WESEP, a town of Holland, on the Vecht; well fortified towards the east. The great business of the inhabitants is to carry fresh water from hence out of the Vecht to Amsterdam, for brewing and other uses, for which traffic they have a particular kind of barges; 4 miles S.E. of Amsterdam.

WESER, a river of Germany, formed by the union of the Werra and Fulda, which falls by Hameln, Rinteln, Minden, Nienburg, Hoya, Bremen, &c. and runs into the German sea, about N. lat. 50° 48'. E. long. 8°.

Wesen, a department of the new kingdom of Welfphalia, composed of the bishopric of Oldenburg, and part of the county of Schaumburg; the number of inhabitants is 33,400. Oldenburg is the capital.

WESLEY, John, in Biography, one of the principal founders of Methodism, was the fon of a clergyman, who, educated under a father who was ejected for nonconformity, became a zealous high-churchman, and composèd the speech delivered by Sacheverel before the house of lords. John was born at Epworth, in Lincolnshire, of which his father was rector, in June 1703. Educated under pious parents, he was religiously disposed from his youth. From the Charter-house, where he received his school-education, he was removed to Christ-church college, Oxford; and after taking his first degree, he was elected, in 1724, fellow of Lincoln college, and, in 1726, proceeded to the degree of M.A. At this time he was esteemed a good classical scholar, and particularly conversant with dialectics. He was also a poet of no mean talents. Soon after his election to a fellowship, he became Greek lecturer and moderator of the claffes, and undertook the instruction of pupils. In 1725 he was ordained by bishop Potter. During some years of his residence at Oxford, he was much esteemed on account of his own character and conduct, and for his attention to discipline and good morals. Upon the perusal of some devotional books, and more especially Law's "Serious Call," he became different as to his own religious fflate, and determined to pay stricter regard to what he conceived to be the essentials of a holy life. In 1729 he associated with a select number of collegians, who met and read together, first the classics on week-days, and on Sundays only divinity; but afterwards their meetings became exclusively religious. They visited the prisons and fick poor, conversed together on the state of their minds, observed the ancient farts of the church, and communicated every week. This society, which consisted of fifteen members, attracted notice on account of the strictness of their manners and deportment; and became the objects of ridicule to some young men in the university, who denominated them Sacramentarians, the Godly club, and Methodists. (See the article.) Some of the seniors of the colleges were alarmed by an introduction of fanaticism; and others encouraged them to proceed, and they received the approbation of the bishop of Oxford. Welley, after his ordination, settled as anfilit to his father at Epworth, who being defirous of retaining this church preferment in his family, wished him to seek interest for obtaining it; but his attachment to Oxford, and to the society which had been there formed, prevailed over every other consideration. In process of time he formed a purpose of going to Georgia, as a missionary; and accordingly he embarked for this province in the year 1735. The prospect of success in this mission seemed at first to be favourable; but several circumstances occurred which changed his views, and induced him to leave Georgia, after a residence of one year and nine months. These circumstances, as some persons have related them, reflect no great honour on We1sey's disposition and character. It appears, however, upon the whole, more especially when we consider Whitefield's successes in the same part of the world, that he was less qualified for a missionary than his fellowlabourer. After his return to England, he felt dissatisfied with his own state, and entertained suspicions of the reality of his own conversion, though he had undertaken to convert others. Prepared for a sudden conversion, it actually happened at a place and time, and in a manner, which he has recorded. According to his own account, this memorable event is referred to the 24th day of May, in the year 1738, at a quarter before nine in the evening, when some person at a society in Aldergate-street was reading Luther's preface to the epistle to the Romans. "He felt his heart strangely warmed. He felt that he trusted in Christ alone for salvation; and an assurance was given to him, that Christ had taken away his sins, and faved him from the law of sin and death." These feelings of assurance, however, were blended with occasional misgivings; and it seems that, in his cafe, enthusiasm could not instantaneously overpower his philosophical reallonings. His cafe is far from being singular in the history of persons of the same description. About this time
time he took a journey to Germany, in order to derive a further confirmation of his faith from intercourse with congenial spirits at the head-quarters of the Moravians, at Harnhuth. (See Unitas Fratrum.) After his return to England, in September 1738, he entered on his course of labours; and preached or exhorted, frequently three or four times a day, in prisons and other places of the metropolis, as well as in various parts of the country, where the fervour of his zeal bore a proportion to the degree of obloquy which he incurred. His exercises produced wonderful effects, and occasioned in the hearers swoonings, exclamations, convulsions, &c. which have been often the accompaniments of violent emotions. At Bristol, where he had been preceded by Whitfield, he collected large crowds of attendants in the open air. But it was now desirable that a building should be erected for the accommodation of the followers of these popular preachers. In May 1739, the first stone of such an edifice was laid at Bristol; and with this building commenced the absolute and unlimited power which Wesley exercised over his followers. "The direction of the work was first committed to eleven seoffees of his nomination; but as it became necessary for him to engage for the payment of the workmen, and to collect money for this purpose, he visited London, and upon consulting Whitfield and others, he was told, that they would do nothing in the matter, unless he would discharge the seoffees, and take the whole business into his own hands. They gave various reasons for this determination; but one," says Wesley, "was enough, viz., that such seoffees would always have it in their power to control us; and if I preached not as they liked, turn me out of the room that I had built." He, therefore, assembled the seoffees, and with their consent cancelled the instruments made before, and took the whole management into his own hands; and this precedent he ever after followed, so that all the numerous meetings of his classes of Methodists were either held in him, or in trustees who were bound to give admission into the pulpit either to him, or to such preachers as he shall appoint. Unable to associate clergymen in the prosecution of his plan, which seems to have been his first design, he determined to employ lay-preachers as itinerants to the different societies; and of these talents he formed some judgment by their performances at the meetings for prayer and mere private exhortation. Referring to himself the nomination of his preachers, his authority was extended as his societies were multiplied. For the use of these societies, he and his brother Charles drew up a set of rules for the direction of their moral and religious conduct, which are said to have been formed upon the pattern of primitive Christianity. A circumstance occurred which threatened injury to the cause of Methodism; but it eventually contributed to its extension, and to the establishment of Wesley without a rival at the head of his own body. Whitfield had imbibed a predilection for the doctrines of the Puritan divines, which were in general Calvinistic. Wesley's opinions were Arminian; so that it was impossible for these two leaders of separate tenets to unite. "The differences between them turned upon the three points, unconditional election, irresistible grace, and final perseverance, concerning which topics their notions varied so much, that Whitfield plainly told his brother reformer, that they preached two different gospels, and that he would not only refuse to give him the right hand of fellowship, but was resolved publicly to preach against him and his brother wherever he preached at all." Although they afterwards spoke of each other with esteem, yet their separation was enture and lasting.

The system of discipline formed by Wesley was admirably contrived both for gaining profelytes, and for extending and making permanent his own influence. As he did not profess to establish a new or distinct sect, he did not interfere with the regular ordination either of the establishment or of Dillenants, so that he and his preachers robbed no other ministers of their hearers; and they availed themselves of those feactions, which gave persons that were desirous of attending leasure for this purpose. That he might not be charged with drawing people away from the established church, or other societies of Christians, he did not administer the sacrament of the Lord's Supper in his own chapels, but recommended attendance for this purpose in the established church. (See Methodists.) The plan of itinerancy was a political measure in the system of Mr. Wesley, as variety serves to excite curiosity, and to increase the number of his followers. It seems also to relieve preachers and hearers, when the flock of the former is small; and it also prevents these missionaries, if they may be so called, from forming permanent connections in any place whether they are fent, and of acquiring an influence, which would be inconvenient with the supremacy of the chief. In order to maintain an union between the members of this body, and to exercise a degree of vigilant inspection with regard to their conduct, Wesley has divided each society into companies of ten or fifteen, called classes, to each of which belongs a leader, whose services it was every week to see every person of his class, and to inquire into his religious state. Many of these companies were divided into smaller parties, called bands, in which the married and single men, and the married and single women, were ranged apart, and they were directed to maintain a confidential intercourse with regard to their character and state with each other. From these bands again were formed feoffees bands, consisting of those who had attained to perfection. Of his lovers, &c. we have given an account under Methodists. Stewards were appointed to receive contributions, which the lowest members were expected to pay, however small the sums, and to superintend the temporal concerns of the societies. In order to preserve a connection between the preachers, as well as to maintain their ultimate subordination to him, Wesley found it useful to summon annually a considerable body of them, in order to consult with him, and with one another, concerning the general affairs of the societies. These assemblies were called "Conferences," and the great number of them at which Wesley had to preside was a principal means of consolidating the whole frame of the society, and maintaining his permanent authority over every part. Wesley and his first followers had many difficulties with which to contend; but their constancy and fortitude, and the apparently beneficial effects of their endeavours in reforming some of the most abandoned members of the community, enabled them ultimately to triumph over all opposition, and to pursue their labours without molestation. On account of his fanaticism and enthusiasm he has suffered ridicule and reproach; and some have even suspected his sincerity in the details which he has given of the extraordinary manifestations of light that have been communicated to him, and the no less extraordinary interpositions of Providence in his favour; alleging that he possessed a degree of understanding which could not be disputed, and, therefore, charging him with a design of deluding others, in order to serve his own purposes. But these are harsh reflections, the justice of which we cannot be induced easily to allow. About the year 1759, Wesley, who had long been the eulogist of a single life, thought proper to marry a rich widow, whose fortune he settled wholly upon herself; but this connection proved an occasion of in felicity.
to question; and he will be a memorable person as long as the fabric which he so much contributed to raise shall endure." Lives of J. Wesley, by Hampson, Coke, and Whitehead. Gen. Biog. See METHODISTS.

WESLINGBUHREN, in Geography, a town and duchy of Holstein, situated near the coast of the North sea; 53 miles N.W. of Hamburg.

WESOWKA, a town of Poland, in Volhynia; 60 miles N.N.E. of Zyтомiers.

WESSEL, John, in Biography, an eminent philosopher and divine, was born at Groningen about the year 1409, or 1419, and pursued his studies with incredible ardour both at Zwoll and at Cologne. At the latter place his orthodoxy was suspected, as he propaded difficulties which his masters could not solve. He taught philosophy for some time at Heidelberg, and after visiting several universities, went to Paris, where the disputes ran high between the Realists, Formalists, and Nominalists. He fluctuated between the opinions of these different sects. He predicted the decline of the doctrines of Thomas Aquinas, Bonaventure, and other disputants of that class; and intimated his apprehension that they would be exploded by all true Christian divines, and that the irrefragable doctors themselves would be little regarded. His reputation procured for him the esteem of Francis delle Rovere, general of the Friars Minor, whom he accompanied to the court of Basil, and with whom he returned to Paris, where he resided many years. When his patron was made pope, under the name of Sixtus IV., he paid him a visit at Rome, and being told that his holiness would grant him whatsoever he asked, he limited his request to a Hebrew and a Greek bible from the Vatican. "You shall have them," said the pontiff; "but, simple man that you are! why did not you ask a bishopric?"

