maliciously to set on fire any underwood, wood, or coppice, is made single felony. By the Black-act, to cut down or destroy any trees planted in an avenue, or growing in a garden, orchard, or plantation for ornament, shelter, or profit, is felony without benefit of clergy; and the hundred shall be chargeable for the damages, unless the offender be convicted. By 6 Geo. III. cap. 36. and cap. 48. wilfully to spoil or destroy any timber or other trees, roots, shrubs, or plants, is, for the two first offences, liable to pecuniary penalties; and for the third, if in the day-time, and even for the first, if at night, the offender shall be guilty of felony, and liable to transportation for seven years.

TREES. Fruit, Barkini of, in Rural Economy, the injury of their having the bark eaten off by hares and rabbits in the winter season. It is particularly the cafe with young apple and pear trees, and occasionally with forest-trees and shrubs. Several different methods of preventing it, and of protecting the trees, have been proposed at different times; such as twisting straw-ropes round the trees; driving in small flat stakes all about them; and the use of strong-scented oils. But better and nearer modes of effecting the business have lately been juggled in the Transactions of the Scotch Horticultural Society; and as hog's-lard, and as much whale-oil as will work it up into a thin paste or paint, with which the limbs of the trees are to be gently rubbed upwards, at the time of the fall of the leaf. It may be done once in two years, and will, it is said, effectually prevent such animals from touching them.

Another and still nearer method, is to take three pints of melted tallow to one pint of tar, mixing them well together over a gentle fire. Then, in the month of November, to take a small brush, and go over the rind or bark of the trees with the composition, in a milk-warm state, as thin
as it can be laid on with the brush. It is found that such a coating does not hinder the juices or sap from expanding in the smallest degree; and the efficacy of the plan is proved in preventing the attacks of the animals, by applying the liquid composition to one tree and marring another, when it was found that the former was left, while the latter was attacked. Its efficacy has been shewn by the experience of five years. The trees that were gone over the first two years have not been touched since; and none of them have been injured by the hares.

It is a mode particularly well adapted for nurseries, where the ground is not well secured with a fence to protect the young fruit-trees and tender shrubs from hares. The above is the proportion of the materials; whatever may be the extent of trees.

Trees, Mossing of, their becoming much affected and covered with the moss-plant or mossy sublance. It is found to prevail in fruit-groves of the apple kind, and in other situations, when they are in low, close, confined places, where the damp or moisture of the trees is not readily removed. It is thought to be an indication of weakens in the growth, or of a diseased state of the trees, and to require nice attention in preventing or eradicating it. The modes of removing it have usually been those of scraping, rubbing, and washing, but they are obviously calculated for trees only on a small scale. How far the use of powdery matters, such as lime, chalk, and others, which are capable of readily absorbing and taking up the wetness that may hang about the branches and other parts of the trees, by being well dusted over them, may be beneficial, is not known, but they would seem to promise success by the taking away the nourishment and support of the moss, when employed at proper seasons. And they are known to answer in destroying moss in some other cases, when laid about the stems of the plants, as in thorn-hedges, and c.

In the fruit-groves of Gloucestershire it is recommended, the writer of the account of the agriculture of that district says, to wash with soap-suds, and rub off the moss with a brush, in wet weather when it is soft, and easily separable from the different parts of the trees. This work should be begun at an early period of the growth of the trees, when the branches are few and open, and be repeated every season; otherwise the labour would be too great to undertake on a large extent, when the trees are full-headed, and entangled with hoots. The fruit-farmer should not, however, be too easily discouraged, since it has been discovered, that the eggs of caterpillars are often lodged between the moss and the rind of the trees, and probably the insects issue forth from these depositaries in the spring, to the destruction of leaf and blossom.

In this district, the mossing of the trees is attributed to the plantations being made on gras-sands, which is the common practice in a great part of the county; as, it is said, that in the neighbouring counties, where the fruit-trees are planted in hop-groves and arable fields, the trees, though not free, are less affected by it. This may, it is supposed, be owing to the frequent manuring and flailing of the mould near the roots, by which means the sun and rain have power to exert their influence, and by invigorating the fibres, promote a general kindred in the growth of the trees.

The mossing in all sorts of trees is injurious to their growth by depriving them of a portion of their nourishment, but more particularly hurtful to those of the fruit-tree kind, as preventing them from bearing full good crops of fruit by rendering them in a weak and unhealthy state.

Trees, Espalier, Cafl-iron Rails for, a new mode of forming this sort of rails. It is noticed in a Paper in the first volume of the Memoirs of the Caledonian Horticultural Society, that the advantages attending rails of this kind in gardens, in respect to utility as well as ornament, are well known and acknowledged. The greater chance they afford to the fruit in setting and ripening, by the branches being laid in at regular and equal distances, the neatness of appearance which the trees exhibit, and the elegant vistas produced by the rail and trees when bordering the sides of well-kept walks, are all matters with which the admirers of horticulture have long been acquainted. It does not appear, however, whatever may have been the cause, that this, by no means uninterseting branch of the art, has hitherto in any considerable degree engaged the attention of the improver.

The rails for trees of this kind have, for the most part, been made of wood, though not without objections; the principal of which are, want of durability in the substance; the difficulty of keeping them in a perfectly rectilinear position; and the chumines of appearance which they constantly, in some degree, exhibit, when made of the dimensions necessary for the proper extension of the trees.

The most usual modes of constructing such rails are two: first, the having upright splits of dressed timber funk into the ground, and morticed into a horizontal top-rail. This is greatly objectionable on account of the speedy decay, and from the splits always found giving way where funk into the ground, as well as from its being scarcely practicable to keep them straight. The second, or that which is the most generally practised, is to sink upright posts into flones, to mortice two crofs-bars into them, and to nail upright frills to the bars. The great defect in this mode is, that by the bulk of the posts, rails, and frills, so great a strain is thrown upon the flones during high winds, that they cannot long resist it; and the consequence is, that the rail soon begins to twist, while the part funk into the flones, in spite of every precaution, will at no great length of time decay, in consequence of moisture getting in between the wood and the flone.

In order to obviate these objections, the substitution of espalier rails formed of cast-iron instead of wood, has been proposed and tried with success by a gentleman in Dunbartonshire, Scotland.

Each portion of rail is formed of two rails inserted at the different ends into handsome upright columns or posts, having erect arrows or pieces fixed into them, somewhat in the manner of common iron paling, the whole height or portion resting upon three supports at the bottom, in the way directed below. The supports on which it stands are thus contrived: the centre one is a piece of seasoned oak, driven firmly into the ground, and funk a little below its surface. It receives the upright middle arrow-piece, which keeps up the centre of the bottom rail, and through which the different upright arrow-pieces to each side of it are put. It is supported below the rail by two pieces of the same metal in a triangular manner. Those at the ends are flones of two feet in length, having their tops hewn into an hemispherical shape, and perforated in the middle by a hole of four inches in depth, and two in diameter, which receives the bottom ends of the columns or posts. The upright arrow-pieces are each furnished with a ruff at the places where they meet the top and bottom rail.

The columns or posts have the length of six feet, their bottoms being funk, as above, into the flones: the diameter of them at the bottom rail is an inch and a half, and at the top, one inch and one-eighth; the upright arrow-pieces are five feet in length, and their diameter half an inch; the bottom rails are three-eighths of an inch in thickness, and in breadth.
The columns, at the parts where the rails enter them, have a flank projecting at right angles to them, with a hole, through which, and through a hole in the end of the rail, a leaden rivet is put, for fastening the rail to the column or post. See Treillage.

Tree, Onion, in Gardening, that fort of onion-plant which rises somewhat in the tree-like form, and which affords its produce or bulbs at the top of the item or flake. At what period this valuable and useful bulb-rooted plant was first introduced into this country, feems now to be quite uncertain; and it has never yet perhaps been grown or cultivated to any extent in any part, being mostly had in growth merely for the sake of curiosity. From a Paper inferted in the firft volume of the Memoirs of the Caledonian Horticultural Society, it would appear, however, to be capable of being raised with advantage as a substitute, in part, for onions of the keeping kind, as might have been supposed from the severe nature of the climate from which it originally came.

In addition to the little which has been said of the nature of its culture for the purposes of ornament and variety under the head Allium, (which see,) the following observations on its culinary use may be given in this place.

It is stated, on the experience of some years, in the Paper alluded to above, that the root-bulbs, when two years old, put up each a stem from thirty inches to three feet in height, on which good-sized bulbs are formed at top: that from these, others push out of a second flake; and that sometimes a third lift is produced, which are still smaller; but that the third and second stars are the only ones which are fit for planting. Towards the end of summer, the top-bulbs are in a proper flate for gathering, and should be collected carefully dried in a shady place, then put in a dry airy situation, until the leaflon for planting them out. This at the same time the old root-bulbs should be lifted, which have mostly one or two onions to each of them, which are of good quality, and keep well until late in the following spring leaflon.

About the laft week in the month of April is the most proper time for planting out the young top-bulbs for the purpose of a crop, as if sooner planted, they are apt to put that leaflon, and neither produce good root-bulbs nor top-bulbs. The old roots should be planted out any time in the month of February, or the following one, as early planting has the power of making them produce good bulbs at top. The young bulbs of the firfl flake should be separated and planted out in rows in any good garden ground, which is in an open situation, six inches by four: the second flake in rows six inches by three, in shallow drills of very little depth, as the swelling and ripening of the roots are spoiled when they are deep.

The whole of these will, it is said, produce onions of a good flake, which will keep, when well taken care of, until the middle of May. The old root-bulbs, when not all wanted for planting, will likewise keep equally well; and after a sufficent flock of them has been provided, the rest may be used with the other principal forts.

It is noticed that the old roots are the best for replanting for a crop of top-bulbs, as they are the molt certain of running to items.

The writer has never known these crops to be infelted with vermin in any flage of their growth; the reason of which is, it is thought, their quick growth and coming to maturity before the leaflon at which vermin commonly attack the usual spring-bulb roots, as it has been found that the late or autumn-bulb crops of the common kind, when allowed to stand for an over-year produce, are seldom or ever affected in this way, even on light dry ground.

This fort of onion, besides its property of long keeping, is a strong well-flavoured kind, equal, if not superior, to most of the common forts.

It is, however, perhaps the best calculated for private gardens, as requiring a good deal of attention, as in such, when once provided with a certain quantity of root-bulbs, the proprietors would be rendered independent of the failure of the crops of common onions; and it is confidently afferted, that if the cultivation of it were generally well understood, it would be capable of being grown with both pleasure and profit in a great many cafes.

Tree, Gelseminum. See Bocconia.
Tree, Cork. See Cork and Oak.
Tree, Chafta. See Agonis Cajuora.
Tree of Life, Arbor vita, in Botany. See Thuja.

The accidental, which grows naturally in Canada and other northern countries, is used, according to professor Kalm, for many medicinal purposes. It is much extolled for rheumatic pains; with this intention the fresh leaves are pounded in a mortar, and mixed with hog's grease, or any other grease; this is boiled together, till it becomes a froth, which is spread on linen, and applied to the part where the pain is. This froth gives certain relief in a short time.

Against violent pains which move up and down in the thighs, and sometimes spread all over the body, they recommend four-fifths of the leaves of polypody (polypodium frande pinnata, &c.) and one-fifth of the cones of the thuja, reduced separately to a coarse powder, and afterwards mixed. With this powder, and milk-warm water, they make a poultice, which they spread on linen, and wrap round the body; but they commonly lay a cloth between it and the body, otherwise it would burn and scorch the skin.

The decoction of thuja leaves is used as a remedy for the cough; and they use this at Saratoga for the intermittin fever.

Tree-Frog. See Ranunculus Viridis.
Tree, Germander. See Teucrium.
Tree, Mallow. See Lavatera.
Tree, Mealy, or White-leaf. See Wayfaring-Tree.
Tree-Moss, a species of Lieben; which fee.
Tree, Primrose. See Oenothera.
Tree-Loose. See Apist.
Tree, Diana's, in Chemistry. See Arbor.
Tree, Dormant. See Dormant.
Tree-Fold, in Sheep-farming, a term applied to that fort of sheep-fold which is formed or surrounded by trees in the growing flate, and which is well fitted for protecting them in certain exposed situations, as well as affording them other advantages. See Sheep.

Trees, in a Ship, are of several sorts, as chest-tree, cross-tree, roof-tree, waft-tree, trefoil-tree. See Chess-trees, &c.

Tree Island, in Geography, a small island in the Indian sea, near the coast of Africa. N. lat. 17° 10'. — Also, a small island in the East Indian sea, near the E. coast of Sumatra. S. lat. 3° 50'. E. long. 105° 51'. — Also, a small island near the W. coast of Sumatra. S. lat. 1° 58'. E. long. 106° 15'. — Also, an island in the bay of Bengal, near the coast of Ava. N. lat. 18° 12'. E. long. 94° 15'.

Tree-a-top Island, one of the Chusan islands, which undoubtedly deserted the appellation given to it, when it was first described by the Europeans above half a century ago, at which time they were permitted to trade to Chusan; but
but the tree is gone, and this island, which is as bare as those surrounding it, is only known by its relative position in the chart. To the southward of this island, about three or four miles, there is excellent anchorage in five or six fathoms water, where ships are sheltered from every wind.

TREE-NAILS, or TRENNELS, in a Ship, are long cylin-
drical wooden pins, employed to connect the planks of a ship's side and bottom to the corresponding timbers, and to fasten the anchor-flock.

The tree-nails are suitably esteemed superior to spike-nails or bolts, which are liable to rust and loosen, as well as to rot the timber: but it is necessary that the oak of which they are formed should be solid, close, and replete with gum, to prevent them from breaking and rotting in the ship's frame. They ought also to be well dried, so as to fill their holes when swelled with moisture. They have usually one inch in thickness in 100 feet in the vessel's length; so that the tree-nails of a ship that is 100 feet long, are one inch in diameter, and one inch and a half for a ship of 150 feet.

TREET, TRIFICUM, in our Statutes, is used for fine wheat. See lat. 51 Hen. III. Hence bread. See Bread.

TRE-PALLOW, To, in Husbandry, is to plough land the third time before sowing.

TREFFEN, in Geography, a river of Carinthia, which runs into the Drave, 6 miles below Villach.

TREFFORT, a town of France, in the department of the Ain; 7 miles N.E. of Bourg-en-Bresse. N. lat. 46° 16'. E. long. 5° 27'.

TREFFURT, a town of Weitphalia, in the territory of Eichsfeld; 10 miles W.S.W. of Muhlhausen.—Allo, a town of Germany, in the principality of Hesse-Rinflms, situated on a hill near the Werra; 36 miles E.S.E. of Caffel. N. lat. 51° 8'. E. long. 10° 18'.

TREFOIL, in Architecture, the usual mode of ornamenting an arch in the pointed style by the insertion of a cuff or point on each side of it. Other trefoils are incribed within a circle, and resemble a head of clover-grafs more perfectly.

TREFOIL, in Botany. See Trifolium.

Trefoil is a plant of the clover kind, which is not un-
frequently sown or met with in grafs-lands. It is always a
valuable plant in such grounds as are kept under a permanent
state of grafs; and not much lefs useful, when sown and
 cultivated in thofe of the arable kind. See Clover and Medicago Lupidina.

It succeeds well on foils of different descriptions, as on
thofe of the dry, loamy, and the calcareous kinds and qua-
litics. It was found to succeed perfectly on the itone-brash
kinds, by Mr. Davis, in Oxfordshire; and it has been
greatly advised for the chalky and some other dry forts, by
Mr. Boys of Kent. It is constantly known to anwer well
in all the lefs moist loams. It is a plant, however, which
has been objected to by some farmers, as being only a bienni-
al; but as it sheds its seeds annually in great abundance,
this is probably a matter of little confquence; and it is well
known to seldom wear out of lands, in which it has been
once well established. Its feed is readily procured, and
with little expence or trouble.

The plant is of much lefs growth than that of common
clover, being considerably flender in the item or stalk part;
yet notwithstanding this, it is not unfrequently found with
creep of the grain kinds, in the manner of that grafs-feed.
The proportion of feed, which is made ufe of in such cafes,
is ufually about three pottles, or two gallons, when per-
fectly cleared of the hulks; but when in the contrary flate,
two buhells are mostly the quantity that is fufficient for the
purpofe. These quantities should, however, be constantly
varied, according to the nature, circumstances, and condi-
tions of the lands.

By fome it is fuppofed to be a beneficial practice to fow
it in these ways, efpecially where large flocks of animals are
kept; as with the oats or wheats in the fpring feafon, when
they are to be followed with grain in the next; as, by this
means, good feed is provided in the burlies for the flock,
in the latter part of the fummer and in the autumnal months,
while, at the fame time, the land is left free for the pur-
pofes of tillage in the fpring. When it is employed in the
way of laying down land for paflure, as it is always of
much importance to the farmer to have fuch land to produce
a full crop the firft year, this is proper; and as there are
fome grafs-plants which require two or more years to es-
tablish themselves, and acquire their full growth, while
others arrive at their extreme and perfect size and expansion
the firft year after being fown; fome of the latter foft should
conftantly be had recourse to, among which this fhould
never be neglected, as it is found, in moft cafes, to be
highly valuable and ufeful in fuch circumstances. Hence,
too, the advantage of mixing it with other fown grafs-feeds
is fhewn in different inftances. Some farmers confider
the quantity of four pounds of trefoil-feed to the acre as too
small a proportion; and think it an improvement to either
double the quantity, or to add as much red clover-feed,
which is probably the preferable method. In this quantity,
it is fuppoled, they will not injure the other grafs-feeds
which may be fown at the fame time, but furnifh a copious
vegetation, until the other may come to perfection; at
which period, both the trefoil and clover have a natural ten-
dency to disappear and be worn out of the land.

Trefoil is laid to produce excellent paflurage for cattle-
flock, but to be more particularly calculated for sheep,
when either in mixture with clover or alone, as it is found
not to be fo liable to hurt them by dwelling or fowing them
as clover. It is of great importance in the feeding and sup-
port of sheep, in confquence of its being more early than
clover, and its coming in well after the confumption of the
rye and turnip crops, before the clovers become ready in the
fpring feafon.

The writer of the "Experienced Farmer" rates, that this,
by fome, is fuppoled a bitter plant, and that sheep are not
fond of it, but that he muft own that nothing within the
comps of his experience has led him to form such an
opinion. It vegetates about a month earlier than white
clover, and long before the rye-grafs is exhausted. But it
is thought improper for being sown alone, except for the
express purpofe of raifing feed. There are no foils, it is
thought, proper for trefoil but what are capable of pro-
ducing rye-grafs and white clover. Hay made from
this plant alone, is a pretty hay, but fedlom abundant in
produce. It is conceived that more trefoil is capable of
being raised on any fort of land, in any quantity, by fowing
rye-grafs among it, than without; as it has been obferved
that trefoil, like the vine and pea, wants support from fome
stronger material to which it may cling. For this reafon it
prospers well with red clover, round which its tendrils twine
as woodbine in a thorn-hedge. It is believed, too, that the
crop of clover will be very little lefs in quantity or weight
from the trefoil growing in a flate of mixture with it.

The after-grafs of trefoil is confidered as not worth much,
and which account fome recommend it to be followed with
wheat, but it can be declared on the grounds of confitant
experience, that land intended for wheat, cannot pollfibly
be
be too much smothered with crops of every sort of the clofe-growing shady kinds.

It has been flated by a late writer, that upon light and poor fandy soils, or lands on which clover does not succeed well, it is common husbandry to sow trefoil with a portion of white clover and ryegrass, with the intention of leaving it two years. In this cafe, six pounds of trefoil, four of white clover, and half a buffel of ryegrass feeds are the common quantities. These are with the intention of providing fleec-feed.

Where trefoil is left for hay, it does not afford a large produce, but a fort which is highly useful and advantageous as a fheep-fodder in the winter feafon, and left wallful than molt other kinds, when used in that way. At the fame time, it is supposed to be fels troublesome in the process of making into hay. However, it is affected by Mr. Kent that it readily runs together, and becomes mouldy by wet.

The feed is to be collected from the fecond shoot, in the fame manner as in common clover, the produce being in general from six to eight buffels of clear feed from the acre. In diffrits where it is grown for the feed, the crops are mown in the beginning of July; the heads or huks being often threfhed off the fraw in the field on a cloth, and then fold by the quarter to thofe who have mills and collect them, who grind the feed out of the huks, and then difpofe of it to others, in different places, for theufe of the farmers in thofe diffrits where it is rarely faved. The acre moftly proceeds from about four or five to ten quarters in the hulk, each of which affords about two buffels of clean feed when grown solely in this intention.

This plant has often the names of black-grafs, nonefuch, yellow clover, and others, given it by writers on husbandry.

There are other different forts or varieties of this plant occasionally cultivated by the farmer, fuch as the trefoil termed bird’s-foot, which has been found ufeful when cultivated in meadows that are inclined to be moif, as growing to a great height, and affording an excellent hay. In fome places too it is ranked as paflurage for fheep. Alfo the trefoil called by the name of hop, which is often confounded with the red trefoil, as being nearly of the fame duration, but which is more grateful to animals. The trefoils feem, on the whole, not to be fo much difcriminated by agricultural writers, as their importance as artificial grades would appear to demand. Befides, much confusion is introduced in confequence of the diversity of their provincial titles. It has been remarked, that as fome are annual, fome biennial, and others perennial, where the two former forts are fown where it is intended to have a permanent paflure, disappointment muit of necefly be the confequence.

Trefoil, Bean, a fpecies of Cytifus; which fee. Trefoil, Stinking Bean. See Anagyris. Trefoil, Bird’s-foot. See Lotus.

The fruit of the lotus was, by the ancients, imagined to be endowed with the virtue of making ftrangers forget their native country.

The fecond fpecies of this genus, or the ptelea with fingle leaves, was formerly thewn for the tea-tree in many of the European gardens, where it many years paffed for it among thofe who knew no better.

The ancient botanists feem to have been acquainted with two very different shrubs under the name cytifus; and there have been no small errors about the true meaning of several passages in Dioscorides and Theophratus, on occasion of the mitaking one of these things for another. Dioscorides describes the cytifus, as being a shrub with leaves white and hoary, both on the upper and under fide, and of no ufe, or value, to mankind: as to its wood, Pliny translates this account, and adds to it from Hyginus, that it was a very hardy and strong shrub, not being affected by heat or cold, snow or hail, or any other injuries of the weather, nor of its enemies, as Pliny expreffes it (bofium).

It is not very easy to conceive what enemies these fhould be; but the moft probable conjecture, as to this odd paflage, is, that Pliny had tranfcribed it in his ufual carelfs way, and that what is called bofium, fhould be the word noftrum.

The fenfe then is clear enough; the author had juft before said that the wood was good for no ufe to mankind; and, therefore, when he was speaking of the trees standing a long time, and fearing the injuries of no weather, he might very well add, nor of us; for the wood being good for nothing, men would not be at the trouble of cutting it up. It is plain, however, that Theophratus means quite a different shrub by this name cytifus; for, as Dioscorides fays, that the wood of his was white throughout, and very light.

Theophratus observes, that it was black at the heart, and as heavy and folid as ebony; and, in many places, where he speaks of the hard and elegant woods used for inlaying, he mentions the cytifus wood, coupling it with the ebony, heart of oak, and other the hardeft and moft elegant woods known in his time.

Pliny mentions no other cytifus than that of Dioscorides, which was the common kind cultivated by the Greeks and Romans, as a food for cattle; he fays it was raised by feed, and came to its perfection in three years, and that it was gathered in the spring juft after the time of its flowering; he adds, that this was usually the office of children, or old women, unfit for other work, and was the cheapest of all the offices of husbandry. It is easy to conceive, that such a shrub as the cytifus of Theophratus, with a wood as firm as the heart of oak, and hard as ebony, did not come to perfection in three years from the fowing: nor could any more be cut up by boys and old women, than eaten by cattle when taken up. There were, therefore, two kinds of cytifus among the ancients, the one fown and cultivated as food for cattle, the other a wild tree, or shrub, growing in woods, and being larger than the fown kind.

Dioscorides and Pliny defcribe the fift, and Theophratus alone the latter, except that Pliny has now and then taken a fentence from Theophratus, when he mentions the cytifus occasionally among other hard woods, and placed it to the account of his manured cytifus.

Ovid, indeed, where he mentions the cytifus as a wild wood shrub, certainly means this kind mentioned by Theophratus:

"Nec tenuis cytifus curtive tinus abel."

And Columella acknowledges both kinds. It may feem a natural objection, that culture could never make fuch a difference in this plant, as that it fhould be hard and black in the wood in its wild state, and foft and white in the cultivated kind. But we are not to fancy that the cultivated and wild cytifus were the fame fpecies of shrub, only altered by these two flates. The ancients were not fo accurate in their names as later botanical writers have been; and if a wood-shrub, in some refpecfs, remembred their manured cytifus, they would call it by that name, though it had
Trefumel, in Geography, a town of France, in the department of the North Coasts; 6 miles S. of Dinan.

Tregarow, or Tregarow, or Caron, a small market-town in the hundred of Pen-arth, and county of Cardigan, South Wales; is situated in a valley watered by the river Berwyn, a contributory stream to the Teifi; 18 miles S. by E. from Aberystwyth, and 170 miles W. from London. It was formerly a corporate town, but for some improper conduct at the election of a member to serve in parliament in the year 1742, the house of commons voted that the corporation had forfeited their charter. A weekly market is held on Tuesday, and an annual fair of three days' continuance in March. The church, which is a spacious structure of very rude masonry, consists of a nave and chancel; it stands on a rocky eminence, regularly circular, and forming an elevated centre to the town. In the churchyard are the remains of a Druidical circle, with the faces filled up with stone-walling. The parish of Tregaron, which extends nine miles in length, and four miles in breadth, comprehends eight parishes or townships, and, according to the population return of the year 1811, contained 244 houses, and 1133 inhabitants. At a place called Caithell Flemys, in this parish, is a very large intrenchment of a semi-circular form, well defended on three sides by a moat. On a hill called Penhirwul are three heaps of stones, called Carneddau, sepulchral monuments of Druidical origin; and a bank of raised earth runs in a straight line for several miles, in this parish as well as that of G-wanns, and is said to lead into the sea, called "the furrow of Bannoy's oxen," the same as were said to be employed in building the church of Llandre Bwth. But it is probably the remains of an old British road. Thomas Jones, an eminent antiquary and poet, who lived at the end of the sixteenth century, was a native of Tregaron.—Malkins's Scenery, &c. of South Wales, 2 vols. 8vo. 1807. Carlisle's Topographical Dictionary of Wales. Beauties of England and Wales, vol. xviii. South Wales; by the Rev. T. Rees. Meyrick's History and Antiquities of the County of Cardigan, 4to. 1808.

Tregiano, a town of Naples, in the province of Barò; 6 miles E.S.E. of Bitteto.

Tregony, a market-town and borough in the western division of the hundred of Powder, and county of Cornwall, England; is situated on the river Fal, 8 miles E. from Truro, 40 miles S.W. from Launceston, and 250 miles S.W. by W. from London. This town was formerly a place of some consequence, but fell to decay when Truro began to flourish, and attract its trade and population. Tregony sent two members to parliament in the reign of Edward I.; and after a long dispute, recovered its ancient privilege in the year 1559; the right of election is vested in the housekeepers: the number of voters who polled in the year 1812 was 183, the exact number of houses returned under the population act of 1811; the number of inhabitants were therein stated to be 923. The town confounds principally of one long street. It was anciently governed by a portreeve, or mayor; but in the year 1620, king James I. granted it a charter of incorporation. The market, which is on Saturday, is held by precepture: Henry de Pomeroy certified his right to it in the reign of Edward I. Henry III. granted a fair to the said Henry in the year 1260. Here are now five fairs. Both the fairs and market have for many years been in a declining state; till the middle of the last century, they were very considerable, and particularly noted for the sale of woollen cloth, of which there was an extensive manufactury in the town. Tregony castle, of which there are now no remains, is said to have been built by Henry de Pomeroy at the time king Richard I. was in the Holy Land; it was standing, and was the seat of the Pomeroy's, in the reign of Edward VI. In the year 1666, Hugh Boscawen founded an hospital for decayed housekeepers, and endowed it with lands, now let at 30s. per annum, but capable of being soon raised to three times that value. On the north side of the town flood, what is called, Old Tregony, where was a church dedicated to St. James, the walls of which were standing till about the middle of the last century.

On the opposite bank of the Fal, is Trewarthienick, the seat of Francis Gregor, esq. The house is seated on an elevated piece of ground, abounding with fine groves, and commanding a variety of interesting prospects.

About two miles south-west of Tregony, is Ruam Lanihorne, a village seated on the banks of the Fal, of which the Rev. John Whitaker, the learned historian of Manchester, was nearly forty years the resident rector. He died Nov. 4, 1808, in the 73rd year of his age, and lies buried within the walls of the communion-table.—Lyfons's Magna Britannia, vol. iii. Cornwall, 1814. Beauties of England and Wales, vol. ii. Cornwall; by J. Britton and E. W. Brayley, 1822.

Treguier, a see-port town of France, in the department of the North Coasts, on a peninsula, near the English Channel; before the revolution the see of a bishop; 9 miles N.E. of Lannion. N. lat. 48° 47'. W. long. 3° 8'.—Alfo, a river of France, which runs into the English Channel, 6 miles N. of Treguier. N. lat. 48° 51'. W. long. 3° 8'.

Trelaw, in Ancient Geography, a town of Italy, in Piccium, S.E. of Cingulum.

Trelaw, in Geography, a town of the Popedom, in the marquefeate of Ancona; 6 miles W. of Macerata.

Tregignac, a town of France, in the department of the Correze; 16 miles N. of Tulle.

Tregigny, a town of France, in the department of the Yonne; 9 miles S.E. of St. Fargeau.

Treillage, in Gardening, a fort of rail-work consisting of ranges of light poll and railings, for the purpose of training espalier trees to, and occasionally for wall-trees, where the walls do not admit of nailing the branches immediately against them; likewise for training wall-trees in forcing-frames, &c. They are made in different ways for use and ornament, as well as of different dimensions, from four or five to six or seven feet high.

For common espalier fruit-trees in the open ground they are absolutely necessary, and may either be formed of common stakes and rails nailed together, or of regular joinery work.

The cheapeft and the eafteft, and fooneft made treillage for common espalier trees, is that formed with any kind of fraight poles or staves of under-wod, as cut in the coping pieces, being then cut into proper lengths, and driven into the ground in a range at distances of a foot each, all of an equal height, and then nailed along the top with the fame kind of poles, to preserve the whole fraight and firm in a regular position. See Espalier.

And to render these flill stronger, two or three horizontal ranges of rods may be nailed along the back part of the uprights, a foot or eighteen inches aunder.

The more elegant and ornamental trealgages are formed with regularly squared poles and rails of hard timber, neatly planed and framed together; having for this purpose deal or oak poles, uniformly worked two or three inches square; but if the main poles are of oak, it will be of advantage
vantage in respect to strength and durability; fixing the
main poles in the ground ten or twelve feet afunder, with
smaller ones between, ranging the horizontal railings from
pole to pole in three or more ranges; the first about a foot
from the bottom, a second at top, and one or two along the
middle space, and, if convenient, one between each of the
intermediate spaces; then fixing thin slips of lath, or the
like, upright to the horizontal railing as far as the branches
of the trees extend, ten inches or a foot afunder; and paint-
ing the whole white in oil colour, to render it more orna-
mental and durable. In training the trees, their branches
are tied both to the railing of the treillage and the upright
laths, according as they extend in length on each side. In

either of the above cases, for an epailer, five feet are gen-
erally of sufficient height, as, if much higher, the winds,
having greater power, will loosen and displace them.

Where walls are built with large stones with the joints
irregular and far afunder, and which do not afford oppor-
tunities, like brick-walls, for nailing properly in the re-
gularity which is required, a neat treillage is sometimes
uniformly erected all along close to the wall, to train and
nail the branches to in a regular manner.

These may be made of coarse pieces of battens, railings,
&c. or of such as are wrought in a neat manner, according
to the convenience and taste of the person who has them.

In constructing trellisages of this nature, some make them
with clean straight rods or poles, and others with squared
laths, which are an inch and a half in thickness; each of
which sorts of materials answers the purpose very well. In
performing the business, the workmen, as soon as they have
provided themselves with a sufficient quantity of either
of these kinds of articles, and a proper supply of hooked iron
hold-fails, first drive some of the hold-fails into the
joints of the walls in rows as much as possible at regular
distances, which are left projecting about an inch or inch
and half from it, in order to receive the rods or laths in
both a horizontal and perpendicular direction, at nine or ten
inches from each other, fixing in the first row of these
hold-fails towards the top or upper part of the walls, the
second near to the bottom, and the third all along the mid-

dle space. When this has been accomplished, and the rods
or laths are in readiness, the latter of which may, if thought
necessary, be squared and planed to the place, they begin to
proceed to the framing of the treillage, by first fixing the
rods horizontally in three rows, in the three ranges of hooks
as above, taking care that these horizontal rods be pre-
viously chopp'd off to nothing at each end, in order that
they may be readily slipped to each other to extend them in
length as far as it may be requisite. Having thus fixed up
the first three rows of horizontal poles, some uprights or
standard rods are latticed up in the front of the horizontal
poles, at the distance of five or six feet, after which the re-
mannder of the horizontal laths are ranged behind the stand-
ards, nine or ten inches afunder, latticing them with wire to
the uprights, when they being all thus placed and fixed,
the rest of the standards are latticed up in front at the
same distance, the whole being made perfectly fast with
wire twisted round the hooks, and the crossbars or inter-
sections of the rods of the treillage or frame-work. Where
square laths are employed for this purpose, they are usu-
ally about an inch and half in the square, being planed quite
even and smooth, and then framed together in a neat manner
by proper mortises, and fixed up with strong hooks and nails.

Either of these kinds of trellisages, when finished and fixed
up, should be well painted over with white lead paint, in
order to render them more lasting and handsome.

In frames and lattices where wall-trees are intended for
forcing, as they are planted both against the back wall, and
occasionally in a detached low range forward towards the
middle or front space; trellisages are indispensible neces-
ary upon which to arrange the branches of the trees in a regular
expansion, not to train them immediately close to the wall
of the flues of that department, but detached several inches,
and formed with light neat squared upright battens, and
small horizontal rails, uniformly framed together, in a light
open manner. See Trees, Epailier, Catted iron rails for.

TREISENFELD, in Geography, a town of Germany, in
the principality of Cullmbach ; 8 miles S.E. of Bayrenth.
TREISH, a town of France, in the department of
the Sarre, on the Moselle ; 19 miles S.W. of Coblenz.
TREIZIÈME, Fr. in Mijoc, is the oétave of the 6th,
or the 6th of the octave; and is called in English the 13th,
from its containing twelve diatonic degrees, that is to say,
thirteen founds.

TRELAWNY, in Geography, a town of Jamaica, and
chief town of the Morors; 60 miles N.W. of Kingston.

the Mayne and Loire; 3 miles E.S.E. of Angers.
TRELECH, a town of England, in the county of
Monmouth; 5 miles S. of Monmouth.
TRELLIS, or Treillis, in Gardening, a term some-
times employed to signify the name as treillage, or a slave
and less strong fort of wooden frame-work of this nature,
which is sometimes used in particular situations and circum-
stances. See Treillage.

TRELON, in Geography, a town of France, in the de-
partment of the North; 9 miles S.E. of Avesnes.
TRELOOBING, in Mining, denotes a flitting
and working the loobs or fliny earth of tin, &c. in a lime-pit,
that the mud may be partly washed off with the water, and
the ore settle at bottom.

TRELOU, in Geography, a town of France, in the de-
partment of the Aline, on the Marne; 9 miles E. of
Chateau Thierry.

TREMA, in Botany, from Τραμα, τραματις, a hole, alluding
to the perforations in the shell of the nut.—Lourcq.
Cochinch. s.62.—Clays and order, Monocotian Pentalndia.
Gen. Ch. Male, Cal. Perianth of five lanceolate spreading
leaves. Cor. none. Stam. Filaments five, longer than the
calyx; anthers roundish.

Female, on the same plant, above the male, Cal. as in the
male, permanent. Cor. none. Pjfl. German superior,
roundish, deprest; style none; stigmata two, short,
filamentous. Peric. Drupa roundish, somewhat deprest,
ingleeved. Seed. Nut minute, pierced with several holes.
Female, Calyx of five leaves. Corolla none. Stigmata
two. Drupa superior, roundish, with a perforated nut.

—Native of the woods of Cochinchina. A tree of mid-
dling hie, with a filamentous bark, and ascending branches.
Leaves alternate, ovato-lanceolate with a long point,
ferrated, downy. Flowers on axillary branched flarks.
Drupa yellow.—We know nothing of this plant but from
the above description.

TREMANDREÆ, a new natural order of plants,
pointed out by Mr. Brown in his truly excellent and in-
structive "Remarks on the Botany of Terra Australis,"
published at the end of captain Flinders's Voyage. This
order is founded on the genus Tetraphtha, (fee that arti-
cle,) and another from the same country, named by Mr.
Brown Tremandra, apparently from Τραμα, a perforation, and
ανεσ, a man, because of the pores of the anthers. The cha-
acters of the order are thus given.

Calyx

Geography,
Calyx of four or five equal leaves, overlapping each other in the bud. Petals four or five, equal, involute, and enfolding the flamen, before expansion. Stamens eight or ten, below the germin, distinct; anthers attached by their base, of two or four cells, burnishing by either a tube or pore at the summit. Germin (superior) of two cells, with one to three pendulous seeds in each; style one; stigmas one or two. Carpels of two cells, and two valves, with partitions from their centres. Seeds albuminous, with a naked fcar, and an appendage at the opposite extremity; embryo in the axis of the flchy albumen, and half as long again; radicle directed towards the scar. The plants are humble shrubs, rehneling Erica, with either scattered or whorled leaves, definite of stipulas. Their flowers axillary, and single-flowered.

Mr. Brown prefers the name he has chosen for this order to one derived, as it ought in right of priority to be, from Tetratheca; because it better describes the structure of the flamen in both genera: the four distinct cells not existing in the ripe slate of the anthers of Tremandra, nor even of all the species of Tetratheca. We are well aware of the truth of his alteration, that bilocular anthers in general have each cell divided by the inflexed valves, till they burst, being while young truly quadrilocular. We were however of opinion, in founding the genus Tetratheca, that the four cells being permanent, afforded an excellent name, as well as character. If this character does not exist in every species, it may be less important; but that it is not found in Tremandra, surely renders it the more descriptive of Tetratheca.

Mr. Brown proceeds to remark, that the writer of this, like Labillardiere, has mistaken the fungous appendage to the apex of the seed for an umbilical caruncule, or appendage to the scar; hence one end of the seeds was taken for the other, and they were supposed erect, not pendulous; Labillardiere moreover was thus led to conceive that the radicle pointed towards the scar.

The Tremandras, as Mr. Brown observes, are nearly related to Polygala, but he eels them sufficiently distinct from the latter, not only in the regularity of the flower, and structure of the anther, but in the activation, or manner of folding, of both calyx and corolla; in the appendage of the seed being at its apex; and, it may be added, in the tendency to produce an indefinite number of seeds in each cell. We would rather confde it than dilate the number of natural orders, as well as genera, and with respect to the first reason of our learned friend, we would recall a remark of the fagacious Correa, that every natural order contains some regular and some irregular-flowered genera. The different activation is perhaps a necessary consequence of the last-mentioned difference. The other characters are fully of small account in this cafe.

"The greater number of Tremandras are found in the principal parallel of New Holland. They extend alfo to the south end of Van Diemen's infern, but none have been observed within the tropic."

TREMBLAGE, in Geography, a town of France, in the department of the Lower Charente; 3 miles S. of Marenses.

TREMBLANT, in Mufic, the name of a very disagreeable fap in large church-organs on the continent. Its name describes its effect. In general, a feedy tone in a voice or wind-instrument capable of fultaining a note, is the most effential requisite; but in the tremblant fap there is a perpetual quivering, such as we sometimes hear in the streets by the vielle and barrel-organ. See ORGAN.

TREMBLAY, Le, in Geography, a town of France, in the department of the Mayenne and Loire; 18 miles N.E. of Angers.

TREMBLAY le Violent, Le, a town of France, in the department of the Eure and Loire; 7 miles S. of Dreux.

TREMBLEMENT, in French Mufic, is equal to trills in Italian, and cadence in old French music: they all mean the same thing, which in English is a shake.

TREMBELEY, Abraham, in Biography, an eminent naturalist, was born at Geneva in 1710, and having finished his own education in Holland, he undertook that of the children of M. Bentinck. He then went to London, and had the charge of the young duke of Richmond. In the course of these employments he travelled into various parts, and directed his attention to various objects, particularly of natural history. His discovery with regard to the propagation of the fresh-water polypes (see POLYPE), engaged general attention, and he gave an account of it in his work printed at Leyden in 1744, and entitled "Memoire pour servir à l'Histoire Naturelle d'un Genre de Polypes d'eau douce un Bras en Forme de Cornes." His papers on other subjects of natural philosophy, as electricity, geology, &c., are printed in the Transactions of the Royal Society, of which he was a member. In 1757, upon his return to Geneva, he became a member of the Grand Council, and his conduct as a citizen contributed no less to his reputation, than his researches and discoveries as a philosopher. Having the superintendence of a granary, he made some useful observations on the infefts that destroy corn, and the mode of counteracting the injury they occasion. To the young he was a pleasing inftuctor, adapting his mode of conveying useful knowledge to their years and capacities. With this view he published "Instructions d'un Père à ses Enfans sur la Nature et la Religion," 2 vols. 8vo. 1775; "Instructions d'un Père à ses Enfans sur la Religion Naturelle et Révélée;" 3 vols. 8vo. 1775; and "Instructions d'un Père à ses Enfans sur le Prince de la Religion, et du Bonheur," 8vo. 1782. This excellent perfon died at Geneva, highly esteemed and respected, in 1784. Haller. TTBREMLING, POPULAR, in Planting, a name often applied to the aspen-tree. See POPULAR-Tree and POPULUS.

TREMBLING-ILL, a difafe in sheep, which often produces great loss among lambs. It is an affection of the paralytic kind, which is sometimes lingering, but at others so speedy, that the animals are not unfrequently dead before it is suspected. Walking in cold water has been found useful. See THWARTER or LOSING-ILL.

TREMBLOWA, in Geography, a town of Austrian Poland; 16 miles S. of Tarnopol.

TREMECEN, or TLEMSN, a city of Algiers, and capital of the western division, which is governed by a bey or viceroy; situated on a rising ground, below some rocky precipices, from which issue a number of springs. In the well part of the city is a large square basin, of Moorish workmanship, 200 yards long, and about half as broad. Most of the walls of Tremecen have been built or rather moulded in frames, a method of building used by the Africans and Spaniards. The mortar of which they confit, is made up of sand, lime, and gravel; which, by being at fir on well tempered and wrought together, has attained a strength and solidity not inferior to stone. About the year 1670, Hassan, then bey of Algiers, laid most of this city in ruins, as a punishment for the disaffection of the inhabitants; so that there is not remaining above one-sixth part of the old Tremecen, which, when entire, might have been four miles in circuit. Among the easterm part of these ruins we meet with several shafts of pillars, and other fragments, of Roman antiquities; and in the walls of a mosque, made out of these old materials, we have a number of altars, dedicated to the Dii Manes; 50 miles S. W. of Oran. N. lat. 35° 1'; W. long. 0° 28'.

TREMELLA, in Botany, so called by Dillenius, from tremo, to tremble, or quake, because of its gelatinous, tender
Illufr. t. 881. Perff. Fung. 622.—Clafs and order, Cryp-
Other ambiguus. Sm. Fung. Perff.

Efl. Ch. Fructification scarcely perceptible, in a mem-
branous, gelatinous, expanded, undulated subftance.

Nothing is more uncertain than the generic character,
and even the natural order, of Tremella. The genus feems
made up of various gelatinous productions, in which no
traces of fructification have been detected. Having no
shields, tuberces or warts, they could not be referred to
Lichen or its allies; neither have they feeds imbedded
throughout their subftance, to make them Uleas; much les
any aggregated feeds with or without a perceptible pericarp,
as in Ficus. They moreover differ from both the latter
genera, in not being submered Alge; for the aquatic speceis
are, as Roth and Perfoon observe, much better excluded.
The abie cryptogamift laft named refers Tremella to the
order of Fungi; but without any attempt to shew that they
produce powdery feeds from the surface of a hynenium, or
superficial membrane, a most material character of such
Fungi (fee that article) as have not a real pericarp with nu-
merous enclosed feeds. Their habit indeed is essentially dif-
terent. They are repeatedly revivificent by means of mois-
ture, thriving in a wet atmoflphere only, though not living
immered in water. In these particulars they agree exactly
with the Lichenes, not with genuine Fungi; which laft,
though they generally thrive in humidty, are scarcely re-
revivificent after having been once dried up.—The various
speceis, of which Perfoon defines twenty-four, are generally
parafitical, on the bark or branches of living trees, or on
dead wood. We doubt the reality of several, which appear
to us mere gummy exudations of the plants on which they
are found. This will prettily form a fubjeft of enquiiry.
We propofe to detail all the Britifh speceis, real or suppozed,
along with any exotic ones that feem particularly worthy of
notice.

We are not much fatified with Perfoon's fectiuns of this
genus, nor do we think it advisable to adopt them here, on
account of the uncertainties above-mentioned. Our deter-
mination does not arise from any difrepute for that excellent
author, one of the moft methodical and accurate in this ob-
ferve and much neglected path.

t. 13. T. juniperina; Hudf. n. 1. Nolocoeiium, mefen-
teris formis; Vaill. Parif. t. 14. f. 4.)—Seffile, plaited,
plaited, lobed, waved, orange-coloured.—Found in rainy
weather in the autumn and spring, on dead branches of oak
and other trees, or on decayed stems of broom or furze;
never on living wood or bark. This very flirking and con-
spicuous speceis forms cluf ters of various dimensions, from
one to four inches broad, of a rich orange hue, more or
less lef soft; when young pale or white. The subftance is
soft and flexible, neither vifcid, nor very tender. In dry
weather, or after being gathered, it shrinks, becomes hard,
and assumes a dirty brown colour; but revives in moifture.

Little taste or smell is perceptible in any part, nor has any
flign of fructification been discovered. Yet the plant ap-
ppears to be annual, and consequently must be propagated
by feed.

et Debr. Fung. 33. t. 8. f. 9.—"Convoluted, extremely
soft, delicatelyfcent, pale yellow."—Obferved by Perfoon on
Vol. XXXVI.

the branches of beech in autumn, but rarely. Half an inch
broad, and of a fofter subftance than the foregoing. We
are unacquainted with this speceis.

T. perficilis. Perennial Purplift Tremella. Bulliard
Fung. v. i. 223. t. 304.—Horizontal, leafy, somewhat
coraceous, smooth, undulated, pale violet.—Foun d on the
Stems of the Savine, Juniperus Sabina, according to Bulliard,
laving for a number of fuccedent years. When dried up it
is hardly diftinguifhable from the black Stems of the bark;
but in very muft or rainy weather it appears in the form of
horifontal leaves, half an inch or more in length, bluntly
rounded and lobed, of a pale vinous purple. Bulliard.

t. 1452.—Seffile, clustered, lobed, waved, of a rufly-brown;
the surface finely pubdecent.—Obferved by the late Mr.
Crowe, at Lakenham, near Norwich, growing on dead
wood, in wet weather in winter, compofing plaited convex-
luted tufts, three or four inches broad, pliable and tender,
flirved and flafeleps when dry, reviving imperfectly with
moifure. The fegments are rounded and waved, not lobed
or notched; their colour a rich brown, white within; the
surface finely downy, or rather covered with pale veftic-like
granulations, interfefted with brown irregular fpecks, more
like fructification than any thing else that has fallen under
our notice in this genus, except perhaps what Bulliard de-
cribes in the following speceis.

T. verticalis. Upright Dark-purple Tremella. Bulliard
Fung. v. i. t. 272. (T. mefenteriformis violacea; Ibid.
v. i. 230. t. 499. f. 6, X. Y.)—Cluf tered, cref, lobed, in-
uated and plaited, smooth.—Found on decayed tufts of
trees in autumn. Of a vinous violet-colour when young;
afterwards of a blackifh red-brown. It always grows cref,
from one to four inches high, gelatinous and latticd,
shining in between the teeth. Laid when fresh on glafs or
white paper, it difchars from every point of its surface a very
fine powder, supposed to be the feeds. This answcrs to the
nature of Fungi, and high microfco pic examinations are
requifite to determine how these feeds are produced; whether
in feies of eight together, from cells of the upper surface,
as in Fuxia, fee that article; or in a lefs regular manner,
from pores of the hynenium inviolating the under surface.
Bulliard has finallly reduced the prefent speceis to a variety
of his mefenteriformis; but it is fully very diflimit in many
efificant points from our mefenterica, and we cannot but
fuspect him to have here confounded feveral things together.
His original verticalis is faid to be valuable for its colouring
principle. When boiled in water for many hours, by which
the form and colour of the plant are not altered, it yields a
deep brown, likely to be ufeful in dyeing. For limning,
Bulliard obtained by infufion of this Tremella in fimple
water, a fub reffidu bifro-colour, very durable, and pre-
ferrable to any that he could buy in the fhop.

t. 1870.—Seffile, clustered, tufted, tumid, brown, thining
and gelatinous; when dry thin and membranous.—Gathered
by Mr. W. Borrer, in January 1807, on a beech in St.
Leonard's forest, Suffex. This conflits of roundifh soft pulpy
maffes, two or three inches broad, convoided and inflated,
like the intestines of some animal, of a darkifh, dull, not
red, brown; but with a thinning vefted surface, obfcurely
dotted. When cut, brown veftical freaks are obfervable a
little way into the subftance, which may contain the feeds,
though none have as yet been defcovered.

—Seffile, clustered, tufted, black, opaque, internally flicy,
deep purple.—Found by Mr. C. E. Soverby, on pale and
rails in Surry, early in June. This grows leflile, on ex-
posed
TREMELLA.

dulosa; Bulliard Fung. v. 1. 220. t. 420. f. 1.) T. arborea nigricans, minus pinguis et fugax; Dill. Mucf. 54. t. 10. f. 15.)—Selfile, gelatinous, roundish, undulated, blackish, befted with mammillary white-headed procefses on the upper side.—Common in autumn and winter on the decayed trunks of trees, and dead ficks, efpecially the Alder. The En-

ligh name, according to Dillenius, arose from the plant being suppofed efficacious againft witchcraft, when thrown into the fire. It confists of roundish, unequal, lobed, indeter-
minate fasses, moft corrugated beneath, farcely elevated on any fhalk, of a brown pulpy fubftance, becoming darker by age, from two lines to half an inch thick; the upper fide bearing fhort fcarced black prominences, each with a little white head.

T. boletiformis. Brown Rough-backed Tremella. Engl. Bot. t. 1819.—Nearly felfile, fcarceloft, roundish, depreffed, brown; smooth and fhining above; rough and dotted bene-

ath.—Found scattered over the dead branches of trees; in Suffix by Mr. W. Borrcr, and in Norfolk by Mr. W. J. Hooker. Each plant is nearly felfile, irregularly orbicular, depreffed, all over of a duff paleumber-brown; unequal, smooth and polished above; rough with prominent points beneath, whence the edges feme crenta. The diameter is from half an inch to an inch.

Bulliard Fung. v. 1. 221. t. 386.)—Selfile, dilated, ob-
tufe, whifh or somewhat brownish, pulpy, femi-pellucid.

—Found on dead or rotten wood, in fhady situations, burfting through cracks in the bark, and compoing ho-

rizontal, rounded, convoluted fasses, white and extremely tender, often very like the brain of an animal. Bulliard fays, a plate of glafs, on which the plant is laid, becomes covered with its powdery feeds. Such Mr. Sowerby found imbedded in the fubftance of the frond, forming round blackifh fasses. This fhould make it an Ulva. There are yellow, brown, or blackifh varieties. The whole require further investigation.

Hudfl. 564. Engl. Bot. t. 461. (T. terrestris fimooa, pinguis et fugax; Dill. Mucf. 52. t. 10. f. 14. Ulva terrestris pinguis et fugax; Dill. in Rau Syn. 64.)—Selfile, roundifh, plaited, waved, of an olive-green. —This much controverted plant occurs after rainy weather in summer, on gravel walks, or in graffy pature, growing flietly attached to the ground. It generally fpreads two or three inches, being of a tender gelatinous fubftance, thin and smooth, variously dilated and timid, of a dull olive-green. When young, it is faid by Dillenius to be small and globular, or like little fefles; but its growth is very rapid, and its exiftence fhort.

We are not sure that it revives after being thrivelled and blackened by dry weather. The duration of the plant is therefore, in the ftriéft fene, annual, and yet we do not know any thing of the feeds. Roth, Perfon, and others elleem it an Ulva; an opinion we cannot refute, if we are unable to confirm it. The molt remarkable circumstances in the history of this vegetable, are its being miftaken by the vulgar for the remains of a Will-of-the-wisp, or fallen flar; and by fome philofophers for an animal production. The latter have been deceived by a fimilar fubftance, proved by Dr. Withering to be the remains of frozen frogs, or as fome fay, the skin and bones of thofe animals digorged by herons. Whether thref or the real plant were the object of examina-

Perf. n. 9. Bulliard Fung. t. 427. f. 2. Engl. Bot. t. 2447. (Peziza Auricula; Bulliard Fung. v. 1. 241. Agaricum auricule formz; Mich. Gen. 122. t. 66. f. 1.)—Selfile, leathery, reddifh-brown; rough beneath; tufted and plaited above, refigbling an ear.—Not rare upon roten elder-trees. Perfon fays he never found this fpecies in any other fitation. It forms large tufts of plaited and convo-

luted flefty cups, of a femi-transparent reddifh-brown; the inner or upper surface palef, smooth and fhining; the outer darkifh, opaque and roughiff. The piaits branch from the middle, fo as to convey an idea of the human ear; whether Jewifh, Pagan, or Chriftian, depends on the complexion or cleanliness of the prototype. Bulliard afferts the feeds to be difcharged from the upper surface entirely. If this be correeft, he is juftified in transferring the plant to

Peziza.
TREMELLIUS, Emanuel, in Biography, an excellent Hebrew scholar, was the son of a Jew at Ferrara, and born there about the year 1510. Having been converted to the Christian faith by cardinal Pole and M. Flaminio, he imbibed the principles of the Reformers, accompanied Peter Martyr, and refided for some time at Strasbourg. From Strasbourg he came to England in the reign of Edward VI., and on his death left this country, and employed himself in teaching Hebrew in the college of Hornbach in Germany. He was afterwards professor of Hebrew at Heidelberg, and at this place translated into Latin the Syriac version of the New Testament, and joined Frances Junius in a translation of the Old Testament from the Hebrew. From hence he removed to Metz, and finally to Sedan, prosecuting his employment of teaching Hebrew, and died at the latter place in 1580. All Tremellius's writings related to the Oriental languages; and of these were Hebrew, Chaldaic, and Syriac grammars, a Hebrew Catechism, Commentaries on the Prophecy of Hosea, and the above-mentioned translations. Of his version of the Bible, F. Simon says that it is not much esteemed by the Protestants; and that the writer's Judaism has given him a singularity of manner, which makes him often wander from the true sense of a passage, and moreover that his Latin style is affected and inaccurate. Simon, Hist. Crit. du Nouv. Téxt.

TREMENTINE, in Geography, a town of France, in the department of the Maine and Loire; 6 miles N.E. of Cholet.

TREMEZZO, a town of Italy, in the department of the Lario; 14 miles N. of Como.

TREMILITI, three small islands in the Adriatic, near the coast of Naples; they are called Caparia, St. Domino, and Tremiti or St. Nicolò. N. lat. 42° 19'. E. long. 15° 34'.

TREMITUS, a town of the island of Cyprus, at one time the fee of a bishop. It was destroyed by Richard I. king of England; 12 miles W.S.W. of Nicosia.

TREMLITZ, a town of Bohemia, in the circle of Bechin; 7 miles S. of Pofchaken.

TREMOLANTE, in the Glass Trade, a name for the preparation of calcined brads, otherwise called arpel, used either for a sky-blue, or a sea-green.

TREMOLITE, in Mineralogy, a mineral which received its name from Tremola, a valley in the Alps, where it was discovered. This mineral is classed by Haly with hornblende or amphibole, and called by him amphibole granulitze. It is divided by some mineralogists into three sub-species: asbelous tremolite, common tremolite, and glaisser tremolite. They have all a fibrous or radiated structure, with a vitreous or pearly luster. The filaments feel harsh.
and rough to the touch, and scratch glass when rubbed upon it under water. By this property it may always be distinguished from albite, to which it bears a considerable resemblance.

Alophous tremolite (amphibole blanc of Haüy) is of various shades of white. It occurs massive in wedge-shaped or sphenitic concretions. The structure is fibrous and radiated: it is translucent on the edges, and somewhat brittle and feltile. The specific gravity is 2.683. It melts before the blowpipe into an opaque white mass. When rubbed or struck in the dark, it emits a pale reddish-coloured light: when thrown on hot coals, it gives out a greenish-coloured light.

Alophous tremolite occurs most frequently in granular foliated lime-stone, or in dolomite. It is sometimes found in chlorite, and more rarely in trap-rocks. It occurs at Glenelg in Inverness-shire, in Aberdeen-shire, and Isolmkill, and in basalt at the cattle-rock of Edinburgh. It is found also in various parts of Europe, and in granular lime-stone with augite on Mount Vesuvius.

Common tremolite (grammatite, Haüy) occurs of various shades of white, and sometimes dark smoke-grey. It occurs massive and crystallized. The primitive form of the crystal, according to Haüy, is an oblique prism, with a rhomboidal base, the planes of which are inclined at an angle of 127° and 53°. The more common form of the crystals is a very acute rhomboidal prism, with the edges more or less truncated, and the lateral planes longitudinally streaked.

This mineral splits easily, not only in the direction of the planes of the crystal, but also in that of its diagonals. When one of the prisms is broken across, we may observe a line strongly marked in the direction of the principal diagonal; hence it may at first sight be considered as a twin crystal, but this is not the fact.

Common tremolite is translucent or semi-transparent; it scratches glass, is brittle, and is fusible, but with great difficulty, by the blowpipe. According to Brongniart, the crystals of tremolite are rarely found pure, but generally contain a portion of the accompanying rock in the interior. The constituent parts are flated as under:

It occurs in the same situations as alophous tremolite, and also in metalliferous beds, and sometimes in serpentine and granite.

Glaity Tremolite.—Its colours are the same as those of common tremolite. It occurs massive, and in acicular crystals. The luster is shining, but in a less degree than that of common tremolite. It is translucent and rather brittle. The constituent parts of this mineral vary in different specimens. According to Langier, the tremolite from St. Gothard varies as under:

Though tremolite is arranged under a distinct species from hornblende and actinolite by professor Jameson, it is classed under the same family. In a general view he observes, that tremolite is characterized by its white colours, actinolite by its bright green colours, and hornblende by its dark green colours. The count de Bourvon states, that the phosphorescence of tremolite is owing to an intermixture with dolomite, and when the latter mineral is separated from it by acids, the property is destroyed.

TREMONT, in Ancient Geography, an island situated near that of Delos, subject to frequent earthquakes.

TREM, a town of Spain, in Catalonia, on the Noguera Palaqева; 20 miles N. of Balaguer.

TREMBUTTEL, a town of the duchy of Holstein; 20 miles E. of Hamburg.

TREMULA, in Ancient Geography, a town of Africa, in Mauritania Tingitana, upon the route from Tncolofoida to Tingis. Anton. Itin. Allo, a town of Hispalis, belonging to the Bafilethi.

TRENCH, in Agriculture, a narrow opening or furrow cut in land by the spade or plough, for the purpose of draining or watering, and some other uses. Allo, a small opening made in digging and working land over in different caves, and in laying it up both in ploughing and gardening. See Spring and Surface Drain, Watering Land, Ridges, and Ridding-up.

The cutting should be very exact for the two first purposes, the different sorts of materials raised being laid to the different sides of the trenches, which, in the latter case, are now mostly made in the wedge form.

Many of the bogs in Ireland have been drained, and made good ground, by only digging trenches round them.

TRENCH Filled-Drain, that fort of surface-drain which is laid with some kind of material for affording a proper passage to the water in its lower part, the upper being covered in with loose earth. See Surface Drain.

TRENCH-Planting, in Agriculture and Gardening, the practice of setting and putting out plants and other productive matters in trenches. It is a method which is had recourse to for many different sorts of crops in each of these departments of cultivation. In the former for potatoes and some others, and in the latter for a very great number of plants and roots, as is seen under their different heads.

It has lately too been practised for asparagus, and some other crops, with very great success. In planting this valuable vegetable in this way, it was done in the early spring, the ground being first dug to the depth of eighteen inches, and well incorporated with rotten dung quite to the surface; a trench four or five inches deep was then formed, in which the plants, at the time twelve inches in height, were planted at three inches apart, keeping the tops perfectly upright, and breaking or cutting the roots as little as possible, covering them in with the spade, and treading them gently with the foot; after which the work was finished by a good watering. The plants scarcely flagg'd at all, though no care had been taken to preserve the mould about their roots, and not one of them died, but they far surpassed in the course of the summer those in the seed-bed rows, and some of them were capable of being cut the following year, in consequence of their great progress. The soil had a large proportion of peat-earth in it.
Sea-kale has likewise been raised in trenches with great advantage. They were made the fame depth as above, eight inches of loose foil being left in the bottom, with which, fix inches depth of river-fand were then intimately blended. The trench was now a foot deep, and being filled with fix inches more of very light sandy loam, and the whole well mixed together, was fowm in a line along the middle; and as the plants grew they were earthed up. The plants became, in this mode, fo flout in the second year, as to be made ufe of by being blanched by means of straw thaken loosely over them, removing it as it became wet and heavy.

There are probably many other plants, seeds, and roots, that have not yet been tried, which may be raised in this method of planting with great success and advantage.

**Trench-Plough,** in Agriculture, that sort of tool of this kind, which is contrived for the purpose of opening and working land to a much greater depth than the common kind, fo as to allow tap-rooted plants to frike them deeper, and form them better. See Plough and Tap-Root.

**Trench-Ploughing,** the practice of opening and loosening the soil of lands to a great depth by means of fuch ploughs, which is a method that is essentially necessary where the roots of crops are to fhoot and frike down to great depths, as without it such roots are incapable of being grown in the belt and most profitable manner. The work is sometimes performed at one operation, but in other cafes the tool does it by going twice in the fame track, rendering the earth foole, and capable of being penetrated to a fill greater depth. This mode of preparing land is much too little had recourse to by farmers in many cafes.

**Trenches,** in Fortification, are ditches which the besiegers cut, to approach more fecurly to the place attacked; whence they are also called lines of approach. See Parallel.

They fay, mount the trenches, that is, go upon duty in them. To relieve the trenches, is to relieve fuch as have been upon duty there.

The enemy is faid to have cleared the trenches, when they have driven away, or killed, the soldiers who guarded them.

**Trench, Tail of the,** is the place where it was begun: and the head, that to which it was carried.

Trenches are of several sorts, according to the nature of the foil: if the adjacent territory be rocky, the trench is only an elevation of bavins, gabions, wool-packs, or epaulements of earth, cast round about the place; but where the ground may be easily opened, the trench is dug in it, and bordered with a parapet on the fide of the besieged.

The breadth of the trenches is from eight to ten feet, and the depth from fix to feven: they are cut in talus, or afflope.

The trenches are to be carried on with winding-lines, in fome manner parallel to the works of the fortrefs, fo as not to be in view of the enemy, nor to expose their length to the enemy's fhot: for then they will be in danger of being falled upon, or fome by the enemy's cannon: this carrying of the trenches obliquely, they call carrying them by courfes, or returns. See Parallel.

**Trenches, Opening of the,** is when the besiegers begin to work upon the line of approaches; which is usually done in the night; sometimes within muskett-shot, and sometimes within half, or only whole cannon-shot of the place, if there be no rifing ground about it, the garrifon ftrong, and their cannon well ferved.

The workmen that open the trenches, are always supported by bodies of men againft the fallacy of the besieged; and sometimes those bodies lie between them and the place, as also on their right and left.

The pioneers fometimes work on their knees; and the men that are to support them, lie flat on their faces, in order to avoid the enemy's fhot; and the pioneers are likewife ufuall covered with mantelets, or faulfons.

**Trench-Guard.** See Guard.

**Trench the Buffaft, To,** is a fem-phrase, signifying to divide the ballaff into feveral trenches in a ship's hold.

**TRENCHARD, John,** in Biography, a political writer, was the fon of Mr. Trenchard, secretary of state under King William, and born in 1669. Liberally educated, he was placed in one of the inns of court, with a view to the study of law. He was called to the bar, but as he preferred a political life, he abandoned the profession, and obtained the place of the commiffioner of the forfeited estates in Ireland. Having acquired confiderable wealthy by marriage, by the death of an uncle, and by the deceafe of his father in 1695, he came into parliament for the borough of Taunton, and appeared as a patriotic member and writer. He was a zealous opponent of a standing army; and foon after the peace of Rylwicke in 1697, which rendered needlefs fuch a force, he pubhcled a pamphlet, entitled "An Argument fhewing that a Standing Army is inconfiftent with a free Government, and absolutely deftructive to the Conftitution of the English Monarchy." This was followed, in 1698, by "A short History of Standing Armies in England." These pamphlets are fpontly to have occasioned the king's fending away his Dutch guards, and the army's being reduced to a very low ettablishment. In many fubfquent years, Mr. Trenchard continued to write occanionally in favour of liberty; and having taken Thomas Gordon, a perfon of fimilar fimilitudes, into his houfe, they began in 1720 to publich periodically a feries of papers, entitled "Cato's Letters," for the profefTed purpose of promoting civil and religious liberty. Trenchard died in 1723, at the age of fifty-four; and Gordon published his eulogy in the "Independent Whig." Biog. Brit.

**TRENCHES, in Heraldry.** See Tranche.

**TRENCHES' Island, in Geography,** an ifland near the coast of South Carolina; 25 miles in circumfrence. N. lat. 32° 13'. W. long. 80° 58'.

**Trenching,** in Agriculture, the operation and pracfice of working over land in trenches by the fpade. It is had recourse to in bringing fome kinds of waste lands into cultivation, in fome cafes and particular situations, as in the northern parts of the ifland, where labour is cheap; but in others it is moftly too expensive.

It, however, anfwers fometimes in cafes where it could hardly have been expected, on account of its being fo very complete, as fearely to require any thing being done afterwards to the ground.

The term afo signifies the laying up land in the ridge form, either by the fpade or plough.

**TRENCHMORE,** the name of an old English dance; of which nothing certain is now known, but that it was a lively movement.

**TRENCK, Frederic, Baron von,** in Biography, an adventurer, was descended from a noble Prussian family, and born at Konigb-rg in 1726. Having been too much indulged in his youth, and losing his father when he was twelve years of age, he became ungovernable, and the fport of his own impetuous pallions. In 1742, at the age of fifteen years, he entered into the Prussian guards, then quartered at Potsdam. In 1744, at the commencement of the fcond Sile-rian war, he attended the king as an aide-de-camp; but being fufpected of a traitorous correspondence, he was arrefted, and confined in the prison of Glitz, and failing in his firft attempt to make his ecape from prifon, he at length succeeeded
ceed by bribery, and got safe to Bohemia, and afterwards to Elbing, in Polish Prussia, in March 1747. After various adventures he arrived at Moscow, where he intimated himself into the good graces of the lady of the grand-chancellor Belzuc, the favourite of Elizabeth. From Moscow he made a circuitous tour to Vienna, with a view of recovering some contested property; and dissatisfied with the reception he found at the Austrian court, he determined to return again to Russia; but in passing through Dantzic, he was arrested at the request of the Prussian resident, and committed to prison at Magdeburg, where he remained ten years. Here he amused himself, during a tedious and rigorous imprisonment, in writing verses; which, long after his release in 1763, he published at Frankfort on the Main, in 1769. He published some other works at Aix-la-Chapelle, where he became editor of a gazette, and married a lady of respectable character and connections. Finding the occupation of a gazette-writer tiresome and not lucrative, he began business as a wine-merchant; but the wine-trade not answering his expectations, he disappeared about the year 1783. In 1792 he edited a journal at Hamburgh and Altona, and from the latter place he removed to France, where he left his life by the guillotine in the month of July 1794. The Memoirs of his own Life appeared at Berlin in 1787, in two parts, 8vo. Of the authenticity of the facts stated in these memoirs, great doubts have been entertained. His life, translated into French by himself, was published at Paris in 1789, 3 vols. 8vo. A new edition of his "Macedonian Hero" was printed in 1788, Frankfort and Leipzig, 8vo.

TRENSIN, in Geography, a town and castle of Hungary, near the river Waig, situated on a rock, and defended by a very strong castle. Near it are some hot baths; 20 miles N.N.W. of Topoltsan.

TREND, that part of the flock of an anchor from which the size is taken.

TRENDING, in Rural Economy, the operation or practice of freeing wool from filth of different kinds. It is usually done by persons who are called tinders, and who are appointed and sworn for the purpose. In mild sheep-districts, the best wool is always understood to have gone through this process, and then to be worth two or three shillings the tod more than other untended wool. The fleeces in such fences are neatly rolled together, and bound with oller or with bands in some places. It is sometimes termed tendering. See Sheep and Wool.

TRENDLE, a term signifying the wheel of a barrow, or any thing which turns round in that manner when of the low wheel kind.

TRENNO, in Geography, a town of Italy, in the department of the Olena; 4 miles N.W. of Milan.

TRENSDORF, a town of Bavaria, in the bishopric of Bamberg; 4 miles S. of Bamberg.

TRENT, a city of the county of Tyrol; in Latin Tridentum, called by the Italians Trento, and by the Germans Trient; and situated upon the Adige or Etzch, in a very fruitful valley, surrounnded with high hills. It was built by the Cenomani Gauls, who were dispossessed by the Romans. The Goths became masters of it when they came into Italy, and after them the Lombards. Afterwards it was pos.sessed by the German emperors, until 1377, when Wenceslaus, son to Charles IV., gave it to the church of Rome. Afterwards its bishops, being made princes of the empire, became temporal as well as spiritual lords of the city. Some authors affirm that the name Tridentum is derived from Neptune's fceptrum, or trident, to whom they say the city was once consecrated. This opinion took its rise from an ancient marble being found there, on which was a Neptune holding his trident. Others derive the name from three rivers and torrents that fall into the Adige, a little above and below the city. Others say it owes its name to three high rocks in the neighbourhood, which appear like three teeth, tres dentes. The bishop was a prince of the empire, and temporal as well as spiritual lord of his diocese, which is of very considerable extent; but notwithstanding the sovereignty of the bishop, the city of Trent has its own distinct privileges, and magistrate to preserve their own confines of two burgo-masters, who preside by turns, and twelve councilors. Trent contains no streets exactly regular, and the houses are in general old. The palace is large, but in the antique style. Besides the cathedral, there are three parish churches, a college, and some convents; 55 miles N. of Mantua. N. lat. 46°. E. long. 11°. 5'.

TRENT, a princely bishopric of Germany, situated in the Tyrolo, in which this ancient bishopric was gradually increased by the liberality of the ancient Roman emperors. Though the bishop of Trent, after the dilpation ratified in the reeds of the empire, at Augsburg, in the year 1548, held of the archducal house of Austria, as a land fiate, yet he enjoyed, as an immediate prince of the empire, both a seat and voice at the diets, in the college of princes of the empire, and likewise actually fent deputies to the diet of the empire. This prelacy also was a fiate of the circle of Austria. Among the indemnities agreed to at Ratibon, in 1802, the bishopric was given to the grand duke of Tuscany, as archduke of Austria. It was afterwards ceded to Bavaria.

TRENT, a town of the island of Rügen; 11 miles N.W. of Bergen.

TRENT, a river of England, which rises in the north-west part of Staffordshire, on the borders of Cheteford, about six miles south-west from Leek; taking a south-east direction, it crosses the county to the borders of Leicestershire and Derbyshire; it then takes a north-east direction, and crosses the county of Derby and Nottingham to Newark, from whence its direction becomes nearly due south, till after passing a small part in the north of Lincolnshire, it joins the Ouse, and the two streams form the Humber. Canals are made or making, to open a communication between this river and various parts of the kingdom, viz., from the mouth of the Idle, below Gainsborough, to Redford and Chetefeld; to Lincoln, and from hence to Tatterfale, Horncastle, Seafor, Bolton, and the sea; from near Nottingham, to Cromford and Winter; from the mouth of the Derwent, one branch through the counties of Derby, Stafford, and Chetefeld, to the Mersey, which is joined with another branch to Coventry and Bransfor, where it meets with the canal from Brentford: other branches join the Thames at Lechlade, the Avon at Warwick, the Severn at Worcester, and many others. The Trent is of itself navigable from Burton in Staffordshire.

TRENT, a river of Canada, which runs from Rice lake to Lake Ontario.—Alfo, a river of North Carolina, which runs into the Neuf, at Newbern.

TRENT, Council of, in Ecclesiastical History, denotes the council assembled by Paul III. in 1545, and continued by 25 sessions till the year 1563, under Julius III. and Pius IV., in order to correct, illustrate, and fix with perfection, the doctrine of the church, to restore the vigour of its discipline, and to reform the lives of its ministers. But it has been a matter of complaint by many, both in and out of the communion of the church of Rome, that this assembly, instead of reforming ancient abuses, rather gave rise to new enormities. It is alleged, that opinions of the scholastic doctors on intricate
intricate points, which had been left undecided, were by this
council absurdly adopted as articles of faith, and imposed
with violence upon the confidences of the people, under pain
of excommunication: that there is an ambiguity in the decrees
and declarations of this council, which renders the disputes
and differences, that had rent the church, more intricate and
perplexed, and which really multiplies and propagates, in
stead of lefthening and suppreffing them: that matters were
decided in this assembly, according to the despotic will of
the Roman pontiff, without regard to the dictates of truth,
or the authority of Scripture: and that the few wise and
pious regulations that were made in this council, were never
supported by the authority of the church, but suffered to
degenerate into a mere lifeless form or shadow of law, which
was treated with indifference, and transfigured with impun-
ity. It will not, therefore, appear surprising, that there are
certain doctors in the Roman church, who, instead of
submitting to the decisions of the council of Trent, as an
ultimate rule of faith, maintain that these decisions are to
be explained by the dictates of Scripture and the language
of tradition: nor can we wonder that this council has not
ever where the fame degree of credit and authority, even
in those countries that profess the Roman Catholic religion.
Some countries, indeed, such as Germany, Poland, and
Italy, have adopted implicitly and absolutely the decrees of
this council, without the least restriction. But in other
places it has been received and acknowledged on certain
conditions, which modify, not a little, its pretended author-
ity. Among thefe latter we may reckon the Spanish do-
minions, which, during many years, disputed the authority
of this council, and at length acknowledged it only so far
as it could be adopted without any prejudice to the rights
and prerogatives of the king of Spain. In other countries,
such as France and Hungary, it has never been solemnly
received or publicly acknowledged. Indeed in the former
of these kingdoms, thefe decrees of Trent that relate to points
of religious doctrine, tacitly and imperceptibly through the
power of custom, acquired the force and authority of a rule
of faith; but those which regard external discipline, spiri-
tual power, and ecclesiastical government, have been con-
stantly rejected, both in a public and private manner, as in-
confident with the authority and prerogatives of the throne,
and prejudicial to the rights and liberties of the Gallican
church.

Notwithstanding the preceding remarks, the decrees of the
council of Trent, together with the creed of pope
Pius IV., contain a summary of the principal heads of the
Roman Catholic religion. See Popery.

However, in these decrees and confeffion of faith, many
things are expreffed in a vague and ambiguous manner, with
a view to the indefinite divisions then prevalent in the church:
and several tenets are omitted in both, which no Roman Ca-
tholic is allowed to deny, or even to question. But it must
be acknowledged, that in these decrees, and in this confeffion,
several doctrines and rules of worship particularly pertaining
to the doctrine of purgatory, the invocation of saints, and the
worship of images and relics, are inculcated in a much more
rational and decent manner than that in which they appear in
the daily service of the church, and in the public practice
of its members: and it is to be observed, that in deducing a
just notion of the doctrine of Rome from the decrees of the
council of Trent, regard ought to be had, not so much to
the terms made use of in these decrees, as to the real signifi-
cation of these terms, which must be drawn from the cu-
toms, institutions, and observances, that are, every where,
Eng. ed. 8vo.

TRENT, Council of, congregation for interpreting the decrees
of the, is a congregation, the plan of which was formed by
Pius IV. and afterwards instituted and confirmed by
SIXTUS V. It was authorized to examine and decide, in
the name of the pope, all matters of small moment relating
to ecclesiastical discipline; while every debate of any con-
sequence, and particularly all disquisitions concerning points
of faith and doctrine, were left to the decision of the pontiff
alone, as the great oracle of the church. Hence it was,
that the approbation of Innocent XI. was refused to the
artful and injudicious work of Bosquet, bishop of Meaux,
entitled “An Exposition of the Doctrine of the Catholic
Church,” until the author had suppressed entirely the first
edition of that work; and made corrections and alterations
in the second. See Popery.

But though the court of Rome, and all those who favour
the despotic pretensions of its pontiff, maintain, that he
alone who governs the church as Christ’s viceregent, is
entitled to explain and determine the feme of scripture and
tradition in matters pertaining to salvation, and that a
devout and unlimited obedience is due to his decisions; yet
it has been impossible to perforce the wider part of the
Roman Catholic body to acknowledge this exclusive author-
ity in their head. And accordingly, the greater part of
the Gallican church, and a considerable number of learned
men of the popifh religion in other countries, think very
differently from the court of Rome on this subject. They
maintain, that all bishops and doctors have a right to con-
fult the sacred fountains of scripture and tradition, and to
draw from thence the rules of faith and manners for them-
selves and their flock; and that all difficult points and
debates of consequence are to be referred to the cognizance
See Infallible.

TRENTAL, TRIGINTAL, or TRICENNAL, a Romifh
office for the dead, consisting of thirty masses, reafereed for
thirty days succesfively after the party’s death.

The trental is thus called from the Italian, treinta, trinta,
thirty. It is mentioned anno primo Edw. VI.

TRENTON, in Geography, a town of New Jerfey, in
the county of Hunterdon, on the E. fide of the Delaware.
Here the legiflature fatedly meet, the supreme court fit,
and moft of the public offices are kept. The court-houfe is
a handsome building. There is a flourishing academy,
and the number of inhabitants is about 3000; 24 miles N.N.E.
of Philadelphia. N. lat. 40° 13’. W. long. 74° 48’—
Alfo, a poft-town of the province of Maine, in the county
of Hancock, containing 501 inhabitants; 31 miles N.
of Penobfcoet.—Alfo, a town of North Carolina, on the
river Trent; 20 miles S.S.W. of Newbern.—Alfo, a poft-
township of New York, in Oneida county, 12 miles N.
of Utica; bounded northerly by Steuben and Remfien, eafterly
by West Canada creek and Herkimer county, S. by Deer-
field, and W. by Floyd. The town is well watered by
small streams, and by springs. The foil is good: the forest
woods are elm, linden or bafs-wood, butternut, beech,
maple, &c. The inhabitants are principally of New Eng-
land defcent, though fome are of the ancient Dutch from
Holland, and their induftry is well rewarded by the pro-
ducts of agriculture. There are fome very remarkable
falls in West Canada creek, on the easterly border of this
town. This stream affords numerous fices for mills in
Trenton. The population is 1548; the fenatorial electors
are 127. The largest compact settlement in this township
contains from 70 to 80 buildings, and is distant 13 miles
from Utica and 107 from Albany.

TREO, a town on the E. coast of the island of Paros.
TREOGAN, a town of France, in the department of the North Coasts; 9 miles W.S.W. of Roffeneu.

TREOCAT, a town of France, in the department of the Finilhere; 9 miles S.W. of Quimper.

TREPPAN, in Surgery, a circular aw, by means of which the skull is perforated in the operation called trepanning. It bears a considerable resemblance to the well-known instrument named a wimble, and is worked in the same manner. A representation of it is given in Plate VIII. f. 6. of the surgical plates. Formerly, the aw was sometimes made of a conical shape (see f. 5.) but this construction rendered the action of the instrument difficult; and as the fear of a cylindrical aw penetrating too suddenly, so as to injure the brain, was found by experience to be an insufficient reason for the conical shape of the aw, the cylindrical trepan at length came into general use. In this country, the trepan is now superseded by the instrument called a trephine, which has a different kind of handle from that of the trepan, and is not worked in the same way. (See Trephine.) On the continent, however, the trepan still has the preference. Mr. Rodman's trepan (f. 1.) is objectionable, because with it you cannot increase and diminish the pressure on any particular point of the circular groove in the bone, as occasion requires. You must continue to saw every part of the circle. Hence, if the bone be sawn through in one place, and not in another, as generally happens before the operation is finished, the further action of Mr. Rodman's saw will inevitably do mischief to the dura mater, and is not well calculated for completing the division of the bone. See the following article.

TREPPANNING, or Trephining. From what has been said in some preceding articles of this work, (see particularly Head, Injuries of, Extravasation, &c.) the operation of trepanning or trephining, or that of sawing out a portion of the skull, is, in several affections of the brain from compreffion or irritation, the only means of preferring life, and of all other remedies the most urgent and effectual. It should be performed in good time, and the repetition made according to the exigency of the case. In the records of surgery, innumerable facts may be consulted, where the prudent and judicious employment of the trepan has effected wonderful cures, and been the only thing by which the patients' lives could possibly have been saved. The benefit which the operation brings about, is also sometimes so sudden and astounding, that in no instance does the interposition of the surgical art display itself to greater advantage. The immediate restoration of sight by the deprision or extraction of an opaque substance from the eye, is not more beautiful and striking, than the instantaneous communication of the intellectual faculties, and of the powers of speech, of feeling, &c. together with voluntary motion, to a person lying in an apparently lifeless state from an injury of the head. The utility of the trepan is occasionally manifest even in this degree. In the valuable essay of Mr. Abernethy on injuries of the head, a case may be seen, in which the patient, who had been in a condition almost benumbed of animation, rose up and spoke the instant the extravasated blood was removed from the surface of the brain. And among the wounded at the battle of Waterloo, there was a foidier of the 44th regiment, whose state is of equal interest. He had been struck with a musket-ball on the right parietal bone, which was exposed, and had no appearance of being fractured. As, however, the symptoms of compreffion were urgent, and the patient was in nearly a lifeless state, the writer of the present article conceived it right to apply the trephine to the part on which the violence had acted. He had not been long before the external table came away in the hollow of the trephine, leaving the inner table behind, which was not only splintered, but driven at one point more than half an inch into the membranes and subfance of the brain. No sooner were the fragments taken out with a pair of forceps, than the man instantly sat up in his bed, looked round, and began to speak with the utmost rationality. It is a most extraordinary fact, that this patient got up and dressed himself the same day without leave from the medical officers, and never had a bad symptom afterwards. Immediately the operation was finished, the temporal arteries were opened, and some purgative medicines exhibited.

Let not the young surgeon, however, draw from these dazzling cases of success an immoderate foliation of performing the operation; for it should never be undertaken but in the most preffing circumstances, and when the symptoms unequivocally shew, that a dangerous degree of pressure on the brain exists. We recollect an unfortunate example, in which an hospital surgeon of this metropolis ventured to saw out a portion of the frontal bone for a mere long-continued pain in the part: the patient was attacked with inflammation of the dura mater, and perished in three or four days. We may therefore conclude, that the operation is not itself exempt from danger; and it is certain that it ought never to be resoluted on without deep consideration.

The trepan or trephine is never necessary in injuries of the head, except for the purpose of relieving the brain from pressure. Such pressure may be caused by a depressed portion of the cranium, or it may be produced by an extravasation of blood, or the lodgment of matter, betwixt the skull and the dura mater. The chief danger of concussion, when the accident is not directly or soon fatal from the disorganization and mischief done to the brain, depends upon the consequent inflammation of this organ, and therefore can be little likely to be benefited by the use of the trepan. If the operation becomes proper in such a case, it is when an abces has formed under the cranium, and when the confined matter itself creates bad symptoms by its pressure on the brain. This state of things, however, cannot come on till after the inflammation of the brain and its membranes has prevailed a certain time, and it is always accompanied with a detachment of the pericranium and a puffy tumour of the scalp; or, if there be a wound of the latter part immediately over the abces, the lips of the injury acquire suddenly an unfavourable appearance, and lose their vermilion colour. The patient has also had much preceding febrile disorder, pain and tension over the whole head, redness and turgescence of the eyes, and generally more or less delirium. When the matter is forming, there are usually some rigors, and as soon as it is formed, the patient falls into a comatose state, and paralytic symptoms flow themselves. Here the urgency for the prompt application of the trephine is very great, and the patient's chance of living is almost essentially connected with the immediate performance of the operation. This important cafe has been particularly dwelt upon in the writings of Mr. Pott.

In the articles Head, Injuries of, Extravasation, &c. we have laid down the most remarkable symptoms of concussion and compreffion of the brain, a subject which every surgeon should study with earnest attention, before he ever pretends to employ the trepan. For sometimes these accidents are extremely difficult to be discriminated; sometimes they exist together in the same individual, a complication which is peculiarly embarrassing; and in every instance where the symptoms are those of concussion, the oper-
TREPANNING.

operation, so far from being indicated, would be a step of all others the most likely to do harm, by increasing the irritation and inflammation of the brain and its membranes. A fall upon the back, or upon the head, occasions a direct concussion of the brain, and the shock, not being materially weakened by the intervention of any yielding elastic structure, is the more dangerous. When a person has fallen from a certain height, and pitched upon his head, his back, the buttocks, the knees, or even the soles of the feet; when he has been instantly deprived of his senses, and then by degrees recovered them and come to himself again; the fact of his having suffered concussion of the brain is clear and indisputable. Concussion has likewise taken place, though in a slighter degree, when the patient has been only stunned by the fall, and experienced a sensation of sparks. But a multitude of degrees separate this feeble concussion from that, in which the substance of the brain is instantaneously disorganized, so that the patient has not the possibility of recovery.

The symptoms of concussion of the brain are attended with coma, and the compresion of this organ by an extravasation is also accompanied with lethargic heaviness. How, then, is the surgeon to ascertain, whether the coma or disordered arises from one or the other of these affections?

Here, in order to avoid repetitions, we beg leave to refer to the observations already made in the articles quoted above. But there is one criterion of such first-rate importance, that it may prevent innumerable fatal mistakes, and, indeed, without the continual recollection of it, no man ought to be rash enough to interfere with this dark and abstruse part of surgery. On this account we shall mention it here, notwithstanding we have already noticed it elsewhere. If the patient is knocked down and stunned directly by the blow, and remains in a state of insensibility, these primary symptoms are attributable to the concussion. On the contrary, when the coma and loss of sense do not take place till an hour or two after the blow, they are to be imputed to an extravasation.

The shock given to the brain by concussion, must, like every other impulse communicated, continue to diminish until it ceases altogether. If, at the very time of the blow, the shock has not been forcible enough to produce alarming symptoms, such symptoms will not afterwards come on when their cause is weakened. Hence the reason may be discerned, why compresion may be distinguished from concussion of the brain, when there has been an interval of sense between the receipt of the blow, and the occurrence of the bad symptoms. But the distinction of the symptoms into primary and consequent, cannot be made when concussion and extravasation exist together.

Having made these few remarks on concussion and compression of the brain, remarks which seemed necessary before we entered into a description of the operation of the trepan, we shall next premise some observations relative to contusions and fractures of the skull, cases on which the most erroneous opinions have been entertained. It is true, that we have in another place (see Head, Injuries of,) considered the subject; but we think it better to recapitulate certain points here, because they have such immediate connection with the application of the trephine.

Contusions of the head not unfrequently occasion a small kind of tumour, which is soft in the centre, but hard and resisting at the circumference, especially when the violence has been considerable. Now the ease with which the centre or seat of the extravasated fluid admits of being depressed, while the circumference remains hard and elevated, is extremely apt to give rise to the belief, that a fracture with depression has happened. The true nature of this accident was first clearly explained by the eminent M. J. L. Petit, and since his time the proper cautions, not to fall into a mistake concerning it, have been laid down by the generality of surgical writers.

Often nothing is more obscure than the diagnosis of fractures of the cranium: their existence indeed can only be made out with certainty, when they can be felt or seen. Thus a fracture of the skull, attended with a wound of the scalp, and exposure of the bone, shews itself in the form of a fissure more or less wide and extensive, and taking various directions. The accident may also be known by the touch, even when the soft parts continue entire, particularly if the fracture is accompanied with splinters, or the edges of the fissure are materially separated. When there are many splinters, entirely detached, a crepitus will likewise serve to explain the nature of the accident; but, unaffected by these symptoms, imparted to him by the sight, the hearing, or the touch, the practitioner cannot at once offer a decided opinion as to whether a fracture exists or not.

In order to procure more positive information, would it be right and judicious to make several incisions, and uncover the bone? But here the surgeon would be embarrassed in the very commencement of his proceedings; for how would he be able to judge where the knife should be applied? Why also should he resort to unfeels and painful operation, which (to say the least of it) could only render the patient's cure more difficult.

The symptoms indicating compresion of the brain, can alone justify an examination of the fracture. These symptoms also must be urgent and alarming; for when they prevail in a slight degree, bleeding and evacuations promise more benefit than any operation on the skull, and consequently all examination of the part supposed to be broken must be unnecessary. The precept, too commonly given, to cut through the scalp for the purpose of bringing the fracture into view, will no longer be matter of surprize, when it is known that, with some surgeons, the operation of the trepan is a thing of course in all fractures of the cranium.

Even when the cranium has been denuded, so that the sight can convey the information respecting the solution of continuity in the bone, care must be taken not to be deceived by a future, or by the grooves of a vessel. In cases of doubt, a modern surgical author advises us to scrape the outside of the bone; and he tells us, that if, after the removal of the external table, the fissure yet appear, and a thread of blood be seen at its outer part, no doubt exists of its being a real fissure. As, however, making this examination can answer no purpose, except with a view to determining the place where the trepan should be applied, we cannot recommend the plan, except where the symptoms are such as to render this information desirable. On the contrary, it appears to us, that all examinations of the bone, made seemingly from mere curiosity, and without any true surgical object, should be deprecated as rash and hurtful.

The danger of fractures of the skull does not depend upon the simple solution of continuity; it bears altogether a relation to the concussion and compression of the brain, with which the injury of the bone may be complicated. The preffure, which is caused by depressed splinters of bone, is less alarming, inasmuch as the caule of the compresion is easy of removal. The preffure arising from extravasated fluid is far more serious, in consequence of the difficulty of ascertaining positively the existence and precise situation of such extravasation.
TREPANNING.

The feat of the extravasation is sometimes between the skull and the dura mater, which has been detached from the bone. More frequently it occurs either between the dura mater and tunica arachnoidea, in the substance of the brain, or else in the ventricles. The quantity of extravasated fluid is generally less in those extravasations which are situated between the dura mater and the skull. The extravasations, which are formed in the substance of the brain itself, are not only more considerable, but also, as they mostly depend upon concussion, are more alarming, than effusions on the surface of the dura mater. It is indeed extremely difficult, if not impossible, to ascertain the situation of the extravasated fluid. In such cases, the trepan is like a noose; while concussion, when so violent as to produce internal extravasation, is invariably fatal. In extravasations between the dura mater and the skull, which are almost the only cases of the kind to which surgery can administer relief, when the effused fluid lies under a part of the skull accessible to the trepan, the extravasated fluid is almost always small in quantity. The danger, however, is not the less: ten or twelve drops of fluid are sometimes enough to produce a fatal compression. When the extravasation has happened in the substance of the brain, the compression is far more perilous; in short, it may be said to prove, with very few exceptions, certainly mortal. The danger is not so great, when the extravasation is situated between the skull and dura mater.

The lethargy, the degrees of which increase from mere drowsiness unto the most perfect coma, and the paralyses of the opposite side of the body to the seat of the extravasation, are the characteristic symptoms of this accident, in cases of injury of the head. Having explained elsewhere (see Head, Injuries of, Concussion, Extravasation, &c.) some other symptoms, such as floridous respiration, dilated pupils, &c. which usually indicate pressure on the brain, we need not here dwell upon them. The subsequent increase of the coma and paralytic affections, and the gradual augmentation of their intensity, serve to render these symptoms distinguishable from others, which are suddenly brought on by concussion. But there are instances, as every man of experience knows, in which the concussion ruptures the bloodvessels, and produces an extravasation of blood. In this circumstance, it is obvious that the symptoms of compression are blended with those of concussion. The symptoms, proceeding from the latter cause, always diminith in proportion to the time which has elapsed from the moment of the injury; while those of compression succeed, and, on the contrary, increase in intensity, in proportion as the quantity of extravasated fluid becomes more considerable. Notwithstanding these distinctions, however, it must be acknowledged that there are many cases, in which the surgeon is obliged to remain in doubt with regard to the particular cause of the symptoms. This indecision is the more embarrassing, because the operation of the trepan is necessary in cases of extravasation, but useless in those of concussion. Even when extravasation is known to exist, the practitioner requires more information; for he ought to know the precise situtation of the effused fluid. It is true, indeed, that paralysis of one side of the body indicates the prejudice to be upon the opposite hemisphere of the brain. But what surgeon would venture to follow the practice advised by Van Swieten, and apply to the affected side of the head three crowns of the trepan? Possibily not one of them might fall on the situation of the extravasated fluid. When the skull is broken, the extravasation exists on the same side as the fracture. When it is the effect of concussion, or when the breach of continuity in the skull is what is termed a counter-fracture, the effusion is generally on the side of the head most remote from the blow. If the pressure is caused by a detachment of the internal table of the skull, the nature of the case cannot be ascertained, before the operation of the trepan has been performed on the part of the skull upon which the violence has acted. When there are two extravasations; one depending upon a fracture, and situated immediately under it, between the dura mater and the skull; the other arising from concussion, and situated at some point directly opposite, either between the dura mater and tunica arachnoidea, or within the substance of the brain itself; paralysis may occur on the same side as the fracture; and hence it may be inferred, that the palsy does not always take place on the side opposite to the extravasation. But an examination of the body quickly proves, that the case does not deviate from the common rule. The extravasation produced by concussion, being almost invariably more considerable than that caused by a fracture, accounts for the extension of the palsy to the same side of the body. Sometimes the side which is not paralyzed is affected with convulsions, the pulse is full and hard, and the respiration floridous: in short, the symptoms are analogous to those caused by apoplexy.

The evacuating plan, recommended for the treatment of concussion, (see Concussion, and Head, Injuries of,) is all that can be done, when every thing is uncertain relative to the situation of the extravasation. It is all that can be done in those frequent instances, where the effusion has taken place in the substance of the brain, so that it cannot possibly be voided. The trepan then is indicated only when there is an extravasation between the dura mater and the bone, the fracture being situated in a part of the skull accessible to instruments, and not at the base. We will not here dwell upon the doubtful example, where the fluid lies between the dura mater and the arachnoidea. But are the cases, which we have just been describing, as frequent as they are supposed to be? Cannot the effused blood be generally discharged through the interstices of the broken pieces of bone? Is the trepan usually necessary for the relief of injuries of the head, as Quetelet, Pott, and the French Academy of Surgery maintained?—We think not.

The operation is often useless, and sometimes dangerous. We believe that it should be limited to a small number of cases. The exact determination of the cases in which it is absolutely indispensable, is one of the greatest delicacies in modern surgery.

Richerand contends, that extravasations between the skull and the dura mater, so considerable as to produce compression of the brain, and render the trepan necessary, are much less common than many surgeons think. Even when they do occur, the dura mater is always detached to a certain extent; and, according to this writer, if the bone is much broken, the interstices of the fragments are quite a sufficient for the evacuation of the effused fluid. The following case is quoted in proof of this observation. A woman injured her head, by falling from a height of fifteen feet. The fracture reached the whole breadth of the skull, so that when the os frontis was taken hold of with one hand, and the os occipitis with the other, the two halves of the cranium admitted of being manifestly moved and separated. Blood effused from the fissure, the edges of which were kept apart by a small wedge of wood, in such a manner that the pulsations of the brain were visible. On the sixth day, as nothing was discharged from the fissure, the bit of wood was removed; and on the fifty-second, the wound had completely healed without any exfoliation. On the seventy-second, the patient was discharged from the Hôtel-Dieu, perfectly.

Thus we see that the trepan is often unnecessary in injuries of the head, with fracture of the skull, notwithstanding the co-existence of an extravasation between the bone and the dura mater. This doctrine is very different from what is taught in the memoirs of M. Quefnavy, in the first volume of the French Academy of Surgery. Default, in the last years of his practice, abandoned the operation of the trepan altogether. It has been remarked for many years, that in the Hôtel-Dieu this operation has had very little success; a circumstance which has excited a suspicion, that the foul air of the wards of that establishment may have had a share in bringing on the unfavourable event. We shall not here expatiate on the bad effect of the atmospheric air on the membranes of the brain; a thing of which B. Bell seems to have convinced M. Richerand.

When the skull is fractured by a blow or fall, and the cafe is a simple siffure, the trepan ought to be applied upon the solution of continuity, if the symptoms indicate a dangerous degree of pressure on the brain, and the edges of the fracture are not sufficiently separated to let the extravasated fluid escape.

When the detached portions of bone are depressed, so as to comprefs the brain, the operation is still requisite, if they cannot be elevated by other means. But Richerand maintains, that a positive indication for trepanning is not frequent, either because it is difficult to judge of the existence and situation of extravasations, or because extravasated fluids readily escape through the interspaces of the fragments, when there is asplintered fracture. Such facility is also increased, when one of the portions of broken bone is totally detached, so that it can be removed, leaving an aperture equivalent to what would be produced by the application of the trepan.

When the indications render it necessary, there is no point of the external surface of the cranium to which the trepan, or trephine, may not be applied. The region of the frontal spine and sinuses, however, and the situation of the spines and inequalities of the occiput, the lower part of the squamous portion of the temporal bone, and the track of the meningeal artery running under the anterior inferior angle of the parietal bone, are places to which the instrument ought never to be applied without urgent necessity. The surgeon may trepan upon the futures, and over the sinuses of the dura mater, with perfect safety. A wound of the longitudinal sinuses has not only been found to be free from danger, but actually beneficial, by the evacuation of blood that has followed. The experience of Pott, Callifen, &c. confirms this fact; and they have even purposely opened the vessel with a lancet. Callifen, Syll. Chr. Hodin learn. tom. i. p. 659. edit. 1798.

The manner in which the two tables of the skull recede from each other at the frontal sinuses, would make the operation difficult. Besides, here the spine of the os frontis projects inward, so that the whole of the bone could not be fawn through, without the dura mater being lacerated. In an urgent cafe, however, the surgeon might trepan exactly on the frontal sinuses, by removing the outer table of that cavity with a large trephine, and applying a small one to the inner table. Perhaps also, in these pressing examples, it would be proper to trepan on the centre of the os frontis, and use a chisel for breaking the inner spine of that part of the bone. In the same way, although a surgeon would always prefer avoiding the meningeal artery, he ought not, in urgent cafes, to be afraid of it. The belt modern surgeons well know that the hemorrhage from that vessel is capable of being easily suppressed, by the introduction of a small plug into its orifice.

The practitioner can never be too careful not to place the trepan on a fofe part of the fractured bone, as it would be apt to be pressed inward, fo as to do mischief to the brain.

When the cranium has been perforated with the trepan, and nothing is found between the skull and the dura mater, or underneath this membrane, in the situation where an extravasation may be supposed to exist, additional perforations are to be made elsewhere, if the symptoms should indicate such practice. The repetition of the trepan is particularly requisite in cafes where the fissure runs across a future. The intinite adhesion of the dura mater to the future, explains why this membrane often continues undetached in that situation, while on each side it is separated from the bone, and blood effused upon it. There are then two different extravasations, and two perforations of the bone are absolutely necessary for the discharge of the blood.

Foreign surgeons invariably prefer, for the accomplishment of the operation, an instrument called the trepan, which much resembles a wobble, a tool extensively employed by coopers, and, like it, consists of a handle, to which is adapted a circular faw, or, as it is termed, the crown of the trepan. The diameter of the crowns varies from fix to ten lines, and they are about one inch in height.

In England, the trepan (Plate VIII. Surgery) has gone into disuse, the trephine being generally preferred, though perhaps without great reason. The trephine differs from the trepan in having its crown fixed upon and worked with a common tranfverfe handle, instead of being turned with a handle like that of a wobble. On the continent it is objected, that the trephine which the English surgeons make use of, requires a stronger hand and greater pressure than the trepan, fo that at the moment of finishing the division of the bone, one runs a risk of forcing the instrument too deeply, and lacerating the brain and its membranes. We must confess, however, that we have never seen this accident occur, and the trephine is now made in fo excellent a manner, that it will cut the bone fast enough without any occasion for immediate pressure. If some badly made trephines cut with too much difficulty, the trepan may be accused of dividing the bone with too much celerity. A man of ordinary skill may use either instrument, and an awkward practitioner will be apt to do mischief let him employ which he will. See Trephine.

The first object in the performance of trepanning, is to expose the exact part of the bone on which it is intended to apply the instrument. In some cases, the scalp is so torn and injured, that a sufficient extent of the skull is already uncovered, and it is unnecessary to employ a scalpels. But in the majority of instances, the use of the knife must precede that of the saw. Incisions of a crucial form, or shaped like the letter T or V, are found to be most eligible, because they allow their edges to be brought together again with ease, and they enable the surgeon to denude a larger surface of bone than could be managed with an incision of a different figure, but of equal size. The old surgeons ignorantly made circular wounds, and without consideration cut large portions of the scalp away before they applied the trepan. The consequence was, that the patient was fure of being permanently disfigured, and the edges of the perforation, remaining for a long while uncovered, frequently exfoliated.