"Because (answered Wessell) I do not want one," a reply on which Dr. Jortin has bestowed just applause.

This worthy person died at Groningen in 1489. On his death-bed he lamented to a friend that he had been distressed with doubts concerning the truth of the Christian religion; but at his friend's second visit, he told him with great satisfaction that his doubts were all dissipated. So extraordinary was his learning, that he was distinguished by the appellation of the "Light of the World," and such was his spirit of free enquiry, that his name is enrolled in the Protestant Catalogue of Witnesses of the Truth. Of his liberal opinions some were, "that the pope might err—that erring he ought to be refuted—that his commands are obligatory only as far as they are conformable to the word of God—and that his excommunications are lefs to be feared than the disapprobation of the lowest worthy and learned man." We need not wonder then that the monks should have committed all the manuscripts found in his study to the flames. Such as escaped conflagration were printed collectively at Groningen in 1614, and at Amsterdam in 1617. Part of them had been previously printed at Leipsic in 1522, under the title of "Farrago Rerum Theologicarum," with a preface by Martin Luther, Bayle, Molsheim. Brucker by Elnfeid.

WESSELY, in Geography, a town of Moravia, in the circle of Hradisch; 5 miles N.E. of Strzelitz.—Alfo, a town of Bohemia, in the circle of Bechin; 5 miles S. of Sobieslaw.—Alfo, a town of Moravia, in the circle of Bruns; 36 miles N.W. of Bruns.

WESSEM, or WESSEM, a town of France, in the department of the Lower Meuse; 4 miles S.S.W. of Ruremond.

WESSEN, a town of Austria; 9 miles N.W. of Efferling.

WESSNITZ. See WESSNITZ.
WEST, GILBERT, in Biography, the son of the Rev. Dr. Weft, prebendary of Winchester, and of aifter of Sir Richard Temple, afterwards lord Cobham, was born in 1706, and educated for the church at Eton and Christchurch, in Oxford; but preferring a military life, he served in the army till he received an appointment in the office of lord Townshend, secretary of state, with whom he accompanied king George I. to Hanover. In early life he entertained doubts concerning the Christian religion, which were instilled into him and his cousin Lyttelton by lord Cobham. In 1729 he was appointed a clerk-extraordinary of the privy council; and soon after, being married, he settled at Wickham in Kent. His income was not large, but it was sufficient to entertain his friends Pitt and Lyttelton, who often visited him for literary recreation at Wickham. As a poet, he was known in 1742 by a piece on a dramatic plan, intitled "The Institution of the Order of the Garter," distinguished by pure and elevated morality, and containing passages of elegant fancy and splendid diction. Weft's "Observations on the Resurrection of Christ," published in 1747, engaged the particular attention of the public, and even induced the university of Oxford to confer upon the author the degree of doctor of laws. This work was so well executed, that we may well regret his not having lived to have completed his design by another work on the evidence of the truth of the New Testament. In 1752 the circumstances of our author were improved by succeeding, when Mr. Pitt became paymaster-general, to one of the lucrative clerkships of the privy council, and his obtaining the place of treasurer to Chelsea hospital. In 1755 he lost an only son, and in the following year his life was terminated by a paralytic stroke, March 1756, at the age of fifty. "Mr. Weft was a gentleman in manners, agreeable in conversation, and lively though serious. He was regular in the performance of family devotion and in attendance on public worship, and was particularly attached to Dr. Clarke as a preacher.

The other works of Mr. Weft were, "Translations of the Odes of Pindar, with a Dissertatio on the Olympic Games;" "Translations from the Argonautica of Apollonius Rhodius, and the Tragopodagra of Lucian;" "The Aules of Travelling;" and "Education," poems in the imitation of the Flaneus and manner of Spencer; "Iphigenia in Tauris," from Euripides; and "Original Poems on Various Occasions." Several of these pieces were printed in the collections of Dodwell and Pearch, and also in three distinct volumes, 12mo. 1766; and entitle the author, fays his biographer, to a respectable rank among the minor poets. Johnson's Lives. Nichols's Lit. Anecd. Gen. Biog.

West, Occidens, Occa, in Cosmography, one of the cardinal points of the horizon; diametrically opposite to the east.

West is strictly defined, the interception of the prime vertical with the horizon, on that side in which the fun sets.

To draw a true west line, see Meridian.

West, in Astronomy, is chiefly used for the place, in or towards which the sun and stars sink under the horizon. Thus we say, the Sun, Mars, &c. are in the west.

The point in which the fun sets when in the equator, is particularly called the equinoctial west, or point of true west.

West, and Weftem, in Geography, are applied to certain countries, &c. situate towards the point of fun-setting with respect to certain others.

Thus, the empire of Rome, anciently, and of Germany, at present, is called the term of the West, or western empire, in opposition to that of Constantinople, which is called the empire of the East.
West Cape, a cape on the W. coast of Taiw-poe-nam-moo, the southernmost island of New Zealand. S. lat. 45° 54'. W. long. 195° 17'.

West Cappel, a town of Holland, in the island of Walcheren; 6 miles N.W. of Middleburg.

West Chester, a county of New York, containing 30,272 inhabitants.

The following statistical table is founded upon the census of 1810.

It sends three members to the house of assembly. It is situated on the E. side of the Hudson, N. of New York county; bounded N. by Dutchess county, E. by the state of Connecticut, S. by Long island found and East river, W. by Haerlem river and the Hudson; or by New York county, the state of New Jersey, and the county of Rockland. Its area is about 480 square miles, or 307,200 acres, situated between 40° 47' and 41° 22' N. lat.; 3° and 32' E. long. from New York.

West Chester, a township of New York, at the S.W. extremity of Westchester county, on East river; 12 miles from New York. Its mean extent from N. to S. may be 4 miles, and from E. to W. about 5 miles, with an area of 20 square miles. It is a valuable tract of land, somewhat tony, with a large proportion of clayey loam, which, with good husbandry, may be rendered productive. Westchester village, situated at the head of the navigation on Westchester creek, contains about 25 dwellings, an episcopal church, a Friends' meeting-house, a school-house, a gristmill, and about 200 inhabitants. Adjoining to it is a bed of marble and an extensive common. In the township are several manufactories, grist-mills, three houses for worship, one for Friends, one for Episcopalians, and one for Dutch Lutherans, and six school-houses, and many elegant country-seats. For its population, &c. see the preceding article.

West Chester, a county of Pennsylvania, in the county of Chester, containing 471 inhabitants.

West Creek, a river of New Jersey, which runs into the Delaware bay, N. lat. 39° 14'. W. long. 74° 57'.

West Falmouth, a township of Pennsylvania, in the county of Chester, containing 1,157 inhabitants.

West Goshland, or Westrogothia. See Gothland.

West Harbour, a bay on the S. coast of Jamaica, formed by a peninsula, called Portland Ridge. N. lat. 17° 48'. W. long. 77°.

West Indies, in Geography and Commerce, comprehends all the islands that lie in the Caribbean sea, between North and South America; and also a few of the neighbouring settlements on the continent. (See W. Ind. The larger islands, or greater Antilles, are, Jamaica, belonging to the English, Cuba (Spanish), Porto Rico (Spanish), and St. Domingo (French and Spanish). The smaller islands, or lesser Antilles, called also the Caribbean islands, are divided into leeward and windward islands. The former are Tortola, the Saints, Barbuda, Antigua, St. Kitt's, Nevis, Montserrat, and Dominica (English), Guadeloupe and Martinique (French), St. Eustatius and Martin (Dutch), St. Thomas, Santa Cruz, and St. John (Danish), and St. Bartholomew (Swedish). The latter are, Barbadoes, St. Vincent, Grenada, and Tobago (English), Martinico and St. Lucia (French). The islands on the coast of Terra Firma are, Trinidad and Margarita (Spanish), Curacao and Bonaire (Dutch). The settlements on the continent of South America are, Demerara, Berbice, Essequibo, and Surinam (Dutch). In specifying the monies, coins, currencies, and exchanges of the West Indies, we shall avail ourselves of the arrangement of Dr. Kelly in his valuable work, and clas the islands under the five general heads of English, French, Danish, Dutch, and Spanish; premising, that though the several islands and settlements, which we have already enumerated, are subject to various political changes, they nevertheless, for the most part, retain the weights, measures, and denominations of money belonging to the European nations by which they have been colonized.

In the English islands, accounts are kept in pounds, shillings, and pence currency; the West India currency being an imaginary money, which varies considerably in its proportion to sterling, so that it is in some places reckoned at 14o, and in others 200, for 100 English, more or less. The principal coin circulating in the West Indies is the Spanish dollar, and this seems to be the standard by which the value of all other monies is regulated; and with regard to the proportion between sterling and currency, it should be observed, that although it has been declared by different authorities, yet it is chiefly regulated by the course of exchange with London. Of the English islands, the first we shall take notice of is Jamaica. The currency of this island is 10s., and its proportion to sterling is as 7 to 5; so that 1s. sterling is = 20s. currency, and 1d. currency = 1s. 3d. sterling. The price of the dollar is 6s. 8d. currency.

The gold coins current in this island, with their value in currency, appear in the following Table.

R 1.2 The
The deduction for every grain of deficiency of weight is 3d. currency.

The silver coins of Jamaica are dollars, with their halves, quarters, eighths, and sixteenths, passing for 6s. 5d., 3½d., 1½d., and ½d. currency. Besides, there are bits or bitts, being Spanish reals, and passing for ½d. currency; so that 10 bits and ½d. currency make a dollar, and 1 bit is worth ½d. silver. Piftereens, or two-bit pieces, which are Spanish pecetas, pass for ½d. currency, and are worth 1½d. silver. English shillings and sixpences occasionally pass as pitfereens and bits. From the above statement it appears, that the intrinsic pair of the currency of Jamaica with respect to sterling is as follows; the calculations being made according to the mint price of gold and silver in England:

<table>

By a law of the Jamaica assembly, the exchange with England was fixed at 40 per cent.; but it has considerably varied: bills being sometimes at a premium of 20 per cent. above the legal exchange, and seldom under 10; dollars occasionally bear a premium of 3 or 4 per cent.

The currency of Barbadoes is sometimes reckoned at 135, and sometimes at 140, for 100l. /sterling; but it has never been settled by legal authority. The value of the coins has been estimated by proclamation, and according to these values the pair is above 140.