The generality of surgical authors next advise us to be careful to scrape away the pericranium from the part to which the trepan, or trephine, is to be applied, so as to let the saw act with more facility. We have never found this proceeding
proceeding necessary, and conceive that, as more of the pericranium must always be removed than what is absolutely intended, it may sometimes be the cause of exfoliations. We advise, therefore, to be rejected, as well as the old plan of scraping the periosteum off the bones which are to be sawn in amputations. The ruggine, which is kept in most cases of trephining instruments for the purpose of scraping off the pericranium, would be no real loss if omitted.

Now, on first beginning to work either with the trephine or trepan, the practitioner would find that it would flip about and not steadily divide the bone, were it not for a particular contrivance. This is the centre-pin, which admits of being pushed down a little below the level of the teeth, and being very sharply pointed, immediately fixes itself in the mid-point of the circle of bone which is to be removed. As soon, however, as the teeth of the trephine have made a sufficient furrow, the centre-pin should be withdrawn, as it would otherwise wound the dura mater before the sawing of the bone were completed.

In making the incision through the scalp, when there is a fracture, the knife must be used with some degree of caution, lest it should depress the fragments of bone against the cerebrum, or be carried too deep, so as to injure the dura mater. In certain instances, it will be advisable to make the requisite incision with a director and curved bifurcous.

The trephine is worked by being rotated backward and forward; the trepan is turned round continually in one direction. In trepanning upon a simple fracture, or fissure, the crown of the instrument should be so placed as to include an equal portion of the bone on each side. But when there are portions of bone depressed and moveable, it is customary to apply the trepan upon an adjacent solid part of the cranium, which will serve after the operation as a fulcrum for the elevation or extraction of the depressed fragments. We must observe, however, that this method, if practiced indiscriminately, will often lead to an unnecessary removal of bone; a circumstance which it is always devisive to avoid. Loose depressed pieces of bone should constantly be taken away with a pair of forceps, whenever it can be done; and then no trepanning will be needed. Alto, when the fracture is shaped somewhat like the letter V, or when it is of an oblong form, the depressed piece of bone may frequently be entirely removed by sawing through the part which connects it with the rest of the cranium, and no circle of bone will stand in need of being sawn out. For the performance of such operation, Mr. Hey's saws (represented in the surgical plates) will be found exceedingly advantageous.

The surgeon should not press too heavily with the trephine, or trepan, when he is in the act of sawing the bone; but execute the busines with as light a hand as possible. As soon as a sufficient groove is formed for the teeth of the crown, the centre-pin is to be taken out. The first part of the sawing may be done briskly. Afterwards, the operation is to proceed slowly and cautiously. With a bit of quill, the surgeon must examine the depth of the circular groove, in order to be sure that he has not sawn through at any particular point. When one side seems to be more cut than another, the saw must not be allowed to act upon it so much; and if there be any part of the circle which is completely sawn through, the instrument must not be applied to that point any longer. While the surgeon examines the depth of the groove with a piece of quill, an affulent takes care to clean the teeth of the saw with a small brush made for the purpose, by which means the motion of the instrument will not be obstructed by the particles of bone.

When the bone become tinged with blood, the teeth of the saw are known to have reached the diploe; but the practitioner must remember, that the diploe is not a criterion which will be met with in every instance, as in some subjets it is so inconsiderable, that it does not give any tinge of blood to the bone-dust. It is of importance to be aware of this fact; for were a surgeon to saw boldly on in all cases until he sees marks of his having arrived at the diploe, he would frequently be apt to injure the dura mater and brain. When he knows that he is sawing the internal table, he is to proceed with great flowness and circumspection, making repeated examinations of the groove with the pointed quill. When the portion of bone to be taken out appears to be connected with the rest of the skull principally on one side of the groove, the trephine is to be inclined to that side. Immediately the circle is loose enough, it is to be taken out with a pair of forceps constructed for this object, or with the elevator. (See surgical plates.) But rather than run a hazard of sawing too deeply with the trephine, we would always recommend the surgeon to prefer breaking the few last fibres of bone which impede the circle from being taken out.

When there are any inequalities round the margin of the perforation, they must be carefully removed by means of the lenticular knife. (See plates.) In doing this part of the operation, care must be taken not to let the lenticular knife make improper pressure upon the dura mater, a thing which might have the worst consequences.

The circle of bone having been fawn out, the surgeon is to keep in mind the grand object of the operation; viz. that of relieving the brain from the pressure, which is the cause of the alarming symptoms. All depressed fragments of bone are to be raised, and, if quite detached, they ought to be entirely removed. All fculi of bone, penetrating the dura mater and substance of the brain, are to be extracted without delay. If there be blood or matter upon the surface of the dura mater, it now escapes, being expelled by the pulvatory movement of the cerebrum.

When the extravasation is under the dura mater, a puncture may be cautiously made through this membrane with the point of a bifurcous, or lancet. There must be, however, a manifest elevation and tension of the dura mater, arising from the lodgment of a fluid below it, to justify the preceding practice. If blood should be found in the suspected situation, the puncture may be enlarged into a crucial incision.

According to surgical writers, if, after dividing the dura mater, the surface of the brain appears smooth and fabby, with a fluctuation, there is an abieces in its substance. They then function the method of carrying the point of the bifurcous to the depth of an inch, if circumstances render so deep a puncture necessary. But, says Richerand, prudence forbids us to go further. Cutting the surface of the brain causes no pain, and it produces less danger than one could presume to expect; but experience and observation have proved, that the essential parts of this organ are situated in its base, and that its surface may be removed without danger or pain. Nofgr. Chir. t. ii. p. 301. edit. 3.

After the operation of trephining, the divided scalp is to be placed as nearly as possible in its natural situation, and lightly dressed with a simple pledge of any common unirritating ointment. In applying the dressings, the surgeon should invariably keep in view these objects; namely, to let whatever is put on the wound be as light as possible, not apt to make pressure on the brain, and of a nature which cannot excite irritation. All stimulants are to be strictly avoided; nor will any bandage be better than an ordinary
TRE

TRE

ordinary night-cap of sufficient size to be put on with facility. It may be secured with bits of tape, which are to be tied under the jaw.

The aperture in the skull usually becomes closed with soft granulations, which slowly acquire a hard consistence. These almost constantly grow from the edge of the perforation, and seldom from the surface of the dura mater. While the cicatrix is soft, it should be protected from external injury with a thin piece of horn or metal. Exfoliations from the margin of the perforation sometimes retard the healing of the wound; but now that the practice of dressing with drying spirituous applications has been exploded, and the removal of any part of the scalp is condemned by all the best surgeons, these unpleasant consequences are rendered much less frequent than in former days.

Trepanning, in Sheep, the operation of extracting the bags or cysts that contain a watery fluid from the heads of these animals, which are the cause of disease. See Sturdy.

TREPHINE, in Surgery. The operation of trepanning is now frequently called the operation of trephining, from its being generally performed in this country with a trephine, which is a more modern instrument than the trepan.

The trephine consists of a simple cylindrical saw, with a handle placed transversely, like that of a gimlet; and from the centre of the circle, which the teeth of the faw describe, a sharp little perforator projects, named the centre-pin.

The upper part of the centre-pin is made to screw into a corresponding hole at the side of the top of the faw, and is capable of being taken out or put in at the surgeon's option, by means of a little key for the purpose. Its use is to fix and steady the trephine, when the instrument first begins to work, that is, before the teeth of the faw have made a sufficient circular groove, in which they can securely move. But as soon as an adequate groove is formed, the centre-pin must always be taken out; because it is now unnecessary, and, if not removed, it would not only retard the progress of the operation, but inevitably penetrate the dura mater and brain, when the teeth of the faw had cut to a certain depth into the cranium. Some trephines contain centre-pins, which are contrived to slide up or down, and to admit of being fixed in either situation, by turning a little screw. This method leads to us both ingenious and convenient.

The cylindrical part of the trephine is often termed the egnon of the instrument. The surgeon should always have at least two or three cylindrical faws of various sizes; for it is a commendable rule never to faw away any more of the cranium, or indeed of any other bone, than is absolutely requisite for the accomplishment of some assignable object. There is no occasion, however, for having more than one handle, which may be made to fit any of the faws.

The trepan is worked in the manner of a wimple, the instrument turning round and round upon its own axis; but the trephine only performs semicircular movements, which the surgeon imparts to it by the pronation and supination of his hand. As its teeth are arranged perpendicularly, they cut whether the instrument is turned from the left to the right, or from the right to the left.

Certainly caves do frequently present themselves, in which trepanning is absolutely necessary; and yet there is no occasion for removing a complete circular portion of the cranium; the taking away of a piece of smaller size, and different shape, would sometimes be much more advantageous. A very good instrument for effecting this purpose is a common trephine, terminating only in a semicircular saw, instead of a circular one. With this the surgeon can cut across the base of certain depressed portions of bone, and take them away, without any occasion for removing also a circle of the cranium.

The faws, however, which Mr. Hey has described, should constantly be kept in every case of trephining instruments. This practical writer remarks, that 'the purposes for which any portion of the cranium is removed, are, to enable the surgeon to extract broken fragments of bone, to elevate what is depressed, and to afford a proper site to blood or matter that is, or may be confined, &c.'

"When a broken fragment of bone is driven beneath the found contiguous part of the cranium, it frequently happens that the extraction cannot be executed without removing some of the unbroken part under which the fragment is depressed. This might generally be effected with very little loss of sound bone, if a narrow portion of that which lies over the broken fragment could be removed. But such a portion cannot be removed by the trephine. This instrument can only saw out a circular piece. And as, in executing this, the central pin of the saw must be placed upon the uninjured bone, it is evident that a portion of the sound bone, greater than half the area of the trephine, must be removed at every operation. When the broken and depressed fragment is large, a repeated application of the trephine is often necessary, and a great destruction of sound bone must be the consequence.

"When the injury consists merely of a fissure with depression, a small enlargement of the fissure would enable the surgeon to introduce the point of the elevator, so as to raise the depressed bone. But a small enlargement of the fissure cannot be made with the trephine. When it is necessary to apply the elevator to different parts of the depressed bone, a great deal of the found cranium must be removed, where a very narrow aperture would have been sufficient.

"The same reasoning will apply to the case of openings made for the purpose of giving a discharge to extravasated blood or matter.

"If a faw could be contrived, which might be worked with safety in a straight, or gently curvilinear, direction, it would be a great acquisition to the practical surgeon. Such a faw I can now with confidence recommend, after a trial of twenty years, during which time I have rarely used the trephine in fractures of the skull. Its use has been adopted by my colleagues at the General Infirmary in Leeds; and will be adopted, I hope, by every surgeon who has once made trial of it." Mr. Hey next informs us, that the instrument was first shown to him by Dr. Cockell of Pontefract; but that there is a faw, formed on the same principle, in Scullettus's Armamentarium Chirurgicum. The saw alluded to are very short ones, fixed at the end of a long straight handle; their edges are made either straight, or semicircular. The latter construction qualifies the instrument for cutting in a curvilinear direction, which is often proper. The edge of the saw should always be made a little thinner than the rest of the blade, by which means it will work in the groove, which is cut, with more facility.

Saws made on the principle just described, are also of infinite use in cutting away diseased portions of other bones, besides the skull, exostoses, &c. In cases of necrosis, when a dead part of a bone is quite wedged in the substance of the surrounding new bony matter, Mr. Hey's faws may often be advantageously employed for cutting away the parts which mechanically prevent the detachment of the dead

TREPIDATION, in Medicine. See Palsy.

The first symptom of madness in dogs, is a trepidation of the limbs.

TREPIDATION, in Ancient Astronomy, denotes what they called a libration of the eighth sphere; or a motion which the Ptolemaic sytem attributed to the firmament, to account for certain almost inffolent changes and motions observed in the axis of the world; by means of which the latitudes of the fixed stars come to be gradually changed, and the ecliptic seems to approach reciprocally, first towards one pole, then towards the other.

This motion is also called the motion of the first libration.

TREPIGNER, in the Mange, the action of a horse who beats the dust with his fore-feet in mangering, without embracing the volt; and who makes his motions and times short, and near the ground, without being put upon his haunches. This is generally the fault of such horses as have not their shoulders supple, and at liberty, and withal have carelessly any motion with them. A horse may trepigner in going upon a straight line.

REPORT, La, a sea-port town of France, in the department of the Lower Seine, situated on the English Channel, at the mouth of the Brefle. This place is the harbour for the town of Eu; from which it is distant about half a league. N. lat. 50° 14'. E. long. 1° 26'.

TREPT le Grand, a town of France, in the department of the Hier; 21 miles E. of Lyons.

TREPTOW, a town of Anterior Pomerania; 50 miles S. of Stralsund. N. lat. 53° 39'. E. long. 13° 10'.

TREPTOW am Rega, or New Treptow, a town of Hinder Pomerania, on the river Rega, which is here made navigable; 16 miles N.E. of Cammin. N. lat. 54° 2'. E. long. 15° 13'.

TREPUZZI, a town of Naples, in the province of Otranto; 22 miles W.N.W. of Liece.

TREO, a river of the Popedom, in the Campagna di Roma, which runs into the Garigliano, near Isolotta.

TERRUS, in Ancient Geography, a country in the environs of Macedonia, in Pieria and Dardania. Phiny.—Alfo, a river of Italy, in Aulonia, which, according to Strabo, watered the town of Fabrateria, situated in Latium.

TRES HERMANOS, in Geography, three small islands in the bay of Honduras, near the coast. N. lat. 10° 20'. W. long. 88° 50'.

TRES Taberna, Three Taverns, in Ancient Geography, a place of Italy, near the Appian way. Zohmsius says that it was the place where the emperor Severus was put to death by Maxentius. The Itin. of Anton. marks its situation in the Appian way, between Aricia and Appii Forum.

TRESA, a river of the northern part of Italy, which ran among the Leptantii, into the lake Verbanus.

TRESANTIT, in Geography, a town of Naples, in Capitanata; 13 miles S. of Manfredonia.

TRESANTON, in Ancient Geography, a river of Albion, probably the river Telch, which falls into Southampton bay.

TRESAYLE, in Law, the name of a writ (now obsolete) to be sued, on ouster, by abatement, on the death of the grandfather's grandfather.

TRESBES, in Geography, a town of France, in the department of the Aude, near the Aude river; 3 miles E. of Carcassonne. N. lat. 43° 13'. E. long. 2° 52'.

TRESCHEN, a town of Germany, in the principality of Culmbach; 4 miles S.S.E. of Culmbach.

TRESCO, or St. Nicholas, one of the Scilly islands. N. lat. 50°. W. long. 6° 45'.

TRESHANISH ISLANDS, a range of four small islands among the Weblen islands of Scotland, between Mull and Coll. They lie in a line, nearly from north to south. They are small, but the soil is generally fertile. N. lat. 56° 30'. E. long. 6° 25'.

TRESNEL, a town of France, in the department of the Aube; 3 miles from Pont-Fur-Seine.—Alfo, a town of France, in the department of the Sarthe; 7 miles W. of St. Calais.

TRESPASS, in Law, signifies any transgression of the law, under treason, felony, or misprision of either.

TRESPASS, however, is most commonly used either for that wrong or damage which is done to the king in his forest, or by one private man to another.

In this sense, it is of two sorts: trespass general, otherwise called trespass vi et armis, where force or violence is used; to which belong threats, affault, battery, mayhem, &c.; and trespass special, otherwise called trespass upon the common; which should be that done without force, or where the injury is only consequential. See Action on the case.

But the two species are sometimes confounded.

Trespass on lands denotes an uttery on another man's ground without lawful authority, and doing some damage, however inconsiderable, to his real property. Every such unwarrantable entry on another's soil, the law entitles a trespass by breaking his close. But in order to be able to maintain an action of trespass, a man must have property in the soil, and actual possession by entry; or at least it is requisite that the party have a leave and possession of the vextare and herbage of the land. But before entry and actual possession, one cannot maintain an action of trespass, though he hath the freehold in law. However, by 4 Geo. II. c. 28. and 11 Geo. II. c. 19. in case after the determination of any term of life, lives, or years, any person shall wilfully hold over the same, the lessor is entitled to recover by action of debt, either a rent or double the annual value of the premises, in case he himself hath demanded and given notice in writing to deliver the possession; or: else double the usual rent, in case the notice of quitting proceeds from any tenant having power to determine his lease, and he afterwards neglects to carry it into due execution.

A man is answerable not only for his own trespass, but that of his cattle also. See Damage of cattle.

In some cases trespass is justifiable; or, rather, entry on another man's land and house shall not in those cases be accounted trespass; as if a man comes there to demand or pay money, there payable; or to execute, in a legal manner, the process of the law. A man may also justify entering into an inn or public-house, without the leave of the owner: a landlord may justify entering to disfrain for rent: a comonomer to attend his cattle, commoning on another's land; and a reviver to fee if any waife be committed on the estate. It hath also been said, that by the common law and custom of England, the poor are allowed to enter and glean upon another's ground after the harvest, without being guilty of trespass; which humane provision feems borrowed from the Mofialic law, Lev. chap. xiv. ver. 9. chap. xxiii. ver. 22. Dent. chap. xxiv. ver. 19. In like manner, the common law warrants the hunting of ravenous beasts of prey, as badgers and foxes, in another man's land. But in cases where a man makes an ill use of the authority with which the law entruits him, he shall be accounted a trespasser ab initio; as if one comes into a tavern and will not go out in reasonable
TRE

reasonable time; so if a landlord detained for rent, and
willfully killed the diffrets, this made him a trespasser ab
initio; and so would any other irregularity have done, till
the statute 11 Geo. II. c. 19, which enacts that no subse-
quently irregularity of the landlord shall make his first entry a
trespass; but the party injured shall have a special action
on the case for the real specific injury sustained, unless
tender of amends hath been made. But still, if a rever-
sioner, who enters on pretence of feering waeke, breaks
the house, or flays there all night; or if the commoner, who
tends his cattle, cuts down a tree; in these and similar cases the
law judges that he entered for this unlawful purpose; and
therefore, as the act which demonstrates such his purpose is
trespass, he shall be deemed a trespasser ab initio. So also
in the case of hunting the fox or the badger, a man cannot
justly break the soil, and digging him out of his earth.

A man may justify an action of trespass, on account of
the freehold and right of entry being in himself; and this
defence brings the title of the estate in question.—And this
is one of the ways devised, since the diflufe of real actions, to
try the property of estates: though not so usual as that by
ejecution, which being a mixed action, gives damages for
the ejection, and possession of the land; whereas in trespass,
which is a personal suit, the right can be only ascertained,
but no possession delivered; nothing being recovered but
damages for the wrong committed.

In an action of trespass, the plaintiff always sues for
damages, or the value of the hurt done him by the
defendant.

In order to prevent trifling and vexatious actions of
trespass, as well as other personal actions, it is (inter aha)
enacted by statutes 43 Eliz. c. 6. and 21 Jac. I. c. 16.
and 22 & 23 Car. II. c. 9. that where the jury who try an
action of trespass gives less damages than 40s. the plaintiff
shall be allowed no more costs than damages; unless the
judge shall certify under his hand, that the freehold or title
of the land came chiefly in question, or that an actual bat-
tery, and not assault only, was proved. And by statute
4 & 5 W. & M. c. 25. and 8 & 9 W. III. c. 11. if the
trespassers were committed in hunting or sporting by an
inferior tradesman, or if it appear to be willfully and malici-
siously committed, the plaintiff shall have full costs, though
his damages, as asfessed by the jury, amount to less than 40s.
Blackst. Comm. vol. iii.

Trespass is also divided into local and transitory.
Trespass, Local, is that which is so annexed to the place
certain, that if the defendant join issue upon a place, and
traverser the place mentioned in the declaration, and aver it,
it is enough to defeat the action.

Trespass, Transitory, is that which cannot be defeated
by the defendant’s traversal of the place, because the place is
not material.

The action of trespass, quaer clamium fregit, ought to be
local.

Tressel of Trestle-Trees, in a Ship, two strong
bars of oak-timber refting on the cheeks of lower-masts, or
hounds of top-masts. To lower-masts they are secured by
being secured and bolted horizontally on the opposite sides
of the mast, fore and aft, and further supported by two bobs
or brackets, as shoulders under them. Topmast treifle-
trees are supported by the hounds only. See Mast-
Making.

Tressness, in Geography, a cape on the south
coast of the island of Sanday. N. lat. 59° 5'. W. long.
2° 25'.

Tresson, a town of France, in the department of the
Sarthe; 15 miles S.E. of Le Mans.

Tressure, in Heraldry, a diminutive of an orie,
usually supposed to be half the breadth of it.

It is usually horse flory and counter-flory; sometimes
double, and sometimes triple.

Trestiana, in Geography, a town of European
Turkey, in Moldavia; 24 miles S.E. of Jassy.

Trestle, Tresesel, or Trest, in Commerce, an allowance made
for the wale, or the duff, that may be mixed with any com-
modity, which is always four pounds in every 104 pounds
weight. See Tar.

This allowance, which is said to be for a tile or a land,
or for the wale or wear of the commodity, was formerly
made on most foreign articles sold by the pound averdoneus; but
it is now nearly discontinued by merchants, or allowed in
the price. It is wholly abolished at the East India ware-
houses in London; and neither trett nor draft is allowed at the
Custom-house. The weight which trett is allowed is
called the “tullie weight.”

Treta, in Ancient Geography, a town of the island of
Cyprus, in the S.W. part of the island, very near Pae-
Paphos, to the S. Strabo places it between Boeisura and the
promontory from which those who were precipitated who
touch the altar of Apollo.

Trete, an island of the Red sea, upon the coast of
Arabia. Ptolemy.

Trets, in Geography, a town of France, in the de-
partment of the Mouns of the Rhone; 12 miles E.S.E. of
Aix.

Tretum, in Ancient Geography, a small town of the
Argolidhe, nearly N. of Argos. In the mountains near
this town was a cavern, which was the abode of a very fierce
lion, which is said to have been slain by Hercules, and
which formed among the poets one of his labours. It was
called the lion of the forest of Nemea, situated near the
town, to the W. of it.

Tretum, or Tritum, a promontory of Africa propria,
on the coast of the gulf of Numidia.

Tretur, in Geography, a small village of South
Wales, in the county of Brecknock; 3 miles N.W. of
Crickhowel.

Trevia, in Ancient Geography, a town in the northern
part of Germany. Ptolemy.—Also, a town of Italy,
in Flaminia, watered by the river Clytumnus.

Trevannion’s Island, in Geography, an island in
the Southern Pacific ocean, and one of the cluster called Queen
Charlotte’s islands, discovered by captain Carteret in 1767,
near the coast of Egmont island, or New Guernsey, in a bay
called Trevannion’s Lagoon. S. lat. 10° 43’. E. long.
163° 43’.

Treucltlingen, a town of Germany, in the
margravey of Anspach, on the Altmuhl; 28 miles S.S.E.
of Anspach.

Treuken, or Dreyen, a town of Saxon, in the
Vogtland; 9 miles E.N.E. of Plauen.

Treuenbrietzen, a town of the Middle Mark of
Brandenburg. This town was surrounded with walls in
the year 1296. It was at first simply called Brixen, but
for its fidelity to the margrave Louis the Roman, was ho-
noured
noted with the epithet of Trucen, or faithful. In the year 1641, this town was laid waste by the Swedes; 20 miles S. of Brandenburg. N. lat. 52° 8'; E. long. 12° 47'.

TREVENN'S ISLAND, or Roopöat, a small island in the Pacific ocean, discovered by lieutenant Herget, in the Dádusse shore-ship, in 1792. S. lat. 9° 4'. E. long. 22° 21'.

TREVIRI, or TREVIRI, in Ancient Geography, a people who occupied an extensive territory of Germany, from the Meuse to the Rhine. Of Treveri Caesar says, "haec civitas Rheum tangit;' and the bridge constructed over the Rhine secures the bank on which this city was situated. The present Treves answers to the ancient position of Treveri. See Treves.

TREVES, in Geography, lately an archbishops and elector of Cologne; on the W. by the eflates of the electors palatine, and of the house of Nassau; on the S. by France; and on the W. by the duchy of Luxembourg: about eighty miles in length, but of very uncertain breadth. The country is in general mountainous and woody, containing, indeed, good pasturage for cattle, and in many places also fruitful arable land, but yet stands in need of the importation of corn; on the contrary, the growth of wine on the Mosel is very considerable, with plenty of game. There are likewise mineral springs, and mines of coal, calamine, iron, copper, lead, tin, silver, and gold. The electoral subjects are Roman Catholics, but in some other places which the elector of Treves is privileged of in common with other houses, there are like wise Protestants. The ancient Téviri, from whom the principal town here, and the country also, had its name, were, till the fourth century, subject to the Romans, and afterwards to the Franks. In the divisions which the sons and posterity of the emperor Louis I. had made, this country was added, in the year 855, to the kingdom of Lorraine, and in 870, fell to the house of Louis, the German king, ever since which time it has continued annexed to Germany. The church of Treves, however, is held to be the most ancient in Germany. An archibishop of Treves was elected by the chapter there, and swore to a capitulation proposed by them. The pope confirmed such election in the usual manner, empowering one of the new elected bishops, allotted for that purpose, to consecrate him. The archbishop of Treves was in rank the second spiritual elector. At the election of an emperor, he delivered the formula of the election-oath to the elector of Mentz, to be sworn to by him; and he had also the first voice. As elector, the archbishop of Treves enjoyed both seat and voice in the electoral council at the diets of the empire. The suffragans of the archbishop of Treves were the bishops of Metz, Toul, and Verdun. The chapter of Treves consisted of forty canons, among whom were sixteen capitulars, and twenty-four domicii. The archbishops had regular troops, and a land militia. The former of these consisted, in times of peace and ordinarily, only of the circle troops, which the elector of Treves was bound to maintain, and which amounted to between 1100 and 1200 men. The elector also kept up a life-guard of forty persons. By the treaty of Luneburg, the archbishopric and the electorate are no more: and that part of the territories which lay on the left bank of the Rhine is annexed to France, composing chiefly the department of the Sarre. The principal part of the electorate lying on the right side of the Rhine was, in 1802, given as an indemnity to the prince of Nassau-Weilburg.

TREVI, a town of Italy, in the duchy of Spoleto, anciently called Mutiae and afterwards Trebula; 6 miles N. of Spoleto. — Alfo, a town of the Popedom, in the Campagna di Roma; anciently the see of a bishop, erected about the year 1000, but in the year 1260 united to Anagni; 32 miles E. of Rome.

TREVICO, a town of Naples, in Principato Ultra; the see of a bishop, suffragan of Benevento; 14 miles N. of Conza. N. lat. 41° 6'. E. long. 15° 14'.

TREVIERES, a town of France, in the department of the Calvados; 12 miles E. of Carentan.

TREVIGIO, or TREVISIO, a city of Italy, capital of the Trevisian, situated at the confluence of the Sile and the Piave; the see of a bishop, suffragan of Udine. An university was founded here, and afterwards removed to Padua. The town is three miles in circumference, and contains 2500 houses and 22,000 inhabitants; whom the culture of silk, the silk and woollen manufacturies, and particularly the annual fair in the month of October, supply with abundant means of subsistence. Besides the cathedral, the town contains 16 parochial churches, 11 monasteries, 10 nunneries, 4 hospitals, and a pawn-bank. The streets and public squares are in general
TREW, Christopher James, in Biography, a physician and naturalist, was born at Lauffen, in Franconia, in 1695, and settled at Nuremberg, where he gained medical and literary reputation, so as to be made director of the academy "Nature's Curiatorium." He also contributed much towards establishing a society under the title of "Commercum Literarium Nomicum ad Rei Medicæ et Scientiarum Incrementum institutum," which published its memoirs. To these societies he communicated several papers, and he also published several splendid works in anatomy and botany. Among others, we may enumerate the following: "De Differentiis quibusdam inter Hominem natum et natuendo intercedentibus," 1736, 4to.; "Epitola ad Alb. Hallerum de Vitis Lingue salivalibus et fanguiferis," 1734, 4to.; "Tabulae Osteologice Corporis Humani," fol. max. with coloured plates, 1767. In 1750 he commenced his publication of one of the most splendid of the imitations of Flora, under the title of "Planta Selecæ, quorum Imagines pinxit G. Dionysius Ehret." To the incomparable designs of Ehret, Trew added descriptions and remarks; and the work appeared in decades, few of which were completed. In the same year he began a similar publication of garden flowers, intitled "Amoenissirne Florum Imagines," which was carried on to six decades. He also published an improved edition of Blackwell's Herbal, in English and German, with an addition of some plants. Being in possession of Gnefner's wooden plates, he gave an impression of 216 figures of plants from them, intitled "Icones posthumae Gnerferiana," 1748. Trew died in 1769. Haller. Eloy.

TREWARDRETH BAY, in Geography, a bay in the English Channel, on the south coast of Cornwall; 3 miles W. of Fowey, N. lat. 50° 18'. W. long. 4° 42'.

TREWIA, in Bokany, was so named by Linneaus, at the end of his Genera Plantarum, in honour of Christopher James Trew, an opulent physician at Nuremberg, who has distinguished himself as the editor of some of Ehret's figures, in the most splendid style, with learned descriptions and explanations of his own, under the title of Planta Selecæ. Of a similar character are his Florum Imagines, in six decades. His improved edition of Mrs. Blackwell's Herbal, in German, with valuable additions, has proved acceptable to his countrymen; as have his numerous botanical and physiological essays, published chiefly in the Commercum Literarium at Nuremberg, between the years 1730 and 1746, to the scientific world in general. He is charged by Ludwig, in a letter to Haller, with undertaking more than he could accomplish; nor does he stand in the highest rank of correct and philosophical botanists. He died in 1769, aged 74. (See Trew.—) Linn. Gen. 580. Schreb. 354. Wild. Sp. Pl. v. 4. 834. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 466. Jull. 442. Lamarck Illustr. t. 466. (Tetragastris; Gerinl. p. 109. Rottlera; Willd. in the Goettingen Journ. of Nat. Hist. v. 1. 8. Mallotus; Loureir. Cochinch. v. 2. 635.)—

Female, Cal. Perianth inferior, of one leaf in three or four segments. Cor. none. Fil. Germin superior, roundish; style short; stigmas three, very long, feathery on the upper side. Peric. Capsule turbinated, somewhat globular, of three or four lobes and as many cells, with twice as many valves. Seeds solitary, pendulous, angular on one side, convex on the other.

Eff. Ch. Male, Calyx of three leaves. Corolla none. C c

Female,

Obi. We believe the several genera, cited above, are here very properly united; see Mallotus and Tetragastris. The natural number in every part of the female fructification is probably three, though varying to four in the original species. Linnaeus was but ill acquainted with this genus, nor does it appear that he ever examined a specimen.

1. T. nudiflora. Smooth-leaved Trevia. Linn. Sp. Pl. 1661. Willd. n. 1. Ait. n. 1. (Rottleri indica; Willd. as above t. 3, Canchi; Rheede Hort. Malab. v. 1. t. 76. t. 42.)—Leaves ovate, undivided, entire, smooth on both sides.—Native of the East Indies, in sandy ground. It has been introduced into the faves at Kew, but has never yet flowered. This is a tall tree, whose trunk is two or three feet in diameter; its branches numerous, round, smooth, with a filamentous bark. Leaves alternate, on long smooth stalks, broadly ovate, taper-pointed, three or four inches long, with three principal nerves, and many smaller ones, connected by fine transverse parallel veins, and numerous minute reticulations. Male flowers numerous, in axillary aggregate clusters, three or four inches long, greenish-white; sometimes, according to Rheede, four-cleft. Calyx externally downy, about two lines long. Female flowers on a separate tree, likewise axillary, but rarely more than two together, on a long stalk. Their calyx is either very small, or soon deciduous. Fem., not so large as a pepper-corn, hoary. Style about as long as the calyx, thick, hoary. Stigmas three or four, spreading, an inch long, densely covered along their upper side with feathery glands. Capsule rather depressed, slightly lobed, smoothish, of three or four cells.

2. T. tricuspidata. Three-pointed Trevia. Willd. n. 2. (Mallotus cochinchinensis; Loureir. Cochinch. 635.)—Leaves ovate, downy and toothed; generally three-pointed.—For the history of this species we refer the reader to Mallotus.

3. T. pubescens. Downy Trevia.—Leaves ovate, undivided, entire, downy on both sides. Female flowers somewhat capitate, with ovate pointed bracteas.—A female specimen of this was sent us by the late Dr. Roxburgh, as an unknown tree from Amboya. The shape and reticulations of the leaves, with the general habit of the plant, are so like the first species, that we feel confident of their being of the same genus. The branches and footstalks however, and the under side of the leaves, are densely clothed with soft velvety-like pubescence; the upper side of the latter is less downy. Near the base of each footstalk a pair of awl-shaped, very downy, deciduous stipules. Female flowers on simple, axillary, solitary, downy stalks, rather longer than the footstalks, composing small roundish heads, accompanied by four or five somewhat alternate, ovate, pointed, slightly toothed, downy bracteas, an inch long. Each flower appears to have a short partial flalk, which is very hairy, and the germen is no less briefly; inasmuch that we can but imperfectly develop the structure of the flower. The figmas however are large and conspicuous, exactly those of a Trevia; but there is some appearance of their being solitary. Possibly some may have fallen off. We are unacquainted with the male of this species.

4. T. difcolor. White-leaved Trevia.—Leaves ovate, entire; densely downy and white beneath. Communicated by Lamarck to the younger Linnaeus, along with several other plants from the East Indies, but without any name, or indication of its native country. We presume it to be the male of a nondefcript species of Trevia. The form and veins of the leaves strongly indicate this; but their under fide differs from that of the reft, in being covered with the finest depressed, mealy or scaly, snow-white pubescence; while the upper is very smooth to the touch, appearing minutely granulated under a magnifier only. The branches and all the flalks are finely hoary, and, in the dried specimem at leat, have a ruddy hue. Panicle terminal, composed of numerous, alternate, racemose, many-flowered branches. Unexpanded male flowers about the size of a mustard-feed, downy, on short partial flalks. It is evident we can have no certainty at present of the genus of this plant, but there is the greatest probability of its being rightly placed here.

TREYA, in Geography, a town of Denmark, in the duchy of Sleswick; 9 miles W. of Sleswick.

TREYSA, a town of Welfphalia, in the principality of Hesse. In the year 1646, this town was burned down by the Imperialists; 26 miles S. of Caffel. N. lat. 50° 54'. E. long. 9° 10'.

TRIA PRIMA, among Chemists, the three hypoftaltic principles, viz. falt, fulphur, and mercury; of which they hold all bodies to be primarily made, and into which they are all held refolvable by fire.

TRIAD, TRIAS, 7035. See TERNARY, TRIAS, and TRINITY.

TRIADICA, in Botany, from 703, 7030, ternary, alluding to the prevalence of the number three in the fructification; which however is not very remarkable. —Loureir. Cochinch. 610.—Clafs and order, Dioecia Diantria. Nat. Ord. Amenaceae, Linn. Jull.

1. T. cochinchinensis. Cây Soi tia, or Cây Cha dam, of the Cochchine. —Leaves ovate, obtuse.—Found in the woods of Cochchina. A large tree, with spreading branches. Leaves alternate, ovate, entire, smooth, on long red footstalks. Flowers nearly terminal. Berries small, of a brownish green.

2. T. lunifera. U Khu mo of the Chinefe. —Leaves roundish, pointed. —Wild about Canton in China. A large tree, with spreading branches. Leaves alternate, stalked, smooth, entire. Catkins, of the male as well as female flowers, four-cleft. Seeds tunicated. Of this last circumftance nothing is faid in the generic character. —We are not acquainted with any plants answering to the above defcription. Antidesma perhaps (see that article and Stilago) comes the nearest, especially when we contemplate the Stilago diandra of Roxburgh. If allowance be made for some occasional abortion in the cells of the fruit, or if we ourselves have misconceived Loureir's ambiguous defcription, "bcna tribulatiris, monosperma," Triadica may be no other than Antidesma.

Gen. Ch. Cal. a glume of two unequal, lanceolate, keeled,
TRI

keeled, pointed, membranous valves, containing one floret; the outer valve full half the size of the inner, with a rough dorsoal awn, about its own length, united to it half way up. Car. of two unequal, lanceolate, keeled, pointed, membranous valves; the outermost largest, three-ribbed, awnless; innermost narrower, with two keels, and a dorsoal awn, twice its own length, of three equal points, and a common stalk the length of the glume, slightly connected therewith at the base only. Stam. Filaments three, capillary, shorter than the glumes; anthers hanging out of the flower, linear, notched at each end. Pif. German superior, ovate; styles two, thread-shaped, short; stigmas oblong, feathery. Peric. none, except the unconnected corolla. Seed one, ovate.

Eff. Ch. Calyx single-flowered, of two valves, with a dorsoal awn. Corolla of two valves, unconnected with the feed, and a dorsoal awn of three points.

1. T. racemosa. Cluster-flowered Trident-grafs. Kunit as above, 179. t. 61.—Gathered by Humboldt and Bonpland, in dry cultivated ground in Mexico, between Guanaxuato and Villapalido, flowering in September. This is an annual, upright, branching grafs, about eighteen inches high, with a round, smooth, slender, jointed stem. Leaves linear, narrow, sheathing, flat, frilled, rough on both sides, and somewhat hairy on the inner: their sheaths frilled, smooth. Stipula very short, fringed. Clusters terminal, solitary, simple, erect, from one and half to four inches long. Flowers alternate, two-ranked, on short, slender flanks.—We have presumed to alter the original description, chiefly with respect to the three-pointed awn, which Mr. Kunit considers as an abortive floret. The analogy of Triathera (see that article) will fully authorize this alteration.

TRIAL, in Law, the examination of any cause, civil or criminal, according to the laws of the realm, before a proper judge.

Of this there are divers kinds: both in civil and in criminal cases. In civil cases there are seven species of trial, viz. by record: by inspection or examination, when, for the greater expedition of a cause, in some point or point being either the principal question or arising collaterally out of it, but being evidently the object of the cause, the judges of the court, upon the testimony of their own fenses, shall decide the point in dispute; as in case of a suit to reheve a fine for non-age of the cognizor, or to set aside a statute or recognizance entered into by an infant, the king's justices determine, by view of the age of the party; also if a defendant pleads in abatement of the suit that the plaintiff is dead, and a person, calling himself the plaintiff, appears, the judges shall determine by inspection whether he be the plaintiff or not; likewise in the case of an idiot; in the appeal of mayhem; and in determining circumstances relative to a day palt by inspection of an almanac: by certificate, as for matters without the realm, and also within the realm: the customs of the city of London are tried by the certificate of the mayor and aldermen, certified by the mouth of their recorder: marriage, bastardy, excommunication and orders, and other such matters, are tried by the bishop's certificate: ability of a clerk preferred, admission, instruction and deprivation of a clerk, shall be tried by certificate from the ordinary or metropolitan; and the customs of courts by certificate from the proper officers, &c.: by waives: by waiver of battle: by waiver of law: and by jury. In criminal matters, there was formerly the trial by ordeal and by certification: these two methods of trial were chiefly in use among our Saxon ancestors, and are now antiquated; the next, which still remains in force, though very rarely in use, was introduced among us by the princes of the Norman line, and is the trial by battle, duel, or single combat: the fourth method of trial used in criminal cases is that by the peers of Great Britain, in the court of parliament, or the court of the lord high steward, when a peer is capitally indicted: but that which most commonly occurs is the trial by jury, or the country, secured to every Englishman, as the great bulwark of his liberties, by the Great Charter. Blackfi. Comm. vol. iii. &c. vol. iv. &c.

Before trial, in a criminal case, it is usual to ask the criminal how he will be tried? which was anciently a very pertinent question, though not so now; in regard there were formerly several ways of trial: viz. by battle, ordeal, and jury.

When the criminal answered, By God and his country, it showed he made choice to be tried by a jury. But there is now no other way of trial. This is also called trying per pais, or per patriam.

TRIAL, New, is a re-hearing of the cause before another jury, with as little prejudice to either party, as if it had never been heard before. The causes of granting a new trial are such as these: want of notice of trial; or any flagrant malbehaviour of the party prevailing towards the jury, which may have influenced their verdict; or any gross malbehaviour of the jury among themselves: also if it appears by the judge's report, certified to the court, that the jury have brought in a verdict without or contrary to evidence, so that he is reasonably dissatisfied therewith; or if they have given exorbitant damages; and if the judge himself has misdirected the jury, so that they found an unjustifiable verdict: for these, and other reasons of the like kind, it is the practice of the court to award a new, or second trial. But if two juries agree in the same or a similar verdict, a third trial is seldom awarded; for the law will not readily suppofe, that the verdict of any one subsequent jury can counterbalance the oaths of two preceding ones. There are influences of new trials in the year-books of the reign of Edward III., Henry IV., and Henry VII., &c. Blackfi. Comm. vol. iii. &c.

TRIAL, Jean Claude, in Biography, director of the royal academy of music at Paris, and master of the prince of Conti's band, was born in 1734, in the Contat, that country so agreeable and fertile in excellent artists. The fine arts are generally inhabitants of beautiful nature.

At twelve years old, Trial quitted Avignon, in order to acquire knowledge from different masters whom he intended to visit. His talents were so extraordinary for his age, that at fifteen he was appointed director of the concert and opera of Montpellier. The passion which he had for the arts drove him to Paris, where he no sooner arrived, than he was placed at the head of the orchestra at what was then called the Italian theatre, or comic opera. From this orchestra he passed to that of the prince of Conti, of which he was appointed director; and his conduct and manners were such in that office, that on his death the prince designed to say that he had lost a friend.

The protection with which he was honoured, procured him the important place of director of the Academie Royale. Permit us here to define the office of director of the academy of music, or serious opera. The management of the opera is a painful and embarrassing administration. It is necessary for the director of this complicated machine to attend to all the springs, to dissipate all impediments to their action, plant the table and sometimes the caprice of the inconstant public, unite to a point of concord very rarely attainable, a crowd of various and often rival talents, excite emulation without awakening jealousy, distribute rewards with justice.
justice and delicacy, cenure and punish with address, limit the unbounded demands of some by flattery, check the independence of others by apparent concessions, and try to establish in the interior government of this republic as much harmony as reigns in the orchestra. It is manifest that nothing but the most sublime, artful, and plant character can hope to accomplish such Herculean labours.

The time necessary for such a ministry, did not allow Trial leisure for pursuing composition with the ardour and application with which he began his career. During his regency at the opera he composed but little, and that was generally in partnership with others.

In 1770 he was found dead in his bed, without any previous illness or warning. He married, in 1769, Mademoiselle Victoire, well known for her wit and talents, with whom he lived in the utmost harmony. A good son, a good husband, a good brother, and good friend.

His funeral manifested how much he was beloved; every one who attended it was in tears: no funeral oration is equal to such tears; for they are never shed but for objects worthy of them. Flattery lies, but never weeps.

**TRIAL Point**, in Geography, a cape on the south-east coast of the island of Jura. N. lat. 55° 54'. W. long. 5° 52'.

**TRIALETE**, a town of the principality of Carthage, in the province of Carduel; 40 miles S.W. of Gori.

**TRIAMBHO**, in Hindoo Mythology, a name of the Hindu god Siva, who corresponds in many points with the primary deities of the Pantheon of Greece and Rome. The name of Triambho seems to connect him with Dionysus or Bacchus; for after the conquest of India, we are told by Diodorus that the Greek deity assumed the title of Triambo. One of the names of Siva is Baghefa; resembling that of the conqueror of India sufficiently nearly for etymological hypothesis to found an argument on, especially when points of character and attributes also correspond. (Of these see under our articles KARTIKYA and Siva.)

The signification of the title Triambho is not evident. Siva has several names allusive to his triple attributes and energies. Trilokan and Triinctra, for instance, mean with three eyes; Trifungi, with the trident; Triskal, or omnipresent; that is, exiling in all times, the past, the present, and the future. See those articles, and TRIMURTI.

**TRIANA**, in Geography, one of the faubourgs of the city of Seville.

**TRIANDRIA**, in Botany, the third clas of the sexual, or artificial, system of Linnaeus, derives its name from having three unconnected stamens, in the same flower with the pistil, or pistils. This class is chiefly composed of what are termed monocotyledonous plants, the number three, or its double quantity, fixed, prevailing as much in that tribe, as the number five does in the dicotyledonous families. See PENTANDRIA.

The orders of this third clas are three. 1. **Monogynia**, opening with the dicotyledonous and ambiguous genus Valeriana, some of whose species have but one stamen, though most have three. The sword-leaved plants (see ENSATE) follow; and then the Calamaria, or grass-like genera of Schoenus, Cyperus, Scirpus, and their allies. 2. **Digynia** consists of the true grases; see GRAMINA. Some of these, indeed many of them occasionally, have abortive or male flowers interpersified with the perfect ones, and are for that reason placed by Linnaeus in his clas Polygynia. This incapacity, as we have often had occasion to observe, is attended with much inconvenience in various cafes, though in none more than the present. 3. **Trigynia**, a small order, is made up, for the most part, of very limited genera of the pink tribe, Caryophyllae, a tribe which, by its close relationship to the Astrilipes and Amaranthi of Julliff, tends, as that great writer candidly observes, to invalidate the distinction between his apetalous and polyptetalous classes. It at least causes too great a separation in his fylem between orders nearly akin.

**TRIANDRIA** is moreover the title of a few orders of the Linnaean system; as the first of the Monandia, consisting chiefly of sword-leafed genera; the third of Gynandria, which perhaps has scarcely any real existence; the third of Monocot, containing Carex and Sparganium, with some tricoccos genera; and the third of Dioecia, formed of some rulhy, and some anomalous plants.

**TRIANGLE**, in Geometry, a figure comprehended under three lines or sides, and which, of consequence, has three angles.

If the three lines or sides of the triangle be all right, it is said to be a plane or rectilinear triangle.

If all the three sides of the triangle be equal (as A B C, Plate XV. Geometry, fig. 5.) it is said to be equilateral.

If only two of the sides of the triangle be equal (as in D E F, Plate VIII. fig. 105.) it is called an isosceles or equilateral triangle.

If all the sides of the triangle be unequal to each other, (as in A C B, Plate XV. Geometry, fig. 6.) the triangle is said to be scalene.

If one of the angles, as K (fig. 7.) of a triangle KML is a right angle, the triangle is said to be rectangular.

If one of the angles, as N (fig. 8.) be obtuse, the triangle is said to be obtuse-angled, or ambygonous.

If all the angles be acute, (as in A C B, Plate XV. Geometry, fig. 5.) the triangle is said to be acute-angled, or oxygonous.

If the three lines of the triangle be all curves, the triangle is said to be curvilinear.

If some of the sides be right, and others curve, the triangle is said to be mistilinear.

If the sides be all arcs of great circles of the sphere, the triangle is said to be spherical.

**TRIANGLES**, Similar. See **SIMILAR**.

**TRIANGLE**, Characteristic of a curve. See **CURVE**.

**TRIANGLE**, Bases, Canon, Hypotenuse, Legs, and Rightness of. See the several articles.

**TRIANGLES**, Construction of. 1. Two sides, as A B and A C (Plate XV. Geometry, fig. 9.) being given in numbers, or otherwise, together with the quantity of the angle intercepted between them, A; to construct a triangle. Assume A B as a base; and in A make the given angle: on the other leg set off the other given line A C; lastly, draw B C: then well A B C be the triangle required.

Hence, two sides with the intercepted angle being determined, the whole triangle is determined. Wherefore, if in two triangles A B C and a e b; a = A; and a b : a e : A B : A C, the triangles are determined in the same manner, and are therefore similar; consequently e = C, and b = b : e : b ; A B : B C, &c.

2. Three sides, A B, B C, and A C (Plate XV. Geometry, fig. 5.) being given, any two of which, as A C, A B, taken together, are greater than the third: to construct a triangle. Assume A B for a base; and from A, with the interval A C, describe an arc y; and from B, with the interval B C, describe another arc x: draw the right lines A C and B C. Thus is the triangle constructed. Hence, as of any three given right lines, only one triangle can be constructed; by determining the three sides, the whole triangle is determined.

Wherefore,
TRIANGLE.

Wherefore, if in two triangles $A\underline{B}C$ and $a\underline{b}c$ (Plate XV. Geometry, fig. 9.) $A\underline{B}C:AB:ae:a\underline{b};A\underline{C}:CB:ac:b\underline{c};$ the triangles are determined in the same manner, and consequently are similar, and therefore mutually equiangular.

3. A right line, as $A\underline{B}$, and two adjacent angles $A$ and $B$, which, taken together, are less than two right ones, being given, to describe the triangle $A\underline{B}C$. On the given line $A\underline{B}$, make the two given angles $A$ and $B$: continue the sides $A\underline{C}$ and $B\underline{C}$, till they meet in $C$. Then will $A\underline{B}C$ be the triangle required.

Hence, one side and two angles being given, the whole triangle is determined. Wherefore, if in two triangles $A= a$ and $B= b$, the triangles are determined after the same manner, and therefore are similar.

**Triangles, Menfuration of.** To find the area of a triangle, multiply the base $A\underline{B}$ (fig. 10.) by the altitude $C\underline{d}$; half the product is the area of the triangle $A\underline{B}C$.

Or thus; multiply half the base $A\underline{B}$ by the altitude $C\underline{d}$; or by the whole base by the half the altitude; the product is the area of the triangle.

2) 800028  40014  40014 area

See Quadrature.

Or, the area of any triangle is had by adding all the three sides together, and taking half the sum; and from that half sum subtracting each side severally, and multiplying that half sum and the remainder continually into one another, and extracting the square root of the product.

Hence, 1. If between the base and half the altitude, or between the altitude and half the base, be found a mean proportional; it will be the side of a square equal to the triangle.

2. If the area of a triangle be divided by half the base, the quotient is the altitude.

**Triangles, Properties of Plane.** 1. If in two triangles $A\underline{B}C$ and $a\underline{b}c$ (fig. 9.) the angle $A$ be $a\underline{d}$; and the sides $A\underline{B}= ab$, and $A\underline{C}= ac$; then will the side $B\underline{C}= bc$, and the angles $C= c$, and $B= b$; and therefore the whole triangles will be equal and similar.

2. If one side of a triangle $A\underline{B}C$ (fig. 11.) be continued to $D$, the external angle $D\underline{A}B$ will be greater than either of the internal oppolite ones $B$ or $C$.

3. In every triangle, the greatest side is opposed to the greatest angle, and the least to the least.

4. In every triangle, any two sides taken together are greater than the third.

5. In two triangles, if the several sides of the one be respectively equal to the sides of the other, the angles will likewise be respectively equal; and consequently the whole triangles will be equal and similar.

6. If any side, as $B\underline{C}$ (fig. 12.) of a triangle $A\underline{B}C$ be continued to $D$, the external angle $D\underline{A}B$ will be equal to the two internal oppolite ones $y$ and $z$ taken together.

7. In every triangle, as $A\underline{B}C$, the three angles $A$, $B$, $C$, taken together, are equal to two right ones, or $180^\circ$.

Hence, 1. If the triangle be rectangular, as $M\underline{K}L$ (fig. 7.) the two oblique angles $M$ and $L$, taken together, make a right angle, or $90^\circ$; and therefore are half right, if the triangle be isosceles. 2. If one angle of a triangle be oblique, the other two taken together are oblique likewise. 3. In an equilateral triangle, each angle is $60^\circ$.

4. If one angle of a triangle be subtracted from $180^\circ$, the remainder is the sum of the other two; and if the sum of two be subtracted from $180^\circ$, the remainder is the third.

5. If two angles of one triangle be equal to two of another, either together or separately, the third of the one must be likewise equal to the third of the other. 6. Since in an isosceles triangle $D\underline{F}E$ (Plate VIII. fig. 105.) the angles at the base $y$ and $z$ are equal; if the angle at the vertex be subtracted from $180^\circ$, and the remainder be divided by 2, the quotient is the quantity of each of the equal angles: in like manner, if the double of one of the angles at the base be subtracted from $180^\circ$, the remainder is the quantity of the angle at the vertex. See ISOSCELES Triangle.

8. If in two triangles $A\underline{B}C$ and $a\underline{b}c$ (Plate XV. Geometry, fig. 9.) $A\underline{B}= a\underline{c}$, $A= a$, and $B= b$; then will $A\underline{C}= a\underline{c}$, $B\underline{C}= bc$, $C= c$, and the triangle $A\underline{C}B$ equal and similar to the triangle $a\underline{b}c$. Hence, if in two triangles $A\underline{C}B$ and $a\underline{b}c$, $A= a$, $B= b$, and $B\underline{C}= bc$, then will $C= c$; consequently $A\underline{C}= a\underline{c}$, $A\underline{B}= a\underline{b}$; and the triangle $A\underline{C}B= a\underline{b}c$.

9. If in a triangle $D\underline{F}E$, the angles at the base $y$ and $z$ (Plate VIII. Geometry, fig. 105.) be equal, the triangle is isosceles: consequently, if the three angles be equal, it is equilateral.

10. If in a triangle $A\underline{B}C$ (Plate XV. fig. 14.) a right line $D\underline{E}$ be drawn parallel to the base $A\underline{C}$, then will $B\underline{C}= BD$, $B\underline{D}= BE$, $A\underline{D}= EC$, and $B\underline{A}= AC$, $B\underline{D}= DE$; consequently the triangle $B\underline{D}E$ is similar to $B\underline{A}C$. And, vice versa, a right line, which divides two sides of a triangle proportionally, is parallel to the remaining side. Moreover, if another right line $F$ is also drawn parallel to the base $A\underline{C}$, the intercepted parts, $D\underline{F}$, $E\underline{G}$, are in the same ratio with the whole sides $A\underline{B}$, $C\underline{B}$; i.e. $D\underline{F}:E\underline{G}= A\underline{B}:C\underline{B}$. And if any number of lines be drawn parallel to the base, cutting the sides of a triangle, every two corresponding segments will have the same ratio.

11. Every triangle may be inscribed in a circle.

12. The side of an equilateral hexagon, inscribed in a circle, is equal to the radius.

13. Triangles on the same base, and having the same height, that is, being between the same parallel lines, are always equal. See PARALLELOGRAM.

14. Every triangle, as $C\underline{A}D$, (Plate X. Geometry, fig. 14.) is one-half of a parallelogram $A\underline{C}DB$ on the same, or an equal base $C\underline{D}$, and of the same altitude, or between the same parallels: or a triangle is equal to a parallelogram upon the same base, but half the altitude; or half the base, and the same altitude. See PARALLELOGRAM.

15. In every triangle, as well plane as spherical, the sides or lines of the sides are proportional to the lines of the opposite angles.

16. In every plane triangle, as the sum of two sides is to their difference, so is the tangent of half the sum of the opposite angles, to the tangent of half their difference. See TANGENT.

17. If a perpendicular be let fall upon the base of an oblique-angled triangle, the difference of the squares, or, the rectangle under the sum and difference, of the sides is equal to double the rectangle under the base, and the distance of the perpendicular from the middle of the base.

18. The double of the square of a line drawn from the vertex to the middle of the base of any triangle, together with
with double of the square of the semi-bafe, is equal to the
squares of both the sides taken together.
19. A whole triangle is to a triangle cut off by a right
line, as the rectangle under the sides cut off is to the right
angle of the two sides.
20. In a right-angled plane triangle ADE (Plate X.
Geometry, fig. 17.) a line DB drawn from the right
angle or the vertex, perpendicular to the hypotenuse, divides
the triangle into two other right-angled triangles, ADB,
DBE, which are similar to the first triangle, and also to one
another.

Hence it follows: 1. That \( \frac{\text{ED}}{\text{DB}} = \frac{\text{BD}}{\text{BA}} \) and
\( \frac{\text{AE}}{\text{ED}} = \frac{\text{ED}}{\text{EB}} \) and \( \frac{\text{AE}}{\text{AD}} = \frac{\text{AD}}{\text{AB}} \).
(See Proportional.) Whence, 2. As the angle in
a semicircle is a right angle, it follows that, if from any
point D in the periphery of a semicircle ADE, a perpen-
dicular DB is let fall upon the diameter AE, and from the
fame point D, to the extremities of that diameter, two
chords DA, DE, be drawn; the square of that perpen-
dicular will be equal to a rectangle under the two feg-
ments of the diameter; and the square of each chord
equal to a rectangle under the whole diameter and its
adjacent fegment; i.e., \( \text{BD}^2 = \text{BE} \times \text{BA} \) ; \( \text{ED}^2 = \text{EB} \times \text{EA} \); and \( \text{AD}^2 = \text{AB} \times \text{EA} \).
21. In every right-angled triangle, the square of the
hypotenuse is equal to the sum of the squares of the other
two fides. See Hypotenuse and Subtense.
22. If any angle of a triangle be bifefted, the bifefting
line will divide the oppofite fide, in the fame proportion
as the legs of the angle are to one another.
23. If the vertical angle of any triangle be bifefted, the
difference of the rectangles, made by the fides and the
fegments of the bafe, is equal to the square of the line that
bifefts the angle. Thus, if a right line B E (Plate XV.
Geometry, fig. 15.) bifeft an angle ABC of a triangle,
the square of the faid line \( \text{BE} = \text{AB} \times \text{BC} - \text{AE} \times \text{EC} \).
24. To divide a triangle into any given number of equal
parts; divide the bafe CD (fig. 16.) into as many equal
parts as the figure is to be divided into; and draw the lines
A1, A2, &c.
25. If in similar triangles from any two equal angles to the
oppofite fides two right lines be drawn, making equal
angles with the homologous fides; thofe right lines will
have the fame ratio as the fides on which they fall, and
also divide thofe fides proportionally.
26. If in two triangles having one fide common to both,
from any point in that fide, two lines refeptively parallel
to two contiguous fides be drawn, terminating in the two
remaining fides, thofe lines will have the fame ratio as the
fides to which they are parallel. Hence, if thofe fides are
equal, thofe lines will be alfo equal.
27. If through any point within a triangle three right
lines be drawn, from the angular points to cut the oppofite
fides, the fegments of any one fide will be to each other, as
the rectangles under the fegments of the other fides taken
alternately. Hence if the former fegments be equal, the
forementioned rectangles will be equal, and therefore
the fides of the triangle cut proportionally, and a line connect-
ing the points of division will be parallel to the bafe.
28. Triangles having one angle in the one equal to one
angle in the other, are in the ratio of the rectangles
contained under the fides, including the equal angles. Hence,
if the rectangles be equal, or the fides reciprocally propor-
tional, the triangles will be equal.

Triangles, Properties of Spherical. See Spherical
Triangle.

Triangles, Solution of. See Trigonometry.

Triangle, an iron military instrument with three fides,
which ferves as an accompaniment to other instruments in
a military band, and in the streets: the performer supports
it by a ring at the top with his left hand, and beats it with
a small iron rod in his right hand. At the lowest angle iron
rings are placed, which by their vibration augment the
sound.

Triangle Island, in Geography, an island of South Ame-
rica, in the mouth of the Oronoko, where the French fettled
a factory in the year 1765.—Alfo, one of the fmalier Ba-
hama islands, fo called. N. lat. 26° 51', W. long. 69° 53'.

Triangles, a dangerous fhool in the East Indian lea,
near the N. coast of the Pracel, or Prafil.

Triangles, Southern, a reef of rocks and iflets in the
bay of Honduras. N. lat. 17° 45'. W. long. 88° 42'.

Triangular Apple-Ladder, in Rural Economy, a
ladder of this fort for gathering apples from the trees
with eafe and without bruifing them. It is about eighteen
feet in height, and has two other branches, which are each
of the fame length, faftened by iron hoops or rings at its
top-part. These parts all diverge from each other when the
ladder is in ufe, and appear fomewhat in the manner of the
corner rafters of a triangular roof, forming a fort of tri-
gle. At about four feet from the ground, each branch
and the ladder part has a hook fixed to it, for the purpoce
of fretching out a triangular cloth by; in the middle of
which is formed a circular tunnel of the fame material. The
cloth has at each corner a leather flap, pierced with a num-
ber of holes, in order that an equal degree of fension may
conftantly be given, whether the ladder and its branches be
much extended or not.

In collecting the apples, the gatherer, afcending the lad-
der, throws the fruit as he strips it from the boughs of the
trees into the cloth, whence it rolls down the funnel part
into the bafket which is placed to receive it below.

So much injury and mischief are done to apple-trees at all
periods of their growth, by fetting ladders againft the boughs
of them, and the fruit is fo greatly bruifed and depreciated,
as well as subject to decay, by gathering it in the usual
modes, that both practices should be difcontined, and
better ones, fuch as the above, be had recourse to in fuch
cafes.

Triangular Battalion, in the Military Art. See Bat-
tery.

Triangular Canon. See Canon and Sine.

Triangular Compasses, are fuch as have three legs or
feet, by which to take off any triangle at once: thofe are
much ufed in the conftuction of maps, globes, &c. See
Compasses of three legs.

Triangular Fort. See Fort.

Triangular Leaf, in Botany. See Leaf.

Triangular Numbers, are a kind of polygonal num-
bers; being the fums of arithmetical progression, the dif-
fERENCE of whole terms is 1.

Thus, Of arithmetical progres. 1 2 3 4 5 6
are formed trian. numb. 1 3 6 10 15 21

For the rationale and management of these numbers, see
Malcolm's Arith. book v. ch. 2.

Triangular Quadrant, is a fecto furnished with a loftie
piece, by which to make it an equilateral triangle.

The calendar is graduated on it, with the fun's place,
decoration, and other ufeful lines; and by the help of a
string and a plummet, and the divisions graduated on the
lafie piece, it may be made to serve for a quadrant.

Triangular Winding-flairs. See Stair.

TRI-
TRIANGULARIS STERNI, in Anatomy, a muscle of the ribs. See Intercostales.

TRIANGULARIS GENUS, the depreessor anguli oris, a muscle of the mouth. See Deglutition.

TRIANGULARIS PISTIS, in Ichthyology, the name of a sea-fish of a very remarkable figure, called in English the coney-fish, of which there are two species, the one having two horns, the other wanting that character.

The horned kind usually fix or five fingers breadth long, and about three fingers broad; the tail ends in a long fin; the mouth is small, having twelve strong serrated teeth in the upper jaw, and eight larger ones in the lower; the head ribs gibbously from the mouth to the horns, and the back is humped in the middle; it has only one small fin near the tail; its eyes are large and placed near the horns; the fin near the tail, it has four others; the tail being one, and one more being situated on the back, and two on the belly; it has two horns like cocks' spurs, growing straight out of its forehead, and two others in a contrary direction, out of its belly near the tail; it has no scales, but has a hard skin, white on the belly, and brown every where else, and wonderfully marked with trigonal, tetragonal, pentagonal, and hexagonal figures.

The species which has no horns has a broader belly, a longer tail, and is marked all over its body only with hexagonal figures, and innumerable small tubercles: its belly is yellowish, and the rest of its body of a greyish or brownish yellow; the mouth is narrow, and the teeth small, five in the lower and eleven in the upper jaw; the eyes are large and round; it is hollow, and has very little flesh.

Both the species, which belong to the genus octracin in the Linnean system, are caught among the rocks, on the shores of the island of Java, and are sometimes eaten by the inhabitants, being first skinned. Cluf. Exot. lib. ii. cap. 27.

Willughby's Hist, Pisc. p. 150.

Gen. Ch. Cal. Perianth half-inferior, of five oblong leaves, internally coloured, pointed below the fummit, permanent. Cor. none, except the calyx, which partakes of the nature of both parts, be considered as such. Stam. Filaments about ten, (from five to twelve,) capillary, the length of the calyx; anthers roundish. Pist. Germen almost entirely superior, oblong, abrupt; styles one or two, thread-shaped, the length of the germenis, hispid on one side; stigma simple. Peric. Capsule oblong, abrupt, burstling all round, of two, tranversefely interrupted cells. Seeds one or two in each cavity, nearly ovate.

Obs. The number of flaments, as well as of styles, differs in different species.

1. T. monogyna. Purlane Triantema. Linn. Mant. 69. Willd. n. 1. Ait. n. 1. "Decand. Pl. Gracies t. 109." (T. Portulacenftrum; Linn. Sp. Pl. 325. Portulaca curassavica proemunens, caparidas folio, flore mucifo, capillus bifurcatus; Herm. Parad. 213. t. 213. Kali curassavicae proemunens, folis subfutundis; Pluk. Phyt. t. 95. f. 4.)—Stamens more than five. Style one. Leaves elliptic-oblong. Stem with a hairy line along the upper side.—Native of the Weft Indies and South America. Sometimes raised for curiosity's sake, in our floves, where it flowers in summer. The root is annual. Stems a foot long, much branched, leafy, spreading on the ground in every direction, smooth, except a dense, flender, hairy line along their upper side. Leaves opposite, unequal, flaked, oval or roundish, obtuse with a small point, entire, smooth, red at the edge, from one to two inches long. Stipulas membranous, acute, half the length of the footstalk, to which they are united. Flowers axillary, sessile, about three together, pale and membranous, with a pair of bracteas to each. Stamens from six to ten. German with two distant horns. Style, according to Linnaeus, solitary, rough at one side, with a simple stigma.

2. T. crysallina. Cryzalline Triantema. Sm. Spicil. t. 26, unpublished. Vahl. Symb. v. 1. 32. Willd. n. 2. (Papulia cryzzallina; Forf. Egypt.-Arab. 69. Gyropermum depresfum; Linn. MSS.)—Stamens five. Style one. Leaves elliptic- lanceolate. Stem papillary all over.—Native of the East Indies and of Arabia. We received it from Madras, by the favour of Dr. Roxburgh. Linnaeus cultivated it at Uphal, and has left in his herbarium specimens, with a coloured drawing, and a description. He made this plant a new genus by the name of Gyropermum, judging it a kin to Herniaria. It would have appeared in the third number of our Spicilegium, had that work been continued; but the page, though printed, was never published. The root is perennial. Stems herbaceous (not shrubby), depressed, a span long, reddish, branchid, leafy, clothed with pellucid papillary granulations, which in the dried specimen become bagny hairs. Leaves opposite, flaked, like Polygonum avoileure in size and figure, with united membranous flippulas, as in the foregoing. Flowers axillary, sessile, one, two or three together, small, whitish with a red german. Bracteas of two opposite scales under each flower. Stamens five, very short. Style one, with a divided stigma. Ripe capsule of one cell, embraced by the base of the calyx. Seeds two, one above the carker, black, orbicular, depressed, rough, with concentric furrows. This species surely approaches in many points to Sadiola, so far at least as to indicate a great affinity between the two genera.

3. T. pontandra. Smooth Triantema. Linn. Mant. 70. Willd. n. 3. (Rocca; Forf. Egypt.-Arab. 71. Portulaca allius polygmojides, flifo et fabe mediarafienfis; Pluk. Phyt. t. 120. f. 3.)—Stamens five. Styles two. Leaves obvolute. Stipulas pointifes. Stem nearly smooth.—Native of Arabia. Annual, cultivated by Linnaeus at Uphal, but unknown in our gardens. The size and habit of the plant answer to the first species, but the stem has no hairy line, nor more than a light papillary ringlets, on the young branches only. Leaves nearly uniform, obvate rather than elliptical, on long hairles, to which the membranous flippulas are entirely united, without any separate points. Flowers purplish. Styles recurved. Wildenow copies Reichard's error of Rocca, for Rocca.

4. T. fruticosfa. Shrubby Triantema. Vahl Symb. v. 1. 32. Willd. n. 4. (Gymnocarpus decandrum; Forf. Egypt.-Arab. 65. 1c. t. 10. Desf. Atlant. v. 1. 203.)—Stamens ten; five alternate ones imperfect. Style one. Leaves cylindrical, pointed. Stem shrubby, round, smooth.—Native of the sandy deserts of Cago, as well as about Tunis. A rigid spreading shrub, about a foot high; its bark grey and weather-beaten. Leaves flally, glaucescent, smooth, oblongely triangular, about half an inch long, in little tufts. Flowers three to five, in tufts at the ends of the branches, sessile, violet-coloured, a third of an inch broad,
broad, hairy at their base and at their points. *Seed solitary, according to procennial Desfontaines, to whom we are obliged for a specimen. Vahl *fusicae there may be two *fedae.

5. *T. humifusa. Prostrate Cape Trianthema. Thumb. Prodr. 80. Willd. n. 5.—"Style one. Leaves lanceolate. Stem shrubby, round."—Gathered by Thunberg at the Cape of Good Hope, as well as the next. We have seen no specimen of either.

7. *T. decandra. Trailing Indian Trianthema. Linn. Mant. 70. Willd. n. 7. Att. n. 2. (Zaleya decendra; Burm. Ind. 119. t. 31. f. 3.)—Stamens about ten. Styles two. Leaves obovate. Stipules pointeles. Stem nearly smooth.—Native of the East Indies. The herbage of this species bears a great affinity to *T. pentandra, but the flowers are rather shorter. Their flowers indeed are very different, those of the present being much larger, on longish stalks, with a fleshy, scarcely membranous, calyx.

TRIATHASIA, in *Ancient Geography, a town of Asia, in the Lesser Armenia, upon the route from Sebaste to Corduban, between Tonoa and Codrizabala. Anton. Itin.

TRIARIUM, in the Roman *Militia, a kind of infantry, armed with a pike, shield, a helmet, and a cuirass: they were thus called, because they made the third line of battle.

The triarii were also called *poggigno, because ranged behind the princes who bore the standard in a legion.

Polybius distinguishes four kinds of forces in the Roman army: the first, called *pilatus, or velites, he says, were a raw body, lightly armed. The *hatari, or *fiar-men, were a degree older, and more experienced. The third, called *principes, princes, were full older, and better soldiers than the second. The fourth were the oldest, the most experienced, and the bravest; these were always disposted in the third line, as a corps de reserve, to sustain the other two, and to restore the battle, when the others were broken or defeated. See *Legion.

Hence their name of triaarii: and hence the proverb, *Ad triarios ventum est, to shew that one is at the last and hardest struggle.

TRIAGES Harmonica, Lat.; *Triade Harmonique, Fr.; *Harmonical Triad, Eng.; in *Music. This term has two different senses. In *calculation, it is the harmonical proportion; in *practice, it is the perfect major chord resulting from the same proportion, and which is composed of the fundamental sound, its major or sharp third, and its fifth. It is called a *triad, because composed of three sounds; and *harmonic, because in harmonic proportion; and is the feme of all harmony.

TRIATHERA, in *Botany, from *τρια, three, and *αθήν, an awn. Palisot de Beauvois *Agrostogr. 39. t. 9. f. 4.—

1. *T. juncea of Defrance is given as the only species, without account of its native country. By the figure it appears to be a slender grass, with linear leaves, and a simple, upright, unilateral *glumier, rather above an inch long; the flowers not a quarter of an inch in length. Nothing is known of the *flamen, *pilos, or *seed. The *awn, confining of three rough equal bristles, more than twice the length of the *floret, and united by a short fimple base, is considered by the above author as the rudiment of an abortive floret, which idea is adopted in a familiar cafe by Kuntb. (See *Trileana.) We do not doubt that such an *awn may take place of a *floret, by one of those metamorphoses so common in grasses, whose awns are known to be among the least permanent of their distinctions; but it is offering too great violence to language to use one term for the other.

TRIACOURT, in *Geography, a town of France, in the department of the Meuse; 7 miles S. of Clermont en Argonne.

TRIAZEV, a town of Russia, in the government of Upha; 88 miles N. N. W. of Upha.

TRIACHIUCHA, a town of Russia, in the government of Upha, on the Ural; 140 miles E. of Orenburg.

TRIBALE, LA, a town of France, in the department of the Tarus; 6 miles W. N. W. of La Caune.

TRIBALLI, in *Ancient Geography, a people of Lower *Mafia, upon the banks of the Danube, called also *Servians.

TRIBAU, of *Trebohe, in *Geography, a town of Moravia, in the circle of Olmutz; 28 miles N. W. of Olmutz. N. lat. 49° 43'. E. long. 16° 29'.

TRIBE, *Tribus, in *Antiquity, a certain quantity or number of persons; which a division is made of a city or people into quarters or districts.

The city of Athens was divided into ten *tribes: the Jewish nation into twelve; or, if we separate the family of Joseph, thirteen tribes, the descendants of the twelve sons of Jacob, viz. the tribes of Judah, of Reuben, Gad, Asher, Dan, Nephthali, Ephraim, Manes, Simeon, Levi, Zebulon, and Benjamin; the polish of Joseph being divided into two tribes, that of Manes, and that of Ephraim.

There were ten of these tribes that revolted, and followed Jeroboam. The other two, viz. those of Judah and Benjamin, adhered to the house of David, and to the worship of the true God, whilst the other tribes declared for idolatry. This schism, which lasted above 200 years, ended at last in the captivity of the ten tribes, which were carried away by Shalmanefer into Assyria and Media: nor does it appear from history, that they ever returned into their own country, at least all of them, though we find it attested by some modern Jews and ancient fathers of the church.

Mention indeed is often made in the New Testament of the twelve tribes (see Matt. xix. 28. Luke, xxii. 30. Acts, xxvi. 7. James, i. 1.); and St. James directs his epistle to them; but from these passages we cannot conclude, that they were then gathered together; but we may infer, that they were still in being. Perhaps the whole body of the Jewish nation retained the name of the twelve tribes, according to the ancient division, as we find the disciples called the Twelve, after the death of Judas, and before the election of St. Matthias. (John, xx. 24.) Moreover, there were Jews in a sufficient number of the ten tribes mixed with that of Judah, or dispersed into several parts of the world, to afford occasion for speaking of the twelve tribes, as making but one body with the Jewish nation. Of their dispersion into various parts of the East, we have accounts that cannot be questioned. Whether or not we admit Sir W. Jones's opinion, that the *Afghans (which see) were defended from them, Dr. Buchanan has recently confirmed the opinion, that the polish of the Jews still remain in India. A heathen author, quoted by Jofephus, (Antiq. i. ix. and i. xi.) affirms, that the Persians had carried several thousands of Jews into Babylon, from whence it is natural to conclude, that a considerable number returned home with the others, when they were set at liberty by Cyrus. See 2 Chron. xxxiv. 9. 1 Chron. ix. 3. Jer. l. 4. Luke, ii. 36.

The tribe of Judah did not continue more faithful to God...
God than Samaria, the metropolis of the kingdom of Israel, had done. On this account they were often delivered into the hands of their enemies, and at last all carried away captive by Nebuchadnezzar in the 19th year of his reign. See Captivity and Jews.

The Roman people were at first only divided into three tribes; and from this number three, tres, it was that the word tribe, tribus, took its rife. Livy says (l. vi. c. 5.) that the appellation was derived a tributa. This division was accommodated by Romulus to the several nations he had united; the first consisting of the Albans, the second of the Sabines, and the third of a mixture of fugitives, who came to seek an asylum at Rome.

Servius Tullius, fearing this partition might occasion feditious, divided the inhabitants of Rome by cantons, not by nations: accordingly, he distributed the city into four quarters, or tribes; and by reason a great number of citizens had retired into the country about, of those he composed twenty-fix other tribes; so that from this time the Roman people consisted of thirty tribes.

Writers are not agreed concerning the precise number. With the four city tribes, and the seventeen rustic tribes of Servius, as some have arranged and denominated them, the Roman people made up the number of thirty-five tribes. However this be, in after-times the number of tribes amounted to thirty-five; but they then ceased to be ranged according to the quarters of the city. The distribution depended on the cenfors, who formed their lift at discretion, frequently confounding the country tribes with those of the city.

A man was never absolutely a Roman citizen, unless he had the jus tribus, i. e. till he were intituled to the honours of the magistrature, as also a right of voting in assemblies of the people; and this is what they called jus quiritium. Hence the inhabitants of the municipal cities were only imperfect citizens, as being of no tribe.

The freed-men were obliged to purchase this right of tribe, which did not other-wise belong to them, though they were citizens of Rome.

Tribes of Plants, in Gardenig, the particular kinds or forts of cultivated garden vegetables of these descriptions, which are arranged and brought together under peculiar heads or names, according to their similar refemblances or appearances; the sameness of their habits of growth; and the general affinities which they bear, in some way or other, to each other. By these means, and in these several ways, a great number of different tribes of these forts of plants are formed and constituted. Thus the time or duration of the growth of some afford several of these classes or tribes, such as the following: viz. the

Annual Tribe: that which contains all forts of annual

plants, or those only of one year's growth or duration, being often simply, on that account, termed annuals.

Biennial Tribe: that which includes all kinds of plants, which are of two years' duration or length of growth, and which are sometimes called simply biennials.

Perennial Tribe: that which comprehends all forts of plants which are of perennial or many years' growth or duration, and which is applicable to trees as well as herbs, though somewhat more frequently and generally used to herbaceous perennial plants. These are occasionally called perennials merely. See Annual, Biennial, and Perennial Plants.

The nature and form of the root have also some influence in the formation of these tribes, as is evident in the following:

Bulbous-rooted Tribe: that which comprises all kinds of plants which have thick or bulbous roots; such as those of the onion, turnip, lily, crocus, narcissus, and several other kinds.

Tuberous-rooted Tribe: that which contains all forts of plants which have thick, knobby, fibrous roots, such as those of the anemone, potato, Jerusalem artichoke, and many other kinds.

Fibrous-rooted Tribe: that which comprehends all forts of plants which have small firing-like fibrous roots, such as that of endive, and many other kinds. See Root.

The ligneous or woody nature of plants likewise causes distinctions of this description, such as these:

Ligneous or Woody Tribe: that which includes all forts of the tree or shrub kind which have woody or solid durable stalks or limbs, such as those of the oak, ash, beech, and other similar kinds, as well as such shrubs as the holly, alderas, althea, and many other forts. See Tree and Shrub.

Arborescent Tribe: that which contains all forts of plants of the tree kind, which rife with an upright main stem or stalk to a considerable height, as in the ash, beech, &c. See Tree.

Fruiting or Shrubby Tribe: that which takes in all forts of plants of the shrubby kind, or which have any thing of shrub-like growth, and which rise only to a moderate height, having a divided, low, stumpy, and branching bushy appearance about the bottom and other parts, as in the althea frutis, fyringa, &c. See Shrub.

The habits of different forts of plants, in regard to the lofs or the retention of their leaves during particular season of the year, are a further source of the distinction of them in these modes.

Deciduous Tribe: that which comprises all forts of both trees, shrubs, and plants, which call their leaves during the winter season, or before it commences; such as the ash-tree, the fyringa shrub, and the fern, golden-rod, and mith plants.

Sempervirens or Evergreen Tribe: that which comprehends all the various sorts of trees and shrubs, as well as other kinds of plants, which have the property of retaining their green leaves the whole of the year round, such as the holly, yew, box, laurel, and many others. See Deciduous and Evergreen Trees.

Herbaceous Tribe: that which contains all the different sorts of the herbaceous or herb kind of plants, which most commonly rife furnished with leaves immediately from the roots, and with soft herbaceous leaves or stalks, without any sort of woodiness; but which, for the most part, decay and die about the clofe of the fame year in which they were produced, such as the pea, bean, lettuce, mustard, cress, and numerous others. See Herbaceous Plants.
There are others which are arranged in this manner from their juicy or succulent properties, as the following tribes.

**Succulent Tribe**: this is that which includes all the forts of plants which have fleshy, moist, juicy leaves, which are sometimes of considerable thickness, but in other cases not, such as the sedum or house-leek, the aloe, the agave, and several others. See Succulent Plants.

The manner of feeding, and the economical uses to which plants are put, are further causes of their arrangement and distinction in this way.

**Leguminous Tribe**: that in which all the different plants that it embraces have the fort of seed-vessel which is usually denominated a legume, or pod, as in all the pea, bean, kidney-bean, and other paphianaceous-flowered plants.

**Oleraceous Tribe**: that in which the various plants that it contains are of the eficulent or eatable kind for the table, or for being preferred and made use of for other culinary or domestic intentions. See Leguminous and Esculent Plants.

The forms of the leaves and plants, the manner of their flowering, the shapes of their flowers, the methods of feeding or fruiting, and the particular nature, qualities, and properties of plants, all have a further tendency to the introduction of more tribes of these kinds.

**Pinated Tribe**: that in which all the forts of the trees and plants which it contains have pinnate leaves, or those which are in the shape of wings, as is the case in a great number of different kinds, as in the acacia, the fumach, and many others.

**Enfataceous or Sword-leaved Tribe**: that which comprises plants that have sword-shaped leaves, as is the case in many forts, such as the iris or flowering rush, the gladiolus or sword-lily, &c.

**Spathaceous Tribe**: that which contains all such plants as protrude and produce their flowers out of a spatha or sheath, and which are many in number, such as the narcissus, or daffodil and jonquil, the galanthus or snow-drop, and the amaryllis or lily-daffodil, Guernsey lily and the belladonna and jacobaea lily.

**Liliaceous Tribe**: that which comprehends all the forts of plants which have papilionaceous or butterfly-shaped flowers, such as those of the pea, bean, and all the leguminous kinds of plants. See Papilionaceous Flowers.

**Campanaceous Tribe**: that which contains all the various kinds of plants which have campanulated or bell-shaped flowers, as those for instance, of the campanula or bellflower, the convulvulus or bind-weed, and bean-kind, and others of the same fort.

**Rosaceous Tribe**: that which includes all forts of plants which have rotated or wheel-shaped flowers, such as those of the lythrum or loose-flire, the anagallis or pippermel, and some others.

**Umbelliferous Tribe**: that which contains all such plants as produce their flowers in somewhat the form of an umbrella, as in those of the angelica, the anethium or fennel, the paphian or parnep, and some others. See Umbellated Plants.

**Verticillose Tribe**: that which comprises those forts of plants which have their flowers produced in something of the form of a verticillus or whorl, as in those of the thymus or common thyme, the hyssopus or hyloph, the melifera or balm, the origanum or marjoram, the mentha or mint, and several others. See Verteillated Plants.

**Aggregate Tribe**: that which comprehends such plants as produce their flowers in an aggregate form, consisting of numerous florets or small flowers, each having its own proper calyx or cup, but the whole of which are collected into one cluse aggregate, or head, as in those of the fieberia or fieberia, the latese, thrift, or sea-pink, the globularia or globular blue daisy, and some others. See Aggregate, in Botany.

**Composite or Compound Tribe**: that which comprises those forts of plants which have compound flowers, consisting of a great number of florets contained in one common calyx, or cup, as in those of the fun-flowner, the marigold, the alder or tar-wort, and many others. See Compound in Botany.

**Amentaceous Tribe**: that which contains those plants which produce their flowers in amaments or catkins, as in those of the populus or poplar-tree, the corylinus or hazel, the fagus or beech, the betula or birch, and some others. See Amentaceous.

**Baccaceous Tribe**: that which comprehends all those forts of plants which bear and produce any kind of berry, as the ribes or gooseberry and currant, the rapsbury, the, yew, and many others.

**Coniferous Tribe**: that which contains all such forts of trees and plants as bear that kind of fruit or seed which is denominated a cone, as the various forts of firs, &c. See Cone, in Botany.

**Fungous Tribe**: that which takes in all vegetables of the mushroom and other similar kinds, as the common mushroom or agaricus, &c.

**Gramaous Tribe**: that which comprehends all such forts of plants as are of the grass or grain kinds, such as the different field grassless, and those of the wheat, rye, barley, oat, and other similar kinds.

**Lurid Tribe**: that which includes all the sorts of plants which have any thing of an ominous appearance or hurtful or noxious quality about them, as those of the atropaga or deadly nightshade, the datura, thorn-apple or frrammonium, the nicotiana or tobacco-plant, the folium or love-apple, &c. the capuchin or guinea-pepper, the digitals or fox-glove, and several others.

**Nuciferous Tribe**: that which comprehends all the forts of the nut-bearing kinds of plants, as the hazel-nut-tree, the walnut-tree, &c.

**Pomaceous Tribe**: that which comprehends all such forts of plants as bear or produce a fruit of the apple kind, as that of the pyrus malus or apple kind, the pyrus communis or pear kind, the pyrus cydonia or quince kind, the amygdalus or almond kind, the prunus or plum kind, the melipus or medlar kind, the pyricula or pomegranate kind, and some others.

This sort of classification or arrangement of the different plants which are cultivated in the garden or pleasure-ground for the sake of their culinary uses, or the ornament which is afforded by their flowers, is often of very great utility and convenience, as supplying the means of throwing together those forts of plants which have many circumstances and practices in their general culture and growth which have much similarity to each other, by which the common gardener has a far greater facility of raising and managing them, as well as of securing their produce in fruit or other ways. He is thereby also better enabled to make use of these of the ornamental kinds in the borders, clumps, and other parts of the grounds in which they are to be set out and placed.

**TRIBENSEE**, in Geography, a town of Austria; 3 miles N. of Tulln.

**TRIBERG**, a town of the Briegau; 15 miles N.E. of Friburg. N. lat. 48° 9'. E. long. 8° 17'.

**TRIBERL**.
TRIBERL, Bohmisch, a town of Bohemia, in the circle of Chrudim; 4 miles E.N.E. of Leutminislh.

TRIBISA, a river of Saxony, which runs into the Elbe, near Meißen.

TRIBOCOI, Triboci, or Tribecos, in Ancient Geography, a people of Germany, on this side of the Rhine, situated, according to Strabo and Caesar, between the Mediomatrici and the Treveri. Caesar says they formed part of the army of Arriovisius. Their capital was Argentoratum or Strafburg.

TRIBOLI, in Geography, a town of Asiatic Turkey, in the government of Trebizon; 4 miles W.S.W. of Trebizon.

TRIBOMETER, formed of $\tau$, rub, and $\mu$, I measure, in Mechanics, a term applied by Murchenbroek to an instrument invented by him for estimating the friction of metals. It consists of an axis formed of hard steel, passing through a cylindrical piece of wood; the ends of the axis, which are highly polished, are made to rest on the polished semicircular cheeks of various metals, and the degree of friction is estimated by the weight of a weight thatboted by a fine silken string or ribband over the wooden cylinder. For a farther description and figure of this instrument, and the result of various experiments performed with it, see Murchenb. Int. ad Phil. Nat. vol. i. p. 151, &c.

TRIBONIANUS, or TRIBONIAN, in Biography, an eminent jurist, was a native of Side, in Pamphylia, and richly furnished with Greek and Roman literature, so that he composed works on a great variety of subjects. But as he principally devoted himself to the study of civil law, he excelled in this department, and rose to one of the highest posts in the empire. In the office of queller, to which he was advanced, his avarice led to such a degree of oppression, that in the federation of Confantinopole, A.D. 532, his removal was one of the demands of the people. His influence, however, was such, that he was soon restored, and he continued, on account of his talents and by means of his sordid adulation, to enjoy the favour and confidence of his sovereign for twenty years. He was elevated to the dignities of confidant and master of the offices, and was confounded on all important occasions. Of his concern in compiling the code of civil law, we have elsewhere given an account. (See Code and Civil Law.) He has been charged with enmity to the Christian faith, and he has been under the inconcerted imputations of Attilius and Paganinis. Whether charges of this kind be true or false, he was notorious for his avarice and want of integrity; and from the contrivance presented by his heart and his understanding, Gibbon has drawn a parallel between him and our great Bacon. His death is placed about the year 546. Anc. Un. Hist. Gibbon's Rom. Emp.

TRIBACHYS, formed from $\tau$, three, and $\sigma$, short, in the Ancient Prophesy, a foot of verse, consisting of three syllables, and those all short; as, $\mu$.$\mu$. Of the moderns, was so called from the likeness of its fruit to the instrument of war denominated in English a caltrop. (See TRAPA.) Whether the name arose from $\tau$, to tear, or injure; or as some think from $\tau$, three, and $\delta$, a tooth, or a wound, may admit of controversy. The caltrop has four, not exactly three, points; and the seed-veil of our plant has a much greater number, though the appearance of the whole very much resembles the above war-like, or rather treacherous, instrument.—Linn. Gen. 213. Seleng. 289. Willd. Sp. Pl. v. 2. 566. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 41. Sm. Prodr. Pl. Grac. Sibth. v. 1. 273. Juss. 296. Tourn. t. 141. Lamarr. Ill. t. 346. Gartn. t. 69. — Chafes and order, Decandria Monogynia. Nat. Ord. Grumiales. Linn. Rutaceae. Juss. but not correctly.

Obi. T. maximus, Limnaeus by mistake says cissifera, has ten rugose capsules, almost definite of lateral spines.

Eff. Ch. Calyx in five deep segments, rather shorter than the petals. Cor. Petals five, oblong, obtuse, spreading. Stam. Filaments ten, small, awl-shaped; anthers incumbent, simple. Pist. German roundish, bristly, the length of the flamen; style short and thick; stigma capitulate, with five rays. Peric. roundish, thorny, of either five or ten capsules, which are gibbous externally, and armed with three or four thorn thorns; angular on the inner edge and crowded together; their cells several, transverse. Seeds solitary in each cell, oblong.

Obi. T. maximus. Great Caltrops. Linn. Sp. Pl. 553. Willd. n. 1. Ait. n. 1. Jacq. Coll. v. 4. 110. G. Rar. t. 462. (T. n. 2.; Browne Jam. 220. t. 21. f. 3.) T. terrefiris major, flore magnome odorato; Sloane Jam. v. 1. 209. t. 132. f. 1.; the figure at leaf, and part of the description. T. terrefiris, fructo turbinato, foliis lanugino; Plum. Ic. 252. t. 254. f. 1.) — Leaflets about four pair; the outer ones largest. Fruit turbinate, wrinkled, slightly spinous, with ten furrows. Style permanent. — Native of dry waife places, or rocky gravelly ground, in most parts of Jamaica. Sloane. The root is annual, rather deep. Stems several, about two feet long, spreading flat on the ground, branched, round, leafy, flat, rather hairy. Leaves opposite, abruptly pinate, lobed hairy, an inch and a half long, of fix pair of half-ovate, entire, acute leaflets; the first pair smallst, the third largest; on a flat stalk. Stipulas awl-shaped, pale, hairy. Flowers axillary, solitary, inodorous, on simple flakks shorter than the leaves, hairy, and fiddling upward; Calyx permanent. Petals obovate, half an inch long, dirty white, ribbed with dull purple. German roundish, hairy, crowned with a conical permanent style, exceeding its own length; stigma obtuse, marked with five rays. Fruit hairy, composed of ten corrugated tumid capsulces, knobbed rather than spinous, and beaked with the thick style. Limneus certainly alludes to this species, in the observation under his characters of the genus, and not to T. cissifera, which has the proper thorny fruit of the reef. It seems to us, that Sloane's definition and description of the flower belong, on the other hand, to cissifera, and that hence Limneus, nevertheless, took his specific name of maximus, which is nowtife suitable to the plant before us.

D 2
Fruit with ten horizontal awl-shaped thorns. Style deciduous.—Native of Ceylon. The **flem** seem woody, and probably perennial. Whole plant, excepting that circumstance, much like **T. terriferis** hereafter described, but the **leaves** are more hairy, or silky. Each of the five combined wrinkled **capsules** is armed with a pair of sharp, tapering, prominent thorns, twice the length of the capsule; but the base is nearly, or quite, defirute of spines. The flowers seem to be yellow, the fize of the leaf, with a short, thick, deciduous **style**.

Leaflets six pair, rather hairy, nearly equal. Fruit with ten horizontal awl-shaped thorns, and as many defiruted smaller ones. Style deciduous.—Native of the south of Europe, by way fides, as well as in cultivated ground. Dr. Sibthorp observed this species every where in Greece, retaining its ancient name a little altered, *gĕfis*. This is doubtlefs the *παδος χίομα*, or Land Caltrop, of Dioforides. The Turks call it *Demio Dikici*. We have an East Indian fpecimen from the late Dr. Roxburgh. The annual **root** produces many long, reddifh, hairy, leafe, slightly branched, prostrate *flem*. Leaflets smaller, and more numerous, than in our first species; leafs hairy than in the second; all nearly of equal fize, the outer, or terminal, ones being, if any thing, rather the smallest. **Flowers** yellow, on thortifh, fimple, folitary, axillary ifachts. Style thick, hardly fo long as the germin, deciduous. **Stigma** of five prominent rays. **Capsules** tuberculated, each with four awl-shaped thorns, of which the larger are scarcely half fo big as those of *T. lanuginosus*. Thoie at the base are ftrill smaller, pointing directly downwards, and ferve chiefly to diftinguish the furent preffes from the lat. The herb has been reputed cooling and emollient, ever fince the time of Dioforides. He fays the Thracians, who inhabited the banks of the Strymon, fed their hornes with the green plant, and made bread for themselves of its feeds.

4. **T. ciliaefis**. Cifus-flowered Caltrops. Linn. Sp. Pl. 554. Willd. n. 4. Ait. n. 3. Jacq. Hort. Schoenbr. v. 1. 54. t. 103. (T. terriferis major coraffavicis; Herm. Parad. 236. t. 236. T. terriferis americana, argemones flore flavo; Pluck. Phyt. t. 67. f. 4.)—Leaflets about eight pair, silky beneath, nearly equal. Petals twice as long as the calyx.—Native of meadows in the West Indies. A fwayne-plant with us, flowering in June and July, but not in general culture. The **root** is perennial, thick and woody, though Hermann fays annual. **Stems** many, herbaceoufe, difulfce, clothed with handfome leaves, whose upper leaflets are fmalleft. **Flowers** yellow, large and handfome, two inches wide, their ifachts longer than the corresfponding leaves. **Capsules**, according to Jacquin, each armed with four thorns of nearly equal fize.

**TRIBULUS Marinus**, the caltrop-shell, in Natural History, the name of a pecufiar species of the purpura. It is of a whitifh colour, and has three rows of thorns.

**TRIBUNAL, Judgment-Seat**, the seat of a judge.

The **tribunal**, in a court of justice, is properly the seat or bench on which the judge, and his associates, are placed, for the administration of justice, &c.

The word is Latin, and takes its origin from a seat raised from the ground, on which the tribunal of the Roman people was placed to administer justice.

**TRIBUNAL, among the Ancients**, was also a place from whence the people were harangued.

Among the Romans, it was an eminence in a temple, or a forum, as that called *pro rei publica*, where the people were harangued in tribes.

The French architects likewise use the word tribunal for a gallery or eminence in a church, or any other place, in which the muif is placed for a symphony or concert. Tribunal, or tribunal, is also used for a room or hall in which justice is administered; fuch, e.g. as the courts at Weftminster.

**TRIBUNE of the People, Tribune Plebis, in Antiquity**, a Roman magistrate, chosen out of the commons, to protect them against the oppressions of the great, and to defend the liberty of the people against the attempts of the senate and confuls.

The tribunes of the people were firft eftabfihed in the year of Rome 260. The firft defign of the creation was to shelter the people from the cruelties of fufurers, and to engage them to quit the Aventine mount, whither they had retired in difpleafure.

Their number, at firft, was but two; and the next year, under the confulate of A. Polibinus Arunacus and Caffius Viccellinus, there were three more added; and this number of five was afterwards increafed by L. Trebonius to ten.

The appellation tribunal was given them, because they were at firft chosen out of the tribunes of the army. See the article following.

The tribunes were, as it were, the heads and guardians of the people. They called afsemblies of the people when they pleased; and in thofe afsemblies they frequently annulled the decrees of the senate. Nothing could be concluded without their confent, which they expressed by fubfcribing the letter T at the bottom of the decree. They had it alfo in their power to prevent the execution of any decree, without giving any reafon for it, and merely by fubfcribing *Veto*. This interpofition was called *interr附属*.

They fometimes even called the confuls and ditector to account for their conduct before the people. The tribunes of the people, by virtue of their office, claimed and exercifed a power of sumoning the fenate at any time, whenever the affairs of the people required it, though the confuls themselves were in the city. It has been taken for granted, on the authority of Valeriu Maximus, that the tribunes of the people, on their firft creation, were not admitted into the fenate, but had feats placed for them before the door in the vestibule. But we may reafonably conclude, that a magiftrate fo ambitious and powerful, who could controul, by his fingle negative, whatever paffed within doors, would not long be content to fit without. Dionyf. Halic. x. 31. Middlet. of Rom. Senat. p. 129. Val. Max., lib. ii. cap. 27.

A. Gellius fays that they were not made fenators before the law of Atinus, who is suppofed to be C. Atinus Labeo, tribune of the people, A.U. 623; but that cannot possibly be true, fince it is evident from the authority of Dionyfius, that near four centuries before, the tribunes, by the mere weight and great power of their office, had gained an actual admiffion into the fenate, within two years after their firft creation; in which we find them debating and enforcing, with great warmth, the demands of the commons, for a liberty of internarriages with the nobles, and the choice of a plebeian conful. So that the intent of this Atinus law could not be, as it is commonly underftood, that the tribunes fhouid be fenators in virtue of their office, for that they had been from the beginning; but that for the future they should always be chosen out of the body of the fenate, or, which is the fame thing, out of thofe who had already borne the office of quafltor. A. Gell. xiv. S. Vide Pighil.
TRI

Syllus, the dictator, was the first who presumed to put a stop to the encroachments of the tribunes, A.U. 672; but under Cotta, the conful, they recovered part of their power, A.U. 679; and in 683, Pompey the Great re-established them in the possession of their ancient privileges. Their power subsisted till the time of Julius Cæsar. And in the year of Rome 731, the senate by a decree transferred the whole authority of tribunes of the people to Augustus and his successors, so that they had little more than the name and form of magistrates; whence the emperors were laid to be tribunition potestate donati. Accordingly, Augustus himself was tribune for thirty-seven years; Tiberius assumed the fame quality; as likewise did his successor; signifying the year of their tribunate on their medals and coins; but their design in it was only to poffefs themselves of all the authority, that there might be nobody to oppose them.

In the time of the emperors Nerva and Trajan, the dignity of tribune of the people was a mere title, without office and honour; and thus it continued till the reign of Constantine the Great, after which there occurs no mention of this magistrate.

TRIBUNES of the Soldiers, Tribunus Militum, or Militaris, an officer in the Roman army, who commanded in chief over a body of forces, particularly a division of a legion; and was much the fame with our colonel, or the French mestre de camp.

There is a distinction of the tribunes into latidivisi and angulatdivisi, those born of noble families were allowed, after they were made tribunes of a legion, to take the latidivus. The rest were only to wear the angulatdivus; whence Suetonius takes care to inform us, that his father was tribunus latidivus of the thirteenth legion. Over these tribunes of legions and cohorts, there were other tribunes who commanded in the absence of the consuls, and who were invested with a confular authority. Budeus have thefe to be much the fame as the marshals of France, or, at least, as our lieutenants-general.

Romulus likewise established a tribune of the cavalry, tribunus equitum, who was the fame with the magister equitum under the dictators, and the chief officer after the kings.

The tribunes of the soldiery were of an elder standing than those of the people; those latter being elected out of the former. Varro will have it they were called tribunes, because, at first, they were only three in number in each legion, when the legion consisted of three thousand men, taken out of the three tribes then on foot. In proportion as the legion was increased, the number of tribunes was likewise increased to the number of six.

At first, the nomination lay in the general of the army; but in the year of Rome 391, it was appointed, that the people should nominate one part, and the general another; the latter were called Rufus, from Rutilius Rufus, who paffed that law.

Those chosen by the people in the comitia, were called comitati; they were indifferently either patricians or plebeians; and they had the fame marks of honour as the consuls themselves. The tribune of the pretorian cohorts was the captain of the guards.

TRIBUNE was also an appellation given to various other officers; as the tribunus aræs, tribune of the treasury, Tribunus aræs, or Roman light-horse, the officer who commanded them. Tribunus fabricarum, those who had the direction of the making of arms. Tribuni marinorum, tribuni navicorum, and tribuni vulgatissimum, mentioned in the Theodosian Code, as intendants of the public shows, and other diversions.

The title of tribune, tribunus, was also given to the chief of each tribe.

TRIBUNITIAN, Tribunitius, a term among antiquaries and medallists. The tribunitian power was the dignity, office, or authority of a tribune of the people.

This power was assumed by the emperors, and makes one of the chief titles they bear on their medals: the quality was first introduced by Augustus, to keep the sovereign authority over the other magistrates without either taking that of dictator or king. Indeed, it was offered to Julius Cæsar, but he despised it. Augustus is the first who used it, and his successors followed his example. They reckoned the years of their empire on their medals by thofe of their tribunitian power.

This power was sometimes given them for a certain number of years, and sometimes for ever. Sometimes the emperors would communicate the power to such as they associated, or as they intended to succeed them: and Tiberius held it fifteen years with Augustus. But this practice only obtained till the time of Valerian and Gallienus. After them we only find TR. P. II. in Claudius; TR. P. I. in Aurelian; and TR. P. in Probus. This, however, is only to be understood of medals; for in inscriptions we find it after that time.

Cardinal Noris and F. Pagi have disputed about this tribunitian power, in which it confided. The first maintains, that it did not at all differ from that of the ordinary tribunes, which confided in three things: 1. In the right of opposing all the acts and resolutions of the other magistrates. 2. In that it rendered their persons sacred and inviolable. 3. In a power of making edicts and laws.

F. Paggi affirms, that it made an addition to the power of the tribunes; that the privilege it conferred of making edicts, was more ample than that of the ordinary tribunes; besides, that it carried with it a power of convening the senate at pleasure.

M. Spanheim is of F. Pagi's opinion; he believes that the tribunitian power had much the advantage of the tribunes: 1. In that it was peculiar to the patricians, and did not reduce the person who held it to the degree of a plebeian. 2. In that it was not confined to the city of Rome alone, like the other; but that it extended throughout the empire, as well as the proconsular power, which was usually annexed to it. 3. That the dignity of the tribunes was inferior to that of the pretors; whereas the tribunitian power of the Caesars conferred, according to Tacitus, a sovereign authority over all magistrates, and rendered such as it was communicated to, equal to the emperors, and even made them their colleagues in the empire; besides the power of oppressing the enterprizes of all the other magistrates; and that it rendered their persons sacred, and gave them a right to assemble and dismiss the senate; which were privileges the tribunitian power had in common with the tribunes.

F. Hardouin thinks we should distinguish two tribunitian powers; the one civil, the other military; but the proof he brings of them is very weak. M. Spanheim says, his distinction is only founded on vain conjectures, none of which deserve notice.

The learned are greatly divided as to the month and day on which the tribunitian power commenced: Sigonius and Petavius will have it begin on the 1st of January; others, as Perizonius, on the fifth of the calends of July: M. Theinard, on the fourth of the ides of December: Ouerhuis, cardinal Noris, F. Pagi, &c. on the day of the emperor's accession.
acception to the empire; with this difference, that F. Pagi takes it to be on the fifth of the calends of the month in which the emperor was proclaimed; and that this day was, for this reason, held sacred among the Romans.

F. Harodine thinks, that on medals the tribunitian power commences on the anniversary of the building of Rome, viz. the eleventh of the calends of May, excepting on the Greek medals, where it begins in September, in regard this month, which began the Greek year, was near the time when the tribunitian power was first conferred.

Of all these sentiments, the most probable is that of Omphrius, &c. setting aside the restriction of F. Pagi. See M. Spanheim, Dissert. xii. tom. ii. p. 429.

TRIBUTA COMITIA. See COMITIA.

TRIBUTARY, TRIBTARIUS, one who pays tribute to another, in order to live in peace with him, or to share in his protection.

The republic of Ragusa is tributary to the grand Turk; so also is the chieft of Little Tartary, &c.

TRIBUTE, TRIBUTUM, a tax, or impost, which one prince or state is obliged to pay to another, as a token of dependence; or in virtue of a treaty, and as a purchase of peace.

The Romans made all the nations they subdued pay them tribute. Mahomet laid it down as a fundamental of his law, that all the world should pay him tribute.

In the states of the grand signor, Christian children are taken, by way of tribute, to make agemoglans, janizaries, &c.

Tribute is sometimes also used for a personal contribution, which princes levy on their subjects by way of capita tion, or poll-money.

In this it differs from an impost, which is properly what is laid on merchandise.

TRICADIBA, in Ancient Geography, an isle of India, upon the coast, on this side of the Ganges, in paling from the gulf of Caintecilo to the Colchic gulf, and to the S. of the isle of Heptanisia.

Trolemy.

TRICAE, in Botany, so called from ΢.Ε., ζα, a hair, because they seem composed of a horse-hair rolled, or partly folded, into a little round black head, are the peculiar fructification of the genus of Lichens named GYROPHORA. See that article; as well as Lichenina, their eighth kind of receptacle.

TRICALA, in Geography, a town of European Turkey, in Macedonia, on the Strimon; 50 miles E.N.E. of Saloniki.—Alfo, a town of European Turkey, in Thespho; 21 miles S.W. of Larissa.

TRICALORE, a town of Hindostan, in the Carnatic; 38 miles W. of Pondicherry. N. lat. 11° 58'. E. long. 79° 21'.—Alfo, a town of Hindostan, in the Carnatic; 17 miles S. of Tanjore.

TRICARICO, a town of Naples, in Basilicata, the see of a bishop, suffragan of Acerenza; 13 miles S.E. of Acerenza. N. lat. 40° 43'. E. long. 16° 8'.

TRICARIUM, in Botany, a genus of Loureiro's, the name of which alludes to the three nits of the fruit, being derived from τρις, three, and καρδόν, a nut.—Loureir. Cochin. 577.—Clas and order, Monotaet Tetrandria. Nat. Ord. Rhamni, or possibly Ebeni, of Jussieu?

Female, interf ered with the male, Cal. Perianth inferior, minute, in four deep ovate divi lions. Cor. none. Pfl. German superior, roundish; style none; stigma lacinated.

Peric. Drupa roundish, fliehy, of three cells. Seed. Nuts solitary in each cell, roundish, with three furrows.

Female, Calyx in four deep segments. Corolla none. Stigma lacinated. Drupa with three nuts.

T. cochinchenfis.—Found in the woods of Cochinchina, where it is known by the name of Cay Trâm ung. A tree of a middling stature, with ascending branches. Leaves alternate, small, ovate, entire, smooth. Flowers red, in long, simple, slender, aggregate, nearly terminal spikes or clusters. Drupa of a moderate size, yellow, smooth, cat able.—We cannot refer this plant to any described genus, nor are we certain whether it belongs to either of the above natural orders, or to the Euphorbii, or perhaps the Terebin taceae, of Jussieu. Difficulties attend each supposition.

TRICASSES, in Ancient Geography. See TRECASSES.

TRICASTINI, or TRICASTENI, a people of Gallia Narbonensis. Hannibal passed through this country in his way to the Alps. Mention is made of these people at the time of the march of the Gauls into Italy, under the conduct of Bellovicius; and Pliny as well as Ptolemy take notice of them, the former specifying Augusta as their capital. It is certain that they inhabited the left bank of the Rhone, in a small country called Tresca.

TRICCA, a town of Greece, in Thessaly, in the Elykite territory. A modern place, named "Triaca," gives its jult position, and answers to Strabo's account of the situation of this town. Venus was worshipped in this city, and the inhabitants offered her sacrifices of wine.

TRICCIANA, a town of Pannonia, on the route from Sirmium to Carnuntum, between Pons Mauiliitanius and Cimbriae. Anton. Itin.

TRICE, in Geography, one of the Nicobar islands. N. lat. 7° 30'. E. long. 94° 5'.

TRICENNAL. See TRENIAL.

TRICEPS, in Anatomy, a name given to a large muscle of the arm, and to one of the thigh, from the circumstance of its arising by three distinct portions.

Triceps adductor cruris, (triceps femoris; taws-pubis, taws-pubi, and ischi femorii; adductor longus, adductor brevis, and adductor magnus; long, short, and great heads of the triceps). This muscle is placed at the upper and inner part of the thigh, consisting of three flattened portions, distinct from each other, making up the large mafs of muscle on the inside of the limb, and extending from the pelvis to the linea alperea of the thigh-bone.

The long head of the triceps, adductor longus or primus, the first in order of the three portions towards the front, is elongated and flattened, narrow above, and considerably wider below, and extends from the front of the pubes to the middle of the linea alperea. It arises by a narrow but strong tendon from the pubes, close to the symphysis; the muscle descends, passing at the same time obliquely outwards and backwards, and increasing greatly in breadth: it terminates below in a broad and flat aponeurosis, fixed to the middle of the linea alperea, in an extent of about three inches. Some fibres join the tendon of the adductor magnus, while others unite with the vastus externus. The facia lata, the fatorinus, and the crural artery, cover it in front; it covers behind the two other adductors. Its outer edge is parallel to the inner margin of the pectinals, and connected to it by a cellular line: its inner margin is much longer, and covered, in nearly its whole extent, by the gracilis.

The short head, adductor brevis or secundus, is also of a flattened figure, placed at the upper and inner part of the thigh, and extending from the pubes to the upper part of the
TRI

linea afera. It arifes, principally by flechy fibres, from the anterior surface of the body and ramus of the pubes; it paffes obliquely downwards and outwards, with a little obliquity backwards, becoming broader and thinner, and having an attachment of about three inches to the linea afera, from the little trochanter downwards. Here it is closely connected to the two other adductors, and to the pectoralis. The perforating arteries go through its fibres. The pectoralis and adductor longus cover it in front; the adductor magnus behind. The inner edge is partly covered by the gracilis, partly concealed by the frift and third adductors: the outer correfponds to the obturator externus and the tendon of the pefos magnus.

The adductor magnus or tertius, or the great head, is a broad and thick mass, flattened, nearly triangular, placed at the inside of the thigh, where it reaches from the ifhiun to the whole length of the linea afera, and to the tubercle of the internal condyle. It arifes, by a strong aponeurosis and by flechy fibres, from the external surface, and from the margin of the ramus and tuberosity of the ifhiun. From this point the muscular fibres spread out into a great breadth, and take very different directions; the superior going nearly tranfverfly, the middle obliquely, and the inferior almoft perpendicularly downwards. The general direcHon of the muscle is from above downwards, and from within outwards. Its attachment begins at the upper end of the linea afera, juft below that of the quadratus: it is fixed to the whole length of that line, being connected to the two preceding muscles. When the linea afera bifurcates at its termination, the adductor magnus divides into two portions; an external or posterior, which ends in a point between the vallus internus and the short head of the biceps; and an internal or anterior, which is connected to the edge of the vallus, and descends with it to the internal condyle. These two portions have between them an interval, occupied by the femoral artery and vein: this interval is covered in front by an aponeurosis, extended from the adductor to the triceps, and paffing over the femoral artery. There are other openings in the aponeurosis for the paffage of the perforating arteries. The adductor magnus is fixed to the linea afera by short aponeurofes; and to the tubercle of the internal condyle by a strong tendon, which is expanded above into a broad aponeurosis. The muscular fibres paſs between the tendon and aponeurofes, which fix the muscle to the ifhiun, and those which are connected to the femur. The internal fibres are very long, and directed obliquely downwards and outwards: the middle ones are shorter, and directed more outwards, and the external or upper are the shortest, and nearly tranverse.

The firft and second adductors, the fartorius, and the crural artery, cover it in front: the femi-tendinosus, femi-membranofus, biceps, gluteus magnus, and fasciate nerve, cover it behind. The inner edge is covered by the gracilis, fartorius, and fadica: the outer edge is the infcription in the linea afera. The upper margin, or the base of the triangle, is parallel and close to the under edge of the quadratus; the lower extremity, or apex, is the tendinous attachment to the condyle.

The triceps will move the thigh in the direcHon of adducHon, or towards the opposite limb: it will carry one thigh across the other, as in fitting fros'-kneèd: it will pref the thighs against any thing between them, as the fides of the horfe in riding. The firft and second heads will bend the hip; the third will extend it, when it has been previously bent. All three will rotate the thigh outwards. By drawing the thighs inwards, the triceps mufcles keep them perpendicularly under the pelvis, fo that they support it, and through it the whole upper parts of the body. When we stand on one leg, the triceps will regulate the degree of inclination of the pelvis over the thigh, and prevent it from falling over on that side.

TRICEPS extenfor cubiti, (triceps brachialis; anconus longus, externus, and internus, Winthrop; fcapulo-humero-olecranien,) a large thick mufcle, of an elongated figure, covering the back of the arm, and extending from the fcapula and humerus to the olecranon. Its long head arifes from the inferior edge of the fcapula, juft below the glenoid cavity, by a flat tendon, about three-quarters of an inch broad; the second or external head commences, in a pointed form, from the back of the humerus, a little below its head; and the third, internal, or shorteft head, begins on the inner and posterior part of the humerus, an inch below the second. The two latter are separated from each other by an interval, in which the profunda humeri major artery runs, accompanied by the radial or muscular spiral nerve: this veielf and nerve continue their course, from the inner to the outer sides of the limb, between the muscle and the bone. Below the points mentioned already, as the origins of the second and third heads, thefe portions arife by flechy fibres from the whole posterior surface of the humerus, except where the radial nerve and the profunda humeri pars, and from the inter-muscular aponeurofes fixed to the lateral ridges of the bone. The long or middle head continues direct from the others for some distance, paſses behind the shoulder-joint, between the teres major and minor mufcles, and in front of the latissimus dorsi; it then joins the two others. It is firft thin and flattened; then increases in fize. The two other heads are pointed and thin above, and increafed gradually; they all then join about the middle of the humerus, which is the thickest part of the muscle, for below it again decreases. From the aponeurosis of the middle head, and from the back of the humerus, the fibres are continued obliquely downwards and backwards into a broad and flat tendon, which covers the lower and posterior part of the muscle, becomes narrower and thicker as it defends, paſses behind the elbow-joint, clofly adhering to its fynovial membrane, and is inerted into the upper and posterior rough extremity of the olecranon. Several fibres are detached from it to the fadica of the fore-arm, and particularly to that part of the fadica which covers the anconus.

The posterior surface of this muscle is convex; covered above by the teres minor and deltoid, and in the reft of its extent, merely by the fadica and skin. The anterior surface is in contact above with the subcapularis, teres major, and latissimus dorsi; with the whole back of the humerus; and with the fynovial membrane at the back of the elbow. The outer edge is fixed to the external ridge of the bone, and to the external intermuscular aponeurosis, the attachment being interrupted only at the paffage of the radial nerve. The internal edge is fixed to the corresponding parts on the infide: the ulnar nerve lies on it. The upper extremity is divided into three portions, forming the three heads already described: the lower extremity is fingle.

The triceps extends the elbow-joint, by moving either the bones of the fore-arm on the arm, or vice verfa. Its long head may carry the arm backwards.

TRICEPS, in Mythology, a furname given to Mercury, because he exercises his functions in heaven, on earth, and in the infernal regions, and is exhibited under three different forms, according to the three different places in which he is employed.

TRICERA, in Botany, from τρίς, three, and κερας, a horn, because of the three horns, originating in the permanent
nent styles, which crown the seed-vessel. Dr. Swartz had
originally called this genus *Cranzia*, but another having
been so named by Schreber, he adopted the above, which is
very expressive.—Swartz Ind. Occ. 331. t. 7. Schreb.
v. 4. (*Cranzia*; Swartz Prodr. 38.)—Clafs and order,
*Monocica Tetrandria*. Nat. Ord. Tricoca, Linn. Euphor-
bis, Juss.

Gen. Ch. Male, *Cal. Periandrum* of one leaf, deeply di-
vided into four lanceolate, acute, erect, coloured segments.
Cor. none. Stam. Filaments four, fleshy, cylindrical, in-
cining to ovate, erect, longer than the calyx; anthers ter-
mal, ovato-lanceolate, acute, erect, furrowed along oneside, recurved after flowering.

Female, in the same tufft, or cluffer, *Cal. Periandrum* of
five ovate, acute, erect, coloured, permanent leaves. Cor.
none. Pijf. German superior, somewhat triangular; fylies
three, short, somewhat conical, separable at length into two
parts; ftigmas linear, longer than the fylies, spreading, re-
curved, channelled, permanent. Peric. Capsule turbinated,
triangular, with three cells, three valves, and three recurved
horas, each horn splitting, by the opening of the elatic
capsule, into two parts. Seeds two in each cell, oblong,
triangular, polished, each enveloped in a whitish membranous
lac tunic.

Eff. Ch. Male, Calyx in four deep segments. Corolla
none. Stamens fleshy.

Female, Calyx of five leaves, inferior. Corolla none. Styles
three. Capsule with three cells, three elastic valves, and
three horns. Seeds in pairs, with a membranous tunic.

333. Willd. n. 1. (*Cranzia levigata*; Sw. Prodr. 38.
Val. Symb. v. 2. 99.)—Leaves ovate-lanceolate, triple-
rilled; veins beneath. Umbels axillary. Native of
bushy hills, in the western part of Jamaica, flowering in
spring. *Swartz*. Vahl received it from Santa Cruz.—A
branching fhrub, two or three feet high; its branches long
and spreading, smooth, leafy, obscurely quadrangular.
Leaves flaked, opposite, two-ranked, an inch long, acute,
convex, entire, very smooth, rather rigid. Foliage
short, round. Flowers whitish, in small, axillary, opposite, flaked
umbels; the males from four to eight, with little white
opposite *bracteas* on their partial flanks; female solitary in
the centre, rather larger, fefeile, conpous for its long
spreading ftigmas. Capsule the size of a large pea, with three
taper horns, exceeding its own length. Seeds black, and
flining, in a loohe white tunic. Dr. Swartz jufly indicates
the affinity of this plant to *Buxus*, from which it is prin-
cipally distinguishft by the want of a corolla, the form of
the filaments and ftigmas, and the tunic of its seeds.

2. T. citrifolia. Lemon-leaved *Tricera*. Willd. n. 3.
—*Leaves ovate-oblong, pointed, triple-rilled, veiny on
both sides. Clusters axillary.*—Gathered by M. Brede-
meyer in the Caraccas. A fhrub fifteen feet high, refem-
bling the Coffee-tree, branched, with a pale-grey bark, and
hard yellow wood. Leaves rigid and thining, four inches
long, and two broad, on short falks. Clusters about an
inch in length, of about ten white male flowers, on short,
alternate partial falks, with minute, acute *bracteas*, and one
solitary, fefeile, terminal female flower. Filaments a little
compressed, most tuftid in the upper part. Fruit much
in the foregoing.

3. T. cordifolia. Heart-leaved *Tricera*. Willd. n. 3.
—*Leaves elliptical, obtuse, veiny; somewhat heart-shaped
at the base. Flowers in lateral tuffs.*—Native of the
West Indies.—A fhrub, with round grey *branches*; the
young ones somewhat quadrant, smooth. Leaves oppo-
site, falked, half an inch long, corous, entire, finely
veined on both fides, sometimes emarginate; thinning above;
paler beneath. Flowers small, on the last year's branches.
Willdenow.

TRICEROS, a genus of Loureiro's, has precisely the
same derivation as *Tricera*. (See that article.) The
latter being a clear and well-established genus, we cannot
allow one whose history is obscure, and which may possibly
be already known to systematic botanists, under some other
denomination, to "exalt its horns" against its brother.
As to priority of date, there is little to confider, they having
been published within a year of each other, the author of
each thinking his the original name. We shall, with-
standing, here give the characters of the *Tricera*, for the
information of those who may wish to inquire what it is.—
Loureir. Cochinchl. 184. — Clafs and order, *Pentandria*

Gen. Ch. *Cal. Periandrum* inferior, of five acute, spred-
ng, permanent leaves. Cor. Petals five, oblong, spreading,
longer than the calyx. Stam. Filaments five, capillary,
about the length of the petals; anthers ovate, of two cells.
Pijf. German superior, roundifh, unequal; fylies three,
short, distant from each other at the base; ftigmas fimple.
Peric. Berry corous, round, at the base, with three
horns at the top, of three cells. Seeds roundifh, pointed,
two in each cell.

Eff. Ch. Calyx of five leaves. Petals five, oblong,
Berry superior, of three cells. Seeds two in each cell.

Obf. Loureir fays "bacea dfermens," by which, ac-
cording to his frequent mode of expression, he means there
are two feeds in each of the three cells; at leafl, fo we feel
ourfselves oblige here to understand him.

1. T. cochinchenis. Cay áu rang of the natives of
Cochinchna, where this plant grows wild on the hills. It is
a tree of a middling stature, with spreading branches. Leaves
bipinnate, with two pair of ovate, pointed, ferrated, rigid
leaflets, bides a terminal one, in each subdivision. Flowers
white, in loofe, nearly terminal, clusters. Berries small,
ufelies.

TRICTO, in Geography, a town of Naples, in Cala-
Bria Citra 14 miles E.S.E. of Scalea.

TRICHECHUS, in Zooloivy, a genus of the order of
Bras, and clafs of Mammalia, in the Linnean fystem: the
characters of which are, that it has no fore-teeth in the
full-grown animal, either above or below; that it has foltary
ftuks in the upper jaw; that the grinders on both fides are
formed of a rugged forny ifubflance; that the lips are gen-
imated or doubled; and the hinder feet, at the extremity of
the body, united into a fin.

This genus is altogether marine, comprehending few
species. Gmelin, in his edition of the Linnean Syftem,
enumerates the three following

Species and Varieties.

ROSMARUS, the Rosmarus of Johnston, the Morfe of
Baffon, the Sea-borf of Ray and Ellis, and the Arctic
Wurfs of Pennant and Cook's late voyage. It is charac-
terized by its dilant, exfected ftuks. It inhabitsthe Northern
feas, and chiefly within the arctic circle. It grows to a
large ifize, having been found 18 feet long, and 12 feet in
girth round the body. Its form is inelegant; having a
small head, short neck, thick body, and short legs; the lips
thick, and the upper one cleft into two large rounded lobes,
the surface having numerous semi-transparent bristles of a
yellowish tinge, and about the ifize of a fraw in diameter,
and three ifeaces long, pointed at their extremities; the
eyes small; round orifices instead of ears; the skin thick and wrinkled, and scattered over with short brownish hairs; with five toes on each foot, connected by webs; the hind-feet broader than the fore-feet, and the tail very short. In the upper jaw are two long tusks, sometimes two feet but generally about one foot in length, without cutting teeth, and with four roundish grinders. These animals are found about the northern parts of America, in the gulf of St. Lawrence between 47° and 48° lat., in Davis's Straits, and within Hudson's bay in lat. 62°; in great numbers about Spitzbergen, also on the coast of Greenland and of Nova Zembla, and on the headlands extending towards the north pole. They are gregarious, produce their young, one at a time, early in the spring, and feed on sea-plants, shell-fish, &c.

Unprovoked the walrus is harmless, otherwise furious and vindictive. The female, when surprised on the ice, flings its young into the sea, plunges after it, and having carried it to a safe distance, returns with great rage to revenge the injury. They sometimes flay their teeth in the boats, to sink them, or crawl under them, to overcast them, indicating, by gnashing their teeth and roaring frightfully, great tokens of rage. Their attachment to one another is very strong; for a wounded walrus plunges to the bottom, and rises again suddenly with a number of attendants to attack the boat whence they received insult. They are said to lie on the ice in herds of many hundreds, loudly roaring, and giving notice of ice in the night or in a fog, when it could not be seen: some of the herd are always on the watch, who, on the approach of danger, awaken the rest. They are soon frightened by a flash in the moulquet-pan, and plunge into the deep; but the female will defend the young to the last, on the ice or in the water; nor will the young one quit the dam, though he be dead. In the gulf of St. Lawrence, this animal is called a sea-cow, and it is said to resemble a cow much more than a horse, which name may probably be a corruption of the Russian name Morze. The teeth of the walrus are used for ivory: the animals are killed chiefly for the sake of the oil; and it is said that a very strong and elastic leather may be prepared from the skin.

DUGONG, the Dugen of Buffon, and the Indian Walrus of Pennant, with approximate, expired tusks. This animal inhabits the seas about the Cape of Good Hope and the Philippine islands.

MANATUS, the Manati or Sea-cow of Ray, and Lemanis of Buffon; without tusks, or slightly hairy; and with a horizontal tail in place of hind-feet. Found in the larger rivers as well as seas of Guiana, and growing to the length of 16 or 18 feet; the skin being dark-brown, with scattered hairs upon it; the feet with five toes; the body nearly of the same thickness to the tail, when it suddenly narrows; the tail flat, of the shape of a spatula, thicker in the middle, and thinner towards the edges. The T. Chloris, or Clufius's Manati, is supposed to be a variety; it grows to an enormous size in the South American rivers. As an article of food, it is said to be superior to any other animal of this genus, particularly the young. It is taken by means of harpoons. The Indians take great numbers, by making dams across the mouths of the shallow lakes formed by the floods. Dr. Shaw mentions a manati, called by the inhabitants of the country, on account of its gentle nature, "Matum," which, at the time of the arrival of the Spaniards, was kept by a prince of Hispaniola in a lake adjoining to his residence: it hated the Spaniards, but would offer itself to its Indian favourites, and carry over the lake ten at a time, flinging and playing on its back. The T. Hydropitheccus, or Sea-ape Manati of Pennant, is only known from the description of Steller, who, near the coast of America, saw a singular animal which he named a sea-ape, and which Pennant supposed to belong to this genus. It was an animal that delighted in frolic, and sported like a monkey.

T. Augrulis, the variety z of T. manatus, according to Gmelin's Linnaeus, but a distinct species in Shaw's Zoology; hairy, with four-toed ungualate feet, or with a horizontal tail in place of hind-feet; the round-tailed Manati of Pennant; growing to the length of 14 or 15 feet, and found in the rivers of Africa, particularly in the Senegal. The specimen in the Leverian Museum was about six feet and a half long, and three feet eight inches in circumference in the thickest part of the body, and in the thinnest part near the tail about two feet two inches. The flesh of this animal is said to resemble veal; but it is chiefly killed by the Negroes for the sake of its blubber or fat.

T. Borcaulis, a variety of T. manatus in Gmelin's edition of Linnaeus, but a distinct species in Shaw's Zoology; hairy, with feet furnished neither with toes nor nails; or with a horizontal tail in place of hind-feet, the white-tailed Manati of Pennant. It approaches nearly to the whale tribe; it never goes ashore, nor attempts to climb the rocks, like the walrus and the seal. It brings forth in the water, and, like the whale, flocks its young in that element. It inhabits the seas about Bering's and the other Aleutian islands, but never appears off Kamtschatka, unless blown thither by a tempest. It is the same species that inhabits near Rodriguez, or Diego Reys, an island east of the Mauritius, and probably extending to New Holland. These animals live perpetually in the water, but in calm weather frequent the mouths of rivers in great numbers, and approach in time of flood so near the land, that they will suffer themselves to be flattered with the hand; but if hurt, swim out to the sea, prefently returning again. They live in families, one near another; each consisting of a male, a female, a half-grown young one, and a very small one. The affection between the male and female is so great, that if the latter is attacked, the former will defend her to the utmost; and if she is killed, will follow her carcass to the shore, and for some days swim near the place where it was landed. They are very voracious, and when full of the fuit that grow in the sea, fall asleep on their backs. The back and flanks are generally above water, and gulls are found perching on their backs, in order to pick up the insects which they find upon them. They are taken by harpoons fixed to a strong cord; but when struck, it requires the force of thirty men to draw them on shore. When a manati is struck, its companions swim to its assistance, and make many efforts to overturn the boat, or break the rope of the harpoon, and others will strike at the harpoon with their tails. They make a noise, by loud breathing, like the snorting of a horse. Their size is enormous, some being 25 feet long, and 6000 lbs in weight. The circumference of the body near the shoulders is 12 feet, about the belly 20, near the tail 4 feet 8 inches, the head 31 inches, the neck near seven feet; and hence we may infer the deformity of the animal. Near the shoulders are two feet, or rather fins, two feet inches long, without fingers or nails; beneath they are concave, and covered with hair bristles; the tail is thick, strong, and horizontal, terminating in a thick black fin, and resembling the substance of whale bone; the skin is thick, hard, and black, unequal on its surface, like the bark of oak, so hard as scarcely to be cut with an axe, and without hair; beneath the skin is a thick blubber, tallow like oil of almonds. The flesh is coarser than beef, and will not soon putrefy; that of the young ones has the taffe of veal. The skin

TRICHETERÆ, in Natural History, the name of a genus of fossils, of the class of fibraria; the characters of which are, that they are not elastic, and are composed of straight and continuous filaments.

The word is derived from the Greek τριχής, capillary or fibres. The bodies of this genus are divided into those which have narrower filaments; and there are six known species of it, all which burn very readily to a fine powder, like the gypum; and some of them are found in particular places in such great abundance, that it would be very advantageous to collect and burn them. Hill.

TRICHESTRUM, the name of a genus of fossils, of the class of the felenites, but differing extremely in figure and structure from the common kinds.

The word is derived from the Greek τριχής, hairs or filaments, and αερής, a hair, and expresses a set of bodies, composed of filaments arranged into the form of a hair. The felenite of this genus are composed of filaments, scarcely any where visible arranged into plates or scales, but disposed in form of a radiated hair, made up of a number of disjunct fibres.

Of this genus there is only one known species, which is of a pale brown, and is composed of extremely fine and slender filaments. It is formed like the lepadinum in the accidentally open cracks in the septaria, or ludus Helmontii, and is no other way different from the bodies of that genus, than as in all the felenite the plates they are composed of are made up of filaments nicely arranged: in this, as in some other of those bodies, the filaments have never arranged themselves into plates at all, but are disposed into the form of a hair composed of single threads. This body very readily and regularly splits according to the arrangements of the fibres; and is in some parts tolerably pellucid.

It is found only in one place, so far as is yet known, which is under the cliffs of Sheppey island, in Kent; where it is very plentiful, and makes a very elegant figure on the broken masses of septaria, which are in immense numbers strewn upon the shore. Hill.

TRICHIA, in Botany, first, we believe, received its name from Haller, though he admitted some things into this genus of Fungi, which other botanists have rejected, or referred to other places. The above name is formed from τριχής, a hair, or bristle, in allusion to the internal masts of elastic fibres, gradually expanding after the head burfts. — Hall. Hist. v. 3. 114. Perf. Syn. Fung. 176. Lamarck Illust. 1. 896. — Clads and order, Cryptogamia Fungi. Nat. Ord. Fungi. Eff. Ch. Head at length burfting irregularly, permanent. Internal fibres compact, attached to the base of the head, expanding elastically, and discharging the powdery feeds.

To shew the limits of this genus, as defined by the most eminent botanists in this department, we shall give a comprehended view of Perfoon's eleven species.

Sect. 1. Head turbinata, or pear-shaped.

1. T. Botrytis. "Perf. Dip. Meth. 9. and 54." ("T. pyriformis; Hoff. Veg. Crypt. v. 2. t. 1. f. 1." ) — Stalked, clustered, opaque, dark red; flaks longer than the heads, combined, somewhat racemose. — Found on decaying trunks of trees in autumn. Several specimens, cohering together, form a sort of tuft. — Perfoon mentions a small and simple-stalked variety, with a solitary head, which he supposed may be T. serotina of Schradier's Journal, v. 2. 67. t. 3. f. 1, (not f. 2, as erroneously cited by the author, and by Perfoon; that being Stilbium tomens-tum, p. 65.) — The figure having been so widely mistaken, may account for the doubt expressed; but we are left in great uncertainty as to what Perfoon intended by this variety.

2. T. rubiformis. "Perf. Dip. Meth. 54. t. 4. f. 3. and t. 1. f. 3." (T. n. 2167; Hall. Hist. v. 3. 115. t. 48. f. 5.) — Stalked, clustered, of a shining blue; flaks combined, spreading at the base, shorter than the heads. — Not rare on the rotten bark of trees in autumn. There is a smaller variety, of a red or rusty aspect. Perfoon is remarkably incorrect in his citation of Haller, (n. 2162. t. 40. f. 2.)

3. T. fallax. Perf. Obf. Mycol. falc. 1. 59. t. 3. f. 4. 5. ("Clathrus flippitatus, reticulo deciduo; Schmid. Is. t. 33. f. 1—18." Sphaerocarpus ficicoides; Bull. Fung. v. 1. 130. t. 417. f. 3; excluding the synonyms. Mucor minutus; Jacq. Astr. t. 299.) — Simple, stalked; at first red; then of a dull grey. Bale of the head, and top of the flaks, plaited. — Found in autumn, upon soft rotten wood. The head when young is bright red, and roundish; by age it becomes pear-shaped, on a flak about its own length, and altogether of a dirty flat-colour, cracking and expanding at the top into a kind of cup. Jacquin's figure represents the young, Bulliard's the old, plant.

4. T. cladata. Perf. Obf. Mycol. falc. 2. 34. — "Simple, yellow and shining. Stalk rugged, elongated, tapering downwards." — Found on the trunks of trees, either solitary, or coiling dense tufts. It is among the larger species. The flak is slender, of a reddish-yellow. We have seen no specimen nor figure.

5. T. migripes. Perf. n. 5. (T. pyriformis; Perf. Obf. Mycol. falc. 2. 33. Bull. Fung. v. 1. 120. t. 417. f. 2.) — Rather scattered. Head pear-shaped, yellowish, longer than the blackish flak. — On the trunks of trees, but rare. The head is obovate and obtuse. Stalk half a line long, black, flading on a manifest membranous bafe common to many individuals. Perfoon remarks, that the flak in Bulliard's plate is thicker than his, besides being of the same colour as the head. He mentions also a smaller, common variety, verging towards an olive hue, and more brittle than the above-described. The following, originally thought distinct, are now reduced by Perfoon to the species before us.

7. T. cylindrica. Ibid. — Rather scattered, ochre-coloured. Heads cylindrical or ovate, contrasted in the middle. Stalk blackish, extremely short. — A pretty little fungus, occurring rarely on mosses, or the trunks of trees.

8. T. vulgaris. Ibid. 32. (T. turbinata; Sowerb. Fung. t. 85.) — Scattered. Head roundish, somewhat turbinata. Stalk blackish, extremely short; sometimes entirely wanting. — Frequent after heavy rains in autumn, upon rotten beech-trees; appearing when young in the form of white granulations, turning afterwards into the colour of yellow ochre, and more opaque. The flak in an early state is hardly distinguishable. Mr. Sowerby's synonym seems to us to belong to the following, as he himself supposes.

I. Florence. I."

7. T. albaea. Perf. Obs. Mycol. f. c. i. 62.—Scattered, fettie, roundish, or ovobate, abrupt at the base, olive-coloured. Internal hairs compact, yellowish.—Found rarely on the trunks of trees. Heads globular, or hemispherical, becoming by mutual pressure, when crowded, oblong, or somewhat cylindrical. Peronoff is doubtful whether this be a distinct species. We have seen no specimen.

Sect. 2. Head round, or kidney-shaped.

8. T. nitens. Perf. Obs. Mycol. f. c. i. 62. ("Lyco-perdon favagioneum; Batfich Elench. Fung. 257. t. 173.")—Crowded, fettie, globular, of a shining yellow or cinnamon-colour.—Found in autumn, about the decaying trunks of fir-trees, as well as on beeches. In the former case it is more opaque; in the latter more bright and shining. The head is occasionally a little turbinate.

9. T. varia. Perf. Obs. Mycol. f. c. 2. 32. (Lyco-gala latum, omnium minimum, refiforme; Mich. Nov. Gen. 216. t. 195. f. 4).—Rather crowded, yellowish, partly deflexed. Head kidney-shaped, roundish, or somewhat oblong.—Grows on rotten trees in autumn. Found by Michel in the celebrated gardens of Boboli, behind the palace Pitti, at Florence. He represents it as forming globular masses, the size of a large pea, each plant smaller than poppy-feed. The lateral ones appear to be deflexed, or forced outward, by those in the middle.

Sect. 3. Receptacle elongated, thread-shaped, creeping, simple, or interbranching like veins.

10. T. Serpula. "Perf. Dift. Meth. 10." (Mucor Serpula; Scop. Car. 493. t. 65).—Thread-shaped, unbranched, very long, somewhat zigzag, yellow.—On the trunks of trees in Carniola, near the roots. Scopoli. This is represented as a smooth yellowish thread, creeping like a Serpula, or Worm-shell, and resembling a small animal intelleine. It bursts and discharges, from every part, tufts of fine hairs beflreinkel with yellow powder. Scopoli. T. spongiodes, Villars Dauph. v. 3. 1961, is thought by Peronoff to be a variety of this. But the author's description of "from three to five little oblong, cylindrical, worm-like bodies, whole yellowish internal woolliness suffocates, and confounds them in one woolly mafs," indicates rather some of the former species, or perhaps Ansa Rica.

11. T. reitculata. "Perf. 1c. et Defer. Fung. f. c. 2. 46. t. 12. f. 1." (Lyco-perdon lintricular; Batfich Elench. Fung. 259. t. 30. f. 174).—Thread-shaped, branched, reticulated, yellow.—Found in autumn on the trunks and molly bark of trees, but very rare. We have never heard of this or the preceding in Britain. The present species is described as spreading to the extent of an inch, confluting of a yellow net-work, burbling here and there, and protruding tufts of yellow hairs, enveloping a powder, or seeds, of the same colour.

It will readily be perceived that the species of this genus, however curious, can, as yet, be imperfectly defined; nor are we certain how far the Arcycia, Stenonitis, Cribraria, &c. of Peronoff are entitled to rank as generally distinct.

TRICHIASIS, (derived from TRI, the hair,) in Surgery, sometimes also named entereus, is a faulty inclination of the eye-lashes inwards against the globe of the eye. According to Scarpa, the disease preffents itself under two distinct forms: the first is, where the cilia are turned inwards, without the natural position and direction of the tarsus being at all changed; the second consists in a morbid inclination of the tarsus, and consequentlly of the eye-lash towards the ball of the eye.

The first form of this disease is very rare, nor has it come under the observation of the experienced Scarpa more than once; and in this instance, only some of the hairs had changed their direction. The second species or form of trichiasis, or that which consists in a folding inwards of the tarsus and cilia at the same time, is that which is commonly met with in practice. This may be either complete, affecting the whole of the tarsus; or incomplete, occupying only a certain portion of the edge of the eye-lid, and most frequently near the external angle of the eye. Sometimes the disease is confined to one eye-lid; at other times it affects both; and occasionally the patient is afflicted with it in both eyes.

To these two species of trichiasis, some writers have added a third, which they call difficiliae, and which they suppose to be produced by a double and unusual row of hair. But this third species, as Scarpa observes, is only imaginary, and the reason of such subdivision seems to have arisen from not recollecting what was long ago remarked by Winlow and Albiumus, that although the roots of the cilia appear to be disposed in one line only, they nevertheless form two, three, and in the upper eyelid even four rows of hairs, unequally situated, and as it were confused. Whenever, therefore, in consequence of disease, a certain number of hair are separated from each other in a contrary direction and disorderly manner, the eye-lash will appear to be composed of a new and unusual row of them, while, in fact, there has been no change, either with respect to their number or natural implantation.

It is not an easy matter to determine precisely, says Scarpa, what are the causes which sometimes make a few of the hairs deviate from their natural direction, while the tarsus continues in its right position. They are commonly referred to cicatrices in consequence of previous ulceration, whereby the cilia fall off, and those which are growing are hindered from taking their proper direction. There must, however, be other causes sometimes concerned; for in the case seen by professor Scarpa, two or three hairs were turned inwards against the eye-ball, although there had been no preceding ulceration, nor cicatrices of any part of the tarsus. Indeed Scarpa is inclined to believe, that the small ulcers and fcar which are sometimes formed upon the internal margin of the tarsus, are more likely to produce the second form of the disease, or the inversion of the edge of the eyelid, and consequentlly of the cilia towards the globe of the eye. As these ulcers, when neglected, destroy the internal membrane of the eye-lids near the tarsus, it necessarily follows, that in proportion as they heal and dimmish, they draw along with them and turn inwards the tarsus, and hairs inserted into it. And since these little ulcerations do not always occupy the whole extent of the internal margin of the eye-lid, but are sometimes confined to a few lines, in the middle or extremity, near the external angle of the eye-lid; so after the cicatrices are formed, the whole or part of the hairs are not invariably turned inwards, but only a certain number of them, which correspond to the extent of the ulcers previously situated along the internal edge of the tarsus. Indeed, in every case of imperfect trichiasis from a cicatrix of the inner margin of the eye-lid, the tarsus and cilia are everwhere in their natural situation, except opposite the part where the ulcers formerly existed. Also, if the eye-lid be erected, its internal membrane, near that part of the margin of the eye-lid, will be found pale, rigid, and hardened, the inversion of its cartilaginous border and of the cilia being plainly a consequence of the contraction of the cicatrizied point.
Besides these causes, there are others which may produce the complaint. Chronic ophthalmies of long continuance sometimes have this injurious effect, in consequence of the skin of the eye-lid being kept for a long time in a state of dilatation and oedema, terminating in a relaxation of them. The cartilaginous margin of the eye-lid then loses the proper support of the integuments, inclines towards the eye-ball, and afterwards turns inwards, drawing the eye-lashes along with it in the same improper direction. Long-continued puriform discharge from the ciliary glands, likewise spoils the shape and confinence of the cartilage of the eye-lid, and therefore not unfrequently occasion trichiasis. Scarpa doubts, whether a spasmodic contraction of the orbicularis palpbralurum muscle can ever be a cause of the disease, notwithstanding what Mr. B. Bell has asserted upon the subject.

The annoyance which must necessarily result from the hairs perpetually pressing upon the cornea and white of the eye, may be easily imagined, even by those—who have little acquaintance with surgery. The evil is rendered still greater, by the hairs which are turned inwards becoming much longer and thicker than those which retain their natural direction. And although the trichiasis be confined to one eye, both the eyes usually suffer from the effects of the disease. Indeed, generally the eye on the found side cannot be moved without occasioning pain in that which is exposed to the irritation and friction of the inflected hairs. In almost all instances, both the eyes are very irritable, and incapable of bearing the light. As, in cases of incomplete trichiasis, the patient retains some little power of opening the eye-lids for the purpose of seeing, and that most frequently towards the internal angle of the eye, the head and neck are often inclined in an awkward manner, so that in children a distortion of the neck and shoulders is at last produced, which cannot be rectified without difficulty, even after the trichiasis is cured. Unfortunately, also, children are impatient of the uneasiness arising from the inflected hairs, and therefore, are continually rubbing the eye-lids, which act very much increases all the ill effects of the complaint, such as the varicose chronic ophthalmmy, opacity, and ulceration of the cornea.

The cure of the second species of trichiasis, or that which is commonly met with in practice, is accomplished by artificially evi ting the eye-lid, and fixing it permanently in its natural position, together with the eye-lashes, which so grievously irritate and press against the globe of the eye. According to professor Scarpa, this indication is perfectly fulfilled by the excision of a piece of the skin close to the edge of the eye-lid, of such a breadth and extent, that when the cicatrix is formed, the tarbus and margin of the eye-lid may be turned outwards, and sufficiently separated from the eye-ball, the cicatrix of the integuments affording a point of support fully adequate to the parts in their natural position and direction. Scarpa believes that there are now very few modern surgeons, who, with a view to the radical cure of this disease, place any confidence either in plucking out the inflected eye-lashes, bending them outwards, and retaining them by means of adhesive plaster, or in plucking them out and destroying their roots with cautic; much less in extirpating the edge of the eye-lid along with the hairs, or dividing the orbicularis muscle on the internal surface of the eye-lid, under an idea that the disease is sometimes produced by a spasmodic contraction of it.

The following is the mode of proceeding recommended by Scarpa: the patient being seated in a chair, if an adult, or, if a child, laid upon a table, with the head raised, and firmly held by an assistant, who must stand behind the patient, the surgeon is to pull outward, with the end of a probe, the hairs which irritate the eye. Then, with a pair of deftecting forceps, or the ends of his fore-finger and thumb, (which answer equally well, and, in many cases, much better than forceps,) the operator should lift up a fold of the skin of the affected eye-lid, taking great care that the piece which is taken hold of, corresponds exactly to the middle of the whole extent of the trichiasis; for, as we have already explained, sometimes the whole, sometimes a half, and, in other instances, only a third of the extent of the tarbus is inverted. The surgeon, with his left-hand, must raise the fold of the skin, more or less, according as the relaxation of the integuments, and the inversion of the tarbus, are more or less considerable. The reason of this is exceedingly evident, viz. that the greater the quantity of skin which is raised, the greater is the quantity which will be cut away. Supposing the patient to be an adult, as soon as the fold of skin has been raised in a certain degree, the surgeon must request him to open his eye, and if, in this act, the tarbus and eye-lashes resume their natural place and direction, the portion of skin already raised will be sufficient for the purpose. We must trust to our own judgment with regard to children, as they seldom let us have recourse to the mode of differentiation just related. When the integuments are elevated by means of a pair of deflecting forceps, and care is taken to lay hold of the skin precisely at the middle point of the whole extent of the trichiasis, it necessarily follows, that the consequent section of the skin will form an oval, and that the greatest width of the wound will correspond exactly, or nearly so, to the middle of the eye-lid, and its narrowed parts to the angles, or commissures of the same. This contributes very materially to make the cicatrix correspond to the natural fold of the eye-lid, and hinder the origin of a disease of an opposite nature to the one about to be remedied, towards the angles of the eye, viz. an eversion of the commissures of the eye-lids. See Ectropium.

Besides this caution relative to the situation and figure of the fold of the integuments to be cut off, the surgeon must be careful that the division of the skin be made very near the inverted tarbus. Were this circumstance neglected, the operator might have the mortification of finding, after the wound is healed, that although the eye-lid is shortened, on the whole, from the eye-brow to the place of the recession, yet it is not equally so at the space which is between the edge of the eye-lid and the cicatrix of the skin. Hence the tarbus would remain inverted as before, or not be sufficiently turned outward to keep the eye-lashes from rubbing against the eye. This inconvenience would oblige the patient to submit to a second operation, done lower down than the first.

Things being thus arranged, the surgeon, holding up the fold of skin by means of the forceps in his left-hand, is with a pair of probe-pointed, sharp curved scissors, to cut off the whole of the duplicate, being first sure that one of the blades of the instrument is applied close to the edge of the eye-lid. If both eye-lids should be affected, the same operation must immediately be done upon both of them, with such caution, and in such proportion, as the extent of the disease, and the degree of inversion of each eye-lid may require.

Scarpa next diffuses us from employing any future to unite the wound, and represents, that it will be sufficient to keep the eye-brow as much downward as possible, if the operation has been done on the upper eye-lid, or, if on the lower, to support it against the inferior arch of the orbit, by pressing it from below upwards, so as to keep the edges of the wound from becoming separated. Then the lips of
The wound are to be put into exact contact, by means of strips of adhesive plaster, which should extend from the inferior arch of the orbit to the zygoma, and the support of the wound in apposition will be still more securely effected by placing two compresse, one on the eye-brow, and another on the zygoma, together with a bandage.

On taking off the first dressings, the third day after the operation, the surgeon will find that the patient may open his eye with ease, and that the inverting tarus and eyelashes have resumed their natural position and direction. In the partial or incomplete trichiasis, or that which only occupies a half, or a third of the whole length of the tarus, and in subjects who have had the skin of the eye-lids very loose, Scarpa has often had the pleasure of finding the wound perfectly united on removing the first dressing.

When, however, only a part of the incision has healed, while the rest seems disposed to heal by suppuration and granulation, the surgeon covers the wound with a small piece of lint, spread with the ungument cerise; and if the fore should become flabby, it must be touched, every now and then, with the argumen nitrum, until the cure is perfected, which commonly happens in the course of a fortnight.

Thus far, Scarpa’s observations have related to the radical cure of the second, or most frequent kind of trichiasis.

With regard to the first form of this disease, or that in which the eye-lashes project against the eye-ball, without the natural position of the tarus being at all altered (a case which is fortunately very rare), the accomplishment of a cure is very difficult, since, as we have already explained, neither the pulling out of the hairs, nor burning the situation of their roots, are means at all to be depended upon for producing a complete cure of the disorder; and since turning the tarus out of its natural position would make the patient liable to an irreparable flowing of the tears over the cheek, attended with a chronic thickening of the lining of the eye-lid. The treatment of this species of trichiasis is still imperfectly understood, and seems to claim more attention than appears hitherto to have been paid to it. In the instance of this form of the disease which Scarpa met with, only two or three of the eye-lashes inclined against the eye-ball. He found, on turning the eye-lid a little out, opposite to the situation of the faulty hairs, that he could not, indeed, completely put them in their natural position; but he saw that he could thus remove them so far from the cornea, that they would not rub against it, without altering the position of the eye-lids so much as to occasion a perpetual discharge of the tears over the cheek. And, as in the patient alluded to, the skin about the eye-lid was very tene, Scarpa devised from the above rule, by making an incision with the back of a lancet, near the tarus, three lines long, and he took away a small piece of skin of the same length; but very little more than one line broad. When the cut healed, the operation was found to answer as well as the nature of the case would allow, though the cure was not complete, nor would it have obviated all inconveniences in cafes of greater extent.

The trichiasis being cured, something more always remains to be done, for the purpose of correcting the cause of the disease, as well as curing the disorder of the eye, occasioned by the previous friction and irritation of the inverted hairs. The usual indications are, to restore the tone of the vessels of the conjunctiva, to leffen the swollen Meibomian glands, and to remove any cloudsines of the cornea.

Two new methods of performing the operation, for the cure of trichiasis, have been recently proposed by Dr. Crampton and Mr. Saunders.

The following is the account which Dr. Crampton gives of his plan, which he tried in one instance with complete success. “Let the eye-lid be well turned outwards by an assistant; let the operator then with a lancet divide the broad margin of the tarus completely through, by two perpendicular incisions, one on each side of the inverted hair or hairs; let him then, by a transverse section of the conjunctiva of the eye-lid, unite the extremities of the perpendicular incisions. The portion of cartilage contained within the incisions, can then, if inverted, with ease be restored to its original situation, and retained there by small strips of adhesive plaster, or perhaps, what is better, by a suppositorium palpebrarum, adapted to the length of the portion of the tarus which it is intended to sustain, should one or two hair be displaced without inversion of the tarus.” Effay on the Entropion, p. 55.

Mr. Saunders entertained a favourable opinion of Dr. Crampton’s operation for the cure of the disease in its early stage; but he contended, such a vicious bending of the tarus inward was often the consequence of repeated ophthalmic, attended with ulceration of the conjunctiva and infide of the eye-lid; and that every endeavour to rectify the wrong position of the tarus, and restore its original direction, would be fruitless. Hence, he believed, that its excision was decidedly indicated; an operation which is said to be followed by no pain nor uneasiness, and which is sure in its effect. No particular shortening of the eye-lid ensues; the deformity is materially leffened; and unless the cornea be already too opaque, perfect vision is re-established.

Mr. Saunders directs a piece of thin horn, or a plate of silver, having a curvature corresponding to that of the eye-lid, to be introduced under this part, with its concavity towards the eye-ball. On this instrument the eye-lid is to be stretched. An incision is to be made through the integuments and orbicularis palpebrarum, down to the tarus, immediately behind the roots of the cilia. The cut should extend from the punctum lachrymale to the external angle. The exterior surface of the tarus is then to be dissected, until the orbital margin is exposed, when the conjunctiva is to be cut through directly by the side of the tarus, which must now be disengaged at each extremity. The punctum lachrymale must be left uninjured. The operation is described as being exceedingly simple, and if any embarrassment arises, it is from the hemorrhage of the ciliary artery, the blood sometimes obscuring the punctum lachrymale, just when the operator is about to divide the tarus by the side of it. No dressings are required, it being merely necessary to keep the eye covered for a few days. The skin will continue to be elevated, just as the perfect eye-lid was; and though left completely, yet enough to leave the pupil clear, when the eye is moderately directed upward. In all the cases in which Mr. Saunders operated, a fungus grew from the wound. He recommends the excrescence to be destroyed with cautic, or the knife.

Refpecting this operation, we shall merely observe, that it is more severe than that advised by professor Scarpa, and must leave more disfigurement. Unles, therefore, the latter method prove ineffectual, we see no reason for abandoning it.

Inversion of the lower eye-lid is much less common than that of the upper one. The late Mr. Saunders never saw this disease arise from the same causes which induce it in the upper eye-lid, though he acknowledges the possibility of such a cafe. However, he met with several instances of the affection, in consequence of encysted tumours, which,
as they increased, carried the orbital edge of the tarsus outwards, and, in the same proportion, inclined the ciliary edge towards the globe of the eye.

An inversion of the inferior palpebra is sometimes produced by inflammation and swelling of that part of the conjunctiva which connect the eye-lid with the eye-ball. In cases of ophthalmia, this membrane often forms between the latter parts a thick fold, which is situated just on the inside of the orbital edge of the tarsus, and pushes it outward; while the contraction of the orbicularis muscle turns the ciliary edge inwards, and inclines it between the swelling of the conjunctiva and the eye. In this particular case, Mr. Saunders assures us, that replacing the eye-lid in the early stage of the disease, and maintaining it so, until the ophthalmia has been lessened by proper means, will be found effectual. But when the conjunctiva is much thickened and indurated, Mr. Saunders recommends cutting such diseased part of it away, and the application of compresse to keep the orbital margin of the tarsus inward.

Albinus has recorded a species of trichiasis, which originated from the growth and inversion of one of the hairs upon the caruncula lachrymalis. The plan of relief consisted in plucking out the irritating hair; but, as Scarpa observes, it should have been mentioned whether the hair grew again, and in what direction. Scarpa on Diseases of the Eyes, ch. 4. Saunders on Diseases of the Eyes, chap. 3. Crampton on Entoreon. S. Cooper's Practice of Surgery, p. 308. edit. 3.

TRICHIDES, in Ichthyology, a name applied by the ancients for a fish of the harengiform kind, probably the pilchard, which they called also 'sardina and 'sardella.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, short, with five small teeth. Cor. Petals five, lanceolate, spreading. Nectary cylindrical or conical, tubular, with ten teeth, shorter than the petals, formed, as if it were, out of the ten combined filaments. Stam. Filaments none; anthers ten, erect, effile on the margin of the nectary, and rising above it, deciduous. Pfl. Germin superior, obovate, obscurely three-lobed; style short; stigma capitule, with three notches. Peric. Capsule roundish, slightly triangular, of three cells, and three valves at length reflexed, with partitions from the centre of each. Seeds solitary, pendulous, ovate, with a pulpy coat, or tunic.

E. Ch. Calyx with about five small teeth. Petals five. Nectary cylindrical, bearing the anthers on its teeth. Capsule of three cells, and three valves. Seeds solitary, with a pulpy coat.

Obi. The parts of the flower vary, or differ in different species, from five and ten to four and eight. The cells and valves of the capsule are, in some instances, but two, as in the Portea of Cavanilles. The seeds have truly a more or less pulpy coat, though not a distinct tunic. It is remarkable that Cavanilles has not admitted Trichilia into his Differations on Monadelphous Plants, where this genus is as much entitled to a place as any others of Jussieu's Melici. Probably he was not furnised with any materials to describe or delineate the species. The gardens certainly could not supply him.

1. T. birta. Green-flowered Trichilia. Linn. Sp. Pl. 552. Willd. n. 1. Swartz Obs. 171. (T. n. 1; Browne Jam. 278?) Pruno forte affinis arbor, folio alato, flore herbarcio pentaetapelo racememo; Sloane Jam. v. 2. 128. t. 220. f. 1.) -Leaves pinnate, of about seven elliptical, pointed, smooth leaflets. Clusters dense, stamens combined. -Native of Jamaica, in the meadows about Kingston and other places, on a dry gravelly soil. Browne calls it a florbus; Sloane a tree, about twenty feet high, with a smooth greyish bark, and sending out at the height of seven feet, or more, several declining branches. The leaves are feattered, not numerous, pinnate with an odd one; the leaflets opposite, an inch and half long, uniform, smooth, entire, dark green, on short partit flarks. Flowers greenish-white with purple anthers, in axillary compound clusters. Browne says the seeds of all the species are encompassed in a scarlet waxly substance. Linneus, and perhaps Browne, confounded this with the following. We do not find much reason for the specific name birta, which seems more applicable to the following.

2. T. spicoides. White-flowered Trichilia. Jacq. Amer. 128. Hort. Schoenbr. v. 1. 54. t. 102. Willd. n. 2. Swartz Ind. Occ. 730. (Eucymus claudice non ramo, folio alato, fructu rotundo tripyreno; Sloane Jam. v. 2. 103. t. 210. f. 2, 3.) -Leaves pinnate, of about fifteen ovato-lanceolate, pointed leaflets; downy at the edges. Clusters rather lax. Staminis distinct. -Native of mountainous woods in Jamaica and Hispaniola, flowering in the spring. Swartz. In the flowe at Schoenbr, according to Jacquin, it blossoms in September and October. -The stem is fifteen or twenty feet high, slightly branched at the top. Leaves a foot long; their leaflets much more numerous than the former, ovato-lanceolate, not elliptical, more or less hairy, especially at the edges. Clusters several, fewer crowded than in the foregoing. Flowers yellowish or greenish-white. Stamens not united, though closely converging into a cylinder, or cone. Capsule roundish, downy, the size of a small cherry. We should conceive this rather to be Browne's plant, which he terms subbifurata, but we have no specimen to determine the point.

3. T. emetica. Emetic Arabian Trichilia. Vahl Symb. v. 1. 31. Willd. n. 3. (Elcaja; Forsk. Ägypt. -Arab. 127.) -"Leaves pinnate; leaflets elliptical, downy beneath, the outer ones larger." -Frequent on the mountains of Yemen. The Arabs call this tree Roka. The flowers redembrace blooms. The fruit, mixed with perfumes, is used by the Arabian women for washing their hair. The ripe seeds are made into an ointment with oil of Sesamum, against the itch. Forskall found mention of the fruit, in an Arabic book, as an emetic, by the name of Djoum elka, whence he took his barbarous generic name above quoted. He describes this species as a large tree, with alternate downy branches. Leaves alternate, pinnate with an odd one, of nine oval-oblong, thallous leaflets, the lower ones two inches in length, the upper or outer ones three; all smooth above, but, according to Vahl, downy beneath; their common flark, about a fpton long, is also downy. Stipulas none. Stalks axillary, coriaceous panicled. Flowers twice the size of the leaf, greenish-yellow. Stamens united halfway up. Capsule obovate, downy, an inch long, with two seeds in each cell. Forskall, Vahl.

4. T. globa. Smooth Hannah Trichilia. Linn. Syt. Nat. ed. 12. v. 2. 294. Willd. n. 4. (T. havanaensis; Jacq. Amer. 129. t. 175. f. 38.) -Leaves pinnate; leaflets obovate, obtuse, smooth; tapering at the base; the outer-most
moist gradually large.—Native of mountainous woods about
the Hawaiian.—A lofty, branched, spreading tree, exhal- ing
a fetid, very disagreeable scent. Leaves of from five to seven
smooth and shining leaflets, nearly sessile; on a slightly
winged stalk, about five inches long. Clusters axillary, very

Willd. n. 5. (Portea ovata; Cavan. Diff. 369. t. 215.)—Leaves pinnate; leaflets smooth, membranous, elliptic-
oblance. Clusters axillary, simple, somewhat aggregate.
Flowers four-cleft, octandrous. Captiles of two valves only.
—Native of bushy places, in the mountainous parts of His-
paniola, flowering in February and March. A tree, whose
trunk is from fifteen to twenty feet high, branched, smooth,
with nearly horizontal, smooth, round, subdivided branches.
Leaves large and handlobe, thin, reticulated with innumera-
able veins. Leaflets from two to five inches long, the outer-
most gradually larger, the partial stalk of the terminal one
not longer than the rest. Clusters about an inch long, usu-
ally two or three together, somewhat downy, or silky.
Flowers white. Calyx and petals downy. Neatly, or eight
combined filaments, externally smooth, hairy within at the
summit. Captile roundish, of two cells and two valves, with
only one seed in each cell, one above the other, invested with
scarlet viscid pulp.

6. T. molehota. Musky Trichilia, or Musk-wood. Swartz
Ind. Occ. 735. Willd. n. 6.—Leaves alternately pinnate;
leaflets ovate, pointed, smooth. Clusters axillary, compound.
Flowers four or five-cleft, monopetalous. Neatly unidi-
vided. Captile with one seed.—Found in old woods of the
northern part of Jamaica, flowering in May. The inhabi-
tants know this tree by the name of Musk-wood, because
every part, the bark, bruised leaves, flowers, and fruit, smell
powerfully of musk. The pulp of the seed has a sweet taint.
The trunk is twenty feet high, or more. Leaflets alternate,
reapy, shining on the upper side; on very short partial
stalks; their common flaky hoary. Clusters solitary, erect,
of many small whitish flowers. Calyx downy. Corolla in
four or five deep ovoate segments, with a short tube. Neatly
scarcey longer than the tube of the corolla, undivided, bear-
ing rarely more than eight anthers, though the corolla is
generally five-cleft. Captile downy, of three or four valves.
Seed solitary, like a drupa with a brittle skin, and a juicy rich
scarlet pulp, including a hard oblong kernel, separable into
two parts.

t. 637. Alt. Epit. 375.—Leaves oppositely pinnate;
leaflets elliptic-lanceolate, pointed, smooth. Clusters ax-
illary, compound, denile. Petals four. Neatly in ten
dozen-pointed segments, with a slightly flattened anther be-
tween the points.—Native of the West Indies? It was sent
by Dr. A. Anderson, from the botanic garden at St. Vin-
cent's to Sir Abraham Hume, about the year 1801, and
flowered in his hove at Wormleybury, in 1816. The plant
has a musky scent, but appears otherwise different from the
last. The leaflets are seven or nine; their common flaky
smooth, except when very young. Flowers pale green,
numerous, in short, denile, compound clusters. We find them,
as described in Mr. Andrews's work, with four broad-ovoate
sepales, though the neatlily consists of ten flat seg-
ments, united half way up, deeply forked at the summit, and
each bearing from the fork an ovate, inxelled, two-celled
anther, on a very short slender flaky, or filament. Nothing
is known of the fruit.

Forl. Prodr. 35. Willd. n. 7.—"Leaves pinnate; leaflets
ovate. Clusters axillary, compound."—Gathered by
Forster in New Zeeland. His specific character, all we
know of the plant, is not sufficient to distinguish it from our
fourth species, T. glabra, though the two species are
probably widely different.

Wild. n. 8.—"Leaves pinnate; leaflets lanceolate, acute.
Clusters axillary, repeatedly compound."—Native of the
island of Namoka.

10. T. glandulosa. Glandular-veined Trichilia. Leaves
pinnate; leaflets five or seven, elliptic-lanceolate, bluntly
pointed, with axillary hairs on their veins beneath. Petals
four. Neatly undivided. Stigma depressed.—Native of New
South Wales, near Port Jackson. A specimen from
those was communicated to us by Sir Joseph Banks, under
the name of {T. olandra of Solander, which not being pub-
lished, we presume to change, as the octandrous species
of this genus are numerous, though this only was known
to the great botanists who first discovered it. The leaves
agree nearly with T. heterophylla, hereafter described, in
size and shape, but are all pinnate, and remarkable for axillary
glands, bearing tufts of hairs, along the mid-rib of each leaf
beneath, as in the Laurustinus, of which we perceive no indi-
cations in any other species, except perhaps the first. Clusters
axillary, solitary, falked, an inch or two in length, simple,
of few flowers. Calyx four-cleft, minutely fringed. Petals
four. Neatly undivided. Anthers eight, falkile. Stigma
capitate. broad. Captile triangular, depressed, with three
divided lobes. Seeds in a red, pulpy, elastic tunic.

(Portea mucronata; Cavan. Diff. 370. t. 216.)—Leaves
pinnate or ternate; leaflets elliptic-ovate, pointed. Clus-
ters simple, axillary and terminal. Petals four. Neatly
undivided. Anthers eight. Stigma club-shaped.—Gathered
by Commeron in Madagascar. Leaves smooth; of three or
five flaked, mostly elliptical, taper-pointed leaflets, near two
inches long. Clusters an inch long, solitary or in pairs.
Flowers small, four-cleft. Fruit unknown.

12. T. trifoliiata. Three-leaved West Indian Trichilia.
Vahl Symb. v. 1. 31. (T. quae Halefia Loefflingi; Loej.
It. 188.)—Leaves ternate, leaflets obovate, polished, ob-
tate; tapering at the base; the odd one much the largest.
—Native of South America, and some of the West Indian
islands, flowering in April and May. A tree fifteen feet high,
exhaling from every part a disagreeable, though not power-
ful, odour. Leaves alternate, falked; their two opposite
leaflets an inch long, the odd one two inches; all very ob-
tate, tapering greatly at the base, without any partial flalks.
Clusters axillary, very short, of about fix small, whitish, fiv-
cleft flowers. Captile green, with brownish dots, globose,
of three valves. Seeds with a scarlet skin. The negro
women are said to procure abortion by a decoction of the roots.
Jacquin.

Vahl Symb. v. 1. 31. Willd. n. 11. (Mela Koetjape;
Burm. Ind. 101, excluding Plukenet's synonym.)—Leaves
ternate; leaflets ovate, acute; their ribs hairy beneath.
—Native of Java. Branches downy at the extremity. Leaves
flaked; leaflets on short flalsks, entire, two inches long, and
we presume all three about equal in size; common flaky
downy, the length of the leaflets, shorter than the axillary
upright flower-flasks. Lengths in short dense panicles, with
a branched bract at the base of each. Calyx and corolla
villous.

("Turrea virens; Hellenius in Stockh. Transf. 1788. 294.
t. 10. f. 1." We suspeét an error in the page.)—"Leaves
simple,
simple, ovate, emarginate. Branches spinous."—Native of the East Indies. Fruit a berry of three cells, with a seed in each; hence this plant seems intermediate between Trichilia and Limonia. We know nothing of it, but there appears little reason to place it here.

The genus Trichilia is sufficiently natural, not withstanding the aberrations of structure in the notary, or flower, and of number in other parts of the flower. The species are by no means well determined, or correctly named. One alone has appeared in the European floras, nor are well-ascertained specimens frequent in collections. The presence or absence of axillary glands on the leaves, and the structure of the parts bearing the anthers, whatever it may be called, seems to prove the best marks of specific distinction. The seeds in T. glandulosa, the only one whose fruit has fallen under our examination, are each enclosed in a rigid, elastic, permanent, bivalve tunic, whose outer is clothed with red pulp. Whether this be precisely the case in the real, the descriptions of authors are not exact, nor consistent, enough to help us to determine.

The species of this genus are herbaceous, generally perennial, with alternate leaves. Flowers terminal, capitulate or spikelike, each accompanied by three membranaceous filaments. The hairs of the calyx, at first close, afterwards become extended, and give the segments a feathery aspect. Trichinium is truly, as its learned author observes, very closely related to Plutus; see that article. We should indeed feel no scruple in considering them one genus. Perhaps they ought strictly to be referred to the class Monadelphia, or at least they, and their Limnanthes genus Gymnophiona, Aethruranthes, Calophya, &c. should be indicated at the head of that class, for the convenience of young botanists. Why the latter were not all placed there by the author of the sexual system, to the great relief of his fifth class, can only be attributed to his peculiar idea of the function of their flowers. He calls a nectarium, what Mr. Brown efeems the united bafe of their filaments; but we believe an enlarged consideration of the whole tribe will justify the latter opinion.

3. T. dissecta.—Leaves linear, very narrow, smooth as well as the branches. Spike elongated, rather lax.—From the same country.

4. T. spatulatum.—Radical leaves obovato-spatulate, flat, smooth. Spike cylindrical.—Gathered by Mr. Brown in Van Diemen's island.

5. T. macrocephalum.—Stem-leaves lanceolate, wavy, smooth as well as the angular branches. Spike oblong, with a wolly stalk.—Native of the south coast of New Holland.

6. T. incanum.—Leaves lanceolate, hoary and downy as well as the round branches. Spikes nearly oval, lateral as well as terminal.—Gathered by M. Baudin, on the west coast of New Holland.

We have seen no specimens of this genus, any more than of Plutus above-mentioned.

TRICHIRI, in Geography, a small island in the Grecian Archipelago; 5 miles of. of Specula.

TRICHISMOS, from τρίχις, the hair, in Surgery, a capillary fissure, or fracture of the skull, so called from its being so fine as to resemble a hair put upon the bone.

TRICHURUS, in Ichthyology, a genus of the order of Apodes; the characters of which are, that the head is extended, with lateral opercula or Gill-covers; that the teeth are coniform, and semi-facilitated at the apex or points; that it has seven branchiogenic or gill-membrane rays; that the body is compressed and eniform, and the tail subulated, without any fin; whence it is called lepusurus, and in English needle-tail. There are two

Species.

LEPTURUS or Argenteus; Silvery Trichurus. With the lower jaw longer than the upper; and equally distinguished by the singularity of its shape, and brilliancy of its colour; the body very compressed, tapering towards the extremity, and terminating in a fine point; the whole body, except the fins, of a bright silver-colour; the head narrowing and the mouth wide; the lateral line of a gold-colour, commencing at the gills and continued to the tip of the tail; the dorsal fin moderately wide, transparent, and of a yellowish tinge, commencing almost immediately behind the head, and terminating near the end of the tail in a mere membrane, the other parts being strongly radiated; the pectoral fins small and of an oval shape; without any direct vent-fin, but having a series of very small naked spines or rays, about 110 in number, continued from the vent, which is situated about the middle of the body, to nearly the tip of the tail. Its general length is from two to three feet; it is said to be very voracious, swams with rapidity, and in the pursuit of its prey sometimes leaps into small vessels, which happen to be killing by it. It is a native of the rivers and larger lakes of South America, and considered as an edible fish; it is also found in some parts of India and in China.

INDICUS, or Eleutherius, or Fufus; Brown Trichurus. With jaws of equal length; nearly equal in size to the preceding, but different in the conformation of the jaws, which are of equal length, and in the form of its teeth, which are very minute; the tail lads flender and sharp, and the colour of the whole fish pale brown, variegated with spots of a deeper cast; a native of the Indian seas, and polishing a degree of electrical power.

Gen. Ch. Cul. Perianth inferior, of one leaf, in four or five deep, ovate, acute, spreading, permanent segments. Cor. none. Stam. Filaments numerous (sixty or seventy), capitillary, longer than the calyx, inserted into the receptacle; anthers small, roundish. Pist. German simple, papery, ovate, villous; styles two, thread-shaped, erect, much longer than the stamens, divided at the summit: Hymen obtuse. Peric. Capsule elliptical, with four angles, one cell, and four valves,
vals, clothed all over with numerous rigid, projecting deciduous bristles. Seeds numerous, small, infected into an ovate-oblong, central, unconnected receptacle, and enveloped in a fivelid membrane.

Eff. Ch. Calyx in four or five deep segments. Corolla none. Styles two, divided. Capsule brilly, of one cell and four valves, with many seeds.

1 T. laurifolia. (Ablian guianensis; Aubl. t. 234.) Laurel-leaved Ablian, or Trichocarpus.—Found by Aublet, on the banks of rivers in Guiana, particularly about one which empties itself into the Sinemari river, thirty leagues above its mouth. This tree bears flowers and fruit in November, and is known to the Caribe Indians by the name of Goulouran-Ablian. Its trunk is forty or fifty feet high, about two feet and a half thick, with a smooth reddish bark; the wood white, with some reds on the heart. Branches numerous and widely extended in all directions. Leaves alternate, falked, elliptical, bluntly pointed, entire, rigid, smooth, undulated, with one rib and many transverse veins; their greatest length seven inches; breadth two and a half. Flowers small, in short, simple, axillary or terminal, spreading clusters. Stamens white, with yellow anthers. Capsule, when its bristles are fallen, about the size of a filbert. Its valves are likewise foon deciduous, leaving the seeds en-veloped in a red fivelid membrane. Nothing is recorded of the use or qualities of any part.

TRICHOCEPHALUS, in Zoology, a genus of the Infuforia order of Vermes; the characters of which are, that the body is elastic and contorted, the hinder part thick and elevated, the anterior capillary and of double length, some-times terminating knotty. Of this genus there are fiv species, distributed into two classes: viz.

* With simple Head.

Hominis. Above subercrenated, beneath smooth, fore-part very subtilely frilated; two inches long.

Equi. Two inches and a half long.

Apmi. With tail on both fides furnished with crenated scales; equal to the human.

Muris. With the head three-knotted; found in the intestines of the mouse, between the duodenum and rectum.

Vulpis. With an acute head; neck transversely frilated, and unilateral vehicles. Found in the cocum of the fox.

** With uncinated or hooked Head.

Lacertae. With tail on both sides scaly. Found in the intestines of the lizard.

TRICHODA, a genus of the Infuforia order of Vermes; the characters of which are, that the worm is inconspicuous with the naked eye, pellucid, and hairy on the other part. Gmelin’s edition of Linnaeus comprehends forty-four species.

* Without a Tail.

Patella. Univalve; before and behind furnished with extended unequal bristles. Found in the marshes of Denmark.

Inquinus. Vividated with a green small cylindric bag, and retentile pedicel. Found in very pure fiewater.

Anas. Elongated, with the apex of the neck elongated beneath. Found in pure waters.

Larix. Dilated forward, with a gibbous back. Found in marshes in which the leaves of the poplar putrefy.

Ursula. Smooth, elongated, equal, on the fore-part hairy. Found in putrid infusions of hay and other vegetables.

Sannio. Incurred; above ciliated, below truncated. Found rarely in water furnishing duck-weed.
SULCATA. — With ovate ventricose apex, acuminate, ventral furrow and on both sides hairy; as before.

** With Tail.

TRANSFUGA. — Broadly, before hairy, behind bristly, flattened on one side, mucronated on the other. Found in sea-water for some time kept.

DELPHINUS. — Oblong, before hairy, behind truncated with a reflex tail. Found in hay-water.

LUDIO. — Cirratus, above hairy, with an extended tail. Found rarely in the swampy waters of Denmark.

MUSCULUS. — Oval, on the fore-part hairy, the hinder part caudate. Found in hay-water.

PISCES. — Oblong, on the fore-part hairy, behind very finely extended into a tail; in duckweed-water.

CUNICULUS. — Oblong, before hairy, behind somewhat sharpened; in pure water.

CLAVUS. — Before rounded and hairy, behind with an acuminate tail. Found in marshes.

CLAPA. — Aculeated, hairy in front, with a bent tail. Found in duckweed-water.

CALVA. — Clavated, hairy in front, with a reflexed tail. Found rarely in the marshy waters of Denmark.

Eff. Ch. — Naked. Powder copious, mealy, encompassed with a downy or fluffy coat:

1. T. fuliginoides. Perf. n. 1. — "Large, nearly globular, villous, whitish. Powder bright red, intermixed with filaments of threads." — Found in autumn, on the rotten trunks of Spruce Firs. An inch or two wide, soft, but not melting. The threads to which the seeds are attached radiate through the powdery mass, in little tufts, from a subjacent membrane. Perfon.

2. T. roesum. Hoffm. Germ. v. 2. t. 10. f. 1. Perf. n. 2. (Farnnaria roesna; Sowerb. Fung. t. 360. f. 3.) — Role-coloured, encompassed with a fine, spreading, depressed, filamentous border. Frequent in spring on rotten branches, especially between the wood and bark of the Sallow and Aspen. Half an inch broad, roundish or oblong, with a cobweb-like circumference.

3. T. aurantia. (Farnnaria aurantiaca; Sowerb. ibid. f. 2.) — Tawny, orbicular. Powdery particles somewhat ovate, partly scattered, with a flight filamentous border. On leaves, often forming, as it were, a little net, with a few cottony filaments towards the edges. Sowerb.

4. T. seminariurn. (Farnnaria seminariaria; Sowerb. ibid. f. 1.) — Powder black, in little compact globules, on a white, mealy, slightly fibrous, orbicular base. — Observed by the Rev. J. Holme, of Peter-houfe, Cambridge, on the leaves of a Willow. This contains of little white scattered orbicular spots of a white mealy substance, from a quarter to half an inch broad, lodging several minute deciduous masses of black powder, or seeds.

5. T. virtide. Perf. n. 3. "Dipf. Meth. Fung. 12." (Pyrenium lignorum, vulgar Fude Fung. Mecklenb. v. 1. 33. t. 3. f. 29.) — Roundish or unequal, very fott, with bright-green powder, and whitish fugacious filaments. — Found after autumnal rains, among fragments of fallen branches of trees, or on the limbs of large herbaceous plants. Its substance is extremely soft, two or three lines in diameter. The white cobweb coat opens at the top, and exposes the minute condenfed grains, or powder, of a most beautiful verdigris-green. Perfon, Tode.

6. T. aureum. Perf. n. 4. Obsf. Mycol. fusc. 1. 99. — "Widely expanded. Hairy coat whitish, very thin. Powder dull yellow." — This occurs rarely, in fieves or hothouses, on rotten wood, into which it is sunk. Almost three inches broad, being one of the largest of its genus, but scarcely two lines in thickness. The faggot covering is thin and evanescent. Perfon.

8. T. dabium. Perf. n. 6. (See Perf. Obs. Mycol. fusc. 1. 99.) — Linear, flitily downy; firit whitish, then yellowish; of an uniform fiable subftance. — Frequent on decayed trees in autumn. About half an inch long, and one line broad. There is scarcely any difficult fibrous margin, though the whole fungus appears flitily downy. The inside is dense and cohering, not powdery, nor volatile; fo that Perfon expreffes great doubts concerning the genus of this little production.

10. T. leuc. Perf. n. 8. Obsf. Mycol. fusc. 1. 12. — Whitish, spreading, smooth, turning buff-coloured. Powder yellow. This is found on the ground, as well as spreading over mosses, to the breadth of an inch and half or two inches, but is not among the common species. It is more permanent than fonie others.

11. T. tuberculatum. Perf. n. 9. Obsf. Mycol. fusc. 1. 12. t. 2. f. 8. — Pure white, nearly orbicular; at first downy; afterwards tubercular. Powder grey. — Frequent after great rains, on the ground in shady woods. When young it is very white, of a cobweb texture, but soon becomes greyish. When full-grown the surface is beft with oblong tubercles. In a few days the whole changes to a grey powder.

Gen. Ch. Cal. Perianth inferior, of one leaf, in five deep, erect, permanent segments. Cer. of one petal, wheel-shaped; the length of the calyx; tube short, somewhat funnel-shaped; limb spreading, nearly flat, in five deep, equal, keeled, taper-pointed segments; throat naked. Stam. Filaments five, very short, inserted into the throat of the corolla; anthers oblong, prominent, converging, shorter than the limb, tipped with twisted brilly points, and bound together by their two rows of doral hairs. Pif. Germans four, superior; style central, thread-shaped, longer than the flammis; stigma simple, bluntish. Sechs. Nuts four, ovate, gibbous, half sunk in the cells of the four-winged central column near its summit.

Eff. Ch. Corolla wheel-shaped, with a naked throat. Anthers connected by doral hairs.

Mr. Brown has separated this genus, confiding of three known species, from the Linnéan Borago, for the very fufficient reafon of the corolla having no valves or prominences in
in its throat; to say nothing of the connexion of the anthers, or infection of the seeds. The plants are herbaceous, clothed with pungent bristles; their flowers axillary, or racemose with bracteas. See Borago.

1. T. indicum. Indian Trichodesma. (Borago indica; Linn. Sp. Pl. 197. Willd. Sp. Pl. v. i. 777. Ait. Hort. Kew. v. i. 296. Burragrooides angustifolia, flore pallescete caruleo; Boerh. as above 188, with a plate. Cynoglossooides folio caulem amplaxente; Isnard as above, t. 9.)—Flowers axillary. Segments of the calyx auricled at the base. Seeds without a border. Leaves clasping the stem.—Native of the East Indies. A tender annual, cultivated by Miller, and flowering throughout the summer and autumn. The stem is much branched, rather diffuse. Leaves sessile, oblong, bluntish, entire, rough with hairs and callous points; clasping the stem with their sthightly heart-shaped base. Flowers axillary, solitary, flattened, drooping, white, pale blue, or reddish, with five fluffy spots round the mouth. Calyx hairy, each segment acute, much elongated at the base. Seeds pale, nearly smooth.

3. T. zeylanicum. Ceylon Trichodesma. Br. n. 1. (Borago zeylanica; Linn. Mant. 202. Willd. Sp. Pl. v. i. 777. Ait. Hort. Kew. v. i. 297. Jacq. Coll. v. 3. 169. 1c. Rar. t. 314. Burn. Ind. 41. t. 14. f. 2. Anchnua buglossioideae, lithospermiferae; Pluk. Mant. 13. Phyt. t. 335. f. 4.)—Clusters terminal. Calyx without auricles. Seeds smooth, without a border. Leaves nearly sessile, tapering at the base.—Native of Ceylon, and other parts of the East Indies, as well as New Holland, within the tropic. Dr. Roxburgh sent seeds to Sir Joseph Banks, in 1799. This, like the last, is an annual plant, flowering in the flower in July and August. The herbage is, as Mr. Brown remarks, very variable in its quantity of bristles and soft hairs; the latter, in wild species, are sometimes very abundant, giving the long flowery-stalks, and calyx, more especially, a hoary aspect. The leaves are oblong or obovate, mostly opposite. Clusters leafy. Corolla white and semi-transparent. Seeds ovate, grey, smooth and highly polished, like our Common Gromwell.

TRICHODIUM, received that name from Micaux, who constructed it out of Triticum, a bread, and tetricus, form; or appearance, in allusion to the capillary stalks of the panicle.

1. T. laxiflorum. Spreading Trichodium, or Bristle-grasfs. Michaux as above, 42. t. 8. Pursh n. 1. (Coronocype hermaphroditum, Walt. Carolin. 73. Agrolis seabra; Willd. Sp. Pl. v. i. 370, according to Pursh.)—Stems erect. Leaves upright, linear-lanceolate, with roughish teeth. Calyx-valves lanceolate.—Common in all gravelly situations, from Hudson's bay to Florida, flowering from May to August. Michaux, Pursh. Root perennial. Leaves narrow and short, nearly erect. Panicule short, with very fine capillary stalks, loosely spreading, each branch bearing but a few small flowers about the extremity.

2. T. decumbens. Decumbent Bristle-grasfs. Michaux as above. Pursh n. 2. Ait. Epit. 375. (Coronocype perseram; Walt. Carolin. 74. Agrolis anomalus; Willd. Sp. Pl. v. i. 370. A. Coronocype; Frazer Monogr. with a plate.)—Stems decumbent. Leaves spreading, linear-lanceolate, with smooth lens. Calyx-valves taper-pointed.—On moill hills, and in short grass meadows, from Canada to Carolina, flowering from June to August. Root perennial. This and the foregoing are highly valuable grasses. Pursh. Larger than the first species, with longer and broader smooth leaves, which spread in every direction. Stipula, as Willdenow observes, larger, lanceolate, torn. Panicule large and loose. Flowers about the bise of our Agrolis alba, being twice the bise of the foregoing, and much more numerous.

This, known by the name of Frazer's New American Grasfs, was brought from Carolina by that indefatigable collector, in the year 1788. His friend Mr. Walter, in the Flora Caroliniana, extols this grass as one of the Creator's most precious gifts, which he himself was deigned to make first known to mankind. Kalm had indeed, long ago, sent a specimem to Linnaeus, but without any particular account of its use or distinctions, so that his specimen remained undistinguished from other species, which it much resembles. The solitary valve of the corolla led Mr. Walter to refer this plant to the genus Coronocype, to which it has no other affinity. He was moreover flattered by this name, as occurring with his own idea of the value of his discovery. Nor do we doubt the accuracy of his statements, published in Mr. Frazer's Monograph above cited. Nevertheless, this grass has disappointed the hopes of European cultivators, and has now totally disapparred. "The places that knew it, know it no more." It is not even mentioned in Mr. Sinclair's elaborate and valuable experimental work, the Hortus Gramineus Woburnensis, nor by Mr. Dryander in the Hortus Kewensis, though Mr. Aiton has supplied the latter defect in his Epitome. So difficult is it to cultivate grasses, in general, away from their native situations, for any agricultural profit, that the disappointment we are obliged to record, is no impeculation of the accuracy of those who still reckon our Trichodium among the best grasses in America.

TRICHOGAMILLA, a name of Dr. Patrick Brown's, which he has left, according to his usual custom, unexplained. It appears derived from stiri, a hair, and γ, a flower.
TRI

marriage, alluding to the pubescence enveloping both organs of impregnation.—Browne Jam. 218.—We have seen no spicemen of this plant. It is said to grow close to the beach at Bull-bay, in Jamaica. The stem is shrubby, stiff, simple, three or four feet in height, and as many lines in diameter. Leaves round, smooth, alternate. Flowers small and white. Outer calyx (rather bracteae) two small deciduous leaves; inner cup-shaped, of one leaf, divided half way down into five ovate segments. Corolla of five oblong, abrupt, somewhat spreading petals, or of one petal divided to the bafe. Filaments ten, downy, erect, shorter than the corolla. Anthers roundish. Sepals minute, in the bottom of the calyx. Style downy, the length of the flaments, with a blunted stigma. Drupes the size and appearance of a gall-nut, but light and hollow, globose, woody, thin, with a thin coat, of one cell, inflated, rather uneven in its surface. Nut two, oblong-ovate, two-lobed; one of them usually abortive; the other fixed to the bottom of the drupa, but not half occupying its cavity.

Juifieu, Gen. Pl. 260, supposes this to be the same genus with Chalca or Murraya (see those articles); and Linnaeus has written Chalcas against Browne's description. We prefigure it is the same individual species, which, though of East Indian origin, had accidentally been conveyed to the shores of Jamaica. If this be correct, Browne mislabeled the leaves for simple leaves, and perhaps did not meet with the fruit in its natural more juicy state.

TRICHOMA, in Surgery, the dicasfe more commonly called plica Polonica.

TRICHOMANES, in Botany, an ancient Greek name for some small delicate kind of fern, supposed from the description of Dioscorides, book 4. chap. 137, to be Applenium Trichomanes of Linnaeus, which very well answers to that description. The name, from στριμnez, to grow, (whatever may be the origin of the root of the word), about which etymologists disagree, alludes to the slender filiform flavus, common to most of the fern tribe, which procured them the appellation of Capillary herbs, and the reputation of improving the growth of the human hair. Linnaeus fideled this name for a delicate, pellucid, capillary-flaked genus, to which it is very fitful; more especially if we take into consideration, as he probably did, the peculiar character of a prominent hair or bristle, originating from the receptacle of the seed-veils.—Linn. Gen. 560. Schrebb. 758. Willd. Sp. Pl. v. 5. 498. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 529. Sm. Mem. de l'Acad. de Turin, v. 5. 417. Traets 255. Swartz Fl. 141. Ind. Occ. 1724. Brown Prodr. Nov. Holl. v. 1. 159. Spren- gel Crypt. Engl. ed. 164. t. 5. f. 35. Juff. 16. Lamerick Illusr. t. 871.—Clafs and order, Cryptogamia Filices. Nat. Ord. Filices.

Gen. Ch. Fructifications inferred into the margin of the frond, terminal, distinct, tubular. involucrum of one leaf, urn-shaped, of the texture of the frond, opening outward. Capsules of two valves, bound by a ciliate ring, numerous, sessile on the lower part of a cylindrical common receptacle, or column, whose capillary naked point projects beyond the involucrum.

Obs. Hymenophyllum (see that article) was first separated by the writer of this, from Trichomanes, with which it had, on account of their similar membranous pel- lucid habits, been always confounded. The bivalve involu- crum, enclosing the common receptacle, clearly distinguishes it from the genus before us, whose involucrum has a spreading undivided border.

The second edition of Species Plantarum contains eleven, and the fourteenth edition of Systema Vegetabilium thirteen, species of Trichomanes, as Linnaeus understood the genus. But though from these are deduced what are now referred to Hymenophyllum and Davallia, Willdenow enumerates thirty-four species of genuine Trichomanes. These are distributed into four sections, according to the subdivision of their fronds. We shall select examples.

Sect. I. Frond simple. Twelve species in Willdenow. T. reniforme. Kidney-shaped Brilfe-fern. Forjd. Prodr. 84. Willd. n. t. Schkuhr Crypt. 130 t. 134. R. A. Hedw. Fl. Fic. 3. Fronds kidney-shaped, undivided, on bordered flalks. Gathered by Forlzer, as well as by Mr. A. Menzies, in New Zealand. An elegant very singular fern, with long, creeping, thread-shaped, perennial roots, attached by rigid downy fibres, and throwing up fatterer erect fronds, various in size, each on a simple smooth stalk, from one to six inches high, bordered, or slightly winged, especially in the upper part. The leaf itself is vertical, kidney-shaped, from one and a half to three inches wide, of a dull olive-green, membranous, semi-pellucid, smooth, full of numerous, radiating, repeatedly forked veins; the margin entire, slightly wavy in the larger or older fronds befeft with a row of cup-shaped immersed involucrum, each terminating a vein, and each protruding a rough thick column, twice its own length, bearing a number of pale flining annulated capsulae.

T. membranaceum. Membranous Briflle-fern. Linn. Sp. Pl. 1560. Willd. n. 5. Swartz Ind. Occ. 1724. (Darea americana lichenoides; Petiv. Muf. n. 763. Addianum mucufum, lichenis petrai facie; Plum. Fl. 83. t. 101. f. a. Amer. 34. t. 50. f. a; inaccurately copied in Plut. Phyt. t. 285. f. 3; and again in Petiv. t. 13. f. 5.)—Fronds fefile, dilated upwards, obtuse, undivided, or torn; the margin beft with peltate frutes. Found on wet, often inundated, flones and rocks about the banks of rivers, in Hifpania. This has the colour and membranous tex- ture of the foregoing, but with a fily glofs. Its black, faggy, creeping roots bear flattered fronds, diluitle of flalks, sometimes roundish, but moftly wedge-shaped, from one to three inches high, variously split, dilated, and jagged, beft with innumerable crowded radiating veins, and much resembiling the texture of a bat's wing. The margin, as well as the tip of each fegment, bears brown peltate flakes, whose fze is unknown, but which, as Dr. Swartz remarks, might eafily caufe this fern to be taken for an Addianum, were there not founed on the fame individual, though far more fparingly, the proper ftructuration of a Trichomanes, confining of deeply immersed, flender, tubular involucrum, dilated, orbicular, and roughife at the mouth, each with a prominent (not as Swartz fays a concealed) column.

T. muco fades. Mossy Brifle-fern. Swartz Ind. Occ. 1726. Willd. n. 6. (T. hynemoides; R. A. Hedw. Fl. t. 3. f. 3. Phyllitis scandeais minima, mufe facie, folies membranacae subrotundis; Sloane Jam. v. 74. t. 27. f. 1.)—Fronds roundish-oblong, irregularly fquinted, fawy, obtuse, on short hairy flalks. Involuture prominent, cylin- drical; bivalve at the mouth. Found creeping over the trunks of trees, in low wet places, in Jamaica. The root is black, thick, and woolly, spreading to the extent of several inches. Fronds light green, lying over each other, scarcely more than half an inch wide, with strong, branch- ing, but not parallel or crowded veins; the segments rounded and wavy. Involuture at length flipped as it were, and projecting entirely beyond the leaf on winged flalks; their margin

TRI
TRICHOMANES.

margin of two rounded valves, edged with brown. The
column is certainly prominent. Our description differs from
Dr. Swartz's in some material points, though taken from
his own specimens.

1727. Wildl. n. 9. R. A. Hedw. Fil. t. 3. f. 4, bad.
— Fronds obovate-oblong, nearly sessile, irregularly pinna-
ti'fied, with oblong obtuse segments; their base wedge-
shaped. Involucremmered, its orbicular mouth not
projecting beyond the leaf.—Native of old mossy trunks of
trees, in the mountainous part of Jamaica. If we are
right in our ideas of this species, it is browner and thinner
than the lafr, with a larger frond, but shorter flake; the
veins much less thick and prominent. The involucrum
moreover does not project, till stripped by age, nor is its
margin divided. The column is certainly prominent.
We do not boast, in this case, an original specimen from the
author, and therefore may be mistaken.

Lamarec. T. 1. (T. crispsurn; Linnaeus Pl. ed. 1. 1197.
ed. 2. 1560, excluding the synonymy of Plumer and Pe-
tier.)—Frond lanceolate, pinnaTed; taping at the base;
segments ovate, obtuse, somewhat angular, with zigzag
veins, and mollily solitary fructifications.—Native of the
West Indies; Willdenow says of Guadalupe. A very
elegant and distinct species, sometimes resembling the out-
line of an oak-leaf, but it is more usually of a linear-lan-
culate figure, tapering at each end, four inches, more or
less, in height, light olive, pellucid, finely reticulated, flat,
rarely a little hairy, with elegant, zigzag, equally diphered
veins. Involucrum immersed at the blunt point of each
segment, almost always solitary, its dilated orbicular border
not projecting beyond the leaf. Column slender, prominent,
full twice as long as the involucrum. This seems, by the Lin-
næan herbarium, to be what Linnaeus intended for T. cri-
psum; but it is evident from the specific character and name
that he had full as much in his contemplation Plumer's
t. 86, quoted for a synonym; and the latter being univer-
sal as the true crispsurn, we shall so rest it. See the
next section.

ed. 1. 1198. ed. 2. 1561. Swartz Fil. 145. Wildl.
n. 11. — "Frond lanceolate, pinnaTed, wavy. Flowers
solitary, terminal."—Native of India.—"Frond the length
and breadth of the finger, pinnaTed almost to the mid-rib;
lobes lanceolate, bluntly tattered, acute at the summit,
each of them furnished with a solitary flower at the point.
The frond moreover is pellucid, with alternate veins."—
Such is Linnaeus's description of this species, which no per-
son has ever discovered, and which can only be determined
from his works or herbarium. In the latter nothing pre-
ents itself under this name; but the specimens marked
criium, mentioned under our preceding species, so pre-
cisely answers to this description of polypodioides, that we
cannot but believe it is the very plant, and that Linnaeus
has here fallen into a molt complicated mistake. As we
are, nevertheless, unable to prove this, we would still re-
tain the excellent name of finifnsum, to which those who
think as we do may refer polypodioides as a synonym, with
or without a mark of doubt.

t. 35. Wildl. n. 12.—Barren fronds lanceolate, deeply
pinnaTed; fertile ones linear, pinnaTed, on longer flaks.—
Native of watery mossy places in Guiana. Fronds tufted;
the barren ones leafy, pellucid, of numerous, deep, parallel,
linear, bluntish, somewhat jagged segments, that are
near an inch long; their common flake round, about two
inches in length, nearly smooth; fertile ones fewer, their
flakes erect, five or six inches long, the frond itself four or
five, and only half an inch wide, laxely at all leafy, but
composed of two dense rows of numerous, crowded, flaked,
cylindrical, two-edged involucral cups, each with a small or-
bicircular border, and protruding a long, curved, rough,
light, club-shaped column, twice the length of the involu-
crum itself.

sect. 2. Frond pinnaTed. Three species; Wildl.
T. crispsurn. Crispd Britle-fern. Linnaeus Sp. Pl. 1560?
fil. t. 4. f. 2. (Trichomanes n. 1. Linnaeus Hort. Cliff.
476. Polypodium crispsurn calciferum; Plum. Fil. 67.
t. 86; copied in Petiv. Fil. t. 11. f. 8.)—Frond pin-
nate; leaflets oblong, obtuse, wavy, crisped, hairy, man-
dflowered at the extremity; the upper ones confluence.
—Native of various parts of the West Indies. The tufted
hayfh root bears many lanceolate flaked fronds, about a foot
high, of a light pellucid olive-green, very thin and mem-
branous; their numerous leaflets about an inch long, el-
agently crisped and plaited, copiously veined, clothed with
scattered tawny hairs. The blunt extremity of each leaflet,
except some of the inferior ones, bears from four to five or
more, immersed, rather crowded, tubular involucrum, with orbic-
ular entire slightly dilated mouths. From each pro-ceeds a long
flanker, almost capillary, roughish column, whole point when
entire is blunt, or rather capitate.

T. floribundum. Many-flowered Britle-fern. Wildl.
n. 15. (T. pinnaTum; Swartz Fil. 142. R. A. Hedw.
fil. t. 4. f. 1. T. rhizophylla; Cavanil. Leccion. 279.
Swartz Fil. 142.)—Frond pinnaTed; leaflets lanceolate,
cisseated; the upper ones decurrent, confluence. Fructifica-
tion marginal, fringle-like prominent.—Native of several
parts of the West Indies. Twice the size of the last. The
leaflets are usually near two inches long, above half an inch
broad, alternate, bluntish, nearly smooth, befit with innum-
erable close transverse veins, connected by fine reticulations;
their margin undulated and finely serrated; those of the
barren fronds crowded; of the fertile ones remote, most of
their fratures tipped with a little, brown, cup-shaped, en-
tirely prominent and naked involucrum, with a capitae
column about its own length. Cavaflines speaks of this as
the handomest species he had seen. His description leaves
no doubt as to the identity of his plant, though we have not
seen an instance of any sprouting roots from the tip of the
frond, which probably led Dr. Swartz, without seeing spec-
imens, to adopt it as distinct.

sect. 3. Frond doubly pinnaTed. Six species; Wildl.
1730. Wildl. n. 19. R. A. Hedw. Fil. t. 1.—Frond
pinnaTed; leaflets obtuse, pinnaTed, decurrent, confluence;
airy at the margin and veins; segments often cloven. Stalk
airy.—Found on the trunks of trees, on the lofty moun-
tains of Jamaica. Frond about three inches in length, pale,
pellucid; its tawny-haired flake febrcefo long. Involu-
crum here and there imbedded at the ends of the segments
of each leaflet, with a dilated, fringed, orbicular margin.
Column long, roughish, capitae with a taper point. The
segments of the leaflets are lanceolate, bluntish, not so
generally divided in our specimens as in Hedwig's figure.

1561. Swartz Ind. Occ. 1739? Wildl. n. 21. (Filicula
pyxidifera; Plum. Fil. 74. t. 50. f. E; copied in Petiv.
t. 13. f. 13.)—Frond pinnaTed; leaflets oblong, obtuse,
cisseated, pinnaTed, with linear, obtuse, decurrent, entire,
more three-clad segments. Stalks all winged. Involu-
crum cloaked by a lid bearing the column.—Found by Plu-
mier
mier on molly trees in Hispaniola. He is our only certain authority for this species, the description of Swartz not answering exactly to his account, and the figure in R. A. Hedwig, t. 3. f. 2, indicating something very different. The true T. pyxidifera is so named because the involucrum is formed like a box with a convex lid, through which latter the long prominent column is continued. We have seen indications of no such character in any other species. The root is creeping and hairy. Fronds flaked, three or four inches high, smooth, very thin, their common as well as partial fronds winged throughout, and of the same linear form as the segments of the leaflets, which are notched at the end. Involucrum one or two about the lower part of each principal leaflet cup-shaped, quite closed by the above-mentioned lid.

T. europeum. European Brilie-fern. (T. pyxidifera: Hud.f. 401. Bolt. Fil. 56. t. 35. Hymenophyllum turbridgeae β; Fl. Brit. 1142. H. alatum; Engl. Bot. t. 1417.) Felix humilis repens, foliis pellucidis et splendentiis, caule alato; Dill. in Rait Syn. 127. t. 3. f. 3. 4.;—Frond bipinnate; leaflets oblong, decurrent, pinnatifid, with linear, obtuse, decurrent, entire segments. Stalks all winged. Involucrum open, with a slightly spreading border. Few plants of any country have caused more enquiry, or more diversity of opinion, than this fern, originally discovered by Dr. Richardson "at Belbank, near half a mile from Bingley, Yorkshire, at the head of a remarkable spring." From thence Mr. R. Teedle and Mr. Dickson have brought us young plants, like Dillenius's f. 4, but could find none like his f. 3. The botanists of Ireland have been more fortunate. Mr. J. T. Mackay met with perfect specimens in fruitification, on rocks about the cataract, at the bottom of Turk mountain, Killarney. Some of these, more perfect than what is figured in Engl. Bot., lead us to concur with Mr. Brown's opinion, expressed in his Prodromus, in removing this plant from Hymenophyllum, to the present genus. It was indeed confided by Linneus as not distinct from T. pyxidifera, nor is this opinion fo wide of the truth as it has been supposed. By a comparison with Plumer's figure of the latter, this will be found to differ chiefly in being more compound, with a smaller, more slender, two-edged involucrum, in which we can discover nothing like a lid. Its margin is narrow, but rather spreading. The capfules are few and large, bright yellow, with a broad ring. Column long and prominent. Some appearances in this and other species lead us to believe the column, laden with capfules, is generally protruded out of its involucrum after the capfules are ripe, and it may therefore, in a very early state, be found entirely inclosed therein. This being the only European Trichomanes, we hope our specific name may be allowed, that of alatum being procured; see Willd. n. 17.

T. venosum. Veiny Brilie-fern. Brown Prodr. n. 1.—"Frond pinnate; leaflets linear, veiny, wavy, somewhat crenate; the lower ones lobed or pinnatifid at the base, and bearing a solitary involucrum at their inner margin."—Gathered by Mr. Brown, in the island of Van Diemen, and near Port Jackson, New South Wales. This should seem akin to the two last, but we have seen no specimens.

Seft. 4. Frond tripoly pinnaatifid, or pinnate. Thirteen species; Willd.

T. tricholodium. Capillary Brilie-fern. Swartz Ind. Occ. 1741. Willd. n. 23. (T. tenellum; R. A. Hedw. Fil. t. 3. f. 1.)—Frond tripoly pinnate; leaflets linear, almost capillary, divided, marginate. Involucrum flaked, lateral, solitary, near the base of the principal branches.—In moist, shady, grassy places, in the cooler parts of Jamaica and Hispaniola. This is a peculiarly delicate and slender fern, from two to four inches high, whose ramifications are so exceedingly narrow as to appear capillary, though the ultimate divisions are truly leafy, consisting of a wiry midrib, bordered with a continued, even, entire, scarcely discernible, leafy margin at each side, slightly dilated upward, and blunt at the end. The fructification is lateral and solitary, much as in the three preceding; each involucrum flaked, tubular, two-edged, with a broad, orbicular, wavy margin. The column is very long and capillary.

T. rigidum. Rigid Brilie-fern. Swartz Ind. Occ. 1738. Willd. n. 29. R. A. Hedw. Fil. t. 2.—Frond tripoly pinnate; leaflets pinnatifid, with linear, entire, taper-pointed segments. Common flanks two-edged, rigid. Involucrum flaked, lateral, solitary, near the base of the secondary branches. Found about the roots of trees, on the lofty mountains of Jamaica. The creeping root sends up numerous rigid upright fronds, twelve or eighteen inches in height, of which at least one half consists of a brown, shining, round, firm flakt. The leafy part is finely and evenly divided, dark green, peculiarly elatic, and when dry rigid and inflexed. Involucrum urn-shaped, with a membranous spreading border. Column thick, not much protruding.

T. radiatum. Winged Climbing Brilie-fern. Swartz Ind. Occ. 1736. Willd. n. 30. (T. scandens; R. A. Hedw. Fil. t. 6, excluding the synonyms.)—Frond doubly pinnate; leaflets pinnatifid, with linear, cloven, obtuse segments. Common and partial flanks smooth, all winged. Stem climbing, creeping. Found on the mountains of Jamaica, creeping up the trunks of trees to a great extent, the downy rufly-coloured main stem, or root as it might be called, being firmly attached to the bark of the tree, throwing out little radicles as it goes. Fronds fattercd, from nine to twelve inches long, on winged flanks measuring from one to three inches, ovato-lanceolate, twice or thrice pinnate, dark green, smooth, the flanks of all their subdivisions bordered with an entire uninterrupted; wings, leaflets and segments alternate. Involucrum cylindrical or somewhat ovate, slightly winged with a portion of the segment which it terminates; the mouth spreading. Column long and slender. A very different species from the following, for which it has been mistaken by several botanists, to some of whom, though not quoted by Hedwig, we can trace his error.