The gold coins current here, with their legal value, are shewn in the following Table.

| Spanish | Doubloon | - | - | 17 | 8 | 4 | 10 0 |
| Two-pitole piece | - | - | 8 | 16 | 2 | 5 0 |
| Piftole | - | - | 4 | 8 | 1 | 2 6 |
| Half piftole | - | - | 2 | 4 | 0 | 11 3 |
| Portugueese Johanes (called joce) | - | - | 18 | 10 | 5 | 0 0 |
| Half joce | - | - | 9 | 5 | 2 | 10 0 |
| Quarter joce | - | - | 4 | 14 | 1 | 5 0 |
| Moidore | - | - | 6 | 21 | 1 | 17 6 |
| Half moidore | - | - | 3 | 10 | 0 | 18 9 |
| Guinea | - | - | 5 | 8 | 1 | 10 0 |
| Half guinea | - | - | 2 | 16 | 0 | 15 0 |
| Seven-hilling piece | - | - | 1 | 19 | 0 | 10 0 |

N.B.—The deduction for light coin is 2½d. currency for every grain of deficiency.

The current silver coins are dollars, with halves, quarters, eighths, and sixteenths, passing for 6s. 3d., 3½d., 1½d., and ½d. currency. Also bits, which are Spanish reals, and which pass for ½d. currency; thus, 10 bits make 1 dollar, and 1 bit is worth ½d. silver. Piftereens, or two-bit pieces, which are Spanish pecetas, pass for ½d. currency. There are also French bits, called crimbal, or ile du vent bits, which pass for ½d. currency.

The Barbadoes currency compared with sterling is

In the English leeward islands the dollar is reckoned at 9s., and this rate is generally called the leeward currency.

A small circular piece cut out of the centre of the dollar, about one-twelfth of its value, in order to prevent its exportation, is allowed to pass for one-eighth, and is stamped by authority with the initials of the island.

The dollar, thus cut, passes for 8½d. currency; it is called the "cut dollar," by way of distinction from the whole or "round dollar." The piece taken out is sometimes called the "bit," and sometimes the "moco," which moco is, in some places, one-fourth of the dollar, and in others one-eighth. In these islands there are small copper coins, called stampe, dogs, and half dogs, valued as in the following Table.

| 1/2 Dog | make 1 Dog | - | - | 0 | 0 | 1 1 2 |
| 1/2 Dog or 4 stampe | - | - | 1 | 8 0 | 0 | 2 4 0 |
| 1/2 Bit | - | - | 1 | 0 | 0 | 9 0 |
| 12 Bits or 8 mocos | - | - | 1 | Round dollar | 0 | 9 0 |
| 5 Round dollars | - | - | 1 | Guinea | 2 | 5 0 |
| 8 Cut dollars | - | - | 1 | Joe | 3 | 6 0 |
| 16 Round dollars | - | - | 1 | Doubloon | 7 | 4 0 |

For a deficiency of weight, an allowance is made of 4½d. currency for English grain. The exchange with London is generally about 200 per cent.

In the English windward islands the currencies are nearly the same as the former, allowing for some local regulations and customs.

In the French islands accounts are kept by the French settlers in livres, sols, and deniers; and by the English (particularly in exchanges) in pounds, shillings, and pence currency; the livre and shilling being of the same value.

The currency is the same as that of the English leeward and windward islands: but the names of the coins are different; the dog being called the noir, the flambe the tempe, the bit the escalin, and the dollar the gourde.

The value of the coins appears in the following Table.

| 1/4 Dog | make 1 Dog | - | - | 0 | 0 | 1 1 2 |
| 1/4 Dog or 4 stampe | - | - | 1 | 8 0 | 0 | 2 4 0 |
| 1/4 Bit | - | - | 1 | 0 | 0 | 9 0 |
| 12 Bits or 8 mocos | - | - | 1 | Round dollar | 0 | 9 0 |
| 5 Round dollars | - | - | 1 | Guinea | 2 | 5 0 |
| 8 Cut dollars | - | - | 1 | Joe | 3 | 6 0 |
| 16 Round dollars | - | - | 1 | Doubloon | 7 | 4 0 |

The following gold coins are taken by weight.

Portugal pieces, at - - - - 22 livres per gros
Counterfeit ditto, coined in America, at 20 ditto per gros
French and Spanish coins deficient in 19l. 15s. per gross weight, at - - - - 54 livres per ditto.

English ditto at 8 livres, 8 sols per dwt., that is, 7 sols per English grain.
In the French part of St. Domingo, or Hayti, accounts are mostly kept in dollars and cents, as in the United States. The monies in circulation here are nearly the same as in the leeward islands. Dollars are valued at 4½ 6d. sterling, with halves and quarters in proportion; 1 ecusin pafe for 1 dollar, and 1 ecusin is reckoned at 9 cents. Doubloons pafe for 16 dollars; joes for 8 ditto; French crowns for 1 dollar 9 cents, and the half-crowns in proportion; French pieces of 5 francs pafe for 9 ecusins, or 8½ cents.

In the Dutch colonies of St. Eustatia, St. Martin, Curacao, accounts are kept in pieces of eight; that is, piastras current of 8 reals or shillings, each real being subdivided into 6 livres. The piastra gourde or Spanish dollar pafes for 11 reals or bits; and thus the current piastra is worth 3¾ 5d. sterling, reckoning the dollar at 4½ 6d. sterling.

The joes pafe here for 11 piastras current; the Spanish single piftole for 4½ piastras, more or less; the other Spanish and Portuguese gold coins in proportion.

In the settlements of Surinam, Berbice, Demerary, and Essequibo, accounts are kept in guilders of 20 flours; the fliver being divided by some into 8 duits, and by others into 12 pennings.

All the coins of Holland circulate here, and are mostly reckoned at 20 per cent. above their value in Dutch currency. The following is their general rate, as well as that of other monies:

The chief circulating medium here is paper, issued by government.

In 1809 a new silver coinage was minted at the Tower of London for these colonies, consisting of pieces of 3, 2, 1, ½, and ¼ guilders. The larger piece weighs 15 dwt.; and is 1 oz. 6 dwt. worse than English standard. Its value therefore is 3½ 5d. sterling, or computing it as the dollar is now rated in the West Indies (i.e. at 4½ 6d.), its value is 33 8¾d., and the smaller pieces in proportion. They are marked on the reverse, COLONIES OF ESSEQUIBO AND DEMERARY TOKEN; and the king's head is on the obverse.

The exchange with London should be about 12 guilders for 1½ sterling, but it varies considerably above this, even to 20 guilders and upwards.

In the Danish islands accounts are kept in piastras or rixdollars current (called afio pieces of eight), subdivided into 8 schillings or bits, and each bit into 6 flivers: accounts are also kept in dollars of 100 cents, as in America. The silver coins struck for the Danish islands are quadruple, double, and single bits, and pieces of 1 and 3 flivers. The Spanish dollar pafes for 12½ bits, and each bit for 1½ flivers. The leeward currency is used in the Danish islands in the purchase or negotiation of bills on England: gold is valued at 1 dollar per dwt. or 43d. currency per English grain.

The moneys, coins, weights, and measures of the Spanish islands are the same as those in Spanish America, or Mexico; accounts being kept in pefos or dollars of 8 reals, subdivided into 16 parts, and also into 34 maravedes de Plata Mexicanos. The gold coins are doubloons of 8 escudos d'oro, worth 15 pefos; halves and quarters in proportion. The silver coins are, pefos Mexicanos, or dollars, with halves and quarters,
such as pollage, notarial expenses, and difference of exchange.

If a bill, drawn in the West Indies on any part of Great Britain, be noted for non-acceptance, the holder may oblige the drawer, by legal process, to give security in the inland for the amount, without waiting for the bill being protested for non-payment. See Kelly’s Cambium, vol. i.

WEST Iland, in Geography, one of the smaller Philippine islands, near the south coast of Mindoro. N. lat. 12° 18’. E. long. 121° 12’.—Also, a small island at the east entrance of the straits of Sunda. S. lat. 5° 21’. E. long. 106° 20’.—Also, a small island in the East Indian sea, near the south coast of Cumbava. S. lat. 8° 45’. E. long. 119° 21’. 

WES Kirk, a town of the island of Weftra, in a bay on the south coast. N. lat. 5° 9’. W. long. 2° 51’.

WEST Houghton, a township in the parish of Dean, and county of Lancaster, England, contained, in 1811, 653 houses and 3810 inhabitants.

WEST Penn, a township of Pennsylvania, in the county of Northampton, containing 947 inhabitants.

WEST Point, a town of Virginia, on the York river; 35 miles E. of Richmond. N. lat. 37° 30’. W. long. 76° 50’.

WEST Point, a town of New York, on the right bank of the Hudson river, in the county of Orange. This was a poft of great consequence, especially with respect to the communication between the northern and the middle colonies, and the poftoffice very desirable to the British general, who entered into a treaty with general Arnold the commander to betray it. The adjutant-general of the British army, major André, was employed by sir Henry Clinton as the agent on this bufinefs, and being discovered, he was executed as a spy; 42 miles N. of New York. N. lat. 41° 23’. W. long. 74’.

WEST Point, a cape at the western extremity of the island of Anticosti. N. lat. 49° 50’. W. long. 64° 30’.

WEST River, a river of Virginia, which runs into Black bay, N. lat. 36° 30’. W. long. 76° 17’.—Also, a river of Maryland, which runs into the Chefapeak, N. lat. 38° 54’. W. long. 76° 42’.—Also, a river of the province of Maine, which runs into Machias bay, N. lat. 44° 45’. W. long. 67° 19’.

WEST River, or Wantastic, a river of Vermont, which runs into the Connecticut, N. lat. 42° 50’. W. long. 73° 31’.

WEST River Mountain, a mountain of New Hampshire, near Wefit river.

WEST Town, a township of Pennsylvania, in the county of Chester, with 790 inhabitants.

WEST Wain, the west shore of Hudson’s bay.

WESTBROUGH, a town of Machaffattucks, incorporated in 1717, in the county of Worcefter, containing 1048 inhabitants; 33 miles W. of Boston.

WESTBURY, a market-town and borough in the hundred of the same name, and county of Wilts, England, is situated at the distance of 24 miles N.W. by W. from Salisbury, and 97 miles W. by S. from London. Nothing is known with certainty of its history, till the reign of Edward I., when it was constituted a corporate town by charter, under the jurisdiction of a mayor, recorder, and twelve capital burgesses. Wefitbury lends two members to parliament, and has done to regularly since the 27th year of Henry VI., who renewed its charter of incorporation, and bestowed upon it the additional privilege of being represented in the national councils. The right of election is in the holders of burbage tenures, being resident within the borough, and not receiving alms: the mayor is the returning officer. The town consists principally of one long street, running nearly in a direction north and south. According to the population return of the year 1811, it contained 351 houses, and 1790 inhabitants, who were chiefly engaged in the manufacture of woollens. A market is held weekly on Fridays; and two fairs annually, when there is usually a large supply of cattle, horses, sheep, pigs, cheese, &c. The borough and hundred of Wefitbury form only one parish: for the former, a court-leet is held by the mayor in November annually; and for the latter, one in May by the reeve of the lord of the manor, at which two high constables are appointed for securing the public peace. The only public buildings in this town which demand particular notice, are the town-hall and the church. The hall is a convenient edifice, in which the borough-courts are held: it is situated near the centre of the town, and is also appropriated in part as a wool-hall. The church is a large ancient structure of stone, with a tower in the middle. In it are several monuments in honour of persons of considerable note.

About a mile to the south of Wefitbury is the village of Leight, commonly called Wefitbury-Leight; supposed by several antiquaries to be the place designated in After by the word Engles, where king Alfred encamped on the night previous to the battle of Ethandune.

Heywood house, situated about two miles due north from Wefitbury, was built in the reign of king James I., by James, lord Ley, afterwards created earl of Marlborough. It was long possessed by the family of Chipps; but is now the property and seat of Abraham Ludlow, esq.—Beauties of England and Wales, vol. xv. Wiltshire. By J. Britton, F.S.A. 1814.

WESTBURY, a village in the hundred of Ford, and county of Salop, England, situated 8 miles W. by S. from Shrewsbury. In this village is a respectable free-school; and in the church, among other monuments, is one raised to the memory of general Severne, who inherited Wallop-hall, in this parish. About two miles S.W. of Wefitbury is Cawfe, or Caux-Cafile, which is supposed to have been erected by Roger Corbett, who held of earl Roger de Montgomery a tract of land confuting of thirty-nine manors. It is conjectured that he gave the above name to this his capital seat, in allusion to a castle in the Pays de Caux, in Normandy. As he and his son probably joined with Robert de Belesime in his rebellion, the castle is supposed to have been forfeited to Henry I., who gave it to Paris Fitz-John, from whom it was taken by the Welsh. It was restored to the original lords, and in the first of King John a weekly market was obtained for it, at the instance of Robert Corbett. Its proximity to the Welsh frontiers rendered its tenure uncertain, and we find that it was again seized by the Welsh, and restored by Henry II. In the reign of Edward III., the male line of the family becoming extinct, the castle was transferred, by marriage of a daughter of the houfe, to the Staffords, earls of Stafford; on the execution of the last of whom, Edward, duke of Buckingham, it was forfeited to the crown, but was restored to his son Edward. It was alienated in the reign of Elizabeth to Robert Harcourt, from whom it descended to lord vifcount Weymouth. The site of this castle is perhaps one of the most lofty and commanding in the whole range of the Salopian frontier. It is an inflated ridge, rising abruptly from a deep ravine on one side, and sloping towards a vall valley, bounded by the Stiperstones on the other. The keep-mount is singularly steep and towering; it must have been ascended by steps, or by a winding path, but no traces of either at present remain: part of a wall is still distinguishable;
tinguishable; the cattle itself is nearly destroyed. Parts of one of the entrance-gateways, evidently of a more recent date than the original cattle, are still to be discerned.—

**WESTBURY**, a township of Lower Canada, on the river St. Francis.

**WESTENBERG**, a town of the margravate of Anspach; 6 miles N.E. of Anspach.

**WESTENSEE**, a lake of the duchy of Holstein; 8 miles E. of Reindburg.—Also, a town of the duchy of Holstein, on the side of the lake of the same name; 8 miles S.E. of Reindburg.

**WESTERBURG**, a town of Germany, which gives name to a lordship, situated on the Wetterwald. The lords of Wetherburg succeeded the counts of Leiningen. They are counts of Leiningen and lords of Wetherburg; 16 miles W.N.W. of Weilburg.

**WESTERHAM**, a market-town in the hundred of Wetherham and Eden-bridge, lathe of Sutton, and county of Kent, England, is situated near the confines of the county towards Surrey, at the distance of 5 miles W. from Seven-Oaks, and 22 miles S.E. by S. from London. The manor was given by Edward I. to the abbey at Walthamster, for the performance of certain religious services for the repose of the soul of queen Eleanor. He also granted several privileges to the abbots, which were confirmed by Edward III., who also gave permission to hold a weekly market at Wetherham, which is still continued. After the dissolution, Henry VIII. conveyed these estates to Sir John Gretham, younger brother of Sir Thomas Gretham, the founder of the Royal Exchange: and his descendant, Sir Madamduke Gretham, fold this manor to the Warden of Squieres, a respectable feat in this parish, near the west end of the town; and John Warde, eq. is now the owner. Wetherham is rated, in the population return of 1811, to contain 27 houses, and 1,437 inhabitants. The market is now held on Wednesday; and here are two annual fairs. The church, a spacious edifice, contains a great variety of sepulchral memorials; among which is a neat monument in commemoration of major-general James Wolfe, a native of this town, who was slain before Quebec in 1759. This town also gave birth to Dr. Benjamin Hoadley, who, in the last century, was successively bishop of Bangor, Hereford, Salisbury, and Winchester.

Some singular land-slips are recorded by Halsted, as having happened at different periods in this parish. The first which is mentioned occurred in 1596, near Oakham-hill, about a mile and a half southward from the town; where about nine acres of ground continued in motion for eleven days; some parts sinking into pits, and others rising into hills. A similar occurrence took place in 1756, at Toy's-hill, about a mile and a half to the call of the town, where a field of two acres and a half underwent considerable alterations of surface, from an almost imperceptible motion.—

**WESTERHAUSEN**, a town of the bishopric of Halberstadt; 3 miles E. of Regensfeld.

**WESTERLEY**, a town of America, in Rhode island; 30 miles S.S.W. of Providence.

**WESTERLO**, a town of France, in the department of the Two Nethes; 15 miles E.N.E. of Malines.

**WESTERN Amplitude, Church, Horizon, and Ocean.**

See the several articles.
field.—Alfo, a post-town of New York, on the east side of lake George; 6 miles S. of Ticonderoga.—Alfo, a township of New York, in Richmond county, in Staten island. At its southern extremity in the S.W. is a ferry of three-quarters of a mile to Amboy, in New Jersey. It has one church near the centre, and well cultivated land. The whole population in 1810 was 1444, and the number of electors 139.—Alfo, a town of Vermont, in the county of Orleans, containing 149 inhabitants.—Alfo, a town of New Jersey, in the county of Effex, containing 2152 inhabitants; 8 miles W. of Elizabethtown.

WESTFORD, a town of Vermont, in Chittenden county, containing 866 inhabitants.—Alfo, a post-town of Massachusetts, in the county of Middlesex, containing 1330 inhabitants; 28 miles N.W. of Bolton.—Alfo, a township of New York, in Otsego county; 8 miles S.E. of Cooperstown, erected in 1808 from the N.W. part of Worces ter. Its surface is broken by hills and valleys, but has much rich mould in the valleys. The hills are adapted to grazing, and it has many tracts of meadow land. Its timber consists of maple, beech, ash, elm, firs-wood, and pine; and the whole is irrigated abundantly by springs and brooks. In 1810 the whole population consisted of 1215 persons, and the number of electors was 73, and that of taxable inhabitants 177.

WESTGATE BAY, a bay of the Thames, on the coast of Kent, W. of Margate.

WEST GREENWICH, a town of Rhode island, in the county of Kent, with 1619 inhabitants.

WESTHAM, a town of Virginia; 4 miles N.W. of Richmond.

WESTHAMPTON, a post-town of New York, in the south-east part of Long island.—Alfo, a township of Massachusetts, in the county of Hampshire, containing 793 inhabitants; 7 miles W. of Northampton.

WEST HANOVER, a township of Pennsylvania, in the county of Dauphin, containing 2461 inhabitants.

WESTHAVEN, a township of Connecticut; 3 miles W.S.W. of Newhaven.

WESTHOFEN, a town of France, in the department of Mont Tomerne; 5 miles N.N.W. of Worms.—Alfo, a town of France, in the department of the Lower Rhine; 12 miles W. of Strasburg.

WEST HOVEN, a town of Germany, in the county of Mark, at the foot of a mountain near the Roer; once the domain of the celebrated Witikind, and possessed of considerable privileges; 4 miles S.W. of Schwiert.—Alfo, a town of Vermont, in the county of Rutland, containing 679 inhabitants.

WESTING, in Navigation, the fame with departure.

WESTLAND, in Geography, a town of Ohio, in the county of Guernsey, with 250 inhabitants.

WESTMAES, a town of the island of Beyerland; 12 miles W. of Dort.

WESTMAN, or WESTMONIA, an island in the North sea, near the coast of Iceland. N. lat. 63° 20'; W. long. 20° 28'. The Westman islands suffered very much about the commencement of the seventeenth century, by the piracies of the Algerines; almost their whole population being destroyed or carried into captivity. In 1627 a large body of Algerine pirates landed on various parts of the southern coast of Iceland; and not satisfied with the booty they obtained, murdered between forty and fifty of the inhabitants, and carried off nearly four hundred prisoners of both sexes. These unfortunate captives, transported to Algiers, were exposed there to so much wretchedness, that nine years afterwards, when the King of Denmark obtained their liberty by ran-
from Weftmeath; then in its course paffing through the loughs Dervoragh and Iron, it is at length loft in that vast expanse of the Shannon, called Lough Ree, or the Royal Lake. The Brofna, rising in Lough Iron, flows from it to Lough Holye, after quitting which it paffes the town of Mullinger; it then expands into Lough Ennel, and when again contracted, flowing by the town of Kilbeggan, it enters the King's county, through which it proceeds to the Shannon. As Weftmeath is nearly central, fo its streams flow in both directions. Thofe which have been already mentioned, joining the Shannon, are mixed with the Atlantic ocean; whilft other small streams, being collected in the river Dele, take an easterm direction, and being united with the Boyne, flow to the Irish sea.

Besides Lough Shelin on the north, and Lough Ree on the western boundary, there are fix confiderable lakes in this county, and feveral small ones. Thofe are well flored with fift of various kinds, and afford a number of beautiful profts; yet it is to be regretted that fo many acres should be almost an unfuitable wafte. The fift found in thefe lakes are, perch, pike, bream, tench, trout, and very fine eels. The trout are often of ten pounds weight, and as red as a flanfon. Such is the abundance, that Mr. Young tells us that a child with packthread and a crooked pin is able to catch perch enough in an hour to support a family for a day.