T. scandens. Great Climbing Brilie-fern. Linn. Sp. Pl. 1562. Willd. n. 31. Swartz Ind. Occ. 1737. (Adiantum scandens ramosissimum, lacinis retusis discifetum; Plum. Fil. 76. t. 93; copied in Petiv. Fil. t. 12. f. 5.)—Frond tripoly pinnate; leaflets oblong, pinnatifid, with linear obtuse segments. Common flanks round; partial winged, hairy. Stem climbing, creeping. Native of mountainous forests in Hispaniola, where it was gathered by Plumer, and since by Dr. Swartz. A much larger plant than the foregoing, creeping over the trunks of old trees. Each frond, two feet high, has a round, not bordered, main flakt, the partial ones only being winged. All the leaflets and their flanks are clothed with long loose hairs, of a shining or golden brown, such as are often likewise observable on the main flakt. The colour of the whole fern is more olive than the last, and its reticulations much coarser. Involucrum much the same, nor do we find the column, when perfect, shorter than one in the other. Sloane's v. 1. t. 58. may be intended for T. scandens, but it is not sufficiently exact to afford any information.

T. tamarififolium. Tamarisk Brilie-fern. Jacq. Coll. v. 3. 285. t. 21. f. 2. Willd. n. 34. Frond doubly pinnate; leaflets lanceolate, pinnatifid, with linear, very narrow, smooth...
*Native ftyle* the Curt. their Compend. Rar. n. 1 T. March 222. tube Involucrwn The 575. yellow T. very The */fl/i Dickf. the 1. Jacq. 265, Willd. Redout. Cor. I. (Ixia (Romulea; 170.) — 265. Angular Bubocodium a 180. Per'ic. Ann. partments. remaining by blage light and herbaceous funnel-diaped valves. The */fl/i winged, ftamens that feparate They Trichomanes, Gen. Eff. to are vrtjAO., and other filament, their segregating the former to be removed in the winter feaon to the protection of the greenhouse, but the latter to remain where planted, or some put into pots, to be placed out in particular situations, as occasion may require. They both form a singular variety when put in affemblage with other different plants of the exotic greenhouse forts, and other kinds in the borders and various compartments.

Gen. Ch. Cal. Sheath inferior, more than half the length of the corolla, of two lanceolate, entire, permanent valves. Cor. of one petal, superior; tube very short, funnel-shaped; limb regular, divided to its vafe bafe in six nearly equal, somewhat spreading, concave segments. Stam. Filaments three, inserted into the mouth of the tube, erect, much shorter than the corolla, downy; anthers rather large, converging, oblong, cloven at the bafe. Fil. Ger. roundish; fyle thread-shaped, erect, longer than the ftamens; ftigmas three, deeply divided, equal, spreading, very flender, rather abrupt. Peric. Capsule roundish, membranous, tumid, of three cells and three valves. Seeds several, globose.

Obv. The shortnefts of the tube, divided ftigmas, and pubefcent ftamens, diftinguish this genus from *Ixia*. (See that article.) The last character is but lightly perceptible, and the others may perhaps hardly be thought sufficient to separate plants fo precisely alike in habit. We shall nevertheless enumerate the species as given by Mr. Ker, late Gawler.

1. T. Bulboeudium. Channel-leaved Trichonema. Ker n. 1. Ait. n. 1. (Ixia Bulboeudium; Linn. Sp. Pl. 51. Willd. Sp. Pl. v. 1. 196. Jacq. Coll. v. 3. 265. Ltc. Kew. v. 1. 271. Curt. Mag. t. 265. Redout. Liliac. t. 88. Sm. Fl. Grce. Sibth. t. 36. Compend. Fl. Brit. ed. 2. 8. Engl. Bot. t. 2549. Dickf. H. Sicc. t. 18. n. 12. Sistirinchenium Theophrasti; Column. Eclipt. 328. t. 327. Crocus vernus; Ger. Em. 153. t. 1, 2.)—Leaves linear, channelled, recurved, longer than the flower-flalk.—Native of grally hillocks, and sandy ground near the sea, in the south of Europe, from Jersey and Guernsey to the Archipelago, in which last country it is very abundant, flowering in March and April. We have no where seen this pretty plant more beautiful, with its numerous varieties, than on the hillocks around the celebrated fountain of Egeria, near Rome. There all the different appearances of the flower, with respect to size and colour, which the above figures represent, and indeed many more, may be collected at once; nor can they fail to convince an observing botaniff that they are no more distinct species, than our red or blue garden anemones. The *ball* is ovate, the size of a filber, with many entire smooth coats. Leaves radical, recurved and widely spreading, narrow, smooth, rufhly. Stalks one or two, combined at the bafe, single-flowered, more or less curved, round, smooth, much shorter than the leaves, though considerabfly elongated after flowering. *Stem* somewhat coloured. *Corolla* from one to two inches long, purplish, pale rofe-coloured with a yellow bafe, or almost white in the border, always varioufly streaked; the backs of the three outer segments greenish; all the segments elliptical, but various in breadth. *Capsule* membranous, corrugated, purplish. We cannot separate Mr. Ker's *rofeum*, for which he cites Curt. Mag. t. 265, however different that figure may, at firft sight, appear.

2. T. cruciatum. Square-leaved Trichonema. Ker n. 3. Curt. Mag. t. 575. Ait. n. 2. (Ixia cruciata; Willd. Sp. Pl. v. 1. 197. Jacq. Kew. v. 290. Bulboeudium pedunculis nudis anfioris, folius bifulbatis linearibus longi- finis; Mill. Lc. 160. t. 240; not 260, as in Hort. Kew. an almost unique error of the kind in the accurate Mr. Dryander, caused by the awkward roman numerals.)—Leaves linear, four-figured, with many deep channels.—Native of the Cape of Good Hope. The *leaves* are more erect than in the former, various in breadth, but always known by their four-figured figure, displayed in a tranverse fiction. The *flalk* is solitary, short and simple. *Corolla* variable in size, pale crinum or purplifh, firecked, externally green; its segments acute and recurved.

4. T. speciosum. Crinum Trichonema. Ker n. 5. (Ixia Bulboeudium var. flore speciosissimo; Andr. Repol. t. 170.)—Leaves linear, channelled, the length of the flalk, which bears a solitary leaf near the top.—Native of the Cape of Good Hope, whence Mr. G. Hibbert received its bulbs in 1800. These flowered in his garden at Clapham the following March. This appears most akin to the firft species in its *leaves*, except their being more erect, and scarcely exceeding the length of the *flalk*. The latter, though simple, bears one leaf near the top, according to Mr. Andrews, who is our only author. We are aware that the European *T. Bulboeudium*, when it has two flowers, bears
bears also a leaf at the junction of their stalks. The flower of the present plant is uncommonly handsome, near two inches long, of a rich crimson; violet at the base; its three outer segments yellowish at the back, with crimson veins. The flower is narrow, green and leafy, less membranous, or coloured, than in most of the rest.

5. T. pudicu m. This is merely mentioned by Mr. Ker, as the *Tilia pudenta* of Dr. Solander in Sir Joseph Banks’s herbarium, without any indication of its character or distinctions.

The able writers from whom we adopt this genus, indicate several European as well as American species, that remain hitherto undefined. Of the latter we have not sufficient materials to judge; but the probability of there being some such cannot be doubted. What we have seen of the European specimens would, however, render us much on our guard against those of exotic origin.

TRICHONUM, in Ancient Geography, a town of Greece, in Etolia.

TRICHOPHORUM, in Botany, from τρίχα, τριχών, a bristle, and φόρος, to bear, because of the bristles encompasing the seed, in allusion to *Eriophorum*, (see that article,) out of which the present genus is extracted. — *Perfoon Ench. v.* i. 69. Pursh 57.—Clas and order, *Triandria Monogynia*. Nat. Ord. Calarumis, Linn. Cyperoides, Luff.

Gen. Ch. Cal. Spike, or Catkin, imbricated every way, with ovate, flat-tipped, pointed, keeled, loose scales, distinguishing the flowers. Cor. none. Stam. Filaments three, capillary; anthers erect, oblong. Pfl. Germen superior, roundish, very small; style thread-shaped, the length of the scale, deciduous; filigree three, elongated, reflexed. Peric. none. Seed solitary, beaked, ovate, triangular, with short to nine capillary, wavy, brown bristles at the base, six times its own length. Receptacle cylindrical, cellular, and toothed.

Eff. Ch. Glumes chaffy, imbricated every way, Corolla none. Style deciduous. Seed triangular, beaked, surmounted at the base with from six to nine hairs, scarcely longer than the spike.

Obf. The difference between this genus and *Eriophorum* consists in the comparatively small number of hairs surmounting the base of the scale, and their much shorter proportion, to say nothing of their brown hue. All these circumstances certainly give the *Trichophorum* a different, and far less brilliant, aspect. It is in fact more akin to various species of *Scirpus*, whose seeds are accompanied by short, flat, rough bristles.

2. T. alpinum. Alpine Hair-sedge. Pursh n. 2. (Eriophorum alpinum; Michaux Boreal.-Amer. v. i. 34.) — Stem naked. Spike solitary.—In bogs on the mountains of Pennsylvania, Vermont, &c. flowering in August. Perennial. Stem triangular, as in the first species, but quite naked. Leaves radical, few, sedgeaceous, channelled. Mi-

chau, Pursh. We have Newfoundland specimens from Mr. Frazer, which answer to these characters. If so, the spike consists of scarcely more than three or four flowers, and the bristles of the seed are about the length of the shining tawny scales.

TRICHOPUS, from τρίχα, τριχών, a hair, and ποὺς, a foot, expressive of the long taper stalk of the capsule.—Gärtn. v. i. 44. t. 14.—Clas and order unknown.

Eff. Ch. Capsule inferior, membranous, with three wings, and three cells, not furrowing. Seeds two in each cell, triangular, deeply notched.

1. T. acuttnicus. Bent of the Cingalese, described by Gärtnner from the collection at Leydon. Capsule ovato, very thin, without valves, each angle extended into a wavy membranous border; each side marked with a longitudinal furrow; partitions from the centre of each valve, very thin; the base running down into a triangular stalk, gradually tapering to a fine capillary extremity. Seeds rusty-coloured, tawny, and deeply notched or lobed. Skin simple. Albumen conformable to the seed, with a longitudinal furrow, hard, cartilaginous, pale. Embryo very minute, in the lowest part of the albumen, monocotyledonous.

Gärtnner observes some affinity between this plant and the *Commodine* tribe, but the inferior capsule appeared to him to denote a very distinct genus, of which he could discover no traces in any author.

We do not perceive why the great length of the stalk was admitted by Gärtnner into the generic character, as the capsule being inferior, renders it a mere flower-stalk. No following botanist has thrown any light on this genus.

TRICHOPUS, in Ichthyology, a new genus of fishes, described by Cepede from the MSS. and drawings of Commeron; the characters of which are, that the body is compressed, and that the ventral fins have an extremely long filament. Cepede has unnecessarily divided these fishes into two distinct genera, calling one "Ophronemus," and the other "Trichopodus." These fishes are natives of the Indian seas and rivers, and are distinguished, one species excepted, by the remarkable length of one ray of the ventral fins, which extends the whole length of the body, or even beyond it.

Species.

GORAMY; Rufescent Trichopus. With a silvery cach on the sides, and the second ray of the ventral fins extremely long; Ophronemus Goramy of Cepede. Native of the fresh waters of China, where it is greatly esteemed as an article of food, and known by the name of "Goramy." It is a prolific species, and easily introduced into new situations; having been imported into Java, and many other of the eastern islands.

ARABICUS; Greenish Trichopus. With violet and blue stripes, and second ray of the ventral fins extremely long; Ophronemus Cal of Cepede, the Labrus Gallus of Linn. Syrt. Nat. Gmel., and the Scarus Gallus of Forst. Arab. See LABRUS GALLUS.

SATYRUS. With shining forehead, projecting chin, and extremely long, single-rayed ventral fins; Trichopus Montanor of Cepede. This fish is known in some countries by the name of "Goramy," or "Gouramy."

PALLASI; Brown Trichopus. With pale undulations; a black spot on each side of the body and tail; and long single-rayed ventral fins. Described by Dr. Pallas as a species of Labrus, and by Kolreuter, in the Petersburg Transactions, as a Sparus. See LABRUS Trichiopurus.

MONODACTYLYUS; Silvery Trichopus. With brownish back; and short, single-rayed, rigid ventral fins; Monodactylus.
TRI

TRICHOSANthes, in Botany, elegantly so called by Linnaeus, from spatha falciforme of Cepede, and described by him under the genus Monodactylus. Shaw's Zoology, vol. iv. pt. 2.

1. T. anguina. Snake Hair-blossom, or Snake Gourd. Linn. Sp. Pl. 1432. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 722. (Anguina fenis, flore albo elegantiissimo, &c.; Mich. Gen. 12. 9. Mill. Ic. 1. 32. Curcubita fenis, fructu longo anguino, &c.; Till. Ic. 49. t. 22.)—Fruit cylindrical, elongated, incurved. Leaves heart-shaped, lobed, wavy, with little pointed teeth.—Native of China and Cochinchina, according to Micheli and Loureiro. A tender annual in our stoves, whose seeds are often imported from the East Indies. The herbage is trailing, luxuriant, and much branched, like the rest of its tribe, with tendrils, and broadish melon-like leaves, whose under surface is finely downy. Flowers in loose long-flattked clusters, conspicuous for their snowy white tubers, and capillary or cobweb-like border, by which, in the warm stillness of a flow, they seem suspended in the air, though the least breath might deflect them. The fruit, three or four feet long, and an inch or two in diameter, of a dark shining green, often marked with white, more or less coiled or undulated, lies on the ground, partly shaded by the leaves, and has the appearance, at first sight, of a large snake. Hence Micheli took his generic name, which is most commodiously, as a specific one, made into an adjective.

2. T. fistulosa. Fetid Hair-blossom. Jacqu. Coll. v. 2. 341. T. cutifera, pointed, furrowed. Leaves oblong-heart-shaped, vilifed, nearly entire. Corolla fringed with simple teeth.—Native of the coast of Guinea. Jacquin says it proved a greenhouse plant with him, flowering in summer in the open air. The root is perennial, tap-shaped. Whole plant viscid and fetid like putrid flesh, or the Stelphania bifurca, which odour adheres to the hands of any person who touches it. Stems one or more, annual, herbaceous, branched, leafy, rising by tendrils to the height of eight feet. Leaves drooping, hairy, talked, from one and a half to three inches long; paler beneath. Flowers small, yellow; their border betet with slightly teeth. Fruit tawny, measuring with its peak an inch and a half. Nothing can less answer to the idea of the original species than the present, nor ought they to rank in the fame genus.

3. T. trichostachya. Rib-leafed Hair-blossom. Linn. Sp. Pl. 1432. Willd. n. 4. (Tata-piri; Rheede Hort. Malab. v. 8. 30. t. 17. Raii Hiltl. v. 3. 337. not 377)—"Fruit ovate, acute. Leaves oblong-heart-shaped, three-ribbed, toothed."—Found about Craganore, on the coast of Malabar, flowering in the rainy season. Stems slender. Leaves paler beneath. Flowers white, with a long entangled fringe. Fruit like a cucumber. A freezing medicine is made of the leaves, with garlic, supposed useful in the epilepsy. The juice of these leaves, mixed with some -kind of oil, is used to anoint the temples of maniacs; to whom also a fumigation, made by a woollen thread dipped into the juice of the leaves and bruised fruit, and then burnt, is thought in India to be beneficial.

4. T. caudata. Beaked Hair-blossom. Willd. n. 6. (T. cutifera; Lamarck Dict. v. 1. 190. Schuru-pada-alam; Rheede Hort. Malab. v. 8. 31. t. 15. Raii Hiltl. v. 3. 337.)—Fruit turbinate-ovate, with an elongated point. Leaves oblong, heart-shaped, three-ribbed, toothed.—Native of the East Indies. Nearly related to the following, but smaller in every part, and the fruit is turbinate, crowned with the tube of the calyx.

5. T. cucumcrina. Cucumber Hair-blossom. Linn. Sp. Pl. 1432. Willd. n. 6. Ait. n. 2. (Pada-alam; Rheede Hort. Malab. v. 8. 30. t. 15. Raii Hiltl. v. 3. 337.)—Fruit ovate, acute. Leaves roundish-heart-shaped, deeply lobed, angular, wavy.—Native of sandy ground among trees, on the Malabar coast, flowering in June and July. Every part is fetid. Root widely spreading, fibrous, annual. Stems herbaceous, angular, hairy, not very harsh. Leaves soft and downy, divided down to the stalk. Flowers white, small, with a long entangled fringe. Fruit yellowish; the seeds lodged in red pulp. Prepared with sugar, this fruit is thought to help digestion, and cure pains of the stomach and bowels, killing worms, promoting expectoration, &c. The juice of the root is purgative and emetic, useful in intermittent fevers.

6. T. amara. Bitter Hair-blossom. Linn. Sp. Pl. 1432. Willd. n. 7. (Colocynthcy flos bofo fimbratiu, fruto ob- lono; Plum. Amer. 86. t. 100. Raii Hiltl. v. 3. 332.)—Fruit oblong-obovate, obtuse. Leaves heart-shaped, minut; rough; dotted beneath.—Gathered by Planter, in the woods of Hipsaniola, flowering in December, and bearing ripe fruit in April. The leaves are remarkably small, hardly an inch and a half in breadth or length, roughish, Gg

Vol. XXXVI.
with minute points. Flowers white, as large as in T. anguina, but with a simpler, much shorter fringe. Fruit four or five inches long, and an inch and a half in diameter, contracted at the base; its rind thin, smooth, greenish, variegated; the pulp white and very bitter, with brown seeds.

10. T. tuberosa. Tuberous Hair-blossom. Willd. n. 10. Ait. n. 3. (T. corniculata; Lamarck Dict. v. 1. 191. Anguria frutet parvo, florum segmentis ramulos; Plum. Ec. t. 24.) — Fruit elliptic-oblong. Leaves in three deep lobes; the lateral ones cleft; all entire. — Native of the West Indies. M. Thouin sent it in 1810 to Kew, where it bloomed in the flower about June and July. The root is a huge, globular, perennial, tuberculate, fleshy mass, near a foot in diameter. Stems annual, climbing by simple tendrils. Segments of the leaves lanceolate, diversifoliate, two or three inches long. Flowers somewhat umbellate. Corolla with a longish rather spining fringe at the end of each segment, if we may rely on Burman's copy of Plumier's figure. Willdenow has taken rather an unwarrantable liberty in changing Lamarck's printed names, of this and our fifth species; though in the present instance certainly for the better, the resemblance of horns, in the flower, being probably a deception.

11. T. laciniosa. Jagged Hair-blossom. Willd. n. 11. — "Fruit ovate, acute. Leaves heart-shaped, palmate, with five or seven lobes, toothed, smooth." — Native of the East Indies. Sent by Klein to Willdenow, who describes it with a smooth, slender, angular, climbing stem. Leaves two or three inches long, remotely toothed. Male flowers about six together, in axillary corymbose clusters; with ovate toothed petals; female ones solitary, on axillary flanks; their petals fringed.

Gen. Ch. Cal. Perianth inferior, of one leaf, two-lipped; the upper lip twice the largest, in three equal acute segments; lower in two deep acute segments. Cor. of one petal, ribent; tube very short; upper lip compressed, falcate; lower in three deep segments, the middle one oblong, very small. Stam. Filaments four, capillary, remarkably long, incurved, two rather shorter than the rest; anthers simple. Fl. German four-cleft; style capillary, the length and shape of the filaments; stigma cleft. Peric. none, except the enlarged, inflated, cloved calyx, so reflexed that its upper lip becomes the lower. Seeds four, roundish.

Obs. It is necessary to note, that the above characters, as far as respects the stamens, agree with the specific definition of one of the two Linnaean species only. Linnaeus has left a manuscript fragment, that "Adanson refers this genus to TRICURIUM;" see that article. He certainly does so, in his Familles des Plantes, v. 2. 188, like Dillenius; but in contradistinction to his own just character of the latter, consisting in the want of an upper lip.

Pursh adopts from Walter, Fl. Carol. 164, a variety with linear leaves, called by that writer T. linear.

2. T. brachiatum. Sedge-leaved Trichostema. Linn. Sp. Pl. 584. Willd. n. 2. Ait. n. 2. Pursh n. 2. (Teuricum virginiun, originales; Dill. Virg. ed. 190. t. 283.) — Stamens short, within the flower. Leaves ovato-lanceolate. Flowering branches opposite, panicled. — Native of Virginia, according to Dillenius. Mr. Pursh never saw this species but in the Bankian herbarium, nor have we examined an authentic specimen. The habit of the plant seems much like the last, but the leaves are more fuscous. Dillenius's representation of the parts of the flower, though, doubtless, accurate, but ill agrees with the Linnaean generic description, nor are those parts far unlike those of a Teuricum. The stamens are strongly incurved, or involute, and therefore do not project out of the flower. We suspect this may not be a distinct species from the foregoing. Both require elucidation from American botanists.

3. T. spiral. Spiral Trichostema. Lour. Cochin. 371. (Cay tr&cgrave; me de la Cochinchine.) — "Stamens very long and spiral. Leaves ovate, acute." — Native of Cochinchina. Stem herbaceous, erect, square, four feet high, with opposite crouching branches. Leaves opposite, entire, downy. Flowers pale violet, in long terminal spikes. Corolla ringent, its upper lip falcate. Stamens very long, rolled up spirally, and retained within the corolla. Loureiro. This last character answers exactly to Dillenius's plate of T. brachiatum, to which Loureiro thought his plant nearly akin. Not having, probably, access to that plate, he did not discover how well it agreed, even where he thought the difference greatest.

TRICHOSTOMUM, from Sp. 395, 97, a hair, and 29, the mouth, because the fringe of this moss is remarkable

Eff. Ch. Capsule oblong. Fringe of thirty-two capillary straight teeth, approximated or united in pairs. Trichostomum of Hedwig has, or ought to have, all the teeth of its fringe minutely connected together, at the very bafe, in pairs. The genera which the writer of this articleorldl precluded to reduce to the present, as above indicated, have fruittc teeth, though those teeth nevertheless approach each other in a similar manner. These genera differ among themselves in having separated or united flowers. None can be more naturally akin than they are all, and they have been distinguished by obscure and difficult, as well as unnatural marks. Of this fo good a judge as Mr. Turner could not but be aware, and we are happy in having his concurrence. What is said under the article Dicranum of the general habit of that genus, is in a great measure applicable to this; except a remarkable difference in the aspect and texture of their fringes. This part in Trichostomum, instead of being broad, flat, transversely furrowed, red, with pale points, is long, slender, and of even thickness and colour. The small and unbranched species of the two genera most remarkable each other. The great branched hoary Trichostomum, com-"'

T. papillosum. Papillary Fringe-mofs. FL Brit. n. 5. Engl. Bot. t. 2533. (Bryum papillosum; Dickf. Crypt. fac. t. 11. f. 6.)—Leaves awl-shaped, keeled. Capsule elliptical, nearly erect, gibbous on the lower side at the base. Lid conical. Stem branched.—Found by Mr. Dickson alone, on turfy bogs, in the Highlands of Scotland. The fronds are branched and level-tooped about half an inch high. Leaves dark-green, slender, imbricated every way, entire. Fruit-frisks an inch or inch and half high, terminal, erect, red, with a cylindrical sheath at the base. Capsule red-brown, smooth, with a prominence, like a short spur, at the base, which renders this species very remarkable and distinct, but does not seem to be of the nature of an apophysis. The lid is conical, short. Teeth of the fringe certainly thirty-two.

Sec. 2. Teeth of the fringe connected in pairs at the base. Thirteen Britith species.

T. langimosum. Toothed Hoary Fringe-mofs. Hedw. Sp. Mucf. 109. Crypt. v. 3. 3. t. 2. FL Brit. n. 8. Engl. Bot. t. 1348. (T. ferratum; Ehrh. Crypt. n. 94. Bryum hypnoides; Linn. Sp. Pl. 1384. FL Dan. t. 476. B. hypnoides polycalyx, lanuginosum, montanum; Dill. Mucf. 372. t. 47. f. 32.)—Leaves lanceolate, with a pellucid toothed point. Capsule ovate. Stem procumbent, branched in a pinnate manner. —This, a genuine specimen of the habit of a Trichostomum, is a very common mohs in dry mountainous woods, and on exposed rocks, flines, walls or heaths, bearing capsules, though rarely, in autumn. The copiously branched, arching, clastic, leafy fronds compose large light soft tufts, on which many a tried hunter or botanist has reposèd. The leaves are of a dull yellowish-green, rendered hoary, when dry, by their flat white inferred points, which are curiously bordered with short, broad, abrupt teeth, in a manner unlike every other species, and not ill resembling the cogs of a wheel. Fruit-frisks from the small branches, lateral, solitary, half an inch long, tufted when dry. Capsule erect, brown, smooth, thick and short, with an awl-shaped lid, and a pale reddish fringe. The valve is conical, brown-pointed, splitting up in many different parts, not all at one side.

TRICHOSTOMUM.

nelled, with a pellucid finely ferrated point. Capsule ovate. Stem erect, with very short branches.—One of the most handsome, as well as most rare, of its genus. Dr. Richardson originally sent it to Dillenius from the highest part of Snowdon. Two of our best British cryptogamists, Moffris, Borrer and Hooker, found it in fruitification, in 1808, on the sandy shores of the Tay near Dunkeld. The flms are perennial, two or three inches high, erect, in loose tufts, leafy, subdivided, and furnished moreover with abundance of short spreading branches, which give the plant that resemblance to Erica vulgaris, expressed in the name. Leaves deep green, or tawny, spreading and recurved, revolute, entire, keeled with a deep channel resembling a mid-rib, and tipped with a fine ferrated hair-like point, most visible when dry. Fruit-flasks terminating the last year's shoots, about an inch and a half long, red, finally dark purple, twisted. Capsule erect, smooth, brown. Lid red, awl-shaped, straight, nearly of the same length. Fringe purple, almost as long, straight and slender. Vei fringed with jagged teeth, not splitting.

T. canaliculata. Common Hoary Fringe-moss. Hedw. Sp. Mufc. 111. Crypt. v. 3. 5. t. 5. Fl. Brit. n. 10. Engl. Bot. t. 2534. (Bryum hypnoides; Hedw. 480. B. hypnoides hartifigue canaliculata, vulgare; Dill. Mufc. 358. t. 47. f. 27?)—Leaves ovato-lanceolate, with a central channel, but no nerve, and a pellucid rough point. Capsule ovate. Stem erect, with upright branches.—Very common everywhere, on open, dry, sandy heaths, or moors, both in mountainous and maritime situations, bearing capsules about February or March, but not frequently. The branches are more level-topped and ascending than in the last-described, and the leave of a yellower green, becoming very hoary when dry, in consequence of their white points, rough in every direction. The want of a mid-rib in this species, though there is a furrow appearing like one, has been pointed out as a means of distinguishing it from the rest, especially from T. ericoides. But the same character is found, as we have already described, in that species; while some of Dillenius's specimens of the present, very carefully examined, prove to have an actual rib. These are possibly accidental fragments of another species. The present certainly has no mid-rib, and has its capsule, fringe, and lid accord exactly with ericoides. The latter may be, as Hedwig thought, but a variety of this more common and less elegant kind.

Whether there be any permanent difference in the roughness of the points of their leaves, which affords a clearer distinction in T. lanuginosum, can only be determined by a more minute examination than our materials will admit.

T. fasciculare. Beardle Hoary Fringe-moss. Schrad. Spicil. 61. Fl. Brit. n. 11. Engl. Bot. t. 2005. (B. hypnoides β; Linn. Sp. Pl. 1585. B. hypnoides, hartifigue virescens, fasciculare alpinum; Dill. Mufc. 370. t. 47. f. 28.)—Leaves lanceolate, pointed, revolute, keeled. Capsule ovate-oblong. Stem branched, diffuse.—An inhabitant of dry rocky mountains in the North, bearing plenty of capsules in the spring, whose empty blackened remains continue long. This species approaches several mountain kinds of Dicranum in habit, but is a genuine Trichophyllum. The hoariness of the old plants arises partly from a whitish hue assumed by the leaves in decay, and partly from their lightly pellucid edges; but not from any pellucid or hair-like point, the want of which renders T. fasciculare very distinct from the three foregoing. Its fringe too is much shorter, and the leaves have a mid-rib.

T. glaucifolius. Glauous Fringe-moss. Hedw. Crypt. v. 3. 103. t. 37; B. Fl. Brit. n. 14. Engl. Bot. t. 2581. (Bryum glaucifolius; Dickf. Crypt. falc. 4, 10.)—Leaves linear-lanceolate, acute, rather glaucous. Capsule ovate, slightly furrowed. Stem erect, somewhat branched.—Native of Sweden and Scotland, in which half country Mr. Dickson discovered this pretty and uncommon species, growing in shady rather mountainous situations. We have not heard of it from any other perfon. The flms compone perennial leafy tufts, scarcely half an inch high. Leaves erect, pointlets, rather incurved when dry, of a light-green, slightly glaucous, entire, keeled, with a mid-rib; the upper ones more elongated and tapering. Capsules peculiarly light-coloured and hissing, with a purple fringe, and a conical oblique lid, reddish at the base, half the length of the capsule. The internal cavity of the latter does not reach to the bottom, which, as the thin outer coat of the capsule dries, causes a contraction there, like an apophysis, but of a very different nature. The same appearance is observable in some species of Bryum with club-shaped fruit.

T. lineare. Linear-leaved Fringe-moss. Fl. Brit. n. 17. Engl. Bot. t. 1598. (Bryum lineare; Dickf. Crypt. falc. 3. 6. t. 8. f. 2.)—Leaves linear-lanceolate, imbricated, acute. Capsule elliptical. Lid conical, oblique. Stem erect.—Native of Scotland, Wales, and Northumberland, in wet places, on a calcareous or sandy soil, bearing capsules in the spring. Stems tufted, branched, perennial, an inch or more in height, clothed with dark-green leaves, which vary from an almost linear to an ovate form, and turn either yelowish or blackish, from constant immersion in water, or from its dripping upon them. Fruit-flasks red, an inch long. Capsule ovate, smooth, with a taper lid of its own length. The aspect of this moss, especially when growing in a wet shady place, is much like Dicranum plumulosum, and it has caused some mistakes by that means. Still more perhaps does it resemble a Tortula, (see that article,) but the short flat delicate fringe truly indicates a Trichophyllum. The teeth, standing in pairs, are connected by one common base, according to Mr. Sowerby.

β. Fontinalis alpina; Dickf. Crypt. falc. 2. 2. t. 4. f. 1. (Hypnum nigricans; Villars Dauph. v. 3. 905, B.)—Leaves lanceolate. Capsules ovate, nearly falcate at the ends of the lateral shoots. Stem floating, very much branched.—Native of rivers, in various parts of England, as the Thames at Lambeth, the Isf at Oxford, and the Oufe at Oakley, Bedfordshire. The mountain variety β inhabits the stony beds of the more rapid streams of Scotland, Wales, and the north of England. Both are firmly attached to walls or stones under water, their numerous tufted, branched leafy flms, four or five inches long, floating with the stream. The leave are of a very dark dull olive-green, narrower and almost black in the variety β, loosely imbricated, lanceolate, entire, acute, keeled, with a strong rib; all undulated and twisted when dry. Capsules terminating the lateral branches, foliary, erect, ovate, brown, smooth. Lid half as long, conical, rather curved. Fringe long, tawny or red, its teeth variously connected and pierced at the base, slightly convoluted when dry, soon falling off. The habit of this moss is so little like the rest of its genus, that we cannot but with the character of its fringe were more decidedly sufficient to establish a new one. The specific name moreover, though expressive, is barbarously con-structed.

The
TRI

Some species referred to *Trichosorus* by Hedwig, on account of the approximation of their teeth, we consider as *Grimmia*, because they have only sixteen teeth, not thirty-two. An instance occurs in *G. homonella*, Fl. Brit. 1194. Engl. Bot. t. 1900, to like *heteronella*, which immediately precedes it in these works, that they can hardly be distinguished but by the above minute character. We acknowledge indeed that the dwarf species of *Trichosorus*, in general, have almost entirely the habit of *Grimmia*. But the difference between the numbers sixteen and thirty-two, in their teeth, appears, by the analogy of other genera, a most certain and natural generic distinction. See *Grimmia*.

TRICHOURI, in *Natural History*, a term used by some authors to express such flies as have one or more hairs growing out at their tails: these are called also *fetiscuda*.

TRICHUS, the name of a *ftron* debuffed by the ancients, and said to yield three colours: in their common way of preparing bodies of this kind for medicinal use (which was by rubbing them down upon a pharynx, or other hard stone with water), this first coloured the water black, then red, and lastly white. It seems to have been a kind of hamatites, or blood-stone.

TRICKANDORE, in *Geography*, a town used by *Hindooftan*, in the province of Tinevelly; 30 miles E.S.E. of Palamcott.

TRICKUT, one of the Nicobar islands. N. lat. 8° 3'. E. long. 94° 10'.

TRICLARIA, in *Mythology*, an epithet given to Diana, in Achaia; and Pausanias tells us (In Corint.) that Menalippus and Cometho gratified their luft in the temple of Diana tricharia. This profanation, as it is said, was followed with a general barrenness, infinithe that the earth produced no fruit, and with an epidemical distemper, which swept away thousands of people. The Achaians, having consulted the oracle of Apollo, were answered by the priests, that the infamy of Menalippus and Cometho was the cause of all their calamities, and that the only way to appease the gods was to sacrifice to her every year a boy and a young virgin.

TRICLINUM, in *Antiquity*, the name given by the Romans to the room in which they eat; and also to the bed upon which they reclined at meat, so called, because it was contrived to accommodate three persons.

TRICOCCE, in *Botany*, one of the natural orders among the *Fragments* of Linnaeus, which it ranks as the thirty-eighth, between the *Columneae* and *Siliquosae* (see those articles) though without having scarcely any affinity of characters or qualities with either. The name is derived from *tri*., three, and *xoxo*., a grain, or seed, and alludes to the form of the seed-veil, apparently composed of three combined lobes, each of which comprehends a single-seeded cell. (See *Dicoccus*.) We are not however to understand that every such seed-veil belongs to this order. *Thea* is one exception among severals; while, on the other hand, some genera which do belong to it may have only two lobes to their fruit; witness *Mercurialis*; while *Pluckedia* has four, and *Hura* a much greater number. The valves are generally powerfully elastic, serving by that means to scatter the seeds widely, as soon as they are fully ripe.

The plants composing this natural order have alternate, mostly simple, leaves, often furnished with glands. Their seereted fluids are milky, and extremely acrid, their milk being a natural emulsion, of a most virulent reinf, or gum-resin, mixed with a watery liquid. The *calyx* and *corolla* have, as Linnaeus observes, always something unusual in their conformation, especially about the *necurry*. The *flame* is generally peculiar, being three-cleft, sometimes very deeply, and each branch again divided. Many of the genera have separated, either monocious or dioecious, flowers. The *flame* are either shrubby, sometimes very fleshy; or herbaceous, with annual or perennial roots.

*Euphorbia* is selected by Linnaeus to exemplify the order of *Tricocce*. No genus can be more natural or distinct, however different the habit, or herbage, of some of the numerous species from each other. According to the generally received idea of this genus, its *flowers* are simple or united, each having a *calyx* of one concave or inflated leaf, whose four or five marginal teeth bear as many abrupt, coloured, nectariferous glands. These latter, in some instances, as *E. corollata*, assume perfectly the appearance of petals. Yet Linnaeus was always much puzzled and surprized at the petals thus originating from the teeth of the *calyx*, of which he could scarcely find another example. Other peculiarities in this remarkable genus could not escape to accure an observer, as the long *stalk* which elevates the *flame* out of the flower, and turns it to one side; and the progressive nature of the *flame*, as well as their anthers, which come forth in succession. The herbage too is remarkably various, arboreous and succulent, or herbaceous; spinous or unarmed; the leaves opposite, or alternate, or deficient. Two species having an irregular *calyx*, gibbous underneath, were separated into a distinct genus by Dillenius, under the name of *Tithymaloides*, but they are too naturally akin to the rest to justify such a measure.

Although the above is the generally received idea of *Euphorbia*, Julliena, Gen. Pl. 386, has hinted that the flower is perhaps a compound one, consisting of a central female flower, with many monocious male ones, distinguished by chaffy scales, all in one common involucrum. Mr. Brown, in his very instructive Remarks on the Botany of Terra Aultralis, published at the end of captain Flinders's Voyage, has confirmed this opinion, by an additional observation. He conceives what all authors have taken for a joint in each filament, to be in fact the separation of the filament from its *footstalk*; or in other words the bale, or receptacle, of the flower, or *flame*, which is entirely detached from a proper perianth and corolla; the female flower likewise having its *footstalk*, on whose dilated, sometimes obscurely lobed, fummit, the spheric germen is placed. In support of this doctrine, it is sugggested that the real filament is, as in other plants, produced infrequent to the formation of its anther, and of the *footstalk* below the joint; their surfaces moreover, in some species, being different in nature. But the most conclusive certainty is given to Mr. Brown's theory, by the discovery of a new genus, hitherto unpublished, having an involucrum nearly similar to *Euphorbia*, including several *fifliciul* of monocious male flowers, around a solitary female; while in this there is an obvious perianth, regularly divided into lobes, at the joint of each supposed filament, as well as at that by which the germen is connected with its *footstalk*.

The above idea of *Euphorbia* as a monocious genus, brings it nearer to the rest of this natural order, which have almost universally separated, either monocious or dioecious, flowers. At least such is the case with the genera properly belonging to it, and which constitute Julliena's order of *Euphorbia*, or *Euphorbiaceae*.

TRICOLONI, in *Ancient Geography*, a people of Gallia Narbonensis, whose capital was Alarante; who occupied the territory of Siferon.

TRICOLONI, or *Tricolons*, a town of Arcadia, N.E.
N.E. of Megalopolis. Here was a temple of Neptune, near it a sacred wood, and at a small distance a temple of Diana, renowned Calila.

TRICOMIA, a town of Asia, in Phrygia Major.

TRICOR, a name by which some of the chemical writers have called gold.

TRICORD, an ancient musical instrument with three strings. The first lyre of Mercury is supposed by many to have had but three strings. Most of the writers on music among the ancients, have supposed that the three sounds of this primitive lyre, were E, F, G.

Julius Pollux called the pandora, or pandura, the instrument with three strings.

The emperor Heliogabalus, says Lampridius, sung, danced, recited, or declaimed to the sound of the flute, founded the trumpet, played on the pandura and the organ.

Here is work for ingenious conjectures: what was meant by reciting to the flute? What music could an instrument without a neck produce with only three strings? And what kind of instrument was the organ upon which Heliogabalus played, before organs were supposed to have been invented?

TRICORII, in Ancient Geography, a people of Gallia Narbonnensis, mentioned by Lucan in his Pharsalia, and also by Livy and Polybius, in their account of the march of Hannibal. Livy says that Hannibal, having passed the Rhone, took his route on the left, through the country of the Tricarii, and touching on the territory of the Vecontii, entered into that of the Tricorii. Ascending along the Rhone, he arrived on the fourth day of his march at the junction of a river with the Rhone, on the confines of the Allobroges, who inhabited the territory between these rivers. This river is called Scoras by Polybius, and Arar (the Saone) by Livy. Some critics, however, are of opinion that this name is erroneous, and that it was Iare.

TRICORNIS, in Anatomy, an epithet applied to the lateral ventricle of the brain. See Brain.

TRICORYNE, in Botany, from τρίκορυς, three, and κορυς, a club, expressive of the three club-shaped seed-vessels.

This genus ranges naturally between <em>Anthericum</em> and Mr. Brown's <em>Caps</em>. The species are herbaceous, with fibrous, moily perennial, roots. Leaves grasy, narrow. Branches, if any, accompanied by an interior <em>flabellum</em> (or bracteal). Flowers umbellate, erect, yellow, their partial flanks having a point at the summit. Corolla twisted as it fades, and soon falling. Seed-vessels resembling coated nuts, one of them sometimes abortive, but rarely more than one.

1. <em>T. simpliciflorus</em>.—Stem undivided. Leaves flat, roughish at the edges. Umbel solitary, of from ten to fifteen flowers. Partial flanks thrice as long as the involucre.

Oberved by Mr. Brown at Port Jackson, New South Wales.

2. <em>T. elator</em>.—Stem round, smooth, leafy; branches smooth, panicled, angular and frilled. Leaves flat. Umbels of from five to seven flowers. Native of the same country.

3. <em>T. frabræ</em>.—Stem round, hitpid, leafy. Branches panicled, angular and frilled, rough. Leaves flat, minutely toothed. Umbels of from five to seven flowers.

Native of the tropical part of New Holland.

4. <em>T. tenella</em>.—Stem slender, round, forked, smooth, leafy, scaly. Umbels of two or three flowers. Found by Mr. Brown on the south coast of New Holland.

Gathered by Mr. Joseph Banks, in the tropical part of New Holland, and seen only in his herbarium by Mr. Brown.

TRICOT, in Geography, a town of France, in the department of the Oise; 13 miles N.W. of Compiègne.

TRICRANA, in Ancient Geography, an island situated on the coast and to the S.E. of the peninsula of the Argolid, having to the S. the island Arikera, to the N.W. that of Hydra, and to the N. the promontory of Aca. Pauflanias mentions this island.

TRICRATUS, in Botany, so named by the late M. l'Heritier, from τρίκρατος, three, and κορος, power, or diificlion; perhaps in allusion to the three-fold affinity or resemblance of the plant, indicated by Jussieu, who remarks that it has the habit of <em>Valeriana</em>, the flowers of <em>Primula</em>, and nearly the character of <em>Mirabilis</em>. We still do not perceive any reason for Jussieu's original name, <em>Abonia</em>, (from aβοις, pretty and delicate,) being superseded by the above.—L'Hérit. Monogr. with a plate. Willd. Sp. Pl. v. 1. 807. (Abonia; Juss. Gen. 448. Lamarck Illufr. 468. t. 105.)—Clæs and order, <em>Pentandria Monogynia</em>. Nat. Ord. Aggragata, Linn. Nyfagynæ, Juss.

Gen. Ch. Cal. Perianth none. Car. of one petal, inferior; tube funnel-shaped, inflated at the base, then suddenly contracted; limb shorter than the tube, flat, equal, in five deep, inversely heart-shaped segments. Nectary cup-shaped, of one leaf, encompassing the germen, and united with the inflated base of the tube. Stam. Filaments five, thread-shaped, unequal, shorter than the tube, to which they are united in their lower part, and inserted into the nectary; anthers oblong, within the tube. Pfll. Germen superior, roundish, embraced underneath by the nectary; style one, thread-shaped; stigma undivided. Peric. none. Secc. Nut elliptic-oblong, pointed at each end, five-angled, invested with the hardened base of the corolla, of one cell.

1. <em>T. admirable</em>.—L'Herit. as above. Wild. n. 1. (Abonia umbellata; Lamarck Illufr. 459. t. 105.)—Native of the sea-coast of California, where its seeds were collected by M. Colignon, a gardener who was sent out with La Peyrouse. These produced flowering plants in the Paris garden in 1788. The <em>herbage</em> is delicate, with several branches spreading on the ground; whether perennial or annual is not mentioned. Leaves simple, opposite, ovate, entire, on long flanks. Flowers in axillary, long-flanked heads, with an ovate <em>bractea</em> under each flower. <em>Tubus</em> green. <em>Limb</em> of an elegant rose-colour. This little plant is perhaps the only fruit of La Peyrouse's unfortunate expedition.

TRICRENA, or <em>Tricrena</em>, in Ancient Geography, the name of three fountains, a place of Peloponnesus, in Arcadia, E. of Pheneos.

TRICUSPID, in Anatomy, three-pointed, one of the valves of the heart, placed at the right auriculo-ventricular aperture. See Heart.

TRIDACNAE, in Natural History, a genus of bivalve shells.
TRI

TRIDACTYLIA, in Ornithology, a genus of birds, separated by Dr. Shaw from Picus, on account of the number of toes; this having but three, whereas the genuine Picus are all furnished with four. Its generic characters are; beak many-sided, straight, wedge-shaped at the tip; nostrils covered with fetacous recumbent feathers; and feet with only three toes, placed two before and one behind. The species are the following.

HIRSUTA. Downy, varied with black and white. See Picus Tridactylus.

UNDULATA. Waved, varied with black and white, beneath white. The southern three-toed woodpecker of Latham. First described by Brincon, and by him said to inhabit Cayenne.

TRIDAX, in Botany, from τρίος, three, and δακτυλος, to list, or wound, because of the three deep divisions of its marginal florets. Such is the explanation of De Theis, and it seems consonant with the meaning of Linnæus; yet the latter in his Philosophia Botanica enumerates this word, which he considers as synonymous with ἱδρος, letter, among the old Greek names incapable of explanation. Possibly he had forgotten his original idea, between the writing of his Hortus Cliffonianus and the Philosophia; especially as he had not seen the plant. Phly. speaks of Ofiera iridacea, a kind of oyster, so called because one of them was large enough for three bites, or mouthfuls.—Linn. Gen. 435. Schreb. 568. Willd. Sp. Pl. v. 2214. Mart. Mill. Dict. v. 4. Jull. 190. Gerta. v. 2. 451. No figure.—Clas. and order, Syngenesia Polygonia-superfusa. Nat. Ord. Compositae opposifolius, Linn. Caryophylles, Jull.

Gen. Ch. Common Calyx cylindrical, imbricated, with ovate-oblong, sharp, upright scales. Cor. compound, radiant. Florets of the diusk all perfect, tubular, funnel-shaped, erect, five-toothed; those of the radius female, ligulate, in three deep segments of equal length; the middle one narrowest. Stam. in the perfect florets, Filaments five, capillary, very short; anthers united into a cylindrical tube. Pfit. in the perfect florets, German oblong; style bristle-shaped, the length of the stamens; stigma obtuse; in the female ones, German oblong; style thread-shaped, the length of the corolla; stigma obtuse. Peric. none, except the permanent calyx. Seeds, in both kinds of florets, solitary, oblong. Down simple, rather longer than the calyx. Recept. flat, clothed with lanceolate, shaggy scales, shorter than the seeds.

1. T. procumbens. Procumbent Tridax. Linn. Sp. Pl. 1268. Willd. n. 1. Mill. Dict. ed. 8. (Tridax; Linn. Hort. Cliff. 418. After americana procumbens, foliis laminatis et hiutilibus; Houftouan's MSS.)—Gathered at Vera Cruz by Dr. Houftouan, who sent seeds to Miller. The latter cultivated this plant, in his bark-floe at Chelsea, but it flowered sparingly, and seldom perfected seed. He sent a dried specimen to Clifford, which Linnæus described, but there is none preferred in the Linnæan collection, nor has any figure of the Tridax ever appeared. It seems to be herbaceous and perennial, propagating itself by the trailing flacks, which throw out roots, and are hairy, clothed with opposite, nearly sessile, rough, hairy, ovate leaves, an inch and half long, acute at each end, sharply fertilized, their lower and largest feratrices, which are about the middle of the leaf, making a fort of angle at each side. Flowers flacks long, naked, simple, at first terminal, but afterwards becoming lateral. Flowers solitary, erect, palmatus, or white; Linnæus erroneously supposed the radius to be yellow.

TRIDE, in the Mange, signifies short and swift; thus a tride pace, is a going of short and quick motions, though united and easy. A tride career is a very fast gallop, with the times or motion short and nimble; and so of other motions. Some apply the word only to the motion of the haunters.

TRIDENT, a kind of sceptre, which the painters and poets put into the hands of that god. It is in form of a spear, or fork with three prongs, whence the word.

The poets tell us, that Neptune makes the earth open whenever he strikes it with his trident.

Mythologists give several reasons for affixing to Neptune the trident. Some say that it was designed to denote by its three points, the quality of the three forts of waters that are upon the earth; one of the sea, which are salt; those of the fountains, that are sweet; and those of the ponds, that partake of both these qualities. Others say, that it alludes to Neptune's threefold power over the sea, which he troubles, allivages, and prefers. But without hunting after myurities, it is sufficient to allow, that the trident was a kind of sceptre used by ancient kings.

TRIDENT, among Mathemonantians, is used for a kind of parabola, by which Defartes constructed equations of six dimensions.

Female, at the base of the same spike, Cal. Perianth inferior, of the structure of the male. Cor. none. Pfit. German superior, roundish; styles from fifteen to twenty, thread-shaped, longer than the stamens, collected into three bundles; stigmas thickish. Peric. Capsule roundish, brizy, of three cells and three valves. Seeds solitary, angular at the inner side, gibbous externally.

Female, Calyx of five leaves. Corolla none. Styles numerous, in three bundles. Capsule of three cells, with solitary seeds.

We cannot precisely reduce these plants to any known genus,
genus, and yet it is very probable they may be already de-
dered among the numerous species of Creton, which Jussieu
justly calls genus recognoscendum, as requiring perhaps to be
divided, or better defined.

TRIE, in Geography, a town of France, in the depart-
ment of the Upper Pyrenees; 13 miles E.N.E. of Tarbe.

TRIELe Chateau, a town of France, in the depart-
ment of the Oise; 3 miles W.N.W. of Chaumont.

TRIEBEL, a town of Lower Lusatia, in the circle of
Guben; 12 miles W. of Sorau. N. lat. 57° 36'. E. long.
14° 51'.—Alfo, a town of Saxony, in the Vogtland; 3 miles S.S.W. of Oelsnitz.

TRIEESCHEBACH, a river of Saxony, which runs
into the Elbe, near Meifen.

TRIEDROSTYLA, derived from τρί-, trice, ὀκτά-, a
side, and στυλος, a column, in Natural History, the name of a
genus of spars.

The bodies of this genus are spars, in form of trigonal
columns, adhering by one end to some solid body, and ter-
ninated at the other by a trigonal pyramid. Of this genus
there are four known species. Hill.

TRIEL, in Geography, a town of France, in the depart-
ment of the Seine and Oise; 6 miles N. of St. Ger-
main.

TRIELEN, a small island in the English Channel, near
the coast of France. N. lat. 48° 23'. W. long. 4° 50'.

TRIEMERUS, the three-day fly, in Natural History, a
fly somewhat like the butterfly; it has four large yellowish
wings, and a long body, with a head furnished with long
antennae, large eyes, and a spiral trunk. It is found among
the nettles and mallows.

TRIEMINERIS, τριεμινερις, feminernaria, a kind of
caulis in Latin verse, in which, after the first foot of the
verse, there remains an odd syllable, which helps to make
up the next foot.

As in, Ille latus niveum mollis fulsus hyacintho.

TRIENACH, in Geography, a bay of the county of
Donegal, Ireland, on the west coast. N. lat. 54° 53'.
W. long. 8° 17'.

TRIENIAL, an epithet applied chiefly to offices or
employments which last for three years.

Thus we say, a triennial government; most regular ma-
nifctories have triennial superiors; that is, they elect new
ones at the end of each three years.

In 1695, an act was made for triennial parliaments, i.e.
for parliaments which should be dissolved, and the members
be elected anew, every three years. Till that time, the king
had it in his power to prorogue and continue his parliaments
as long as he pleased. This opened a door to corruption,
which the triennial bill was intended to prevent.

The triennial act had, from other views, been since
repealed; for the great struggles usual at elections, the great
ferment it usually put the nation into, the great expenses
upon that occasion, with other considerations, determined
the legislature, in 1717, to change triennial parliaments for
frequently ones. See Dissolution of Parliament.

TRIENS, in Antiquity, a copper money, of the value of
one-third of an as, which on one side bore a Janus's head,
and on the other a water-rat.

This was the piece of money used to be put in the
mouths of the deceased, to pay Charon his fare for their
passage into another world.

TRIENS, or Triental, was also used for a drinking cup;
and that which was ordinarily used. It contained four
cyathis.

TRIENTALIS, in Botany, from triens, the third part of
any thing, usually of a foot measure. A name borrowed
by Linnaeus from John Bauhin, who calls this pretty little
plant Herba trisialis, alluding to its humble stature.—Linn.

275. Gartn. t. 50.—Clas and order, Heptandria Mono-

Gen. Ch. reformed. Col. Perianth inferior, of about seven
linear-lanceolate, pointed, spreading, permanent leaves. Cor.
of one petal, flat-shaped, flat, in seven deep, ovato-lanceolate
segments, alternate with the calyx, very slightly connected.
Stam. Filaments seven, capillary, inserted into the base
of each segment, spreading, the length of the calyx; anthers
simple, recurved. Pist. Germen superior, globose; style
thread-shaped, equal in length to the stamens; stigma capi-
tate. Peric. Capsule ovate, of one cell, and as many ovate,
rigid, cartilaginous, thick-edged valves as there are calyx
leaves, and opposite to them, highly polished internally.
Seeds several, nearly orbicular, convex externally, angular
within, blackish, dotted, each enveloped in a snow-white,
finely reticulated, combined, membrane tunics. Recept.
central, globose, very large, with a cavity for each seed.

Eff. Ch. Calyx of seven leaves. Corolla in seven deep
equal segments, flat. Capsule of one cell, and many valves.
Seeds in a reticulated tunic.

Obf. Linnaeus remarks that feven is the most usual number
in the parts of fructification, though sometimes liable to vary.
He adds, that the fruit is a dry berry, not burrowing with
valves like a capsule. So Gærtner likewise contains this;
and as botanists have rarely seen it, they have, like
ourselves, adopted the opinions and descriptions of the
great writers. Yet nothing is more certain, if we may be
move our eyes, than that the fruit of Trientalis from Scot-
tland, is, as above described, a capsule with rigid spreading
valves, probably soon breaking off from the base, and
leaving a brittle, dry, globular mass of seeds, rolling around
their receptacle, and enveloped in a most elegant white net-
work, originally perhaps pulpy, which has been taken for
the membranous coat of a dry berry. At first we were in-
clined to suppose the valves of the capsule might be a per-
manent hardened corolla, but their being opposite to the
calyx soon decided that point. It is high time for us to
correct this, too long neglected, error.

trisialis; Bauh. Hist. v. 3. 536. Pyrola alines flore ma-
jor; Bauh. Prod. 100; copied in Morison, fæt. 12. t. 10.
f. 6.)—Leaves elliptical.—Native of tufted heaths, or of
woods on the sides of hills, in Scotland and the northern
countries of Europe, as well as some parts of the north of
England, flowering in May and June. The perennial root
is girtly tuberos, with many long whitish fibres. Stem
solitary, simple, erect, four or five inches high, almost
naked, except at the top, where it is crowned with a tuft of
nearly sessile, bright green, smooth, entire leaves, delicately
veined, an inch and half or two inches long; tapering at
the base; more or less blunted at the extremity. Among
them are several axillary, capillary flabell, about the same
length, each bearing a very pretty and delicate white flower,
with yellowish, or pale pink, anther and stigma. Linnaeus
was particularly fond of this plant, and has celebrated its
"fascinating beauty" in his elegant and eloquent Flora
Lapponica.

Pursh
TRI

Purh n. 2. (T. europa; Michaux Boreal.-Amer. v. 1. 220.)—Leaves lanceolate, tapering at each end.—In cedar swamps, and other places, among bog-mofs, on high mountains, from Canada to Virginia, perennial, flowering in July and August, and differing considerably from the European species. Purh. We have this from Newfoundland, as well as from the garden of the late right honourable Charles Greville, at Paddington. The leaves are narrower, more lanceolate, and tapering at each end, but we can discover no difference in the flowers, nor any other part besides. Both kinds bloom at the same time in our gardens.

TRIERARCHI, τίμωποι, among the Athenians, commissioners chosen annually out of the richest citizens, who are obliged to provide all sorts of necessaries for the fleet, and to build ships at their own charge. See Potter, Archcel. Grec. lib. i. c. 15, tom. i. p. 86.

TRIERES, or TRIERI, in Ancient Geography, a town of Syria, burnt by Antiochus.

TRIERON, a promontory of Africa Propria, at the extremity of the Lefler Syrtes. Ptolemy.

TRIERS, in Laws. See TIRIONS.

TRIERTY, in Geography, a small lake of the county of Donegal, Ireland, near the borders of the county of Fermagham.

TRIESING, a river of Aultria, which runs into the Danube, 3 miles N.W. of Fischamund.

TRIESTE, a sea-port town of the duchy of Carniola, situated in the Adriatic, at the north-east part of what is called the Gulf of Trieste. The houses here stand on the front of a mountain, extending themselves quite to the sea, and on top of the mountain is a castle. The harbour confines of the inner and outer. The emperors-queen, Maria Therfia, caused it to be considerably improved and fortified, and also declared it a free port, imparting to it all the requisite immunities and privileges, whence all sorts of wares, both by water and land, in and out of the time of fair, may be imported here, free from any duties and taxes; but from this immunity, iron, steel, copper, quicksilver, salt, gunpowder, mirrors, and crystal, are excepted. By these means many ships and vessels are induced to arrive there, which at this place unladen their goods, and take others on board, which are conveyed from hence by land-carriage out of the hereditary lands belonging to the house of Aultria, and also out of Germany. A wall, fortified with a bastion, serves as for the defence of the harbour against any hostile attempt, as for fencing it against the wind, and also for the security of the shipping. On the north-west side of the town, where formerly were salt-pits, a beautiful suburb has been erected, and thereby the bad air, which formerly arose from these salt-pits, meliorated: but full at the time of flood, which often rises here four or five feet in height, a fench is perceived, the sea at this place having a boggy ground. The water also of a fresh spring has been conducted by pipes from the distance of two Italian miles to the town. These and other improvements and good regulations, have in view the increase of the trade of the place. Triefe is likewise the see of a bishop, who is suffragan to the archbishop of Goritz, and bears the title of the count of Triefe. In its cathedral too are twelve canons. The sovereign captain, who governs the town and its territories, resides in the castle. Lotharius, king of Italy, made a donation of this town and circumjacent country, together with the right of mintage, to John, at that time bishop of the place; but bishop John II. def Wopped of the jurisdiction over it to the community of Triefe for 500 marks. Afterwards it was incorporated with the duchy of Carniola, but again dismembered. In 1795, this place was taken by the French. The number of fixed in-habitants is estimated at 30,000, without including fees-faring people and strangers; 74 miles S.S.W. of Vienna. N. lat. 45° 53'. E. long. 13° 55'.

TRIESTE. See TRIESTE.

TRIESTY, mountains in the north-western part of the county of Mayo, Ireland, near the Mullet, and immediately north of Tullaghon bay.

TRIETERIA, in Antiquity, recalls which the Brotians and Thracians held every three years in honour of Bacchus, and in remembrance of his expedition into India, which lasted three years.

TRIETERIS, τριήτερος, in the Ancient Chronology, a cycle of three years.

Thales, it is said, observing that the lunar revolution never exceeded thirty days, appointed twelve months of thirty days each; so that the year consisted of three hundred and fifty days: and in order to reduce these months to an agreement with the revolution of the sun, he intercalated thirty days at the end of every two years, whence that space of time was called a period of three; because the intercalation was not made till after the expiration of full two years, though really it was only a period of two years; as we are informed by Cen- ferinus, De Die Natali, cap. 18.

TRIEWALD, Martin, in Biography, an eminent mathematician and engineer, was born at Stockholm in 1691, and being intended for trade, he travelled to England for information and improvement on subjects that concerned his commercial pursuits. Disappointed in prospects of this kind, he changed his object; and was fortunately engaged by the proprietor of some coal-mines near Newcastle to superintend the machinery of his works. This situation corresponded to his genius and inclination; and he was thus led to pay particular attention to mechanism, both in theory and practice. In 1726 he returned, after an absence of ten years, to his native country, where he constructed a steam-engine, and read lectures in philosophy, illustrated by a course of experiments, similar to those of Desfagniers, which he had attended in London. He thus attracted the notice of the king and of the States, who conferred upon him a pension, with the title of director of machinery. He also proposed some improvements in the manufacture of iron and steel. Thus diligently and actively employed for the benefit of his country, he received a commission as captain of engineers and inspector of fortifications; and he invented various machines connected with those offices, models of which are preferred in the Academy of Sciences at Stockholm and also in the Academy of Lund. Diving was also an object of his attention, and on this subject he wrote a treatise, entitled "Of the use of Water, or the Art of living under Water," Stockholm, 1741, 4to. (See DIVING-BELL.) For this invention he received honorary rewards both from his own sovereign and the king of France. In 1729 he was elected a member of the Society of Upsal; and the same honour was conferred upon him by the Royal Society of London and other learned bodies. Triewald died suddenly in 1747. He communicated various papers to the Academy of Sciences at Stockholm, which appear in its Memoirs for the years 1739, 1740, and 1747. Beckman's Hist. of Inventions. Desfagniers' Philos. Gen. Biog.

TRIEXAHEDRIA, formed of τρίς, thrice, καὶ, and σατρ, a side, in Natural History, the name of a genus of fisps.

The bodies of this genus are perfect and pellucid crystal-like spars consisting of thrice five plane sides, being composed of an hexagonal column, terminated at each end by an hexagonal pyramid; of this genus there are three known species. Hill.

H H TRIFAL-
TRIFALTIGKERT, in Geography, a town of Prussia, in Natangia; 16 miles S.S.E. of Königberg.

TRIFAX, among the Romans, a javelin three cubits long, which was thrown by the cataphuta.

TRIFELS, in Geography, a citadel of France, in the department of Mont Tonnerre. Here Richard I., king of England, was kept, when he appeared before the diet of Worms; 1 mile S.E. of Anweiler.

TRIFOLIASTRUM, in Botany, Brachard Trefoil, a name given by Micheli, Nov. Gen. Pl. 26. t. 25, to such species of Trifolium as have their legume projecting beyond the calyx, which he, on that account, separates from thence. Neither the character, nor the name, has met with the favour of following writers. See TRIFOLIUM.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, five-toothed, permanent. Cor. papilionaceous, with long claws, mollily permanent, withering; standard reflexed; wings shorter than the standard; keel of one petal, shorter than the wings. Stam. Filaments two, distinct, one simple, one in nine segments; anthers simple, roundish. Pip. Germen oblong-ovate; styleawl-shaped, ascending; stigma simple, smooth. Petals. Legume short, of one valve, and one cell, not burfting, scarcely exceeding the calyx in length, deciduous. Seeds one to four, roundish.

All botanists have perceived the difficulty of defining the technical characters of this genus, and yet none can be, in itself, more natural. Linnaeus reckoned it the most difficult in the whole vegetable kingdom to discriminate by any essential mark. He comprehends under Trifolium, as may be seen above, various other genera of good systematic writers, differenting among themselves as follows. Melliotus of Tournesort and Julliac, has a legume longer than the calyx, with loosely spikéd flowers; Trifoliatum of Micheli, a legume longer than the calyx, with capitate flowers; Lupinatif of Buschman, a legume with several freads, and five leaflets in each leaf: Lupulinum of Rivinus, a permanent corolla, whose standard is inflexed and flattish, ribbed or plaited: Logopus of the fame author, a flabby calyx, equal in length to the corolla; and finally Triphyloides of Pointedera, has a monopetalous corolla, the standard wings and keel being all united into one tube; which is likewise the case with a great many more species than this author, or Linnaeus, has indicated.

Linnaeus admitted the inflorescence as a part of his natural, and even his essential, character of this genus, defining it "a little umbel or head." He was always very unwilling to adopt this measure, and we presume to think he has, in no cafe, referred to it with advantage. In the present it is neither correct nor determinative, scarcely any species being really umbellate, and though many are capitated, as many are spikeled, while several are racemose. We have therefore followed the example of Jussieu, who in this instance wisely lays aside the inflorescence; attempting a more full and explicit character from the parts of fructification themselves.

In natural affinity the present genus comes nearest to Trigonella, which will presently follow in alphabetical order. Some of the Mellioti especially, closely accord therewith, both in characters, habit, and qualities, particularly in an appropriate scent, allied to that of new hay and bitter almonds, most powerful, and very permanent, in the dried herbage. Some compare it to the smell of a pig-fly. The Blue Mellilot, and Common Fenugreek, poife this odour in the greatfet perfection.

Trifolium is a very extensive genus. Linnaeus has forty-six species in the fourteenth edition of his Systema Vegetabilium; Willdenow has seventy-two in his Sp. Pl. — Eighteen are natives of Britain. Fifty-five are enumerated by Mr. Aiton in his Hortus Kewensis. We have three to add from the Prodr. Fl. Græc., two or three American ones of Mr. Pursh, and a few from other sources. It is necessary to take a view of the whole, partly for their more correct botanical distinction, though in general they are better defined than the species of most, equally extensive and natural, genera. A correct knowledge of these plants is supremely important to the agriculturist; because the qualities of some, very near in external appearance, differ widely in utility; and because there are many, hitherto little observed, which promise to be as valuable as any of the rest. Some of these are known and cultivated in other countries, and others may be well worthy of trial. Unless they are first accurately distinguished, nothing respecting them can either be perfectly understood, or clearly communicated.

The species are distributed into five very natural sections, and are all herbaceous. Some in each section are annual, others perennial. The frens are branched. Leaves alternate, more or less flaked, of three, molybly obovate, and equal, toothed or entire, rarely linear, leaflets, with a pair of membraneous ribbed stipules united to the base of the foot-stalk. Inflorescence terminal or lateral, generally flaked, either tufted, capitated, spikéd or racemose. Flowers red, purplish, white or yellow; sometimes, though rarely, fragrant.

Sect. 1. Malolist. Legumes projecting beyond the calyx; with several seeds. Flowers racemose.

1. T. cornaceum. Blue Mellilot Trefoil. Linn. Sp. Pl. 1977. Willd. n. 1. Ait. n. 1. Bieb. Cuff. 1860. T. odaizatam; Gen. Em. 1195. Melliotus carus; Rivin. Tetr. Irr. t. 9. Lotus sylvanis; Camer. Epit. 894; not 721, as in Willd. and Ait. after Linn. The latter being T. arvense. A good coloured figure is wanting.)—Clusus roundish-ovate, long-flaked. Legumes half-naked, beaked, with flight longitudinal ribs, and two seeds. Stem erect. Stipulas entire.—Native of Bohemia, Tauria, Germany, &c. in dry barren ground, flowering in summer. Cultivated in our gardens, for curiosity, ever since the time of Turner, Gerarde, &c. The root is annual, fibrous. Stem two or three feet high, smooth, angular, leafy, scarcely branched. Leaflets pal, elliptical, toothed, an inch long, smooth; the odd one flaked. Flowers pale, blue, in numerous, solitary, long-flaked, axillary heads, all the way up the stem. The whole plant, either fresh or dried, has a sweet liquorice-like scent, lasting...
TRIFOLIUM.

a great number of years, and perfuming every thing near it.

2. T. indicum. Indian Melilot Trefoil. Linn. Sp. Pl. 1077. Willd. n. 2. Ait. n. 2. (Melilotus lutea Indice orientalis erecta, foliculis rotundatis parvis, picis floreum ex folioauris alis multiplicatis; Pluk. Phyt. t. 45. f. 4.)—Clutters cylindrical. Legumes naked, strongly reticulated, single-fed, obtuse. Stem erect. Stipulas nearly entire. —Native of the East Indies. Cultivated at Oxford before 1689. Annual, flowering in summer. Smaller and more slender than the foregoing, with long slender clusters of small, yellow, drooping flowers. The leaflets also are smaller and narrower. Legumes not much bigger than mustard-feed, turgid, pale, roundish-elliptical, strongly corrogated, with a fort of elevated net-work, and tipped with the capillary style, not properly beaked. Such is the Linungan plant, which does not agree with Willdenow's definition. We cannot answer for the varieties enumerated in Sp. Pl. Some are said to have white flowers. The yellow lades greatly in what we have examined, before the corolla falls. Willdenow has in his Enumeratio, 789, distinguished the $\beta$, which is Pluknet's t. 45. f. 5, as a species by the name of Melilotus rugofolus.

3. T. mellifieae. Sicilian Melilot Trefoil. Linn. Mant. 275. Suppl. 339. Willd. n. 3. Ait. n. 3. Sm. Fl. Grac. Sibth. t. 741, unpublished. Desf. Atlant. v. 2. 192. (T. fructu racemoso; Bocc. Muf. 163. t. 124. Melilotus meffanifis procumbens, foliculis rugosis sublongis, picis floreum brevioribus; Rafi Hift. 522. Tourn. Infl. 407. M. minima recta lutea, filigris candidis curitis in capitulum congeiffis, femine fonugreci; Morif. v. 2. 162. fect. 2. t. 15. f. 4. t. 16. f. 9. very good.)—Clutters shorter than the leafer. Legumes naked, ovate, pointed, with crowded, concentric, interbranching ribs, single-fed. Stems decumbent.—Gathered by Ray, in a moist situation, on the tongue of land separating the port of Messina from the Sraits of Sicily. Signor Arrofii, who fent us specimens in 1811, informs us this species is not now found about Messina, but in the fields of Girgenti. Profesfor Desfontaines met with it in fields in Barbary; and Dr. Sibthorpe in cultivated ground every where throughout Greece. It has the name of τριφύλλιον, which belongs indeed to most of this genus, in modern Greek. Dr. Sibthorpe judged it to be the λαυρέα of Dioscorides, a point equally difficult to difprove or establish. This species is little known in our gardens, though cultivated in Morifon's time, whose figure cannot be mistaken. The root is said to be annual, though furnifhing with many little flefty granulations, to enable it to refifit occasional drought, such as occur in Vicia latipetraeis, and other fome annual vetches. Stems feveral, a foot long, diffuse or procumbent, the central one only being erect, all stout, smooth, leafy, scarcely branched. Clutters axillary, oblong, hardly longer than the common foottallks, each on a short stalk, and composed of ten or twelve yellow flowers, twice or thrice as large as the lal$.$ The leaves are not very different. Legume one-third of an inch long, peculiarly diftinguifhing by its ovate, oblique, pointed, somewhat compressed, figure, and especially the numerous concentric elevated lines, like coiled horfe-hair, more or less interbranching in the middle, which occupy its fides. The luxuriance of the herbage, and the nature of its root, indicate this plant as worthy of agricultural experiment, though its proucntement mode of growth may be an objection to the mower. It is certainly very different from Mr. Sinclair's T. macrorhizum, Hort. Gram. Woburn. 296, of which we propofe to speak under T. officinale.

4. T. mauritianum. Barbary Melilot Trefoil. Willd. n. 4. Ait. n. 4. Sm. Fl. Grac. Sibth. t. 742, unpublished. (Melilotus fulteata; Desf. Atlant. v. 2. 193.)—Clutters longer than the leaves. Legumes naked, nearly orbicular, obtuse, pointless, with concentric elevated ribs, fingle-fed. Stems diftuse.—Native of cultivated fields in Barbary and Sicily; very abundant about Meliffa, according to Signor Arrofii. There can be no doubt as to the fynonym of Desfontaines. We have not seen the work of Schousboe, cited by Willdenow. This is an annual species, with numerous branching diffuse fteus, but more flender in every part than the laf$. Legums elliptic-lanceolate, obtufe. Flowers yellow, small, very numerous, in long, slender, linear, longif-foettaked clusters, much exceeding the leaves. Legume hardly fo big as in T. indicum, formed as it were of a convoluted line or hair, fome-what in the manner of the lafte, but the whole legume is not a quarter fo large, nor laks it any elongation or point. These two species have, nevertheless, been confounded by botanists, for want of a good figure of the prefeft, which deficiency the Flora Gracce will supply.

6. T. polonicum. Polish Melilot Trefoil. Linn. Sp. Pl. 1078. Willd. n. 6. Ait. n. 6.—Clutters lax, on very long flals. Legumes naked, two-fed, lanceolate, pointed, tranfverfly corrugated. Stem erect. Leaflets pointed, nearly entire.—Native of Poland. Sent to Kew garden in 1788, by M. Thouin. A very diflinct annual species, of a flender habit. Stem quite round. Leaflets obvato-lanceolate, acutely pointed, rather fikky, and fomewhat glaucous, almost perfectly entire; the odd one hardly an inch long. Flowers yellow, diftant, small, on long and flender partial flals; their common ones at leaft thrice the length of the leaves. Legume rather compreffed, pendulous, a quarter of an inch long, beaked, and tipped with the fstyle, not hairy.

7. T. spicatum. Spiked Melilot Trefoil. Sm. Prodr. Fl. Grac. Sibth. n. 1783. Fl. Grac. t. 743, unpublished.—Legumes naked, single-fed, spiked, erect, corrugated, acute. Stipulas awl-shaped, entire. Stem erect.—Gathered by Dr. Sibthorpe, in the isle of Cyprus. Raxon annual. Stem twelve or eighteen inches high, branched and bulky. Leaflets obovate, toothed, half an inch long. Spikes flalked, about as long as the leaves, confifting of yellow, deflaxed flowers; when in fruit becoming twice as long, more lax, and fome-what racemose, the legumes being flightly flalked, erect, roundifh-obovate, with a fhort broad point, tipped with the capillary white fstyle; their fides marked with concentric elevated corrugations. Seed globose.

8. T. dentatum. Toothed Melilot Trefoil. "Waldif. et Kitaib. Hung. v. 1. 41. t. 42." Willd. n. 7. Ait. n. 7.—"Legumes racemose, naked, two-fed, somewhat rugofe, rather acute. Stipulas toothed at the bafe. Stem erect."—Native of moif meadows in Upper Hungary. Peren-nial. Abundantly different from the officinale, the leaflets being sharply and doubly toothed; the fipulas also toothed, and deeply divided at their bafe. Willdenow.

11 h 2

ivated
tivated fields, on clay or marle, throughout Europe, flowering in June and July. Not rare in England. Dr. Sibthorp met with it in moist low situations, throughout Greece and the Archipelago, and confirmed the old opinion, of its being the wild races of Dioscorides. From this old Grecian's venerable authority the plant has long been esteemed medicinal, but is now out of use; nor is it cultivated, with us at least, for any agricultural purpose. The seeds, even in a very small quantity, possess the flavour of flour. Martin, Sinclair.

The root is annual. Stem branched, two or three feet, or more, in height, angular and furrowed. Leaves dark green, smooth, obovate, serrated. Flowers full yellow, veiny, in long dense clusters. Keel and wings equal, and nearly as long as the standard. Legume hairy, transversely wrinkled, but not very strongly. Sigma capitate.

Mr. Sinclair's specimen named T. macrorhizum, in his elaborate and very valuable agricultural work, the Hortus Graminatus Woburnensis, 391, does not exhibit any marks of specific difference from the officinale, of which however it appears to be an important variety, differing in its biennial root, larger leaves and flowers. The seeds are two in each legum, never, as is sometimes the case with the officinale, more than two. It produces a great crop of fodder, or hay, at the time of flowering, but little afterwards. If kept from flowering, the root will last four or five years. Such is Mr. Sinclair's account, who nevertheless now candidly affents to our opinion of its being a variety. We have no means of ascertaining whether this may be Wildenow's macrorhizum, our n. 5, but it does not answer to his character. We can vouch for its being widely different from muf-.

Can it be Wildenow's officinale γ ?

10. T. germanicum. White German Melilot Trefoil. (T. officinale β; Willd. n. 8. Sm. Prodr. Fl. Grcc. Sibth. v. 2. 94. Melilotus; Rivin. Tetraps. Irr. t. 69. M. germanica; Ger. Em. 1220. M. vulgaris; Willd. Enum. 790. M. officinare germanum, flore albo; Tourn. Init. 407. Lotus sylvaticus, flore albo; Tabernaemontani. 583.) — Legumes racemose, naked, flingle-feeded, corrogated, obovate, acute. Stipulas tetaceous. Stem erect. — Native of cultivated fields in Germany. Dr. Sibthorp observed it near Theifallonica. Root biennial. Stem taller than the leaf. Flowers white. Wings longer than the keel, though shorter than the standard. The figure of Rivinus answers better to this description than to our common T. officinale, and was probably taken from what is the most usual German plant. We have never compared specimens, but must observe, that the stipulas are sometimes perfectly tetaceous in our officinale. — Gerarde feems to have been well acquainted with the germanicum, as was also his editor Johnston.

13. T. italicum. Italian Melilot Trefoil. Linn. Sp. Pl. 1078. Willd. n. 9. Ait. n. 9. (Melilotus italicus; Camer. Hort. 99. t. 29. excellent. Willd. Enum. 790. M. sicilicus pedunculatis, curto, luteo, &c.; Morif. sect. 2. t. 16. f. 4.) — Legumes racemose, naked, two-feeded, elliptical, obtuse, strongly corrugated, and crisped. Stem erect. Leaves roundish-obovate, nearly entire.—Native of Italy, Barbary, and Greece. Dr. Sibthorp gathered it on the dry parts of the famous mount Haynuttus, near Athens. This species has long been cultivated in curious gardens, both in England and on the continent. Gerarde describes it under his Melilotus, n. 2, but the figure does not agree. The root is annual. Stem flout, angular, leafy, about two feet high, overtopped, as the fruit advances, by the numerous, elongated, upright, cylindrical clfflers, of pendulous, almost elliptical legumes, each as big as a small pea, conspicuously for their strong, prominent, zigzag, and plaited wrinkles, by which the present species is clearly distinguished. Its leaves moreover are of a much broader and rounder figure than any of the foregoing, rather way than ferrated. Stilpulas ovate, taper-pointed, toothed. Flowers yellow. Dr. Sibthorp conjectured, with great probability, that this might be the kind of Melilot, mentioned by Dioscorides as growing in the south of Italy, about Nola, of a yellowish colour, and weaker feent.

15. T. creticum. Cretan Melilot Trefoil. Linn. Sp. Pl. 1078. Willd. n. 10. Ait. n. 10. (T. pellatum creticum; Bauh. Fl. t. 142, with a figure. Morif. sect. 2. t. 14. f. 3.) — "Legumes racemose, naked, two-feeded, membranous, compressed, bordered, nearly orbicular. Stem ascending. — Native of Crete, Greece, and Barbary. Root annual. Stem branched, twelve to eighteen inches high. Leaflets broad, thick and fleshy, like those of T. italicum, bordered with shallow teeth, inodorous. Flowers pale yellow. Legumes very remarkable for their broad, elliptical, nearly orbicular, flatthi figure, half an inch in diameter, in loose clfflers, two or three inches long. They are represented much too turgid in the above engravings, especially in Mornifon's.

16. T. ornitohpodus. Bird's-foot Trefoil. Linn. Sp. Pl. 1078. Willd. n. 11. Fl. Brit. n. 2. Eng. Bot. t. 1047. Curt. Lond. fig. 2. t. 53. Fl. Dan. t. 368. (Foenugrecum humile repens, ornithodipolus significant; (Bootyn. 531. t. 14. f. 1.) — "Legumes about three on a falk, naked, eight-feedeed, twice the length of the calyx. Stems procumbent. — Native of England, France, and Denmark, on barren gravelly heaths, among short gras, flowering in June and July. The fibrous annual root is furnished with feet tubercles, such as are mentioned under n. 3. Stems mostly simple, depredd, two or three inches long, clothed with little leaves, resembling many of the third section, the falks of the leaflets being all equal; and neither they, nor the flender pale-purple flowers, two or three on each short axillary falk, having any affinity to the Meli-
TRIFOLIUM.

Mellrots, with which the present species is associated entirely on account of its many-feeded, transversely furrowed, prominent, bivalve legumes, which moreover are umbellate, not racemose. This species therefore connects the Mellots by its fruit, with the true Trefoils by its habit, stipulas, inflorescence, &c. We should gladly have retained the genus Mellotus, adopted of late, from preceding writers, by Willdenow in his Enumeratio Plant. Hort. Berol. had we found his generic characters faithful. These are the deciduous corolla, and the burning legume, longer than the calyx. But the legume of molt of the Mellots does not burn, any more than that of a genuine Trifolium. Their general habit indeed, and their peculiar odour, agree far better with Triconella, (see that article,) than with Trifolium.

Scéé. 2. LOTOIDEA. Legumes covered by the calyx; with several seeds.

17. T. Lupinacfer. Balfard-lupine Trefoil. Linn. Sp. Pl. 1079. Wild. n. 12. Ait. n. 12. Mart. Rúll. t. 16. Curt. Mag. t. 879. (T. leguminus polygonpermus, folis pluribus; Gmel. Sib. v. 4. 19. t. 6. f. i.)—Flowers in short unilateral tufts. Leaflets five, without a naked common flalk. Legume with many seeds.—Native of Siberia. Observed also near Conflantinople by the abbé Seilmi and Dr. Sibthorpe. It sometimes appears in our gardens, from exotic seeds; but though hardy as to cold, does not endure long. The root is naturally perennial, tap-flaked. Stems erect, simple or branched, a foot, more or less, in height. Leaflets lanceolate, about an inch and half long, smooth, elegantly veined and finely toothed, usually five, rarely six or seven, each on a minute partial flalk, crowning the ribbed common one, which is bordered all the way up, on each side, with a long and broad membranous stipula. Flowers crimson, occasionally white, numerous, handflome, in terminal heads; their partial flalks directed one way, hairy, each with a little cup-like membranous bractia at the base.

8. T. levigatum; Desfont. Atlant. v. 2. 195. t. 208. Wild. n. 16.

Heads nearly globose. Legumes two-flaked. Stem erect. Leaflets lanceolate, finely serrated. Stipulas rhomboid, toothed at one side.—Native of Italy, Spain, France, Hungary and Barbary. Micheli gathered it in various grafty or healthy places about Florence, flowering in May. The root is annual. Leaflets somewhat like those of T. Lupinacfer, n. 17, in shape, but the lower leaves have a long common footstalk. The stipulas are remarkable for their square figure. Heads of flowers small, dense, on long, solitary, axillary flalks. Corolla white. Legume half-ovate, with a recurved beak. We agree with Willdenow, though we have not compared specimens, that the plant of Desfontaines is very near that of Micheli. Indeed we cannot find marks to define it as even a variety. Linnaeus adopted his T. fridam from the last-named author, in writing the second edition of Sp. Pl., but before that work was printed, he obtained a speci- men of what he thought the same, and this is elaborately described there, though the sorts annexed to the specific character, as in the original manuscript before us, indicates his not having seen the plant. What he there described is T. purisfìorum of Ehliart, Willdenow's n. 56, our n. 66. We must presume that this description, according so very ill with what professor Desfontaines found in Barbary, pre- vented his recognizing the Linnaean plant.

21. T. caespitosum. Tufted White Trefoil. Wild. n. 17. Reynier Mem. pour servir à l'Hift. Phyf. et Nat. de la Suisse, v. 1. 162, with a plate, under the French name of Treffe gazonnant. (T. Thali; Villars Dauph. v. 3. 478. t. 41.)—Heads roundish. Flowers flightly flalked, erect. Legumes mostly four-flaked. Leaflets obovate, minutely toothed. Stems decumbent, tufted, shorter than the flower-flalks. Native of the mountains of Switzerland and Dauphin, in barren, wafe, or trodden places. This most resembles our Common White Trefoil, or Dutch Clover, hereafter described, but the short, deprested, entangled stems, though composing a dense turf, do not creep. The root is woody and perennial. Stalks of the flowers, and even of the leaves, longer than the stems; the former terminal, solitary, erect, from two to five inches in length, bearing a globular, but flightly racemose, head of white flowers, purplish at the base, leaves deprested than in T. repens, but we find no perceptible difference as to the comparative inequality of their calyx-teeth. Legume small, elliptical, compressed, strongly ridged at each margin, beaked with the permanent style and capitate stigma, enveloped in the dry, brown, ribbed corolla, and containing three or four small seeds. No valuable properties with respect to agriculture have been discovered in this plant, nor has it been hitherto raised in England.

whom also we are indebted for the character of the legume having but two seeds, which we have never had an opportunity of examining. Stem upright, twelve or eighteen inches high, hollow, ferrated, smooth, leafy, with three or four upright branches, under each of which the main stem divergates at an obtuse angle. Leaves on very long stalks, with a pair of large, ovate, somewhat deltoid, pale, membranous, veiny, long, and taper-pointed stipulas: leaflets all equally nearly sessile, an inch long, broadly elliptical, rather ovate than obovate, emarginate, finely ferrated; the lower ones partly entire. Flowers white, on hairy partial stalks, composing numerous dense globose heads, hardly an inch in diameter, whole common stalks are but of a moderate length, stout, and angular. Such is the genuine T. hybridum of Linnaeus, whose synonymus above quoted cannot be disputed, though others have been confounded herewith. This is one of the species well worthy of agricultural experiment, though hitherto unnoticed in England. Its crop must be very considerable.

Linnaeus calls the stem "ascending" yet the specimen in his herbarium is perfectly erect, though zig-zag in the upper part. Ehrhart, in his Physiophyllum, n. 26, gives, under the name of T. hybridum, Upfal specimens whose stem is decumbent, or partly ascending, hollow, but not zig-zag. The leaflets are narrower, as well as much more sharply and copiously ferrated, than in the Linnaean specimen, and the flower-stalks are longer. This appears to be the Trifolium superficial corymbiferum annuum album majus, folsio longo obuto, filigium incurvum latam compressa ac dispermum; Mich. Gen. 28, t. 236, f. 5. The form of the leaflets perhaps is variable, as those of neither this, nor the true hybridum above described, do really answer well to Micheli's figures. This decumbent or ascending plant, doublets known to Linnaeus, must have been comprehended in his idea of T. hybridum, of which it is probably a variety. Ehrhart has named it, according to a mode of his own, Bubroma, indicating its value as food for oxen. The tubular flavescently distinguishes these two plants, whether species or varieties, from all to which they are near akin, especially from the following, and T. repens.

23. T. Vaillantii. Trailling White Clover, or Trefoil. Poiret in Lamarch Diet. v. 8, 4. Prodr. Fl. Græc. n. 1789. (T. n. 758; Hall. Enum. Rar. 41. Trifolium annuum corymbiferum album et procumbens, folio cordato, suffusus atro-viridem splendente, filigine tetraspermum, inferne falcatum diffimulatum; Mich. Gen. 27, t. 235, f. 6. Meibomius parasiticus humifusus, folis ferratis glabras; Vaill. Parif. t. 22, f. 1.)—Heads globular. Flowers flarked. Legumes four-seeded. Leaflets elliptico-obovate, finely ferrated. Stems branched, decumbent, folid, many-flowered.—Found in meadows and pastures about Florence very abundantly. Micheli. About Paris. Vaillant. In the meadows of Switzerland. Holter, Lachenal. In the Morea. Sibth. Some dried specimens of this do not, at first sight, look much unlike the Linnaean one of T. hybridum, though smaller, and the general size of every part is much less. The leaflets vary greatly, and are sometimes wedge-shaped. The deciduous character of the stem being not tubular, but filled with fpongy pith, and always decumbent, though not creeping, will ever clearly distinguish this from every variety of the last, to which we may add Micheli's mark of the four seeds, doublets correct; but some of them are liable to prove abortive, so that only one ripe seed can sometimes be found. The present species promises far less advantages to the cultivator than the hybridum or the repens, and therefore ought carefully to be distinguished from both.

24. T. repens. Common White Trefoil, or Dutch Clover. Linn. Sp. Pl. 1082. Fl. Suec. 259. Wildl. n. 18. Fl. Brit. n. 3, excluding the syn. of Vaillant. Prodr. Fl. Græc. n. 1790. Engl. Bot. t. 1769. Pursh n. 2. Curt. Lond. falc. 3, t. 46. Mart. Rufft. t. 34. Fl. Dan. t. 950. Riv. Tetr. Irr. t. 13, f. 2. (T. pratense; Ger. Em. 1185, the figure only. Trifolium pratense corymbiferum majus repens, n. 1—9; Mich. Gen. 26, t. 25, f. 1, 3 and 4.)—Heads nearly globose. Flowers flarked. Legumes four-seeded. Leaflets irregularly heart-shaped, or round. Stems creeping, folid, many-flowered.—Very common in meadows and pastures throughout Europe, from Sweden to Greece, and all the islands of the Archipelago, flowering from May to September, and varying exceedingly with regard to luxuriance, as well as in the pale and whithit, or dark and purplish, marks of its leaves. Mr. Puffin says it is found in fields, pastures, and cleared lands on the mountains of North America, making its appearance wherever lands are cleared of timber, in the most remote parts of the country; from 60 to 100 miles distant from any place where it grew naturally. So it springs up in recently cleared ground in England, being one of the most universal plants of the temperate zone. It forms an excellent bottom for pastures, and is particularly valuable for fodder in the dry autumnal months. Mr. Sinclair thinks it less eligible in the spring, except mixed with grasses, being apt to caustic in sheep the delicate termed red-water, especially if the weather be cold and moist. The roots are fibrous and perennial. Stems many, quite prostrate, branched near their origin, creeping to a great extent, with radicles from most of the joints; they are round, smooth, full of pith. Leaves very variable in size, and somewhat in shape, sharply toothed, on long stalks. Stipulas tubular. Flowers stalks much longer than the leaves, axillary, solitary, mostly erect, angular, folid. Heads rather depressed. Flowers white, brown in decay. Legumes oblong, smooth, with three or four seeds. In oler-holts, and fuch rich moor places, the stem is much upright and luxuriant, but being folid, cannot be confounded with T. hybridum, a species never yet discovered in England, any more than T. Vaillantii. Linnaeus blames Micheli for making a great number of imaginary species out of this common T. repens, but he himself, in some degree, has erred, on the other hand, in confounding two or three very different species together. How far we are correct in citing Micheli as above, and whether some other things, distinguished by him, do not likewise come under the repens, could be determined only by a most careful scrutiny of his own specimens, and perhaps the cultivation of the plants themselves.

25. T. ambiguum. Doubtful Pale Trefoil or Clover. Bieb. Taur. v. 2, 208, excluding the syn. of Haller, n. 368, not 138. (See T. hybridum, n. 22.)—Heads with flarked flowers. Legumes with one or two seeds. Calyx-teeth nearly equal. Standard lanceolate. Leaflets ovate, bluntsih, finely ferrated. Stem creeping.—Frequent in the meadows of Tauria and Caucassus, as well as about the Don and the Wolga, flowering in summer. Larger and more robust than the hybridum and repens, equally creeping and forming tufts. Flowering flaves a span, rarely a foot, in length. Stipulas lanceolate, withering. Leaflets the size of T. alpina, but broader and blunter, yet not emarginate, frilated in like manner with very prominent ribs, ending in extremely sharp and crowded marginal teeth. Heads dense, twice the size of the two species just mentioned, as are also the flowers, which are bent downwards as they fade. Calyx frilated, with awl-shaped divericat

[teeth,]

26. T. compositum. Tufted Trefoil. Linn. Sp. Pl. 1860. Wildl. n. 20. Ait. n. 18. (T. carolinianum; Michaux Boreal.-Am. v. 2. 58; Pursh n. 3; Poiré in Lamarck n. 2; Lagopus americanus, floribus majoribus comosib; Petiv. Mut. 26. n. 254.) — "Heads globose. Flowers stalked, imbricated. Standard deflexed, permanent. Legs four-seeded." — Native of America. Linnaeus. The carolinianum of authors, here quoted with doubt, is described as diminutive and erect; its leaves ineruption, heart-shaped, roundish, smooth, fringed and finely crenate; stipules cloven; heads reflexed, of few flowers; corolla hardly projecting beyond the calyx; seeds about three. This is found in sandy fields near Charlestown, South Carolina, flowering from June to August, and is perennial. Flowers small, white. Pursh. How far the opinion of Poiré, adopted by Pursh, that the above two plants constitute one species, is correct, we are utterly unable to determine, having seen neither; but Poiré's definition of the flowers is altogether at variance with that of Michaux and Pursh.

27. T. alpinum. Dwarf Alpine Trefoil. Linn. Sp. Pl. 1860. Wildl. n. 21. Ait. n. 19. Dickf. Dr. Pl. 38. (T. n. 363; Hall. Hist. v. i. 161. T. alpinum, flore magno, radice dulci; Bauh. Prod. 143, no figure. T. alpinum, T. rheticum, atfragaloides; Bauh. Hist. v. 2. 376. T. angustifolium alpinum; Germ. Em. 1207. Trifolium angustifolium alpinum; Po, Bald. 194.) — Heads hemispherical, somewhat racemose and whorled. Flower-flats radical, naked. Legumes two-seeded, pendulous. Leaves linear-lanceolate. — Abundant in the alpine pastures of Switzerland, Italy, the Pyrenees, and the south of France, flowering in August. The most unscientific visitant of these beautiful scenes could hardly overlook this plant, whose large bright crimson flowers, each above an inch long, seem to spring almost immediately from dense tufts of no less elegant leaves. If this species, procured for the English gardens above forty years ago by Dr. Pitcairn and Dr. Fothergill, be still preferred, a coloured figure of it would be highly acceptable to the public. The root is perennial, thick and woody, running very deep into the ground, and fail to have the sweetnens of liquorice. Stems very short, or scarcely any. Herbace smooth. Stipulas long, lanceolate, membranous, finely frilled. Common flower-flats simple, often not taller than the leaves. No other species can be confounded with this.

28. T. involucratum. Striped-flowered Trefoil. Wildl. n. 49. Dorn. Cant. ed. 5. 183. — Heads roundish, dense, each with an orbicular, ribbed, many-toothed, spinous involucrum. Stem erect, branched. Leaves lanceolate. Stipulas many-toothed. Legumes two-seeded. — Native of the west coast of North America, from whence its seeds were brought by Mr. Menzies, and raised in the Cambridge garden in 1791. We obtained specimens there Augst 24, 1796. Yet this species does not occur either in Hert. Kew, or in Pursh, nor did we discover it in Willdenow, till we had hit on the same name, he having greatly misplac'd it, in the next section, after T. angustifolium. The root is annual. Stem twelve or eighteen inches high, branched, leafy, hollow, round, smooth like the rest of the plant. Stipulas membranous, with many unequal bristly teeth. Leaflets elliptic-lanceolate, toothed, an inch or an inch and half long. Heads of flowers above an inch broad, on long, flout, fribated, axillary flaks, and each subtended by a very remarkable membranous orbicular involucrum, whose strong, close, radiating ribs, end in unequal spinous teeth. Flowers sessile. Calys ribbed and spinous, membranous, pale with green teeth. Corolla variegated with purple and white. Legume ovate, abrupt, compressed, with two entirely distinct valves, and two seeds. The whole plant sometimes becomes very diminutive from irritation. Sect. 3. LAGOPODA. Calys more or less villous.

29. T. subterraneum. Subterraneous Trefoil. Linn. Sp. Pl. 1860. Wildl. n. 22. Fl. Brit. n. 4. Engl. Bot. t. 1038. Curt. Lond. falc. 2. t. 54. Rivin. Tetrap. l. 13. f. 1. (T. pulchrum, florulis longis albis; Hall. Syn. 327. t. 13. f. 2.) — Heads of about four flowers. Calys-teeth linear, hairy. Involucrum central, reflexed, rigid, flower-like, embracing the fruit. — Native of Italy, the Levant, France, and England, on dry gravelly heaths, among short grats, flowering in May, and very common in Hyde park, Greenwich park, &c. Root annual, knobbled. Stems defcribed, spreading, almost concealed by the numerous, broad, pale purple-veined stipulas. Leaflets ineruption, heart-shaped, dark green, hairy. Flower-flats at first erect, each bearing three or four flowers, conpicious for their long white corolla. After flowering, these flaks bury the legumes, which are thin and single-seeded, in the ground, and fix them there, by shooting out several spreading stems and thick fibres, constituting an involucrum of the fruit, though apparently like roots. The herbage of this species is triiling, and it conduces to the spring vurder of many of an other barren tract, has nothing to encourage cultivation.

30. T. globosum. Globular Cotton-headed Trefoil. Linn. Sp. Pl. 1861. Wildl. n. 23. Ait. n. 21. Sm. Fl. Græc. Sibth. t. 744. unpubil. (T. orientale, capitare lanceolato; Tourn. Cor. 27.) — Heads globosum, many-flowered. Calyx very hairy all over, with linear teeth. Upper flowers numerous, abortive, densely villous. Stems decumbent. Native of Arabia and Syria, as well as of Cyprus and Asia Minor. A rare annual species, which Linnaeus cultivated from Haakель's seeds, and which may have been in our gardens a century ago, though not at present to be met with. It preserves some analogy with the last, though very unlike in appearance, having many pink flowers, in upright heads, and the stems are few less defcribed. The leaflets have each a white transverse stripe, but not constantly. The analogy allude to the flowers, which perfect seed, being overwhelmed and borne down by a number of abortive ones above them. These seem to grow out as the others fade, in the form of empty calyces with innumerable, woolly, entangled teeth. No figure of the present species has yet appeared, but Mr. Bauer has prepared a very admirable drawing for the Flora Græc. 31. T. bifidum. Brilly-headed Trefoil. Desfont. Atlant. v. 2. 300. t. 209. f. 1. Wildl. n. 24. (T. hierium; Allion. Auctuar. 26.) — Heads terminal, solitary, globose. Calyx very hairy, with taper teeth. Involucrum of several roundish-ovate pointed leaves. Stem erect. — Gathered by Desfontaines in fields in Barbary, near Maf-
car; by Allioni in Monteferrato. Root annual, long and tapering. Stem erect, a palm high, more or less branched in a corymbose manner, fristated, leafy, flabby with soft hairs, as are likewise the leaves and their footflaks. Leaf-
lets obovate, finely toothed, obtuse, not emarginate. Heads many-flowered, sessile, subtended by three or four clove, membranaceous, ribbed, hairy bracteas, all pointed, and a foliary
TRIFOLIUM.

Solitary leaf like those lower down. *Corolla rose-coloured, longer than the calyx-teeth, which however gradually extend beyond it as the flower fades. We much doubt whether this be a distinct species from the following. The *bracteae* are very similar, except being pointed, and the position of the *florum* to the *leaflets*, as well as the form of the *leaflets*, are known to be uncertain marks.

32. *T. Cheriellii.* Hairy Pink Trefoil. *Linn. Sp. Pl. 1821*. Wild. n. 25. *Sm. Fl. Græc. Sibth. t. 745*. unpubl. *(T. glomerulus, perforans; Cheriellii; Bauh. Hift. v. 2. 377).* Lagopus minor, minupus, mollis et compresso capitatum, flore albo; *Barrel. Leit. t. 899.*—Heads terminal, solitary, globosum. Calyx very hairy, with taper teeth. *Involucrum* of three roundish-ovate pointless leaves. Stems procumbent.—Native of France, Spain, and Barbary, in barren dry places. Dr. Sibthorp gathered it on the shores of Greece and the Archipelago. The seeds are sometimes introduced into our gardens from abroad. This is a little annual species, usually with several procumbent *florum*, three or four inches long; in a starded state having a solitary more erect one. *Leaflets* inerexly heart-shaped, with a dark-purple mark. *Flowers* numerous, in dense heads. *Corolla* twice as long as the calyx, pale bluish-coloured, with a long crimson standard; but the calyx-teeth subsequently rise above it. The *involucrums* leaves are like the leaf, except in being blunt, and are also accompanied by a leaf.—*T. pietum*, Wild. n. 26. Bieberf. *Taur. v. 2. 210,* appears not to differ from *T. Cheriellii*, and is doubtless Dr. Sibthorp's plant gathered on the shores of Greece and the Bosphorus. Nothing can be more uncertain than the spots on the leaves, which gave occasion to the name; and the proportion of the *corolla* to the calyx depends on the period of examination. Barrelier faithfully represents it longer than the calyx in *Cheriellii*, when the flower is in perfection.

33. *T. sphaerocapum.* Round-headed White Trefoil. *Desfont. Atlant. v. 2. 201. t. 209.* f. 2. Wild. n. 27.—Heads terminal, solitary, globosum. Calyx very hairy, with taper teeth, twice the length of the *corolla*. *Involucrum* of three rounded leaves. Stems procumbent.—Native of fields in Barbary, near Mascara. *Desfontaines.* Very like the leaf, except its little white *corolla*, shorter than the *calyx*. The citation of Barrelier, copied by Willdenow from Desfontaines, is the very name which, in the preceding page, he had transferred from *Linnæus*, though let exactly given by the latter. The proportion of the *corolla* does not answer to this, but to *T. Cheriellii*, which may very probably have occasionally, as Barrelier says it, have a white *flower*. We should hardly scruple to reduce these three last described, with *pietum*, to one species.

34. *T. faxatilis.* Thyme-headed Trefoil. *Allion. Pedem. v. 1. 305. t. 59.* f. 5. Wild. n. 28. *(T. thymiflorum*; Villars. *Dauph. v. 3. 487.* T. parum rectum, flore glomerato cum una globulis; *Bauh. Hift. v. 2. 378.* Trefte des glaciers, *Reyn. Mem. pour servir a l'Hist. Phyf. et Nat. de la Suisse*; v. 1. 166.)—Heads terminal, mostly in pairs, hemispherical, leafy. *Calyx* densely hairy, with taper teeth, as long as the *corolla*. Upper *florum* bracteaceous, ovate, acute. *Leaflets* wedge-shaped, emarginate.—Native of the sandy beds of torrents, among the alps of Dauphiny and Piedmont, or the glaciers of Switzerland. Our *specimens* from M. Reynier's herbarium were gathered at the glaciers of mount Sylvia, which terminates the valley of St. Nicholas in the Valsis, by the celebrated herbalist M. Thomas. The *root* is described as biennial. *Stems* several, a finger's length, fimple, leafy, rather filthy than hairy, crowned with one or two small, densely filthy *heads*, of little white *flowers*; the central ones, according to Villars, imperfect or abortive. *Leaflets* small, silky, scarcely toothed, deeply emarginate. *Stipula* purplish, ribbed, acute, for the most part lanceolate, but those of the two opposite leaves, close under the heads of flowers, are broad and ovate, serving as *bracteae*.

37. *T. bifolium.* Hairy Cape Trefoil. *Thunb. Prodr. 136.* Wild. n. 31.—Heads globose, hairy. Stems herbaceous, diffuse. *Leaflets* oblong, hairy.—*Found also at the Cape, by Thunberg. It is impossible to form a correct idea of these three last species, from the above characters, which fuit equally well a number already known, to wchich the author appears never to have adverted. We merely register these plants here for future inquiry.