This territory once belonged to Mortimer, earl of March, who married the daughter and heirefs of Lionel, duke of Clarence, third fon of Edward III. This nobleman refted much in Ireland, and was probably induced by the beauties of the fituation to build a palace at Fahatty, on the banks of Lough Derveragh, one of the finest of thefe lakes, the remains of which were faid above a century ago to retain "the lineaments and footsteps of ancient flate and magnificence." When Richard II. was deposed by Henry of Lancaster, Mortimer was the next in fuccofion to the throne, and he found it neccafary to conceal himfelf, which he did by retiring to Fahatty. By a marriage with his daughter, Richard, duke of York, fucceeded to his Irish property, and to his right of fuccofion. This nobleman refted in Ireland for fome years as lord-lieutenant, before circumftances enabled him to urge his claim to the crown, which, after a long and bloody civil war, was obtained by his fon. The attachment of the fettlers in Ireland to this family was fhewn in the reign of Henry VII., by their readily embracing the caufe of Simnel and Warbeck.

Mullinger is the flire town of Weftmeath; but Athlone is a place of more confluence. For an account of thofe, and of Kinnegad, Kilbeggan, Fore, &c. fee their repective articles in this work. Weftmeath has three representatives in the imperial parliament, two for the county, and one for the borough of Athlone.—Beaufort, Young, Collectanea, &c.

WESMINSTER, a fpacious, populous, and important city of the county of Middlefex, England, is ftituated on the north bank of the river Thames, and conftitutes the easterm extremity of the metropolis. Although in every refpect, local poftion alone excepted, independent of London, Weftminster confifts a moft eflential portion of the great metropolis of the British empire. The line of demarcation between these two cities has long indeed, by the rapid increafe of buildings, ceafed to be perceptible to general obervation; but it is not the lefs real and efficient.

The inhabitants of Weftminster, it is true, confider themfelves, in a general fenfe, as belonging to London; but for the purpofe of internal dirermination, they confine the term Weftminster to its original fignification, the feite and the environs of the prefent collegiate, formerly the abbey-church of St. Peter. Considering the city in this refticted

Considering the city in this refticted

Vol. XXXVIII.
reigned from 1216 to 1272, the court usually resided in Westminster. The courts of justice, which had before accompanied the king in his motions, were, by his confirmation of Magna Charta in 1225, made stationary in Westminster, where the parliament also generally met. For the convenience of attendance on the king, the courts of justice, and the parliament, for the enjoyment also of good open air, and an agreeable prospect, many of the nobles, and especially the bishops, erected palaces along the banks of the river. Pavements of inferior flatness, whose chief dependance for business and subsistence rested on those great men, were necessarily induced to fix their abode in their vicinity. In this way, a chain of dwellings, of various forts, was progressively raised between the cities of London and Westminster, and united both with the intervening village of Charing. The situations of those palaces, or mansions, as they were called, are preserved to the present day, in the succession of streets retaining their names, which communicate from the Strand on both sides, especially to the river. Thus, for instance, from Temple-bar we come to streets bearing the names of Exef, Arundel, Norfolk, Surry, Someret, Savoy, Beaumont, Cecill, Salisbury, Durham, York, &c., all calling up personages memorable in former times; but of the houses to which those names belonged, not a vestige, if we except the fragments of the palace of the Savoy, and the present Northumberland-houfe, can now be said to remain. The opposite side of the Strand being cut off from the ufe and the view of the Thames, was of course little frequented; but Exeter-chage still indicates the residence of the celebrated Cecill, lord Burleigh, whose son Thomas became earl of Exeter. Bedford and Southampton streets declare the origin of their names. As late as in the year 1553, when Edward III., was on the throne, the Strand was an open highway, crossed and cut up by water-courses from the higher grounds. It was then repaired, but not before great complaints had been made: for in the petition of the persons who lived near the palace of Westminster to Edward II., "the footway from Temple-bar to the palace" is stated to be so bad, that "the feet of horses, and rich and poor men, received constant damage, especially in the rainy season; the footway being interrupted by thickets and bushes." From Temple-bar to the palace of Savoy, the Strand feems to have been paved, or properly made about 1385, in the reign of Richard II.; but the paving went no further till the latter part of Elizabeth's reign; and in the 35th of Henry VIII. the road was stated to be "full of pits and sloughs, very perilous and noisome." In the year 1533 the Strand took the form of a street, bordered on each side with houses and gardens; among which was Covent-garden, corrupted so called from the garden of the convent, or abbey of Westminster, to which it belonged. Charing was still a detached village; St. Martin's church stood literally in the fields; and St. Giles's, also surmounted in the fields, stood in a distant hamlet in the country. Such, however, was the increase of the town in the end of Elizabeth's reign, that in 1600 St. Martin's-lane was built on both sides; and although St. Giles's church still stood detached, the great west road, now called Holborn, (properly Old-bourne, from the name of a small brook running along it,) was formed into a street all the way into London at Fleet-ditch. Covent-garden and Lincoln's-inn-fields were partially built on, as were Drury-lane and Long-acre, and principally inhabited by the gentry. The village of Charing was long before this time, or in 1202, adorned with a crofs by Edward I., being the last spot where the body of his queen refted on the way to Westminster. In 1647 it was removed, and in part employed in pavement at Whitehall; but soon after the Restoration, its place was filled, as it now is, by a statue of Charles I. on horseback. From Charing to Westminster, the bank of the Thames was occupied by the residences of royal, or other distinguished personages. First was a palace for the king of Scotland, when he came to court to attend the parliament, of which, on account of lands he held in England, he was considered a member. An ancient painting, formerly in the college of arms in London, represented Edward I. sitting in parliament, having on his right-hand Alexander III., king of Scotland; and on his left, Llewellyn, prince of Wales. The palace has long been effaced, but its site is still called Scotland-yard. To this succeeded in position the palace of Whitehall, which will be noticed in another place. The church of St. Martin stands within the limits of the old quarter, but its parish originally extended over the whole of the new quarter of Westminster; and out of it, as buildings increased, the parishes of St. Paul, Covent-garden, St. James, St. Anne, and St. George, have successively been formed. Among the various improvements lately introduced into the streets of Westminster, must be reckoned the substitution of gas-lights for oil-lamps, now much in use in shops as well as without doors. The gas, or vapour, is extracted, by a species of distillation, from coal. Purified from the inflammable aerial substances with which it is extricated from the coal, by transmifion through a body of water, the inflammable or carburetted hydrogen gas is conveyed by pipes, like water, to the places where it is wanted. By the admiffion of flame to the orifice of the pipe, the gas takes fire, producing together with a strong heat, a lively light of peculiar force and brilliancy. The coals from which, in London and Westminster, the gas is obtained with the greatest effect, are the Lancashire cannel, and the Scotch flint coals. Newcastle coal is found to be much less pure, but from its cheapness is now mostly used.

Origin and History of Westminster.—Much learning and more fancy have been employed in devising an etymology for the name of London; but the name of Westminster is too obvious to afford exercise for the skill or the ingenuity of the philologer or the antiquary. The Saxons compounding the latter name evidently refer to the church of St. Paul, in London, in the east. Stowe indeed, and some later writers, carry the reference to a monastery, not far from the Tower of London, called the East-minster. But that establishment was founded only by Edward III., in the middle of the fourteenth century, long posterior to that of Westminster, and could not therefore have given origin to the latter institution. The history of Westminster is founded on, and closely interwoven with that of the monastery of St. Peter: for to the existence and importance of the latter, the rife, progress, and prosperity of the former must be attributed.

The feite of the church and monastery of St. Peter was in early times an island, inclosed by the main channel of the Thames on the east, and by a collateral branch of that river on the west. History furnishes no information concerning the limits or the extent of this inflated tract; but by a careful examination of the ground, even under all its alterations, the course of the collateral branch may still be discovered. This branch seems to have broken off from the Thames to the east of Chelsea hospital, to have passed northward, along the natural hollow in which the water still flows to supply Chelsea water-works, and thence over a short interval, now covered with the houses of Pimlico, into the depression occupied by the canal in St. James's park, acrofs the feite of Whitehall into the Thames. In this case the island was in length from S.W.
to N.E. about one mile and three-quarters, and in breadth in the middle about half that distance. Of this spacious tract, by far the greatest portion must, in former times, have been regularly overflowed by each returning tide of the river; as it would be at the present time, were not the embankments bordering the Thames carefully preferred. The age of these mounds is unknown; but to no others than the heads of the monastery to whom the island belonged can their formation be reasonably ascribed; and to them is Westminster therefore indebted for the many advantages derived from the lands refuced from inundation. The embankments must have been constructed, and the ground within them well improved in 1386: for in that year abbott Littleton died in the manor-house of Nejfe, situated within that space. So desirable was that situation, that the duke of Lancaster, flying himself king of Cafille, had requested leave to reside in the house during the sitting of a parliament. The name of this place still survives, although absurdly corrupted into Nest-hous. In an authentic charter, dated in 785, Offa, king of Mercia, grants certain lands to the monastery of St. Peter; its situation is described to be in "Torncia in loco terribili ad Welfminster." In the writings of Sulcardus, a monk of this monastery who wrote in the eleventh century, the name is Thorne. Both these names are supposed to be formed from the Saxon Thorney, the isle of thorns and briars, expressing the wild uncultivated state of the "terrible spot" noticed by Offa. Forbidding as such a situation now would be, it bore a different aspect in ancient times; for it professed alike security from attack, and seclusion from the world. To the religious establishment on Thorney, the rife, progress, and prosperity of Welfminster are to be ascribed; but the origin and the date of that establishment itself are involved in obscurity. The probability, however, is, that it was founded by Sebert, king of the East Saxons, who died in 616. That it had in 785 acquired celebrity, is evident from the charter before-mentioned, granted by Offa. From Sebert's time the monastery seems to have been only a priory; but by Offa it was changed to an abbey, of which the abbeys arose, in the course of a few years, to the highest dignity of which their rank was insufficient. To demonstrate more fully his attachment to the patron of the abbey, St. Peter, Offa in it deposited his coronation-robes and regalia. From this circumstance, perhaps, as much as from subsequent papal authority, St. Peter's church afterwards became, and still is used for the inauguration of the English sovereigns; and to the dean, as successor of the abbey, are intrusted many of the implements and ornaments employed in that important function, which was first there performed on William the Conqueror, in 1066. After suffering severely in common with other works of the same character, by the ravages of the Danes, the abbey was restored by Edgar, who began to reign in 967, on the instigation of Dunstan, who removed thither, probably from Glen- tonbury, twelve monks of the order of St. Benedict. It is nevertheless to Edward the Confessor that the institution is principally indebted for its splendour. Sulcardus informs us that Edward had vowed to go to Rome, there to express his pious gratitude to heaven for his unexpected establishment on the English throne. The many inconveniences, however, by which the performance of this engagement must have been attended, induced him to substitute in its stead some other mode of testifying his thankfulness. He therefore undertook to rebuild the church and monastery of St. Peter in a magnificent manner, and endow them with ample revenues. Of the structure itself we only know from Matthew Paris, that "it was constructed in a new kind of arrangement, from which many perfous in erecting churches took a pattern, and strove to imitate it." Speaking of the same edifice, sir Christopher Wren refers to an account printed from an ancient manuscript. This account he translates into language proper for builders, in this way. "The principal area or nave of the church being raised high, and vaulted with square and uniform ribs, is turned circular to the east. This on each side is strongly fortified with a double vaulting of the aisles in two stories, with their pillars and arches. The crofs-building, continued to contain the choir in the middle, and the better to support the lofty tower, roof with a planer and lower vaulting; which tower then spreading with artificial winding-flairs, was continued with plain walls to its timberroof, which was wellcovered with lead." The frieking novelty in this structure was probably the introduction of an imitation of a crofs in the plan: for the earlier Saxons churches are supposed to have had no transepts. The grants of lands, and of relics, beffowed by Edward on his new foundation, were ample beyond all precedent. He likewise invested it with peculiar privileges, exempting it from all fecular services and authority, even from episcopal superintendence. But this laft exemption brought on each new abbot the trouble and expeince of a journey to Rome, to be confirmed by his holiness in perfon. Edward died on the 5th of January, 1066, having survived but a few days the splendid ceremony of the consecration of the new structure. From these privileges, afterwards extended to a considerable space connected with the abbey, may be traced in a great measure the prefeft civil constitufion of Welfminster. While Laurence was abbot in 1163, in the reign of Henry II., the power was obtained from pope Alexander III. for his using the mitre, ring, and gloves, dijtinguishing marks of episcopal dignity. But this privilege became, in the sequel, of still higher importance; for mitred abbeys came to fit in parliament as well as bishops, and to enjoy every honour to which bishops, as lords of parliament, were entitled. Laurence dying before the papal approbation of the measure was formally announced, his successor Walter was the firfl abbot of Welfminster who actually enjoyed the honours of the mitre. The reign of Henry III., of great importance in the history of England in general, is not left fo to that of Welfminster abbey in particular. In it the greater part of the edifice was rebuilt, in the lofty elegant fyle by which it is chiefly characterized; a fyle which about that time began to be adopted in ecclefiafical buildings throughout Europe. As early as 1220, although then only a youth, Henry laid the firfl fone of the chapel of the Virgin, which was afterwards superfeeded by the gorjeous structure of Henry VII.; but it was not until 1245 that he directed the church to be enlarged, and the tower, with the eastern part, to be conflrued anew. In 1260 the building was opened for divine service, and the body of Edward the Confessor was deposited in a splendid shrine erected behind the high altar.

The abbey of Welfminster is entitled to the peculiar veneration of every friend of literature, of science, and of civil and religious liberty; for within its bounds was erected the firfl apparatus for printing books employed in this island. William Caxton, a mercer of London, during a long reference on the continent as agent for the affairs of his company, and in 1464 as minister from Edward IV. to the duke of Burgundy, became acquainted with the art of printing, then very recently practised in Lower Germany. In 1471 he printed at Cologne a work which he had translated from the French into English; and returning home in the following year, he, under the patronage of the abbat of Welfminster, commenced printing in the almonry, or eleemosynary adjoining to the abbey. In March 1474 appeared his book

S I 2 on
on the "Game at Chefs," which may be regarded as the first production of the English press. (See Printing.) The
honour of being the first protector of printing in England
has been frequently assigned to John Hill; but this must be
erroneous; for he became a monk only in 1480, and arose to
be abbot only in 1500. To one of his predececssors, there-
fore, to Effenny, elected in 1474, or rather to Millyng,
elected in 1469, is the introduction of printing to be attri-
buted. The abbacy of Hill is however memorable on an-
other account. It was founded, on the 24th of January,
1502-3, the celebrated chapel of Henry VII. Having
obtained the crown as heir to Henry VI., he resolved to
erect a tumphant monument for his remains, in the expecta-
tion of his canonization. The first part of the project
was carried into effect, but the court of Rome requiring a
greater sum for compliance with its solicitation than the
prudent Henry of Richmond cared to bestow, the last part
of the project was relinquished. Westminster-abbey was
now on the eve of great alterations. The schemes of
Henry VIII. began to be put in practice. On the 16th of
January, 1539-40, a surrender of the whole establishment
was executed by abbot Benfon of Bolton, and twenty-four
of the monks. The annual revenue is estimated to have then
been nearly 4000l.; a sum of great real value, when the
pound of beef was regulated at one halfpenny, and that of
veal and mutton at three farthings.

Prior to the dissolution of the monasteries, Henry had
resolved to convert some of them into episcopal sees, to be
endowed with a portion of the lands or the revenues which
that dissolution would place at his disposal. Of the pro-
exed fees, Westminster was to be one; and on the 17th of
December, 1540, the abbey-church was, by letters patent,
constituted a cathedral, with a bishop, a dean, twelve pre-
bendaries, and other inferior officers. The new bishop was
Thomas Thirlby, then dean of the chapel-royal. The late
abbot Benfon was, for his ready compliance with Henry's
wishes, in the change of the abbey, appointed dean of the
new cathedral; certain monks became prebendaries, minor
canons, and students in the university; the others were di-
mified with penions, decreasing from ten pounds down to
five marks. The abbatial mansion was converted into a
palace for the bishop, whose annual revenue is variously
estimated from six hundred to eight hundred pounds. The
diocese included the whole county of Middlesex, with the
exception of Fulham, the rural residence of the bishops of
London. The endowment of the dean and chapter was not
completed till the 5th of August 1542, when lands, in var-
ious parts of the kingdom, were assigned, of the yearly
value of 2591l., out of which, however, the sum of 400l.
was to be paid for the salaries of five professors of divinity,
law, phyfic, Hebrew, and Greek, in each of the univer-
sities. A further sum of 160l. 3s. 4d. was to support 20
students in the universities; and two masters, with 40 gram-
mar scholars, were to be maintained in the school of West-
minster. The new bishopric was, however, but of short
duration; for on the 29th of March 1550, bishop Thirlby
was required to surrender it to Edward VI., and it was soon
afterwards reunited to that of London. Part of the pos-
fessions of St. Peter's cathedral were appropriated to the
repairs of St. Paul's in London; whence arose the prov-
er of "robbing Peter to pay Paul." In the edit for sup-
prefling the fee of Westminster, no mention was made of
the establishment of a dean and prebendaries, &c.; it be-
came consequently a question whether they were to be con-
tinued. To remove all doubt on this head, an act passed in
parliament, declaring the church still to remain a cathedral,
with the former establishment, but within the diocese of

London. On the accession of Mary to the throne, the re-
toration of the monastery to its primitive condition was car-
rried into effect. The abbot, John Packenham, surviving
Mary, was the only ecclesiastic of his rank who sat in the
first parliament of Elizabeth in 1558; and he took the
lowest place on the bishops' bench. But on the 24th of
May 1560, the monks were again displaced, and the church
again rendered collegiate, on a basis very similar to that
which had been established by her father, Henry VIII.
The last dean of Elizabeth's appointment was the learned
Lancelot Andrews, afterwards bishop of Winchester, dean
of the chapel-royal, and a special favourite of James I.
Since the restoration by Elizabeth, if we exclude the gen-
eral disorganization of similar institutions, in consequence
of the internal disorders which commenced in the reign of
Charles I., the collegiate establishment of the abbey-church
of Westminster has undergone no material alteration.

Abbey-Church.—Such is briefly the history of the reli-
gious establishment on Thorney, to which modern West-
minster is indebted for its origin and prosperity. Of this
establishment, the church remains in a great measure entire;
the buildings appropriated for the abbey and the monks have
undergone great alterations; but their general arrangement
may still be traced, and they are still allotted for the re-
ference of the perfons attached to the service of the church
and the dependent school. For a fully detailed descrip-
tion of this celebrated church, of its architectural beauties and
defects, of the sepulchral monuments it contains, of the cer-
emonies performed within its walls, and for a recapitula-
tion of the important transactions connected with its his-
ory, recourse must be had to the various works published spe-
cially on the subject. This church is a distinguished spec-
imen of that mode of architecture, commonly but absurdly
styled Gothic, a term which, however improper, most writers
still continue to employ, though no specific style or class of
building is defined by it. Erected in the 13th century,
when buildings in this style of architecture were well un-
tderstood, and skilfully constructed, it would doubtless have
possessed, if not the spaciousness, at least the light and airy
and elegant appearance for which such structures are generally
remarkable. But by the introduction of sepulchral mon-
uments, elevated above the level of the choir, many of them
magnificent indeed in themselves, but certainly misplaced
as far as regards the internal arrangement of the building,
that attractive appearance must very early, perhaps from the
beginning, have been injured. Owing to those encroachments,
it has been necessary to bring forward the present choir
much beyond its usual fation, not only intercepting the tran-
septs, but advancing a considerable way into the nave,
or body of the church. The building consists of a nave
and two side aisles, separated by ranges of tall, slender,
clustered columns, supporting the roof raised to a great
elevation, till further increased in appearance by the narrow-
ness of the space between the columns. The length of the whole
edifice within the walls is 360 feet, the breadth of the
nave and aisles 72 feet, the length of the choir or transept 195.
The infusion of St. Edward's chapel in the choir is partic-
ularly unfavourable; for that important division of the build-
ing was from the beginning very short: nor is it easy to dis-
cover the reason of this deviation from general usage. On
entering the great western door, the whole body of the
church displays itself to view in a very striking manner.
Lofthalls, lightposts, and elegance, are its marking fea-
tures; but these features are much obscured, and distracted by
the numerous discordant monuments, which fill up the open
spaces, and cover the walls. The nave is separated from
the choir by a screen; and east of the latter is a chapel,
WESTMINSTER.

raised above the level of the pavement, appropriated to the shrine of Edward the Confessor, but also occupied by several monuments to royal and noble persons. At the east end of this is a sumptuous architectural chantry to the memory of Henry V. Still more to the east is the splendid and interesting chapel, called Henry the Seventh's, because begun by him, and founded for his mausoleum. On the north and south sides of the choir are aisles, and also some small chapels, dedicated to different saints.