40. *T. rotundifolium.* Round-leaved Lilac Trefoil. *Sm. Prodr. Fl. Græc. Sibth. t. 1795.* *Fl. Græc. t. 747.* unpubl.—Heads globose, terminal, fimple, with lanceolate *bracteae*. *Calyx* very hairy, longer than its teeth. Stems fimple, diffuse. *Leaflets* nearly orbicular, toothed, hairy.—Gathered by Dr. Sibthorp in the Morea. A very pretty and distinct annual species, which seems never to have been noticed before. The *florum* are scarcely a fpan long, clothed, like the rest of the herbage, with copious hairy hairs. *Leaflets* remarkably round, not half an inch in diameter, strongly and unequally toothed. *Calyx* tubular, very slightly inflated, with short, lanceolate, upright teeth. *Corolla* twice the length of the *calyx*, elegantly variegated with
with pale purple and white, its petals distinct. *Germen* hairy.

41. *T. Lagopus*. Oblong Hairy Trefoil. Wild. n. 34.

42. *T. foliolatum*. Stipulaceous Cape Trefoil. Thunb. Prodr. 237. Wild. n. 35.—"Heads villous, ovate, terminal. Stems herbaceous, decumbent at the base. Leaflets jagged, villous."—Found at the Cape of Good Hope, by Thunberg, whose specific character is all we know of this species. The word "herbaceous" is truly superfluous in any specific character of a *Trifolium*!

44. *T. rubens*. Red Long-spiked Trefoil, or Clover. Linn. Sp. Pl. 1081. Wildl. n. 36. *App. n. 26*. *Jacq. Annu. t. 385*. Mart. Ruff. t. 9. (Lagopus major, *spicis longioribus*; *Gen. Em. 1192*.) —Spikes long and cylindrical. *Calyx* teathy, the lowermost about the length of the monopetalous corolla. *Stipulas* sword-shaped, longer than the footstalk. Leaflets lanceolate, sharroweared. Stem erect.—Native of Italy, the south of France, Germany, and Switzerland, especially in the warmer meadows of the latter, where, according to Haller, this handsom* species* is very common. It flowers in summer, and found a place in our English gardens in Gerarde's days. *Root* perennial. Stem one or two feet high, erect, firm, full of solid pith, smooth like the very elegant, finely ferrated, and veined, leaflets, which are two inches long. Their common *flask* is united almost entirely to the long, entire, even, sharp-pointed *flippers*, which reach far beyond it. *Flowcrs* crimson, in dense, cylindrical, thick, blunt *flippers*, two or three inches long, becf with the prominent bristle *calyx-teeth*, of which the lowermost is much the most conspicuous. This Trefoil, though not hitherto brought into cultivation, feems, as profeftor Martyn obferves, of a good quality, and sufficiently productive.

45. *T. pratense*. Common Purple Trefoil, or Clover. Linn. Sp. Pl. 1082. Wildl. n. 37. *Fl. Brit. n. 6*. *Engl. Bot. t. 1770*. Mart. Ruff. t. 31, and t. 36. *Fl. Dan. t. 989*. *Afcz. Tr. of Linn. Soc. v. 1. 240*. *Matth. Valgr. v. 2. 189*. (T. pratense purpureum; *Fuck. Hilt. 817*. *Trifolium*; *Rivin. Tetrap. Irr. t. 11. f. 1*.) —Spikes ovate, dense. Stems ascending. Corolla monopetalous, unequal. *Four of the calyx-teeth equal. Stipulas* awned.—Common in draffy meadows and pastures throughout Europe, flowering from May to September. In its native situations, particularly on dry calcareous or gravelly hills, this valuable plant is truly perennial, though, like Saintjohn, lefs permanent in cultivated manured land. For its agricultural properties, and management, fee *Clover*. Great difficulties have long attended the botanical discrimination of this and some other species, which we shall presently describe; but they are for ever fet at reit, by the moft minute and laborious details of Mr. Afheus, in the firft volume of the Linncean Society's Transactions. Nor is this question merely curious or speculativė; for the qualities of the plants, in an economical view, are as widely different as can well be. The *root* of *T. pratense* is tapering and branched, but not creeping. *Stems* about a foot high, more or lefs, slightly branched, leafy, folid, downy in the upper part. Leaflets elliptical, more or lefs acute, entire, smooth, with a pale lunate spot. *Upper leaves*, near the flowers, moftly opppofite. *Stipulas* rather broad, ovate, pale, purple-ribbed, with taper points. *Spikes* terminal, folitary, fefile, of numerous light-purple flowers, with a sweet, but faint fcent, their petals united at the base, and combined with the *filaments*. *Calyx* hairy, ten-ribbed, its lowest tooth longer than the reit, but much shorter than the corolla. The figures in Fl. Dan. and *Martyn* represent the cultivated plant; that of *Engl. Bot.* the wild one. What *Dillenius* represents, in his edition of *Ray's Synops*, t. 13. f. 1, feems merely a varief plant. There is faid to be a procumbent, very hairy, kind, found on the loftielt mountains of Switzerland and Dau- phiny, which is alfo a variety.

47. *T. alpefr*. Oval-spiked Narrow-leaved Trefoil, or Clover. *Linn. Sp. Pl. 1082*. Wildl. n. 39. *App. n. 29*. *Jacq. Annu. t. 433*. Mart. Ruff. t. 1. *Afcz. Tr. of Linn. Soc. v. 1. 234*. (T. folio longior, folio purpureo; *Rivin. Tetrap. Irr. t. 12. f. 1*.) —Spikes oblonge, mostly folitary. Calyx-teeth hairy; the lowermost as long as the monopetalous corolla. *Stipulas* bristle-pointed. *Leaflets* lanceolate, nearly entire. Stem fimple, erect.—Native of mountain forests, in Siberia, Germany, Thracet, and Swit- zerland. The late Mr. Davall, who never met with this species, except in one little spot, in a foil near Orbe, was perfuaded it was unknown to Haller, his n. 376, though taken for this, being probably our *medium*. Among fifteen or fixteen piant*, Mr. Davall faid but one with two heads of flowers. *Root* perennial. *Stems* ftraight, angular, downy, a foot high. *Leaves* moft like *T. rubens*, as beautifully ftriated with veins, but far lefs viufibly toothed. *Stipulas* hairy, linear, united to the *footstalk* about half its length only; their points almost thread-flaped, very long, hairy, shorter than the lower *footstalks*, longer than the upper. *Flowers* crimson, in a round head, overtopped by the upper leaves. *No use for cultivation, affording few leaves, and never branching."

**TRIFOLIUM.**

Stipulas awned. Stem branched. Leaflets ovate, obtuse, slightly and minutely toothed."—Found by Mr. Schouboe in Morocco. Root annual, or biennial. Willd. We know nothing more of this species.

50. **T. pannonicum.** Hungarian Trefoil, or Clover. Jacq. Obs. falc. 2. 41. t. 42. Linn. Nat. ed. 2. 376. Willd. n. 40. Ehrb. Pl. Select. n. 9. Allion. Pedem. v. 3. t. 334. f. 2. (T. orientale major villosissimum, floribus flavescensibus; Tourn. Cor. 27.)—Spikes dense, elliptical-oblong, solitary. Calyx hairy; its lowest tooth longest. Corolla monopetalous; standard very long and linear-lanceolate. Stipulas with awl-shaped points. Leaflets hairy, nearly entire, minutely pointed. Stem erect.—Native of meadows in Lower Hungary, Armenia, and about the Bithynian Olympus. Cultivated by professor Williams, at Oxford, in 1790. One of the most striking species, on account of its very large and dense oblong spikes of innumerable cream-coloured flowers, whose corolla is about an inch and a quarter long. The root is perennial. Stem a foot and a half or two feet high, sometimes a little branched. Leaflets an inch and a half or two inches long, elliptic-lanceolate, either quite entire, or bluntly toothed towards the end, which is tipped with a little spiny point. Stipulas oblong, ribbed, united to the lower half of each footstalk; their points nearly twice as long, awl-shaped, hairy. Calyx furrowed, its upper part, and long teeth, clothed with long and dense silky hairs. The prominent rounded angle of each wing of the corolla retains, in the dried specimens, a remarkable whitish, sometimelike of which may be seen in *T. ochroleucum*.

Professor Willdenow, in a note to his Enumeratio, 793, has separated Tournefort’s plant by the name of arnatum, distinguishing it chiefly by the leaflets being linear-lanceolate, and emarginate; for the slight differences in the proportion of the lower calyx-tooth and tube of the corolla, as well as the casual branching of the flaps, are of no moment. Our Bithynian specimens have certainly narrower leaflets than one sent from Piedmont; but those in the Linnaean herbarium, as well as the plates of Jacquin and Allioni, are intermediate between the two. We have not examined an authentic specimen of Tournefort, but there is no reason, from Willdenow’s definition, to suppose his a different species.

51. **T. elongatum.** Long-beaked Trefoil. Willd. n. 41. —Spikes lax, elliptical, solitary. Lower calyx-tooth the length of the wings of the monopetalous corolla. Standard very long. Stipulas lanceolate. Leaflets lanceolate, vitous. Stem ascending, branched."—Native of Galatia. Perennial. The whole plant is villous. Stem half a foot high, branched from the base, round, flattened. Leaflets toothed at the extremity. Stipula oblong, with a lanceolate point. Calyx tubular, villous; with falcate teeth, four of which are nearly equal. Standard lanceolate, twice as long as the wings or keel. Differences from *T. alpestris* in having small leaves, a longer standard, a branched ascending stem, and in being a hairy plant. Willdenow.

52. **T. cernuum.** Hoary Oriental Trefoil. Willd. n. 42. Ait. n. 31. Sims in Curt. Mag. t. 1168. (T. trichocephalum; Bieberf. Taur. v. 2. 212. T. orientale canecens, capitulo oblongo, fordidè albo; Tourn. Cor. 27.)—Spikes ovate, lax, solitary. Calyx-teeth hairy, lanceolate, all nearly equal. Corolla monopetalous. Stipulas taper-pointed. Leaflets elliptical, villous. Stem simple, ascending.—Native of Cappadocia, and of the alpine heights of Caucasus, towards Armenia. Mr. Lodiges of Hackney received it from the neighbourhood of mount Caucasus. A hardly perennial, flowering in May. Root cylindrical, rather woody, branching at the top into several leafy tufts. Stems several, a span high, or not so much, covered with close silky hairs, slightly leafy. Leaflets hardly an inch long, more or less acute, very nearly entire; most frizzed with fine elevated ribs near the edge. Stipulas pale, membranous, gradually tapering into a hairy point. Spike thick, two inches long. Calyx hairy; its lower tooth very little the longest. Corolla cream-coloured. We conceive there can be no doubt of the correctness of the above synonymes, though we have not compared specimens.

53. **T. ochroleucum.** Sulphur-coloured Trefoil. Linn. Syn. Nat. ed. 2. v. 3. 233. Wild. n. 47. Ait. n. 36. Fl. Brit. n. 5. Engl. Bot. t. 1224. Jacq. Auffr. t. 40. Curt. Lond. falc. 6. t. 49. Mart. Ruff. t. 35. Azel. Tr. of Linn. Soc. v. 1. 229. (T. squarrosum; Linn. Sp. Pl. 1882. Wild. n. 44. Ait. n. 33.)—Spikes elliptical, hairy. Lower calyx-tooth very long, linear, finally reflexed and rigid. Stem erect, downy. Lowest leaflets inverversly heart-shaped.—Found in dry, bushy, gravelly or calcareous pastures, in England, Switzerland, Austria, and the south of Europe, as far as Constaninople, flowering in June or July. Root branching, perennial. Habit of the plant between pretensis, medium, &c., with which it agrees in size, and pannonicum, which it resembles in colour of the flowers. The whole point of the wings, when dry, is conspicuous in both. The leaflets are twelve or eighteen inches high, fohd, but little branched, and of a fliff, slender, bare aspect. Leaves dilatant, on longish stalks; the uppermost opposite; leaflets linear-oblong, or somewhat elliptical, those of the lower leaves short, rounded, or obcordate; all hairy, and almost perfectly entire. Stipulas linear, tubular, close, with simple ribs, and an very taper point. Head terminal, flat, and erect, of a dirty, brownish or yellowish colour. Calyx furrowed, hairy, with bristle-shaped teeth, the lower one twice the length of the rest; and, after flowering, still more elongated, hairy, and reflexed, giving the head a fleshy-like aspect. Corolla monopetalous, yellowish cream-coloured, with a long erect standard. Legume membranous, with one seed, in the swelling tube of the calyx.

We remove this species nearer to its allies than were Willdenow has placed it. In an advanced state, it was described by Linnaeus as distinct, by the name of squarrosum, but the original specimen from Sauvages’s herbarium has enabled us to correct this mistake. The synonym of Morphon, sect. 2. t. 15. f. 1, evidently belongs to *T. angustifolium*, n. 57, though possibly his "other species, with a round leaf," may be ochroleucum; but this is of little importance. What *T. squarrosum* of Bieberf. Taur. v. 2. 214, with a purplish flower, may be, we cannot determine. It is requisite to correct an error in Fl. Brit. where Fuchs is cited improperly, his plant being *T. montanum*, hereafter described.

55. T. maritimum. Teasel-headed Trefoil. Hudf. ed. 1. 284. Fl. Brit. t. 220. Willd. n. 43. (T. flaccidum; Hudf. ed. 2. 326. T. flaccidum gracilis; Ger. Emm. 1208. Pluk. Phyt. t. 113. f. 4.) Spikes terminal, nearly globose. Calyx-teeth lanceolate, leafy; finally spreading. Stipulas lanceolate. Leaflets oblong. Native of dry sandy fields, throughout Europe and the Levant, as well as in North America, from Canada to Virginia, flowering in July and August. Root annual. Herb very various as to luxuriance, erect or decumbent. Stems much branched, rather zigzag, round, hairy. Leaflets from half an inch to an inch long. Stipulas ovato-lanceolate, acute, ribbed, often red. Spikes from half an inch to an inch and a half long, but always about half an inch thick, very soft and downy, the flender, prominent, equal calyx-teeth being densely fringed, with fine, silky, reddish hairs, and projecting far beyond the little white corolla. Legume very small. An entirely useless weed, not eaten readily by any animals that we are acquainted with.

The herb is annual, varying much as to luxuriance, always considerably spreading, or diffuse. Leaflets small and abrupt. Flowers white, or bluish-coloured, monopetalous, the standard erect, rising much above the very hairy calyx, whose enlarged, red or tawny, teeth spread in a flary manner after flowering, when their crimson bafes are elegantly contrasted with a dense tuft of white cottony hairs, which clofe the mouth, and conceal the little membranous single-fed legume.

60. T. leucanthum. White-blossomed Tartaric Trefoil. Bieb. Taur. v. 2. 214.—Spikes villous, nearly globose, flaked. Calyx spreading, with nearly equal teeth, shorter than the corolla. Stipulas awl-shaped. Leaflets obovate-oblong, slightly serrated at the extremity. —Native of dry hills, in the southern parts of Tartary, flowering in May and June. Pallas mitook it for T. flaccidum, to which it is described, in the above work, as being very near; but the stems are only about a finger’s length, stipulas lanceolate-awl-shaped, entire, (which is the most material distinction,) leaflets more oblong, at least the upper ones, flowers smaller, the villous hairs of the calyx (we presume in its mouth) reddish, not white.

T. pratense,
TRIFOLIUM.

T. pratense, but the leaflets are shorter and rounder, sometimes marked at each side with a small marginal purple streak, not a central spot. Flowers either light roselicoloured, or white. Calyx very remarkable, especially as the fruit advances, for its broad, ovate, pointed, hairy, many-ribbed teeth, or segments, forming a sort of five-angled shield, green and leafy, its mouth closed by an oblong valve, under which is the small, membranous legume, with a gibbous seed. The great inequality of its calyx-teeth distinguishes this plant from the flailatum and maritimum; its broad stipulae approach the former, but are totally unlike the latter. Indeed these three species, though more naturally allied, by the peculiarities of their calyx, to each other than to any of the foregoing besides, are very unlike in habit. Many of the following accord with them in the leafy nature of their calyx, but differ in having lateral heads, to say nothing of their much smaller dimensions.

62. T. albifidum. Whitith Starry Trefoil. Retzius. Obf. fasc. 4. 30. Willd. n. 53. Ait. n. 41.—"Spikes falked, nearly globular. Calyx spreching; its lower tooth linear-awl-shaped. Stipulae linear-awl-shaped. Leaflets oblong. Stems diffuse."—The native country of this species is unknown. Professors Retzius raised the plant from seeds sent him under a wrong name. Mr. Aiton mentions it as introduced at Kew about 1796. It proves a hardy annual, flowering in July and August. The stems are branched, round, slightly downy; branches knotty at the base. Leaves opposite; leaflets of the lower ones ovate, of the upper lanceolate, with a short recurved terminal bristle, the margin and keel fringed. Stipulae falked with green and white. Heads on long straight stalks, without floral leaves; nearly globular when in flower, ovate in fruit. Calyx cylinrical, downy, with close-pretted awl-shaped teeth; the lowestmost three-ribbed, about the length of the corolla, which is yellowish-white and monopetalous; the dorsal ones, which are rather shorter than the two next, are clapped to close to the corolla, that their points are hidden under the lateral teeth. As the fruit advances, the calyx-teeth become dilated and spreading, as in T. flailatum. Retzius. We have seen no specimen.

64. T. echinatum. Little Hedge-dog Trefoil. Bieberf. Taur. v. 2. 216.—Heads ovate, terminal and axillary, falked, leaflets. Calyx-teeth awl-shaped, unequal, hairy, shorter than the corolla. Stems declining, branched. Leaflets obovate-oblong, entire."—Native of mountainous. Annual. Habit of T. lappaceum, n. 38. Stem rather hairy, with subdivided branches. Stipulae awl-shaped, hairy. Leaflets entire, slightly hairy. Flowers-stalks much longer than the heads. Calyx falked, downy all over; tube very short; teeth extremely narrow, finely pointed, clothed with spreading hairs; the lowermost longest; all widely expanded when the fruit ripens, as in T. lappaceum. Corolla monopetalous, pale, twice the length of the calyx, with a long lanceolate standard. We have seen no specimen. This species appears indeed to be very near lappaceum, though ranged after fcalbria by the learned author who is our only guide.

66. T. parviforrum. Small-flowered Trailing Trefoil. Ehren. Beitr. v. 7. 165. Fl. Seelci. n. 29. Willd. n. 56. Bieberf. Taur. v. 2. 218.—Heads globoso, axillary, falked, nearly smooth. Calyx-teeth awl-shaped, rather unequal, spreading, recurved, longer than the corolla. Stem procumbent. Leaflets ovate, toothed. Native of Hungary and Siberia. Willdenow. Linneus knew this plant, but confounded it with his fetrion; see n. 20. It is most akin to gloomeratum, in size, habit, smoothness, mode of growth, and peculiar characters; but differs essentiually in the length and form of its calyx-teeth, as well as the falked heads, and remarkably membranous pellucid stipulae, with green awl-shaped teeth. The corolla seems to be rofe-coloured. A few hairs are sometimes seen on the calyx, which is very strongly falked.

67. T. fexfutum. Soft Knotted Trefoil. Linn. Sp. Pl. 1805. Willd. n. 57. Fl. Brit. n. 12. Engl. Bot. t. 1843. (T. parvum hirtutum, floribus parvis dilutae purpureis, in glomerulis mollisibus et oblongis, femine magni; Raiti Syn. 329. t. 13. f. 5; Vaill. Parif. t. 33. f. 2.) Heads ovate, falked, lateral and terminal. Calyx elliptical, hairy, furrowed, with brifile-shaped, rather unequal, teeth. Leaves downy. Native of dry, rather barren, sandy pastures, in Germany, Hungary, France, Spain, and England, flowering in June. Root annual, with small fethy knobs. Whole herb downy, and very soft to the touch, by which it is known from all the species which it otherwise resembles. Stems procumbent, from three to six inches long, branched, round, often zigzag. Leaflets ovate, finely toothed. Stipulae ovate, broad, pointed, somewhat membranous between the ribs. Heads mostly terminal. Calyx-teeth green, fringed, lengthened out after flowering. Corolla pale rofe-coloured, about as long as the calyx. Germin with rudiments of two seeds; legume with only one, which is thrice as large as that of gloomeratum, n. 65.

68. T. gemelum. Twin-headed Trefoil. Willd. n. 58. —Heads oblong, terminal, in pairs. Calyx hairy: its teeth brifile-shaped, unequal, longer than the corolla. Leaflets wedge-shaped, emarginate, finely toothed at the extremity. Stems simple."—Native of Spain, from whence specimens were sent by the abbé Pourret, to professor Willdenow, under the above name. Root annual. Stems a finger's

70. *T. alexandrinum.* Egyptian Trefoil. *Linn.* Sp. Pl. 1885. Ameon. *Acad.* v. 4. 286. *Wild.* n. 60. *Ait.* n. 45. Forks. *Egypt.-Arab.* 139.—Heads ovate, on axillary flanks, longer than the leaves. Calyx hairy; teeth awl-shaped, unequal. Stem erect. Floral leaves opposite. *Leaflets* elliptic-lanceolate, with shallow teeth. —Native of *Egypt.* The root is annual. Stem a foot or more in height, nacked in the lower half, round, fracted, smooth. *Leaflets* uniform, an inch or inch and half long, somewhat downy, about the length of the common flanks. *Stipulas* oblong, veiny, with green leafy awl-shaped points, of their own length. The lowest leaves only are opposite, one of them embracing the flower-flank, the other the main stem, which rises six inches above it, bearing many alternate leaves, and perhaps more flowers. *Heads* solitary, near an inch long. *Corolla* monopetalous, white; *standard* linear, obtuse, longer than the wings, which are marked by a small prominent calloheit at their base. *Stigma* downy towards the standard.

Fork'fill says, this is the Trefoil universally cultivated in *Egypt,* being the bell, and indeed the principal fodder for cattle in that country. It is fown only at the reeds of the Nile; and where the fields are too high to be inundated by that river, they are watered by means of hydraulic engines, the seeds being committed to the earth while it is wet. The produce is three separate crops, the plants growing each time about half an ell in height, and there are three months between each harvest. After the half they die. The first crop is the bell. When the Trefoil is wanted for feed, it is fown with the wheat. Both are gathered at once, by the hand, not reaped or mown, and are threlched out together, the Trefoil feed being afterwards separated by a sieve. Our British agriculturists do not appear to know any thing of this species of Clover, which being so important in its own country, might be worth trying, at least, in this. We beg leave to recommend it to their notice. The plant was introduced at Kew, in 1798, by Mr. Hadoo, and we trust its progeny has been continued. For the occupiers of low oozy lands in the fen it promises most benefit, provided the Egyptian mode of culture be the most eligible.

71. *T. suffruticum.* Suffocated Trefoil. *Linn.* Mant. 276. *Wild.* n. 61. *Fl.* Brit. n. 13. *Engl.* Bot. t. 1049. *Tr.* of *Linn.* Soc. v. 2. 357. *Jacq.* Hort. *Vind.* v. 1. 24. t. 60.—Heads sessile, lateral, roundish, nearly smooth. Calyx-teeth lanceolate, acute, recurved, longer than the corolla.—Found in the loose blowing fand of the sea-coasts of Sicily and England, flowering in June and July. Mr. Wigg firm discovered and afermented it near Yarmouth. Others have met with the plant, along the coasts, from that place to Landguard fort. This little annual *species* is more truly subterraneous than our n. 29, the *flens* and flowers being often buried entirely in dry sand, the leaves only peeping above the surface, so that the species might well remain in obscurity. In smoothness and general habit it comes so near to *gloeratum,* n. 65, that we have somewhat doubted its being more than a variety, caused by peculiarity of situation. But the calyx-teeth are lanceolate, by no means heart-shaped, and extend considerably beyond the corolla, which is closed so as to protect the organs of impregnation, which perform their functions under the dry sand. To provide against accident, each *legume* has two *seeds,* both of which are often perfected. The *petals,* naturally rose-coloured, are rendered whithish by the excision of light. The *corolla* tubes are broad. *Leaflets* wedge-shaped, finely toothed, smooth.

72. *T. uniflorum.* Dwarf White Trefoil. *Linn.* Sp. Pl. 1885. Ameon. *Acad.* v. 4. 285. *Wild.* n. 62. *Sm.* Fl. *Gras. Sib.* t. 752, unpubl. (T. vernalis repens, *flore alsè exiguis*; Buxb. Cent. 3. 18. t. 31. f. 2. *Melilotus* cretis humilissima humifusa, *flore albo magnico*; *Tourn.* Cor. 28. *Spica* triloba; *Alpin.* Fast. 169. t. 168.)—Stems much shorter than the footstalks, defunctified. Stalks single-flowered, aggregate, shorter than the points of the *stipulas.* *Tube* of the calyx longer than its awl-shaped teeth. —Native of *Syria,* *Arabia,* and the neighbourhood of *Constantinople.* Dr. *Sibthorp* observed it on the loftiest mountains of *Creta,* as well as in *Lemnos,* *Greece,* and *Afia Minor.* The root is perennia. Stems several, most like those of *T. caespitosa,* n. 21, in their defunctified position, but still shorter, closely invested with sheathing membranous *stipulas,* whose long, green, awl-shaped points extend beyond the axillary *flower-flanks.* The latter, a quarter or half an inch long, grow usually three together, from one common base, attended by very minute *bracteas,* each of them bearing a large white *flower,* full an inch long, whose *calyx* is tubular, ten-ribbed, nearly smooth, with rather unequal hairy teeth, half the length of the tube, having curved points. *Standard* broadish, erect, marginate, longer than the *wings* or *keel.* *Footstalks* twice as long as the *flowers,* measuring full two inches, slightly hairy. *Leaflets* broadly obovate, smoothish, strongly ribbed, with fine, sharp, partly hooked, marginal teeth. It is very probable this species may have several *seeds* in each *legume,* and may belong to the second section. This point we want materials to determine.

Sec. 4. *VESICARIA.* *Calyx* inflated, swelling after flowering.

73. *T. spumosum.* Bladdery Trefoil. *Linn.* Sp. Pl. 1885. *Wild.* n. 63. *Ait.* n. 47. *Sm.* Fl. *Gras. Sib.* t. 753, unpubl. (T. caule nudo, *gloeratum gallabris,* &c.; *Bauh.* Hift. v. 2. 379, bid. )—Heads ovate. Calys of the fruit ovate, tumid, smooth, with bristle-shaped recurved teeth. *Bracteas* membranous, lanceolate. Stem and branches erect.—Native of *Languedoc,* Italy, and *Cyprus,* in cultivated fields. Root annual. Stems numerous, spreading, a span high, leafy, branched, smooth like the whole plant, which has the general aspect of our common *purple* *Clover,* though totally different when examined. *Footstalks* from two to four inches long. *Leaflets* obovate, fracted, toothed, marked with white. *Stipulas* pale, membranous, ovate, taper-pointed, entire. *Heads* solitary, terminal, ovate or roundish. *Corolla* long and slender, crimson, with a white tube; *standard* ovato-lanceolate, erect, entire. *Calyx* tubular, membrane, five-coloured, very smooth, with five nearly equal, green, slender, spreading teeth, one-third the length of the tube. As the *fruit* advances, the tube becomes inflated, obliquely elliptical, with many red ribs, connected by fine reticulations; the teeth rather unequal, and recurved; the *corolla* remaining dry and hardened in the mouth of the calyx, and invelling the *legume,* which
which is four-seeded, furnished with a long prominent beak. Each flower has a narrow lanceolate bract; befits the five broader ones under the head. The latter are said to be wanting in T. turgidum, Bieberl. Taur. v. 2. 216, which is perhaps a variety, with paler flowers.

75. T. refusinatum. Reversed, or Salamanca, Trefoil. Linn. Sp. Pl. 1086. Willd. n. 64. Ait. n. 48. (T. foliiculatum, five vesica rum, minus purpureum; Bauh. Hift. 379. T. praenfe foliiculatum, flore invero; Barcel. l. c. v. i. 73. n. 824. t. 872.)—Heads roundish. Flowers reversed. Calyx of the fruit inflated, oblong, membranous, reticulated, downy, with two terminal spinous teeth. Stems prostrate.—Native of Germany, Flanders, Italy, all Greece, and the Archipelago, flowering in the spring. A smooth annual plant, much agreeing in habit with our English glomeratum, but larger, and the lateral heads of little crimson flowers are supported by longish stalks. Each flower is turned on its back. The heads in seed are twice as large, being then near an inch broad. Calyx of the fruit much enlarged, split lengthwise, pale green, beautifully reticulated with strong veins, terminating in two teeth only, and besprinkled with short twaity hairs. Leaves two-seeded. Leaflets obovate, ribbed, serrated. Stipulas short, abrupt, with lanceolate teeth. We presume T. bicorne, Fork. Egypt.-Arab. 139, can hardly be different from the present species.

76. T. tomentosum. Woolly Ball Trefoil. Linn. Sp. Pl. 1086. Willd. n. 65. Ait. n. 49. (T. fragiferum; Rivin. Tetrap. Irr. t. 10. f. 2. T. fragiferum tomentosum; Magn. Monsp. 265. t. 264. T. germerulis tomen tofis per caulium longitudinem; Bauh. Hift. v. 2. 379.)—Heads globoso. Calyx of the fruit inflated, globoso, membranous, reticulated, denfooly woolly, with two minute terminal teeth. Stems prostrate.—Native of the south of France, as well as of Spain, Portugal, Barbary, Greece, and the Levant. Cultivated by Parkinson, before 1640. Ait. Root perennial. Stems numerous, from two to six inches long, branched, prostrate, but not creeping. Leaflets obovate, smooth, obtuse, nearly ribbed, bordered with minutely spinous teeth. Stipulas ovato-lanceolate, pointed. Heads lateral, stalked, shorter than the leaves and footstalks, hemispherical while in flower, in which flate the tube of the calyx very smooth, with three teeth, on the under side; gibbous and wooly on the upper, with two teeth. As the fruit ripens, each head becomes an aggregate ball, half an inch in diameter, of globular, crowded, denfooly woolly calyces, exquisitely reticulated with pink veins. Nothing can be more distinct from the leaf, yet their specific characters are not easy to define in a striking manner. Linnaeus justly remarks, that this species comes nearer to refusinatum, with which its corolla agrees, than to fragiferum, which it so much resembles in fruitt. Some copies of Rivinus want the figure above cited, which was added to the plate after its first publication.

77. T. fragiferum. Strawberry-headed Trefoil. Linn. Sp. Pl. 1086. Willd. n. 66. Fl. Brit. n. 14. Engl. Bot. t. 1050. Curt. Lond. f. f. 2. t. 55. Fl. Dan. t. 1042. Ger. Em. 1208. (T. fragiferum, folio oblongo; Vaill. Paris. t. 22. f. 2.)—Heads roundish, on stalks much longer than the leaves. Calyx of the fruit inflated, globoso, membranous, reticulated, nearly smooth, with two awl-shaped, terminal, curved teeth. Stems creeping.—Native of low moilt pastures or heaths, especially by rivers, in a black boggy foil, throughout Europe, from Sweden to Greece, and in Alia Minor, flowering in summer. Root perennial. Herbage to like T. repens as to be easily con founded therewith, except that the heads of flowers are smaller, and most generally pink; though oftenest white in Sweden. Stipulas lanceolate, large, acute, white and membranous, with green veins. The heads, when perfecting fruit, strikingly resemble a hautbois strawbery, in fize and colour, being larger than those of the last species, nearly smooth, and more richly coloured with red and green. The two spinous points of the calyx are also far more considerable. Legume with two feets. This Trefoil is eaten by cattle, but its crop is late, and of trifling amount.

78. T. physodes. Bladder-headed Trefoil. Bieberl. Taur. v. 2. 217.—"Heads roundish. Calyx of the fruit inflated, membranous, downy, with five nearly equal bristle shaped teeth, as long as the tube. Flower-stalks as long as the leaves. Stems procumbent, very smooth."—Native of Georgia. Chev. de Steven. Refembles the last, but is a distinct species. Stems scarcely taking root, long and slender, very smooth, not clothed with scattered spreading hairs as in T. fragiferum, any more than the footstalks and flower-stalks. Stipulas narrower, with a longer point. Leaflets larger, and of a brighter green. Flower-stalks shorter. Flowers with partial stalks a line in length, which render the head less denfe. Calysx-teeth all nearly equal, resembling the two terminal teeth of the last. Corolla redder; with a longer and narrower standard. Such is the description of the author quoted. The calyx-teeth appear to us to afford the most decided specific distinction. T. humens of the same writer is probably, as he suspects, only a more slender variety of his physodes, with longer stalks, smaller heads, and fewer flowers; but especially smaller calyx-teeth.

s. 5. Lupinula. Standards of the flowers inflamed.

79. T. montanum. White Mountain Trefoil. Linn. Sp. Pl. 1087. Willd. n. 67. Ait. n. 51. Bieberl. Taur. v. 2. 218. (T. folio longiore, flore albo; Rivin. Tetrap. Irr. t. 12. f. 2. T. pratense album; Fuchh. Hift. 818. l. c. 472. T. majus primum; Cluf. Hift. v. 2. 245. T. majus flore albo; Ger. Em. 1185.)—Spikes roundish. Standard awl-shaped, withering. Stem erect. Leaflets elliptical, with bristly teeth.—Native of dry mountainous pastures, in Germany, Switzerland, Savoy, and Crete, flowering in August. Dr. Pitcairn is said to have imported it in 1786. The root is woody and perennial. Stems about a foot high, filky as well as the foot stalks. Lower leaflets broadest and obtuse; upper more lanceolate and very acute; all smooth above, light green, nearly ribbed. Heads stalked, at first hemispherical, but from the drooping of the lowermost flowers, as they fade, soon becoming elliptical, and near an inch long. Corolla white. Tube of the calyx pale, hairy about the top only; teeth about as long, awl-shaped, erect, rather unequal, remaining uncharged. The standard, like the other petals, does indeed remain in a dried hardened flate, but scarcely more than in T. hybridum, repens, &c. to which the present species is so nearly related in every other respect, and so little like the rest of this section, that we could with to remove it from hence, we were not Linnaeus and every other author against us.

80. T. speciosum. Purple and Yellow Trefoil. Zant Hay. Willd. n. 68. Ait. n. 52. Sm. Fl. Græc. Sibth. t. 754, unpubl. (T. creticum elegantiflimum, magnpo flore; Tourn. Cor. 27.)—Spikes hemispherical. Standard kidney shaped, toothed as well as the wings. Stems zigzag, decumbent,
TRIFOLIUM.

decumbent.—Found wild on the mountains of Crete, and in the
isles of Cyprus and Zanz. Mr. Hawkins observed this
beautiful Trefoil as the only plant made hay in the
latter country. It might perhaps be tried with advantage
in the dry open parts of the south of England. The
root is annual, if we may judge by appearances. 
Herbage rather
fuscent, nearly smooth. Stems spreading in every
direction, much branched, purplish, about a foot high, but by
culture they would certainly become more luxuriant.
Leaflets obovate, toothed, emarginate. Stipulas lanceolate.
Heads numerous, above an inch broad, on axillary 
flakes, longer than the leaves. Calyx smooth or-hairy, its tube
very short, and two upper teeth not longer; three lower
(Wildenow erroneously says the upper) thrice as long,
though shorter than the claws of the petioles. Standard of a
dull but elegant lilac hue, strongly ribbed, sharply toothed,
withering and permanent, turning brown as it fades.
Wings and keel yellow, shorter, the latter very small.
The flowers are not reverted. Wildenow was milled by a 
dried specimen.
Dickfl. Dr. Pl. n. 80. Ehrh. Herb. n. 29. Fl. Dan.
t. 558. (T. aureum; Pollich Palat. v. 2. 344. T. mo-
tanum lupinum; Baulh. Prodr. 140. Lotus montanus
auraeus, anlro lupuli capitae, annuus; Barrel. Ic. t. 1024,
excellent.)—Heads oval, nearly globular. Standard ellipti-
cal, deflexed, entire. Calyx-teeth linear-awhlshed,
elongated, unequal, smooth. Leaflets all equally feehle.
Stem erect.—Native of Sweden, Germany, Switzerland,
Savoy, Greece, Crete, and Asia Minor, but not of England;
generally in woods and copsipes, in hilly or alpine situations,
flowering in July and August. Root annual. Stems from
four to twelve or fifteen inches high, scarcely branched.
Leaflets obvate-oblong, more or less toothed, ribbed,
shorter than their common flalk. Stipulas ovato-lanceolate.
Heads one, two, or three, full as big as the hal, about
the top of the stem, on longish, stout, angular, hairy flalks.
Corolla of a bright golden yellow, large, flowering,
turning brown by age or drying only; standard furrowed, infixed.
Tube of the calyx short, bottle-shaped, smooth as well as the
teeth, which are all more or less elongated, though the two
uppermoft are shorter. Legume small, elliptical, 
ingleeeded. See the next species.
Pl. 1087. Wildl. n. 70. Ait. n. 53. Curt. Mag. t. 557.
Ehrh. Herb. n. 19.—Heads oval, nearly cylindrical. Stand-
ard elliptical, deflexed, entire. Three lower calyx-teeth
awhlshed, hairy; two upper oblonge, or very short. 
Leaflets all equally fellele. Stem erect.—Native of Sweden, in
mountainous meadows at Gottfurd, near Upfal, and other
places, but rarely. Linnaeus. Whether it be found also
in Germany, we are not certain; but whatever has been tak-
enn for this species in other parts of Europe, we have aconsterned
to be the foregoing, to which all its synonyms, except the
above, belong; even, probably, Lupinum montanum, capitulis
spadiceis; Ruppi. Gen. 248. ed. 2. 256. The excellent figure
in Curtis is therefore a great acquisition. Indeed the syn-
onyms of agrarium, cited by Linnaeus, are wrong. T. agra-
rarium of Dodoens, Pamp. 576, is actually Medicago lupu-
lina! Yet hence the specific name, a very inapplicable one,
was taken. T. spadiceum, sent to Kew by M. Thouin in 1778,
is a hardy annual, flowering in July and August. It differs
very decidedly from the hal, in being a smaller more flender
plant, though equally upright. The heads in particular are
but half the fize of that species, or if sometimes nearly as
long, they are much more flender and cylindrical. The flowers,
though at first yellow, soon change to a peculiarly rich dark
nuft-colour, and are essentially distinguished by the very
small upper teeth of their calyx, as well as the long brifly
hairs which clothe the lower ones.
Fl. Suec. ed. 2. 261. Wildl. n. 71. Fl. Brit. n. 15. 792,
Lond. fabe. 3. t. 45. Mart. Ruft. t. 121. T. lupinum;
Rivin. Tetrap. Irr. t. 10. f. 1. T. pratense luteum, capi-
tulo Lupuli, vel agrarium; Rau Syn. 330. Melothius, qui
Trifolium pratense luteum, capitulo Lupuli, vel agrarium;
Vail. Paril. t. 22. f. 3.)—Heads oval, many-flowered.
Common footstalk elongated in the lower part.—Native of
dry gravelly pastures and fields throughout Europe, from
Sweden to Greece and Asia Minor, as also in North America,
flowering in June and July. This is one of three common
annual procumbent species, with yellow flowers, all of
which have been confounded, in some respect or other, by Lin-
naeus and his discipies, and for the right understanding of which
we acknowledge ourselves obliged to the Rev. Dr. Becke,
now dean of Britfol, see Engl. Bot. t. 18. Before the pub-
ication of Fl. Brit. v. 1 and 2, the present plant was taken,
by all British botanists, for the Linnaean agrarium, n. 81.
From that it differs in being much smaller, with procumbent
branching flalks, which are only occasionally supported by
neighbouring plants, or a little ascending at the end. From
the two following it differs in having oval, many-flowered heads,
which assume in fading a hop-like aspect; but they have
never the shining bronzed hue of the real agrarium, though
the standard, like that, is furrowed. The leaflets are obvate,
emarginate, toothed, smooth, slightly glaucous; their com-
mon footstalk much longer below the fide leaflets than beyond
them, the odd leaflet being sometimes nearly feehle. Stipulas
half-ovate, acute, ribbed, entire, often fringed, branches and
flower-flalks more or less hairy, especially upward. Heads
at most half an inch long. Calyx-teeth unequal, but variable.
Corolla lemon-coloured, changing to a light, tawny brown;
the standard rounded, strongly furrowed. Legume small,
eliptical, pointed, with one feed. Professer Martyn recom-
ends this species to the notice of the agriculturist. Cattle
are fond of it, but the crop will probably not be so abundant
as the Noneuch, or Medicago lupulina.
n. 55. (T. filiforine ß; Fl. Brit. 793. T. silifolle; Ehrh.
Herb. n. 49. T. procumbens; Hudf. 328. Curt. Lond.
fabe. 3. t. 53. T. lupinum alternum minus; Rau Syn. 330.
t. 14. f. 3. T. luteum minimum; Ger. Em. 1186.)—Heads
hemipherical. Flower-flalks straight and rigid. Standard
nearly smooth. Stems prostrate. Common footflalk very short
below the leaflets.—Very frequent in dry gravelly pastures,
of England, Germany, and Switzerland, flowering in June
and July. Root small, annual, often furnished with the little
fleshy knobs. Stems but little branched, from fix to twenty-
four inches long; most succulent and brittle in the large
variety, Engl. Bot. t. 1, which Dr. Becke recommends as
likely to prove a moft valuable plant, for cultivation in upland
pastures, being highly acceptable to cows and sheep. The
central leaflet is elevated on a much more considerable partial
flalk than in the foregoing or the following species; while
the common footflalk, though variable, is in general remark-
ably short. Leaflets obvate and emarginate, or obcordate,
ferrated. Flowers from twelve to fifteen only, pale yel-
low, making a little hemipherical head, and all finally de-
flexed. Standard scarcely wrinkled or furrowed. Legume
obvate,
TRI

obovate, obtuse. *Seeds* rarely more than one in each legume. *Calyx-teeth* very unequal, taper, hairy. Linnaeus confounded this with the preceding, as appears by his herbarium. Others have thought it not distinct from the following; but we trust both those mistakes are now sufficiently cleared up.

85. *T. filiforme.* Slender Yellow Trefoil. Linn. Sp. Pl. 1088. Fl. Suec. ed. 2, 261. Wildl. n. 72. Fl. Brit. 1404. Engl. Bot. t. 1257. (T. lupulinum minimum; Dill. in Rauh. Syn. 331. t. 14. f. 4.)—Heads lax, of few flowers. *Flowers* capitate, wavy. Standard fimbroid. Stems prostrate. Leaflets all nearly sessile.—Native of rather moist gravelly pastures, among short grass, in Scania, as well as in England, flowering in June and July. Annual, like the last, but usually more prostrate, and much smaller, discoverable chiefly by its little yellow heads of *flowers,* entangled by their capillary *flanks,* among the radical leaves of short grass, on grass-plats, where the soil, though gravelly or sandy, is somewhat moist, and prone to bear mofs. The *stems* are about a finger's length, numerous, slender, and branched. *Leaflets* narrow, nearly or quite sessile, on a short common *flxors.* *Flowers* from three to eight, dropping, each on a very slender, though elongated, partial *flank,* and all leaning toward one side. *Calyx* quite smooth; its teeth less remarkably disportioned than in *T. minus.* *Legume* obovate, sometimes two-seeded, scarcely covered by the withered pale-brown *corolla,* whole standard is not at all furrowed.—Sometimes the fruit of this species exceeds that of the smaller variety of the last; but if the above characters be attended to, no confusion can arise.

For *T. biflorum,* Linn. Sp. Pl. 1088, and *T. guianense,* Aubl. Guian. t. 399, see *Stylasanthus,* n. 4 and 5.

Linnaeus, at the end of this genus, classes the various species according to their inflorescence, whether racemose, umbellate, fasciculate, capitate, or spicate; which serves to show the impropriety of any generic character derived from thence.

TRIFORIUM, the gallery which usually goes round a church of the pointed style, over the sfe-aflies, so called by Germain and other ancient writers.

TRIFORMIS, in *Mythology,* an epithet given to *Diana,* which see.

TRIGA, in *Antiquity,* a kind of car, or chariot, with three horfes.

The triga, in reality, was only drawn by two horses; so that it was properly a biga; but it had, besides, a third horse tied to the others, like a led horse, for change. Status calls the third horse, *equus fanalis*; Hedisius, *exanops,* and Dionysius Halicarnassus, *leucops.*

We do not find the triga on any ancient monument; but it was a long time in use among the Romans, at their *ludi Cirienfes.* The Greeks, who first introduced it, soon abandoned it.

TRIGAL, in *Geography,* a town of Prussia, in Natangen; 9 miles S. of Lick.

TRIGAMY, a third marriage; or the state of a person who hath been married three times.

In the ancient church, trigamy was only allowed to such as had no children by their former marriages.

If, having children by one or both the former, they married again, after forty years of age, they were excluded from communion for five years. If they were only forty years old, the penance was but four years. See BIGNY.

TRIGAULT, NICOLAS, in *Biography,* a Jefuit missionary, was born at Douay in 1577, and having entered into the Society of Jesus, was sent, in 1616, on a mission to the East Indies. After a year's residence in China, he came to Europe for a recruit of missionaries, and returned with forty-four associates. At length his life and labours terminated at Nanking in 1628. Of his works, which were numerous, we shall only mention his treatise entitled "De Christiana Expeditione ad Sinas ex Matthei Ricci Commentariis," 1615, 4to. This work, composed from the memoirs of Ricci, contains a description of the manners, laws, and customs of the empire of China, with an account of the acts of the Jefuits in that country. "A Chinese Dictionary," 3 vols. printed in China. Moreri.

TRIGEMINI NERVI, in *Anatomy,* the nerves of the fifth pair of the head. See NERVE.

TRIGINTAL. See TRENATAL.

TRIGLIA, or GURNAU, in *Ichthyology,* a genus of fish of the order of the Thoracici; the characters of which are, that the head is large, mailed, and marked by rough lines; the eyes large and round at the vertex; the mouth large; the palate and mandibles armed with sharpened teeth; and the nostrils double; the aperture of the branchial or gills large; the gill-cover spinous, and the gill-membrane seven-rayed; the body covered with scales, wedge-formed; the back straight, with a longitudinal furrow on both sides spinous; the lateral line near the back, straight; the abdomen thick, the ventral and pectoral fins large, and, in some species, near the pectoral fins are finger-shaped processes.

Species.

CATAPHRACTA; Red Gurnard. With double fingers; forked elongated snout, and octagonal mailed body; its length is about twelve inches; the longitudinal rows or divisions of the body are marked by as many ferrated or aculeated lines; beneath the throat is a pair of ramified cirti; the pectoral fins and tail are pale-brown; the other fins pale-yellow, and nearly transparent; rays of the first dorsal fin running out beyond the membrane. A native of the Mediterranean.

LYRA; Red Gurnard. Silvery beneath, with triple fingers, and bifid denticulated snout. This is the Piper of the British Zoology. Its length is from one to two feet or more; its lateral line formed of small scales; its scales are small, pectoral fins large, slightly tinged with dull blue; tail of like colour; the other fins yellowish, with red rays. Native of the European seas, and considered as an excellent fish for the table.

GURNARDUS; Grey Gurnard. With triple fingers, and lateral line mailed with rounded whitish scales; length the fame as that of the former: colour above dark grey, with blackish and red spots, beneath silver; scales small, lateral line strongly marked with a series of larger, rounded, whitish scales, with a dusky central spot. Native of the European seas, and not uncommon about our own coasts, feeding on worms, insects, &c.

CUCELIUS; Red Cuckow Gurnard. Silvery beneath, with triple fingers, and first dorsal fin marked by a black spot; an elegant species, about a foot in length, of a more slender shape than the last; colour on the upper parts a beautiful red, more or less distinctly marked by whitish transverse bars; scales extremely small; lateral line composed of pointed white scales edged with black, and a similar row on each side of the back; fins transparent; the first dorsal marked on the edge by a black spot, the second tinged near its edge with yellow. Native of the European seas, and esteemed as a food.

LUCERNA. With triple fingers, sub-bifid snout, and lateral line bifid at the tail. Native of the Northern seas, and conjectured to be a variety of *T. hirundo.*

HIRUNDO; Grey-brown Gurnard. Silvery beneath, with triple fingers, and very large olivaceous pectoral fins spotted with
with blue: the Sapphiric gurnard of the British Zoology; and stock-fish of Willughby. Of the same size with the grey gurnard; scales middle-sized, lateral line rough, pectoral fins very large, of a violaceous olive, sometimes richly edged and spotted with blue. Native of the European seas, occasionally springing out of the water to some distance by means of its large pectoral fins.

**Lineata; Red Gurnard.** Marked above by dusky-fangtune spots, with the body crosscd on each side by numerous perpendicular lines; the streaked gurnard of the British Zoology. Size and habit of T. cuculus; colour bright-red, abdomen silvery; on each side of the back, close to the base of the dorsal fins, a row of broad, serrated, short prociples of a yellow colour; lateral line formed by a row of similar ones; scales small, fides above and below the lateral line marked into very numerous, narrow perpendicular divisions; pectoral fins large, rounded, of a dusky-brown, spotted with black; rest of the fins yellowish, with a tinge of red, especially the tail, which is slightly lunate. Native of the Mediterranean sea.

**Asiatica; Silvery Gurnard.** With quadruple fingers; body smooth, finot smooth and prominent; anterior gill-covers ferrated; pectoral fins falcated. Native of the Indian seas.

**Evolans; Springing Gurnard.** With triple fingers, and three ferrated spines between the dorsal fins; allied to the T. volitans, but furnished with three separate pectoral processes; the pectoral fins very large, but less than those of the next species; the pectoral fins blackish. Native of the American seas.

**Volitans; Red Gurnard.** With aculeated scales, very large pectoral fins spotted with blue, and fextuple fingers connected by a membrane; the Milia de Salvian, Aldrovandus, Willughby, &c. This is a highly singular and beautiful species; length about twelve inches; colour crimson above, pale or whitish beneath; head blunt, armed on each side with two very strong large spines, pointing backwards; the whole body covered with very strong carinated and sharp-pointed scales, hardly separable; first dorsal fin pale violet, croffed with deeper lines, and at its origin two separate rays longer than the rest; second dorsal fin pale, with the rays barred by brown; pectoral fins very large, transparent, of an olive-green, richly varied with numerous bright-blue spots, fix pectoral processes, not separa, but united, and appearing like a small fin on each side of the thorax; tail pale violet, with the rays croffed by dusky spots, and strengthened on each side of the base by two obliquely tranverfe bony ribs or bars. Native of the Mediterranean, Atlantic, and Indian seas, where it swims in shoals, and is often seen flying out of the water to a considerable distance.

**Japonica, or Alata; the Japanece Gurnard.** With eleven fingers on each side, palmed by a membrane. About four inches in length; head angular; lower jaw and hinder margin of the gill-covers furnished with two strong spines. Native of the Japanece sea.

**Adriatica.** With the body verticillated by scales, with aculeated lateral line; pectoral fins black beneath, and triple fingers; supposred to be a variety of T. lineata, and differing from it by being varied with bands of black spots, and having the spots of the pectoral fins disposed into two tranverfe bands, the edges being marked beneath by a row of blue spots. Observed in the Adriatic sea.

**Minuta.** With triple fingers, and biccarnated back. A small species: head hard and rough, emarginated and denticulated in front, and furnished with two spines above the eyes; posterior gill-covers spiny; pectoral and ventral fins very sharp-pointed; tail rounded. Native of the Indian seas.

**Carolina; Whitish Gurnard.** Speckled with red, with triple fingers, and brown pectoral fins transversely banded with black; length about ten inches; dorsal fins pale orange spotted with brown; the first fin marked by a black spot; tail slightly rounded at the end, and crofled by three or four rows of brown spots. Native of the American seas.

**Cavillone; Red Gurnard.** With a single spine above each eye, and fix on each side of the back of the head. Length about three inches; body covered with small, denticulated, rough scales; colour red; pectoral fins white above, and dark-green or olive beneath. Native of the Mediterranean, and known on the French coasts by the appellation of Cavillone.

**Punctata; Roe-red Gurnard.** With blood-red speckles, and broad obfute head, spined on the hind-part. Length about eight inches; head broad, obfute, and furnished behind with strong spines; scales middle-sized; pectoral fins very large, rounded, and of a dusky-blue colour, speckled with red, and inclining to yellow towards their tips; rest of the fins and tail yellow speckled with red. Native of the American seas.

**Pint; Red Gurnard.** With triple fingers, and body marked on each side by numerous tranverse convex lines. Similar in habit to that of T. piper, but in other respects much allied to T. lineata; colour red, with yellowish abdomen; scales small; dorsal and lateral line aculeated, from which pafs perpendicular convex lines terminating rather obtusely above and below, and bearing some resemblance to pine-leaves; fins and tail yellowish; ventral fins red, with an obscure blueish tinge. Native region unknown.

**Charonterea; With the body mailed beneath, and red fins.** Allied to the T. cataphracta, but differing by not having the body marked into an octagonal form; the under parts only being furnished with bony divisions; above the front are several spines pointing backwards: and above and below the tail are also placed three spines: all the fins, except the tail, are of a bright red. Native of the Mediterranean. Shaw’s Zoology, vol. iv. pt. 2.

**Triga, in Mythology, the name of a divinity among the Germans with three heads, which was undoubtedly Diana Trivia, or Hecate.

**TRIGLAND, James, in Biography, a learned theologian, was born at Harelem in 1657, and educated at the universities of Harderwyk and Leyden, where he diligently studied the Oriental languages. He became a candidate for the ministry in 1676, and having exercised it for some time at different places, he at length settled at Leyden, where, in 1686, he was made professor of theology, to which was afterwards added the office of explaining Hebrew antiquities. He was twice nominated rector of the university by William prince of Orange, by whom he was greatly esteemed. He died in 1705. His erudition was profound, and his works, on literary and theological subjects, various. Morei.

Gen. Ch. *Cal.* Perianth inferior, of three roundish, obtuse, concave, deciduous leaves. *Cor.* Petals three, ovate, concave, obtuse, similar to the calyx. *Stam.* Filaments fix, very short; anthers at the back of the filaments, shorter than the corolla. *Pist.* German superior, large; styles none; stigmas three or fix, reflexed, feathery. *Perc.* Capsule ovate-oblhq, obtuse, with as many cells as there are stigmas, bursting at the base, with acute valves. *Seeds* solitary, oblong, erect.

Obi. Garten and Brown, perhaps more justly, consider the fruit as an assemblage of three or fix single-seeded capsules, without valves. *Analogy* confirms this opinion.

3. *T. mexicanum*. Mexican Arrow-grafs. Kunth Nov. Gen. and Sp. v. 1. 244.—Capsules of fix cells. Spike very long. Leaves cylindrical. Root tuberous.—Native of moist exposed situations in New Spain, flowering in January. *Root* perennial, oblong, horizontal, the thickened of a fawn’s quill, very densely clothed with the rudiments (rather probably the remains) of leaves. All the leaves are radical, linear, narrow, blunter, smooth, two or three inches long, spreading at the base. *Stalk* erect, round, smooth, fix or eight inches high, including its cluster, which measures half as much. *Stamens* fix. Stigmas red. Two or three of the cells, or *capsules,* are generally abortive. _Kunth._

9. *T. mucronatum*. Pointed-fruit or Arrow-grafs. Brown n. 4.—"Capsules somewhat turbinate; the points of their three perfect cells divaricated; three abortive ones like partitions. Leaves nearly cylindrical. Spike of few flowers."—Gathered by Mr. Brown, without flowers, on the southern coast of New Holland.

**TRIGLOCHINE,** in Anatomy, a synonym of the triguspin valve. See *Tricuspis.*

**TRIGLYPSIS,** formed from τριγωμος, g. d. three engravings, from γραφω, sculpio, in Architecture, a sort of ornaments repeated at equal intervals in the Doric firece. Each triglyph consists of two entire gutters, or channels, cut to a right angle, called *glyps,* and separated by three interludes, called by Vitruvius *femora,* from each other, as well as from two other half-channels which are at the sides.

The ordinary proportion of triglyphs, is to be a module broad, and one and a half high. But this proportion, M. le Clerc observes, sometimes occasions ill-proportioned intercolumnations in the porticoes, for which reason he chooses to accommodate the proportion of his triglyphs to that of the intercolumnation.

The intervals between the triglyphs are called *metopes.*

—Under the channels, or glyps, are placed guttae, or drops.

The triglyphs make the most distinguishing character of the Doric order. Some imagine them originally intended for the conveyance of the gutta that are underneath them: others fancy they bear some resemblance to a lyre, and thence conjecture the ornament to have been originally invented for some temple faced to Apollo. See *Doric.*

**TRICLYPS,** Capital of a. See *CAPITAL.*

**TRIGLYPTON,** in *Ancient Geography,* a town of Italy, on the other side of the Ganges, in the country called Randa-marcotta.

**TRIGNO,** in *Geography,* a river of Naples, which runs into the Adriatic, 12 miles N.W. of Termoli.

**TRIGOLO,** a town of Italy, in the department of the Upper Po; 5 miles S.E. of Crema.

**TRIGON, TRIGONUS,** formed from τριγωμος, triangle, in *Geometry,* a triangle.

**TRIGON,** in *Astronomy.* See *TRIPEDILY.*

**TRIGON,** in *Astronomy,* denotes an aspect of two planets, wherein they are 120 degrees distant from each other: this is called also *trine.*
The trigons of Mars and Saturn are by astrologers held malicious aspects.

**Trigon, Trigonum,** was also a musical instrument, used among the ancients. The trigon was a kind of triangular lyre, or harp, and was invented by Pythagoras.

It was used at feasts, and played on by women, who thrum it either with a quill, or beat it with small rods of different lengths and weights, to occasion a diversity in the sounds. See **Trigonum.**

**Trigon or Triangle of Signs,** is the name of an instrument used for drawing the arcs of the signs upon dials: it may be made of brass or any other solid matter, and of any size at pleasure. This instrument is constructed after the following manner: first draw the line $a b$ (Plate XXI. Astronomy, fig. 5) representing the axis of the world, and $a c$ perpendicular to it, representing the radius of the equinoctial; and about the point $a$ describe the circular arc $d e f$ at pleasure. Then reckon $23^1/2$ both ways from the point $e$ upon the said arc for the sun's greatest declination, and draw the two lines $a d$, $a e$, for the summer and winter tropics; likewise draw the line $d f$, which will be bisected by the radius of the equinoctial in $q$; about which point, as a centre, draw a circle, whose circumference passes through the points $d$ and $e$ of the tropics, and divide the circumference into $12$ equal parts, beginning from $d$: through each point of division equally distant from $d$ and $e$, draw occult lines parallel to the radius of the equinoctial circle; these lines will intersect the arc $d e f$ in the points, through which and the centre $a$, lines being drawn, will represent the beginnings of the signs of the zodiac at $30^\circ$ distance from each other. But to divide the signs into every $10th$ or $5th$ degree, the circumference must be divided into thirty-six or forty-two equal parts. The characters of the signs are annexed as in the figure; and when the trigon is divided into every $10th$ or $5th$ degree, the letter of the month is placed to the first $10^\circ$ of each sign agreeing with it. However, this instrument may more readily be made by means of a table of the sun's declination; for having drawn the two lines $a b$ and $a c$ at right angles, lay the centre of a protractor on the point $a$, with its limb towards the point $c$; and keeping it fixed, count $23^1/2$ on both sides of the radius $a c$ for the tropics of $\varphi$ and $\varphi$, $20^\circ$ for the beginnings of the signs $\alpha$, $\beta$, $\gamma$, and $\delta$, and $11^\circ$ for $\varepsilon$, $\zeta$, $\eta$, and $\xi$. And thus the spaces for each sign may be graduated in every $10th$ and $5th$ degree by means of a table. The equinoctial points of $\gamma$ and $\omega$ are placed at the end of the radius of the equinoctial $a e$.

**Trigon of Diurnal and Nocturnal Arcs.** These are drawn upon fun-dials by curve-lines, like the arcs of the signs, and by means of them the shadow of the style shows how many hours the sun is above the horizon, in any given day, &c.

The trigon of signs is the same for all latitudes, the sun's declination being the same for the whole earth; but the diurnal arcs are different for every particular latitude, and as many of these arcs are drawn upon a dial, as there are hours of difference between the longest and shortest days of the year. For the construction of this fort of trigon, draw the right line $R Z$ (fig. 6) for the radius of the hour-line of $12$, or of the equinoctial: and about the point $R$, with any opening of the compasses at pleasure, describe the circular arc $T S V$, and lay off both ways on it from the point $S$ two arcs, $S V$, $S T$, each equal to the complement of the latitude. Then draw the right line $T X V$, and about the point $X$, as a centre, describe the circumference of a circle $T Z V Y$, which divide into forty-eight equal parts by dotted lines, drawn parallel to the radius of the equinoctial $R Z$; then these lines will intersect the diameter $T X V$ in points, through which and the point $R$ you may draw the radii of the hours. The angles which all the radii make at the point $R$ may be found trigonometrically by the following proportion: as radius is to the co-tangent of the latitude, $\phi$, so is the tangent of the difference between the semi diurnal arc at the time of the equinox, and the arc proposed to the tangent of the sun's required declination.

The trigon of signs may be annexed to a rule or index $A$ (fig. 7) in order to draw the arcs of the signs upon great dials. The diurnal arcs may be drawn likewise upon this trigon, but the arcs of the signs and diurnal too must not be drawn upon one and the same dial, for avoiding confusion. In the centre of the index there is a small hole, through which is put a pin, that the instrument may turn about the centre of a dial. The trigon slides along the index, and may be fixed in any part of it by means of the screw $B$. The arcs of the signs with their characters are round about the circumference, and there is a fine thread fixed in the centre, in order to extend over the radii quite to the half-lines of a dial.—For a farther account of these instruments and their use, see Bion's Contr. and Uso of Math. Infr. by Stone, p. 231, &c.

**TRIGONAL Leaf,** among Botanists. See Leaf.

**Trigonala Numbers.** See Triangular Numbers.

Gen. Ch. Cal. Pierian inferior, of one leaf, bell-shaped, divided half way down into five little, awl-shaped, nearly equal, teeth. Cor. papilionaceous, apparently tripetalous; standard nearly ovate, obtuse, reflexed and spreading; wings two, ovate-oblong, reflexed and spreading outwards, in such a manner that, with the standard, they almost constitute a regular tripetalous corolla; keel very short, obtuse, occupying the centre of the flower. Stam. Filaments in two distinct sets, one simple, one in nine segments, short, ascending; anthers simple, roundish. Pipf. German ovate-oblong, compressed; style simple, ascending; stigma simple. Peric. Legume linear-oblong, somewhat curved, compressed, much longer than the calyx, of one cell, and two valves. Seed numerous, roundish.

Eff. Ch. Standard and wings nearly equal, spreading, in the form of a tripetalous corolla. Stigma smooth. Legume of one cell, with many seeds, compressed, longer than the calyx.

Obi. Linneas remarks that the figure of the corolla alone stamps this as a distinct genus. We could with that character were more evident. The closest affinity exists between some Trigone, which we shall indicate, and the Medites, constituting the first section of Trifolium. See that article.

The species of this genus, seveventeen in Willdenow, are herbaceous, for the most part annual, strong-stemmed plants, with three leaflets on a stalk, and indeed the general habit of Trifolium. Their flowers are tufted rather than properly capitulate, usually yellow. T. Fianum gracccus has blueish flowers, which are quite seffile, or truly capitulate, their corolla that of a Trifolium, and their beaked legume splitting chiefly along its upper margin. This species certainly does not well accord with the rest.**
TRIGONELLA.

1. T. rubenica. Small, or Ruffian, Fenugreek. Linn. Sp. Pl. 1093. Willd. n. 1. Ait. n. 1; excluding the synonym of Gmelin, which Linnaeus subfrequently discovered to belong to Medicago falcata. (Lotus n. 156; Ainn. Ruth. 119, and Melilotus n. 159; ibid. 120.)—Legumes stalked, crowded, drooping, linear-lanceolate, straight. Leaflets lanceolate-obovate, abruptly divided by three terminal teeth.—Common throughout Siberia. A hardy perennial, flowering in June and July, sent by the Siberian botanist Amman, to Miller, before the year 1741. Herb nearly smooth. Stems numerous, spreading or decumbent, much branched; round, leafy. Leaves alternate, stalked, of three narrow, delicate leaflets, tapering and entire towards the base, toothed about the extremity; the odd one largest, an inch long, on an elongated partial stalk. Stapulas small, awn-headed. Flowers yellow within, purplish externally, in short, axillary, capitate clusters. Standard broad, almost orbicular. Calyx hairy, bell-shaped, with five lanceolate, rather unequal, teeth. Legume half an inch long, compressed, with four or five kidney-shaped seeds. We know of no figure of this species.

3. T. hybrida. Mule Fenugreek. Pourret in Act. Tolof. v. 3. 331. —Legumes stalked, rather crowded, pendulous, half-oval, compressed, reticulated with prominent veins. Stem diffuse. Leaflets roundish-obovate, nearly entire.—Native of the south of France. A specimen from the author cited this to be nearly related to the last; but the legume, though full-grown, is but one-third of an inch long, most elegantly marked with elevated reticulations. The leaves too are smaller, and scarcely toothed or wavy.

4. T. friata. Striated, or Abyssinian, Fenugreek. Linn. Suppl. 340. Willd. n. 3. —Legumes umbellate, linear, compressed, incurved, reticulated; their common stalk longer than the leaves. Leaflets wedge-shaped, toothed.—Native of Abyssinia, according to the herbarium of Linnaeus, who cultivated the plant at Upsal. Root annual. Stems square, diffuse. Leaflets half an inch long, ribbed, sharply toothed, as well as the stipulas. Flowers light yellow, about six in each long-stalked head, or umbel. Legumes an inch long, narrow, slightly hairy, with five or seven seeds.

5. T. pohycarta. Many-horned, or Spanish, Fenugreek. Linn. Sp. Pl. 1093. Willd. n. 4. Ait. n. 3. (Fenugrum graecum fylvicole; Ger. Em. 1196. Lob. 1c. v. 2. 45.) —Legumes nearly sessile, crowded, erect, nearly straight, longer than the leaves; the common stalk pointless.—Native of Spain, Italy, and the south of France. Cultivated here in the middle of the seventeenth century. Annual. Stem branched from the bottom, diffuse, twelve or eighteen inches long. Leaflets obovate, toothed. Flowers yellow, three or four together in little, axillary, almost sessile, heads. Calyx hairy, as well as the young leaves. Legumes three or four, an inch and half long, narrow, clothed with close hairs, and beautifully reticulated.

6. T. hamafol. Hooked Egyptian Fenugreek. Linn. Sp. Pl. 1094. Willd. n. 5. Ait. n. 4. Sm. Pl. Græc. Sibth. t. 764, unpubl. (Melilotus Egyptianus, Alchemich vocatus; Alpin. Egypt. 122. t. 124. Bauh. Hist. v. 2. 567.) —Legumes racemose, stalked, declining, recurved, nearly cylindrical, even, hairy; their common stalk spinous, longer than the leaf. —Native of Egypt, from whence the Linnaean specimen was brought by Hassell. Dr. Sibthorp met with it in Cyprus. A small, diffuse, annual, hairy herb, whose leaflets are wedge-shaped, strongly toothed, on a long common stalk. Flowers deep yellow, fragrant, in stalked clusters, half an inch long. Legumes an inch long, curved into a semicircle, quite delitlute of reticulations, both futures peculiarly dilated, pale and even; the sages green and very hairy. The seeds are said to be used by the Egyptians, in formenations, for all kinds of pains.

7. T. torta. Twisted Egyptian Fenugreek. —Legumes umbellate, cylindrical, twisted, reticulated; their common stalk much shorter than the leaves. Leaflets ineriously heart-shaped, toothed, obtusely ribbed.—Native of Egypt, from whence Dr. Delile favoured us with wild speciments, under the name of hamafol, but they do not agree with the Linnaean specimen, nor with the specific character, any more than with the figure in alpinus, as far as anything can be determined therefrom. The plant of Dr. Delile is as smooth as possible in every part. Its stems round, branched, firm, hardly a half inch. Leaves on long footstalks, rather flathy; leaflets all of equal size and shape, one-third of an inch long; the odd one on a stalk nearly its own length. Flowers yellow, drooping, five or six in each axillary umbel, whose stalk is not half the length of the adjoining common footstalk, and, after flowering, becomes very stout, round, and firm. Legumes drooping, rather more than half an inch long, rigid, pale, slightly twisted spirally, quite delitlute of hairs, but marked with peculiar oblong reticulations of elevated veins.

8. T. flexuosa. Zigzag Egyptian Fenugreek. Delile Aegypt. MSS.—Legumes in nearly sessile umbels, compressed, reticulated, zigzag. Leaflets ineriously heart-shaped, toothed, obtusely ribbed—Native of Egypt. A figure of this plant was defined, under the above name, for the great work on Egypt, but we have not heard that it has proceeded for far. This species very closely accords with the half in habit, and precisely in foliage, but the umbels are nearly sessile, flowers smaller, calyx-teeth longer and more pointed. The legumes are essentially different, not only in their compressed figure, but in being strongly folded, or plaited, as it were, into a zigzag position. If expanded, they might possibly equal the length of the half. Both appear to be annual, and probably grow prostrate.

11. T. armata. Thorny-branched Cape Fenugreek. Thunb. Prodr. 137. Willd. n. 8. —"Legumes lateral, hairy. Leaflets ovate, smooth. Branches becoming spinous."—Native also of the Cape.—We have no further information concerning the three last species.

12. T. spinosa. Thorny-stalked Fenugreek. Linn. Sp. Pl. 1094. Willd. n. 9. Ait. n. 5. (Fenugrum graecum var. spinosa; Ger. Em. 1196. Lob. 1c. v. 2. 45.) —Legumes sessile, crowded, erect, nearly straight, longer than the leaves; the common stalk pointless. Leaflets obovate, toothed. Flowers yellow, three or four together in little, axillary, almost sessile, heads. Calyx hairy, as well as the young leaves. Legumes three or four, an inch and half long, narrow, clothed with close hairs, and beautifully reticulated.
TRIGONELLA.

15. T. fiscata. Spiked Fenugreek. Sm. Prodr. Fl. Græc. Sibth. n. 1831. Fl. Græc. t. 763, unpublished.—Legumes spiked, pendulous, short, hairy, on a spinous-tipped axillary flalk, longer than the leaves. Stipulas awl-shaped, entire. —Gathered by Dr. Sibthorp in the isle of Seriphus. This is an annual species, with many fants, about a foot high, which partakes of the fame ambiguity, respecting the Melilots, as the foregoing. At leaf the shortness of the legume, and consequent small number of seeds, anwers beft to Trifolium. But we want certain information on this point, having not seen any ripe fruit. The habit of the plant, especially the spinous flower-flalk, belongs to Trigonelella. The leaves are half an inch in length, obovate-oblong, narrow, smooth, serrated. Flowers yellow, in crowded clusters resembling spikes, half an inch long, becoming afterwards twice that length, beft with the numerous reflexed beaks of the crowded pendulous legumes. The lowest tooth of the calyx is very shght; the four others long and awl-shaped.

16. T. parviflora. Small-flowered Fenugreek.—Legumes in capitulate clusters, ascending, linear-lanceolate, compressed, slightly curved, with about two seeds; their flalk as long as the leaves, pointed. Stem ascending. Stipulas ovate, pointed, toothed. —Found by M. Du Cros, in a meadow near the mill of Coinius, in Switzerland. The fants are a span high, decumbent at the base. Size and apect of the plant like T. monspeliaca, hereafter described, but some of its characters accord more with elatior, to which it has other- wise little resemblance. The flalks, calyx, legumes, and young leaves, are more or less silky. Leaves broadly ovate, the lower ones rather quadrangular, none more than half an inch long, most of them less; all toothed, ribbed, of a light green. Flowers very small, yellow, on partial flalks as long as themselves, collected into hemispherical silky heads. Calyx-teeth lanceolate, as long as the corolla, somewhat unequal. Legume half an inch long, curved upwards, veiny, constricted at each end, containing only one or two seeds. This species seems to have escaped the notice of all authors that have fallen in our way. It was sent for corniculata, but the legumes are totally different, and the flowers not a quarter so large, neither is the fants zigzag.

17. T. monspeliaca. Trailing Fenugreek. Linn. Sp. Pl. 1095. Willd. n. 11. Ait. n. 7. "Waldii et Kitaib. Hung. v. 2. 152. t. 142." Sm. Fl. Græc. Sibth. t. 765, unpublished. (Fenugrecum polyceraton; Rivin. Tetrap. Irr. t. 82. F. minus monspeliaca; Breyn. Cent. t. 33. f. 2. Securidaca genus triphyllon; Bauh. Hill. v. 2. 373.)—Legumes spreading, crowded, curved, compressed, hairy, obliquely veined, shorter than the leaves, on a very short pointed flalk. Stems prostrate. —Native of the south of France, Hungary, Switzerland, Greece, Cyprus, and Afia Minor. A hardy annual with us, sometimes cultivated for curiosity, flowering in June and July. Stems quite flat on the ground, hardly a span long, a little hairy, like the leaf of the plant. Leaves sharply toothed; their common flalks an inch long. Flowers deep yellow, twice the size of the leaf. Calyx hairy, with rather unequal teeth, scarcely half so long as the corolla. Legumes declining, not an inch in length, prettily marked with oblique transverse ribs, and clothed with featttered clofe hairs. Seeds several, rough.

18. T. glabra. Smooth Cape Fenugreek. Thunb. Prodr. 137. Willd. n. 12. —"Legumes umbellate, reflexed, smooth. Leaflets ovate, smooth, toothed."—Found by Thunberg, at the Cape of Good Hope. We have not seen
seen this plant. If the leaflets be really ovate, not obovate, it is a very remarkable species indeed.

20. T. laciniata. Jagged Fenugreek. Linn. Sp. Pl. 1095. Wild. n. 14. (Melilotus aegyptius annus, folis elegantè incisè; Lippi MSS.) —Legumes stalked, somewhat umbellate, elliptical, reticulated. Leaflets wedge-shaped, toothed. Stipulas laciniated. The Linnaean specimen of this rare species was sent by Burman, with the above synonym, by which we learn that it was gathered in Egypt by Lippi, who did not live to publish his discoveries. (See Litt. Ph.) This is a slender, delicate, smooth, apparently decumbent, plant, resembling Medicago laciniata. The stems are about six inches long, unbranched, angular. Leaflets a quarter of an inch long, abrupt, ribbed, very deeply and sharply toothed at the end. Stipulas palmate, acute. Flower-flanks axillary, shorter than the footflanks, tipped with a small point. Flowers from three to five, yellow. Calyx pale, slightly hairy, with awl-shaped teeth of its own length. Legume twice the length of the calyx, minutely reticulated, rather hairy, acute at each end. 21. T. pinnatifida. Pinnatifid Fenugreek. Cavcn. Ic. v. 1. t. 26. t. 38. Wild. n. 15. Ait. n. 8.—Legumes nearly sessile, axillary, linear, compressed, two or three together. Leaflets pinnatifid. Stipulas toothed. —Native of the borders of fields about Madrid, flowering in May. Its seeds were brought from thence to Kew, by the late marchioness of Bute. "This little annual species is closely related to the last, being of the same size, with several quadrangular stems. But the leaflets are more oblong, and deeply pinnatifid, not merely cut about the extremity. Flowers from three to five in the bosom of each leaf, on very short stalks, pale yellow. Calyx like the leaf. The legumes, as Cavunilles observes, are totally different, an inch or more in length, very narrow, slightly curved, with many seeds. Only two or three legumes seem to be perfected, though the flowers are described as rather more numerous. 22. T. Fenugraceum. Common Fenugreek. Linn. Sp. Pl. 1095. Wild. n. 16. Ait. n. 9. Woody. Med. Bot. t. 158. Sm. Fl. Grce. Sibth. t. 766, unpublished. (Fenugraceum; Camer. Epit. 199. Ger. Em. 1196. f. 1. Fenuagraceum; Rivin. Tetr. Irr. t. 81. Fenugraceum; Fuch. Hilt. 798. Matth. Valgr. v. 1. 374.) —Legumes axillary, sessile, oblong, compressed, hairy, with an oblique, awl-shaped beak. Stems spreading. Stipulas ovate, entire. —Native of the south of Europe. Dr. Sibthorp found it plentifully on the shores of Ais Minor, as well as in Rhodes and Cyprus; more sparingly on mount Hymettus near Athens. It has long been cultivated for the sake of its seeds, which from the days of Dioscorides have been thought cooling and detergent. Their scent is very powerful, resembling Mellilot; which renders them disagreeable in fomentations and cataplasmata, the only uses for which they have been retained in the apothecaries' shops. They are now nearly exploded. (See Fenugreek.) This herbage is used in some European countries for fodder. The root is annual. Stems various in luxuriance and direction, from one to two feet long, reddish, flout, leafy and hairy. Leaflets inerferly heart-shaped, various in size from a quarter of an inch to an inch, moistly smooth, of a deep, rather glaucous, green, more or less toothed. Flower-flanks hairy, rather longer than the leaflets. Flowers two or three, axillary, sessile, yellow, white, or pale blue; standard an inch long, emarginate, crect; veins and keel much shorter, by no means answering to the generic character. Calyx hairy, with awl-shaped, nearly equal, teeth. Legume, in a wild state, about an inch long, very, a quarter of an inch broad, tapering into an oblique beak, longer than itself, but very various in that respect; in the cultivated plant, the length of the legume, containing above a dozen seeds, greatly exceeds that of the beak. Dr. F. Buchanan, in his Journey through the Mysores, v. 1. 374. relates, that this herb, known by the name of Menteca, when cultivated in gardens is always used green. When grown for the feed, as grain, the ground is plowed twice at the same place, seafon, and divided into plots like a kitchen-garden. The seed is fown, covered by hand, and according to the nature of the soil, and watered once in ten or fifteen days. "The ripe feed," says this author, "fells very high, and is reckoned the most delicate kind of pulse. The young leaves are used as greens, and the unripe legumes put into Curries." We find these seeds are one ingredient in the receipts for Curry powder, communicated from India. T. gladiata, Bieberl. Taur. v. 2. 222, must be premised a variety of the species before us.

23. T. indica. Indian Fenugreek. Linn. Sp. Pl. 1095. Wild. n. 17. Ait. n. 100. (Lotus madraspatanus, villosus, ornithopodii silquâ singulari; Pluk. Phyt. t. 200. f. 71, faulty, as representing the legumes terminal.—Legumes linear, nearly sessile, mostly solitary, slightly curved, much longer than the leaves. Leaflets entire. Stem diffuse. —Native of the East Indies, from whence its seeds were sent by Dr. Roxburgh to Kew, in 1793. An annual flowe plant, flowering in July and August. The whole herb is minutely hairy, or silky. Stems a foot long, round, branched. Leaflets obvate, narrow, three-quarters of an inch long, all equally nearly sessile, on a flatile of their own length. Flowers small, yellow or reddish, drooping, on very short stalks, usually two together, from the foboms of the leaves. Calyx-teeth lanceolate, leafy. Legumes an inch and a quarter or an inch and a half long, compressed, narrow, pale, hairy, with many seeds. We should have fupposed the seeds of this species to have made an ingredient in the Curry powders of India; but we find nothing of this kind recorded, nor is the plant mentioned in the admirable work of Dr. Buchanan, cited under the last species.
TRI

sheath, separate above, some of them often abortive, and the common sheath finally splits into two; anthers oblong, *P. amplexicaule*. Superior ovate, minute; style short, ascending; stigma capitate, flat, with a membranous border. Capsule oblong, acute, with three angles and three intermediate channels, of one cell and three valves, which are boat-shaped, double, the outer coat coriaceous, inner membranous, lined with wool. Seeds numerous, roundish, enveloped in long wool, and connected with a triple thread-shaped receptacle.

1. T. villosa. Villous Trigonia. Aubl. 388. t. 149. Willd. n. 1. — Leaves oblong, downy and hoary beneath. Native of Guiana, growing chiefly by way of fides, in cultivated grounds, or in the borders of groves and thickets, bearing flowers and fruit at various seasons. The stem is shrubby, with twining branches, supporting themselves upon neighbouring trees, round, downy and leafy. Leaves opposite, falked, entire, three inches long and one and a half broad, venous. *Sipularia* ovate, in pairs, deciduous. Clusters compound, terminal. Flowers aggregate, small, yellow, with a red keel. Fruit three inches, or more, in length, clothed with reddish down, splitting from the base.

2. T. leiis. Smooth Trigonia. Aubl. 390. t. 150. Willd. n. 2. — Leaves elliptical, smooth and shining on both sides. — Found on the banks of a rivulet, near the base of the hill of Courou, in Guiana. The branches of this species are smooth, but twine round any thing in their way, like the preceding. Leaves only one and a half or two inches long, oval, entire, on fhortith stalks. Clusters several at the ends of the branches, accompanied by some leaves. Flowers opposite, accompanied by small bracteas, white, with yellow anthers. Fruit about an inch long, greenish, rather rough to the touch. Seeds enveloped in soft white wool. Nothing is mentioned of any useful properties in either of these plants.

TRIGONIS, so called by Jacquin, because each of its petals forms an inverted isosceles triangle. See *Cupania*.

TRIGONOMETER, ARMILLARY. See Armillary Trigonometer.

TRIGONOMETRY, from τριγώνω, triangle, and μετρητω, measure, signifies literally the measure of triangles; but it is used here to denote that science which relates to the determination of the fides and angles of triangles, from certain parts which are given. When it is applied to the solution of plane triangles, it is called plane trigonometry; and its application to spherical triangles, is called spherical trigonometry.

Trigonometry, from its numerous and important uses, may be considered as one of the most interesting branches of the pure mathematics: practical and physical astronomy, navigation, surveying, geodesia, mechanics, in short nearly every branch of the pure and mixed mathematics, with the exception of geometry and arithmetic, are either wholly or in part connected with the principles of trigonometry; and we accordingly find that the improvements in this department have kept pace with, or rather perhaps have preceded, those which modern authors have introduced into all the other branches of the exact sciences: in fact, the trigonometry of the Greeks, and that of the moderns, which immediately followed the invention of logarithms, and, lastly, the analytical form given to it by Euler, Lagrange, &c. exhibit the same science under three very distinct characters, of which it will be proper to give a short sketch as an introduction to the present article.

It is very uncertain at what time trigonometry first began to be cultivated as a science, no records having yet been discovered which enable us to trace it to a higher age than that of Hipparchus, who flourished about 150 years before Chrilt, and who, as we are informed by Theon, wrote a work, in twelve books, on the chords of circular arcs, which, from the nature of the title, must have been a treatise on trigonometry; but the earliest work extant on this subject is the Spheres of Thodofius, in which the several propositions are demonstrated after the manner of Euclid; and the next in order to this, is a work by Menelaus, who flourished about the middle of the first century of the Christian era, and who is said to have written nine books on this subject; but of which, only three have been transmitted down to our times. The fix that are lost consisted principally of tables and the nature of their construction, which if we pollieled them would, in all probability, be rather matters of curiosity than of real utility. The earliest tables of trigonometry, of any importance, that we possess of the ancients, are those given by Ptolemy in his Almagest, in which he adopts the sexagesimal division of the radius, and of the arc whose chord is equal to radius, and then establishes all the other arcs by 60ths of that arc, and all the other chords by 60ths of that chord. From the time of Ptolemy, we from about the beginning of the second century, nothing of importance, except what we owe to Theon, was added to the science of trigonometry, till about the close of the eighth century after Chrilt, when the ancient method of computing by chords was changed for that of sines, an alteration first introduced by the Arabsians, to whom we are also indebted for several axioms and theorems which are at present considered as the foundation of modern trigonometry; but they still continued the sexagesimal division; and in this state it remained till Purbach, about the middle of the 15th century, constructed a table of sines to the division of the radius into 600,000 equal parts, and computed them for every ten minutes of the quadrant; and afterwards Regiomontanus, the disciple and friend of Purbach, carried the computation to every minute, dividing the radius into 1,000,000. He also enriched this science with many new theorems and precepts, which, except for the use of logarithms, render the trigonometry of this author little inferior to that of our times.

Soon after the period here mentioned, several other mathematicians also contributed to the advancement of this science, either by some useful alterations in the form of the tables, or by other improvements; amongst whom we may mention, as the most distinguished, Werner, Copernicus, Rheinold and Maurolycus: but the most complete work which had yet appeared, was published by Vieta in 1579; and some other tracts on the same subject and due to the fame author were published by Schooten in 1646.

The first part of the work to which we have above alluded, was entitled "Canon Mathematicus seu ad Triangulam, cum Appendicibus," in which there is given a table of fides, tangents, and secants for every minute of the quadrant to radius 100,000, with their differences; and towards the end of the quadrant, the tangents and secants are extended to eight or nine places of figures. They are also arranged after the manner of our modern tables, increasing from the right-hand side to 45°, and then returning backwards from the right-hand to 90°, so that each number and its complement stand upon the same line.

The second part, entitled "Univeralium infcriptionum ad canonem mathematicum," contains, besides a regular account
count of the construction of the tables, a compendious treatise on plane and spherical trigonometry, with their application to a variety of curious subjects in geometry and menursion, and other branches of mathematics; as also a number of particulars relating to the quadrature of the circle, the duplication of the cube, and similar problems, which are all treated of in a manner worthy of the genius of their author. The tract published by Schooten likewise contains many curious theorems due to Viete, particularly those relating to what the author calls angular sections; viz. to the multiples and submultiples of arcs; and general formulae for the chords and consequently for the sines of the sums and differences of arcs; and of such as are in arithmetical progression, which have since been so extensively and usefully applied, both in this science and in some of the higher branches of analysis. See Arithmetie of Sines.

The next writer on this subject, deferving of particular notice, was Reticus, who formed the design of computing the trigonometrical canon for every ten seconds of the quadrant to fifteen places of figures; and although he did not execute the whole of this laborious enterprise, he nevertheless accomplished that part of it which related to the sines and cofines, all of which he calculated according to his original plan; besides those of every single second for the first and last degrees of the quadrant; but was deterred from publishing the table on account of the expense attending the impession. The work, however, was afterwards completed and published by his disciple and friend Otho, under the title of "Opus Palatinum de Triangulis" (folio 1596); but it was found to contain many errors, which were afterwards corrected by Piticus, and the whole published under the new title of "Thefaurus Mathematicus, &c." (folio 1613).

The Trigonometry of the same author, which was published in 1599, is also a very complete work, and was long considered, both with respect to its tables and its numerous practical applications, as the most commodious and useful treatise on the subject then extant.

We might here enumerate many other writers of this period, who distinguished themselves either by their computation of new tables, or by their inventions of theorems; but the discovery of the use of logarithms, which happened about this time, produced a complete revolution in the method of treating this subject, and which therefore renders it unnecessary for us to enter into any minute explanation of the particular inventions and improvements of the authors to whom we have above alluded.

Amongst the earliest promoters of trigonometry, after the invention of logarithms, was Napier himself, to whom we are not only indebted for that admirable discovery, but also for the new and excellent analogies which he introduced into trigonometry, and which still bear his name, as likewise for the well-known rules called the five circular parts. (See Parts.) Our limits, however, will not allow of tracing the history of this science, through all its successive improvements, from the time of Napier to the present day; we shall therefore content ourselves with referring to the article Logarithm for an account of many of the most useful and valuable tables of the logarithmic kind, and shall merely mention Briggs as an author who contributed much to the advancement of this science, both by the affilience that he afforded to the practical calculator in many intricate and abstruse computations, and by the numerous improvements of a higher kind, with which his works abound. Other writers afterwards, either by the contraction of tables, or by the simplification of the rules and processes hitherto adopted, reduced the practice of trigonometrical operations to their simplest possible state, at least while it retained that geometrical form, which in the earlier stages of this science it naturally assumed. But about the middle or rather towards the close of the last century, trigonometry was again subjected to another complete revolution, by changing the geometrical form for the analytical one; and it is probable that to this change we are indebted for many of the most brilliant discoveries that of late years have enriched the two great branches of astronomic and science. The foundation of this method, however, may be traced to a much higher date than that to which we have above alluded; viz. to the time of Viete, whose theorems for the differences and sums, as also for the multiples and submultiples of the chords of arcs, which, although left without demonstration, and in the latter case probably formed by induction from the law of the terms and their coefficients, have nevertheless been the germ of most of the numerous and elegant formulae which have since enlarged and enriched this branch of the mathematics.

The exponential formula also for the sines and cosines of arcs, first given by de Moivre, greatly contributed to the progress of the analytical branch of this subject, by abbreviating its operations, and shortening the labour of investigation. See Arithmetie of Sines.

Having given this brief sketch of the history of trigonometry, it now remains for us to explain and illustrate its principles, and the various methods of applying it and of performing the requisite computation. With this view we shall commence with the definitions of all the terms which most frequently occur in this doctrine, in order to save the references which it would otherwise become necessary to make to the different articles in the body of the work.

In plane trigonometry, the circle is supposed to be divided into 360 equal parts, called degrees; every degree into 60 equal parts, called minutes; and every minute into 60 equal parts, called seconds; and so on into thirds, fourths, &c.; and the measure or quantity of an angle is estimated by the number of degrees, minutes, and seconds, contained in the arc by which it is bounded; the degrees being marked or denoted by a small °, the minutes by one dash, and the seconds by two dashes ′, &c.; thus, 70 degrees 16 minutes 17 seconds, is written 70° 16′ 17″.

It may be observed, however, that the division of the circle is perfectly arbitrary, and that any other number might have been employed instead of 360; and the sub-divisions might also have proceeded upon any other scale as well as the sexagesimal; and accordingly, the modern French mathematicians have adopted a different division; viz. they suppose the entire circle to be divided into 400 degrees, or each quadrant into 100 degrees; the next subdivision is the 10th of a degree, the next 100th, and so on; and hence the measure of an angle is expressed by them in the same manner as any other integral and decimal quantity, which notation is undoubtedly far superior to that in common use.

The complement of an arc or angle, is what it wants of 90°, or of a quadrant; and the supplement of an angle, is what it wants of 180°, or of a semicircle; thus, if an angle measures 50°, its complement is 40°, and its supplement 130°. As to the several lines made use of in this science, they will be readily understood by a reference to Plate II. Trigonometry, fig. 14. aided by the following definitions; viz.

The fine or right fine of an arc, is a line drawn from one extremity of an arc perpendicular to the diameter which passes through the other extremity: thus, B F is the fine of the arc A B, or of the supplemental arc B D E.

The verfed fine of an arc, is that part of the diameter which is intercepted between the arc and its fine: thus, A F is the verfed fine of the arc A B, and D F the verfed fine of the arc E D B.

The
The tangent of an arc, is a line touching the circle in one extremity of that arc, and continued thence to meet a line drawn from the centre through the other extremity of it, which last line is called the secant of the fame arc: thus, A H is the tangent, and C H the secant of the arc A B; also E I is the tangent, and C I the secant of the supplemental arc B D E; and this latter tangent and secant are equal to the former, but are accounted negative, as being drawn in an opposite or contrary direction to the former.

The co sine, cotangent, and cofe cante, of an arc, are the fine, tangent, and secant of the complement of that arc; the letters co. being only a contraction of the word complement.

Thus the arcs A B, B D, being the complement of each other, the fine, tangent, and secant of the one of these, is respectively the co sine, cotangent, and cofe cante of the other: thus,

\[ B F, \text{ the fin. of } A B, \text{ is the cof. of } B D. \]
\[ B K, \text{ the fin. of } B D, \text{ is the cof. of } A B. \]
\[ A H, \text{ the tan. of } A B, \text{ is the cotan. of } B D. \]
\[ D L, \text{ the tan. of } B D, \text{ is the cotan. of } A B. \]
\[ C H, \text{ the sec. of } A B, \text{ is the cofec. of } B D. \]
\[ C L, \text{ the sec. of } B D, \text{ is the cofec. of } A B. \]
\[ F A, \text{ the verf. of } A B, \text{ is the coverf. of } B D. \]
\[ D K, \text{ the verf. of } B D, \text{ is the coverf. of } A B. \]

The above arc the principal definitions relating to plane trigonometry, as far as regards the solution of plane triangles, which is that part of the subject to which we must more particularly confine our remarks in this article: what concerns the mutations or changes in the quantities above defined in paffing successively round the circumference, and their particular values at certain points, have been already explained under the article Arithmetic of Sines, to which the reader is referred. In every triangle there are fix parts; viz. three fides and three angles, any three of which being given (except the three angles), the other three may be found; and that either by geometrical construction, arithmetical or logarithmic computation, or by instrumental operation: that is, either by constructing the figure with the fides and a scale of chords, or other instrument for measuring angles; or by means of tables of natural or logarithmic fines, tangents, &c. in which the computation depends upon the propotionality of the fides of similar triangles; and lastly, by means of a Gunter or other scale constructed for this particular purpose, by which the results are obtained by the proper application of a pair of compasses to certain lines on the scale: in the present article, however, we shall only attempt an illustration of the second method.

There are only three distinct cases in trigonometry; viz.

1. When a fide and its opposite angle are two of the given parts.
2. When two fides and the included angle are given.
3. When the three fides are given.

Case 1.—When a fide and its opposite angle are two of the given parts.

As any one fide:
Is to any other fide::
So is the fine of the angle opposite to the former:
To the fine of the angle opposite to the latter.

This analogy supposes two fides and one angle to be given: if two angles and one fide be given, the order of the terms becomes,

As the fine of any angle:
Is to the fine of any other angle::
So is the fide opposite to the former:
To the fide opposite to the latter.

For let \( \triangle ABC \) (fig. 15.) represent any triangle; take \( A C, B C \), equal to each other, and let them represent the tabular radius; then \( a c, c b \), will also be the tabular fines of the angles \( A \) and \( B \). Now by similar triangles,

\[ \frac{AC}{BC} = \frac{AC}{BC} = \frac{AC}{BC} \]

Consequently, since \( A C = B C \), and the third terms being equal, we have

\[ \frac{AC}{BC} = \frac{BC}{AC} = \frac{AC}{BC} \]

or \[ \frac{AC}{BC} = \frac{AC}{BC} = \frac{AC}{BC} \]

Again, if the angles \( A \) and \( B \) were given, and the fide \( BC \); then,

\[ \sin A \times \sin B = \sin A \times \sin B = \sin A \times \sin B \]

or \[ \sin A \times \sin B = \sin A \times \sin B = \sin A \times \sin B \]

which is the fame as the theorem in words.

Hence in the triangle \( \triangle ABC \) (fig. 16.), let \( A B, BC, \) and the angle \( A \) be given; then it will be

\[ \frac{AC}{BC} = \frac{AC}{BC} = \frac{AC}{BC} \]

or log. \( \sin C = \log B A + \log A - \log B C \).

Again, if the angles \( A \) and \( B \) were given, and the fide \( BC \); then,

\[ \frac{AC}{BC} = \frac{AC}{BC} = \frac{AC}{BC} \]

or \[ \frac{AC}{BC} = \frac{AC}{BC} = \frac{AC}{BC} \]

It should be observed here, that the angle found by the firft of these analogies is ambiguous, or uncertain, viz. whether it be acute or obtufe, unless its magnitude be such as to prevent the ambiguity; for when this is not the cafe, there will be two different triangles, which have the fame three parts, but the other three different in each; and there is nothing in the abstract solution to determine which of the two is the required one; but in any practical cafe, there will be always found some circumstance or other to decide the question. This will be understood from fig. 17, where there are two triangles \( \triangle ABC \), \( \triangle ABC \); in each of which the fides \( A B, BC, \) or \( BC \), and the angle \( A \), are the fame; and, therefore, the angle \( C \), determined by the analogy, may be either \( BCA \) or \( BC A \), which are the supplements of each other, and which two angles, we have fewn in the definitions, have always the fame finite. The tabular fince, however, is always that belonging to the acute angle; and, therefore, when the obtufe angle is required, the acute angle must be fubtracted from \( 180^\circ \), which will be the obtufe angle. But if the angle be a right angle, or greater than a right angle, the acute angle found by the table must be the required angle; and, therefore, in this cafe, there is no ambiguity.

Let us propose, as an example, a triangle \( \triangle ABC \), in which the fide \( AB = 345 \), \( BC = 232 \), and angle \( A = 37^\circ 20' \).

First, to find the angle at \( C \).

As the fide \( BC = 232 \) \[ \begin{array}{c} 2.3654880 \\ \text{It to fide } AB = 345 \end{array} \]
\[ \text{So is } \sin A = 37^\circ 20' \]
\[ \text{To } \sin A = 37^\circ 20' \]

That is, by adding together the logarithms of the second and third terms, and subtracting the firft, we obtain the logarithmic value of the fine of \( C \), which is found in the table to answer to the angle \( 64^\circ 24' \). But we have feen that
an angle and its supplement have the same base; therefore, the
ine we have found may either answer to the angle 64° 24',
or to its supplement 115° 36'. This question, therefore,
involved in ambiguity to which we have above alluded;
and we must proceed to find the third side under each of the
values of the angle C, and the two corresponding values of the
angle B.

Since the sum of the three angles of a triangle = 180°,
\[\triangle ABC = \angle A + \angle B + \angle C = 180°\]

Hence, from the first values of the angles C and B, we have,
\[\angle A = 37° 20'\]
\[\angle C = 64° 24'\]

Again,
\[\angle A = 37° 20'\]
\[\angle C = 115° 36'\]

Hence, from the first values of the angles C and B, we have,
\[\angle A = 37° 20'\]
\[\angle C = 64° 24'\]

The sine and angles sought are, therefore, \(\triangle ABC = 37° 20'\),
or 174.07; and the angle \(B = 78° 16'\), or 27° 4'; and
angle \(C = 64° 24'\), or 115° 36'; either of which results
equally answer all the conditions of the original data. But
it is obvious, that if the given angle A had been a right
angle, or greater than a right angle, this ambiguity could
not have had place; because, in that case, the other two
angles are necessarily acute.

Cafe 2.—When two sides and their included angle are the
three given parts.

As the sum of the sides:
Is to the difference of the sides ::
So is the half sum of the required angles :
To the tangent of their half difference.

Then to half the sum add half the difference for the
greater angle, and subtract it for the less. The three angles
of the triangle being thus known, the required side may be
found by Cafe 1.

Note.—The half sum of the angles is found by subtracting
the given angle from 180°, and taking half the remainder;
or, instead of the tangent of the half sum, the cotangent
of half the given angle may be used, being the same thing.

Let \(\triangle ABC\) (fig. 18.) be any triangle; produce \(AB\),
making \(BE = BC\); also take \(BD = BC\); join \(DC\) and
\(CE\), and draw \(DF\) perpendicular to \(DC\). Now since
\(DB\), \(BC\), and \(BE\), are all equal to each other, a
semicircle described from the centre \(B\), and with the radius \(DB\),
would pass through \(D\), \(C\), and \(E\); consequently \(DCE\) is a
right angle, or \(CE\) is perpendicular to \(DC\), and is there-
fore parallel to \(DF\); and hence \(DF\) and \(EC\) are respect-
ively the tangents to the angles \(DCF\), and \(CDE\) to the
fame radius \(DC\). But \(CDE\) or \(CDB\) is half the sum
of the angles \(BAC\) and \(BCA\); for since \(DB = BC\),
the angle \(BDC\) is obviously = to the external angle
\(CBE\), which is equal to the sum of the angles \(A\) and \(C\);
therefore, \(CDB\) = = to half that sum, and \(DCF\) = half
the difference of the fame angles \(ABC\) and \(CAB\); for
\(ABC = BCD + DCA\), and consequently \(BAC =
BDC\), or \(BCD - DCA\); therefore \(DCA\) = half their
difference. Whence \(C\) = tangent of half the sum,
and \(DF\) the tangent of half the difference of the angles \(A\)
and \(C\); and it is evident from the construction that \(AE =\)
the sum of the sides, and \(AD =\) the difference of the
fame; consequently, since \(DF\) and \(CE\) are parallel, we have
\[AE : AD :: CE : DF;\]

demns the angle, and \(AB = BC\):
Is to the difference of the sides \(AB - BC ::
So is the tangent of half the sum of the angles \(A\) and \(C\):
To the tangent of half their difference.

Let us take as an example a triangle (fig. 19.), in which
the following dimensions are given, viz.

\[AB = 75, AC = 58, A = 108° 24';\]
then will \(AB = 75, AB = 75, A + B + C = 180° 0'\)
\[AC = 58, AB = 58, A = 108° 24';\]
\[BC = 73 36\]
\[\frac{1}{2}(B + C) = 35° 48'\]
\[\log. of A + B + C, 12238516\]
\[\log. of A - B, 1.32204489\]
\[\log. of \tan. \frac{1}{2}(B + C), 9.8586694\]
\[\log. of (C - B), -11.0837183\]
\[\log. of \tan. \frac{1}{2}(C - B), 8.9468667\]
\[\frac{1}{2}(C - B) = 5° 16', \frac{1}{2}(B + C) = 35° 48';\]
\[C = 41° 4', B = 30° 32';\]

If the other side \(CB\) were required, having found the
angles, it may be earlyly determined by the first cafe.

Cafe 3.—When the three sides of a triangle are given, to
find the three angles.

Assume any side of the triangle as a base (fig. 20.), and let
fall a perpendicular upon it from the opposite angle; then say,

As the base :
Is to the sum of the other two sides ::
So is the difference of the same sides :
To the difference of the segments of the base.

To the base or sum of the segments add the half difference
for the greater segment, and subtract it for the less.

The segments being thus found, the angles may be de-
termined by the first cafe. The demonstration is here very
obvious; for, by the 47th proposition of the first book of
Euclid,

\[AD^2 + DC^2 = AC^2;\]
\[BD^2 + DC^2 = BC^2;\]
TRIGONOMETRY.

therefore, \( AD^2 - BD^2 = AC^2 - BC^2 \);

consequently,

\[
AD + DB : AC + BC :: AC - BC : AD - DB;
\]

which is the same as the theorem in words.