From the time of Henry VII. little was done, although very requisite, to the exterior of Westminster church, till that of George II., when many parts of it were coated over with stone, and otherwise repaired at the public expense. Some time before this, the two towers at the west end were completed from designs of Sir Christopher Wren, as they now appear. In covering the outside of the church, the rich sculpture, and the statues which formerly adorned the buttresses, could not be restored. Tho parts seem now, therefore, unsuitable to the highly ornamented building to which they are attached: nor do the western towers affiliate with the style of the fabric to which they belong. The paintings in the great west window were executed in 1735: the window in the south transept was also renewed in 1765. In the interior of the church, the pillars dividing the nave from the side aisles guide the eye to the fine painted window at the extremity of the choir, which, in former times, when the altar-piece was low, must have had a fine effect in giving a lighter air to that part of the building. The altar-piece was brought hither by Anne in 1706: it had formerly belonged to Whitehall chapel. The marble columns of the Corinthian order, however elegant in themselves, but all accord with the style of the structure around them; an incongruity but too often functioned in other edifices of the same kind in England. In front of the communion-table is still to be seen, although woefully mutilated, a curious Mosaic pavement of lapis lazuli, porphyry, Jasper, Serpentine, touchstone, &c. placed there by abbots Ware in 1272, who brought it from the continent, where he procured the materials during a mission to Rome. The black and white checkered marble pavement of the choir, was the gift of the celebrated Dr. Bushy, master of the school annexed to the church. In the centre of Edward the Confessor's chapel stands the mutilated body of the shrine, containing, in a wooden case, the ashes of St. Edward; and around the sides of the chapel are ranged the monuments of several kings, queens, and princesses, from Henry III. to Elizabeth, the daughter of Henry VII.; all of which are extremely curious and interesting. In this chapel are preserved the chairs, one very ancient, the other made for the last queen Mary, in which our kings and queens are seated within the choir at their coronation. In the frame of that used by the king is the fatal stone, to the position of which the sovereignty of Scotland, or rather of the Scotch nation, was attached.

The choir of the church, in the form of a semi-octagon, was surrounded by eight chapels, now reduced to seven, by the appropriation of the central chapel to be the porch of that of Henry VII.

The crofs-aisles or transepts of the church, as well as the nave, have long been consecrated to the interment of persons in various ways distinguished in the world. The south transept has only an eastern aisle, the west being occupied by part of the cloisters. This transept, named Poets' corner, contains many interesting memorials of men whose genius and talents in science, literature, and the arts, entitle them to the honourable recollection of posterity. Of these monuments, many are highly interesting as memorials of eminent characters, and others as specimens of the sculptor's art. No small number of them, however, and those not the least sumptuous and ornate, are entitled to no regard on either account, being vaft masses of marble devoid of beauty and taste. It is, however, to be remembered, that to be numbered among the illustrious dead,' within the walls of the abbey-church of Westminster, now is and long has been purely a question of finance with the officers attached to the foundation.

Chapel of Henry VII.—In ancient cathedrals and other churches of considerable extent, it was the practice to appropriate to the peculiar service of the Virgin, the chapel situated immediately behind the high altar, and in the eastern recess of the building. Such a chapel originally belonged to the abbey-church; and on its site was some adjoining space, under the same patronage, but now best known by its own name, Henry VII. constructed his magnificent and admirable chapel. When we contemplate this most curious specimen of English architecture, and consider the expense which must have been encountered to complete it, we are utterly unable, on any rational grounds, to reconcile its erection with the acknowledged disposition and character of the founder. In perusing the history of nations, we must be struck with the frequent recurrence of this fact, that men of all degrees, particularly of the highest, have acted on the vain supposition, that by a single ostentatious act of beneficence or munificence, not unfrequently profligate, they could acquire immortal fame, and even secure the favour of heaven, however unworthy they may have performed their duty in life. Of this fact, the chapel of Henry VII. stands a memorable example; for in no one of his life and reign, did that prince give evidence of any one of those feelings from which the construction of this superb structure could be expected to proceed. Of benevolence, however, in a certain sense, no sovereign ever had a better conception than Henry. The vaft sums he exacted under this inauspicious title, far exceeded the demands for which they were required: he accordingly amassed great wealth, and at his death his treasury was enormously rich. Towards his end, Henry, sensible of a mil-spent reign, endeavoured to atone for his offences by various charitable works, by bequeathing a large sum on the college chapel in Cambridge, and in particular by founding, erecting, and endowing his chapel in Westminster. From the elegance and richness of the design, and from the skill and labour necessary to complete it, we are warranted to conclude that the most eminent artists and architects of the country were employed. The first stone of the new chapel was laid by the hands of abbot John ilip, and otherpersons of the court, in the presence of Henry, on the 24th of January 1502-3. How much of the work was executed at the king's death, on the 21st of April 1509, is unknown; but most probably the masonry must have been nearly, if not altogether, completed. Towards the finishing of the whole, Henry left, in the hands of the abbot, 500l., with provision for more if required. The superb tomb for the king is particularly described in his will; but a different plan was followed, and the work was finished by his son Henry VIII. The ground-plan of the building consists of a body nearly a square, terminated at the east end by a semicircular part, composed of five sides of an octagon. The extreme length of the whole chapel, including the porch, is 134 feet, and the corresponding breadth 82 feet 6 inches. On viewing the exterior of the building, we are struck by the apparent lightness of the work; for instead of walls, the principal weight and quantity of the whole rests on a few detached piers and lateral buttresses. This peculiar character of ancient
ancient ecclesiastical buildings, manifests great science and skill in the architects; for to raise lofty walls, and poise ponderous wide-spread roofs on piers and columns, requires the nicest geometrical accuracy. The fides are supported by five octagonal piers; those of the semicircular end are united to wedge-shaped mafles, falling to the nave, as to correspond with the pillars separating the aisles from the nave. The interlaces between the external piers are filled by windows of a peculiar plan and great delicacy of workmanship. The roof over the nave refts on perpendicular walls, supported by very slender internal pillars, and is strengthened all round by flying buttresses or semi-arches from the external piers. Within, the chapel is divided by two ranges of pillars into a nave 33 feet 6 inches in width, and side-aisles each 11 feet 3 inches wide. The internal roof is executed in fone, with pendants and numerous ribs. By the advance of the piers in the circular part, the end is formed into five small chapels or oratories; but the side-aisles in their original had no separation from the nave, except the ranges of pillars. They are now, however, unfortunately cut off by a row of stalls on each side, on the line of the pillars, and shooting up with their fretted and frittered canopies as high as the roof of the aisles. What tends to heighten the deformity of these stalls, is the number of gaudy flags of the knights of the Bath, who are interred in this chapel, fupended all around, at once concealing many beautiful parts of the architecture and sculpture, and utterly at variance with the elegance and the design of the edifice. The entrance to the chapel is by a flight of steps to a magnificent gateway, but from its situation dark in itself, and darkening the extremity of the adjoining church. The chief object within the chapel is the tomb of the founder, inclosed by a screen of gilt brafs: it is a piece of admirable workmanship, executed by Torregiano of Florence, a rival of Michael Angelo. There also, flill in opposition, lie the jealous and vindictive Elizabeth and her unfortunate victim Mary Stuart. Thus in a corner of the abbey-church, a few feet only of earth now separate the once formidable political antagonists William Pitt and Charles James Fox. The bronze figure of Margaret Tudor, mother of Henry VII., is one of the finest pieces of sculpture in the whole building. In viewing this chapel, two subjects always excite regret; the situation in which it stands, and the materials of which the exterior is constructed. Attached to the end of the abbey-church, with which its mode of construction has but a very distant relation; although in itself, if furnished with a fitable front-piece, worthy to be a separate and independent work, it now links into a mere appendage. The exterior surface of the chapel is in many parts corroded and confounded; and moff of the sculpture is now quite defaced. Some years ago parliament voted a confiderable sum of money, to be annually applied to defray the expense of new-casting the whole edifice with Bath fone, and the work has been carried on under the directions of Mr. T. Gayfere, with ferupulous attention to the form and manner of the original workmanship. Beneath the chapel is the vault prepared on the death of Caroline, queen of George II., containing the remains of several members of the present royal family. The cloister of the abbey, fufficiently ftrengthened, and containing numerous sepulchral inscriptions, communicates with the ancient chapter-houfe, which is of octagonal form, and the roof is supported by a branching central column. It was erefted, according to Matthew of Welfminster, in 1258, by Henry III. This building, which, till the time of Edward VI., served as a houfe for the commons of England, is now employed to preferve public records; amongst them, the celebrated Liber de Wintonia, as it was called by the compilers, or Domesday-book, as it was not unaptly named by thofe persons whom it regarded. This work, the moft ancient and venerable record, or iflatificable account, as we now fpeak, of which this or any other country can boast, was completed about 1086, in the end of the reign of William the Conqueror. (See Domesday-Book.) In the fame chapter-house are also preferved the recorded proceedings of the notorious star-chamber, to called from the ftar-like ornaments of the roof.

School.—The cloifor also communicates with the celebrated school of Welfminster, which was refounded by Elizabeth in 1590, with an eftabliffment for the classical instruction of forty boys. After a certain time, the scholars, if duly qualified, are flected alternately for their respective institutions, by the dean of Chrift-church, Oxford, and the master of Trinity college, Cambridge. Besides the youths on the foundation, from three to four hundred, others usually receive their education in the school, at the ex- pense of their respective parents.