As an example, let a triangle be proposed (fig. 21.), in which the three sides are as follow, \( \text{viz.} \)

\[
\begin{align*}
A &= 36, \quad AC = 45, \quad BC = 40 \\
A &= 45, \quad AC = 45, \quad AB = 36, \quad AB = 36
\end{align*}
\]

\[
\begin{align*}
AC + AB &= 81, \quad FC = 9 \\
\text{Log. of } BC &= 1.60226600 \\
\text{Log. of } AC + AB &= 1.90848500 \\
\text{Log. of } FC &= 0.95442500
\end{align*}
\]

\[
\text{Sum of log.} = 2.86272750
\]

Log. of \( CG = 1.26666750 \) The nearest corresponding number to which, in the tables, is 18.22

\[
\begin{align*}
BC &= 40.00, \quad EG = 10.89 \\
CG &= 18.22, \quad CG = 18.22
\end{align*}
\]

\[
\begin{align*}
BG &= 21.78, \quad CE = 29.11
\end{align*}
\]

\[
\begin{align*}
BE &= 10.89, \quad \text{Log. of } AB &= 1.55630250 \\
\text{Log. of whole sine} &= 10.00000000 \\
\text{Log. of } EB &= 1.03702790
\end{align*}
\]

Log. of \( \text{fin. of } EAB = 9.48072540 \) The corresponding number to which, in the tables, is 17° 36'.

\[
\begin{align*}
\text{Log. of } AC &= 1.65321250 \\
\text{Log. of the whole sine} &= 10.00000000 \\
\text{Log. of } CE &= 1.46404220
\end{align*}
\]

Log. of \( \text{fin. of } EAC = 9.81082970 \) To which the nearest corresponding number, in the tables, is 40° 18'; therefore \( A \) \( E \) \( C \) \( 45^\circ \) 42', and \( C \) \( A \) \( B \) \( 5^\circ \) \( 54' \).

The three preceding cases include all the possible varieties that can arise in the solution of plane triangles; but, under certain relations of the data, more simple operations may frequently be employed. Some of these solutions we shall investigate analytically at the conclusion of this article, and it will therefore be sufficient to point out in this place a few particulars relative to the solution of right-angled plane triangles.

In any right-angled triangle, any of the unknown parts may be found by the following proportions.

As radius:

Ist to either leg of the triangle:

So is the tangent of the adjacent angle:

To the opposite leg:

So is the secant of the same angle:

To the hypothenuse.

For \( A \) \( B \) (fig. 22.) being supposed the given leg, let \( AD \) represent the tabular radius, describe the arc \( DE \), and draw \( DF \) perpendicular to \( AD \); so shall \( DF \) represent the tabular tangent, and \( A \) \( F \) the tabular secant of the angle \( A \); and because of the parallels, \( A \) \( D \) \( A \) \( B \) :: \( A \) \( F \) :: \( A \) \( C \), which is the same as the theorem in words.

\[
\begin{align*}
\text{Whence } BC &= \frac{AB \times DF}{AD} = \frac{AB \times \tan A}{\text{rad.}} \\
AC &= \frac{AB \times AF}{AD} = \frac{AB \times \sec A}{\text{rad.}}
\end{align*}
\]

When the hypothenuse is given, each of the legs will represent, or have the ratio of, the sines of their opposite angles, the hypothenuse itself being assumed for the radius.

In this case, therefore, it will be

As radius:

Ist to the hypothenuse:

So is the sine of either acute angle:

To the opposite side.

That is, \( A \) \( E \) :: \( A \) \( C \) :: \( A \) \( G \) :: \( B \) \( C \);

\[
\begin{align*}
\text{rad.} : AC &= \sin A \cdot \frac{AC}{\text{rad.}} \\
\text{rad.} : AC &= \sin B \cdot \frac{AC}{\text{rad.}}
\end{align*}
\]

Note.—The radius is equal to the sine of 90°, or to the tangent of 45°.

The preceding theorems have been deduced from the geometrical properties of triangles and of their several parts; and they exhibit the simplest and most direct mode of solution that can be obtained generally for each case; but there are certain other forms of solution which are much more readily applied under particular relations of the data, which it will be proper now to consider, and in which we shall adopt the analytical mode of investigation instead of the geometrical one hitherto pursued.

Let \( A \) \( B \) \( C \) (Plate III. fig. 1.) be any plane triangle; \( C \) the vertical angle; \( C \) \( D \) a perpendicular let fall upon the base \( A \) \( B \); and let \( a, b, c, \) denote the sides respectively that are opposite to the angles \( A, B, C \).

Then because \( A \) \( C \) \( = b, A \) \( D \) is the cosine of \( A \) to that radius; consequently, when radius \( = 1, A \) \( D \) = \( b \) \text{cof. } A.

In like manner, \( B \) \( D \) = \( a \) \text{cof. } B; therefore \( A \) \( D \) + \( B \) \( D \) = \( A \) \( B \) = \( a \) \text{cof. } B + \text{bcof. } A.

If one of the angles, as \( A \), were obtuse, the result would still be the same; because, while on the one hand \( A \) would be negative, \( A \) \( D \), lying on the contrary side of \( A \) to what it does in the figure referred to, it must be deducted from \( B \) \( D \) to leave \( A \) \( B \); and a negative quantity subtracted, is equivalent to a positive quantity added; and by letting fall perpendiculars from the angles \( A \) and \( B \) upon the opposite sides, or upon their continuations, precisely analogous results will be obtained; and hence we derive immediately the following fundamental equations.

\[
\begin{align*}
a &= b \text{cof. } C + c \text{cof. } B \quad \left( \text{I.} \right) \\
b &= a \text{cof. } C + c \text{cof. } A \\
c &= a \text{cof. } B + b \text{cof. } A
\end{align*}
\]

Again, it is obvious, that in the same manner as we found \( A \) \( D \) = \( b \) \text{cof. } A, and \( D \) \( B \) = \( a \) \text{cof. } B, we might also obtain \( \text{DC} = b \) \text{fin. } A, and \( \text{DC} = a \) \text{fin. } B; therefore \( a \) \text{fin. } B = b \text{ fin. } A; \text{ whence also } \frac{a}{b} = \frac{\text{fin. } A}{\text{fin. } B}; \text{ and in like manner we have } \frac{a}{c} = \frac{\text{fin. } A}{\text{fin. } C} \text{ and } \frac{b}{c} = \frac{\text{fin. } B}{\text{fin. } C}. \text{ Or changing the denominators, the relations of all the six quantities may be thus expressed:}

\[
\begin{align*}
\frac{\text{fin. } A}{a} &= \frac{\text{fin. } B}{b} = \frac{\text{fin. } C}{c}
\end{align*}
\]

These
TRIGONOMETRY.

These formulae shew immediately the truth of our first theorem, viz. "the sides of plane triangles have the same ratio as the sines of their opposite angles."

Again, since \(a : b :: \sin A : \sin B\), we have \(a + b :: \sin A + \sin B; \) that is,

\[
\frac{a + b}{a - b} = \tan \frac{1}{2} (A + B).
\]

But \(\tan \frac{1}{2} (A + B) = \frac{a + b}{a - b} \cdot \tan \frac{1}{2} (A - B)
\]

See Arithmetic of Sines; consequently

\[
a + b = \tan \frac{1}{2} (A + B) \cdot a - b = \tan \frac{1}{2} (A - B)
\]

Or \(a + b : a - b :: \tan \frac{1}{2} (A + B) : \tan \frac{1}{2} (A - B)\);

that is, "the sum of the sides is to the difference of the sides, as the tangent of half the sum of the opposite angles is to the tangent of half the difference," which is our second theorem:

and other forms of solution are readily obtained from the two fundamental equations (I.) and (II.) viz.

\[
a = b \cos C + c \cos B
\]

\[
b = a \cos C + c \cos A
\]

\[
c = c \cos B + a \cos C
\]

For multiplying the first of these equations by \(a\), the second by \(b\), and the third by \(c\), and each of the equations thus obtained being taken from the sum of the other two, there will arise

\[
\begin{align*}
\frac{b^2 + c^2 - a^2}{2bc} &= \cos A \\
\frac{a^2 + c^2 - b^2}{2ac} &= \cos B \\
\frac{a^2 + b^2 - c^2}{2ab} &= \cos C
\end{align*}
\]

(III.)

\[
cos \frac{1}{2} A = \sqrt{\frac{1}{2} \left( \frac{a + b + c}{b} \right) - \left( \frac{a + b + c - a}{b} \right)}
\]

(VII.)

which is purely logarithmic: the \(\frac{1}{2} B\), and \(\frac{1}{2} C\), being precisely analogous to the above, are omitted.

And in a similar manner, we find

\[
\sin \frac{1}{2} A = \sqrt{\frac{1}{2} \left( \frac{a + b + c}{b} \right) - \left( \frac{a + b + c - a}{b} \right)}
\]

(VIII.)

\[
\tan \frac{1}{2} A = \sqrt{\frac{1}{2} \left( \frac{a + b + c}{b} \right) - \left( \frac{a + b + c - a}{b} \right)}
\]

(IX.)

Of these several rules for the determination of the sides and angles of plane triangles, we have before observed, that the formulae (IV.) and (V.) are best adapted to small integral values of the sides; and to real fractional values of the cosine, in other cases, one or other of the three latter will best apply. When the angle sought is very small, it is usually better to employ \(N^3\) (VIII.) than \(N^0\) (VII.) The method indicated in \(N^0\) (IX.) is commodious, and very correct, except when \(A\) is either very small or near 180°.

In some cases, where great accuracy is required, the operator may wish to obviate the uncertainties that would arise from the use of some of these formulae; for which purpose Dr. Maclise has given, in the Introduction to Taylor's Logarithms, the following rules in reference to the sines and tangents of very small arcs.

1. To find the Sine.—To the log. of the arc reduced into seconds, with the decimal annexed, add the constant quantity 4.6855749, and from the sum subtract one-third of the arithmetical complement of the log. cosine, and the remainder will be the log. sine of the given arc.

2. To find the Arc from the Sine.—To the given log. sine of a small arc, add 5.3144251, and one-third of the arithmetical complement of log. cosine; subtract 10 from the index of the sum, the remainder will be the logarithm of the number of seconds and decimals in the given arc.

3. To find the Tangent.—To the log. arc and the constant quantity 4.6855749, add two-thirds of the arithmetical complement of the log. cosine, and the sum is the log. tangent of the given arc.

4. To find the Arc from the Tangent.—To the log. tangent add 5.3144251, and from the sum subtract two-thirds of the arithmetical complement of log. cosine; take 10 from the index, and there will remain the logarithm of the number of seconds and decimals in the given arc.

Trigon—
TRIGONOMETRY.

TRIGONOMETRY, Spherical, relates to the resolution and calculation of the sides and angles of spherical triangles, which are formed by the intersection of three great circles of the sphere, and which, like plane triangles, consist of six parts, viz. three sides and three angles. See Spherical Triangle.

In plane trigonometry, any three of the six parts of a triangle being given, except the three angles, the other parts may be found; but in spherical trigonometry this exception has not place, for any three of the fix parts being given, the rest may thence be determined, the sides being measured or estimated by degrees, minutes, &c. the same as the angles.

Spherical trigonometry is divided into right-angled and oblique-angled, or the resolution of right and oblique-angled spherical triangles. When a spherical triangle has a right angle, it is called a right-angled spherical triangle; and when one of its sides is a quadrant, or 90°, it is called a quadrantal triangle.

The solution of all the cases of spherical trigonometry, although much more numerous than those in plane trigonometry, depends upon only three fundamental equations.

Theorem 1.—In any spherical triangle, the sines of the sides have the same ratio as the sines of their opposite angles.

Let O (fig. 2.) be the centre of the sphere, and having joined OA, OC, OB, draw AD perpendicular to the plane OBC; also make DE perpendicular to OB, and DF to OC; and join AE, AF.

Then, because AD is perpendicular to the plane OBC, each of the planes ADE, ADF, which passes through AD, will also be perpendicular to that plane; and hence ED is perpendicular to OB, and the plane ADE to the plane OBC, the line AE, which lies in the plane ADE, and is drawn from the same point E, is also perpendicular to OB.

Again, in like manner, because FD is perpendicular to OC, and the plane AFD to the plane OBC, the line FA, which lies in the plane AFD, and is drawn from the same point F, is perpendicular to OC; and, therefore, the angles AED and AFD, which measure the inclination of the planes AOB, AOC, will measure the angles CBA, BCA, of the spherical triangle ABC. Also, AF being perpendicular to OC, is the sine of the angle AOF, or of the arc AC; and AE, which is perpendicular to OB, is the sine of the angle AOB, or of the arc AB. But ADE, AFD, being right-angled plane triangles, right-angled at D, we shall have AD = AE sin. AED, and AD = AF sin. AFD.

Whence, by equality, AE sin. AED = AF sin. AFD; consequently

\[ A \cdot \sin. A \cdot \sin. AED :: A \cdot \sin. AED :: \sin. A \cdot \sin. B :: \sin. B \cdot \sin. C \]

\[ \sin. a \cdot \sin. b \cdot \sin. c \] (I)

Theorem 2.—In any spherical triangle,

As the rectangle of the sines of any two sides is to the radius ::

So is the rectangle of radius and the cofine of the other side, minus the rectangle of the cofines of the fame two sides:

To the cofine of the angle included by those sides.

For, having joined OA, OB, OC, (fig. 3.) draw FD in the plane OBC, and DE in the plane OAB, each perpendicular to their common section OB, and join EF. Then, because the angle EDF is the measure of the inclination of the planes OBC, OAB, it is also the measure of the spherical angle ABC or B. And because

\[ \text{cof. EDF} = \frac{DE^2 + DF^2 - EF^2}{2 DE \times DF}, \]

\[ \text{cof. EOF} = \frac{OE^2 + OF^2 - EF^2}{2 OE \times OF}, \]

\[ \text{EF}^2 = OE^2 + OF^2 - 2 OE \times OF \times \text{cof. EOF}. \]

See Form (V.) Plane Trigonometry.

And by substituting this in the first equation, \( \text{cof. EDF} = \frac{DE^2 + DF^2 - OE^2 - OF^2 + 2 OE \times OF \times \text{cof. EOF}}{2 DE \times DF} \)

But \( OE^2 - ED^2 \), and \( OF^2 - DF^2 \), are each equal to \( OD^2 \); whence \( \text{cof. EDF} \), or its equal,

\[ \text{cof. B} = \frac{OE \times OF \times \text{cof. EOF} - OD^2}{DE \times DF} \]

or

\[ \text{cof. B} = \frac{OE \times OF \times \text{cof. EOF} - OD^2}{DE \times DF} \]

\[ = \frac{1}{\sin. DOE}, \text{&c. if these values be substituted in the former} \]

\[ \text{equation, we shall have} \]

\[ \text{cof. B} = \frac{\text{cof. AC} - \text{cof. AB} \cdot \text{cof. BC}}{\sin. AB \cdot \sin. BC} \]

which necessarily involves the conditions given in the enunciation of the theorem.

Here again, affixing A, B, C, to denote the angles, and \( a, b, c \), the corresponding opposite sides, we deduce the following set of equations, \( \text{viz.} \)

\[ \text{cof.} a = \text{cof.} b \cdot \text{cof.} c + \sin. b \cdot \sin. c \cdot \text{cof.} A \]

\[ \text{cof.} b = \text{cof.} a \cdot \text{cof.} c + \sin. a \cdot \sin. c \cdot \text{cof.} B \]

\[ \text{cof.} c = \text{cof.} a \cdot \text{cof.} b + \sin. a \cdot \sin. b \cdot \text{cof. C} \] (II)

These equations will apply equally to the supplemental triangle; thus putting for the sides \( a, b, c \), \( 180^\circ - A', \ 180^\circ - B', \ 180^\circ - C' \); and for the angles \( A, B, C \), \( 180^\circ - a', \ 180^\circ - b', \ 180^\circ - c' \), we shall have

\[ - \text{cof.} A' = \text{cof.} B' \cdot \text{cof.} C' - \sin. B' \cdot \sin. C' \cdot \text{cof.} a' \]

And here, again, we have three symmetrical equations applying to any spherical triangles, \( \text{viz.} \)

\[ \text{cof.} A = \text{cof.} a \cdot \sin. B \cdot \sin. C - \text{cof.} B \cdot \sin. C \]

\[ \text{cof. B} = \text{cof.} b \cdot \sin. A \cdot \sin. C - \text{cof.} A \cdot \sin. C \]

\[ \text{cof. C} = \text{cof.} c \cdot \sin. A \cdot \sin. B - \text{cof.} A \cdot \sin. B \] (III)

Another important relation may also thence be readily deduced; for, substituting for the cof. \( b \) in the third of the equations \( N^0 (\text{II}) \) its value in the second; substituting also for \( \text{cof.} a' \), its value \( 1 - \text{fin.} a' \), and then striking out the common factor fin. \( a \), we shall have

\[ \text{cof.} c \cdot \sin. a = \text{fin.} c \cdot \text{cof.} a \cdot \text{cof.} B + \sin. b \cdot \text{cof. C} \]

But equation \( N^0 (\text{I}) \) gives \( \text{fin.} \cdot b = \frac{\text{fin.} \cdot B \cdot \text{fin.} c}{\text{fin.} C} \); and hence,
hence, by substitution,
\[
\text{cot} \cdot \sin a = \sin \cdot \text{cot} \cdot a \cdot \text{cot} \cdot B + \frac{\text{sin} \cdot B \cdot \text{cot} \cdot C \cdot \sin \cdot c}{\sin \cdot C}.
\]
Dividing by \( \sin \cdot c \), we have
\[
\frac{\text{cot} \cdot c}{\sin \cdot c} = \text{cot} \cdot a = \frac{\text{cot} \cdot a \cdot \text{cot} \cdot B + \frac{\text{sin} \cdot B \cdot \text{cot} \cdot C}{\sin \cdot C}}{\sin \cdot c}.
\]
But \( \text{cot} \cdot c = \cos \cdot c \). See Arithmetic of Sines.

Therefore, \( \text{cot} \cdot c \cdot \sin a = \cos \cdot a \cdot \cos \cdot B + \frac{\text{sin} \cdot B \cdot \cos \cdot C}{\sin \cdot C} \).
Thus, again, we get three symmetrical equations:
\[
\begin{align*}
\cos \cdot a \cdot \sin a &= \cos \cdot a \cdot \cos \cdot B + \frac{\text{sin} \cdot B \cdot \cos \cdot C}{\sin \cdot C} \tag{IV.} \\
\cos \cdot b \cdot \sin c &= \cos \cdot c \cdot \cos \cdot A + \frac{\text{sin} \cdot A \cdot \cos \cdot B}{\sin \cdot B} \tag{V.} \\
\cos \cdot c \cdot \sin a &= \cos \cdot a \cdot \cos \cdot B + \frac{\text{sin} \cdot B \cdot \cos \cdot C}{\sin \cdot C} \tag{VI.}
\end{align*}
\]

The classes of equations Nos. (I.) (II.) (III.) and (IV.) comprehend the whole of spherical trigonometry; or, in fact, Nos. (II.), from which all the others can be derived, may be regarded as comprehending the whole.
They require, however, some modifications to adapt them to logarithmic computations, which we shall now endeavour to illustrate.

I. Solution of right-angled spherical Triangles.—Let us suppose the angle \( A \) to be the right angle, then since \( \sin \cdot A = 1 \), \( \cos \cdot a \) (I.) gives
\[
\frac{\sin \cdot B}{\sin \cdot b} = \frac{\sin \cdot C}{\sin \cdot c} \tag{VII.}
\]
And upon the same hypothesis, \( \cos \cdot A = 0 \); so that Equation 1. Nos. (III.) becomes
\[
\begin{align*}
\cos \cdot a &= \cos \cdot B \cdot \cos \cdot C, \text{ or} \tag{VIII.} \\
\cos \cdot a &= \cos \cdot b \cdot \cos \cdot C
\end{align*}
\]
The Equations 2. and 3. of Nos. (III.) give also upon the same hypothesis, that is, angle \( A = 90^\circ \),
\[
\begin{align*}
\cos \cdot B &= \cos \cdot c \cdot \cos \cdot b \tag{IX.} \\
\cos \cdot C &= \cos \cdot b \cdot \cos \cdot c
\end{align*}
\]
And, lastly, from Nos. (IV.)
\[
\begin{align*}
\cos \cdot B &= \cos \cdot b \cdot \sin \cdot c \tag{X.} \\
\cos \cdot C &= \cos \cdot e \cdot \sin \cdot b
\end{align*}
\]
From these equations, by a few obvious transformations, the six usual cases of spherical right-angled triangles may be solved as follow.

Cafe 1.—Given the hypotenuse \( a \), and an angle \( B \), to find the other parts.

Here,
\[
\frac{\sin \cdot b}{\sin \cdot a} = \frac{\sin \cdot a}{\sin \cdot B} \tag{II.}
\]
or,
\[
\text{sin} \cdot b \cdot \text{sin} \cdot a = \sin \cdot a \cdot \sin \cdot B \tag{II.}
\]
Again, \( \sin \cdot e = \sin \cdot a \cdot \sin \cdot B \); or,
\[
\sin \cdot e = \sin \cdot a \cdot \sin \cdot B \tag{II.}
\]
Lastly, \( \cos \cdot C = \cos \cdot B \cdot \cos \cdot a \); or,
\[
\cos \cdot C = \cos \cdot B \cdot \cos \cdot a \tag{II.}
\]
In this case there can be nothing ambiguous, for in applying the first form, it is known that the angle and the opposite side are always of the same affection; and in the two latter, the rules for the change of lines in the different quadrants (see Arithmetic of Sines), will determine to which the result belongs.

Cafe 2.—Given the hypotenuse \( a \), and one of the sides, to find the other parts:
\[
\begin{align*}
\sin \cdot B &= \frac{\sin \cdot b}{\sin \cdot a} \text{ or } \sin \cdot \text{ang. req.} = \frac{\sin \cdot \text{giv. side}}{\sin \cdot \text{hyp.}} \tag{II.} \\
\sin \cdot c &= \frac{\cos \cdot a}{\cos \cdot b} \text{ or } \cos \cdot \text{side req.} = \frac{\cos \cdot \text{hyp.}}{\cos \cdot \text{giv. side}} \tag{II.} \\
\cos \cdot C &= \tan \cdot b \cdot \cos \cdot a \text{ or } \cos \cdot \text{ang. req.} = \tan \cdot \text{giv. side} \text{ and } \cos \cdot \text{hyp.} \tag{II.}
\end{align*}
\]

Cafe 3.—Given two sides, including the right angle, namely \( b \) and \( c \), to find the other parts.

Here,
\[
\cos \cdot a = \cos \cdot b \cdot \cos \cdot c \tag{II.}
\]
or,
\[
\cos \cdot \text{hyp.} = \text{rect. of } \cos \cdot \text{giv. sides.} \tag{II.}
\]
Again,
\[
\tan \cdot B = \frac{\tan \cdot b}{\tan \cdot a} \text{ and } \tan \cdot C = \frac{\tan \cdot c}{\tan \cdot a} \tag{II.}
\]
or,
\[
\tan \cdot \text{ang. req.} = \frac{\tan \cdot \text{opp. side}}{\tan \cdot \text{adj. side}} \tag{II.}
\]

Cafe 4.—Given a side \( c \), and its opposite angle \( B \), to find the other parts.

Here,
\[
\sin \cdot b = \sin \cdot a \cdot \sin \cdot B \tag{II.}
\]
or,
\[
\text{sin} \cdot \text{side req.} = \text{tan} \cdot \text{opp. side} \times \text{cot} \cdot \text{opp. ang.} \tag{II.}
\]
Lastly,
\[
\cos \cdot b = \cos \cdot a \cdot \cos \cdot B \tag{II.}
\]
or,
\[
\cos \cdot \text{ang. req.} = \cos \cdot \text{opp. side} \times \sin \cdot \text{giv. ang.} \tag{II.}
\]

Cafe 5.—Given a side \( a \), and its adjacent angle \( B \), to find the other parts.

Here,
\[
\tan \cdot b = \tan \cdot a \cdot \tan \cdot B \tag{II.}
\]
or,
\[
\text{tan} \cdot \text{side req.} = \text{tan} \cdot \text{opp. side} \times \sin \cdot \text{giv. ang.} \tag{II.}
\]
Again, \( \tan \cdot a = \frac{\tan \cdot b}{\cos \cdot B} \text{ or } \tan \cdot \text{hyp.} = \frac{\tan \cdot \text{giv. side}}{\cos \cdot \text{giv. ang.}} \tag{II.}
\]
or,
\[
\tan \cdot a = \cos \cdot B \cdot \tan \cdot B \tag{II.}
\]
That is,
\[
\cos \cdot \text{hyp.} = \cos \cdot \text{giv. ang.} \times \cot \cdot \text{giv. side.} \tag{II.}
\]
Lastly, \( \cos \cdot B = \cos \cdot a \cdot \cos \cdot C \); or,
\[
\cos \cdot \text{ang. req.} = \cos \cdot \text{opp. side} \times \sin \cdot \text{giv. ang.} \tag{II.}
\]

Cafe 6.—Given the two oblique angles \( B \) and \( C \), to find the right.

Here,
\[
\cos \cdot a = \cos \cdot B \cdot \cos \cdot C \tag{II.}
\]
or,
\[
\cos \cdot \text{hyp.} = \text{cot. of one side } \times \text{cot. of the other;} \tag{II.}
\]
or,
\[
\cos \cdot b = \cos \cdot a \cdot \cos \cdot \text{B} \tag{II.}
\]
or,
\[
\cos \cdot \text{req. side} = \frac{\cos \cdot \text{opp. ang.}}{\sin \cdot \text{adj. ang.}} \tag{II.}
\]

It may be proper to observe, that the rule of the signs, given under the article Arithmetic of Sines, will serve in all these cases to determine the kind or affection of the unknown parts.

In working by logarithms it must be observed, that when the resulting logarithm is the logarithm of a quotient, 10 must be added to the index; and when it is the logarithm of a product, 10 must be subtracted from the index.

II. Resolu-
II. Resolution of oblique-angled spherical Triangles.—This may be effected by means of four general cases, comprehending two or more problems.

Case 1. Given three of these four things, viz. two sides, b, c, and their opposite angles B and C, to find the fourth.

This case comprehends two problems, in one of which the unknown quantity is an angle, in the other a side; which are both resolved by means of equation No. (I.) from which we have

\[ \sin C = \frac{\sin b \sin B}{\sin b} \quad \text{and} \quad \sin C = \frac{\sin b \sin C}{\sin b} \]

Case 2. Of the four following things; viz. a, b, c, and an angle, any three being given, to find the fourth.

This case comprehends three problems.

1. When the three sides are given, to find an angle.

Here, from equation No. (II.) we have

\[ \cos A = \frac{\cos b \cos c}{\cos b} \quad \text{and} \quad \cos A = \frac{\cos a \cos b}{\cos a} \]

\[ \cos B = \frac{\cos b \cos c}{\cos b} \quad \text{and} \quad \cos B = \frac{\cos a \cos b}{\cos a} \]

\[ \cos C = \frac{\cos c \cos b}{\cos c} \quad \text{and} \quad \cos C = \frac{\cos a \cos b}{\cos a} \]

In this form, however, the equations are not adapted to logarithmic computation. We shall therefore refer to the form given under the article Sines, where we have

\[ 1 + \cos A = 2 \cos^2 \frac{A}{2} \quad \text{and} \quad 1 - \cos A = 2 \sin^2 \frac{A}{2} \]

Hence,

\[ 2 \cos^2 \frac{A}{2} = \frac{\sin b \sin c + \cos a - \cos b \cos c}{\sin b \sin c} = \frac{\cos a - \cos (b + c)}{\sin b \sin c} \]

Hence, also, 2 \sin^2 \frac{A}{2} = \frac{\cos (b - c) - \cos a}{\sin b \sin c} \]

The latter of these, divided by the former, gives

\[ \tan^2 \frac{A}{2} = \frac{\cos (b - c) - \cos a}{\cos a - \cos (b + c)} \]

which is equivalent to

\[ \tan^2 \frac{A}{2} = \frac{\sin \frac{1}{2} (a + b - c) \sin \frac{1}{2} (a + c - b)}{\sin \frac{1}{2} (a + b + c) \sin \frac{1}{2} (b + c - a)} \]

See Sines.

Hence we have, for the tangents of the half angles, these three symmetrical equations; viz.

\[ \tan \frac{1}{2} A = \sqrt{\frac{\sin \frac{1}{2} (a + b - c) \sin \frac{1}{2} (a + c - b)}{\sin b \sin c}} \]

\[ \tan \frac{1}{2} B = \sqrt{\frac{\sin \frac{1}{2} (a + b + c) \sin \frac{1}{2} (b + c - a)}{\sin b \sin c}} \]

\[ \tan \frac{1}{2} C = \sqrt{\frac{\sin \frac{1}{2} (a + b + c) \sin \frac{1}{2} (b + c - a)}{\sin b \sin c}} \]

The expressions for the sines of the half angles might be obtained with equal facility. As they are symmetrical, we shall put down but one; viz.

\[ \sin \frac{1}{2} A = \sqrt{\frac{\sin \frac{1}{2} (a + b - c) \sin \frac{1}{2} (a + c - b)}{\sin b \sin c}} \]

And expressions for the cofines and cotangents of the half angles may be readily found from the above by the forms \( \cos \frac{1}{2} A = \frac{1}{\tan \frac{1}{2} A} \), \( \cot \frac{1}{2} C = \frac{1}{\tan \frac{1}{2} C} \), \( \tan \frac{1}{2} A = \frac{\sin \frac{1}{2} A}{\cos \frac{1}{2} A} \), \( \tan \frac{1}{2} B = \frac{\sin \frac{1}{2} B}{\cos \frac{1}{2} B} \), \( \tan \frac{1}{2} C = \frac{\sin \frac{1}{2} C}{\cos \frac{1}{2} C} \).

When two sides, as b and c, become equal, the expression for \( \cos \frac{1}{2} A \), becomes \( \sin \frac{1}{2} A = \frac{\sin \frac{1}{2} a}{\cos \frac{1}{2} b} \).

If \( a = b = c = 90^\circ \), then \( \sin \frac{1}{2} A = \frac{1}{\sqrt{2}} = \frac{1}{2} \sqrt{2} \)

\( = \sin 45^\circ \); and \( A = B = C = 90^\circ \).

Leaving other corollaries to be deduced by the reader, let us proceed to the next problem in this case.

2. To find the sine opposite to the given angle C; that is, given two sides and the included angle, to find the third side.

Find from the data a dependent angle \( \phi \) such, that

\[ \tan \phi = \cos C \tan b \]

Substitute for \( \cos C \), in the third equation No. (II.) its value in this, and it will become

\[ \cos \phi = \cos \frac{a}{\cos \phi \cos b \sin \phi} \quad \cos \frac{a}{\cos \phi \sin \phi} \quad \cos \phi \sin \phi \]

\[ = \cos \frac{b}{\cos \phi \sin \phi} \]

\[ \cos \phi \sin \phi \]

\[ \cos \phi \sin \phi \]

Hence \( a \) is known by adding \( \phi \).

Case 3. Of the four following parts; viz. two sides, a and c, and two angles, B and C, one opposite, the other adjacent; three being given, to find a fourth.

This case presents four problems.

1. Given \( a, c, B \), to find \( C \).

Determine an arc \( \phi \) by this condition,

\[ \cot \phi = \cot \phi \quad \cot B, \quad \text{or} \quad \cot \phi = \cot \phi \]

Substitute
Substitute this value of cot. $c$ for it in Equation 3. 

$N^o$ (IV.) and it will become

$\sin a \cot \phi' \cot B = \cot a \cot \phi'$

Whence

$\cot \phi' = \frac{\cot a \sin \alpha - \cot \alpha}{\cot B}$

(XVI.)

It may be observed, that equation $N^o$ (V.) is analogous to $N^o$ (VIII.) ; which shews, that the operation here performed, is equivalent to letting fall a perpendicular arc from the angle $A$ to the base $a$; the subsidiary arc of $F^o$ being the segment adjacent to the given angle $B$.

2. Given $B$, $C$, $\phi$, to find $a$.

Here $\phi'$ must be found by $N^o$ (V.) and then from $N^o$ (VI.) we have

$\sin (a - \phi') = \frac{\cot C \sin \phi'}{\cot B}$.

(XVII.)

Whence $a$ becomes known.

3. Given $B$, $C$, $a$, to find $c$.

Find a dependent angle $\phi''$, by making

$\cot C = \cot C \tan \phi''$, or $\frac{\cot C}{\cot a} = \tan \phi''$.

(XVIII.)

The following are the expressions for the sines of the half angles; viz.

$\sin \frac{1}{2} a = \sqrt{\frac{\cot \frac{1}{2} (A + B - C) \cot \frac{1}{2} (A + B + C)}{\cot \frac{1}{2} (B + C + A) \cot \frac{1}{2} (B + C - A)}}$

$\sin \frac{1}{2} b = \sqrt{\frac{\cot \frac{1}{2} (B + C - A) \cot \frac{1}{2} (B + C + A)}{\cot \frac{1}{2} (B + C + A) \cot \frac{1}{2} (B + C - A)}}$

$\sin \frac{1}{2} c = \sqrt{\frac{\cot \frac{1}{2} (A + B - C) \cot \frac{1}{2} (A + B + C)}{\cot \frac{1}{2} (A + B + C) \cot \frac{1}{2} (A + B - C)}}$

(XIX.)

The prefent article we had occasion to mention the analogies of Napier, which it may not be amifs to illustrate before we proceed any farther in our investigations. These analogies are four simple and elegant formulas, which we owe to the celebrated inventor of logarithms, of which two ferve to determine any two angles of a spherical triangle by means of two oppofite fides and their included angle; while the other two ferve to fnd any two fides by means of their oppofite angle and the contained fide. They, therefore, together with equation $N^o$ (I.), will ferve for the folution of all the cofes of oblique-angled spherical triangles. The investigation of these analogies may be given as follow.

If from Equation I. $N^o$ (II.) $\cot C$ be exarninated, there will result, after a little reduction,

$\cot a \sin \phi = \cot a \sin \phi' - \cot \phi'$

and, by a simple permutation of letters,

$\cot b \sin \phi = \cot b \sin \phi' - \cot \phi'$

Adding these equations together, and reducing them, we have

$\sin \phi \sin \phi' = (1 + \cot C \sin \phi) \sin \phi'$

Now
TRIGONOMETRY.

Now from No. (I.) we have

\[
\sin a \sin b \sin c.
\]

Clearing these equations of their denominators, and respectively adding and subtracting them, there results

\[
\sin (\sin A + \sin B) = \sin (\sin A - \sin B).
\]

Dividing each of these two equations by the preceding,

\[
\frac{\sin A + \sin B}{\cos A + \cos B} = \frac{\sin A - \sin B}{\cos A - \cos B}.
\]

Consequently, from the relation established under Arithmetic of Sines,

\[
\tan \frac{1}{2} (A + B) = \cot \frac{1}{2} (a - b).
\]

And these equations, expressed as analogies, are,

\begin{align*}
\text{cof.} \frac{1}{2} (a + b) : \text{cof.} \frac{1}{2} (a - b) & : : \text{tan.} \frac{1}{2} (A + B) : \text{tan.} \frac{1}{2} (A - B) \\
\text{fin.} \frac{1}{2} (a + b) : \text{fin.} \frac{1}{2} (a - b) & : : \text{fin.} \frac{1}{2} C : \text{tan.} \frac{1}{2} (A - B)
\end{align*}

These analogies being applied to the supplemental triangle, by putting \(180^\circ - A\), \(180^\circ - B\), \&c. for \(a\), \(b\), \&c. we have

\begin{align*}
\text{cof.} \frac{1}{2} (A + B) : \text{cof.} \frac{1}{2} (A - B) & : : \tan. \frac{1}{2} c : \text{tan.} \frac{1}{2} (a + b) \\
\text{cof.} \frac{1}{2} (A + B) : \text{cof.} \frac{1}{2} (A - B) & : : \tan. \frac{1}{2} c : \text{tan.} \frac{1}{2} (a - b)
\end{align*}

From a due consideration of these four analogies, it results,

1. That \(\frac{1}{2} (A - B) < 90^\circ\), or that the difference of two angles of a spherical triangle is less than \(180^\circ\).

2. That \(\frac{1}{2} (a + b)\) and \(\frac{1}{2} (A + B)\) are always of the same affection.

3. That the difference of two sides is always less than \(180^\circ\).

4. That \((a - b)\) and \((A - B)\) have always the same sign; whence it follows, that the greatest angle is opposite to the greatest side, and reciprocally.

To these it may be added,

5. That the least angle is opposite to the least side, and the mean angle to the mean side.

One or other of these observations will serve to remove the ambiguity in the doubtful cases where \(a\), \(b\), and \(B\), or \(A\), \(B\), and \(b\), are given.

We may now collect the most commodious of these theorems, and present in one place all that will be usually required in the solution of oblique-angled spherical triangles.

\begin{align*}
\tan \frac{1}{2} A = \sqrt{\left\{ \begin{align*}
\sin \frac{1}{2} (a + b - c) & \sin \frac{1}{2} (a + c - b) \\
\sin \frac{1}{2} (b + c - a) & \sin \frac{1}{2} (a + c + b)
\end{align*} \right.} \\
\tan \frac{1}{2} B = \sqrt{\left\{ \begin{align*}
\sin \frac{1}{2} (b + c - a) & \sin \frac{1}{2} (a + b - c) \\
\sin \frac{1}{2} (a + c - b) & \sin \frac{1}{2} (a + b + c)
\end{align*} \right.} \\
\tan \frac{1}{2} C = \sqrt{\left\{ \begin{align*}
\sin \frac{1}{2} (a + b - c) & \sin \frac{1}{2} (b + c - a) \\
\sin \frac{1}{2} (a + b + c) & \sin \frac{1}{2} (a + b - c)
\end{align*} \right.} \\
\tan \frac{1}{2} a = \sqrt{\left\{ \begin{align*}
- \cos \frac{1}{2} (B + C - A) & \cos \frac{1}{2} (A + B + C) \\
\cos \frac{1}{2} (A + B - C) & \cos \frac{1}{2} (A + C - B)
\end{align*} \right.} \\
\tan \frac{1}{2} b = \sqrt{\left\{ \begin{align*}
- \cos \frac{1}{2} (A + C - B) & \cos \frac{1}{2} (A + B + C) \\
\cos \frac{1}{2} (B + C - A) & \cos \frac{1}{2} (A + B - C)
\end{align*} \right.} \\
\tan \frac{1}{2} c = \sqrt{\left\{ \begin{align*}
- \cos \frac{1}{2} (A + B - C) & \cos \frac{1}{2} (A + B + C) \\
\cos \frac{1}{2} (A + C - B) & \cos \frac{1}{2} (B + C - A)
\end{align*} \right.}
\end{align*}

\begin{align*}
\tan \frac{b - a}{2} = \tan \frac{1}{2} c & \sin \frac{1}{2} (B - A) \\
\tan \frac{b + a}{2} = \tan \frac{1}{2} c & \cos \frac{1}{2} (B - A) \\
\tan \frac{c - b}{2} = \tan \frac{1}{2} a & \sin \frac{1}{2} (C - B) \\
\tan \frac{c + b}{2} = \tan \frac{1}{2} a & \cos \frac{1}{2} (C - B) \\
\tan \frac{a - c}{2} = \tan \frac{1}{2} b & \sin \frac{1}{2} (A - C) \\
\tan \frac{b - a}{2} = \tan \frac{1}{2} b & \cos \frac{1}{2} (A - C) \\
\tan \frac{B - A}{2} = \cot \frac{1}{2} C
\end{align*}
TRIGONOMETRY.

15. \( \tan \frac{B + A}{2} = \cot \frac{1}{2} C \)
\( \cot \frac{1}{2} (b - a) \)
\( \tan \frac{1}{2} (b + a) \)

16. \( \tan \frac{C - B}{2} = \cot \frac{1}{2} A \)
\( \tan \frac{1}{2} (c - b) \)
\( \cot \frac{1}{2} (c + b) \)

17. \( \tan \frac{C + B}{2} = \cot \frac{1}{2} A \)
\( \tan \frac{1}{2} (c - b) \)
\( \cot \frac{1}{2} (c + b) \)

18. \( \tan \frac{A - C}{2} = \cot \frac{1}{2} B \)
\( \tan \frac{1}{2} (a - c) \)
\( \cot \frac{1}{2} (a + c) \)

19. \( \tan \frac{A + C}{2} = \cot \frac{1}{2} B \)
\( \tan \frac{1}{2} (a - c) \)
\( \cot \frac{1}{2} (a + c) \)

20. \( \tan \frac{1}{2} e = \tan \frac{1}{2} (b - a) \)
\( \tan \frac{1}{2} (b + a) \)

21. \( \tan \frac{1}{2} c = \tan \frac{1}{2} (b + a) \)
\( \tan \frac{1}{2} (b - a) \)

22. \( \tan \frac{1}{2} a = \tan \frac{1}{2} (c - b) \)
\( \tan \frac{1}{2} (c + b) \)

23. \( \tan \frac{1}{2} a = \tan \frac{1}{2} (c + b) \)
\( \tan \frac{1}{2} (c - b) \)

24. \( \tan \frac{1}{2} b = \tan \frac{1}{2} (a - e) \)
\( \tan \frac{1}{2} (a + e) \)

25. \( \tan \frac{1}{2} b = \tan \frac{1}{2} (a + e) \)
\( \tan \frac{1}{2} (a - e) \)

26. \( \cot \frac{1}{2} C = \tan \frac{1}{2} (B - A) \)
\( \tan \frac{1}{2} (A - C) \)
\( \cot \frac{1}{2} (B - A) \)
\( \cot \frac{1}{2} (A - C) \)

27. \( \cot \frac{1}{2} C = \tan \frac{1}{2} (B + A) \)
\( \tan \frac{1}{2} (A + C) \)
\( \cot \frac{1}{2} (B + A) \)
\( \cot \frac{1}{2} (A + C) \)

28. \( \cot \frac{1}{2} A = \tan \frac{1}{2} (C - B) \)
\( \tan \frac{1}{2} (B - A) \)
\( \cot \frac{1}{2} (C - B) \)
\( \cot \frac{1}{2} (B - A) \)

29. \( \cot \frac{1}{2} A = \tan \frac{1}{2} (C + B) \)
\( \tan \frac{1}{2} (A + C) \)
\( \cot \frac{1}{2} (C + B) \)
\( \cot \frac{1}{2} (A + C) \)

30. \( \cot \frac{1}{2} B = \tan \frac{1}{2} (A - C) \)
\( \tan \frac{1}{2} (A + C) \)
\( \cot \frac{1}{2} (A - C) \)
\( \cot \frac{1}{2} (A + C) \)

31. \( \cot \frac{1}{2} B = \tan \frac{1}{2} (A + C) \)
\( \tan \frac{1}{2} (A - C) \)
\( \cot \frac{1}{2} (A - C) \)
\( \cot \frac{1}{2} (A + C) \)

We are indebted for many of the above transformations to Gregory's *Trigonometry*; others have been derived from Bonnycastle's *treatise* on the same subject.

We shall now conclude this article, by illustrating the solution of spherical triangles by means of Napier's *five circular parts*. See *PART AND CIRCULAR PART*.

Solution of right-angled spherical Triangles, by Napier's *circilar Parts*—If either one or both the sides, including the right angle, come into the question, for it among the data, write its complement to a quadrant. Since then by the general rule delivered under the article *CIRCULAR PARTS*, and rendered logarithmic, the whole fine, with the fine complement of the middle part, must be equal to the fines of the disjunct parts, and the cotangents of the conjunct parts; from the sum of those data subtract the third datum; the remainder will be some fine or tangent, the side or angle corresponding to which, in the table of fines, &c. is the side or angle sought.

This universal rule being of great service in trigonometry, we shall apply it to the various cases thereof, and illustrate it with examples; which examples, in the case of disjunct or separate parts, will at the same time illustrate the common method; but in the case of contiguous parts they admit of other solutions.

1. Given the hypotenuse \( BC \), \( 60^\circ \), and the angle \( C, 23^\circ 30' \); to find the opposite leg \( AB \) (fig. 4.) Since \( AB \) is the middle part, \( C \) and \( BC \) are disjunct (see PART); the product of the whole fine, into the cofine of the comple ment \( A B \), i.e. the fine itself of \( A B \), is equal to the product of the fines of \( C \) and \( BC \).

Therefore from the fine of \( C \) 9.6006997
+ fine of \( BC \) 9.3757306

Subtract whole fine 10.0000000

Remains fine of \( A B \) 9.5382303

The nearest correponding number to which, in the tables, is \( 20^\circ 12' \).

2. Given the hypotenuse \( BC \), \( 60^\circ \), and the leg \( AB, 20^\circ 12' \); to find the opposite angle \( C \). It is evident from the preceding problem, that from the sum of the whole fine, and the fine of the leg \( AB \), the fine of the hypotenuse \( B C \) is to be subtracted, the remainder is the fine of the angle \( C \). The example therefore of the former case is easily converted into an example of this.

3. Given the leg \( AB, 20^\circ 12' \), and the opposite angle \( C, 23^\circ 30' \); to find the hypotenuse \( BC \). It is evident from the first case, that from the sum of the whole fine, and the fine of \( AB \), is to be subtracted the fine of the angle \( C \), and the remainder is the fine of the hypotenuse \( BC \).

4. Given the hypotenuse \( BC \), \( 60^\circ \), and one leg \( AB, 20^\circ 12' \); to find the other leg. Since \( BC \) is a mean part, and \( A \) and \( AB \) and \( AC \) are disjunct parts, the product of the whole fine, into the cofine of the hypotenuse \( BC \), is equal to the product of the fines of the complements, i.e. the cofines of the legs \( A B \) and \( AC \).

Therefore from the whole fine

\( \cot \) fine of \( BC \) 9.6989700

Subtract cofine of \( AB \) 9.9724310

Remains cofine of \( AC \) 9.7265390

The corresponding number to which, in the tables, is \( 32^\circ 11' \); therefore \( AC = 57^\circ 49' \).

5. Given the legs \( AC, 57^\circ 49' \), and \( AB, 20^\circ 12' \); to find the hypotenuse \( BC \). It is evident from the preceding case, that the whole fine is to be subtracted from the sum of the cofines of the legs \( AB \) and \( AC \); the remainder is the cofine of the hypotenuse \( BC \). The example, therefore, of the preceding case is easily applied to this.

6. Given the leg \( AC, 57^\circ 49' \), and the adjacent angle \( C, 23^\circ 30' \); to find the opposite angle \( B \). Since \( B \) is a middle part, and \( A \) and \( C \) are disjunct parts; the product of the whole fine, by the cofine of \( B \), is equal to the product of the fine of \( C \), and the fine of the complement, i.e. the cofine of \( A \).

Therefore from the fine of \( C \)

\( \cot \) cofine of \( AC \) 9.6006997

Subtract whole fine 10.0000000

Remains cofine of \( B \) 9.3272307

The nearest number corresponding to which, in the tables, is \( 12^\circ 15' \); therefore \( B = 77^\circ 45' \).

7. Given the leg \( AC, 57^\circ 49' \), and the opposite angle \( B, 77^\circ 45' \); to find the adjacent angle \( C \). It is evident from the preceding case, that the cofine of \( AC \) is to be subtracted...
TRIGONOMETRY.

16. Given the oblique angles B, 77° 44', and C, 23° 30'; to find the hypotenuse B C. From the sum of the cotangents of C and B, subtract the whole fine; the remainder is the cofine of B C.

Solution of oblique-angled spherical Triangles.—1. In an oblique-angled spherical triangle A B C, (fig. 5.) two sides, A B and B C, being given, together with an angle, A, opposite to one of them, to find the other, C; the rule is,

As the sine of the side B C is to the sine of the opposite angle A; so is the sine of the side A B to the sine of the opposite angle C.

Suppose, for example, B C, 39° 29'; A, 43° 20'; B A, 66° 45'; then will

Sine of B C 9.8033572
Sine of A 9.8364771
Sine of B A 9.9632168

Sine of C 9.799939 The nearest corresponding number to which, in the tables, is 82° 34'.

2. Given two angles C, 82° 34', and A, 43° 20', together with the side A B, 66° 45', opposite to one of them, C; to find the side B C opposite to the other of them, A; say, as the sine of the angle C is to the sine of the opposite side A B; so is the sine of the angle A to the sine of the opposite side B C. The former example may suffice for the present case.

3. Given two sides A B, 66° 45', and B C, 39° 29', together with an angle opposite to one of them A, 43° 20'; to find the angle included by them, B. Suppose the angle C to be acute, since the other, A, is also acute, the perpendicular B E falls within the triangle. In the right-angled triangle A B E, therefore, from the given angle A, and side A B, find the angle A B E. Since B E is assumed as a lateral part in the triangle A B E, the angle E B C is a middle part, and the side B C must be a conjoint part; the cofine of the angle E B C will be found by subtracting the cotangent of A B from the sum of the cofine of the angle A B E, and the cotangent of B C. If then the angles A B E and E B C be added together, or in case the perpendicular fall without the triangle, be subtracted from each other, you will have the angle required B.

E. gr. Whole fine 10.000000
Cofine of A B 9.5963154

Sum - 19.5963154

Cotangent of A - 10.0252805

Cotangent of A B E 9.5710349 The nearest number corresponding to which, in the tables, is 20° 26'.

A B E, therefore, is 69° 34'.

Cofine of A B E 9.5429713
Cotangent of B C 10.0841529

Sum - 19.6271242

Cotangent of A B - 9.6330985

Cofine of E B C 9.9940257 The nearest number corresponding to which, in the tables, is 92° 29'; therefore A B C = 79° 31'.

4. Given two angles A, 43° 20', and B, 79° 34', together with the adjacent side A B, 66° 45', to find the side B C opposite to one of them.

From one of the given angles B, let fall a perpendicular E B to the unknown side of A C; and in the right-angled triangle A B E, from the given angle A, and hypotenuse A B, find the angle A B E; which, subtracted from the angle...
angle A B C, leaves the angle E B C. But if the perpendicular shall fall without the triangle, the angle A B C should have been subtracted from A B E. Since as the perpendicular B E is taken for one of the lateral parts, the middle part in the triangle A B E is the angle B, and the

conjoint part A B; in the triangle E B C the middle part is the angle A, and the conjoint part B C; the cotangent of the side B C is found by subtracting the cofine of E B A from the sum of the cotangent of A B, and the cofine of E B C. The example of the preceding case is easily applied to this.

5. Given two sides A B, 66° 45', and B C, 39° 29', with the angle A opposite to one of them, 43° 20'; to find the third side A C.

Letting fall, as before, the perpendicular B E; in the right-angled triangle A B E, from the given angle and hypothenuse A B, find the side A E. Since affining B E for a lateral part in the triangle A E B, A B is the middle part, and A E is the separate part; and in the triangle B E C, B C is the mean part, and E C a conjoint part; the cofine of E C is found by subtracting the cofine of A B from the sum of the cofines of A E and C B. If then the segments A E and E C be added together, or in case the perpendicular fall without the triangle, be subtracted from each other, the side A C will be had.

6. Given two sides A C, 65° 31', and A B, 66° 45', together with the included angle A, 43° 20'; to find the third side B C opposite thereto.

Letting fall the perpendicular B E, find, in the right-angled triangle, the segment A E; which, subtracted from A C, leaves E C. If the perpendicular fall without the triangle, A C is to be subtracted from A E. Since by affining the perpendicular B E for a lateral part in the triangle A E B, A B becomes a middle part, and A E a separate part; in the triangle E B C, C B is the middle part, E C a conjoint part; the cofine of B C is found by subtracting the cofine of A E from the sum of the cofines of A B and E C.

7. Given two angles A, 43° 20', and B, 79° 3'; together with the side C B, 39° 29', opposite to one of them; to find the side A B adjacent to both.

Letting fall the perpendicular C D from the unknown angle C, to the opposite side A B; and that falling within the triangle; from the given A B, and the hypothenuse B C, seek in the right-angled triangle B C D for the segment B D. Since affining the perpendicular C D for a lateral part in the triangle C D B, D B is the mean part, and the angle B a conjoint part; and in the triangle C D A, A D is the middle part, and the angle A a conjoint part: the cofine of the segment A D is found by subtracting the cotangent of the angle of A B from the sum of the cofine of D B, and the cotangent of the angle A. If then the segments A D and D B be added, or in case the perpendicular fall without the triangle, be subtracted from each other, the result will be the side A B required.

8. Given two sides A B, 66° 45', and B C, 39° 29', with the included angle 79° 3'; to find the angle A opposite to one of them.

Letting fall the perpendicular C D, find the segment B D, as in the preceding problem. This, subtracted from A B, leaves A D. If the perpendicular fall without the triangle, A B is to be added to D B. And since by affining the perpendicular C D for a lateral part in the triangle C D B, B D is the middle part, and the angle B a conjoint part; and in the triangle C D A, A D is the middle part, and the angle A a conjoint part, the cotangent of the angle A is formed by subtracting the sine of D B from the sum of the cotangent of the angle B, and of the sine of A B.

9. Given two angles A, 43° 20', and B, 79° 3', together with the adjacent side A B, 66° 45'; to find the angle C opposite to the same.

From one of the given angles B, letting fall the perpendicular to the opposite side A C; in the right-angled triangle A B E, from the given angle A, and hypothenuse A B, we find the angle A B E; which, subtracted from A B C, leaves the angle E B C. In case the perpendicular fall without the triangle, A B C is to be subtracted from A B E. Since by affining B E for a lateral part in the triangle C E B, the angle C is a middle part, and the angle C B E a conjoint part; and in the triangle A B E, the angle A is the middle part, and the angle A B E the conjoint part: the cofine of the angle C is found by subtracting the sine of the angle A B E, from the sum of the cofines of the angle A, and the sine of E B C.

10. Given two angles A, 43° 20', and C, 82° 34', together with the side A B, 66° 45', opposite to one of them; to find the other angle.

From the angle B sought, let fall a perpendicular B E; and in the right-angled triangle A E B, from the given angle A, and hypothenuse B A, find the angle A B E. Since affining the perpendicular E B for a lateral part in the triangle E C B, the angle C is the middle part, and the angle C B E a conjoint part; and in the triangle A B E, the angle A is the middle part, and the angle A B E a conjoint part: the cofine of the angle E B C is found by subtracting the cofine of A from the sum of the cofine of C, and of the cofine of E B C. If then A B E and E B C be added, or in case the perpendicular fall without the triangle, be subtracted from each other, the result will be the angle required A B C.

11. Given the three sides, to find an angle opposite to one of them. 1. If one side A C (Plate II. fig. 8a) be a quadrant, and the leg A B be less than a quadrant, find the angle A. Continue A B to F, till A F become equal to a quadrant; and from the pole A draw the arc C F, to cut the arc B F at right angles in F. Since in the right-angled triangle C B F, we have given the hypothenuse B C, and the side F B, or its complement A B to a quadrant; we shall find the perpendicular C F, which being the measure of the angle C A B, that angle is found of course.

2. If one side A C be a quadrant, and the other A B greater than a quadrant, seek again the angle A: from A B subtract the quadrant A D, and from the pole A describe the arc C D, cutting the arc A B at right angles in D. Since in the right-angled triangle C D B, the hypothenuse C B, and side D B, or excess of the side A B beyond a quadrant, is given, the perpendicular C D will be found as before, which is the measure of the angle A required.

3. If the triangle be isosceles, and A C = C F; and the angle A C F be required; bisect A F in D, and through D and C draw the arc D C. Since D C is perpendicular to A F, the angles A and F, and A C D and D C F, are equal; from the hypothenuse A C, and leg A D, given in the right-angled triangle A C D, we find the angle A C D; the double of which is the angle required A C F; and from the same data may the angle A or F be found.

4. If the triangle be scalene, and the angle A (Plate III. fig. 5.) be required; from C let fall the perpendicular C D, and seek the half-difference of the segments A D and D B, by saying, as the tangent of half the base A B is to the tangent of half the sum of the legs A C and C B; so is the tangent of their half-difference to the tangent of the half-difference of the segments A D and D B: add then the half-difference of the segments to the half-base, to find the greater segment; and subtract the same from the side for the less.
Thus having in the right-angled triangle $C A D$, the hypothema $A C$, and the side $A D$, the angle $A$ is found thence. After the fame manner is $B$ found in the other $C D B$, from $C B$ and $D B$ given.

12. Given the three angles $A$, $B$, and $C$, to find any of the sides. Since in lieu of the given triangle, another may be assumed, whose sides are equal to the given angles, and the angles to the given sides: this problem is resolved after the fame manner as the preceding one.

**TRIGONUM**, or **Triangular Harp**, an ancient musical instrument. (See Plate of ancient Instruments.) One of this kind was taken from an ancient painting in the museum of the king of Naples, in which it is placed on the shouder of a little dancing Cupid, who supports the instrument with his left hand, and plays upon it with his right. The trigonum is mentioned by Athenæus, lib. iv. and by Julius Pollux, lib. iv. cap. 9. According to Athenæus, Sophocles calls it a Phrygian instrument; and one of his Deinopisophyta tells us, that a certain musician of the name of Alexander Alexandrinus was so admirable a performer upon it, and had given such proofs of his abilities at Rome, that he made the inhabitants μουσικώς, musically mad. It may not be unworthy of remark, that this little instrument resembles the Theban harp, in the circumstance of wanting one side to complete the triangle. The performer too, being a native of Alexandria, as his name implies, makes it probable it was an Egyptian instrument upon which he gained his reputation at Rome.

**TRIGUERA**, in Botany, was so called by the late abbé Cavanilles, in honour of his friend Don Candido Maria de Trigueros, who gathered this plant, then suppos'd entirely non defept, in Andalusia. Another genus was originally thus designated, now *Lugaeu lobata* of Willdenow, Sp. Pl. v. 3. 753. The present seems to be a good genus, though the plant on which it is founded proves to be the rare and little-known *Verbasum Ofbecii* of Linnaeus, as the writer of the present article first discovered.—Cavan. Diff. 2. after page 166. Schreb. Gen. 114. Willd. Sp. Pl. v. 1. 839. Mart. Mill. Dict. v. 4.—Clas and order, *Pentandria Monogyonia*. Nat. Ord. Libida. Linn. Salts. Juff.

Gen. Ch. Col. Perianth inferior, of one leaf, permanent, divided half way down, into five unequal acute segments. Core. of one petal, bell-shaped; tube very short; limb inflated, plaited, five-cleft, longer than the calyx; the two upper segments reflexed. Nectary a short, membranous, five-toothed cup, surrounding the germen. Stam. Filaments five, very short, inserted into the teeth of the nectary at the outside; anthers arrow-shaped, converging. Pith. Gemen superior, roundish, with two furrows; style thread-shaped, straight, rather longer than the flaments; stigma obtuse. Peric. Berry dry, nearly globular, of four cells. Seeds two in each cell, roundish, compressed, rough, one over the other.

Eff. Ch. Corolla bell-shaped, irregular. Nectary with five teeth, surrounding the germen, and bearing the flaments. Berry dry, of four cells, with two seeds in each.

Obf. Cavanilles observed one or two of the cells to be occasionally abortive.

1. *T. ambrofiaca*. Musky Triguera. Cavan. Diff. 2. t. A. Willd. n. 1. (Vertebacum Ofbecki; Linn. Sp. Pl. 255. Willd. Sp. Pl. v. 1. 1006; excluding, from both, the reference to Tournefort, and the last-named place of growth. Obf. It. 52.)—Leaves decurrent, obturate, serrated. Calyx villous.—Native of Spain, towards the coast, and of Saléè in Barbary, flowering in the spring. Root annual. Stems simple, erect or decumbent, angular, leafy, a span high. Leaves alternate, two inches long, somewhat hairy, coarsely serrated, tapering at the base, and somewhat decurrent; the upper ones smaller. Flower-flaks axillary, in pairs, single-flowered, drooping. Calyx covered with woolly hairs. Corolla deep violet, an inch wide; nearly black in the throat. Seeds blackish, hard. The whole plant, called in Spanish *Almizquena*, and *Mordilla*, has a pleasant musky scent. It is spoken of as possessing the emollient narcotic virtues of Deadly Nightshade, and Hemlock, being, like those plants, useful in cancers of the breast; so far at least as to allay the pain.

2. *T. inodora*. Scentless Triguera. Cavan. as above. Willd. n. 2.—Leaves sessile, ovato-lanceolate, entire. Calyx smooth.—Found in Andalusia with the foregoing, and vulgarly named *Mordilla blandaqueina*. Differs from the first in the smoothness of every part. The flowers are handsome, drooping. Throat very pale violet, or yellowish-white, with five aries; limb pale violet, or purple, with entire pointles lobes.

**TRIGUEROS**, in Geography, a town of Spain, in the province of Seville; 8 miles N.N.E. of Moguer.

**TRIGYNIA**, in Botany, from *trigyna*, three, and *gynia*, a female, the name of an order in many classes of the Linnæean artificial system, distinguished by the flowers having three types, pistils, or female figmas. Of the latter, *Viburnum* and *Sambucus*, in the fifth class, are instances. The order in question occurs in the 18, 2d, 3d, 5th, 6th, 8th, 9th, 10th, 11th, 12th, and 15th classes; in the 4th and 7th it is wanting. Indeed in the 15th class, this order is but uncertain, *Delphinium* and *Aconitum*, on which Linnaeus founded it, being variable in the number of pistils. In the 12th class, *Icognaria*, it forms such unnatural and troublesome distinctions, as to be much better abolished. See *Pentagynia*.

**TRIHALAT.E**, so denominated from *tres*, three, and *bisum*, the fear of a feed, because some of the principal genera are remarkable for the broad scars of their three feeds; the 2d natural order among the *fragments* of Linneus, banding between his *Caryophyllae* and *Corydalis*, to the latter of which only it has any, even the slightest, affinity.

This is in itself but a heterogeneous assemblage, embracing several of Jullien's orders, particularly the *Sapindo*, *Aceret* and *Malpighhia*, as also his *Melia*. It consists of three fections. In the first are *Melia*, *Trichilia*, *Guarea* and *Turraez*; to which Linneus was afterwards inclined to add *Cedrela* and *Siiutenia*. The second fection consists of *Malpighia*, *Bannisteria*, *Hira*, *Tripoteris*, *Acer* and *Alcubius*; and the third, of *Staphylea*, *Spindus*, *Paulonia*, *Cardioporum* and *Tropolum*, to which Linneus afterwards added *Hippocratea*, more certainly belonging to the second fection.

Cavanilles, in his *Dyferations on Monadphous Plants*, has added many new genera to the *Trihala*; but he is ex-tolled beyond measure by Giseke in his edition of the *Praelectiones* of Linneus; where an account is given, not only of these genera, but of various others, considered by Cavanilles as monadphous, though contrary to the general opinion. See *Monadelphia*.

**TRIHING, TRIHING, or TRIHING**, from the Saxon *drihting*, an extent containing three or four hundreds, or the third part of a thire, or province. See *Tithing*.

Mr. Thoreby thinks the word ought to be written *thringing*. See Thoreby. Ducatus Leodens. p. 85.

These *trithings* still fulfil the part of a county, where by an easy corruption they are denominated *ridings*.

The word is also used for a court held within that circuit, which was the same with what we now call a *court-leet*, which is above a court-beron, and inferior to the county-court.

**TRIKALA**,
TRIALA, in Mythology, is a name of the Hindoo deity Siva. One of his names is Kala, Time, and the epithet Tri prefixed denotes his omniscience and omnipresence as to all times, past, present, and to come; a mythical triad or union of time. The honourable designation of Trikala is sometimes given to, or assumed by, individuals of supposed profundity of knowledge, especially if of an inspired or prophetic description. The confection of Siva in this form or character is Trikali, or Trikala-devi-kumari, meaning the divine triple maid, or triform divine maiden Kali. See Trisakti.

TRIALA-DEVI. See the preceding article.

TRILATERAL, a term applied to all three-sided figures. See Triangle.

TRILEUCUM PROMONTORIUM, or Lapacia Cory, in Ancient Geography, a promontory on the northern coast of Spain, N. of the country of the Callaei. According to Ptolemy, it lay between Flavium Brigantium and the mouth of the river Meturus or Meurus.

TRILL, in Botany, a Latin word, used for a tussle of three threads, woven or twinned together; but how it applies to this plant, we are not informed. Mutis, its discoverer, called the genus Jacquinia. De Theis understands the above name as merely equivalent to triple, and alluding to the three calyx-leaves, and three petals, which perhaps is right.—Linn. Mant. 153. Schreb. 347. Willd. Sp. Pl. v. 2. 1129. Mart. Mill. Dict. v. 4. Juss. 435.—Clas and order, Polyandra Monegyna. Nat. Ord. uncertain.

Gen. Ch. Cal. Perianth inferior, of three ovate, acute, spreading, flat, permanent leaves. Cor. Petals three, lanceolate, acute, smaller than the calyx. Stam. Filaments numerous, capillary, the length of the corolla; anthers roundish, minute, two-lobed. Pist. Germin superior, five-angled; style cylindrical; stigma simple. Peric. Berry oblong, feveral five-angled, of five cells, covered by the calyx. Seeds numerous, roundish, minute.

Eff. Ch. Petals three. Calyx of three leaves. Berry of five cells, with many seeds.

1. T. lutea. Linn. Mant. 247. Willd. n. 1.—Gathered at Carthagena, in South America, by Mutis, from whose description alone, contrary to his usual practice, Linnaeus adopted this genus into his System. This, the only species, is a shrub two fathoms in height, with very numerous, round, roughish branches. Leaves alternate, flaked, somewhat peltate, ovate, rather heart-shaped, pointed, serrated, veiny, downy. Footstalks round, smooth. Flowers; yellow, not from the corolla, but the anthers, generally terminal, racemose, their partial flaks simple, round, downy.

TRILL, in Mythic, a plain shake upon a single note, formed by a beating in the throat on the vowel o, or by the shaking of the palate on the throat in one found upon a note: this grace is usually made in clohes or cadences, and when on a long note exclamation or passion is expressed, the trill is made in the latter part of such note: but most commonly on binding notes and such as precede the closing note. See Trillo.

TRILL-Hookts, those used to hold the sides of a cart up to the horse.

TRILLETTO, in the Italian Mythic, a little short shake or quaver; it differs from trillo only in point of continuance, being its diminutive.

TRILLION, in Arithmetic, the number of a billion of billions.

After billions, we reckon by trillions, which makes a class of numeration, and is divided, like the other classes, into three places: thus we say, trillions, tens of trillions, hundreds of trillions, &c.

This genus is entirely confined, as far as botanists have hitherto observed, to North America. Linnaeus has described three species, nor has Willdenow any more, in his Sp. Pl. Pursh has given by far the best account of the genus, greatly increasing the number of species. We shall therefore follow him in the greater part of their arrangement. All are perennial, herbaceous, smooth, with a simple, erect, round, bit. n., bearing three simple entire leaves at the top, and a solitary flower, sessile or flaked, in the centre between them. Five of these plants are mentioned by Mr. Aiton, as cultivated in England, all hardy, flowering in April or May, in natural affinity, Trillium comes very near to Paris. See that article.

2. T. petiolatum. Plantain-leaved Trillium. Pursh n. 2. —Flower sessile, erect. Petals linear-lanceolate, upright, rather longer than the calyx. Leaves elliptic-lanceolate, acute, on very long footstalks. —About the waters of the Kookroofy. Goo. Lesis. Flowering in June. This singular species, whose flowers resemble those of the foregoing, has leaves very much like Plantago major. Pursh.

TRILLIUM.

flattened."—In sphagnum bogs, on the high mountains of Pennsylvania, Carolina, and Canada, flowering in May and June. Flowers white, with purple veins at the bottom. Berry scarlet. Pursh. We received from the late Rev. Dr. Muhlenberg, in 1799, a specimen answering precisely to this description, but not at all to Willdenow's name of undulatum. The leaves are an inch and half long, taper-pointed, on short stalks. Flower-stalk half that length. Petals an inch long, white, with slender parallel veins, which are of a fine purple at the base, even in the dried specimen. Anthers purple. Germs and style yellowish-white.

Pursh.

5. T. pumilum. Blunt-leaved Trillium. Pursh n. 5. (T. pumilum; Michaux Boreal.-Amer. v. 1. 215.)—Flower-stalk erect. Petals scarcely longer than the calyx. Leaves oval-oblong, obtuse, feltile. Native of the pine-woods of Lower Carolina, flowering in May. Petals pale flesh-coloured. Michaux. Specimens in the Linnaean herbarium, which answer well to this description, were most unaccountably confounded by Linnaeus with his "flabellum." They are inscribed "Trillium, Nova Tradevfallsia affinis, flore odora, unius trilpetato, radice tuberiflata."—Clayton. The stem is slender, five or six inches high. Leaves an inch and a quarter, or an inch and a half, broad, of a rather narrow elliptical shape. Flower on a very short stalk; in one specimen nearly feltile. Calyx-leaves exactly like the foliage, but only a quarter the size. Petals with fine, copious, interbranching veins, becoming purplish as they advance in age.

6. T. cernuum. Drooping Trillium. Linn. Sp. Pl. 484. Wild. n. 1. Ait. n. 1. Pursh n. 6. Sm. Spicil. 3. t. 4. Curt. Mag. t. 954. (Solanum trillimum, flore hexapetalaceo; Carex Carol. v. 1. 45. t. 45.)—On the authority of the author's herbarium, though his figure gives no idea of the plant. —Flower-stalk recurved. Petals lanceolate, the size and shape of the calyx-leaves, reflexed. Leaves rhomboid, abruptly pointed, on very short stalks.—In shady rocky situations, from Pennsylvania to Carolina, particularly on the banks of Schuylkill, near Philadelphia, flowering in May. Petals white. Barries purple. This may be called the largest of the genus, as I have often seen it near two feet high, with leaves measuring nine inches in diameter. Pursh. Our garden specimens are but one-third as large. The flower is perfectly reflexed. Petals white, with green ribs. Anthers and styles purple. Germs pale yellow, ovate, with six wings.

7. T. erectum. Upright-flaked Trillium. Linn. Sp. Pl. 484. Wild. n. 2. Ait. n. 2. Pursh n. 7. Curt. Mag. t. 470. (T. rhomboidum; Michaux Boreal.-Amer. v. 1. 215. Redout. Liliac. t. 134. Solanum trilphillum canadense; Carol. Canad. t. 166. t. 167.)—Flower-stalk erect. Flower inclining. Petals elliptical, pointed, spreading, the length of the calyx. Leaves rhomboid, pointed, feltile. —On the mountains, in boggy soil, from Pennsylvania to Carolina, flowering in May. Pursh. The leaves are three or four inches long, and three broad at the obtuse lateral angles. Flower-stalk nearly three inches long, erect, except a little curve at the top, from the drooping of the flower, which is fetid, and larger than any of the foregoing species. Calyx-leaves an inch and quarter long, ovate, pointed, spreading, green. Petals the same length, but broader and more elliptical, dark purplish-brown. Germs and filaments purple. Berry, according to Pursh, almost black. This is certainly T. erectum Linnaeus, though the specimen in his herbarium has no resemblance to it, having half a dozen flower-stalks, and not being an original specimen, nor of any authority. The specific name is not one of the best, there being several species equally erect, but rhomboidum is liable to the same objection. Had we found a better in any work of character, we might have been induced to swerve from our general rule of not changing eставлен names. We do not profess to be bound to keep any others, unless they are good.

8. T. pendulum. White Small-flowered Trillium.—"Wild. Hort. Berolin. t. 35." Ait. n. 3. Pursh n. 9. (T. erectum B; Curt. Mag. t. 1227. Pursh n. 7.)—Flower-stalk erect. Flower inclining. Petals ovate, pointed, spreading, longer than the calyx. Leaves rhomboid, pointed, feltile. —Native of the mountains of Pennsylvania and Carolina. We received a specimen from Dr. Muhlenberg in 1805, the same year in which Mr. Maffon sent plants to Kew. If flowers in April and May, and though nearly allied to the last, must surely be a distinct species. Every part is much smaller; the leaves more rhomboid; flower less strongly feticid than the erectum, with white petals, a reddish green, and yellow anthers and styles. Mr. Pursh seems to have infected this species twice; see his n. 7. and 9. We have not had an opportunity of consulting the Hortus Berolensis, but we rely on Mr. Dryander in Hort. Kew.

9. T. grandiflorum. Large-flowered Trillium. Salis. Parad. t. 1. Pursh n. 10. Ait. n. 4. (T. erythrocarpum; Curt. Mag. t. 855, excluding Michaux's synonym. T. rhomboideum; Michaux Boreal.-Amer. v. 1. 216.)—Flower and its stalk drooping. Petals ovate, their claws convoluting into a tube; limb spreading thrice as broad as the calyx, and much longer. Leaves ovate, somewhat rhomboid, pointed. —On the mountains and rocky banks of rivers, in Virginia and Carolina, flowering in May. We received a specimen in 1797 from the honourable Mrs. Barrington's garden at Mongewell, the root having been sent perhaps a year or two before from North America. Mr. Maffon is said to have sent the same to Kew in 1799. This is a large and handsome species. The petals are snow-white, veiny, two inches long; their bases convoluting into a sort of tube. Anthers yellow. Calyx-leaves ovate-lanceolate, an inch and half long, green.

10. T. obvatum. Ovate Trillium. Pursh n. 8.—"Flower-stalk erect. Petals obovate, bluntish, flat, spreading, scarcely longer or broader than the calyx. Leaves ovate, rhomboid, pointed, perfectly feltile."—Found in Canada, near Montreal. Flowers dark rose-coloured, probably white when first opening. Pursh. This author mentions some specimens in the herbarium of A. B. Lambert, Esq. agreeing in every respect herewith, which are the T. camacharum of Pallas. This perhaps is what Dr. Sims speaks of, under a similar name, in Curt. Mag. t. 855. We have not examined either.

TRILLIUM, in Gardening, furnishes plants of the low, tuberous-rooted, flowered, perennial kind, among which the species mostly cultivated are, the drooping trillium (T. cernuum); the upright trillium (T. erectum); and the feathery-flowered trillium (T. feifstream). Method of Culture.—These plants may be increased by seeds, which should be sown on a shady border as soon as they become ripe in the autumn; when they appear in the spring, the plants should be kept clean from weeds, and in the
the autumn following be planted out where they are to remain and flower. They succeed best in light soils, where the situation is rather shaded.

They all afford variety in such places.

TRILLO, in Geography, a village of Spain, situated on a small river near its union with the Tagus, and once famous for its curious water-mills, for sawing of timber brought down by the stream, but no longer existing. It is now celebrated for its medicinal waters, efficacious in cutaneous complaints, both externally and internally applied. The baths are up the river, on the opposite side of the Tagus, about the distance of a mile. They are divided into “Los cuatro Banos,” called the king’s bath, divided into four separate baths, all equally commodious and handsonal, with their proper appurtenances. The countef’s bath, so named after the lady of the count de Cifuentes, who is lord of the place, is close to the river, but judiciously built and remarkably solid, to resist every impulse of the stream. According to the analysis of Dr. Ortega, these waters participate of five substances, two volatile, and three fixed: viz. a phlogistic vapour, extremely anodyne, penetrating, and friendly to the nervous system; of a moderate quantity of gas, calcareous earth, common salt, felenitic salt; and that to sixteen ounces of water, one may calculate twenty-five grains and a half of fixed principle. Dr. Ortega observes, that the lightness of this water may enter into competition with that of distilled water, the purest we know of: therefore its effects may be more easily accounted for: that the heat of the water does not equal that of the blood, in a person in good health, and comes near to that tepid degree prescribed by the physicians in artificial baths.

TRILLO, Ital. a shake, in Music. Tofi has devoted his third chapter (in Galliard’s Translation, p. 41.) to the importance, use, and acquisition of a shake. He advises the vocal student, with the assistance of the master, to strive at attaining one that is “equal, distinctly marked, easy, and moderately quick, which are most beautiful qualifications.” The student will find the shake on the femitone or half-note much easier to acquire than that on the whole tone; which it will be necessary to practice first, and most frequently, as it includes the other. Tofi describes seven different kinds of shake, but none are worth the study but those on the tone and half-tone, which must at first be practiced slow, and its rapidity increased by minute degrees. The beat, or trillo mordente, differs little from the shake; in fact it is the shake reversed, ending upon the upper of two notes, instead of the lower. This grace was much used by singers in the former part of the last century, particularly in recitatives, and after the appoggiation from the note below. Mingotti was the last great singer whom we remember to have frequently used the trillo mordente, or beat. Mancini, however, gave a chapter to it in 1774. But he was of the Bernacchi school, which would now be called anticca.

TRILOBOUS LEAF, among Botanists. See Leaf.

TRILOCULAR CAPSULE. See Capsule.

TRILOKAN, in Mythology, a name of the Hindoo deity Siva. The name means with three eyes, that god being in some of his forms, and often in pictures and statues, so represented. Siva corresponds in many points with the many-named and multifortem Jupiter of the Greeks. We are informed by Pausianias, that Triophthalmus was an epithet of Zeus, and that a statue of him with three eyes was found so early as the Trojan war. From these circumstances, combined with many others, sir W. Jones was led to conclude that the identity of Jove and Siva, falls little short of being demonstrated. See Siva.

TRILOPUS, in Botany, a name given by Mitchell to the Linnaean genus Hamamelis. See that article.

TRIM, in Carpentry, is to fit one piece into another.

TRIM, in Geography, the thire-town of the county of Meath, Ireland, situated on the river Bayne. Though the affize-town, it is a place of no importance, but it was formerly walled and defended by a strong castle, and it has some ruins of religious foundations. Before the Union, it was re-presented in parliament. It is 225 miles N.W. by W. from Dublin.

TRIMACRUS, or Trimacer, in the Ancient Proseody, a foot in verse, consisting of three long syllables.

TRIMALORE, in Geography, a town of Hindooftan, in the Carnatic; 15 miles N. of Tanjore.

TRIMANETORE, a town of Hindooftan, in the Carnatic; 15 miles E. of Warriore.

TRIMAPORE, a town of Hindooftan, in Marawar; 9 miles N. of Trimian.

TRIMARKISIA, in the Mange and War, a body of horse among the ancient Gauls, so called because each soldier had three horses attending him, so that when one was either killed in battle, or overcome by fatigue, he might immediately mount another. The Tartars of the Krim retain the practice; for they never undertake an excursion, without allowing three horses to one rider; and many ancient nations, beside the Gauls, observed the same method.

TRIMBERG, or Trimperg, in Geography, a town of the duchy of Wurzburg; 20 miles E. of Schweinfurt.

TRIMBUCK, a town of Hindooftan, in Bagala; 18 miles W.N.W. of Nafluck.

TRIMELES, in the Ancient Greek Music, a name or air for flutes.

TRIMELWADY, in Geography, a town of Hindooftan, in the Carnatic; 15 miles N.N.W. of Tanjore.

TRIMERES, in the Ancient Greek Music, a name which was executed in three different modes successively: the Phrygian, the Dorian, and the Lydian. Some ascribe the invention of this compound name to Saccadas the Argian, and others to Clonas of Thegra.

TRIMILCHI, a name by which the English Saxons called the month of May; because they always milked their cattle three times a day in that month.
TRIMITHUS, in Ancient Geography, a town in the eastern part of Cyprus, at some distance from the coasts, N. of Encolla, and E. of the promontory Pedalium.

TRIMMANIUM, or Trimamion, a town of Lower Media, on the Danube; marked in Anton. Itin. on the route from Vinimacium to Nicomedia, between Scaldania and Antaparthis.

TRIMMERS, in Architecture, pieces of timber framed at right angles to the joints, against the ways for chimneys, and well-holes for flars.

TRIMODIA, among the Romans, a bag like an inverted cone, in which fowls carried their feed. It was suspended from their neck, and was so called from its containing three buhels.

TRIMONEER, a corruption of timoner.

TRIMONTIUM, or Tramontium, in Ancient Geography, a town of Albion, belonging to the Selgovae, according to Ptolemy; probably situated where Annan now stands.—Also, one of the names of Philippopolis in Thrace. Ptol.

TRIMPEND, in Geography, a town of Prussia, in Bartenland; 12 miles S. of Inflenburg.

TRIMURTI, in the theological disquisitions of the Hindus, is a word of mythical and varied import. Its most obvious meaning in the Sanscrit tongue is three forms; but as some facts of Eastern theologians prefers to recognize the unity of the deity, the term is used singularly, and is equivalent to triform. In the Trimurti, the Hindus fancy a union or reunion of the three great powers or attributes of the godhead, personified in Brahma, Vishnu, and Siva; or creation, preservation, and destruction. Many other triune conjuctions are found typified by this mysterious affemblage, of which some notice is taken under our articles Om, Siva, and Trisula.

The Trimurti, or divine triad, is represented to the sense under the form of three heads joined. The well-known monstros sculpture in the Elephanta cavern temple is of this subject. Of this triune bust, Niebuhr, Maurice, and others have given representations. (See Elephanta and Mahakala.) One very like it was dug out of the ruins of an ancient temple on the island of Bombay, by the author of the Hindoo Pautheon, and an engraving is given of it in plate 81. of that work. A second Trimurti was found at the same time, but instead of being merely three heads, they are furnished with a body. This unusual form is also engraved for the work just mentioned; and the granite originals of both plates are deposited by the author in the museum at the East India House. The miniature bust of the gigantic sculpture in the Elephant cave is so large as to weigh several tons. The Hindoos have other modes of representing the Trimurti; three heads and bodies on one leg, and other similar whimiscalities, not unlike the crude delineations of the early Trinitarians of the West.

The Hindoos are very prone to combinations of three in one, and fancy they see something very myblendous in such typifications. As well as that just noticed of the powers or attributes of the deity, they combine three letters in a monogram, and have such a reverence for it, that the found which its articulation would convey is never uttered, or uttered most reverentially. These characters are equivalent to our A, U, M, and the found would be like Om.

The sun is a Trimurti, his properties of creative heat, preserving light, and destructive energy in an igneous form, comprehending the grand attributes of the deity, personified in Brahma, Vishnu, and Siva.

The Hindoos have a female Trimurti, composed of courge of the comforts or Sakti, or energies of the great powers. Thee are Sarasvuti, Lashmi, and Parvati; which fee.

Comparing the Hindoos with three of the gods of Greece, Cronus, Jupiter, and Mars, they are those nearest in character and attributes to the Eastern polytheistic trinity. But the Greeks, largely as they seem to have borrowed from the mythology of the Hindoos, do not appear to have popularly adopted their male Trimurti. The female triad may be recognizable in the Parac of the Weft, as noticed under Sakti. The three goddesses give each a name to a sacred river, and a supposed junction of these waters is a fruitful subject to the Hindoos enthusiast or poet. See Trivint and Saraswati.

Several other articles beginning with the Sanscrit word tri, contain something illustrative of the propencty of the Hindoos to triune combinations.

TRINACIA, or Trinacia, in Ancient Geography, a rich and powerful town of Sicily, and considered as the chief town of the island. Some writers have called it Tiraccia.

TRINCA, in Geography, a town of South America, in the province of Tucuman; 66 miles N. of St. Miguel de Tucman.

TRINCATITY, one of the Nicobar islands. N. lat. 8° 6'. E. long. 94° 5'.

TRINCAVELLI, Vettor, in Biography, an eminent physician, was born at Venice about 1491. He studied at Bologna and Padua; and having graduated at the latter university, he settled at Venice, where he became professor of philosophy, and acquired distinction in the practice of medicine. In 1551 he was promoted to the chair of medical professor at Padua, with a very considerable stipend. He died at Venice in 1563, and was honoured with a public funeral. He was a good Greek scholar, and was the first professor at Padua who commented on the works of Hippocrates in the originals. He also translated many of Galen's treatises; and edited in the original Greek the works of Themistius, of Johannes Grammaticus, the Manual of Epictetus with Arrian's Commentary, Arrian's Alexander's Expedition, Stobius, Hefiod, and other Greek writers. A collection of his works has been printed in 2 vols. fol. Haller. Gen. Biog.

TRINCOLI, in Geography, a town of the island of Ceylon, near the E. coast; 84 miles E.S.E. of Candy. N. lat. 7° 10'. E. long. 82° 6'.

TRINCOMALEE, or Trincomale, a town and harbour of Ceylon, lying in N. lat. 8° 30'. E. long. 81° 24'. The town runs in a N.E. direction along one branch of the bay. The country around it is mountainous and woody; the soil uncultivated and barren; and the whole appearance wild. The woods, which are very thick, contain abundance of wild beasts of various decriptions; particularly wild hogs, buffaloes, and elephants. The latter often come down to the lakes in the neighbourhood of the fort to drink and bathe; and have been frequently shot within a mile of the town. Trincomale, from its situation and constriction, is naturally strong. It occupies more ground than Columbo, but contains a much smaller number of houses, and those inferior in size and appearance to any that are met with in several towns on the S.W. coast. The circumference of Trincomalee, within the walls, is about three miles; within this space is also included a hill, or rising point, immediately over the sea, and covered with a great quantity of thick jungle, in which wild deer and other game find shelter. This rising ground is very little inhabited, N

N
most of the houses being close to the landing place, which lies in the lowest part. Even the lower parts of the fort were much incumbered with wood till within these few years. The fort is strong, and commands the principal bays, and particularly the entrance into the grand harbour, or inner bay, which affords in all seasons and in every variety of weather a secure shelter to ships of all descriptions, being land-locked on all sides, and sufficiently deep and capacious to receive the largest vessel, or any number of vessels. The whole navy of England might find accommodation in this harbour. Its situation is such, that in either monsoon, ships can arrive at or depart from it, and make their passage good from or to any part of the eastern world, and whole fleets may remain within it, at every season of the year, in perfect security. This harbour is overlooked by fort Ostenburg, a strong fort standing on a cliff, which projects into the sea; it was originally built by the Portuguese out of the ruins of some celebrated pagodas which once stood here. This fort cannot be attacked by sea, unless the fort of Trincomalee be first taken, and the entrance of the harbour forced. In the bay the shores are so bold, and the water so deep close up to them, that it is almost possible to leap from the rocks into the vessels that moor alongside of them. At the extremity of the rock, on which the fort stands, a strong battery is erected, where the flag-staff of the fort is placed.

This harbour, from its nature and situation, is that which flanks Ceylon one of our most valuable acquisitions in the East Indies. As soon as the violent monsoons commence, every vessel which is caught by them in any other part of the bay of Bengal is obliged immediately to put to sea, to prevent inevitable destruction. At these seasons Trincomalee and Bombay alone, of all the ports on the different coasts of the peninsula of India, are capable of affording a safe retreat. The inextricable advantages to be derived from such a harbour are increased by its proximity and easy access to our settlements in the bay of Bengal. A vessel from Madras may arrive here in two days, and can at any time enter the harbour. These circumstances point out Trincomalee as an object of particular attention to our government, and of far more consequence to retain than the whole of the rest of the island. It will, however, require great encouragement and many improvements to render the town populous or anywise equal to Colombo. For the country around is not by any means so fertile as to tempt settlers to reside there; nor are the natural productions calculated to attract commerce. The climate has also been looked upon as the hottest and most unhealthy of the whole island. But the woods and marshes which rendered the climate infalubrious have been already in great measure cleared and drained, and the beneficial effects of these improvements were soon experienced. It is to be hoped that remedies may in the same manner be applied to the other defects under which Trincomalee at present labours: its trade is nothing, as there are no valuable natural productions to nourish it; but, from its situation, it is capable of becoming the richest emporium of the East. The want of commerce, and the uncultivated state of the surrounding country, are defects which flow mutually from each other; and the removal of one would soon, in a great measure, do away the other.

The Malavagons (which fee) falls into the magnificent bay of Trincomalee. (Percival's Ceylon.) This harbour, says Barrow (Travels in Southern Africa, vol. ii.), is to a maritime province a jewel of inestimable value; it holds the bay of Bengal at its mercy, and affords every facility of overawing and controlling the navigation of the straits of Sunda and Malacca. Our Asiatic poiffessions, commerce and marine, would consequently lie open to the depredations of the masters of Ceylon. Trincomalee was taken by the British troops in 1795; 70 miles N.E. of Candy.

TRINDELEN, a rock in the Scagglarac, at about equal distances between the coast of North Jutland and the coast of Norway; 7 miles N.N.E. from the island of Lesoe. N. lat. 67° 27'. E. long. 11° 1'.

TRINE, Dimension, or threefold dimension, includes length, breadth, and thickness.

The trine dimension is peculiar to bodies or solids.

TRINE, in Astrology, is the aspect or situation of one star with regard to another, when they are distant 120 degrees.

It is also called trigon, and is usually signified by the character Δ.

TRINE, in Rural Economy, a term applied to the quantities of same forts of articles, as the bullies and spokes of wheels, which of the former is thirteen, and of the latter twenty-five.

TRINETRA, in Mythology, a name of the Hindoo god Siva. It means with three eyes, similar to Trishala; which fee.

TRING, in Geography, a small market-town in the hundred of Dacorum, and county of Hertford, England; is situated within a short distance of the Icknield way, 30 miles W. by N. from the county-town, and 31 N.W. by W. from London. The manor was granted by William the Conqueror to Robert, earl of Ewe, but it soon afterwards reverted to the crown; and in the year 1148 was given by king Stephen, with all its appurtenances, to the abbey of Feverham, which he had then founded. His grant was confirmed to the monks by succeeding sovereigns; and Edward II. gave them a charter for a weekly market, and two annual fairs to be held at Tring. After the dissolution, Henry VIII. granted the manor to the archbishop of Canterbury; it is now the property of Sir Drummond Smith, bart. The parish church of Tring is a spacious, well-proportioned edifice, and consists of a nave, side aisles, and chancel, with a massive tower at the west end: the walls are supported by strong buttresses, and the whole is embattled. The nave is separated from the aisles by fix pointed arches, raking from high clustered columns. The roof is of timber frame-work, with strong beams going across: the supports on each side are terminated by carved figures. Most of the windows have obtuse pointed arches, and are divided into three compartments by mullions. In the interior are various monuments. Tring contains four meeting-houses for Dissenters of different denominations. A Sunday school for about eighty boys and girls has been established by subscription. The market-house is a mean edifice on wooden pillars, having a pillory and a cage beneath. The market is held on Fridays; principally for the sale of corn, meat, and straw-plait; the manufacture of the latter constitutes the employment of most of the females in this part of the country. Five fairs are now held annually. The population of Tring, as ascertained under the act of the year 1811, was 1847, occupying 352 houses.

Tring park, the seat of Sir Drummond Smith, bart. consists of between three and four hundred acres, ranging on the S.E. side of the town. The mansion is large and convenient, and the principal apartments are spacious and neatly fitted up. The hall is ornamented with Corinthian pillars. On the floor above the hall, and running across the house, is a gallery or ball-room, with a circular dome in the centre. This house was erected about the time of Charles II. by Henry Guy, efg.

At a short distance N.E. from Tring, is Tring Grove, the

TRINGA, Sand-piper, in Ornithology, the name of a distinct genus of birds, of the order of the Grallae; the distinguishing characters of which are, that the beak is roundish, and of the length of the head; the nostrils linear; and that the feet have each four toes, the outermost being generally connected at bottom by a small membrane. The species are numerous, and as follow.

Pugnax. With red bill and legs; three lateral tail-feathers unfotted, and face granulated with fleshly papilae. See RUFFE.

Vanellus. With red legs, dependent crest, and black breast. This is the lapwing or baardar plover of Ray, Willughby, Pennant, &c. See LAPIWING.

Gambara. With red bill and feet; body variegated with yellow and cinereous; beneath white. This is the totanus ruber of Brion, the totanus alter of Willughby and Ray, and gambet of Pennant and Latham.

Icteretes. With red legs; black body, varied with white and ferruginous; and white breast and abdomen. This is the arenaria of Brion, the Hebridal sand-piper of Pennant, the turnstone or sea-dotted of Ray, Willughby, Latham, &c. See TURNSTONE.

The Maricella, or tringa with red feet, blackish tail-feathers, white at the base, grey body, and black breast; or arenaria cinerea of Brion, is a variety.

Strya. With bafe of bill and legs red; tail-feathers white with bands of brown, and many white tail-feathers. This is the totanus frattius of Brion, and frattius sand-piper of Pennant, &c. The totanus navius of Brion is a variety.

Bononiiens. With ochraceous legs; long head and neck; body above black, and beneath white; throat and breast marked with ferruginous spots. The greater lapwing of Latham.

Macularis. With bafe of bill and legs incarnated; body spotted; eye-brows and double band of the wings white. This is the turdus aquaticus of Brion, the spotted tringa of Edwards, and the spotted sand-piper of Pennant.

Lobata. With subulate bill, bent at the apex; pinnated legs, and white undulated breast: the grey croo-footed tringa of Edwards, and grey phalarope of Pennant and Latham. Of this there is a variety, white beneath, black above, with yellowish longitudinal streaks; the band of the wings white; and legs lobated.

Hyperborea. With subulate bill, bent at the apex; pinnated legs; cinereous breast, and fides of the neck ferruginous; the cock croo-footed tringa of Edwards, the small cloven-footed gull of Willughby, and red phalarope of Pennant and Latham.

Erythrops. With red legs, front, rump and tail red and white; body above and wings cinereous-brown; the abdomen ferruginous: the red-legged sand-piper of Latham.

Alpina. Teffaceous-brown, with blackish breast; tail-feathers cinereous, white; legs brownish.

Helvetica. With black bill and legs; beneath black; white vent; tail-feathers white with black bands; the Swifi sand-piper of Pennant.

Ochropus. With the apex of the bill pointed; legs greenish; back brown and green; abdomen and outermost tail-feathers white: the cinclus tertius of Aldbr., Ray, and Will., the opcrorus medius of Gefner, and green sand-piper of Pennant and Latham. Of this there is a variety, viz. Littorea, with smooth bill, cinereous legs, and brown tail-feathers: the thore sand-piper of Pennant; and also another variety, with the back and wings cinereous, with obfolute whitish spots.

Hyphaleuca. With smooth bill; livid legs; body cinereous with black streaks; beneath white: the common sand-piper of Ray, Willughby, and Pennant.

Canus. With smooth bill; cinereous legs; first tail-feathers ferrated; and the outer white unpotted. This is the knot of Pennant, &c. See Knot.

Arca. With black bill and legs; grey body; under and whole face white; collars grey.

Facista. With bill, vertex, hind part of the head, spot near the eyes, and abdomen, black; front and rounded tail white; back cinereous; seven first tail-feathers white.

Cinclus. With bill and legs black; collars white; tail and rump grey and brown. This is the leaff skipe of Ray and Sloane, the wagtail of Brown, the fanderling of Albinus, and the purer of Pennant. The cinclus with brown legs is a variety.

Calidris. With bill and legs blackish; body beneath olivaceous; and rump variegated: the dusky sand-piper of Latham.

Pusilla. With brown bill and legs; body beneath reddish; outer tail-feathers with a white shaft, and variegated rump: the little sand-piper of Pennant; found in St. Domingo, north of Europe, and rarely in England.

Glareola. With smooth bill; greenish legs; body punctated brown and white; breast whitish: the wood sand-piper of Pennant and Latham; found in Sweden.

Reficollis. With black legs; head above and neck frattated with ferruginous and black; and ferruginous throat: the red-necked purue of Latham.

Squatula. With black bill; greenish legs; grey body, beneath whitish: the grey plover of Ray, &c. and grey sand-piper of Pennant and Latham. Of this there is a variety, with black bill and legs; body brown, variegated with white; tail-feathers white with brown bands.

Islandica. With brown bill and legs; body beneath ferruginous; secondary tail-feather with a white margin: the red sand-piper of Pennant.

Cinerea. Cinereous; beneath white; legs obscurcly green; head with black spots; neck obscurcly virgatcd: the ash-coloured sand-piper of Pennant and Latham.

Atra. With black head and neck; back and wings brownish, mixed with black; breast and abdomen cinereous; rump cinereous, undulated with white and black.

Novoboreascens. Obscurcly, beneath white; breast spotted with brown; tail cinereous: New York sand-piper of Pennant and Latham.

Vircata. Obscurcly, beneath white; with yellowish legs; head and neck obscurcly frattated lengthwise with white: frattated sand-piper of Latham.

Borealis. With brown bill and legs; body above cinereous, beneath white; tail and tail-feathers obscurcly.

Novo-terre. Above black, beneath ash-white; bill, purpous wings, tail-feathers, and tail, black; with cinereous legs: Newfoundland sand-piper of Latham.

Variegata. Above varied with brown, black, and red; front and throat pale; neck and breast frattated with whitish and black longitudinally; abdomen white; bill and legs obscurcly: variegated sand-piper of Latham.

Glacialis. With pinnated yellowish legs; apex of black bill dilated; cheeks and throat teffaceous; body above obscurcly, beneath white: plain phalarope of Pennant.

Fusca. With bill, vertex, and legs pinnated and black; body above brownish and cinereous, beneath white; throat cine-
cinereous, tinctured with red: the coot-footed tringa of Edwards, and brown phalarope of Pennant and Latham.

**Cancellatus.** With upper feathers brown, white at the margin; lower white lineated transversely obscurely; pinnated legs obscure.

**Eucoptera.** Black, beneath red, with cinereous bill, green legs, and yellow vent: the white-winged sand-piper of Latham.

**Maritima.** Above varied with grey and white; beneath white, with yellow legs; middle of the back violet; throat and tail obscure: the sedge sand-piper of Pennant and Latham.

**Undata.** Obfuscure, undulated with yellow and white; the rump, the tip of the secondary tail-feathers, and wing-coverts, white; tail cinereous, white at the apex: the waved sand-piper of Pennant and Latham.

**Uniformis.** Wholly dilutely cinereous, with a short black bill: uniform sand-piper of Pennant and Latham.

**Australis.** Above cinereous, spotted brown; beneath reddish; abdomen and rump whitish; tail and tail-feathers obscure; bill and legs black: southern sand-piper of Latham.

**Nevia.** With obscure bill; legs greenish; body above cinereous, spotted with red and black; beneath reddish and white, spotted with obscure or bay: the freckled sand-piper of Pennant and Latham.

**Girnea.** With black bill and legs; body above grey, beneath white; primary tail-feathers brown; tail grey and white at the margin; a band obscurely grey parallel to the margin: the freckled sand-piper of Latham.

**Keptusica.** With cinereous body; black vertex; abdomen blackish, terminating reddish.

**Tringan.** In Geography. See **Trangano.**

**Tringenstein.** A town of Germany, in the principality of Naflau Dillenburg; 6 miles E. of Dillenburg.

**Tringle.** In Architecture, a name common to several little square members, or ornaments; as roglets, liflets, and platbands.

The word is French, where it signifies the fame.

**Tringle** is more particularly used for a little member fixed exactly over every triglyph, under the platband of the architrave; from whence hang down the gutter, or pendant drops.

**Trinidad.** In Geography, a town of South America, in New Granada; 20 miles N.W. of Santa Fé.

**Trinidad,** an island near the coast of South America, about thirty leagues long, and from two to ten broad. This island was discovered by Columbus in his third voyage, who landed here in 1498, and was named by him after the Holy Trinity: beause, says Herrera, having been in great danger in a violent storm, he made a vow to give that name to the first land he should find: soon after which a sailor, in the main-top, faw three points of land, by which the name was in every respect suitable to his vow. The original inhabitants were a colony of Arosovuuki; which fce. The climate is faid by fome to be nattohole; the ifland being very often covered with thick fogs. The abbé Raynal fays that it is excellent, being free from hurricanes. Heavy rains fall from the middle of May to the end of October. It is subject to flight earthquakes, and in the interior are four groups of mountains. The quality of its soil is variously reported; however, Dr Walter Raleigh, who was there fome time in the year 1593, and examined the ifland, gives an account, that the northern part of it is high land; but that its soil is good, proper for planting of fugar-canef, tobacco, &c. The southern coast is well adapted to the culture of coffee; and on the weft is a large harbour, secure in all leasons. Here are several forts of animals, plenty of wild hogs, fih, fowl, and fruit. It also produces maize, cafafva, and other roots, and in general all that is commonly found in America. The Spaniards owed to fit Walter, that they found gold in the rivers of this ifland, but nothing in comparison of what the main land produces. The natives called this ifland "Cairi;" but they themselves had diver names, according to the different parts of the ifland where they dwelt. In 1797, it was taken by the Britifh troops; and by the peace of Aminen, the ifland was ceded to Great Britain. The island of Tobago is separated from Trinidad by a channel called "Trinidad Channel." This ifland, situated at the easter extremity of Terra Firma, from which it is only four leagues distant, is the natural magazine and refort where the contraband traders of Cumana, Barea, Margaretta, and Guiana, make their purchases. The poftion of the ifland is singularly favourable to this commerce. The Spanish coafts, extenfive, solitary, deficiency, and to leeward, offer both to the Englifh and Spaniards the greatest facility for prosecuting it. The gulf of Paria, which washes the western part of Trinidad, receives the waters of the river Guarpiche, which penetrates the province of Cumana. By this river animals for labour and for the fhamble are brought from Terra Firma to Trinidad; and through the fame channel all the contraband articles consumed in this province can ac fend with perfect convenience, or may be landed at several points without the leaft danger. In general, the cargoes which are defined for Barcelona proceed up this river: they are thence distributed to Caraeus and other cities. The mouths of the Oranoko, which eofs the gulf of Paria from fiouth and north, and which are compelled by Trinidad to discharge into the sea by the florm mouths, open to this ifland the commerce of Guiana, whither the florys goes by the river Apurr to Barquifimeto, Truxillo, Varinas, Merida, &c. Dr. Anforfon has given a particular account of a remarkable phefhomenon in this ifland, which is a bituminous lake, or rather plain, denominated Tar-lake, and by the French La Brea, from its refemblance to ship-pitch, and from its anfwering a fimilar intention. It lies on the leeward ifde of the ifland, on a point of land extending into the fea about two miles, and opposite to the high mountains of Paria on the north ifde of the gulf. The headland, or cape, is about 30 feet above the level of the fea, and is the greates elevation on this ifde of the ifland. From the fea it appears a mass of black vitrified rocks; but on clofer examination, it is found to be a composition of bituminous fcorif, vitrified fand, and earth, cemented together: in some parts, beds of cinders only are found. In approaching this cape, there is a frong fulphurous smell, fometimes disagreeable. This smell is prevalent in many parts of the ground to the distance of eight or ten miles from it. The point of land is about two miles, and falls with a decifivity to the fea, the bituminous plain being on the highfeft part of it, and separated from the fea by a margin of wood which surrounds it. It appears at firft like a lake of water; and in hot and dry weather its surface, about an inch deep, is liquid, whence it obtained the appellation of lake. Its form is circular, about three miles in circumference. Its more common conftance and appearance are those of pit-coal, the colour being rather greyer. No appearance of sulphur is difcernible, though, in passing over it, a frong fulphurous smell was experienced. Dr. Anforfon apprehended that this bituminous fulbfance is the bitumen aphalame of Limeneus. By a gentle heat it was rendered ductile; and mixed with greafe or common pitch, it is much used for the bottoms of ifhips; and he conceives it to be a prefervative against the infect called the borer, to deluctive
destrucrive to ships in that part of the world. Every part of the country, he says, to the distance of 30 miles round, has the appearance of being formed by convulsions of nature from subterraneous fires; and the whole island, he thinks, is formed of an argillaceous earth, either in its primitive state, or under its different metamorphoses. This argillaceous earth is formed, as he conceives, from the sediment of the ocean, and its formation is easily accounted for from the situation of Trinidad. The great influx of currents into the gulf of Paria, from the coasts of Brazil and Andalusia, must bring down a vast quantity of light earthy particles from the mouths of the numerous large rivers which traverse those parts of the continent; but the currents being repelled by the sides of adjacent mountains, eddies and smooth water will be produced when they meet and oppose one another; and, therefore, the earthy particles would subside, and form banks of mud, and by the accession of fresh accumulations form dry land; and thus such a tract of country as Trinidad must be formed. The cauces fill operate, for the island is daily increasing on the leeward side, as is visible in the mud-beds that extend a great way into the gulf, and are there continually augmented. But from the great influx from the ocean at the south end of the island, and its egress to the Atlantic again through the Bocas, a channel must ever exist between the continent and Trinidad. N. lat. 9° 48' to 10° 42'. W. long. 60° 6' to 61° 30'.

TRINIDAD, La, a town of South America, in the province of Moxes; 200 miles N.E. of La Plata. S. lat. 14° 46'. W. long. 65° 50'.

TRINIDAD, a sea-port town of the island of Cuba, situated in a bay on the south coast of the Havana. N. lat. 51° 56'. W. long. 80° 18'.

TRINIDAD, La, or Sanfpective, a sea-port town of Mexico, in the province of Guatemala; 80 miles E.S.E. of Guatemala. N. lat. 14° 3'. W. long. 91° 9'.

TRINIDAD, La, a town of Mexico, in the province of Veragua, on a river which runs into the gulf of Mexico; 18 miles S.E. of La Conception.

TRINIDAD, La, a town of Mexico, in the province of Nicaragua, on the east coast of Nicaragua lake; 30 miles N.W. of St. Carlos.

TRINIDAD, a town of South America, in the province of Paraguay; 170 miles S.E. of Asunciation.

TRINIDAD, a small island in the South Atlantic ocean, and one of those called "Martin Vas's Islands;" taken possession of by the Portugueze about the year 1783, who keep a small garrison here, but, according to M. Perouze, ill furnisched. This island presents nothing to the eye but a rock, almost entirely ferifer. A little vudure, and a few shrubs, are alone to be seen in the narrow pasies between the mountains. It is in one of these vallyes situated in the south-east quarter of the island, and about three hundred toises wide, that the Portugueze have formed their establishment. Nature certainly did not intend this rock to be inhabited; neither men nor animals being able to find a subsistence upon it; but the Portugueze were afraid lest some European nation should avail themselves of the vicinity, and carry on a contraband trade with the Brasis. S. lat. 26° 31'. W. long. of the south point 26° 37'.

TRINIDAD Bays, a small open bay or cove on the west coast of North America. N. lat. 41° 3'. E. long. 236° 6'.

TRINITARIANS, a term used very variously, and arbitrarily: frequently it stands as a common name for all persons who have sentiments on the mystery of the Trinity, different from those of the Catholic church.

Sometimes it is more immediately restrained to some one or other particular class of such persons.

It is now applied to the orthodox themselves, in contradistinction to the others who are then called Antitrinitarians, or Unitarians, who deny or impugn the doctrine of the Trinity.

Thus the Socinians and others called the Athanarians, Trinitarians.

The Trinitarians of the present age, and especially those who, in England, have written on the subject of the Trinity, are far from being agreed in their opinions, and, therefore, ought to be called very differently from one another.

A late writer (Priestley's Hist. Corrupt. of Chrillity, vol. i. p. 147.) thinks that they are all reducible to two classes, viz. that of those who believe that there is no proper divinity in Christ, besides that of the Father; and the class of Trinitarians, who maintain that there are three equal and distinct Gods. Dr. Waterland and the rest of the Athanarians affirm three proper distinct persons, equally equal to and independent upon each other, yet making up one and the same being. Mr. Howe (Works, vol. ii. p. 560—568.) seems to suppose that there are three distinct eternal spirits, or distinct intelligent hypostases; each having its own distinct, singular, intelligent nature, united in such an inexplicable manner, as that upon account of their perfect harmony, consent, and affection, to which he adds their mutual self-consciousness, they may be called the one God, as properly as the different corporeal, sentient, and intellectual natures united may be called one man. Bishop Pearson (on the Creed, p. 134, &c. 322, &c.), bishop Bull (Serm. vol. iv. p. 829.), and Dr. Owen (on the Heb. i. 3. p. 55, &c.), are of opinion, that though God the Father is the fountain of the Deity, the whole divine nature is communicated from the Father to the Son, and from both to the Spirit; yet so as that the Father and Son are not separate, or separable from the divinity, but do equally exist in it, and are most intimately united to it. Dr. Thomas Burnet (Script. Doctr. p. 173.) maintains one self-existent and two dependent beings; but affirms, that the two latter are so united to and inhabited by the former, that by virtue of that union divine perfections may be ascribed and divine worship paid to them. In this opinion Dr. Doddridge is said to have concurred. Dr. Wallis (Lett. on the Trin.) thought, that the distinction between the three persons was only modal; which seems, says Dr. Doddridge, to have been the opinion of archbishop Tillotson. (Tillotson. Serm. vol. i. p. 492—494.) Dr. Watts (Diff. N. 7) maintained one supreme God dwelling in the human nature of Christ, which he supposeth to have exalted the first of all creatures; and speaks of the divine Logos, as the wisdom of God, and the Holy Spirit, as the divine power, or the influence and effect of it; which, he says, is a Scriptural person, i.e. spoken of figuratively in scripture under personal characters. Doddridge's Lectures, p. 402, &c.

TRINITARIANS also denote an order of religious, instituted in honour of the Trinity, for the redeeming of Christian captives from the infidels; vulgarly called Mathurins, and brothers of the redemption.

They are clothed in white, and hear on the Romans a crost, partly red and partly blue; by which three colours, white, red, and blue, is suppos'd to be represented the mystery of the Trinity; but the habit of this order is different in different provinces.

The Trinitarians made it their business to go and ransom Christians held in slavery in the republics of Algiers, Tunis, and Tripoli, and the rates of Morocco. They have a rule peculiar to themselves; though several historians rank them among the obscurers of the rule of St. Auguin.
The order had its rise in 1198, under the pontificate of Innocent III. The founders were John de Matha and Felix de Valois; the first of Faucon in Provence; the second, not of the royal family of Valois, as some have imagined, but thus called, in all probability, as being a native of the country Valois.

Gauthier of Chatillon was the first who gave them a place in his lands to build a convent; and afterwards became the chief of the whole order: Honorius III. confirmed their rule; and Urban IV. appointed the bishop of Paris and others to reform them: they did it; and the reform was approved, in 1267, by Clement IV.

This order possessed about 250 convents, divided into thirteen provinces; of which six are in France, three in Spain, one in Italy, and one in Portugal. And formerly there was one in England, another in Scotland, and a third in Ireland.

Broughton, and some other writers, make a distinction between the order of the redemption of captives, and the fraternity of the Holy Trinity.

TRINITARIANS, Barefooted, are a reform of this order, made in Spain, in a general chapter held in 1594, where it was resolved, that each province should establish two or three houses, where the primitive rule should be observed, and where the religious should live up to a greater austerity, use coarser clothes, &c. and yet should have the liberty of returning to their ancient convent, when they thought fit.

Don Alvares Bafan, intending to found a monastery at Valdepeñas, and desiring to have it occupied by barefooted religious, it was agreed to add nudity of feet to the reform, that the Trinitarians might have the benefit of that establishment. The reform afterwards grew into three provinces, and was at length introduced into Poland and Rúflia, and thence into Germany and Italy.

There are also barefooted Trinitarians in France, established by F. Jeron Hallies, who, being sent to Rome to solicit the first reform mentioned above, not content with this, carried it farther, and obtained a permission of pope Gregory, to add a coarser habit and nudity of feet thereto. He began with the convent of St. Dionysius at Rome, and thence of Aix in Provence.

In 1670, there were houses enough of this reform to make a province, and, accordingly, they held their first general chapter the same year.

There are also nuns of the Trinitarian order established in Spain by St. John de Matha himself, who built them a convent in 1201. Those who first took the habit were only oblates, and made no vows; but in 1201, the monastery was filled with real religious, under the direction of the infanta Constançia, daughter of Peter II. king of Aragon, who was the first religious, and the first superior of the order.

There are also barefooted nuns of this order, established at Madrid about the year 1612, by Frances de Romero, daughter of Julian de Romero, a lieutenant-general in the Spanish army.

Lastly, there is a third order of Trinitarians.

TRINITE, in Geography, a town of France, in the department of the Stura; 4 miles S.W. of Bene. Also, a name given to two islands and a rock in the South Atlantic ocean; uninhabited and little known. S. lat. 19° 30'. W. long. 40°.—Allo, a town of France, in the department of the Morbihan; 15 miles E. of Pontivy.

TRINITY, TRINITAS, TRIAS, TRIAD, in Theology, the ineffable mystery of three persons in one God, Father, Son, and Holy Spirit.

It is an article in some systems of theology, that there is one God, an unity in nature and essence, and a Trinity of persons. The term Trinity implies the unity of three, the unity of three divine persons really different, and the identity of an indivisible nature: the Trinity is a ternary of divine persons of the fame essence, nature, and substance.

Perfon is defined an individual, reasonable, or intellectual substance; or an intellectual and incommunicable substance.

The hypostasis, or substance, is what constitutes the person. There are three in the Holy Trinity three persons, Father, Son, and Holy Spirit, which have all things in common, except their relations; whence that axiom in theology comes to have place, in the divine persons there is no distinction, where there is no opposition of relation.

The Father is the first person in the Holy Trinity, by reason the Father alone produces the Word, by the way of understanding; and with the Word produces the Holy Spirit, by way of will.

Here it is to be observed, that the Holy Spirit is not thus called from his spirituality, that being common and essential to all the three persons; but from the passive spiration (as some popish theologians express the manner in which the personaly of the Holy Spirit is derived from the Father and Son), which is peculiar to him alone.

Add, that when one person in the Holy Trinity is called first, another second, and another third, it must not be understood of a priority of time, or of nature, which would imply some dependence; but of a priority of origin and emanation, which confits in this, that one person produces the other, in such manner, as that the person which produces cannot be, or be conceived, without that produced.

Those who maintain the doctrine of the Trinity allege, that the names titles, attributes, works, and worship, are ascribed by the sacred writers to the Father, Son, and Holy Spirit: nevertheless they contend, in different ways, for the proper unity of the divine nature. For the sentiments of some of the chief modern Trinitarians, see TRINITARIANS: and for the sentiments of others, who have rejected what has been usually denominated the orthodox doctrine of the Trinity, see Arians, Macedonians, Noetians, Sabellians, Semi-arians, Socinians, and Unitarians. See also TRINITISM.

It is observed by Dr. Waterland and many other writers, that the term Trinity first occurs in the works of Theophilus, bishop of Antioch, about the year 180. Theophil. ad Autolyi. lib. ii. c. 14. p. 148. 150, ed. Wofilli.

But at this time the words, persons, and substances, were not in use; however, they were introduced on occasion of the disputes with Praxias, Noetus, and Sabellius, either by Clement of Alexandria, or by Tertullian.

For the punishment inflicted by the English law on those who deny the Trinity, see HERESY.

Many of the heathens are said to have had a notion of a Trinity. Stueth. Eugub. de Peren. Philos. lib. i. c. 3. observes, that there is nothing in all theology more deeply grounded, or more generally allowed by them, than the mystery of the Trinity. The Chaldaeans, Phænicians, Greeks, and Romans, both in their writings, and their oracles, acknowledged that the Supreme Being had begot another Being from all eternity, which they sometimes called the Son of God, sometimes the Word, sometimes the Mind, and sometimes the Wisdom of God, and asserted it to be the creator of all things.

Among the sayings of the Magi, the descendants of Zoroaster, this is one, Παντα ἐγουταί οὐάμαν, θαρείους, νους: the Father finished all things, and delivered them to the second Mind.
Mind. The Egyptians called their Trinity, Hemepha, and represented it by a globe, a serpent, and a wing, dispensed into one hieroglyphic symbol. Kircher, Gale, &c. suppose the Egyptians learned their doctrine of the Trinity from Joseph and the Hebrews.

The philosophers, says St. Cyril, owned three hypostases, or persons; they have extended their divinity to three persons, and even sometimes used the word Trias, Trinity: they wanted nothing but to admit the confubstantiality of the three hypostases, to signify the unity of the divine nature, in exclusion of all triality with regard to difference of nature; and not to hold it necessary to conceive any inferiority of hypostases.

We learn from Dr. Cudworth, that, besides the inferior gods, generally received by all the Pagans, (viz. animated stars, demons, and heroes,) the more refined of them, who accounted not the world the supreme deity, acknowledged a Trinity of divine hypostases superior to them all. This doctrine, according to Platonius, is very ancient, and observed to be affected even by Pythagoreans. Some have referred its origin to the Pythagoreans, and others to Orpheus, who adopted this principle, called Phanes, Uranus, and Cronus. Dr. Cudworth apprehends, that Pythagoras and Orpheus derived this doctrine from the theology of the Egyptian Hermes; and, as it is not probable that it should have been discovered by human reason, he concurs with Proclus in affirming, that it was at first a theology of divine tradition, or revelation, imparted first to the Hebrews, and from them communicated to the Egyptians and other nations; among whom it was depraved and adulterated. Cudw. Intell. System, book i. c. 4.

Plato, and some of his followers, speak of a Trinity in such terms, that the primitive fathers have been accused of borrowing the very doctrine from the Platonic school; but M. Mourguès, who has examined the point, affirms, that nothing can be more absurd, than to suppose the Platonic Trinity brought into the church; and to have recourse to the Platonism of the fathers to discredit their authority with regard to this dogma.

Trinity, Friery, or Fraternity of the Holy, is a society instituted at Rome, by St. Philip Neri, in 1548, to take care of pilgrims coming from all parts of the world to that capital, to visit the tombs of St. Peter and St. Paul.

In 1558, pope Paul IV. gave the fraternity the church of St. Benedict, to which they gave the title of the Holy Trinity. Since that time, they have built close by a very ample hospital for pilgrims, and persons on the recovery.

The fraternity has since become very considerable, and most of the nobile of Rome, of either sex, have done it the honour to be members of it.

Trinity, Congregation of the Holy, is a congregation of twelve priests established in the hospital of the fraternity just mentioned, to take care of pilgrims, and persons on the recovery.

Trinity, Order of the Holy. See Trinitarians.

Trinity-Sunday, is the next Sunday after Whit-Sunday, thus called, because on that day was anciently held a festival (as it still continues to be in the Romish church) in honour of the Holy Trinity. The observance of this festival was first enjoined by the sixth canon of the council of Arles, in 1206; and John XXII. who distinguished himself so much by his opinion concerning the beatific vision, is said to have fixed the office for this festival in 1354.

Trinity-Herb, in Botany. See Violet.

Trinity-House, is a kind of college at Deptford, belonging to a society of seafaring persons, founded for the regulation of seamen, and security and convenience of ships and mariners on our coasts.

This society was incorporated by Henry VIII. in 1515, who confirmed to them not only all the ancient rights and privileges of the mariners of England, but also their several pothosion; which, together with various grants of queen Elizabeth and king Charles II. were confirmed by letters patent of the 1st of James II. in 1685; under the name of the master, wardens, and affiliates of the guild or fraternity of the most glorious and undivided Trinity, and of St. Clement, in the parish of Deptford Strand, in the county of Kent.

This corporation is governed by a master, four wardens, eight affiliates, and eighteen elder brethren: the inferior members of the fraternity, denominated younger brethren, and chosen among the masters and mates expert in navigation, are of an unlimited number, and serve for supplying vacancies among the thirty-one elder brethren. The master, &c. of this corporation, are invelled by charter with a power to examine the mathematical children of Christ's Hospital, to examine the masters of his majesty's ships; to appoint pilots for conducting ships in and out of the river Thames; and to amerce such as shall act as masters or pilots without their approbation in a fine of 20/-; to settle the several rates of pilotage, and erect light-houses, and other sea-marks, on the several coasts of the kingdom, for the security of navigation; to prevent aliens from serving on board English ships, without their licence, under penalty of £l. for each offence; to punish seamen for desertion or mutiny in the merchant service: to hear and determine the complaints of officers and seamen in this service, under an appeal to the court of admiralty; and to grant licences to poor seamen (non-freemen) to row on the river Thames.

To this company belongs the ballast-office, for cleaning and deepening the river Thames, by taking from it a sufficient quantity of ballast for the supply of all ships that sail out of the river; in which service sixty barges, of the burden of thirty tons, and two men each, are constantly employed: all ships taking in ballast pay to them 1 2s. 6d. a ton.

This corporation is empowered by charter to purchase lands, &c. to the amount of 500l. per annum, and also to receive charitable benefactions to the like amount. They have also light-houses, to which all ships pay a halfpenny per ton.

Out of the income of this corporation, about three thousand poor seamen, their widows and orphans, are annually relieved, at the expense of about 6000l.

The house in which the brethren of this corporation usually meet for the dispatch of business, is on Tower-Hill. (See London.) They have three hospitals, two at Deptford, and one at Mile-End, which last is designed for decayed sea-officers, masters of vessels, pilots, and their widows.

Trinity Term. See Term.

Trinity, or La Trinié, in Geography, a sea-port town of the island of Martimico: the harbour is formed on the south-east side by the point Caravelle, which is two leagues in length; and on the other side by a very high hill, about 350 or 400 paces in length, which only joins to the main land by an illusory not above 200 feet broad. The east side, opposite to the bottom of this bay, is flapped up by a chain of rocks, which appear level with the water when the ebb tide is spent. The town here is a very thriving place, being the residence of several merchants, as well as of the lieutenant-governor of the Cabes-terre; and much frequented by shipping, especially from Nantes; the cargoes of which are here to meet with a quick sale, the people, who
who are very numerous in the adjacent parts, choosing rather to buy what they want near at hand, than to fend for it from the Baileterre. Besides, during the hurricane season, ships have a safe station in this port; another advantage they have here is, that when they set out for Europe, they are to the windward of all the islands, and save about 300 leagues in their passage, which they would find by the way of St. Domingo, or Porto Rico. N. lat. 14° 53'. W. long. 61° 8'.

TRINITY Bay, a large but not a very deep bay of the South Pacific ocean, on the north-east coast of New Holland, between Cape Grant and Cape Tribulation.—Also, a large bay on the east coast of Newfoundland. N. lat. 48°. W. long. 53° 10'.

TRINITY Harbour, a cove on the north-west end of Trinity bay, on the east coast of Newfoundland. N. lat. 48°. W. long. 53° 10'.

TRINITY Inlet, a bay of the North Pacific ocean, on the west coast of North America; 30 miles S. of Queen Charlotte's Sound.

TRINITY Island, an island in the North Pacific ocean, discovered by captain Cook. Captain Vancouver passed this coast in the year 1794, and says it appeared to be divided into two islands, with several others of inferior size lying to the north, between them and the land about Cape Trinity. The eait point of the easternmost is, according to his observations, situated in N. lat. 56° 33'. E. long. 206° 47'.

TRINUMGELD, or TRINUMGELD, a compensation used among our Saxon ancestors for great crimes, which were not abhored but by paying a fine thrice nine times. See GELD.

TRINK, in our Statutes, is used for a fishing-net.

2 Hen. VI. cap. 15. Blount.

TRINO, in Geography, a town of France, in the department of the Seine, lately belonging to the duchy of Montferrat, situated in a marshy soil: the country near produces great quantities of corn, rice, and cheese, by some supposed equal to those of Piacenza or Parma. The fortifications are for the most part demolished. It has one collegiate and several parochial churches, and religious houses; 10 miles S.S.W. of Vercelli. N. lat. 45° 17'. E. long. 8° 16'.

TRINOBANTES, TRINOVANTES, or TRINOVANTES, in Ancient Geography, were inhabitants of Britain, situated next to the Cantii northward, and occupied, according to Camden and Baxter, that country which now composes the counties of Essex and Middlesex, and some part of Surrey. But if Ptolemy be not mistaken, their territories were not so extensive in his time, as London did not then belong to them. The name of this British nation seems to be derived from the three following Britih words; Tri, Now, Hunt, which signify the inhabitants of the new city. This name was perhaps given to them by their neighbours, on account of their having newly come from the continent into Britain, and having there founded a city called Tri-Now, or the New City, the most ancient name of the renowned metropolis of Britain. The Trinobantes had come hither lately from Belgium, that they seem hardly to have been firmly established in Britain, at the time of the first Roman invasion. For their new city, which soon after became so famous, was then so inconsiderable, that it is not mentioned by Caesar, though he must have been within sight of the place where it was situated. They were then at war with their neighbours, the Catuvellauni, whose king, Calibelenus, commanded the confederated Britons against the Romans; and, on this account, the Trinobantes were amongst the first of the British states who deferred that confederacy and submitted to Caesar. They submitted again to the Romans, on their next invasion in the reign of Claudius, with the same facility, and almost for the same reason. For, in the interval between the invasion of Julius and that of Claudius, the Catuvellauni had reduced them under their obedience; and, in order to emancipate themselves from this subjection to their neighbours, they put themselves under the protection of the Romans. But the Trinobantes soon became weary of their obedience to their new masters. For the Roman colony at Camulodunum, which was within their territories, depriving some of them of their estates, and oppressing them several other ways, they joined in the great revolt of the Britons under Boadicea, and shared very deeply in the miseries of that revolt. From that time the Trinobantes remained in peaceable submission to the Romans, as long as they continued in Britain. The country of the Trinobantes was greatly valued and much frequented by the Romans, on account of the excellence of its soil and climate, and the many advantages of its situation. That fagacious people soon fixed their eyes on the new town of the Trinobantes; and observing its admirable situation for health, for pleasure, and for trade, great numbers of them settled in it, and giving it the name of Londonium from its situation, and of Augusta from its grandeur, it became in a little time the largest and most opulent city in this island. In the reign of Nero, as Tacitus informs us, London was become a city highly famous for the great conflux of merchants, her extensive commerce, and plenty of all things. No fewer than seven of the fourteen journeys of Antoninus begin or end at London; a plain proof, among many others, that this city was the capital of Britain in the Roman times, as it is at present the great and flourishing metropolis of the British empire. Camulodunum, now Malden in Essex, was the seat of the first Roman colony in Britain, and a place of great beauty and magnificence in these times; though at present few or no vestiges of its ancient grandeur remain. Caerfaromagus, from its pompous name, was probably a place of some note in the Roman times; but it is now entirely ruined, that it is difficult to discover the ground where it once stood; some of our antiquaries placing it at Chelmsford, and others at Dunmow. The Colonia of Antoninus was probably Colchester, and Durulumi, as some think, Leiston, but, according to others, Waltham. But though the county of Essex was certainly very much frequented by the Romans, who erected many noble works in it, yet time, cultivation, and various accidents, have made it great a change in the face of that country, that very few vestiges of these works are now remaining. The territories of the Trinobantes were included in that Roman province which was called Britannia Prima. See CAMULODUNUM.

TRINODA Necessitas, in our Ancient Cullons, a threefold necessary tax, to which all lands are liable; viz. expeditio, a capitation, and a tithe; going to the wars, and repairing of bridges and of calls.

These were the three exceptions anciently permitted in the king's grants of land to the church, after the words that freed them from all secular service.

TRINODA, or TRINODA Terra, in some Ancient Writers, denotes a quantity of land containing three perches.

TRINOMALY, in Geography, a town of Hindooitan, in the Carnatic, near which the troops of Hyder Ally were defeated by the British, under colonel Smith in the year 1768, with the loss of the greatest part of their artillery; 45 miles S.S.W. of Arcot. N. lat. 12° 13'. E. long. 79° 10'.

TRINOMIAL or TRINOMINAL Root, in Mathematics, is a root consisting of three parts, or monomes, connected together by the signs + or —.
Such is \[ \frac{x^3 + y^3 + z^3}{a + b - c}. \] See Involution.

Trio, in Italian Terzetto, a vocal composition in three principal parts, exclusive of the accompaniments. In chamber duets and trios, such as those of Steffani and Clari, in which each part repeats the same words, the great merit was pure harmony, and ingenious subjects of fugue and imitation. But in the dramatic duets and trios of modern times, the several parts have different words and different passions to express. In an opera trio, the several characters are dialogued, and seldom singing together; and in each part, there a beautiful, interesting, and characteristic melody is required. But in moments of passion, where the three parts are united, expressing with energy and passion their several complaints and accusations, it is that, with the organ, an interest will be produced at once by combinations of poetry, harmony, and figural effects.

There is nothing more difficult, perhaps, for the poet to write, or the composer to set, than a dramatic trio.

Trioctile, in Astrology, an aspect, or situation, of two planets with regard to the earth, when they are three octants, or eight parts of a circle, i.e. 135 degrees, distant from each other.

This aspect, which some call the sesquiangular, is one of the new aspects superadded to the old ones by Kepler.

Trioidea, in Botany, from \( \tau \tau \tau, \tau \tau \tau, \tau \tau \tau, \) and \( \tau \tau \tau \), a tooth, alluding to the three, nearly equal, teeth, of the outer valve of the corolla. — Brown Prodr. Nov. Holl. v. 1. 182. Kunth Nov. Gen. et Sp. v. 1. 126. — Claph and order, Triandria Digynia. Nat. Ord. Gramina. Eff. Ch. Calyx, many- or two nearly equal valves. Outer valve of the corolla with three, nearly equal, teeth; the middle one straight. Nectary of two scales.

A genus of perennial, rather rigid grasses, with panicle flowers, and the habit of a Poa or Festuca. Mr. Brown suspects Festuca decumbens of Linneus, which is Poa decumbens of Sm. Fl. Brit., and Dautonia decumbens of Decandolle, ought to be removed hither. Our learned friend has hinted to us, that the two South American species of Humboldt and Bonpland, here subjoined to his own New Holland, though they answer to the generic character, are considerably different in appearance from the rest.

1. T. pungens. Br. n. 1. — "Panicle rather close, erect; with alternate, softly simple, branches. Spikelets lanceolate, of about four flowers. Outer valve of the corolla woolly at the edges and keel, in its lower half. Leaves spreading, involute, pungent; sheaths of the lower ones villos.

— Found by Mr. Brown, in the tropical part of New Holland.

2. T. prosera. Br. n. 2. — "Panicle loose; its branches undivided, spike. Spikelets somewhat filamented, of three or four flowers. Calyx roughish. Outer valve of the corolla very smooth at the keel, and nearly so at the edges. Leaves involute, rather lax; their sheath with a silky beard." — From the same country.

4. T. microstachya. Br. n. 4. — "Panicle elongated, rather close; its branches undivided, spike. Spikelets about three-flowered. Glumes rough. Outer valve of the corolla blunt, with three very short teeth; its keel and edges smooth. Leaves involute; their sheath bearded." — From the same country as the foregoing.

at the base. Leaves involute, spreading, rigid, pungent." — Native of the southern coast of New Holland.

6. T. ambiguus. Br. n. 6. — "Panicle lax; its branches half-woolly, undivided, spike. Spikelets nearly fertile, linear, of eight or ten flowers. Outer valve of the corolla silky at the edges; inner fringed. Leaves involute. Stirpes torn." — Found in the tropical part of New Holland, by Mr. Brown, who doubts whether this be a genuine species of Triodia. Its aspect is perfectly that of a Poa.

7. T. pulchella. Kunth as above, n. 1. t. 47. — Panicle leafy, of about three flowers. Spikelets about five-flowered. Corolla hairy at the base; its inner valve toothed. Scyons trailing. Leaves rough. — Native of cool dry exposed situations in Mexico, flowering in September. Root fibrous, with trailing runners, taking root as they go, and sending up flims two or three inches high, solitary or aggregate, whose simple panicle is accompanied by many awl-shaped leaves, resembling the radical foliage.

8. T. arenacea. Kunth n. 2. t. 48. — Panicle close. Spikelets about five-flowered. Corolla hairy in its lower half; inner valve entire. Scyons trailing. Leaves slightly hairy. Native of valleys in Mexico, flowering in April. This increases by runners, like the last. But the flims are twice as tall; the panicle leaflets, rather compound, resembling a Festuca; the leaves flat, blunter, not unlike Poa annua.

Trioion, the title of an ecclesiastical book in the Greek church, which comprehends the office of a particular part of the year. This book is called Triodion, because it contains the hymns or odes of three triplpes. The hymn of two triplpes is called "Diodon;" and that of four, "Tetradon." Leo Allatius.

Trioia, in Geography, a town of the Ligurian republic; 18 miles N.E. of Vintimiglia.

Triond, a town of European Turkey, in Albania; 12 miles W.N.W. of Aledia.

Trionda, a small island in the gulf of Saltilia, near the coast of Nafplia. N. lat. 36° 36'. E. long. 35° 26'.

Triones, in Astronomy, a sort of constellation, or assemblage of seven stars in the Ursa Major, popularly called Charlie's Wain.

From the Septem Triones, the north pole takes the denomination Septentrio.

Trionto, in Geography, a river of Naples, which runs into the gulf of Tarento; 10 miles E. of Rossano. Also, a cape of Italy, on the coast of Calabria Citra, in the gulf of Tarento, at the mouth of the Trionto. N. lat. 39° 46'. E. long. 16° 54'.

Trionum, in Botany. (See Hibiscus.) There is a \( \gamma \) in Theophrastus, said to be one of the Mallow tribe; like the Hibiscus in question, whose leaves, having three lobes, are supposed to function the present application of this name.

Triopthalmus, formed of \( \gamma \), three, and \( \sigma \), a name given by authors to such pieces of agate, or other semi-pellucid stones, as happen to have three small circular spots, resembling eyes, upon them; these are of the nature of the common agate, &c. The spots are mere accidental varieties in the disposition of the veins, and do not make a distinct species of Rome.

Triopium, in Ancient Geography, a country or town, or, as others say, a promontory of Caria, near the sea, and belonging to the Cnidians. On this promontory was a temple of Apollo, where the Dorians celebrated games in honour of this god. At this temple was held an assembly of the Dorians of Asia, similar to the assemblies of the European Greeks at Thermopylae. See Cape Cnus.

Trip-
**TRIOPTERIS**, in Botany, from τρις, three, and πτερον, a wing, very expressive of the three prominent membranous wings of each capsule, at least in the original species. —Linn. Gen. 228. Schreb. 307. Willd. Sp. Pl. v. 2. 743.

**Results.** The plant which was first described as *Triopteris* was *T. acutifolia*, a small fern, native to the West Indies. It was later discovered that the species cultivated in Jamaica is not *T. acutifolia*, but a different species, *T. jamaicensis*. The plant is indigenous to the West Indies and is found in the Antilles. The fronds are small, with three nearly equal wings, and the capsule is surrounded by the fronds. The plant is a tender exotic plant, which constantly requires the protection and warmth of a greenhouse or frame in this climate.

**Method of Culture.** This plant is propagated and increased by seeds, cuttings of the branches, and layers. In striking roots, the cuttings are frequently used for the purpose of propagating the plant. The plants, after they are raised, are always to be kept in pots, which are to be placed amongst those of the greenhouse or frame kinds. They should have occasional waterings during hot weather.

They afford a desirable variety in collections of the above kinds of plants.

**TRIARCHIS**, a word used by some to express a man who has three teeth.

It is also used as the name of a buzzard; and of a plant, called ladies' traces.

**TRIORS** or **TRIERS**, in Law, such as are chosen by the court to examine whether a challenge made to the panel of jurors, or any of them, be just or not.

The triors, in case the first man called be challenged, are two indifferent persons named by the court; and if they try one man and find him indifferent, he shall be sworn; and then he and the two triors shall try the next; and when another is found indifferent and sworn, the two triors shall be superceded, and the two first sworn on the jury shall try the reef.

**Gen. Ch. Cal.** Perianth inferior, minute, permanent, in five deep segments. Cor. Petals five, roundish, with long claws. Stam. Filaments ten, capillary, slightly connected at the base, five longer than the intermediate ones; anthers simple, roundish. Pilt. Germen superior, three-leaf; styles three, erect; stigmas obtuse. Peric. Capsules three, oval, not burling, each with one, three, or four, flat, membranous, dative; Seeds solitary.

Eff. Ch. Calyx in five deep segments. Petals five, roundish, with slender claws. Filaments combined at the base. Capsules three, single-feathered, each with one, three, or four, membranous wings.

6. **T. acuminata.** Pointed-leaved Triple-wing. Willd. n. 6. (Tetrapetes acuminata; Cavan. Diff. n. 596; t. 262. f. 2.) —Leaves elliptic-oblong, pointed, smooth. Umbels panicled, terminal. Capsules with four wings; the two lowermost smallest. —Found in Cayenne by M. Stoupy.

7. **T. buxifolia.** Box-leaved Triple-wing. Willd. n. 7. (Tetrapetes buxifolia; Cavan. Diff. n. 597; t. 262. f. 1. Banisteria microphylla; Jacq. Obs. faece. 3. t. 56.) —Leaves elliptic-oblong, bluntish, smooth. Umbels foliaceous, terminal. Capsules with four nearly equal wings. Native of the Antilles. The leaves are much smaller than any of the foregoing, being hardly above an inch long, and nearly sessile.

8. **T. citrifolia.** Orange-leaved Triple-wing. Swartz Ind. Occ. 857. Willd. n. 8. (Tetrapetes inaequalis; Cavan. Diff. n. 594; t. 262. Acer sacrandum triococcos, folis citri, flore luteo minore; Planch. t. 9. t. 16.) —Leaves ovate, acute, smooth. Umbels axillary, flattened. Capsules with four wings; the two lowermost smallest. Native of woods on the mountains of Jamaica. The frond is shorter than the tube, in five deep, erect, rounded lobes, the lower ones smallest. Stam. Filaments five, thread-shaped, the length of the corolla, and inserted into its tube; anthers oblong. Pilt. Germen inferior, roundish; style cylindrical, the length of the stamens; stigma thickish. Peric. Berry obovate, bluntly triangular, of three cells. Seeds solitary, bony, bluntly triangular, obtuse, furrowed.

Eff. Ch. Corolla of one petal, scarcely longer than the calyx, nearly regular. Calyx in five deep segments. Berry inferior, of three cells, with solitary seeds.

TRIPELAAIDEÆ, in Botany, the 5th order among the
Fragmenta of Linnaeus, confifts of Juncus, Aphyllantes,
Triphelia, Scheuchzeria, Elegia and Refio in one section;
then Flagellaria, Colomus, Butomus, Althina and Sagittaria.
Linnaeus has hinted, in a manuscript note, that the three
last ought probably to be removed to an order near akin
to the Palma, or a subdivision thereof. The name alludes
to the three petals, for so we must call them, though Linnaeus,
like the French botanists, has spoken of them, sometimes,
as petal-like leaves of the calyx.

TRIPETALOUS FLOWERS, in Botany, such which
confift of three leaves, which are called petals, to differ
from the leaves of plants.

TRIPETYLY, in Geography, a town of Hindoosfan,
in the Carnatic, where was a celebrated pagoda, reftored to
by vast crowds of pilgrims from all parts of Hindoosfan;
49 miles S.S.W. of Nellore. N. lat. 12° 45' E. long.

TRIPHACA, in Botany, was so named by Loureiro,
from τρίς, three, and ρέ, a lentil, or, as he takes the liberty
of saying, a legumes, in allusion to the three leguminous feed-
vellets.—Loureiro. Cochinch. 577.—Clafs and order, Mon-
ocota Polyandra.

This is a large tree, found on the eastern coast of Africa.
Mr. Brown has suggested to us that it is undoubtedly a
Sterculia; see that article. In species it seems to come
near S. Balangbas and its allies. The number of the foli-
ces doublets varies.

TRIPHARMACUM, an ointment in the late London
Difpensatory, so called from its being composed of three
ingredients: the prescription is this: Take common platter
four ounces; oil olive two ounces; vinegar one ounce: let
them over a gentle fire, and stir them continually till they
become an ointment.

TRIPHASIA, in Botany, so named by Loureiro,
Cochinch. 152, (omitted in his index,) from τρίς, three,
thre-Fold, because of the three leaflets, petals, and calyx-teeth,
proves, by his experiments at Sir Joseph Bank's, to be no
other than Limonia trifoliata of Linnaeus.

TRIPHOLINUS MOSG, in Ancient Geography, a moun-
tain of Italy, in Campania. Phly speaks of the vines which
grew upon the mountain, and calls the territory which pro-
duced them, Tripholinus ager. These vines are also mentioned

TRIPHTHONGUE, in Grammar, an affemblage, or
concurrence, of three vowels in the fame syllable; as in quaef.
Quinellian, lib. i. cap. 6. denies the exiftence of thrif-
thongues; and afferts, that there never was any syllable of
three vowels, but that one of them was always turned into
a confonant: Scipion afferts the contrary. However
this may be in the Latin and Greek, which were the only
languages Quinellian underftood, it is certain there are
ferval languages in Europe where thriphthongues are in use.

TRIPA, in Ancient Geography, a country of the
Peloponnesus, in the Elide. Strabo mentions its maritime
town Samicam.

TRIELI, in Geography, a town of Sicily, in the valley of
Demona; 8 miles S. of Pati. N. lat. 38° 10'. E. long.

TRIPINA, in Botany, fo denominated from the
triply-pinnate leaves.—Loureiro. Cochinch. 391.—Clafs and
order, Didynamia Angiospermae.

This appears to be a very handfome and large tree, with
panicled orange-coloured flowers, a berry of one cell, with
four seeds, and smooth, ovate, pointed leaflets. It may be
referred to Jussieu's order of Plites, but whether to any
described genus, we want materials to determine. This
tree
TRIPLARIS, from Triplex, threefold, because of the prevalence of the number 3, in all the parts of fructification.

Gen. Ch. Male, Cal. Perianth of one leaf, turbinate, in fix ovate, acute, concave segments, externally hairy. Cor. none. Stam. Filaments nine to twelve, thread-shaped, inserted into the calyx below its divisions, which they exceed in length, behind a crown of very short hairs; anthers heart-shaped, erect.

Female, Cal. Perianth of one leaf, inferior, large, permanent; tube ovate, swelling; limb erect, in three deep, lanceolate, membranous, veiny, obtuse segments. Cor. Petals three, linear, obtuse, veiny, permanent, closely pressed to the germin. Stam. Filaments about twelve, very short, awl-shaped, erect, inserted in the male, but diminutive of anthers, and often altogether wanting. Pil. Germen superior, large, triangular; styles three, very short; stigmas awl-shaped, keeled, hairy. Peric. none, except the permanent calyx. Seed. Nut triangular, pointed, invested with the tube of the calyx.

Female, Calyx inferior, in three deep segments. Petals three. Styles three. Nut triangular, clothed with the calyx.

TRIPLE, Threefold. See Ratio and Sub-TRIPLE.

TRIPLE, in Music, is one of the species of measure, or time.

Triple time consists of many different species, of which there are in general four, each of which has its varieties. The common name of triple is taken hence, that the whole, or half measure, is divisible into three equal parts, and is beaten accordingly.

The first species is called the simple triple, in which the measure is equal to three semi-breves, three minims, three crotchets, three quavers, or three semi-quavers, which are marked thus, \( \frac{3}{4} \), or \( \frac{2}{4} + \frac{1}{4} \), but the last is not much used, except in church music.

In all these the measure is divided into three equal parts, or times, called the triple times, or the measure of three times; of which two are beat down, and the third up.

The second species is the mixt triple; its measure is equal to fix crotchets, or fix quavers, or fix semi-quavers, and according it is marked \( \frac{4}{4} \), or \( \frac{3}{4} + \frac{1}{4} \); but the last is seldom used.

Some authors add other two; viz. fix semi-breves and fix minimis, marked \( \frac{5}{4} \), or \( \frac{4}{4} + \frac{1}{4} \); but these are not in use.

The measure here is usually divided into two equal parts, or times, of which one is beat down and one up; but it may also be divided into fix times; of which the first two are beat down, and the third up; then the next two down, and the last up; i.e. each half of the measure is beat like the simple triple (on which account it may be called compound triple), and because it may be thus divided either into two or six times (i.e. two triples), it is called mixed; and, by some, the measure of six times.

The third species is the compound triple, consisting of nine crotchets, or quavers, or semi-quavers, and marked \( \frac{9}{4} \), \( \frac{3}{4} + \frac{3}{4} + \frac{3}{4} \); the first and last are little used; and also add \( \frac{1}{2} \), \( \frac{1}{2} \), which are never used.

This measure is divided into three equal parts, or times, of which two are beat down, and one up; or each third part may be divided into three times, and beat like the simple triple; on which account it is called the measure of nine times.

The fourth species is a compound of the second species, containing twelve crotchets or quavers, or semi-quavers, marked \( \frac{12}{4} \), \( \frac{4}{4} + \frac{4}{4} + \frac{4}{4} \); to which some add \( \frac{1}{2} \), and \( \frac{1}{2} \), which are never used; nor are the first and last much used, especially the latter.

The measure here may be divided into two times, and beat one down, and one up; or each half may be divided and beat as the second species, either by two or three; in which case it will make in all twelve times, and hence is called the measure of twelve times.

The French and Italian authors make a great many more species and diversions of triple time, unknown, or at least unregarded by our English musicians, and therefore not fo necessary to be dwelt upon here.

While the modes or moods were in use, triple time was the most difficult part of a musician's study; and, indeed, feems not to have been well understood by the masters themselves, as no two writers of elementary tracts on the subject seem to agree. But at present, by the use of bars and points, with the Italian technical terms for the degrees of quick and flow, triple time is fo simplified, that young students find it easier, and feel it sooner than common time. (See Plate Time-Table, and the article Notation.) When every gentleman's child learned to dance a minuet, young musicians found it easier to beat and to keep triple time, though it seems to limp, than common, which is the most simple, natural, and equable of all measures and motions. See Mixuer.

TRIPLE Progresion, in Harmonics, supposed to have been the invention, or rather to have been first applied to musical ratios by Pythagoras. To speak practically of this division of the monochord, or general system of music, it was the guide not only of Pythagoras, but Eudox, and all the Greek and Roman writers on harmonics, except Arisloccenus. It precluded all idea of temperament, by a series of perfect 5ths; nor was a temperament thought of by any of the ancients, except Didymus and Ptolemy; but they seem never to have been implicitly followed.

Nothing but mere melody being in question, and the major 3d being so harsh as to be ranked among discord, temperament was not much wanted till counterpoint had made some progress; and then it was as much opposed by the adherents to the practice of the ancients, as the Copernican system was by the adherents to the Ptolemaic. These prejudices, however, had been nearly annihilated, and the temperament of keyed and wind instruments became so habitual, that the triple progression had had no champion for a long time, till the abbé Rouffier, a Pythagorean enraged,
TRI

tragedy, arose, and treated all musicians as ignorant and absurd, who had not opposed temperament, and regarded all music as dissonance which had been composed for tempered scales. But we have heard nothing of the learned abbe since the Revolution; and there seems to be no more true believers left in Pythagoras's doctrine of the triple progression, in Europe at least, than in that of the transmigration of souls.

TRIPLE QUARTAN FEVER. See FEVER.

TRIPLE ENGRAVING. See ENGRAVING.

TRIPlicate Ratio, is the ratio which cubes bear to each other.

This ratio is to be distinguished from triple ratio, and may be thus conceived. In the geometrical proportions 2, 4, 8, 16, 32, as the ratio of the first term (2) is to the third (8) duplicate of that of the first to the second, or of the second to the third: so the ratio of the first to the fourth is said to be triplicate of the ratio of the first to the second, or of that of the second to the third, or that of the third to the fourth, as being compounded of three equal ratios.

TRIPLICatio, Triplication, in Civil Law, is the fame with far-rejoinder in common law.

TRIPlicity, or Trigon, among Astrologers, is a division of the signs, according to the number of the elements; each division consisting of three signs.

Triplicity is frequently confounded with trine aspect; though, strictly speaking, the two are very different things: triplicity is only used with regard to the signs, and trine, on the contrary, with regard to the planets.

The signs of triplicity are those which are of the same nature, and not those which are in trine aspect. Thus Leo, Sagittario, and Aries, are signs of triplicity, because those signs are, by those writers, all supposed fiery.

TRIPLOLOGY, in Geography, a common of England, remarkable for being the spot where the army formed the council of agitators, and chose Oliver Cromwell for their commander, in 1648; 8 miles S. of Cambridge.

TRIPLOIDES, a surgeon's instrument, with a threefold bafis, used in the refinishing of great depreffions of the skull. Blanc.

TRIPOD, Tripods, in Antiquity, a famed sculpted seat or foot, supported by three feet, on which the priests and sibyls were placed to render oracles.

It was on the tripods that the gods inspired the Pythians with that divine fury and enthusiasm with which they were seized at the delivering of their predictions.

M. Spanheim observes, that, on Roman medals, the tripod express some priesthood, or sacerdotal dignity. A tripod, with a raven and a dolphin, is also the symbol of the duumvir, deputed for keeping of the tripolyne oracles, and for consulting them on occasion.

Atheneus admits only two sorts of tripods, that are reduced to great and small tripods. But Baner distinguishes three kinds. Under the first he includes those used by the Pythians, when she delivered the oracles of Apollo in the temple of Delphos. The second kind comprehends whatever stood upon three feet, such as vases, tables, &c. of which there was a great number. Under the third class are included the votive tripods, which princes or private persons dedicated in the temples of Apollo. Herodotus (lib. ix.) speaks of a golden tripod, which the Greeks, upon their victory over the Periads, sent to Delphos. Molt of the tripods found in the cabinets of the curious, are of brass or of bronze.

TRIPOD of EAF. See TRITON.

TRIPODIUM. In the laws of Henry I. occurs this pallage—"Inquibus vero causis triplicem ladam haberet, ferat judicium tripodium." i.e. 60 solid. The meaning of this, according to some, is, that, as for a small offence, the composition was twenty shillings: so for a great offence, which was to be purged triplici lada, the composition was three times twenty shillings, and this was called tripodium.

TRIPOLDA, in Geography, a town of Naples, in Principato Ultra; 16 miles S. of Benevento.

TRIPOLI, a country of Africa, which, though tributary to the grand signior, is called a kingdom or regency; bounded on the N. by the Mediterranean, on the E. by Barca, or, considering Barca as a province of Tripoli, by Egypt; on the S. by the Atlas mountain; and on the W. by Tunis and Biledolgerid; about 60 miles from N. to W. The breadth, from N. to S., is various, from 120 to 250.

It has formerly been divided into seven provinces, or with Barca, eight; but it is generally distinguished into Maritime and inland: the inhabitants of the former generally live upon commerce and piracy; the latter for the most part on plunder and robbery. Each division hath some cities and towns, besides a number of villages, which lie scattered chiefly through the latter; most of them very poor and thinly inhabited: the country being almost everywhere sandy and barren: as for cities and towns, there are few, and for commerce, the greater part being either wholly depopulated and gone to ruins, or only inhabited by a few fishermen, lime-burners, potash-makers, and here and there a few labourers: the chief part reduced to the lowest degree of misery and wretchedness, through the cruel exactions of the government, or the frequent depredations of the Arabs.

The government, religion, laws, and customs of this kingdom are in a great measure the same with those of Algiers and Tunis. Only with respect to the first of these articles, it will not be amiss to observe, that the bey's of Tripoli are not mere titular vassals to the Porte, but really under subjection and tribute. This joined to the other exigencies of the regency, the avarice of the Turkish Bashaws, and the difficulty of Constantinople, and the general decay of commerce, obliges them to load the subjects with heavy duties, and extortions, as hath reduced the greatest part of the kingdom to the lowest degree of indigence and misery. The revenues arise chiefly from their corsairs, which are nevertheless but few, seldom exceeding seven or eight, and of these only one can properly be styled a ship, the rest are small galleys, poorly manned and equipped. The next is the duty on imports and exports; the tax on the Jews, who are here very numerous; on the natives, who, though ever so poor, must yet pay part of the produce of their ground, or manufactures; and lastly on the country Moors and Arabs, among whom the bey sends his flying camp of janizaries to levy it; for the last, as well as the Moors, are kept so poor by these heavy taxes, that nothing but force, and sometimes exemplary severity, can extort it from them. The bey, by means of his protection from the Porte, makes shift to keep up a kind of despotism, as he is besides generalissimo of all the forces. As for their commerce, it chiefly consists in slaves, either such as are taken by their corsairs, or such as they traffic for with their neighbours: the greatest part of both they send into Turkey, where they can dispose of them to the best advantage. The next branch is that of slaves, which they buy from the Barbarians, and sell to the Europeans, to make glass and soap; the rest of their traffic is not worth mentioning. One circumstance in the conduct of this regency deserves notice: they are more scrupulous observers of their treaties with other nations than any of their neighbours: which punctuality, whether it proceeds from real probity, or a consciousness of their own
own weakness, is nevertheless of no small advantage to navigation and commerce. This rate, as well as the rest of Barbary, after being freed from the Roman yoke, paffed successively under the Vandals, Saracens, and the kings of Morocco, Fez, and Tunis; till, weary of their effravity and oppression, they revolted to have a monarch of their own, whom they chose from among themselves; and the new monarch governed them at first with great equity and moderation; but he no sooner saw himself out of danger, than he began to play the tyrant in his turn to such a degree, that the citizens confpired against him, and he was murdered by his own brother-in-law. They chose in his room another, named Abubacer, who had been formerly an officer under him, but had since retired, and turned marabout or hermit; but he had not reigned many months, before Ferdinand, king of Castile and Aragon, sent thither Peter, count of Navarre, with a powerful fleet and army, which laid siege to the capital. Abubacer, finding himself unequal to fo powerful an enemy, surrendered on honourable terms, and was sent with his wife, two sons, and an uncle, to the emperor Charles V. then at Palermo, who soon after restored him to his former dignity, on condition that he should become his vassal and tributary. Abubacer rebuilt and re-peopled the city, which he held in the emperor's name, till the knights of Rhodes were driven out of that island, and forced to retire into Syracuse, when Charles was pleased to bellow the island of Malta upon them, together with the city and castle of Tripoli. They fought accordingly, and took possession of both, made one of their order governor, and put a garrison into it of their own troops. They were fearfully settled in this new acquisition, before Barbarossa made himself master of it, but it was soon after retaken by the emperor, and restored to them, who continued in possession of it till the reign of Solyman, who, under pretence that it had been retaken during the truce, sent thither a naval armament, consisting of about 110 royal galleys, and 30 other vessels, under the command of Sinan bashaw, who had under him the famed Salta Rais, surnamed Devil-driver, and the no less famous Dragut; and notwithstanding every means of defence, it was obliged to surrender, and delivered up to the Turks, after it had continued in the possession of the Christians a little above forty years, from the time of its being taken by the count of Navarre. Sinan committed the government of it to the aga Morat, upon condition that he should hold it under the grand signor, and resign it whenever he should appoint another governor. It was not long, however, before the famed corsair Dragut got possession of this place. He fortified both city and castle with strong walls, and two forts near the sea-fide, well supplied with artillery and ammunition; by which means it became one of the strongest cities in Africa, and the common retreat of most of the corsairs that roved under Turkish colours, from whence they infested the coasts of Italy, Sicily, Naples and Spain, and a fruitless attempt was made by the Christians to retake it. After the death of Dragut, the Porte continued sending either a fanjaghe or bahaw to Tripoli, the castle being garrisoned with Turks, and the city inhabited by Moors, and the kingdom still paying tribute to the grand signor. The piratical trade went on with success; the renegades met with the usual encouragement from the Turks, and were promoted to the command of the corsairs, and even of their own fleets, and sometimes to the bahawship; these recommending themselves to the regency, not only by their desperate behaviour, but much more by their peculiar barbarity to the Christian prisoners, which often provoked reprisals, that were carried on both sides to such extents as can hardly be particularized without horror. In this condition the kingdom continued till the Turkish government, becoming more and more intolerable, by the avarice and tyranny of those bahaws, a certain marabout named Sid Hajah, about the close of the sixteenth century, found means to raise a general revolt both in the city and country. Unfortunately for him, he did not take care to secure a foreign alliance, before he broke out into open rebellion; so that Haicen bahaw, the Turkish admiral, came suddenly upon him, at the head of sixty galleys, and a number of other ships and vessels, which he had procured from Tunis and Algiers, and defeated him so often, that he was at length abandoned by his troops, and assassinated by his own partizans. Haicen sent the marabout's head to Constantinople, and had hardly settled the government on the old footing, when a new governor, sent thither from the Porte, found a much more effectual way to free them from this tyranny. This man was a renegado Greek, of the ancient family of the Juttiani, known by the name of Mahmet Beygh, who, by his intrigues and bribes, had obtained a banner or government from the grand signor. He failed directly to Tripoli, and having got possession of the castle, refused to acknowledge or receive any bahaw from Constantinople. He took the reins of government wholly upon himself, not indeed as independent, but as vassal and tributary to the Porte, to whom he obliged himself to pay a tribute and homage, as an acknowledgment of his submission and dependence.

TRIPOLI, a city and sea-port of Africa, and capital of the country so called, situated on the coast of the Mediterranean. It was formerly divided into two parts, the Old and New; the former, which was the native country of the emperor Severus, is supposed to have been built by the Romans, was twice conquered by the Vandals, and at last destroyed by the Mahometans, under their caliph Omar II., which time it hath never recovered its importance, and is now almost gone to ruin; the latter, which stands at a small distance from it, though of no great extent, is populous, and in a flourishing condition. It stands on a foundation of rock, by the sea-side, surrounded with high walls and stout ramparts, flanked with pyramidal towers, but not kept in good repair. The sea washes the town on three sides; and on the fourth a sandy plain, called the Mecca, joins it to the rest of the country. On the E. it is divided from Egypt by the dreary deserts of Barea, where none reside but occasionally the wandering Arab. It hath but two gates, one towards the inland on the S., and the other to the sea on the N., where it expands itself in form of a crescent, near a spacious and commodious harbour. On entering the harbour, the town manifests the dilapidations of time, large heaps of rubbish appearing in various parts of it. The castle, or royal palace, where the bahaw resides, is at the E. end of the town within the walls, with a dockyard adjoining, where the bay (the bahaw's eldest son) builds his cruisers. The castle is very ancient, and is inclosed by a strong wall, that appears impenetrable; but within, it is totally destitute of symmetry.

New Tripoli is supposed to have been built by the natives, who gave it the name of Tarabilla, or Trebbile, whence the Latins call it Tripolis. Some authors pretend that it was once a place of vall trade, on account of its neighbourly to Numidia and Tunis, resorted to by vessels from Malta, Venice, Sicily, Marselles, and other parts; there being hardly such another commodious sea-port along this whole coast, except Alexandría; by which means it became so opulent, that it was filled with rich merchants, abounded with fine mosques, hospitals, and other public buildings, and
TRIPOLI.

and excelled Tunis in beauty and wealth. It retains now but few traces of its ancient splendour. The baths form clusters of cupolas, very large, to the number of nine or ten, crowded together in different parts of the town. The mosques have generally a small plantation of Indian figs and dates close to them, which give to the town a novel and pleasing aspect. The houses are low and mean, the streets narrow, dirty, and irregular; there are in it nevertheless some monuments still standing, which evince its former magnificence; particularly a triumphal arch, one half of which now lies buried in the sand, and some remains of Roman pavement.

We need not wonder at this extraordinary decay, if we consider the two great inconveniences which this city labours under: first, the want of sweet water, here being neither rivers, springs, nor wells, nor any other means of supplying it with that useful element but cisterns and reservoirs of rain-water; secondly, the great finacity of corn, and the other products of the ground, occasioned by the dry sandy soil that surrounds it on the land side for several miles. It produces, however, palm-trees in great plenty, that yield the most delightful dates, which constitute a considerable part of their food; besides these, they have the lothos or lotus, a tree whose fruit is reckoned still finer than the dates, and makes a most excellent wine. That plant serves them for meat and drink, for which reason they have been called by the ancients Lotophagi. But upon the whole, were it not for the continual supply of provisions brought in by their corsairs, and other trading vessels, Tripoli could never subsist by the products of its own territories; and hence we may infer the cause of its present decay.

Adjacent to the walls of the city is a famous burying-ground, in which are found coffins, urns, medals, and other curious relics of antiquity. The Franciscan friars have here a very handsome church, convent, and hospital, the last of which is the more necessary, as the city is so often and so feverishly visited by the plague. Other orders of monks were here settled, who have since obliged to abandon it, probably on account of its decay. The country around is adorned with a multiplicity of handsome villas, cultivated chiefly by Chillian slaves, and much like those about Algiers and Tunis. The people here carry on a considerable trade in linen cloths, great quantities of which are wrought by the inhabitants; but their chief dependence is on their own corsairs, and those of other nations, which resort to their harbour. Its shops are little better than booths, though they contain pearls, gold, gems, and precious drugs. Here are two covered bazaars, one very large, composed of four aisles meeting in a crofs, furnished on each side with shops, which contain every kind of merchandise: the other is much smaller, without shops, and destined to the sale of black men and women. (See the preceding article.) A late traveller says, the date-trees, which spread themselves like a foret behind the town, and the hills beyond them, which bound the prospect on the north, are interesting objects; but the town itself is built in too low a situation to compose a part of the general scene: for it is scarcely visible at the distance of a mile. Its scanty limits, though scarcely four miles in circumference, are too great for its present population; and its ancient castle, though once the pride and chief reliance of the reigning family, is now a mouldering ruin: 300 miles S.E. of Tunis. N. lat. 32° 54'. E. long. 13° 18'.

Tripoli, or Tarabulus, a town of Syria, and capital of a pachalik, and residence of the pasha, situated near the mouth of a small river, called Kadifca, at the foot of Mount Lebanon, which overlooks and surrounds it with its branches to the E. the S. and even a little to the N.W. The Greek name Tripoli, denoting three cities, is derived from its having been built by three colonies, from Tyre, Sidon, and Aridus, each of which formed settlements in or near each other that they were soon united into one. It is separated from the sea by a small triangular plain, half a league in breadth, at the point of which is the village where the vessels land their goods. The Franks call this village La Marine, the general name given by them to these places in the Levant. There is no harbour, but a simple road, which extends from the shore to shoals, called the Rabbit and Pigeon Islands. The bottom is rocky, and mariners are not fond of remaining here, as the cables are soon worn out, and the vessels exposed to the N.W. winds, which are frequent and violent on all this coast. In the time of the crusades, this road was defended by towers, seven of which are still subsisting from the mouth of the river to the village. They are strong built, but now serve only as a place of resort for birds of prey. All the environs of Tripoli are laid out in orchards, where the nopal grows spontaneously, and the white mulberry is cultivated for the silk-worm; and the pomegranate, the orange, and the lemon-tree, for their fruit, which is of the greatest beauty. The grounds belonging to it extend as far as Mount Lebanon, and abound in vineyards. Each hill produces a different wine; but the golden wine is most admired. But these places, though delightful to the eye, are unhealthy. Every year, from July to September, epidemic fevers, like those of Alexandria and Cyprus, rage here: these are owing to the artificial inundations with which the mulberry-trees are watered, in order that they may throw out their second leaves. Besides, as the city is open only to the west, the air does not circulate, and the spirits are in a constant state of oppression, which makes health at best but a kind of convalescence. At La Marine the air is more fabulous, its circulation being less impeded. The commerce of Tripoli consists almost wholly in indifferent coarse silks, which are made use of for rags, and is in the hands of the French alone. But they are losing their quality, which is owing to the decay of the mulberry-trees. They have a conful here, and three commercial houses. They export silks, and sponges filled up in the road; these they exchange for cloths, cochineal, sugar, and West India coffee; but this factory, both with respect to imports and exports, is inferior to Latakia; which see.

The pachalik of Tripoli comprehends the country which stretches along the Mediterranean from Latakia to the Narh-el-Kelb, and is bounded on the W. by that torrent, and the chain of mountains which overlook the Orontes. The principal part of this government is hilly, the sea-coast alone between Tripoli and Latakia being a level country. The numerous rivulets which water it contribute greatly to its fertility; but notwithstanding this advantage, this plain is much less cultivated than the mountains, without even excepting Lebanon, with its numerous rocks and pine-trees. Its chief productions are corn, barley, and cotton. In the territory of Latakia, tobacco and olives are principally cultivated; but in Lebanon and the Kefrawan, white mulberry-trees and vineyards. This pachalik contains several tribes and religions. From Lebanon to above Latakia, the mountains are peopled by the Anfarians, a particular sect of religious, which first rose in the latter end of the ninth century; Lebanon and the Kefrawan are inhabited entirely by the Maronites; and the sea-coast and cities, by chilismic Greeks, and Latins, Turks, and descendants of the Arabs. The pacha of Tripoli enjoys all the privileges of his place. The military and finances are in his hands; he holds the government in quality of a farm from the Porte, on a lease of one year only, at the annual rent of 750 purses (39,000l.)
In 1101, this town was taken by the Christians, and held by Bertrand, son of Raymond, count of Toulouse, as a county, in which situation it remained till the year 1288, when it was taken by Melec Messer, sultan of Egypt, who ordered it to be razed to its foundation; 75 miles N.N.W. of Damascus. N. lat. 34° 28′. E. long. 35° 36′. Volney’s Travels in Egypt, &c. vol. ii.

**Tripoli**, in Mineralogy, a mineral originally brought from Tripoli for the polishing of flounces and metals, whence it derives its name. It has a dull argillaceous appearance, but is not compact; it has a fine but hard grain, and does not soften by water, or mix with it. The colours are grey, inclining to red or yellow. From analysis, it proves to be principally composed of filex. Tripoli appears to be of two formations; the one by fire, which has hardened flates and sand-flones, and converted them into this substance; the other by water, decomposing beds containing filex, clay, and iron.

The tripoli from Derbyshire, called rotten-flone, may be referred to the latter formation; it occurs in the upper part of the great slate stratum which covers the mountain lime-flone of that district: it is dug near the surface, and is sold for 60s. per ton. Farray’s Derbyshire, vol. i. p. 231.

The tripoli of Poligné, near Rennes, in Brittany, is fuscile. It is of a red colour of different shades. Trunks of trees are found changed into tripoli in the middle of the beds, which are covered by beds of sand-flone in an inclined position.

The tripoli of Venice is the most esteemed; it comes from the island of Corfu. It is chalcolite, and has a yellowish-red colour. Sauvage has remarked in this tripoli, and in the preceding, a multitude of small cylindrical pores.

Tripoli is found at Menal, near Riom, in the department of Puy-de-Dôme. It occurs in beds which appear to have been formerly schists changed by the action of volcanic fire. This substance is found in the quarries of chalcedony of Volterra in Tuscany, and is said to be so situated as to appear evidently the result of the decomposition of the chalcedony. It occurs in coal strata at Polichapello, in Saxony. The tripoli from Bilin, in Bohemia, occurs in thin beds, which pass insensibly into pitch-flone. Acids produce no effervescence with it, nor is it melted by the r@ll violent heat; though it is somewhat hardened.

In fact, we sometimes find tripoli in volcanic mountains, or in strata which contain beds of coal in a state of combustion; and sometimes in beds formed evidently by deposition from water. It should appear that certain strata, composed principally of filex in a slate of extremely minute division, and combined with iron and clay, are decomposed by the agency of water, and the latter materials being in a great part removed, the filex is left porous and friable, and coloured by iron: it then forms tripoli; and beds of this mineral may have been so formed, and afterwards covered by strata of lava, where they occur in volcanic mountains. Where filex is intermixed with a portion of alumine and iron, as in schills, the alumine by exposure to a great heat may be hardened and contract, and leave the flone in a porous or friable flate. The specific gravity of tripoli is stated by Bucholz at 2.022, and its constituent parts:

<table>
<thead>
<tr>
<th>Substance</th>
<th>Specific Gravity</th>

</table>

The sulphuric acid and water are considered as accidental.

For the method of imitating gems by means of tripoli, see Gems.

**Tripolis**, in Ancient Geography, a country of the Peloponnesus, in Arcadia, so called on account of its three towns, according to Pausanias.—Alfo, a town of Phocis, situated about half a league from the sea, and 18 miles from Orthoia. Diodorus and Strabo derive its name from three towns of which it originally consisted, about a stadium from one another.

Alexander the Great subdued this city, which, after his death, passed to Tolemy Soter, whose successors retained possession of it till the reign of Antiochus the Great, king of Syria, who made himself master of this town and the whole of Phocias, towards the year 219 B.C. After its subjugation by Pompey, it passed under the dominion of the Romans, but was allowed the privilege of being a free city, and of being governed by its own laws. Under the empire of Vespasian, Tripoli assumed the epithet of Flavian. The territory of Tripoli was watered by many rivers and streams, which descended from Libanus. About two leagues E. of Tripoli was a tomb formed in a rock, which the Syrian Christians held to be the sepulchre of Canaan, the father of the Phenicians.

**Tripolis**, a town or country of the Peloponnesus, in Arcadia, which afforded an ample supply both of men and cattle, according to Pausanias.—Alfo, a town of Thelfaly, in which were the towns of Pythium, Azorum, and Dolicha, according to Livy.—Alfo, a town of Aisa, on the Meander, and capital of Caria.—Alfo, a town of Asia, on the banks of the Euxine sea, W. of Trebicolon.

**TRIPOLITANA REGIO**, or Tripoli, a country of Africa, bounded N. by the Mediterranean sea, E. by the river Çinyes or Cinypus; situated in the middle of Libya Interior, and W. of the river Triton. Procopius says, that Sergius was appointed governor of this province by Justinian, at whose instigation the inhabitants embraced the Christian religion. They were called the “allies of the Romans,” because they faithfully maintained their peace with them. Some have confounded Pentapolis with Tripolis. See Tripoli, in Geography.

**Tripolizza**, in Geography, a town of European Turkey, in the Morea, the capital of a pacha, having about 12,000 inhabitants. In 1770, this town was besieged by the Russians and revolted Greeks, but a numerous detachment of Albanian cavalry coming up, the Greeks fled and left the Russians to the contents alone, of whom hardly one escaped. The Albanians afterwards, under a pretence that the inhabitants had held a correspondence with the enemy, put three thousand of them to the sword in less than two hours, and then plundered and set fire to the town; 18 miles W. of Napoli di Románta.

**Tripontio**, or **Triponzio**, a town of the Penedem, in the duchy of Spoletto, on the Ner; 12 miles N.W. of Norcia.

**Tripontium**, in Ancient Geography, a place of Italy, in Latium, on the Appian way; which appears by the military column to be at the 30th mile: it was repaired by the emperor Trajan. The Goths conquered a tower in this place.

**Tripontium**, a town of Great Britain, in the fifth Iter of Antonine, supposed to be Rugby. Drs. Gale and Stukeley place it at Downbridge, and the last of these authors derives its name from trs, a town, and pant, a little valley, in which Downbridge is situated. Camden and Baxter fix Tripontium at Toweled, and Camden derives its name from the British words *Taur-ponti*, signifying three.
three bridges. But Mr. Horsey supposes it to have been situated where the town of Rugby now stands.

TRIPOOR, in Geography, a town of Hindoosfan, in Myf ore; 25 miles N.E. of Coimbeore.

TRIPPING, in Heraldry, denotes the quick motion of all sorts of deer, and of some other creatures, represented with one foot up, as it were, on a trot.

In speaking of lions, they say pasiant, instead of tripping.

TRIPPING, in Sea Language, denotes the movement by which an anchor is loosened from the bottom by its cable or buoy-ropes. See ATRIP.

Gen. Ch. circumspect by Schreber. Male flowers in pairs, unilaterial, alternate, mostly in the upper part of the spike. Cal. Glume two-floreted; the outer floret male; inner neuter; each of two valves: outer valve lanceolate, flat-topped, obtuse, awnless, carinate, thiniger at the edges; embracing the inner valve, which is oblong, triangular, keeled, acute, about the same length. Cor. in each floret of two nearly equal valves, membranous, very thin, awnless, smaller than the calyx; the outer valve oblong, boat-like, blunt; inner lanceolate, cloven at the end. Nept. of two minute, triangular, fleshy, convex, abrupt valves, pointed at each end, thinnest at the upper margin, notched in the middle. Stam. in the outer floret, Filaments three, capillary, longer than the calyx; anthers parallelepipedal; in the inner, Filaments three, very slender, somewhat combined; anthers none.

Female flowers in the lower part of the same spike, alternately sunk in the common flake, at each side. Cal. Involucre oblong, carinate, very thick, tupid below, polished; obliquely bordered at each side externally; blunt and somewhat emarginate at the end; embracing the inner glumes with its thinner margin. Glume of two valves; the outermost oblong, tumid, taper-pointed, thickish, double; inner fimal, but rather blunt. Car. of two valves, smaller and thinner than the calyx; the outer valve largest, tumid, bluntly three-toothed; inner rather smaller, flat at the back, emarginate. Abortive glume of one valve, oblong, folded in at each margin, furnished with two teeth, and situated at the fore-side of the fertile floret, to which it is much inferior in size. Nept. minute, of two linear, membranous, very thin scales, acutely notched at the summit. Stam. Filaments three, minute, at the base of the genitum, capillary, dilated below; anthers linear, minute, imperfect. Pet. Germen superior, oblong; fylle one, compressed, longer than the calyx; fylle two, very long, villous, twisted. Peric. none. Seed solitary, ovate, a little compressed, pointed with the permanent style.

Obf. At the base of the involucrum, at each side, is an opening, lined internally, on one side, with bristly hairs.

Eff. Ch. Male, Calyx a glume of two flowers, the innermost neuter. Corolla of two membranous valves.

Female, Calyx a single-flowered glume, enclosed in a single-leaved involucre, pierced at each side. Corolla of two valves. Stigmas two. Seed one.

Hort. Cliff. 438. Gramen dactyloides maximum americanum; Pluk. Phyt. t. 190. f. 2. G. dactyloides indicum esculentum, fipica articulata; Ambrofin. Phyt. 546, 547, rude, but expressive, Setamo perenne indico, pianta frumentacea; Zonan. 18. 181. t. 69, not 68.—Spikes aggregate, about three together, male in the upper part, female at the base.—On the banks of rivers, and along the sea-shore, in Virginia, Carolina, and the country of the Illinois, flowering in August. Pursh. Root perennial, thick and woody, with many strong zigzag fibres. Stems numerous, erect, reedy, four or five feet high, round, smooth, as thick as a goose-quill, knotty; leafy below. Leaves long, linear, taper-pointed, an inch broad, smooth. Spike a fpan long, smooth, usually three together, often more or fewer; the male flowers very numerous.

T. monilifrons, Willd. n. 2. Hort. Berolin. t. 1, found in fall meadows and ditches, from New York to Carolina, seems, as Pursh remarks, to be but a single-flaked variety of the former; probably such as is represented by Miller above cited.

TRIPETEREA, a diminutive from τρίς, three, and ώπος, a wing, used by Michaux to express the character of the three little narrow wings, projecting from the angles of the calyx, or rather corolla; not, as De Theis says, of the capsule.—Michaux Bore. Amer. v. 1. 19. Vahl Enum. v. 2. 42. Pursh 28.—Cliffs and order, Triandra Monogynia. Nat. Ord. akin to Burmannia, and perhaps Hypoxis; genera whose place in Jussieu's system is not well settled.

Gen. Ch. Cal. none, unlees the corolla be taken for such. Cor. of one petal, permanent, superior; tube swelling at the base, contracted in the middle, angular, with three flight wings, at the summit; limb shorter than the tube, in six deep segments, the three intermediate ones minute. Stam. Filaments three, very short, inserted into the tube below the three smaller segments of the limb; anthers within the tube, of two widely separated lobes. Fil. Germen inferior; fylle the length of the flaments, triangular; fylle in three short, thickish, blunt segments. Peric. Capsule membranous, triangular, of three cells, crowned with the withered corolla. Seeds numerous, minute, oblong, cylindrical, striated.

Eff. Ch. Calyx none. Corolla superior, of one petal; its tube angular, swelling at the base; limb in five segments, the three intermediate ones minute. Capsule of three cells, with many seeds.

TRI

TRIPTYCHION. See Triphthongue.

Gen. Ch. Common Calyx imbricat, nearly cylindrical, of several lanceolate, keeled, spinous-pointed, nearly equal, scales, containing four or five flowers, in a simple series. Cor. compound, uniform, radiant; florets all uniform, perfect, fertile, monopetalous, tubular, two-lipped; the lower lip spreading, ovate, three-toothed; upper much smaller, erect, oblong, entire. Stam. Filaments five, capillary; anthers united into a tube, shorter than the corolla, dwelling in the middle. Pfyl. German solitary under each floret, obovate; style thread-shaped, longer than the filaments; stigmas two, oblong, spreading. Peric. none, except the permanent calyx. Stigma foliary, oblong, angular; down of five equal, linear, channelled scales, the length of the calyx, each terminating in a denes, oblong, pointed, spreading plume, about half as long as the scale. Recept. small, clothed with soft shaggy hairs.

1. T. luciariatum. Blue and White Triptilium. Willd. n. 3. (T. spinoiun; Cavan. MSS.) - Native of Peru and Chili. We received a specimen from the late abbé Cava- nilles in 1804. Few plants constitute a more distinct genus, or make a more elegant appearance, even after being in many years dried. The root is said to be annual. Herbage hard and rigid, besprenckled with fine, long, loose, rather copious, hairs. Stem round, slender, branched, corimboose, brown, very leafy. Leaves scattered, nearly or quite felse, spreading, about an inch long, pinnated, with three or five spinous-pointed, convexit forms; pales, and moss hairy, beneath; accompanied by short, axillary, leafy shoots, whose leaves are linear and undivides. Flowers numeros, in a denes, composed, level-topped, corimboose, leafy panicle. Calyx about one-third of an inch long; its scales slightly hairy, with membranous edges. Lower lip of each floret of a bright permanent blue; upper whitish. The feathery tips of the feed-down, nearly the length of the florets, are snow-white, and, contrasted with their fine blue, make a singularly elegant appearance. We have not heard of this plant in any European garden.

TRIPTIS, in Geography, a town of Saxony, in the circle of Neudalt; 4 miles E. of Neudalt. N. lat. 50° 29'. E. long. 11° 50'.

TRIPOLEMUS, in Mythology. See Ceres.

TRIPTOTES, compounded of tri, three, and choros, chef, in Grammar, defective nouns, which have only three cases; such is foris, fortis, forte; or dicem, dicam, dicea.

TRIPUDIUM, in Antiquity, a species of divination, in which omens were drawn from the rebounding of corn thrown to chickens.

TRIPUNETAIRE, in Geography, a town of Hindooftan; 35 miles E.N.E. of Cochín.

TRIPURA, a city often mentioned in the mythological relations of the Hindoos, as having been destroyed, together with its wicked sovereign Tareka, by their god Siva, who is hence called Tripuranteka, or the destroyer of Tripura. See Sura and Tareka.

TRIPURANITEKA, in Mythology, a name of the Hindoo god Siva, so called from a mythological relation of his having destroyed a city and tyrant named Tripura.

TRIPYRAMIDES, derived from tri, three, and pyram, a pyramid, in Natural History, the name of a genus of spars.

The bodies of this genus are spars composed of single pyramids, each of three sides, standing on no column, but affixed by their bases to some solid body.

Of this genus there are only two known species: 1. A short and thick one, found on the sides of the facks of stone in Northamptonshire, and elsewhere; but this is not common, and is usually small. 2. A long one with a narrow base: this is not found in England, but is common in the German mines. Hill.

TRIQUETRA Ossia, in Anatomy, the small irregular bones occasionally found between the regular bones of the cranium. See Cranium.

TRIQUETRUM Foliurn, among Botanists. See Leaf.

Eff. Ch. Calyx many-flowered, of two equal, awlnees valves. Spikelet two-ranked; two, or more, of the lowest florets perfect, the rest male, or neuter. Outer valve of the corolla with three terminal straight awns; inner awlnees. Nectary of two valves. Stigmas villous.

A genus of grasses found within the tropics, akin to the Triodia and Pappodorum of Mr. Brown, (see those articles); and therefore to his Ebroea, and the Chloris of Schwaert, which are said to be very little different from each other. The flowers are panicked. Two New Holland species, gathered by the learned author in the tropical part of that country, are all that occur in his Prodrus; nor does this genus find a place in Mr. Kunt's South American work. Probably however there may be East Indian species, unknown to us.

1. T. pupen. - Panicle loose. Outer valve of the corolla carious, minutely downy. Awns equal; the middle one simple. Leaves involute, spreading, straight.

2. T. mollis. - Panicle close. Outer valve of the corolla bearded with spreading hairs. Middle awn furnished at each side with a bristle-like appendage.

TRIEME, or Three-men, in Antiquity, a galley with three ranks of oars on a side. See Enneris.

TRISACRAMENTARIANS, or Triessacramen- tiarians, an appellation given to a sect in religion, who admit of three sacraments, and no more.

There have been several Triessacramentarians who allowed of baptism, the eucharist, and abfission for sacraments.

The English are often misinterpreted by foreigners as Tri- sacramentarians, from an opinion that they allow ordination to be a sacrament.

TRISACTIS, in Natural History, the name of a genus of tar-fat, composed of a body and three rays, the more usual number being five.

TRISAGA, in Geography, a town of Italy, in the Cadern; 14 miles N.N.E. of Cadore.
TRISAGION, or TRISAGIUM, τρισάγιον, compounded of τρίς, three, and αὐγίς, favūs, holy, in Church History, a hymn, in which the word holy is repeated three times.

The proper Trisagion is those words, Holy, Holy, Holy, Lord God of Sabaoth, which we read in Isaiah, vi. 3, and in the Apocalypse. From these words the church formed another trisagion, which is rehearsed in Latin and Greek, in the respective churches, to this effect, Holy God, Holy Mighty, Holy Immortal! have mercy upon us. Petrus Ful- lenius to this trisagion added, o θεός, εὐλογησε τοὺς, They who ought to be merciful — have mercy, &c. thus attributing the pailion, not to the Son alone, but to all the three persons of the Trinity; and he pronounced anathema to all such as would not say the same. See THEOFASCHITAE.

The use of the second trisagion (exclusive of the addition of Fullenus) began in the church of Constantinople, whence it passed into the other churches of the East, and afterwards into those of the West: and still subsists in its pristine purity, both in Latin, Greek, Ethiopic, and Mozarabic offices.

TRISAKTI, or TRISAKTI-DENI, in Hindoo Mythology, is a name of the goddess Parvati, consort of Siva. It means of triple energy; both god and goddess having various triform characters and potencies, and many names indicative of three-fold properties. Parvati is found to have many attributes and appellations corresponding with those of the Grecian Juno or Diana: among them several derived from their three-fold character. Triva, for instance; and by the way, the meeting or junction of roads was mysteriously sacred to both. See JUNCTION.

Tritonea, Tergemania, &c. are appellations of the Triple Hecate. See Potter's Archæol. Græc. ch. xix.

TRISANTHUS, in Botany, from τρίς, three, and αὖμος, a flower, because there are three flowers in one common calyx.—Lour. Cochin. 175.—Clois and order, Pentandria Dignum. Nat. Ord. Umbelliferae.

1. T. cochinichinifis. Rau mā of the Cochinichines. The only described species, frequent among hedges in Cochinchina, where, though an excelent herb, it is not cultivated. The author thought he had also met with this plant in China, as well as other parts of the East Indies; and he cites the Des cuspidatus of Rumphius, book 9. chap. 69. t. 169. f. 1, which is no other than Hydrocotyle diffusa of Linnaeus. They may be one and the same, as Lourêre was most inclined to believe. He describes his Trisantus with a long, trailing, slender, thread-shaped flower, taking root at nearly regular intervals. Leaves from the same points as the roots, roundish, concave, rugose, smooth, crenate, divided half way down, on long, erect stalks. German purple, which Lourêre takes for a perianth investing the seed, and becoming a pericarp. The flower-stalks are radical, crowded, rather long.

The whole plant is said to be vulnerary, cleansing, diuretic, and nephritic. Lourêre knew a man who, having deprived himself, at a stroke, of parts which most people with to prefer, healed the wound readily by the applica-

TRISCAEDACTILIS, in Natural History, a name given by Linkius, and some other authors, to a kind of branched star-fish, or astrophyte, whose rays are thirteen in number, where they first leave the body, and each divides into many more.

TRIS-DIAPIASON, TRIPLE-DIAPIASON, in Music, what is otherwise called a triple eighth.

TRISE, at Sea, the seamen's word for haling up of any thing with a dead-rope, or one that doth not run in a block, but is pulled by hand or by main strength: thus if any cask, cheif, or other goods, hath only a rope fastened to it, and so without a tackle be pulled up into a ship by hand, they say it is trisèd up.

TRISECTION, or TRISSECTION, the dividing of a thing into three.

The term is chiefly used in Geometry, for the division of an angle into three equal parts.

The trisection of an angle geometrically, is one of those great problems whose whole solution has been so much sought by mathematicians for two thousand years; being, in this respect, on a footing with the quadrature of the circle, and the duplicature of the cube angle.

Several late authors have written of the trisection of the angle, and pretend to have found out the demonstration of it; but they have all committed fallacies.

TRISTÈCE, the three-haired file, a term used by the writers in Natural History, to express a certain genus of the fetaeacae, or bristle-tailed files, which are distinguished from the rest, by having three hairs or bristles growing from the tail; there are several kinds of these files, found frequently among our hedges.

TRISTÈUM, in Botany, apparently so called because the corolla was supposed to have three awns, is a genus of grases, adopted by Parsh, Pl. Amer. Sept. 26 and 76, for which he cites Persoon's Enchorrhina, v. 1. 97, and gives the following essential character.

Calyx two or three-flowered, pointed, keeled. Corolla with two terminal awns, and a solitary dorsal one, which is straight, not twisted. Flutes smooth.

The only species mentioned by Mr. Parsh, is called T. pratense, and is said to be Avena flavescens of former authors.

If it be the European plant, so well known under that name, we can not indubitably aver that it does not answer to the above character, the corolla having two taper points, like many other grasses; but nothing like awns except the large solitary dorsal one, which is as certainly twilled as that of all other Avenae.

TRISÉUS, in Ichtyology, a name given by Salian, Benedictus Jobius, and others, to that species of the gadi which we call the eelpout, and authors in general the mytilis fluviatilis. See GADUS LATA.

TRISIRAS, in Hindoo Mythology, is the name of a dog appertaining to their god Yama, the regent of hell. This reminds us at once of the Cerberus of the Grecian Plato, the more particularly as the Hindoo dog is represented to be three-headed, which indeed is the literal translation of Triiras.

TRISMEGISTUS, derived from τρίς, three, and μεγαλ. great, an epithet, or surname, given to one of the two Hermes, or Mercuries, kings of Thebes, in Egypt, who was contemporary with Moses.

Mercury, or Hermes Trismegistus, is the latter of the
two Hermēs; the former having reigned about the time of the Deluge. They are both of them represented as authors of many of the arts and institutions of the Egyptians. See HERMES.

TRISMIS, or TROSMIS, in Ancient Geography, a town of Lower Macedonia, near the Danube. Ptol. This place is marked in Ant. Itin. on the route from Viminacium to Nicomedia, between Biren and Arrubium.

TRIMOS, τρίμος, or τρίγος, a convolution of the muscles of the temples, causing the teeth to gnash.

TRISOULYPIONICA, τρισούλυπιονικα, compounded of τρίς, three, ολυμπικα, Olympic games, and νικα, victory, among the Ancients, a person who had thrice borne away the prize at the Olympic games.

The trisoulypionica, or trisoulypiotics, had great privileges and honours allowed them. Statues were erected to them, of the kind called iconia, which were modelled to the size and form of their persons.

They were also exempted from all taxes and incumbrances, and could never be marked with infamy.

TRISPAST, TRISPASTON, compounded of τρίς, three, and πάστον, I draw, in Mechanic, a machine with three pulleys, or an amlangement of three pulleys, for raising great weights.

The trispaston is a species of polyptalon.

TRISPERMUM, in Pharmacy, the name of a catalpa, or poulique, confisting of three ingredients; these are cummin and opium seed, and bay-berrys.

TRISSA, in Ichthyology, a name used by some authors for the fish more commonly known by the name of alauna, and called in English shad, or the mother of herrings.

TRISSACRAMENTARIANS. See TRISSACRAMENTARIANS.

TRISSANTON Bay, in Geography. See Southampton.

TRISSARRI, a town of France, in the department of the Lower Pyrénées; 9 miles S.W. of St. Palais.

TRISSILD, a town of Norway, in the diocese of Aggerhus; 65 miles N. of Kongfanger.

TRISSINO, GIANGIORGIO, in Biography, an Italian poet, was descended from a noble lineage, and born in 1478 at Vicenza. In his youthful studies he was industrious and ardent. Besides the Latin and Greek languages, the latter of which he acquired under Demetrius Chalcondylas, he became a proficient in mathematics, physics, architecture, and other fine arts. He was employed in polls of truth and honour by the popes Leo X. and Clement VII., and he also received many tokens of distinction from the Venetian republic and his native city. He was twice married; and with both his wives he lived happily at Vicenza. But a law-suit, in which he engaged with the son of his first wife, obliged him to retire to Murano, near Venice, and having lost his caufe and a great part of his property, he went to Rome, where he died in 1550. Ambitious of being a poet, he cultivated an imitation of the ancients; and his tragedy of "Sofonisba," formed after the laws and manners of their drama, and the first in which verse without rhyme was employed, has been considered as the first Italian work of that class. This tragedy, framed by the author in 1515, was not printed till the year 1524. His next production was a comedy, intitled "Similimi," which was well received. But his great work, in which he was engaged for twenty years, was his epic poem, intitled "Italia Libera da Goti," the subject of which was the deliverance of Italy from the Goths in the reign of the emperor Justinian.

His model in the composition of this work was Homer, whom he fervently imitated, infomuch that, according to Voltaire, "he took every thing from him but his genius." The success of this poem by no means corresponded to his expectations. Of his other works, and his whimsical but ineffectual project of introducing certain Greek letters into the Italian alphabet, we need take no notice. Gen. Biog.

TRISTAN d'Acunha, in Geography, the largest of three islands in the South Atlantic ocean, about 1500 miles from any land either to the west or north, very lofty, and about 15 miles in circumference. A part of the island, for Ermans Gower observes, (quoting the author of the Authentic Account of the Embassy to China,) towards the north rises perpendicularly from the sea to a height apparent of 1000 feet, or more. A level then commences, forming what among seamen is termed table land, and extending towards the centre of the island; from whence a conical mountain rises, not unlike in appearance to the Peak of Teneriffe, as seen from the bay of Santa Cruz. Boats were sent to sound and examine the shore for a convenient place to land and water. In consequence of their report the Lion flood in, and came to anchor in the evening on the north side, in 30 fathoms water, one mile from the shore; the bottom black sand with flame; a small rock of the weft point bearing south-west by south, jut open with the western extremity of the island; a cascade or fall of water emptying itself upon the beach by eait. All the shore from the southern point to the eastern extremity appears to be clear of danger, and deep, except the weft point, where there are breakers about two cables' length, or near 500 yards, from the shore. The ship, when anchored, was overshadowed by the dark mafs of that portion of the island, whose fides seem to ride like a moos-grown wall immediately from the ocean. On the right the elevation was less rapid, and between the rising part and the fan was a flat of some extent, covered with fedge-grasfs, interperfed with small shrubs, which being perfecty green, looked from the ship like a pleafant meadow, watered by a stream that fell aftewards from its banks upon the beach. The officers who went ashore reported, that the caiks might be filled with fresh water by means of a long hose, without moving them from the boats. The landings-place thereabouts was alfo defcribed as being safe and superior to any other that had been examined. From the plain the land rofe gradually towards the central mountain, in ridges covered with trees of a moderate fize and height. The coast abounded with sea-lions and fells, penguins and albatrosses; one of the latter was brought on board, his wings measured ten feet from tip to tip; but others are said to have been found much larger. The coast was covered with a broad sea- weed feveral fathoms long, and defervedly by naturalifts termed gigantic fucus. Some good fish was caught with the hook and line. The accident of a sudden gulf, by which the anchor was in a few hours driven from its hold, and the ship forced out to sea, prevented the island from being explored as was intended. It is probable, that if the Lion had anchored in twenty infeed of thirty fathoms water, the anchor would have held firmly. Some advantage was obtained, however, from coming to this place. The juft position of thofe islands in refept to their longitude was ascertained, by the means of feveral time-pieces, to be about two degrees more eafterward than generally laid down in charts. Thofe islands are certainly worthy of a more particular enquiry; for they are not fifty leagues from the general track of veffels bound to China, and to the coast of Coromandel by the outer passage. In war-time, an excel lent rendezvous might be fettled there for ships that wanted no other supply than that of water. When circumstances require particular difpatch, it is prafticable to come from England to Triflan d'Acunha without flogging in
TRI

in the way, and afterwards to the end of the voyage to India or China. These islands are separated by a space of about 1500 miles from any land to the westward or northward of them. They are situated in that part of the southern hemisphere, in the neighbourhood of which a continent, to balance the quantity of land in the northern hemisphere, was once expected to be found; but where it has since been discovered that there is none. The spot where the Lion anchored was determined by good meridional observations, and by accurate time-pieces, to be in S. lat. 37°.

W. long. 15° 30'.

TRISTANIA, in Botany, from τρίσταν, three, and ἵππος, a horse; in allusion, as we presume, to the tertiary disposition of the flowers and their stalks; the three-foled inflorescence of this, doublef very different, genus, being strikingly different from all to which it is nearly allied in the parts of fructification.—Brown in Ait. Hort. Kew. v. 4. 417.

Gen. Ch. Cal. Perianth superior, of one leaf, turbinate, in five deep, triangular, nearly equal segments. Cor. Petals five, roundish, inserted into the rim of the calyx between its segments. Stam. Filaments numerous, in five sets, opposite to the petals, and about the same length, mostly paltry; anthers roundish, incumbent. Pfl. German inferior, turbinate, somewhat angular; lyle thread-shaped, about the length of the flaments; stigma obtuse. Peric. Capsule roundish, more or less completely coated, of three cells and three valves, the partitions from the centre of each valve. Seeds numerous, minute, angular.

Eff. Ch. Calyx superior, in five deep segments. Petals five. Stamens numerous, in five palmary parcels, opposite to the petals, and scarcely longer. Style one. Capsule of three cells.

This genus is selected from Melaleuca, (see that article,) whose character however may stand as it does, distinguished by the great length of its flaments. Our 4th, 5th, and 18th species belong to Tristania, with one more already published, and probably several others, known as yet to Mr. Brown alone, defined for the sequel of his Pro- drorus. All the true Melaleuca have perfectly selffie, generally crowded, flowers. Having already described the above three species, we shall here merely enumerate them, with the appropriate specific characters of Mr. Brown, as far as he has given any.

1. T. nigrofus. Oleander-leaved Tristania. Ait. n. 1. (Melaleuca nigrofus; Sims in Curt. Mag. t. 1058. M. ilicifolfa; Audry. Repof. t. 485.)—Leaves opposite, lanceolate, Stalks from three to five in each set.—Observed by Mr. Brown, in New South Wales, from whence its seeds were lent to England, about the year 1804, according to Mr. Aiton, who marks it as a greenhouse shrub, flowering from July to September. The flaments are much fewer than in any other species which has come to our knowledge, and their connexion at the base is but slight. The flavour of the plant is said to be bitterish and astringent, scarcely aromatic, in which it differs from the Melaleuca.

—Native of New Holland, near Endeavour river. Sir J. Banks. Not as yet introduced into our gardens.

3. T. laurina. Laurel-leaved Tristania. Ait. n. 2. (Mel- aleuca laurina; Sm. Tr. of Linn. Soc. v. 3. 6275. Wili. Sp. Pl. v. 3. 1429.)—Leaves alternate, obovato-lanceolate, zappering at the base. Calyx, flalks, and branches downy. Capsule half superior.—Gathered by admiral Phillip in New South Wales, and introduced, from feed, to Kew in 1798, by sir Joseph Banks. It is a greenhouse shrub, but has not yet flowered. After.

4. T. conferta. Pittosporum-leaved Tristania. Brown MSS. Ait. n. 3.—"Leaves alternate, elliptical, or some- what lanceolate, acute; the terminal ones crowd-d. Seg- ments of the calyx acute, leafy."—Found by Mr. Brown in New South Wales, and introduced at Kew in 1805. A greenhouse shrub, flowering from July to September.—We have seen no specimen of this last species, nor have we any account of the colour of its flowers, which are probably white, like those of the two immediately preceding.

TRISTE, in Geography, an island near the coast of Ame- rica, on the south side of the bay of Campeachy, situated on the west of Port Royal island, from which it is separated only by a narrow channel, about 18 miles in circumference. N. lat. 18° 20'.

TRISTE, a name given by the Spaniards to the gulf of Paria; which see. This gulf, according to Depons, is twenty-five leagues from E. to W., and fifteen from N. to S., and has anchorage in that whole extent, but its depth varies from eight to thirty fathoms. Upon the coast of Paria its foundings are much less. This gulf is, in fact, a real port, which for excellence and extent vies with the handomell in the world. It has a muddy bottom, except near the coast of Terra Firma, where are shoals and banks of sand. Its waters are as salt as those of the sea, though some have erroneously represented them as fresh. This gulf is difficult of entrance; and the wind must be from the S.E. to enter it with any prospect of safety. The tide is formidable, and has a violence inconceivable by those who are not well acquainted with the great ebbings and flowings of the sea.

TRISTEMMA, in Botany, from τρίσταν, three, and ψυχι, a crown, "because the fruit is surmounted by a triple permanent crown," a genus mentioned by De Theis, but without reference to any author, nor have we met with any indication of it elsewhere.

TRISTEN, in Geography, a town of Germany, in the county of Feldkirch; 11 miles S.S.W. of Feldkirch.

TRISTO, a word used by Paracelsus, to express what he calls the material fire, lodged in the matter of all the four elements, and exerting upon occasion its influence, under the form of the proper effects of each element.

TRISTONBOROUGH, in Geography, a town of Strafford county, in the State of New Hampshire, containing 709 inhabitants.

TRISTR, TRUSTRA, or TRJ aesthetics, in our old Law- Books, an immunity, by which a man is excused from attending on the lord of the forest, when he is disposed to chance within the forest; so that he cannot be compelled to hold a dog, follow the chase, nor stand at the place appointed, which otherwise he might be, under pain of amercement.

"Sint quiets, &c. de chevagio, homedenni, bucktel, et trifis, et de omnibus misericordias, &c." Privileg. de Sempingham.

TRISULA, in Hindoo Mythology, the name of one of the commonest attributes of the Hindoo deity Siva. In pictures of him, it is represented as a tridentated implement, similar to that seen in the hands of the Neptune of the West.

The seat of Hindoos who are Saivas, that is, exclusive worshippers of Siva as the deity, maintain that the Trisula is sym- bolical of his trial of powers; meaning that he comprims the whole of the powers of creation, preservation, and destruction. Others explain
explain the Trifula as allusive to Siva's supremacy over the three worlds; or earth, heaven, and hell; a mysterious triad, awefully indicated by the compound trivertical phrase Bhur-bhuvanayastr, of which see under the article O'm.

The word Trifula means, in the Sanscrit tongue, three-pointed. In the west of India, it is sometimes called triphala; and hence, connected with other coincidences, Mr. Wilford (Af. Ref. vol. iii.) considers the Jupiter Triphylius of the Panchaen islands to be no other than Siva holding a triphala; he being also represented with three eyes, to denote a triple energy; as Vifhnu and Prithvi are severally typified by an equilateral triangle, and conjointly, when their powers are suppos'd to be combined, by two such triangles intersecting each other. The mysterious properties of the triangle, or cone, with its apex upward or downward, and of two intersecting triangles, are noticed in our articles Linda, O'm, Farvati, Pavaka, Siva, Vishnu, and others thence referred to. The intersected equilateral triangles, mentioned by Mr. Wilford as typical of Vifhnu and Prithvi, have an allusion in natural philosophy to the influence of humidity on the earth; Vifhnu representing the aqueous principle of nature, and Prithvi the material, or the earth. (See Prithu and Vishnu.) Of the resemblance of Jupiter Triphylius, or Triopthalmos, with the three-eyed Siva, see under his name of Trilokan, which means with three eyes. Trireta has also a similar meaning.

Trisuli, a name of the Hindoo deity Siva. He is so called from bearing the symbol Trifula, or trident. See Trisula.

Trisyllable, Trissyllable, in Grammar, a word consisting of three syllables.

Tritea, in Ancient Geography, a town of Achaia, in the southern part, on the river Melas; said to be founded by Menalippus, son of Trittia, a priest of Minerva, in consequence of her amours with the god Mars. The principal temple of this city was that of the greater gods, who were annually honoured by feasts similar to those of Bacchus. The statue of Minerva, which was reckoned beautiful, was transported from hence to Rome. This town was one of those which Augustus put into a state of dependence upon Patras.

Tritéophys, a word used by the medical writers of the ancients, to express a kind of fever, much of the nature of the tertian, and taking its rise from it.

Tríteny, in Geography, a town of Hindostan, in the Carnatic; 16 miles S. of Bombaurezzapollam.

Tritchingode, a town of Hindostan, in Miyore; 6 miles S. of Sankerdurgam.

Tritchinopoly, a town of Hindostan, in the Carnatic. It is surrounded with two walls, flanked with towers, and encompassed with a ditch. It was taken by the British under major-general Lawrence and captain (afterwards lord) Clive, in 1751, and since that time it has been made the capital of Madura; 67 miles W. of Tranquebar. N. lat. 10° 48'. E. long. 78° 45'.

Trite, in Music, the third musical chord in the system of the ancients. There are three triads under this denomination in the ancient diagram, viz. the trite hyperboleon, trite diezengemonon, and trite synemonon. This chord of the ancient tetrachord was so named from its being the third from the note; and hence we might call it the anti-penultimate. It was otherwise, in some tetrachords, called parypate. See Diagram and Interval.

Trite Diezengemonon, in the Greek Music, was the anti-penultimate note of the diezengemonon tetrachord, and answers to Guido's c, fa, fa, ut.

Trite Hyperboleon, was the anti-penultimate note of the hyperboleon tetrachord, and answers to Guido's f, fa, ut.

Trite Synemonon, was the anti-penultimate note of the synemonon tetrachord, and answers to Guido's b, fa, ut.

Tritéa, or Triflua, in Ancient Geography, a town of Asia, in the Troad.

Tritheism, the opinion of the Triteists, or the heresy of believing three Gods.

Tritheism consists in admitting not only of three persons in the Godhead; but of three substances, three essences or hypostases, and indeed three Gods.

Several people, out of fear of giving into Triteism, have become Sabellians; and several others, to avoid Sabellianism, have commenced Triteists; so delicate and subtle is the distinction.

In the famous controversy between Dr. South and Dr. Sherlock, the first is judged to have run into Sabellianism, by a too rigorous assertion of the unity of the Godhead; and the latter into Triteism, by a too absolute maintaining of the Trinity.

John the Grammian, a named Philoponus, lover of labour, is held the author of the sect of the Triteists, under the emperor Phocas; at least it appears that he was a zealous advocate of it.

The chief of this sect, according to Mohheim, Eccl. Hist. vol. i. was John Aecusnaghe, a Syrian philosopher, and a Monophysite. He imagined in the Deity three natures or substances, absolutely equal in all respects, and joined together by no common essence.

Tritheism, in Church History, a name given to such heretics, as admit not only of three persons, but of three distinct substances and natures, in the Holy Trinity. See Trinity and Tritheism.

Trithemius, John, Abbot, in Biography, was born in the year 1442, at the village of Trittenheim, near Treves, whence he took his name. Having finished his course of education in the universities of Treves and Heidelberg, he was chosen abbot of the Benedictine monastery of Spanheim in 1483, which he superintended for twenty-two years, and when he withdrew from it in consequence of a faction of the monks, he was placed by the bishop of Wurzburg at the head of a monastery in that city, where he died in 1518, at the age of seventy-six. "Trithemius," says one of his biographers, "was a person of vaft erudition, a philosopher, mathematician, chemist, poet, historian, and divine, and conversant in the Hebrew, Greek, and Latin languages." His works, written in Latin, are numerous, but those in biography and history are held in the highest estimation. His writings on piety and morality chiefly relate to the monastic and facerdotal life, miracles of saints, and such topics. His philosophy bore the mystic character of the age in which he lived. His "Steganographie, or the Art of writing in Cyphers," containing some singular characters ignorantly taken for talismans, subjected him very unjustly to the charge of magic. Upon the whole, "he appears to have been a person whose great learning was considerately tinctured with credulity, and whose industry was superior to his judgment." Dupin. Gen. Biog.

Trithing. See Trinling.

Triticum, in Botany, an old Latin name, very factitious, but derived, by Varro himself, from tritum, ground or rubbed, because of the manner in which its grain is prepared for the food of mankind. Wheat, or Wheat-grafs. Linn. Gen.
TRITICUM.

Gen. Ch. Col. Common receptacle zigzag, toothed, elongated into a spike. Glume tranverse, containing about one or more flowers, and confiding of two ovate, bluntish, concave valves. Cor. of two nearly equal valves, the fize of the calyx; the outermost tumid, obtuse with a point, orawn; the inner flat. Sted of two acute scales, gibbous at the base. Stam. Filaments three, capillary; anthers pendulous, oblong, clonied at each end. Pfijt. Cernua inferior, turbinate; styles two, capillary, reflexed; sigmas feathery. Peric. none, the corolla embracing the feed till it is full-grown and ripe, then letting it go. Seed solitary, ovate-oblong, blunt at each end, convex at the outer side, marked with a longitudinal furrow on the inner.

Eff. Ch. Calyx of two valves, solitary, tranverse, many-flowered, on a zigzag, toothed receptacle.

We have already adverted to the difficulty of distinguishing this genus from Secale; see that article. They both agree in the tranverse, or lateral, position of their bivalve calyx, by which position the side of each spikelet is parallel to the common receptacle, not, as in Lolium, contrary. The greater number of fpecies in Triticum, which are only two in Secale, is the only technical diftinction. The outer valve of the corolla of the present genus is often terminated by a long awn; but this appendage varies, even in the same species.

Section 1. Root annual.

1. T. aegyptium. Summer Wheat. Linn. Sp. Pl. 126. Wildl. n. 1. Ait. n. 1. Bauh. Pin. 21. ("T. aegyptium; Blackw. Herb. t. 40. f. 4. 5.");—"T. loculicis quadrifloris, bufi subfuscinis, glumis exteriouribus floribus arisatis; Hall. in Com. Nov. Goett. v. 5. t. 1. f. 1.")—Calyx four-flowered, tumid, smooth, imbricated, awned.—Supposed to be a native of Siberia. It is known in the spring, and produces a speedy but uncertain crop. We have never seen an authentic specimen, nor are we at all certain that what has generally been taken for this species is anything more than a variety of the following.

2. T. hybrida. Winter, or Lammas, Wheat. Common Cultivated Wheat. Linn. Sp. Pl. 126. Wildl. n. 2. Ait. n. 2. Ehrl. Pl. Off. n. 151. Gurtz. f. 1. (T. vulgare; Hoff. Gram. Aufr. v. 3. 13. t. 26. T. hybrida, arisitas carenas; Tourn. Infl. 512. t. 292. T. epica mutica; Ger. Em. 65. Silico epica mutica; Lob. 19. 2.)—Calyx four-flowered, tumid, even, imbricated, abrupt, with a short comprefted point.—Native country unknown. Cultivated in various parts of the world; being fown in autumn, it flands the winter, and ripens feed in the following fimmer, so that it may be reckoned a biennial. The root consists of downy fibres. Stem one or more, erect, straight, from three to five feet high, round, jointed, smooth, leafy. Leaves linear, pointed, flat, many-rilled, rough, entire, rather glaucous. Stipula jagged, bearded. Spike solitary, two or three inches long, dense, two-ranked, smooth, joints of the common flach or line. Glumes smooth. Calyx in the upper part of the spike with a more elongated point. Corolla of the upper spikelets frequently more or less awned.

Under this most important and familiar species are comprehended a great number of varieties, the knowledge and history of which are more peculiarly the province of the agriculturalist, and will be treated of under the article Wheat. By the botanist they have not been sufficiently investigated, either as varieties or species. Some of them appear entitled to the latter denomination; particularly the White Wheat, T. album, Gurtz. f. 2, which is orbiculate calyx, and the long awns of its corolla, seem to indicate a specific difference. This last character indeed occurs in many of them; see Tourn. t. 293. Some of the reputed species of Linnæus are less decisively marked. The determination of these points, with the respective qualities of each species or variety, might very advantageously occupy the attention of some accurate rustic botanist, continually on the spot, by whose labours the question might be set for ever at rest, and probably a moft important service rendered to scientific agriculture. Not to embroil the subject, we shall not, with insufficient materials, enter upon it.

3. T. compositum. Many-spike Wheat. Linn. Suppl. 115. Willd. n. 3. (T. epica multiplex; Bauh. Pin. 21. Ger. Em. 66. Moriz. leef. 8. t. 1. f. 7.)—Spice compound; spikelets crowded. Corolla awned—Native of Egypt; cultivated at Naples. The glumes are smooth. Awns three or four inches long. This is probably a variety of the last, rather than, as Linnæus says, of T. aegyptium.

5. T. polonicum. Polish Wheat. Linn. Sp. Pl. 127. Willd. n. 5. Ait. n. 4. Hoff Gram. Aufr. v. 3. 21. t. 31. Pluck. Phyt. 231. f. 6. Moriz. leef. 8. t. 1. f. 8.—Calyx three or four-flowered, pointed, naked, lanceolate like the corolla, which is comprefted, with a long awn. The native country of this likewife is unknown. It was cultivated here in the latter part of the seventeenth century, for curiosities at leaft, and is still seen in botanic gardens, though not much regarded by the farmer, being easily laid by rain. That this is a different species there can be no doubt. The strength of the whole plant, its large ears, and long, narrow, scarcely tumid glumes, readily distinguish it at first sight. Linnæus defines this Triticum as having a two-flowered calyx, the character of Secale; but Haller afferts the presence of one, if not two, imperfect fpecies.

6. T. spelta. Spelt Wheat. Linn. Sp. Pl. 127. Willd. n. 6. Ait. n. 5. Ehrl. Pl. Off. 431. Hoff Gram. Aufr. v. 3. 21. t. 30. (Zen dicoccus five major; Bauh. Theatr. 472. t. 413. Z. epica mutica dicoccus, vel major; Moriz. leef. 8. t. 6. f. 1.)—Calyx imperfectly four-flowered, elliptical, obliquely pointed, shorter than the long-awned corolla.—The origin of this species is likewise unknown, nor is its specific character satisfactory. The glumes are very glaucous. It is chiefly cultivated in the fouth of Europe, and is given to horfes in Spain, when barren is scarce. The bread it makes is of a dry quality, but no kind of flour is better for pastry.

7. T. monocolococcos. Single-grained Wheat, or St. Peter's Corn. Linn. Sp. Pl. 127. Wildl. n. 7. Ait. n. 6. Ehrl. Pl. Select. n. 33. Hoff Gram. Aufr. v. 3. 22. t. 32. (Zen epica barbata, &c.; Moriz. leef. 8. t. 6. f. 2. Briza monocolo; Ger. Em. 73.)—Calyx angular, strongly toothed, about three-flowered. First fcore awned; intermediate one imperfect.—Native country unknown. This species is cultivated in the most mountainous parts of Switzerland.
Switzerland. The next quadrangular form of the ripe ear, as if carved out of ivory, is remarkable. The spike is hard and firm, excellent for thatching. Flower rather better than that of the preceding, making good, though not white, bread, and chiefly esteemed for gruel.

8. T. prostratum. Trailing Wheat-grafs. Linn. Sp. Suppl. 114. Willd. n. 9. Ait. n. 7. (T. pumilum; Linn. Sp. Suppl. 115. Willd. n. 10. Secale prostratum; Pallas It. v. 1. 485. Jacq. Hort. Vind. v. 3. 25 t. 44.)—Spike ovate, compressed, two-ranked. Glumes of the calyx and corolla strongly keeled, longer than their awns.—Found by Pallas in the most barren sandy and stony desert near the Caspian sea. M. Thouin, in 1780, sent seeds to Kew garden. A hardy annual, flowering in June. The spikes sometimes fall off entire, and vegetate in the sand, producing a tuft of decumbent slender plants, from three to six inches long, with narrow, finely downy, leaves. Spike solitary, terminal, from half to three-quarters of an inch long, smooth, elegantly two-ranked, with ten or twelve closely imbricated, furrowed, incurved spikelets. Awns of the calyx awl-shaped, nearly as long as those of the corolla, being about a quarter the length of the glumes. T. pumilum of Linnaeus is the very rare species, described twice over.

9. T. tenellum. Dwarf Wheat-grafs. Linn. Sp. Pl. 127. Willd. n. 15. Ait. n. 11. (T. n. 1430; Hall. Hift. v. 2. 212, most certainly according to Mr. Davall. Gramen loliaceum minus, piccis simplici; Bauh. Fl. Pin. n. 35. Prodr. 19.)—Spike simple, linear. Spikelets alternate, elliptic-lanceolate, awnless. Calyx furrowed. Corolla even, emarginate. Leaves bristle-shaped.—Native of Switzerland, and the south of France. Root annual, of a few woolly fibres. Stem one or more, erect, straight, from four to eighteen inches high, scarcely branched, leafy, with several dark-brown joints. Leaves short, slender, erect. Spike terminal, solitary, erect, very slender. Spikelets more or less diffus, erect, close-preferred, rather turgid, smooth. Florets from four to eight or ten, polished, somewhat cylindrical, pale and blunt at the tip, with light indications of lateral ribs. We can meet with no certain figure of this very distinct species, under which, as Schrader remarks in Fl. Germ. v. 1. 346, Linnaeus has confounded several different things. Gramen paeulum unicaule, paniculæ loliacæ; Bocc. Muf. 69. t. 57, quoted by him for the following, is most like T. tenellum, and may perhaps be intended for it.

10. T. unilaterale. Unilateral Wheat-grafs. Linn. Mant. 35, excluding certainly the first two synonyms, and probably the third; see the preceding species. Wild. n. 18. (G. loliaceum minus, piccis tenuissimis; Morif. sect. 8. t. 2. f. 3.)—Spike simple, linear. Spikelets alternate, close, turned to one side. Calyx unequal, taper-pointed. Corolla short-awned, smooth. Native of Italy, Syria, and the south of France. Root annual, of many capillary fibres, partly downy. Stem numerous, a span high, finely branched, smooth, leafy. Leaves narrow, channelled, ribbed; their sheaths long, furrowed, sometimes clothed with very short, soft, deflexed hairs. Spike solitary, long, slender, a little curved, of numerous, rather close spikelets, half the size of the foregoing, and less turgid. Florets three or four, awl-shaped, with bristly awns of various lengths, but scarcely above half so long as the glumes.

This appears to us a mere variety of the last, with downy glumes, and longer awns to the florets. Loefling’s specimens are of humbler growth than those of the preceding that have in general fallen under our inspection, but there is no specific difference between them.

12. T. maritimum. Sea Wheat-grafs. Linn. Sp. Pl. 128. Willd. n. 14. Vahl Symb. v. 2. 26. (Gramen loliaceum paniculæ ramosa, maritimum; Bauh. Theatr. 130. Scheuchz. Agroft. 274. t. 6. f. 5.)—Spikelets panicled. Spikelets many-flowered, compressed. Florets linear-flakeolate, ribbed, pointed, awnless. Stem branched.—Native of the sea-coasts of the south of France, Greece, and Egypt. Root annual, of many woolly fibres. Stems branched from the base, leafy, a foot high, more or less bent at the joints, and partly decumbent; often purplish, as well as the sheaths of the leaves, and branches of the panicule. Leaves longish and tapering, narrow, flattened, smooth. Sheaths broader than the leaves, but much shorter. Stipula membranous, torn, decurrent. Panicle about three inches long, forked, with many spreading, spiked, triangular, smooth branches. Spikelets alternate, slightly flaked, half an inch long, smooth, of about eight crowded florets, each strongly keeled, and acutely pointed, smooth, with a strong marginal rib at each side. Calyx-calvus furrowed, nearly equal. Some synonyms referred to this, belong to the following. That of Boccione, t. 95, is at least doubtful.

13. T. loliaceum. Dwarf Sea Wheat-grafs. Fl. Brit. n. 4. Engl. Bot. t. 221. Willd. n. 17. Knapp t. 114. Gramen pumilum, loliaceum simile; Rall. Syn. 295. G. loliaceum exile durium; Sm. Rel. Rudb. 13. G. exile durifculum maritimum, foliolis circumsulatis, velutiniuncibus, brevibus; Pluk. Phyt. t. 32. f. 7. G. parvum marium, piccis loliacæ; Morif. sect. 8. t. 2. f. 6.)—Spike mostly simple, unilateral. Spikelets many-flowered, compressed. Florets elliptical, oblong, awnless, with marginal ribs. Stem branched.—Native of the sandy sea-beach, on the east and south coasts of England, as well as in Italy. We have it from a Piedmontese botanist, under the name of T. unilaterale. Root annual. Stems rigid, spreading, smooth, from three to five inches high. Leaves tapering; involute when dry. Spike erect, mostly simple, linear, rigid, of from nine to twelve alternate, slightly flaked, two-ranked spikelets, turned most to one side; in very luxuriant, or cultivated, specimens the lower part of the spike is branched. This plant is very nearly allied to Poa rigidus, nor is the position of their spikelets dissimilar. It serves however to connect our last species of Triticum with the following one.

Section 2. Root perennial.

TRI

lis pungentibus, nofras; Pluk. Phyt. t. 33. f. 4. G. anguilli-sixium, spicis tritici, mattice finili; Bauh. Prodr. t. 17. Morif. feet. 8. t. 1. f. 5.—Calyx abrupt, five-flowered. Leaves involute, sharp-pointed. Root creeping.—Found abundantly on the loose sands of the sea-coast, throughout Europe, flowering in July. The long (ringly tough roots fixed by woolly fibres, co-operate with Carex arenaria, Elymus arenarius, &c. in fixing the sand, and forming a barrier against the encroachments of the ocean. The whole plant is very glaucous, hard and rigid, with spinous-pointed leaves, strongly furrowed on their upper side. The stems are two feet high, often tinged with violet in the lower part, and very smooth. Spikes solitary, simple, compressed, stiff, of several alternate, flat spikelets, quite smooth and awl-like. Calyx many-ribbed, July. Schrad. Germ. v. t. 392.

17. T. renfis. Creeping Wheat-grafs. Conch-grafs. Linn. Sp. Pl. 128. Willd. n. 13. Fl. Brit. n. 2. Engl. Bot. t. 909. Leers t. 12. f. 3. Knapp t. 111. Mart. Ruff. t. 124. Dan. t. 748. Schreb. Gram. part 2. t. 25. (Gramen canum vulgatius; Morif. feet. 8. t. 1. f. 8.)—Calyx awl-shaped, many-ribbed, five-flowered. Florets pointed. Leaves flat. Root creeping.—But too common throughout Europe, in all kinds of cultivated ground, flowering in summer and autumn. The long and deeply creeping roots are of all things most difficult to exterminate. Yet when collected in sufficient quantity, they afford wholesome nourishment for cattle, and in some countries have been made into bread in times of scarcity. The stems are two feet high, slender. Herbage green, except in a maritime variety, the y of Fl. Brit. T. juncum of Relhan, T. intermedium of Holft Gram. auct. v. 2. 23, which is glaucous, with pubescent leaves, and possibly deliquescent to rank as a separate species. The leaves of our common kind spread horizontally, often all to one side, by which this species becomes conspicuous among bushes or hedges in autumn. Spikes two or three inches long, much smaller in every part than those of T. juncum. Florets from five to eight, either linear, pointed, or furnished with awns, which vary in length, but are scarcely equal to the glumes.

19. T. crifitatum. Crefted Wheat-grafs. Schreb. Gram. tafe. 2. t. 23. f. 2. Sm. Compend. ed. 2. 27. Engl. Bot. t. 2267. (Bromus critalutus; Linn. Sp. Pl. 115. Willd. Sp. Pl. v. 1. 439. Festuca culmo spicato, spiculis multihoris; Gmel. Sib. v. t. 11. t. 23. Gramen triticum, spicis latiore comparatæ; Buxb. Cent. t. 32. t. 50. f. 3.)—Calyx elliptical, awned, keeled, obscurely ribbed. Florets awned. Spikelets closely imbricated, two-ranked, defiined, straight. Stems simple.—Common in Siberia and Tartary. The late Mr. George Don discovered it on steep banks and rocks, by the sea-side in Scotland, between Arbroath and Montrose, flowering very sparingly. The roots are perennial, with very long, strong, woolly fibres, defined to grow in sand. Stems twelve or eighteen inches high, ascending, slender, rigid, leafy; hairy at the top. Leaves linear, shortish, sometimes hairy; their theae long and stiff. Spike elliptic-oblong, very close, pale, most resembling T. proliferum, n. 8, but longer, and differing essentially in the lateral ribs of the calyx-glumes, which are obsolete, or smoothed away, not turgid and curved. That these two grusses most belong to one and the same genus, is evident to the most casual observer.

21. T. foliwm. Rough New-Holland Wheat-grafs. Brown n. t. (Festuca scabra; Labill. Nov. Holl. v. 1. 22. t. 26.)—Spikes elongated, lax. Calyx lanceolate, ribbed, pointed, many-flowered, half the length of the corolla. Florets rough, taper-pointed, shorter than their awns. Leaves flat, rough, with smooth sheaths.—Native of New South Wales, and the Cape of Van Diemen. Root apparently perennial, with thick downy fibres, not creeping. Stems slender, erect, eighteen inches high, smooth. Leaves narrow, hairy. Florets from five to ten, in thefele, alternate, rather distant, upright, oblong, spikelike, from an inch to an inch and half in length.

22. T. petinatum. Petiñate New-Holland Wheat-grafs. Brown n. 2. (Festuca petinata; Labill. Nov. Holl. v. 1. 21. t. 25.)—Spikelets two-ranked, horizontally disarrayed. Calyx awl-shaped, pointed, about six-flowered. Awns shorter than the florets. Leaves flat, ciliated.—Found by Labillardiere, in the island of Van Diemen. The root is fibrous, presumed to be perennial. Stems numerous, tufted, erect, simple, a foot or more in height; leafy below; downy upwards. Leaves narrow, spreading, hairy and fringed, acutely pointed. Spike solitary, erect, ovate-oblong, flat, two-ranked, two or three inches in length, of a dozen or more alternate, rather crowded,形成 spikelets, each near an inch long, which in the flowering season spread horizontally, but subsequently become reflexed. The calyx-glumes are slender, somewhat unequal, pointed, but not awned, rather shorter than the florets, which are rough, ribbed, and furnished with straight awns, whose length, however, is less than that of each corresponding glume. The inner valve of the corolla is elliptic-lanceolate, fringed with hairs.

TRITNU, or TRITVNU, in Hindoo Mythology, a name of Surya, the Hindoo regent of the sun. The word means three-bodied. See SURYA and TRIMURTI.

TRITOMA, in Botany, so named by Mr. Ker, late Gawler, from τρίτομα, three, and τιμορτος, to cut, whence comes the adjective τριτομάτος, cut, or fit for cutting; in allusion to the three sharp angles of the leaves. — Ker in Curt. Mag. Vol. XXXVI. Q 744.
TRI

44. Dryandr. in Ait. Hort. Kew. v. 2. 290.—Clas
and order, Hexandra Monogynia. Nat. Ord. Coran

Gen. Ch. Cat. nonc. Cor. of one petal, inferior, cy
lindrical, even, with fixed shallow, regular, marginal teeth. Stam.
Filaments fixed, inserted into the receptacle, thread-
shaped, simple, straight, projecting beyond the corolla, three alternate ones
longer than the rest; anthers roundish, two-lobed. Pist. Germin superior, roundish; style of
the shape and length of the longer filaments; stigma acute, some
what downy. Peric. Capsule ovate, bluntly triangular, of
three rather rigid valves, and three cells. Seeds numerous,
smooth, crowded, in two rows, angular.

Eff. Ch. Corolla tubular, of one petal, with fixed mar
ginal teeth. Stamens prominent, straight, inserted into the
receptacle; three intermediate ones longest. Capsule ovate,
of three cells, with many angular smooth seeds.

The present genus is well distinguished from Aletris, as
well as from the Veltheimia of some botanists; being, as
its author observes, nearer in character to Aloe; from which,
however, it differs greatly in its less succulent habit, and
more absolutely monopetalous corolla; but especially in
the long, prominent, unequal, straight, not ascending,
filaments, and more firm, or harder, capsule. The insertion
of the filaments into the receptacle, not into any part of
the corolla, to say nothing of other characters, or of the
different habit, essentially distinguishes this from the two
other above-mentioned genera. (See all in their proper places.)
When habit functions such a division of genera, we mut,
especially in a very natural order of plants, like the present,
be content with technical characters which might otherwise
is distinguished from all the above by its brilly feed, im
bricated upwards, in a prismatic capsule.

v. 2. 182. Aloe Uvaria; Linn. Sp. Pl. 460. A. afr
icana, folio triangulari longifimo et angustifumo, floribus
luteis festis; Commel. Hort. v. 2. 29. t. 15.)—Leaves
rough with minute prickles on the edges and keel. Corolla
cylindrical-clubshaped.—Native of the Cape of Good
Hope. Cultivated in Chelsea garden at the beginning of
the 18th century. The plant is almost perfectly hardy in
our climate, flowering in the open ground in August or
September, only requiring a moderate protection from se
vere frost. The root is tuberous, perennial, tufted, bearing
plenty of long, tapering, deep-green, three-edged leaves.
Stems three feet high, round, stout, nearly naked, each
bearing a dense clustcr of very numerous, but short-lived,
dropping flowers, richly coloured with orange and scarlet.
Corolla above an inch long. Stamens yellow.

Mag. t. 744. Ait. n. 2. Redout. Lilac. t. 161. (Ale
tris fermentofa; Andr. Repof. t. 54.)—Leaves smooth at
the edges and keel. Corolla cylindrical-clubshaped.—Native
of the Cape of Good Hope, from whence it is said to have
been introduced in 1780, by Mr. Williams, nursery-man,
of Turnham Green. As hardy as the last, but flowering
either in winter or the early spring, so that a frame, or
greenhouse, is requisite to have it in perfection. It is
smaller than the preceding, with a glaucous tinge on the
leaves, whose edges and keel are perfectly smooth. Stems
a foot and half or two feet high. Flowers sometimes
elegantly tipped with green.

n. 3. Curt. Mag. t. 764. (Veltheimia punica; Willd.
Sp. Pl. v. 2. 182.)—Leaves two-ranked, roughish at the edges and keel. Corolla cylindrical at the base; bell-shaped
above.—Native of the Cape, from whence it was sent by
Mr. Maffon to Kew, in 1774. It flowers late in autumn,
and seems as hardy as the others, but is smaller than even
the last. The flowers are of a uniform orange, and distigu
ished by their bell-shaped, or globose, limb. Leaves not
at all glaucous.

TRITOMA, in Entomology, a genus of the Coleoptera
order of insects; the characters of which are, that the
antennae are elevated or club-shaped, the club being perfolate,
and the anterior palpi or fkrkers hatchet-formed. It has
seven species, as follow.

BIPUSTULATUM. Black, with wing-sheaths marked by
a scarlet lateral spot. Found in England.

GLABRUM. Smooth, black, with pitchy antennae
and feet. Found in Sweden.

DUBIUM. Black, with wing-sheaths and feet tesselaceous.

VITTATUM. Red, with black wing-sheaths; fillet red.
Found in India.

MORBIS. Black, filky, with antennae and feet of the
same colour.

SERICEUM. Blackish, filky, with feet tesselaceous. Found
in Germany.

COLLARE. Black, with the sides of the thorax and ab
domen red. Found in New Holland.

TRITON, in Ancient Geography, a marsh of Africa
Propria, in which is the source of a river of the fame name;
summered by Pliny Pallantius. This lake was 20 leagues in
length from E. to W., and about six leagues wide; and it
contained several islets. The mouth of the river was in the
Meditteranean, in the gulf of the Lesser Syrtis. Herodotus
mentions this river.—Alf, a river of the ile of Crete.
Near its source was a temple, dedicated to Minerva Trito
genia.—Alf, a town of Africa, in Libya.—Alf, a town of
Greece, in Boeotia.

TRITON, in Mythology, a sea demi-god, held by the an
cients to be an officer, or trumpet, of Neptune, attending
on him, and carrying his orders and commands from sea
to sea.

The poets and painters represent him as half man, half
fish, terminating in a dolphin's tail, and bearing in one hand
a sea-shell, which ferved him as a trumpet.

Some of the ancients make him the son of Neptune, and
the nymph Salacia; Hesiod, of Neptune and Amphitrite:
Numenius, in his book De Pificationibus, makes him the
son of Oceanus and Tethys; and Lycothron, the son of
Nereus.

But though Hesiod and the mythologists only speak of
one Triton, the poets have imagined several; giving some
of them for trumpeters to all the sea-gods, particularly
to Neptune and Venus; accordingly they were frequently in
troduced on the ancient theatre, and in the naumachia.

In effect, the Tritons not only officiated as trumpeters in
Neptune's retinue, but were also supposed to draw his chariot,
i.e. the sea-shell in which he rode over the waters:
as we find in Virgil, Æneid, x. 209; Ovid, Metam. l. 10.
333; and on a medal of Claudius.

The fable of the Tritons, no doubt, took its rife from
what are called the sea-men, or mermen; for that there are
such things as sea-men has been believed in many ages. See
Marmaid and Sea-Cow.

The poets ordinarily attribute to Triton the office of calming
the waves, and of making tempefts cease. Thus, in the
first of the Metamorphoses, we read that Neptune, defiring
to
TRI

to recall the waters of the deluge, commanded Triton to
found his trumpet, at the noise of which the waters all
retired.

Thus Ovid:

"Caruleum Tritona vocat, conchaque sonanti
Inspirare jubet, fluituque et flumina signo
Jam revocare dato," &c.

And Virgil:

"Huc venit immanis Triton, et carulea concha
Exterrens freta: cui laterum tenus hispida nanti
Frons hominem prefert, in Prtin definit alvus."

Of Triton, as connected with the Argonautic expedition,
Herodotus gives the following account. Speaking of the
river Triton, which discharged itself into the lake
Tritonic, where was an island called Phla, he says it was believed
that the island must have been inhabited by the Lacedemonians;
and he adds, it was reported by tradition, that when Jason
had built at the foot of mount Pelion the ship which was
called Argo (see ARGONAUTIC), and had flowed in it a
beaumont, and a tripod of brafs, he undertook the voyage to
Delphi by the tour of Peneus creating; and that, taking his
route by the promontory of Malea, the north wind drove
him upon Libya, where he found his ship run aground in the
lake Tritonic; and while he was endeavouring to extricate
himself, a Triton appeared to him, and told him, that
if he would give him the tripod he had in his ship, he would
show him how to get clear of this danger; upon which Jason,
agreeing to the proposal, gave him the tripod, which the
Triton laid up in his temple, and foretold Jason and his crew,
that when one of their descendants should carry off
that tripod, it was fixed by fate that there should be one
hundred Greek towns built upon the lake Tritonic; in fine,
that the Libyans being informed of this oracle, kept the
tripod carefully concealed. The explication given of this
fable is, that the Triton who appeared to the voyagers
under a human form was a prince who reigned in that place,
whom Pindar and his chofistait name Eurypilus. He gave
good instructions to the heroes to avoid the fund-banks
which lie in and about the Syrtis. This, says Banier, is the
whole mythology; the prediction which they put in his mouth
having only been invented after the event; that is, after the
Greeks were settled in that part of Africa, and had built
cities there. Our heroes, in gratitude for the signal service
done them by Eurypilus, made him a present of the above-
mentioned tripod. Diodorus, who also speaks of it, says
there was upon the tripod an inscription in very ancient char-
acters, and adds, that it was preferred to the latest times,
among the people called Hesperians, in Cyrenaicum.

TRITON, in the Linnean System of Natural History, a
genus of the Mollufca order of worms; the characters of
which are, that the body is oblong, the tongue spiral, the
tentacula twelve in number, and bipartite, fix on each side,
and the three hinder ones cheliferous. There is one species,
viz. T. tibitores, which is found in the cliefs of submarine
rocks.

TRITON Avis, in Ornithology, a name under which Nie-
remberg has described a bird of the West Indies, famous for
its fine ringing, and found in Hispaniola: it is said to have
three different notes, and to be able to give breath to sounds
of all three kinds at the same time: it is also said to be a
very beautiful bird. Ray.

TRITONEA, or TRITONIA, in Mythology, a name
given to Minerva, derived from the river Triton, near which
she was born, and where she had been seen for the first

TRITONIA, in Botany, was so named by Mr. Ker,
later Gawler, from triton, a weather-cock, in allusion to the
variable direction of the flames of the different species.
Mr. Ker in Sims and Konig's Ann. of Bot. v. 1. 227.
Dryand, in Ait. Hort. Kew. v. 1. 90.—Clus and order, Tritonia
Gen. Ch. Cal. Spatia inferior, shorter than the corolla,
of two oblong, membranous, pointed or toothed valves.
Cor. of one petal, superior; tubular at the base; flurcking
in the throat; limb divided to its very bottom into fix,
regularly equal, segments, each of which, in the
lower part, is more or less contracted into a claw.
Stam. Filaments three, inserted into the tube, unconnected
with the throat, variously directed, curved, shorter than
the limb; anthers oblong, curved. Pfl. Gemen roundish;
style thread-shaped, erect; stigma three, linear, recurved,
spreading. Peric. Capsule roundish-ovate, membranous,
tumid, of three cells and three valves. Seds numerous,
globose, simple, neither winged nor pulpy, rather small.
Eff. Ch. Spatha of two membranous valves. Corolla
oblong; its limb in fix deep segments, contracted at the
base, nearly regular. Stigmas three, narrow, spreading.

The characters of this genus are confoundedly very difficult
to define; yet its intelligent author confers the species to
be easily discernible by their common habit. The corolla
in some is quite regular, in others more or less irregular, yet
never in a very strong or evident degree. "The bulb
is solid, ovate and depressed, or roundish with a point; its
coats reticulated; the outermost spotted. Leaves grassy,
broadish; very rarely crisped at the edges. Flowers never,
various in the different species, in some their limb is large,
bell-shaped, regular, recurved, the segments broad, the tube
short, with an inflated spreading throat; in others the corolla
is of a smaller size, with a longer tube, a turbinate
throat, the segments oblong, little dilated, disposed so as
slightly to imitate a two-lipped flower, one of them broader
than the rest; in others again the segments are linear-
oblong, spreading in a wheel-shaped manner, equal, the
throat but slightly dilated, and the tube very long. The
filaments of the two-lipped species are ascending, of the
regular reverse ones erect; anther in the wheel-shaped flowers
contiguous, incumbent."

Andr. Repof. t. 142.)—Leaves wavy and crisped at the margin.
Segments of the corolla flat, shorter than the tube, not quite uniform.—Native of the hills of Roda Sand
and Picketberg at the Cape of Good Hope, flowering from
October to December. Thunberg. Sent by Mr. Maillon in
1789 to Kew garden. In England it flowers in the spring,
or summer. The shortish, many-ribbed, wavy, but not
fringed, leaves mark this species. The flowers are spliced,
not numerous, of a tawny flesh-colour; the tube often red,
two inches long, curved; three lower segments of the limb
furnished with a deep-red central sripes.

Curt. Mag. t. 1275. (Gladiolus viridis; Ait. ed. 1. v. 3.
481. Vahl Enum. v. 2. 296. Ker Ann. of Bot. v. 1. 231.)
—Stalk triangular, with membranous angles. Segments
of the corolla lanceolate, shorter than the tube; five of them
ascending; one deflexed.—Found at the Cape by Mr.
Maillon, who sent it to Kew garden, in 1788, where it
blooms in July. The leaves are linear-lanceolate, with a
strong mid-rib. Spike zigzag. Flowers not numerous,
pale green, with a purplish tinge, especially in the tube, and

Q 2 at
Tritonia.

at the back of the limb. We should suppose these flowers, by their colour, to be fragrant at night.

4. **T. rosea**. Trumpet-flowered Tritonia. *Ait.* n. 3. (T. capensis; *Curt. Mag.* t. 618, and t. 1531. Gladiolus rosea; Jacq. *IC. Rar.* t. 251. *Willd. Sp. Pl.* v. i. 217. Vahl *Enum.* v. 2. 110.)—Sheath taper-pointed. Upper segment of the corolla broadest; throat funnel-shaped; tube twice the length of the limb.—Native of the Cape. Sent to Kew by Mr. Maffon in 1793, where it flowers in June and July. The stem is leafy. Leaves green, many-ribbed, taper-pointed. *Flowers* spiky, three or four inches long, flesh-coloured, or buff with purplish veins; the three lower segments fringed with crimson at the base. The corolla however varies in size as well as colour; see the figures cited.

5. **T. longiflora**. Long-flowered Tritonia. *Ait.* n. 4. (Ixia longiflora; *Willd. Sp. Pl.* v. i. 203. Redout. *Liliac.* t. 34. *Curt. Mag.* t. 256; and t. 1502. *Tritonia*. Gladiolus longiflora; *Linn. Suppl.* 96.)—Segments of the corolla regular, linear-oblong, obtuse; tube thread-shaped, angular and slightly dilated at the top; four times as long as the limb, and five times as long as the nearly equal valves of the spatha.—Native of the Cape. Introduced by Mr. Maffon in 1774, and now a general favourite in our greenhouses, flowering in the spring. The very long and slender, regular, buff-coloured *flowers*, often tinged with a rose-colour, sufficiently distinguish this elegant species. The *flask* is very tall and slender, naked except at the lower part.

6. **T. Rockenfis**. Bending-flowered Tritonia. *Ker in Curt. Mag.* t. 1503. *Ait. Epit.* 375. (Ixia paniculata; *De la Roche Diff.* 26. t. 1, according to *Mr. Ker*. Gladiolus longiflora; *Thunb. Diff.* n. 22.)—Segments of the corolla regular, elliptical, concave, scarcely as long as the slender, deflexed tube. Stamens and style prominent.—Imported from the Cape in 1839, by Messrs. Lee and Kennedy. Nearly akin to the last, to which we should, but for Mr. Ker's authority, have referred the branched variety, figured by *De la Roche*.

7. **T. lineata**. Pencilled Tritonia. *Ker Ann. of Bot.* v. i. 228. *Ait.* n. 5. (Gladiolus lineatus; *Salis. Prod.* 40. Curt. *Mag.* t. 487. Redout. *Liliac.* t. 55. *Ixia squalida*; *Willd. Sp. Pl.* v. i. 206.)—Limb of the corolla three times the length of the curved tube, bell-shaped; its upper segment large; outer ones abrupt.—Native of the Cape. Sent to Kew by Mr. Maffon in 1774, but more recently introduced into our greenhouses by way of Holland, flowering in May. The *flam* is two feet high. Leaves green, with a solitary mid-rib. Spike drooping before the flowers open, which are large, of a straw-colour, tinged with orange, and marked with dark, dark, parallel and branching, veins. Each of the three lower segments has a yellow internal spot near the base. The tube, about half an inch long, scarcely equals the length of the *spatha*.

8. **T. secuirta**. Dwarf Copper-coloured Tritonia. *Ker Ann. of Bot.* v. i. 228. *Ait.* n. 6. (Gladiolus secuirta; *Willd. Sp. Pl.* v. i. 219. Vahl *Enum.* v. 2. 109. Curt. *Mag.* t. 583. Montbretia secuirta; Redout. *Liliac.* t. 53.)—Limb of the corolla twice the length of the tube; its upper segment largest; each of the three lower bearing at its base an erect, compressed prominence. Outer valve of the *spatha* thin, with three teeth.—Found at the Cape by Mr. Maffon, who sent it to Kew in 1774. It flowers freely in May and June, and increases by offsets. The *flam* is but a span high. *Leaves* two-ranked. *Flowers* tawny; the three lower segments yellow at the base, with a deeper hue of red about the middle.

9. **T. flavus**. Yellow Tritonia. *Ker Ann. of Bot.* v. i. 228. *Ait.* n. 7. (Gladiolus flavus; *Willd. Sp. Pl.* v. i. 218. Vahl *Enum.* v. 2. 110.)—Limb of the corolla twice the length of the tube; each of the three lower segments bearing at its base an erect, compressed prominence. Outer valve of the *spatha* pointed.—Found at the Cape by Colonel William Paterion, who sent it to the famous coutes of Strathamore in 1783. The somewhat broader *leaves*, pointed at the base, and uniform deep yellow of the corolla, are said in the first edition of *Hort. Kew.* to distinglish this from the last.

10. **T. refracta**. Bent-spiked Tritonia. *Ker Ann. of Bot.* v. i. 228. (Gladiolus refractus; Jacq. *IC. Rar.* t. 241. *Willd. Sp. Pl.* v. i. 215. Vahl *Enum.* v. 2. 109.)—Spikes bent backwards. *Flowers* erect, reversed. Limb of the corolla twice the length of the tube, bell-shaped, two-lipped; its three lower segments small.—Native of the Cape. We have not heard of it in any English garden. The *flam* is branched, singularly bent, scarcely rising above the long, erect, two-ranked *leaves*. Spikes horizontal, of several *flowers*, whose three upper segments are purplish, lower yellow or orange.

11. **T. squalida**. Sweet-scented Pink Tritonia. *Ker in Curt. Mag.* t. 581. *Ait.* n. 8. (Ixia squalida; *Willd. Sp. Pl.* v. i. 206. Vahl *Enum.* v. 2. 73. I. hyalina; Redout. *Liliac.* t. 87.)—Limb of the corolla bell-shaped, regular; its segments rounded, transparent in the margin below, close together; one of them gibbous at the base.—Native of the Cape. Sent to Kew by Mr. Maffon, in 1774. The *flam* is naked, ascending, much taller than the *leaves*, which are many-ribbed, equitant; the outer ones bluntish. *Spikes* reclining, of about half a dozen large, very sweet-scented *flowers*, whose tube is scarcely half the length or their limb, and whose colours are a mixture of dull pink, with a dirty pellucid white, like wet paper. The *claw* of each segment is red, with a distinctly defined white membranous border, that of the three innermost segments lying over the others. *Style* longer than the *stamen*, as in the two following. The depreciating name of *squalida* is surely not suitable to this elegant species.

12. **T. senilis**. Open-flowered Orange Tritonia. *Ker in Curt. Mag.* t. 704. *Ait.* n. 9. (Ixia senilis; Jacq. *IC. Rar.* t. 289.)—Limb of the corolla funnel-shaped, regular; its segments obovate, dilated, transparent in the margin below. Stamens and style reclining.—Native of the Cape, said to have been imported in 1801, by Mr. W. Salibury, of the Sloane-street Botanic Garden. It blossoms in the spring, and differs from the last in having few-leaved *flowers*, of a deep rich orange-colour; the membranes edges of their segments pink. The *corolla* is also differently shaped, as its specific character expresses. The *flam* is short, scarcely exceeding the *flatha*. *Stamens* often branched.

in their lower half.—Native of the Cape, and one of the
first of its tribe cultivated in the gardens of Europe, where
it has always been a great favourite, flowering in spring.
The brilliant orange-colour of its corolla, contrasted with
the membranous transparency of the lower half of its seg-
ments, all close together, has a very striking appearance.
We have some doubts whether Miller's t. 239. f. 2. be
not rather taken from the foregoing species, which in the
shape and disposition of its segments that figure most
resembles.

14. T. deufla. Tall Copper-coloured Tritonia. Ker in
Pl. v. 1. 205. Vahl Enum. v. 1. 74. I. crocata, nigro
maculata; Andr. Repol. t. 134. I. miniatia, nigro
maculata; Redout. Lilac. t. 89.)—Limb of the corolla regular,
widely spreading; its segments imbricated, obovate, solid
throughout; the three outermost gibbous underneath. Tube
rather shorter than thespatha.—Found at the Cape of
Good Hope, by Mr. Maffon, who sent it to Kew in 1774.
Allied to the two last, but taller, with still deeper orange-
coloured flowers, whose segments have no marginal tran-
sparency. The three outermost have a sort of hollow, or de-
pression, just above the base, marked with a very dark spot,
and prominent beneath. Jacquin's Ixia miniatia is taken by
Vahl for a variety of the present, defilute of spots; but
the figure more resembles out fengnirata, n. 12, in the shape
and position of the segments of the corolla, though without
their membranous margin. See the following.

15. T. miniatia. Tall Late-flowering Tritonia. Ker in
Hort. Schoenbr. v. 1. 10. t. 24?)—Limb of the corolla
funnel-shaped, somewhat two-lipped, reversed; its segments
obovate, close, solid throughout. Tube the length of the
spatha. Found at the Cape of Good Hope, by Mr.
Maffon, who sent it to Kew garden in 1795. It flowers in
August, and is the tallest and strongest of this genus,
having a branched stem, eighteen inches or more in height.
The flowers are scentles, of a rather dull orange-colour;
their three lower segments, (turned upwards by the
reverted pouture of the flower,) marked at the base with an
eblong yellow spot, indicating a degree of irregularity in
the corolla. This circumstance does not appear in Jacquin's
figure, above quoted, where all the segments have a similar
mark. How far such characters are variable in this diffi-
cult tribe, requires a longer experience, and more intimate
practical acquaintance with it, than we can boast, to decide
with certainty. More has been done by Mr. Ker than any
other person, to clear up the subject; but a wider range of
practical observations and experiments is still wanted, in
order to a correct understanding of what makes a permanent
species. In the perception of natural genera, this botanist
seems to us to display great abilities, whether their tech-
nical limitations be, as yet, perfected or not. With respect
to colour, and even proportion of parts, in the flowers of
this family, Jacquin's reputed varieties of Ixia maculata,
in the 1st vol. of his Hortus Schonbrunnetfis, are sufficient
to drive any botanist to despair.

TRITONUS, in Music, a dissonant interval, composed
of three tones, two major and one minor; and which is,
in practice, called the sharp 4th. This interval on key
instruments is equal in nominal femitones to the falle 4th:
the numerical ratios, however, are not equal; that of
the tritonus being only 32 to 45; which is occasioned by
the tritonus having only one tone major instead of two femi-
tones major, which the falle 5th contains. See Fifth.

But the most considerable difference between the falle 5th
and the sharp 4th is, that the latter is a major discord, and

that the parts are resolved by separation; and whereas the
other is a minor discord, and resolved by approximation of
the two parts.

The chord of the sharp 4th is only an inversion of the
chord of the 5th to the sharp 7th of the key, by giving the
discord to the base.

TRITOPATORIA, τριτοπατορος, in Antiquity, a fo-
lemnity in which it was usual to pray for children to the
Στροφατορος, or gods of generation, who were sometimes called
τριτοπατορος.

TRITORIUM, in Chemistry, a vessel generally made
of glass, used for the separation of liquors of different den-

tsities, as oil and water. Its largest diameter is in the middle,
and it terminates with an aperture at each of the two extre-
mities. The lower extremity, the aperture of which is very
narrow, is dipped into the mixed liquor, and when it is suffi-
ciently filled, the upper orifice is to be flopped close, by
pressing the thumb upon it, by which means the liquor con-
tained will not run out at the lower aperture, when the vessel
is raised from the mixed liquor. When the fluids of this
liquor consists have perfectly separated according to
their respective densities, by removing the thumb, the heavy
fluid will run out at the lower extremity, and the separation
will be thus effected. Macquer's Dist. Chem.

TRITTAU, in Geography, a town of the duchy of Hol-
stein; 20 miles E. of Hamburg.

TRITYARCHI, τριταρχος, among the Athenians,
were magistrates who had the command or government of
the third part of a tribe. See Phyarchus.

TRITUM PROMONTORIUM, Seba-Row, in Ancient
Geography, a promontory of Africa, at the west entrance
of the gulf of Numidia; called by Pomponius Mela Meta-
genium.

TRITURATION, Tritura, or Tritus, formed from
triturare, to trough, of terra, I ear, rub, or grind, in Phar-
acy; grinding; the act of reducing a solid body into a subtle
powder, called also levigation, pulverisation, &c.

The trituration of woods, barks, minerals, and other hard
and dry bodies, is performed by the rotatory motion of a
pestle in metalline, glafs, agate, or Wedgwood-ware mortars;
and in mills, by means of large rollers of hard stone.

The same term is also applied to the comminuting, bruiss-
ing, and dividing of humid matters into little parts.
The trituration of moist bodies is performed in marble or flute
mortars, with pestles of wood, glafs, ivory, &c. The word
trituration is generally applied to denote the division that is
made of several bodies together, to unite them with each other;
as, e. g. the extintion of mercury in the operation of
Ethiopis mineral, and others similar.

Trituration, Boerhaave observes, has a wonderful force to
dissolve some bodies, and will render them as fluid as if they
were fused by the fire. Thus if you grind the powder of
myrrh and salt of tartar together, they will dissolve each
other. By rubbing new and bright filings of iron in a mor-
tar, with double their weight of clean sulphur, the iron
will be dissolved, fo as by diluting it with water to afford the vitri-
olum Martis.

Gold long ground in a mortar with salt of tartar, will
yield a kind of tincture; and rubbed with mercury in a mor-
tar of glafs, it entirely dissolves into a purple liquor, and be-
comes a most powerful medicine.

Dr. Langlet has written a curious treatise of the great
effects of trituration in chemistry, and describes a peculiar
way
way he employed to grind gold, by which, he says, he could render it as fluid as the fire does, and make an aurum potabile by the bare motion of a mill.

The author, in the Philosophical Transactions, mentions his way of grinding gold, and describes two engines, or philosophical mills, for the purpose; with one of which, in the space of fourteen natural days, he reduced a leaf of gold to a ducly powder, and, putting it into a shallow retort, placed in a sand-heat, he thence obtained, by gradually increasing the fire, and giving a strong one at last, a very few red drops, which, digested per se, or with tartarized spirit of wine, afforded a pure and genuine aurum potabile.

The success of this operation the doctor attributes, in a great measure, to the salt of the air, which, in grinding, plentifully mixes and unites itself with the gold.

It has been observed, that there appears to be an error in reducing vegetable matter to the lake of impalpable powder; as in this state, both during the process of grinding and afterwards, the air and light act powerfully upon them, and produce changes, which, although they be not well understood, yet appear to alter the medicinal virtues of the substances.

Trituration is also used, in Medicine, for the action of the stomoch on the food, by which it is fitted for nutriment. See Digestion.

TRIVADI, in Geography, a town of Hindoostan, in the Carnatic. The pagoda forms a citadel; 23 miles S.W. of Pondicherry. N. lat. 11° 42'. E. long. 79° 45'.

TRIVANDOOR, a town of Hindoostan, in Madura; 16 miles N. of Nattam.

TRIVATOOR, a town of Hindoostan, in Madura; 20 miles N. of Trumian.

TRIVATORE, a town of Hindoostan, in the Carnatic; 6 miles S.E. of Arcot.

TRIVELAWARY, a town of Hindoostan, in the Carnatic; 12 miles N. of Trichinopoly.

TRIVEMBAR, a town of Hindoostan, in Marawar; 27 miles N. of Ramanadporum.

TRIVENALORE, a town of Hindoostan, in the Carnatic; 13 miles N. of Tiagar.

TRIVENI, a term in the Sanscrit tongue, said to mean a triad of rivers; a junction of three of the most important streams of Hindoostan being pre-eminently distinguished by this appellation. These are the Yamuna or Jumna, the Ganga or Ganges, and the Saraswati; being, in the mythological mysticisms of the Hindoos, personifications or symbols of their three great goddesses, Lakshmi, Parvati, and Saraswati.

The Hindoo poets, as indeed all their writing priests or philosophers, and even mathematicians, seem to be, call the Triveni the three plaited locks; and elegantly wreath this idea into many pleasing allegories. See Radia.

The spot of junction of the three river-goddesses in question, near Allahabad in Bengal, is extensively esteemed very sacred; and pilgrims resort thither from distant regions to bathe in the purifying triune stream. Of this we have taken sufficient notice under our article JUNCTIONS; and under that of Suicide, an account is given of meritorious self-destruction at this revered spot. See also Sati.

The Triveni has been noticed as a fruitful source of poetical allusion.

We cannot refrain from briefly alluding, in this place, to some supposed coincidences in Irish and Indian mythology, of which see something under our articles Soma and Surya. And we allude to them here in view to the opportunity of saying that poetical traditions exist, and perhaps still exist, in Ireland of a mythological origin and junction of three rivers, reminding us strongly of the Indian Triveni. The Irish rivers appertain to the county of Kilkenny; and our own Sperner has described them so exactly in the style of Eastern hyperbole, that we must invite the reader to turn to our article KILKENNY, where he will find an extract from Sperner descriptive of the mythological origin and junction of the Irish Triveni, that may be almost suspected as of Oriental origin.

TRIVENTO, in Geography, a town of Naples, in the county of Molise, the see of a bishop, immediately under the pope; 11 miles N. of Molise.

TRIVERBIAL DAYS, in the Roman Calendar, denoted judicial days, or such as were allowed to the prator for hearing of cauæ.

They were otherwise called dies fasti, in quibus licebat pratoori fari tria verba, do, dicho, addicio.

Of these court-days, the Romans had only twenty-eight in the whole year; whereas three courts in the year is term-time, in which three courts constantly fit for the dispatch of business; besides the close attendance of the court of chancery for determining suits in equity, and the numerous courts of alizse and nifi prius that sit in vacation for the trial of matters of fact.

TRIVESPER, in Mythology, one of the epithets of Hercules.

TRIVET, NICHOLAS, in Biography, an English historian of the thirteenth century, was the descendant of a respectable family in Norfolk. Having entered among the Dominicans in London, he studied at Oxford and at Paris; and at the latter place collected from books on the history of the Normans and Franks such passages as related to the English nation, and supplied their defects from the best accounts which he could procure in his own country. In this way he composed his ‘‘Annals of the Six Kings of England sprung from the Counts of Anjou,’’ introducing a detail of the most remarkable events that occurred under the Roman pontiffs, the emperors, the kings of France, and other contemporary princes, together with an account of learned men, particularly of his own order, and intending that his work should be a continuation of that of William of Malmibury. He also wrote various other works, partly containing illustrations of ancient authors, but none of them were printed, except his commentary on St. Augustine’s book De Civitate Dei.” Soon after his return from France he became prior of a monastery in London, where he died in 1328, at the age of nearly 70 years. His historical work has passed through several editions under different titles, for which we refer to Aikin’s Gen. Biog.

TRIVIAL NAMES, Nomina Trivialia, in Botany, were first used by Linnaeus in his dissertation entitled Pan Sueus, published at Upsal in 1749. The plants there enumerated, with a view to their economical qualities as the food of domestic cattle, are each designated by its generic and specific name. The same measure was adopted in the first edition of the Species Plantarum, published four years after, and was extended subsequently to every department of natural history. Linnaeus originally intended his specific definitions to be used as names; but however compendiously such might be constructed, they were soon found totally unmanageable for that purpose. He therefore adopted the method of Rinvus, of mentioning each plant by a sort of appellative, in addition to its generic name; not intending, like Rinvus, that such appellative should comprehend the specific definition of the plant, which Linnaeus knew to be impossible. That no such expectation might be formed of these names, and that students might not too much rely on them, as any thing like definitions, he termed them nomina trivialia, as serving for common
They are now however usually called specific names, in contradistinction to generic ones; the original specific names of Linnaeus being at present more properly termed specific definitions, or differences. Trivial names may contain the essential characters of the several species, as Sagina procumbens and aptata, in which case they are but a repetition, or an anticipation, of the specific differences. They more usually serve to express some concomitant circumstance, tolerably certain as a distinctive mark of each species, though not in the specific character, such as annua, perennis, fruticosa; or alba, lutea, rubra, &c. Former appellations of each species, such as Hydrophytus and Pericarpo, especially if the plants be remarkable for their medical or economic usages, as Cinnamomum, Rhubarb, Althaea, Napus, Rapa, &c. are very commodious, though injudiciously laid aside by some reformers. These must always begin with a capital letter, being proper names, not required to agree in gender with the generic name. In Zoology, such appellations of species as we have last mentioned are peculiarly useful, and generally preferred by Linnaeus to all others.

TRIVICAR Y, in Geography, a town of Hindooftan, in the Carnatic; 20 miles S.E. of Gingeer.

TRIVICUM, Trivio, in Ancient Geography, a small town of Italy, on the frontiers of the Hirpin and of Apulia. It lay on the Trajan way, at a distance E. of Benevento.

TRIVIDHA, in Mythology, a name of the Hindoo goddes Parvati. The word is said to mean three-fold, the Hindoo goddesses corresponding in many points with the triple Hecate of the Greeks.

TRIVIER, in Geography, a town of France, in the department of the Seine; 6 miles N.E. of Biella.

TRIVIGGLO BOY, a bay in the gulf of Honduras, on the coast of Mexico.

TRIVIGNANO, a town of Italy, in the Trevisian; 7 miles W.N.W. of Treviso.

TRIVIKERA, or Trivikrama, in Mythology, a name of the Hindoo god Vishnu. It means the three-steeper, alluding to his having in one of his avatars, or incarnations, received a powerful sovereign into a promise of giving him all he could cover in the three steps.

TRIVIUM, a term invented in the times of barbarism to express the three sciences that were first learned in the schools, viz. grammar, rhetoric, and logic; and the schools in which their sciences were taught were called triacites. The quadrivium, to which the scholastic next proceeded in his way to the summit of literary fame, comprehended the four mathematical sciences, viz. arithmetic, music, geometry, and astronomy.

TRIUMFETTA, in Botany, named by Plinier, serves to commemorate John Baptist Triumfetti, of Bologna, doctor in medicine and philosophy, and lecturer at the botanical garden of Rome, which was under his direction. He published there, in 1685, a thin quarto volume entitled Observationes de ortu ac vegetazione plantarum, including descriptions and engravings of several new species. This is an able work, though more frequently quoted for its figures than its philosophy, a very common cafe. The author published in 1703 a refutation of some criticisms that had appeared against his book. He died in 1707. His brother, Leibus Triumfetti, likewise professor of botany at Rome, is said to have been well supplied in the knowledge of plants, though he does not appear as an author.—Linn. Gen. 239. Schreb. 321. 832. Willd. Sp. Pl. v. 2. 853. Mart. Mill. Dict. v. 4. Ait. Hort. Kew-v. 3. 145. Plun. Gen. 60 t. 8. Juss. 290. Lamarck Illustr. t. 400. Gérard. t. 111. (Bartramia; Linn. Gen. cd. 5. 184. Lamarck Illustr. t. 400. Gérard. t. 111.)—Clads and order, Dodonaea Monogynia. Nat. Ord. Columnifera, Linn. Tibare, Jaffi.

Gen. Ch. Cal. Perianth inferior, of five lanceolate, deciduous leaves, with a brilfly point just below the summit. Cor. Petals five, linear, obtuse, cret, concave, bent backward just above the base. Stam. Filaments sixteen, equal, ascending, awl-shaped, straight, the length of the corolla; anthers simple, roundish, of two cells. Pfl. Germin superior, roundish; fyle the length of the stamens; frigmon in two acute divisions. Peric. Capsule globose, covered all over with hooked prickles, separaring into four cells. Seeds or two or in each cell, cret, convex at the outside, angular at the inner.

Eff. Ch. Calyx of five leaves, deciduous. Petals five. Capsule prickly, separaring into four parts.

Obi. The supposedwant of a calyx in the original Triumfetta is a manifest error, subsequently corrected by Linnaeus; as is likewise, if we mistake not, the dorfal point attributed to each petal. Yet Gérard uses the former character to strengthen the difference between Triumfetta and the original Bartramia, though purely every principle of character and habit proclaim their identity. Bartramia therefor Pe, is now retained as the name of a very difficult and elegant genus of Mofes. See Moxey.

1. T. Lappula. Bar Triumfetta. Linn. Sp. Pl. 637. Willd. n. 11. Ait. n. 1. (T. fructu echinato racemoso; Plum. Is. 253. t. 255.) Lappula bermondus althoeides fructa, fructu orbiculari majore; Phant. Phyt. 1. 245 f. 7.)—Leaves heart-shaped at the base. Calyx soon deciduous. Flowers in densely whorled aggregate spikes.—Native of the West Indies and South America. A shrub or four or five feet high, flowering about July and August in our foves, where it was cultivated in Miller's time, bat is seldom much noticed, the yellow flowers being small and inconspicuous. The leaves are divided, alternate, several inches broad, roundish, toothed, downy, with three or five fround acuté lobes. Capsule the size of a pea, armed with prominent hooked prickles, which flick to the coats of animals, and are widely diterferent, each capsule splitting when ripe into four parts, lodging solitary seeds. The spikes are terminal, several together, very fevere.

2. T. glandulosa. Glandular Triumfetta. Forsk. Cat. Fl. Arab. Fel. 112. n. 297. Val. Symb. v. 3. 62. Willd. n. 239.—Leaves ovato-lanceolate; downy and hoary beneath; their lower ferratures more or less glandular. Flowers axillary, from the upper leaves.—Gathered by Forskall in the middle region of the hills of Arabia Felix. Branches woody, round, villous. Leaves on short stalks, numeros, three inches long, gradually smaller upward, clothed on both fides with soft hairy hairs, but greened on the upper; entire at the base, but otherwise ferrated. Stipulas awl-shaped.

3. T. Bartramia. Currant-leaved Triumfetta. Linn. Sp. Pl. 638. Willd. n. 3. Ait. n. 2. (Lappago amboinica; Rumph. Amboin. v. 6. book 15. p. 15. f. 2.) Lappula bermondus tetraspermom fructi falo, echinus orbicularius ad foliis exortis plurrima ad foliis felfibus; Phant. Phyt. 1. 41 f. 5.)—Leaves acutely lobed and toothed; entire at the base; roughish on both fides. Flowers racemo-ro, partly aggregate; the lower ones axillary.—Native of the East Indies. The leaves are roughish to the touch, not downy. We are not certain of having seen authentic specimens, Linnaeus having been very superficially acquainted with the species of this genus. Our's has but four feed in each capsule.

loped, pointed; softly downy on both sides. Stem erect.
—Native of the island of Mauritius. We have a specimen from thence, given by Thouin to the younger Linnaeus, which we conceive must be Vahl's plant, though, being in seed, the inflorescence has a racemose appearance, the floral leaves having perhaps fallen off. The stem is round, downy.

Leaves alternate, flaked, two or three inches long, more or less evidently five-ribbed, unequally ferrated, clothed with soft hairy hairs on both sides, but much the most copiously on the under; the base is undivided, not heart-shaped. Stipules lanceolate, tapering, fringed, of a rusty hue. Flowers from the biforms of the upper leaves, according to Vahl.

In our specimen, which answers in other respects to his description, the calyx, smaller than a pea, form compound, terminal, interrupted clusters; their partial flanks aggregate, deflexed, from a quarter to half an inch long. The prickles of each capsule are copiously barbed with minute, reflexed, pale hairs.

5. **T. procumbens**. Procentum Triumfetta. Forl. Prodr. 35. Willd. n. 5. — Leaves roundish-heart-shaped, obtuse, slightly three-lobed; very downy beneath. Stem procumbent.—Native of the Society isles. Our specimen is from Otaheite, gathered by the younger Forster. The stem is woody, round, downy and hoary; the younger branches leafy. Leaves about the size and shape of those of a gooseberry, bluntly ferrated, usually three-lobed, on long downy stalks; their upper side green, nearly even, clothed with scattered, simple, deciduous hairs; the under pale, covered with soft hairy hairs, and reticulated with prominent veins. Of the flowers or fruit nothing is mentioned, nor does the specimen before us show traces of either.

6. **T. hirta**. Hairy-panicled Triumfetta. Vahl Symb. v. 3. 63. Willd. n. 6. — Leaves three-lobed, acute; smooth above. Panicle terminal, compound, hairy. — Found by Von Rohr, in the West Indian island of St. Martin. Stem shrubbery. Leaves three or four inches in length and breadth, seven-ribbed, unequally ferrated; three or five of the lowermost ferratures glandular; the base rather heart-shaped; the extremity divided into three ovate, dilated, pointed lobes: the under side is clothed with very minute hairy pubescence, and its ribs with long scattered hairs.

Footstalks most hairy when young. Panicle diffuse, with alternate, twice or thrice forked branches, most hairy in the lower part. Flowers small, flaked, solitary at the forks of the panicle, but otherwise aggregate. Calyx hoary. Vahl.

7. **T. semilirata**. Mallow-leaved Triumfetta. Linn. Mant. 73. Willd. n. 7. Alt. n. 3. Jacq. Amer. 147. Hort. Ind. v. 3. 41. t. 76. (T. n. 2; Browne Jam. 233.) — Leaves divided half way down into three lobes. Panicle terminal, compound, downy.—Native of the West Indies. Introduced at Kew in 1773, by John earl of Bute. It flowers in the flower in July. The stem is shrubbery, bushy. Leaves clothed on both sides with fine, soft, silky hairs. Flowers yellow, not many together, in more or less compound terminal panicles. Browne says, the leaves, steeped for some time in water, give out a copious clear mucus; and that the fibres of the bark serve, in the inland parts of Jamaica, to make ropes, &c. We do not by any means understand Linnaeus's companion of this species to be *T. Lappula*. He had no authentic specimen of either.

8. **T. grandiflora**. Large-flowered Triumfetta. "Vahl Eclog. v. 2. 34." Willd. n. 8. — "Leaves ovate, undivided, somewhat heart-shaped, ferrated, rather hairy; the floral ones lanceolate. Branches hairy." — Native of the

island of Monteferrat. Corolla twice or thrice as large as in any other species with which Vahl was acquainted.

9. **T. macrophylla**. Large-leaved Triumfetta. "Vahl Eclog. v. 2. 34." Willd. n. 9. — "Leaves ovate-heart-shaped, undivided, unequally ferrated, pointed, downy; glandular at the base." — Native of South America. Like *T. Lappula*, but having a calyx. Vahl judged it to be a different species. We have already expressed our disbelieve of the want of a calyx in any species of this genus. Plummer distinctly represents one in his generic figures, taken from *T. Lappula* itself. The *macrophylla* is said to differ from what we shall next describe, in the shape, as well as downy, of its foliage.

10. **T. rhombifolia**. Rhomb-leaved Triumfetta. Swartz Inc. Oec. 863. Willd. n. 10. misprint. (T. rhomboidea; Jacq. Amer. 147. t. 90.) — Leaves rhomboid, slightly hairy; the uppermost ovato-lanceolate, nearly fleshy. Flowers in axillary tufts.—Native of dry, waste, bushy places in Jamaica, and other parts of the West Indies. The stem is shrubby, two or three feet high, erect, branched, downy. Leaves contracted and entire at the base; the lower ones rhombid, and somewhat hexagonal, an inch and half long, on footstalks nearly of their own length; all rugose and more or less hairy. Flowers pale, in axillary tufts, accompanying most of the upper or smaller, each tuft of about three or three and a half flower-stalks. Petals with hairy claws, and five nectariferous glands at their base. Capsule of three single-seeded cells. Swartz.

11. **T. annua**. Annual Triumfetta. Linn. Mant. 73. Willd. n. 11. Alt. n. 4. (F. foliis oblongo-ovatis, obv. ferratis, petolis longiflimal; Mill. Lc. v. 2. 159. t. 298.) — Leaves ovate, acute, ferrated, undivided; rarely three-lobed.—Native of the East Indies, flowering with us in August and September. Miller cultivated this for curiosity; but it has nothing to excite popular admiration. The root is annual. Leaves three or four inches long, on long stalks; but it does not appear from Miller's description, whether they are smooth, downy, or rough. Flowers small, deep yellow, in tufts at the ends of the branches; sometimes with only four petals and eight stamens. Capsule of four single-seeded cells.

**Triumfetta**, in Gardening, furnishes plants of the shrubbery and herbageous kinds; among which the species cultivated are, the prickly-seeded *Triumfetta* (T. lappula), and the annual *Triumfetta* (T. annua).

**Method of Culture**. These plants are increased by seeds, which must be procured from their native places, and be sown on a hot-bed, or in pots plunged in the sand-bed of the flower: when the plants have one or two inches growth, they should be removed into separate pots, re-plunging them in the sand-bed till well re-rooted.

They afterwards require to be kept constantly in the flower, or hot-house, and to have the management of other ligeous plants of the flower kind.

They produce variety in flower collections.

**TRIUMPH, Triumphus, a ceremony, or solemnity, practised among the ancient Romans, to do honour to a victorious general, by affording him a magnificent entry into their city.**

The triumph was the most pompous spectacle known among the ancients; authors usually attribute its invention to Buceus, and derive the term from στίμωρον, one of his titles; and tell us, that he first triumphed upon the conquest of the Indians; and yet this ceremony was only in use among the Romans.

As long as the ancient discipline of the republic continued, no general could pretend to a triumph who had not extended the...
the limits of the empire, and slain at least five thousand of his enemies in battle, without any considerable loss on his own part; to this purpose an express law was established, and he was obliged to make oath before the senators, that the account delivered to the senate was true. But this law became obsolete, and intrigue and faction procured a triumph in favour of generals whose merit was not very considerable.

The general who vanquished his enemies in a naval engagement, had also the honour of a naval triumph. These were first granted to C. Duilius, in the year 449, after his defeat of the Carthaginians.

The triumph was of two kinds, the left and the greater. The left triumph was granted upon a victory over some unequal and unworthy enemy, as over pirates, slaves, &c. This they called ovatio, because the only sacrifices offered in it were sheep.

The greater triumph, called also curulis, and simply the triumph, was decreed by the senate to a general upon the conquering of a province, or gaining a single battle. The order and economy of the triumph were thus: the general having disparched couriers with tidings of his success, the senate met in Bellona's temple to read the letters; this done, they fend him the title Imperator, with orders for him to return, and bring his victorious troops along with him.

When he was arrived near the city, the general and principal officers took oath of the truth of the victory; and the day of triumph was appointed.

The day being arrived, the senate went to meet the conqueror without the gate called Capena, or Triumphalis, and marched in order before him to the Capitol. He was richly clad in a purple robe, embroidered with figures of gold, setting forth his glorious achievements; his buffoons were beted with pearl, and he wore a crown, which at first was only laurel, but afterwards was gold; in one hand he bore a laurel branch, and in the other a truncheon. He was drawn in a car, or chariot, adorned with ivory and plates of gold, drawn usually by two white horses; though sometimes by other animals, as that of Pompey, when he triumphed over Africa, by elephants; that of Mark Antony, by lions; that of Heliogabalus, by tygers; that of Aurelian, by deer; and that of Nero, by hermaphrodite mares, &c.

At his feet were his children, or sometimes on the chariot-horses. It is added, that the public executioner was behind him, to remind him, from time to time, that these honours were transitory, and would not screen him from the severity of the laws, if he should ever be found delinquent.

The cavalcade was led up by the musicians, who had crowns on their heads; after them came several chariots, in which were plans of the cities and countries subdued, done in relief: they were followed by the spoils taken from the enemy, their horses, arms, gold, silver, machines, tents, &c. After these came the kings, princes, or generals subdued, loaded with chains, and followed by mimics and buffoons, who infulted over their misfortunes. Next came the officers of the conquering troops, with crowns on their heads.

After these appeared the triumphal chariot, before which, as it passed, they all along flrewed flowers, and the music played in praise of the conqueror amidst the loud acclamations of the people, crying Io triumphi!

The chariot was followed by the senate, clad in white robes; and the senate by such citizens as had been set at liberty or ransomed.

The procession was closed by the priests, and their officers andutenils, with a white ox led along for the chief victim. In this order they proceeded through the triumphal gate, along the Via Sacra, to the Capitol, where the victims were slain.

In the mean time all the temples were open, and all the altars loaded with offerings and incense; games and combats were celebrated in the public places, and rejoicings appeared everywhere.

What was terrible amidst all this mirth was, that the captives, when arrived at the forum, were led back to prison and strangled; it being a point of religion with them, not to touch the victims till they had taken full revenge of their enemies. The rites and sacrifices being concluded, the triumpher treated the people in the Capitol, under the porticoes, and sometimes in Hercules's temple.

The most considerable triumphs were those of Caesar after the taking of Utica, and of Augustus after the victory of Actium. Caesar had four triumphs, which lasted four days, and were conducted with the most extraordinary splendour and magnificence. The first was the triumph of the Gauls, on which occasion there were presented to the view of the Romans the names ofthree hundred nations and eight hundred cities subdued by the death of a million of enemies, which Caesar had defeated in several battles. The second triumph was that of Egypt: the third represented the defeat of Pharnaces; and the fourth exhibited pictures of Scipio, Petreius, and Cato.

The triumph of Augustus lasted three successive days, and was not less magnificent than the former.

After Augustus, the honour of a triumph became an appendage of sovereignty.

TRIUMPHAL Arch, Car, and Column. See the articles.

TRIUMPHAL Crown, or Garland. See CROWN. This is said to have been taken from Apollo's crowning his head with a laurel, after killing the Delphian serpent.

TRIUMPHAL Gown, toga triumphalis. See TOGA.

TRIUMPHANT CHURCH. See CHURCH.

TRIUMPHO de la Cruz, in Geography, a cape on the coast of Honduras. N. lat. 15° 50'. W. long. 88° 25'.

TRIUMVIR, one of three persons who govern absolutely, and with equal authority, in a state.

The word is little used but in the Roman history. Caesar, Crassus, and Pompey, were the first triumvirs, i.e. the first who divided the government of the republic among them.

There were also other officers, called triumviri, triumviris; as the triumviri, or triumviri capitales, created in the year of Rome 463, to take care of prisoners, and superintend the execution of criminals.

Triumviri monetales, who were magistrates created at the same time to superintend the coining of the money: whence that mark still extant on many ancient coins, IIIVIRI. They seem to have been created about the time of the first coinage of silver in Rome, or 266 years B.C. Pomponius ascribes their first creation to the year of Rome 463, or 289 B.C. These officers were very considerable, and were chosen out of the senatorial rank, till Augustus appointed them from the equestrian, and the alteration seems to have continued. However this be, the title triumviri remained till after Caracalla, as appears from inscriptions given us by Gruter, and by Buteroue. But under Aurelian it is probable there was but one matter of the Roman mint, called the “Rationalis,” which change is supposed to have taken place under Gallienus. The “Rationalis” was succeeded by the “Procurator monetae.” The triumviri made part of the centumviri. The title they bear on medals, which is common on the coins of Augustus and Tiberius, is IIIVIRI. A.A.E.F, triumviri auro, argento, are, flancl, sertiendo, Rr.
which signifies, that they had the direction of casting and striking of gold, silver, and brass. Julius made quattuor virii, who continued for 15 years, till the battle of Actium, when Augustus reformed the triumvirii.

There were also triumvirii aditus reficiendi, officers appointed to look at the reparation of temples; triumvirii colonis deducendi, for the conducting and settling of colonies; triumvirii, for the raising of troops; nocturnal triumvirii, to prevent or extinguishe fires; triumvirii, to review the forces, &c.

In the Acilian family we read of one M. Acilius IIIIVIR VALETU; that is, triumvir of health, or a magistrate of health. M. Spanheim takes him to have been a magistrate established to perform sacrifices to the gods of health, to dedicate their temples, &c.

Onuphrius and Vaillant read triumvir valetudinis; Patin, triumvir valetudinariorum; but M. Spanheim, with much more reason, reads triumvir valetudo; in like manner, as on a medal of the Aquilian family, we read IIIIVIR VIRTUS; signifying that one M. Aquilius had been made triumvir to repair the temple of Virtue, and Acilius that of Health.

TRIUMVIRATE, TRIUMVIRATUS, an absolute government administered by three persons, with an equal authority.

There are two famous triumvirates at Rome; Pompey, Caesar, and Crassus, established the first; and Augustus, Mark Antony, and Lepidus, the second.

This latter triumvirate gave the last blow to the liberty of the republic. Augustus having vanquished Lepidus and Antony, the triumvirate funk into a monarchy.

TRIUNE, Tri in Uno, three in one; a term sometimes applied to God, to express the unity of the Godhead, in a trinity of persons.

Gen. Ch. Common Calyx imbricated, ovate, of eight or ten ovate-oblong, pointed, convex, nearly equal scales; the outermost slightly keeled, membranous at the tip. Cor. compound. Perfect florets, in the dish, numerous, funnel-shaped, with a very short tube, and upright five-leaf limb. Female ones, in the radius, fewer, shorter, funnel-shaped, with a compressed tube, and a three-leaf limb, whose hinder segment is larger than the two in front. Stam. in the florets of the dish, Filaments five, the length of the tube; anthers united into a five-toothed cylinder, rising above the limb. Pîf. in the florets of the dish, German linear, downy; style thread-shaped, the length of the flamines, divided at the top; ligmas reflexed: in the female florets, German oblong; style thread-shaped, divided at the top; ligmas reflexed. Peric. none, except the closed unalter d calyx. Seed of the florets of the dish, often abortive: of the female ones ovate, slightly compressed, bordered, convex behind, obtuse, hairy, and somewhat triangular, at the summit. Down none. Recept. chaffy, with oblong, acute, concave, membranous scales.

1. T. tersinithinae. Balsamic Trixis. Swartz Ind. Occ. 1375. Willd. n. 1.—Branches rough. Leaves ovate, finely serrated; rough with minute bristles above; with short dense hairs beneath.—Native of rocky valleys among the mountains of the west side of Jamaica, flowering in May. The stem is shaggy, six feet high, rough, with opposite, round, leafy branches, rough with very dense, short, rigid hairs, as are also the footstalk. Leaves opposite, crossing each other, from four to six inches, or more, in length, and three, or more, in breadth, bright green, finely and acutely serrated, veiny, somewhat triple-ribbed; rough like a file above; hairy or downy beneath; tapering at each end. Stipulas none. Flowers very numerous, small, white, fragrant, but acquiring a turpentine scent when bruised. They compose large, terminal, corymbose, dense panicules, with opposite downy stalks, and hairy awl-shaped bracteas.

2. T. apera. Harsh-leaved Trixis. Swartz Prodr. 115. Wild. n. 2. (T. icabara; Swartz Ind. Occ. 1378. Baileyera apera; Aubl. Guian. 804. t. 317.)—Branches silky, with close-pressed hairs. Leaves ovate, serrated, taper-pointed; harsh above; rough with depressed hairs beneath.—Native of Guiana, Cayenne, and the West Indies. As tall as the last, but of a more slender habit. Branches smooth to the touch, being covered with close hairs, pointing upwards, not with rigid prominent bristles, as in the foregoing. Leaves not half so large, rough like a fine file, on the upper surface, when full-grown; pale beneath, with flattened, not prominent, bristly hairs. Flowers larger, but fewer, in looser panicles. We cannot, on an examination of specimens, doubt this being Aublet's plant, and therefore we retain the original specific name. His B. stylophorus appears to be, as Willdenow makes it, a mere variety, though his apera only is used for intoxicating fish.

3. T. esula. Jagged Trixis. Swartz Prodr. 115. Ind. Occ. 1377. Willd. n. 3.—Branches bristle. Leaves broadly-ovate, with deep irregular notches and fissions; roughish on both sides; pale beneath.—Native of various parts of the West Indies. This is the size of the first species, but its leaves are more detoid, deeply jagged, and less hairy, though roughish with minute scattered bristles. Flowers white, much like the first, but fewer and rather larger, on hairy stalks. The calyx-scales, in every one of our specimens, much broader and rounder than Swartz's figure represents. Aublet gives five teeth to all his florets.

TROADENSE MAMM, in Natural History, a name given by the ancients to a species of white marble, dug in Mount Ida, and greatly used in building.

TROARN, or Trouard, in Geography, a town of France, in the department of the Calvados, on the Dive; 6 miles E. of Caen.

TROAS, the Troads, in Ancient Geography, a country of Asia Minor, commencing at the premonitory Leuctum, and extending as far as the Propontide. It took its name from the famous city of Troy, its capital. It extended a little towards the south. If indeed under the appellation of Troade we comprehend the whole extent of the country which was subject to the Trojans, that is, almost the whole kingdom of Priam, we must comprehend almost the whole extent of the two Mygian and Lesser Phrygia. But the Troade, properly speaking, comprised merely the country which lay between the Dardania to the north-east, and the country of the Leleges, to the south-east, the Hellepont and the Aegean sea. Ptolemy includes the Troade in Lesser Phrygia. Its principal rivers were the Simois, the Scamander or Xanthippus, and the Andrus. Its principal towns were Troja or Ilum Sigeum, Sminthe, &c.

TROAS—ALEXANDRIA. See Alexandria.
TROAT, among Sportsmen, the cry of a buck in rutting time.

TROCADIE, in Geography, a small island in the gulf of St. Lawrence, near the north coast of St. John's island.

TROCAR, or TROCHAR, an instrument commonly used in Surgery, for tapping the abdomen, in cafes of ascites and ovarian dropsy; the tunica vaginalis, in cafes of hydrocele; the joints, in bad cafes of hydrops articuli, &c. Trocars are also employed for tapping the bladder, when there is no other mode of evacuating the urine, and the symptoms which the patient suffers are so urgent, that no time remains for the trial of milder plans of relief. Abscesses have likewise been opened in some instances with a trocar; though it must be allowed that, in these cafes, the lancet is generally a better instrument.

A trocar consists of two pieces, viz. a perforator or fillet, and a silver canula. The latter is so constructed and adapted to the first part of the instrument, that when the puncture is made, they both enter the wound together with perfect ease; after which, the fillet being withdrawn, the canula remains in the wound, and affords a convenient channel for the escape of the fluid outward.

Such are the uses of a trocar, and the principles upon which the instrument ought to be made. It has been proposed to make the perforator with a flat lancet-point, in order that it may enter the flesh with greater facility; but time and experience seem still to give the preference to the fillet, which is of a triangular shape. It is true, that it cannot so readily make the necessary puncture; yet if sharp, and in good condition, no great fault can be found with it, in regard to the difficulty of making it enter the flesh; and it is certain, that its canula is better calculated than the tube of a flat trocar to afford an outlet to fluids, which are at all thick and gelatinous.

The trocar is an instrument which should never be used for the discharge of fluids, except when the practioner knows with certainty, not only that such fluids are present, but also that their quantity is considerable, so that no injury will be done to the parts beyond them by the sudden introduction of the instrument. In all other cafes, cautiously making a small puncture with a lancet, is the most prudent practice. Whenever a trocar is used, surgeons likewise avoid introducing the instrument to a dangerous depth.

The infant the perforator has passed through such parts as intervene between the fluid and the surface of the body, it has performed all that it ought to do: the attentive operator feels a sudden cessation of respiration to the infant, and he immediately holds back the fillet, whilst he only pushes forward the canula. See PARACENTESIS.

TROCHAIC, TROCHAICUS, in the Latin Poetry, a kind of verse consisting of trochees, or in which that foot predominates; as the iambus does in the iambic.

The 18th ode of the 2d book of Horace's Odes consists of strophes of two verses, the first of which is trochaic; meter catalectic, i.e. trochaic, composed of three trochees, and a syllable at the end, or wanting a syllable in the first foot; which some call the Euripidean trochaic:

---\n
Nōn | ēbār | nēque | ā̄u | rē̄m
Largiūra | flēgōs.

Long verses of fifteen half feet, which are more particularly distinguished by the name of trochaic, are nothing more than tetrameter iambics, or of eight feet, the first of which wants a syllable; as there are others where it is wanting at the end. Thus,---

Prō | pēōs | tē māg | nōs, pāu | ĕm fūp | pēićī | fātīs | īd
pārīs. Ter.

TROCHANTER, MAJOR and MINOR, in Anatomy, two considerable processes of the thigh-bone. See EXTREMITIES.

TROCHAR, in Surgery. See TROCAR.

TROCHE, TROCHICUS, in Pharmacy, a form of medicine, made into a cake or tablet, to be held in the mouth to diffuse gradually.

The troche is properly a dry composition; the chief ingredients of which, after having been brought into a very fine powder, and mixed with sugar, are incorporated with some proper liquor, as distilled waters, wine, vinegar, or mucilages, and reduced into a mafs, which is moulded into little cakes, or bulls of any form, at pleasure, and dried in the air, far from the fire. As remedies they are of little importance; and the preparation of them properly belongs to the confectioners; and they should be altogether rejected from the Pharmacopœia, as the London and Dublin colleges have done.

There have been and still are troches of various kinds, and for various intentions; as purgative, alterative, operative, corrosive, &c. troches.

Latin authors call them paffilli, rotula, placntula, orbes, and orbiculi; and the English, frequently, loosers.

The following troches are described in the Edinburgh Pharmacopoeia; viz.

Troches of Carbonate of Lime, prepared by rubbing to powder four ounces of prepared carbonate of lime, an ounce of gum arabic, one dram of nutmegs, and fix ounces of refined sugar, and forming them by means of water into a mafs fit for making troches. These are intended as antacids; but in the flat of the stomach which requires them, the efficacy of the carbonate of lime is counteracted by the sugar.

Troches of Liquorice are formed by dissolving in hot water extract of liquorice and gum arabic, of each one part, and two parts of refined sugar, and then straining; and afterwards evaporating the solution into a proper flat for troches. These troches are demulcent, and serve to allay the tickling irritation which occasions coughing; but the simple extract of liquorice, refined by straining and infilpation, found in the shops under the name of refined liquorice, will answer the same purpose.

Troches of Liquorice with Opium are obtained by well rubbing two drachms of opium, with half an ounce of the tincture of halfan of Tolu; adding gradually eight ounces of simple syrup, and five ounces of extract of liquorice, softened by hot water, and afterwards sprinkling in five ounces of powdered gum arabic; then drying the mafs, and forming it into troches, each weighing ten grains. These troches are rendered more efficacious than the former for the same purpose, by the opium; fix troches containing one grain of opium, and from fix to ten may be taken in twenty-four hours.

Troches, Gum, are prepared by rubbing four parts of gum arabic, one part of flarc, and twelve parts of refined sugar to powder, and forming them into a mafs fit for forming troches. These are simple demulcents, and serve to allay a tickling cough.

Troches of Nitrates of Potash are obtained by beating to powder one part of nitrate of potafs, and three parts of refined sugar, and forming them into a mafs fit for troches, by means of mucilage of gum tragacanth. Thus nitre may be agreeably taken in the dry state, and the troches may serve to cool the mouth in inflamations, and to stop the progress of inflammatory fore-throat, when taken at its commencement. They may also be used as a general refrigerant in fevers, diluting largely during the use of them.
TROCHILUS.

do is one or two taken every second or third hour.
Thomson's Lond. Diph.

**TROCHEE.** TROCHEUS, formed of τρικελιμα, I rns, be-
cause it moves quickly, in Greek and Latin Poetry, a kind of
foot consisting of two syllables, the first long, the latter
short; such as the words νυκτε and μαμά.

The trochee is the reverse of the iambus, and has just a
contrary effect; the latter being light and sprightly, and
the former weak and languid, as all those measures which are
move from a long to a short syllable.

Some called the trochee, chezeus, because it is proper for
songs and dances. These give the denomination trocheus
 to the tribrachys. Quint. lib. x. cap. 4.

**TROCHERA.** in Botany. See EHRHARTA.

**TROCHILUS, in Architecture.** a hollow member, more
usuall called, by modern architechts, the scotia; and, by our
English workmen, the c檃efent.

TROCHILUS, the Humming-bird, or Henny-shucker, in Ornitho-
ylogy, a genus of birds of the order Pica; the characters of
which are, that the bill is longer than the head, fabulate-
filiform, or cylindric, slender, with slightly-thickened tip;
the upper mandible being the lower; the tongue fili-
form, consisting of two conjoined slips forming a tube, and
extenfe; the legs flender and rather short, and feet formed
for walking; the tail composed of ten feathers.

The humming-birds constitute a lively brilliant race, dif-
tinguished by their beautiful colours and diminutive fize,
peculiar natives of the American continent and adjacent
lands, and, with few exceptions, confined to the hotter re-

The genus is extensive, and it has therefore been
found convenient to divide them into two fections, viz.
the curve-billed and the straight-billed.

* Curve-billed.

**PARADISEUS.** Red; head creffed; blue wings, and two
of the tail-feathers very long. This is the Paradife hum-

**PELLA.** Red (purple-red, Shaw), with brown (black,
Shaw) head; golden (topazine, Shaw) throat; green rump,
and two very long middle tail-feathers. This is the Colibri
topaze of Buffon, the long-tailed red humming-bird of
Edwards, and the topaz humming-bird of Latham. It is
the most brilliant of this fection, and has a decided su-
periority to all the rest by its magnitude as well as colours.
The female is far inferior to the male with respect to bril-
liancy of colour. This bird is a native of several parts of
South America, but is principally found in Surinam and
Guiana, frequenting the banks of rivers and brooks. Dur-
ing flight, they flun the surface of the water like swallows.

**SUPERCILIOSUS.** Gilded or shining brown; elongated
middle tail-feathers (white at the tips, Shaw), grey be-
nath, with long bill and white eye-brows. Shaw. The
supercilious humming-bird of Latham, distinguifped from
all others by the great length of its bill, and its strongly
euneated tail. The female differs by being of a pale rufo-
grey beneath, by having a shorter bill, the lower mandible
white, and the tail chiefly cuneiform and tipped with
white. Found in Cayenne.

**POLYMUS.** Glossy-green, with black crown and tail;
violet-brown wings, and two very long outer tail-feathers.
This is the long-tailed black-cap humming-bird of Edwards,
and black-capped humming-bird of Latham. An elegant
species, of considerable fize. A native of South America,
and found also in Jamaica. The female is greenish above
and white below; the sides of the neck varied with white
and green, and the tail defitute of the two long plumes so
conspicuous in that of the male.

**FORICATUS.** Gold-green, with blue crown, and gold-
blue forked tail, and two outer feathers very long. The
long-tailed green humming-bird of Edwards, and fork-
tailed humming-bird of Latham. An elegant but rare
species; found in Jamaica.

**LEUCURUS.** Coppery-green, with brown quill-feathers;
a reddish cresent in front of the neck, and white even tail.
The white-tailed humming-bird of Edwards and Latham.
Native of Surinam.

**JUGULARIS.** Gold-green, with a tinge of dusky-blue;
with blood-red throat and breast, blackish abdomen, and
even tail. Red-breasted humming-bird of Edwards and La-
tham. The garnet-throated humming-bird of Latham is of
the same species. Found in Surinam.

**THAUMANTHIS.** Gold-green, with blackish quill-feathers,
and tail-feathers edged with white; the exterior one entirely
white on the outdfe. The admirable humming-bird of
Latham, firft defcribed by Maregrave. A native of Brazil
and several other regions of South America.

**DOMINICUS, or PECTORALIS.** Green-gold, with velvet-
black breast; white belly, and purplifh blue-tail. The
black-breasted and St. Domingo humming-birds of Latham.
The female is said to be disfigured from the male by hav-
ing the green on the fore-part of the neck divided by two
white freaks, and the breast of a paler black than that of
the male. A native of the Weft India islands.

**MANGO.** Copper-green, with black defcending throat-
festrup and abdomen; violet-brown wings, and ferrigious
tail edged with black. The Mango humming-bird of
Latham. The female is said to differ in having the two middle
tail-feathers gold-green, like the back. A native of South
America, particularly of Brazil, but found in St. Domingo,
Jamaica, and other Weft India islands. Dr. Latham men-
tions a variety of this species, in which the throat, on each
side of the black stripe, was white. Gmelin makes the
"mellivora avis maxima" of Ray and Sloane a variety of
this.

**HOLOSERICEUS.** Gilded-green, with brown wings; black
tail and abdomen, and blue pectoral bar. The black-bellied
humming-bird of Edwards and Latham. Native of Mexico
and Guiana.

**GALERITUS.** Green-gold, with brown quill-feathers, and
purple creft. Found in Chili.

**EXILIS.** Brownish-green, with a glas of red; glossy-
green creft with gilt tip, and black wings and tail. The
little humming-bird of Latham, and humming-bird of a
black colour of Bancroft. The smallest of the curve-billed
fection. Native of Guiana.

**CYANEUS.** Velvet-crimfon, with blue back, and black
wings. The crimfon-headed blue humming-bird of Latham.
A native of Mexico.

**FURCATUS.** Glossy violet-blue, with gold-green crown
and throat, and black wings, abdomen, and forked tail.
The leffer fork-tailed humming-bird of Latham. A native
of several parts of South America, and of some of the
larger West India islands.

**MACROURUS, or FORICATUS.** Gold-green, with violet
eye and neck; abdomen marked by a white spot, and
forked tail. Cayenne fork-tailed humming-bird of La-
tham.

**PURPURATUS.** Green, with crown, wings, and bifur-
cated tail purple, and wreath blue. The purple-crowned
humming-bird of Latham.

**AURATUS.** See JUGULARIS. Of this Gmelin gives a
variety, viz. with cheeks, nape and throat golden-brown; head
and body black, with shining-green.

**GRamineus.** See DOMINICUS or PECTORALIS.
VIOlaceus. Dark purple-violet, glossy on the forehead, with green and gold wings and tail, the latter tinged with black. The violet humming-bird of Latham. Native of Cayenne.

Maculatus. See Gutturalis.

Punctulatus. Gold-green, with blackish wings; shoulders and back spotted with white, and brown tail with white tip. The spotted humming-bird of Latham. Native of Mexico, where it is called "Hottentot." Albicollis. See Gutturalis, of which it is a variety.

Aurantius. Brown, with orange head; yellow throat and breast, purple wings, and ferruginous tail. The orange-headed humming-bird of Latham. Native of South America.

Flavifrons. Green, with yellow front, and black wings and tail. The yellow-fronted humming-bird of Latham, and yellow-fronted honey-fucker of Pennant.

Venusissimus. See Cyanus.

Margaritaceus. Bright-green, pearl-grey beneath, with the tail steel-blue at the base, purple-brown in the middle, and white at the tip. The grey-necked humming-bird of Latham. Conjectured by Dr. Shaw to be female?

Hirsutus. See Brasilensis.

Multicolor. See Histrio.

Cineresus. Green, ash-coloured beneath, with violet-brown wings, and rounded steel-blue tail with white tips. The ash-bellied humming-bird of Latham.

Gularis. Gold-green; white beneath, with blackish wings and tail, and deep-blue throat and vent. Probably a native of South America.

Fulvus. Yellow, with the tail-feathers and covers thick; beneath brownish. A native of South America.

Varius. Green-gold; beneath white-brown, with a double pectoral band green-blue and blood-red. Found in South America.

Cyanurus. Green; cinerous beneath, with the throat, breast, and two very long middle tail-feathers blue. The blue-tailed humming-bird of Latham. Native of New Spain.

Fucifer. Gold-green, with brown wings; white throat, and glossy blue-green breast and forked tail. Native of Paraguay.

Capensis. Green, with long middle tail-feathers, and blue wing-coverts. Ekelberg's humming-bird of Latham.

Chrysochromos. Gold-green, with very bright throat and breast; subferruginous wings, and white-edged tail. Native of Guiana.

Sparganurus. Gold-green, with emerald throat, and black forked tail, with a gold-crimson bar across the feathers. The bar-tailed humming-bird. A very beautiful species, said to be a native of Peru.

Porphyurus. Brown, with velvet-black throat, and purple neck-striped and tail. A variety of the mango, according to Latham. Native of South America and the West India islands.

Gutturalis. Green-gold, with emerald throat; whitish-rufous on each side; black breast, and black abdominal stripe. The T. gularis of Latham; and maculatus of Gmelin. The green-throated humming-bird of Latham.

Nitidus. Violet-tailed humming-bird of Latham, and T. albus of Gmelin's Linneus. Supposed by Shaw to be a variety of the preceding.

Brasilensis. Gold-green; rufescent beneath, with violet-brown wings and tail; the latter tipped with white, and white-feathered legs. The rufous-bellied humming-bird of Latham. The T. hirsutus of Gmelin's Linneus. An elegant species. Native of Brazil.

Pascuatus. Green-gold, with rufous underparts; blackish-rufous head; and a black band edged with white along each side of the body. Banded humming-bird. Native of Paraguay.

Punctatus. Gold-green; beneath brownish undulated with white; with subviolaceous wings, and tail white at the base and tip. Scalloped humming-bird, strongly allied to the Mango, and it is not impossible, says Dr. Shaw, that it may be the young, in its first year's plumage.

Auroviridis. Gold-green, with blackish wings; and steel-blue tail with white tip. Native of the West India islands.

Aurulentus. Dark gold-green, with brighter throat and shoulders; black breast, brown abdomen, and subviolaceous tail. A native of the island of Porto-Rico.

Trichiatus. Gold-green; black beneath, with three white spots on each side; brown quill-feathers, and steel-blue tail. Native of South America. Dr. Shaw conjectures that this may be only a variety of T. mango, hololocularis, or pectoralis.

Elegans. Gold-green, with black breast; violet-black wings; and greenish-black forked tail. Native of St. Domingo.

Histrio. Brown, with gold-green crown, throat, breast, and shoulders; red belly, and blue cheeks. The harlequin humming-bird of Latham and Shaw, and the multicolor of Latham and others. A highly elegant species, and remarkable for its variety of colours. Native country uncertain.

Cristatellus. Green, with shining gold-green crest; and black wings and tail. Gilt-crested humming-bird of Latham. A small and elegant species, much allied to the T. exilis.

** With straight Bills.**

Platurus. Gold-green, with brown belly, quill-feathers, and tail; the two middle tail-feathers naked with webbed tips. The racket-tailed humming-bird of Latham. This is a rare species, and a native of South America.

Latipennis, of Campylopterus of Linnaeus. Gmel. Gold-green; grey beneath, with brown wings and tail; and the shafts of the greater quill-feathers dilated and incurvated. The broad-tailed humming-bird of Latham. One of the larger humming-birds, a native of Cayenne, and a very rare species.

Auritus. Gold-green; white beneath, with slightly elongated violaceous ear-feathers, black wings, and lateral tail-feathers. The violet-eared humming-bird of Latham; an elegant species. Native of Cayenne. Gmelin mentions a variety with a purple band below the eyes, a large area near the ears, below which is a green-blue spot.

Mellichorum. Gold-green, with blue head, neck, and breast, and white nuchal bar, abdomen and tail. White-bellied humming-bird of Edwards and Latham. Native of South America, and not uncommon in Cayenne. The T. simbratus, or spotted-necked humming-bird of Latham and Gmel. Linnaeus, is supposed to be a variety. There are also other varieties mentioned by Vieillot.

Ouiriassia. Gold-green, with blue back, breast, and belly; brown quill-feathers, and golden-brown tail. The green and blue humming-bird of Edwards and Latham. Native of Surinam. N. B. The American word "Ourilia," signifying a fun-beam, is applied by some of the earlier writers to certain species of humming-birds, on account of the
the splendour of their colours. Gmelin mentions a variety, viz. T. green; beneath blue, with orange spot on the chin; quill-feathers and tail obscure.

Superbus. Gold-green, with blue crown; double black-and-white cheek-stripe, and crimson throat and breast. Stripe-checked humming-bird of Shaw. This superb humming-bird is a most beautiful species, and one of the finest of this brilliant race. Native, probably, of South America.

Sapphirinus. Bright sapphire-coloured, with slighly-gilded back; brown wings; black abdomen, and fleck-blue tail. The sapphire humming-bird of Latham. Native of South America. Gmelin mentions a variety, viz. T. with sapphire breast, white belly, and tail blue-black.

Smaragdo-sapphirinus. With bright sapphire-blue head and throat; gold-green body; brown wings, and fleck-blue tail. The sapphire and emerald humming-bird of Latham. Native of South America and the West Indies. Shaw suggests that the two last mentioned humming-birds really constitute one species. He mentions a variety of the last from Viollet, viz. the blue-gorge humming-bird.

Lucidus. Bright gold-green, with deep-blue throat, breast, and tail; and a white spot behind each eye. Supposed by Azara and Somnini to be the same with the sapphire and emerald humming-bird. Native of Paraguay.

Amerystinus. Gold-green, varied beneath with grey and brown, with amethystine throat, and forked tail. The amethystine humming-bird of Latham. Native of Cayenne.

Moschitus. Purple-brown; blackish beneath, with ruby-gold crown, topazine throat, and black-tipped tail. The ruby-necked humming-bird of Latham. To this species Dr. Shaw refers the T. elatus of Gmelin’s Linnaeus, or ruby-crested humming-bird of Edwards and Latham. This is one of the most beautiful of the straight-billed humming-birds. Native of South America, and particularly of Brazil, Guiana, and Surinam. The ruby-crested humming-bird is a variety.

Pegasus. Gold-green; grey beneath, with brown wings, and blackish-purple tail with greenish hue. Grey-bellied humming-bird and gold-throated humming-bird of Latham. Dr. Shaw suggests that this may be a young female of T. moschitus.

Hypholcus. Gilded-brown; whitish beneath, with brown crown, and gold-green stripe down the middle of the throat. The brown-crowned humming-bird of Latham, conjectured by M. Viollet to be no other than an advancing young of T. moschitus.

Carumbulus. Glossy-black, with dark-red crown and nape, fiery-red throat and breast, and gilded-rufous tail. The caruncle humming-bird of Latham is supposed to be a variety of T. moschitus; rare in Cayenne.

Chrysurus. Gold-green, with cinnamon throat, brown quill-feathers, and topazine tail. Native of Paraguay.

Colubris. Gold-green; about three inches in length; beneath white, with gold-red throat, and purple-brown wings and tail. The red-throated humming-bird of Edwards and Latham, red-throated honey-fucker of Pennant, guainumbi of Maregrave. A beautiful species. A native of America, breeding in Carolina, Florida, and, as some say, in Canada; and also a native of Jamaica and some other West India islands. The female differs in having the whole under side white, without any redness on the throat, and all the tail-feathers, exclusive of the two middle ones, tipped with white. The general history of this beautiful bird is detailed by Mr. Pennant in his Arctic Zoology. Its flight is rapid, so that it is transient as lightning, and resembling this meteor in the glare of its colours: it feeds only upon the wing, suspended over the flower from which it extracts nourishment. The most violent passions sometimes agitate the little bodies of these birds. Their contests in disputing possession of the same flower are very violent; tilting against one another with such fury, as if they intended to transfuse their antagonists with their long bills. They are fearful of mankind, coming into apartments of houses, the windows of which are left open, but when approached, darting away with admirable velocity. Their nests, made in branches of trees amidst the thick foliage, are found with difficulty: they are of elegant structure, formed on the outside with moss, and within lined with down or mossy foliage collected from the great mullein, but sometimes constructed of flax, hemp, hair, and other soft materials. The female is said to be the builder, and the male supplies her with materials: both affight in the labour of incubation, which lasts twelve days: they lay only two eggs, which are white, and as small as peas. It is suggested that the patch-necked humming-bird of Latham’s first supplement is no other than a young male of this species. The tominoe of Gmelin is a variety.

Rubineus. Green-gold, with gold-red throat, purplish-brown wings, and rufous tail. The ruby-throated humming-bird of Latham. Native of South America, and particularly of Brazil, and is considered as one of the rarer kinds of humming-birds.

Mellisugus. Gold-green, with glossy blue-green throat, violet-black wings, and feathered legs. The emerald-throated humming-bird of Shaw, the all-green humming-bird of Edwards, and the Cayenne humming-bird of Latham. This is one of Maregrave’s guainumbi.

Collaris. Rufous, paler beneath, with gold-green crown, and gold-red throat, with the feathers elongated on each side. The rufus-necked humming-bird of Latham. This species is numerous in Nootka Sound.

Eubrostris. Blackish, with gold-green throat; each feather edged with grey, and white bill, thighs, and vent. The white-billed humming-bird of Shaw. Native of Cayenne.

Violleti. Blackish-olive, with golden gliss; beneath whitish, with violet-brown quill-feathers. Viollet’s humming-bird, and black humming-bird of Latham. This small species is common in the island of St. Domingo, supposed by Viollet to be the T. niger of Linnaeus.

Lecocrotophos. Gold-green; beneath grey, with white belly; a whitish stripe behind the eyes, and blue-black quill and tail-feathers. The most common species in Paraguay.

Maugeanus. Gold-green; beneath glossed with violet-blue, with violaceous-black wings and tail, the latter slightly forked. Maugean humming-bird, or Tobago humming-bird of Latham. Native of the island of Porto-Rico, whence it was brought by M. Mauge.

Ruber. Sub-ferruginous; slightly spotted with brown, with the side-feathers of the tail violet-brown. The little brown humming-bird of Latham. Brought from Surinam.

Cristatus. Gold-green, cinereous beneath; with golden-blue pointed crest, and violet quill-feathers and tail. The crested green humming-bird of Edwards and Latham. The female differs in wanting the crest, and in being ash-coloured beneath. Native of South America, and some of the West India islands.

Pileatus. Brown, with glossy-blue pointed crest. The T. puni-
T. puniceus of Linnaeus, Gmel., and crested brown humming-bird of Latham.

**minimus.** Gold-green; measuring about an inch and half in length; beneath whitish, with violet-brown wings and tail. Leafy humming-bird of Edwards and Shaw, &c. The smallest of the genus, and consequently of the whole feathered tribe: its general length being somewhat more than an inch and a quarter. Shaw’s General Zoology, vol. viii.

**striatus.** Brown; beneath white, with a longitudinal flria or streak green-gold; brown cap; black quill-feathers; base of the tail cinnamon-coloured, tip obscure. The brown-crowned humming-bird of Latham. Found in the island of Tobago.

**oscurus.** Blue; crown obscure; chin and throat glossy-green; middle of the back greenish; rump, wings, and tail purple. The dusky-crowned humming-bird of Latham.

**cyanoperculus.** Green-gold, with head, tail-feathers, and crown blue; abdomen red. Found in Chili.

**glaucopus.** Green-gold, with blue front; white vent; violet-brown tail-feathers; penated feet; tail fleck-blue sub-fuscated. The blue-fronted humming-bird of Latham. Found in Brazil.

**cyanomelas.** Variegated with white and blue; throat and breast red. Black and blue humming-bird of Bancroft and Latham. Found in Terra Firme and the Caribbee islands.

**guianensis.** Green, with crest and breast red; quill-feathers and tail-feathers green, variegated with red and purple. Guiana humming-bird of Latham.