Paroh Church of Welfminster.—The city and liberties are now diftributed into ten parishes. Within the city are St. Margaret's and St. John the evangelft's; within the liberties, St. Martin's, St. James's, St. George's, St. Anne's, St. Paul's, St. Clement's, St. Mark's, and the Savoy. St. Margaret's, the original church of the city, is a fimple plain ftucture. It is handsomely fupported up to accommodate the commons of the kingdom on certain folemn occasions. As the choir of the neighbouring abbey-church is allotted to the peers of parliament. One peculiar ornament of St. Margaret's church is a magnificent painted window representing the crucifixion. This very interefting picture was executed in Holland as a present for Henry VII. St. John's church, belonging to a parish formed out of St. Margaret's, furnifhes an admirable example of what imagination, unrestrained by judgment and taste, can produce. It ought however to be known, that Mr. Archer, and not Sir John Vanburgh, who has been oftener blamed than underflood, was the architect of this fabric. St. Martin's and St. George's churches are remarkable for their noble porticoes; but both are, unfortunately, not to pay abfurdly fét, that it is impoffible to have a view of them in any way fatisfactory. St. Paul's, Covent-garden, is noted for its fimplicity, and its plain, heavy, Tuscan portico. In erefting the latter at the end of the church, where it can be feen, Inigo Jones effayed a bold deviation from eftablished practice; but to change the interior diftribution of parts was perhaps beyond his power. The portico therefore stands where no entrance can be opened, for there with flands the communion-table, and the entrance is opened at the eft end, where there fould be, but is not, a portico. The church of St. Mary, like that of St. Clement, is strangely placed in the midft of the Strand, a moft public and noify freet; and instead of poifefing the fimple dignity of a Christian temple, feems rather a model contrived to fhow the skill of the architect in comprehending the greatest quantity of ornament devoid of utility, within the narrow fet bounds. But Mr. Gibbs the architect followed his instructions in adorning an edifice to be fo oftentatiously exhibited. He had besides but jufi returned from Italy, where fimilar structures abound. It is no wonder, therefore, that, in both the interior and the exterior of the New church of St. Mary, he was led to imitate the buildings he might, as a mere fudent of architectural defign, long have admired. Besides the churches and chapels of the eftabliffment, Welfminster contains places of worship for Chrifrians of all denominations, and of professions the moft contradictory, from the moft Spanifh to the moft Swedenborough, who maintains the fole
and absolute divinity, to the simple Unitarian, who afferts the pure humanity of the great founder of the Christian religion. French, Swiss, Dutch, and German Protestants, have proper places where the service is performed in their own languages. The Society of Friends or Quakers have a respectable place of assembly in St. Martin's-lane; and various chapels are open for the members of the church of Rome. In Denmark-court, in the Strand, is a well-frequented Jewish synagogue.

Civill and Political State of Westminster.—The first dwellings constructed around the monastery in Thorney, stood on the lands of the establishment, which consequently had full authority to govern the inhabitants. These were rapidly increased in numbers by the privilege of sanctuary granted to the abbey for offenders; but the great causes of the growth, population, and importance of Westminster, were the residence there of the kings, and the transference of all public business within its precincts. Although the Strand, Whitehall, and a few other places were inhabited, at the elevation of the abbacy into an episcopal see in 1540, yet the quarter only immediately enclosing the cathedral church was honoured with the title of city. The whole of this quarter was included in the original and ancient parish of St. Margaret; but in order to accommodate the increas'd number of inhabitants, especially in the southern parts, a new parish was formed out of the old in 1728, and named after St. John the evangelist. All the other quarters of the present Westminster, erected on the liberties of the abbey, are contained within the following eight parishes, arranged in the order of their establishment. St. Clement's Danes, St. Martin's in the Fields, and St. Mary's in the Strand, all of uncertain antiquity. St. John the Baptist's, in the Savoy, also ancient, St. Paul's, Covent-garden, St. James's, St. Anne's, Soho, and St. George's, Hanover-square; the last four all formed within the last 200 years. In designating Westminster in the aggregate, the city and the liberties are necessarily mentioned; but in no respect does any distinctive rank, right, or privilege exist between the inhabitants of those different quarters, who are all equally citizens and members of the same community. On the public change of religion, and the conversion of the abbey of St. Peter into a collegiate establishment of a dean and chapter in 1560, the latter were placed, as to all their civil rights and authority, in the situation poffessed by their predecessors; but the sanctuary was, with all other similar privileges, suppreffed in the 21st year of James I. The dean and chapter of St. Peter's have, therefore, continued ever since to be the supreme magistrates and administrators of the inhabitants of the city and liberties of Westminster. Since the Reformation, however, the exerçís of all civil powers has always been vested in lay persons, elected or confirmed by the dean and chapter. Of this singular and anomalous system of government, which, though applicable forever to the original, seems wholly unsuitable to the modern Westminster, the following are the principal members, as feated by an act of the year 1585:—The first is the high-steward, usually a resident nobleman of distinction (the present is the duke of Northumberland), who is elected by the chapter of St. Peter's; the dean acting as high-steward during and previously to the election. By this principal officer a deputy steward is nominated; but his appointment must be confirmed by the dean and chapter. This deputy acts as a sheriff, holding the court-leet with the other magistrates: he is always chairman of the quarter-sefions of Westminster, which are independent of those of Middlesex. Next in rank is the high-bailiff, nominated on the other hand by the dean and chapter, but confirmed by the high-steward. He is the returning officer in the election of the representatives in parliament for the city and liberties; and to him all the other bailiffs are subordinate. He summons juries, and has a right to all fines, forfeitures, and fines, within his jurisdiction: he also, on due requisition, calls together and is present in all assemblies of the electors, for the purpose of petitioning parliament or the crown, or of transacting any other public business within which they are all concerned. The high-official, chosen at a court-leet of the magistrates, has all the other offices under his superintendance. In addition to these officers, sixteen householders, styled burgesses, are chosen, with their affiliates out of the different parishes. These re semble the aldermen and common-council of London, each having a particular ward or district under his inspection; and of their number two head burgesses are chosen, who, at the court-leet, sit next to the high-bailiff. The inhabitants of Westminster form no corporation, nor do they possess such any exclusive privileges; neither do any companies of trade or profession exist within the jurisdiction. The various courts of justice belonging peculiarly to Westminster are, 1. The court of the duchy of Lancaster, a supreme court of record, held in Someret-place, for deciding by the chancellor of the duchy all matters of law or equity concerning the estates belonging to the county-palatine of Lancaster. 2. The quarter-sefions of the peace, a court of record, held by the justices of the peace at the Guildhall, near the abbey-church, for all trefpafs, &c. committed within the city and liberties. 3. The court-leet, held by the dean, or his steward, for choosing parish officers, preventing and removing nuisances, &c. 4. Courts of requits, or of confidence, as they are called, for deciding without appeal by commissioners, all pleas for debt under forty shillings. 5. Courts of petty-sefions, held every lawful day at the offices in Bowstreet, Marlborough-street, and Queen-square, for matters of police, misdemeanors, or offenses. 6. To these must be added the court of St. Martin-le-grand, in London, but belonging to Westminster. The jurisdiction of the dean and chapter of St. Peter's, widely extended as the liberties are, is not confined to their bounds. In the very heart of London, under the walls as it were of St. Paul's, is the precint, as it is termed, of St. Martin-le-grand, an integral part of Westminster, and wholly independent of London. This precint took its name from a college church founded in 1556, dedicated to St. Martin and qualified le-grand, on account of the great privilege of sanctuary conferred on it. By Henry VII. it was belowed on the abbey of St. Peter; but on the surrender to Edward VI. it was pulled down, and houses were built on the ground. Being let out to strangers not freemen of London, they claimed the privileges before enjoyed by the canons of the suppreffed institution. These claims produced many contentions which were never definitively settled; and the exemption of St. Martin's precint from the jurisdiction of London seems now to be effectually, rather than long-continued usage than by any regular or authoritative declaration of right. This small precint (a term in London signifying specifically a subdivision of a ward) consists of one short street of its own name, leading north from the east end of Newgate-street to the beginning of Aldergate-street, and a few lanes and courts on each side. In this precint persons not freemen of London, exercise their several trades or professions without control; the inhabitants also concur in the election of representatives for Westminster, in the same way with those who actually dwell within that city. A very material change is now (1818) in progress in St. Martin-le-grand. The chief office of the general post, domestic and foreign, situated in Lombard-street, in Lon-
Westminster.

London, has long ceased to be either central in position or commodious in distribution, for the prodigious business transacted in it. After many attempts, chiefly on the part of the inhabitants of the west end of the town, where many of the principal men of business reside, parliamentary function has at last been obtained for the erection of a new post-office, properly adapted, in situation and internal arrangement, to the purposes of the establishment. The situation selected is in St. Martin-le-grand; and the necessary preparations in removing houses and clearing the ground, have made considerable progress. The expense of this enterprise must be great; but the edifice may be rendered highly ornamental as well as useful to the metropolis. Mr. Kay is the architect. The jurisdiction of the dean and chapter of Westminster extends also over some places in Essex, on that account independent of the diocesan bishop of London, and even of the metropolitan of Canterbury; for while the Roman Catholic religion prevailed, the abbey was immediately under the pope. If the jurisdiction of the abbey thus extended over places remote from its bounds, it on the other hand comprehended within its bounds, a district exempt from its jurisdiction. This is what is commonly called "the liberties, or the duchy of Lancaster." The district comprehends all the south side of the Strand, from the Temple to Cecil-street, with nearly the same extent on the north side. The palace and district of the Savoy having been a part of the possessions of the house of Lancaster, which were separated from the crown by Henry IV., that part of the Strand belonging to the Savoy became a district or liberty of itself. It has a supreme court under the chancellor of the duchy of Lancaster, as already mentioned; and formerly no inhabitant of this district voted for the representatives of Westminster. But at the election in March 1795, those of the duchy-liberties who lived within the parishes of St. Mary in the Strand, and St. Martin's in the Fields, were admitted to give their suffrages. Until the dissolution of the abbey, Westminster lent no representatives to parliament; being virtually represented by the abbot, who sat with the bishops in the house of peers. In the records of the late parliament of Henry VIII. no mention appears of any summons or returns relative to Westminster, Peterborough, or any other abbey-town. The first parliament of Edward VI., therefore, is, that in which the members for Westminster began to take their place. The two representatives of the city and liberties are elected by the inhabitant householders, or those paying scot and lot, who are now estimated at about 17,000; the number being considerably increased by the enlargement before-mentioned in 1795. The elective franchise being thus widely diffused among all ranks of the inhabitants, and the popular favor being commonly in the inverse proportion of that of the court, one if not both of the representatives of Westminster may generally be expected to be decidedly hostile to the measures of the existing administration. So well is this understood by ministers, that, to have at least one member favourable to their views, they have frequently encouraged some distinguished naval commander to offer his services to the electors.

Having for many years been the ordinary residence of the sovereign, Westminster has of course contained the principal departments of every branch of legislative and executive administration. The parliament, originally ambulatory and attached to the peron of the king, was rendered flable in Westminster on the confirmation of Magna Charta by Henry III. in 1216. Long before that period, the royal palace was erected adjoining to the abbey; and as in those early times justice was often administered by the king in person, or in his presence, the various courts of judges were of course established in or near his residence. When the palace of Westminster ceased to be occupied by the monarch, and Henry VIII., in 1512, transported his court to Whitehall, the parliament and the judges still retained their original station; but the executive branches of administration, relative to financial and military affairs, accompanied the court. Hence we find those departments all established in what is still called Whitehall; although the king has long ceased to reside in that quarter, and that a very small portion of the old palace is either occupied by public offices, or even in existence. Hence also it is that all public acts of government are dated from Whitehall. From the prodigious multiplication and subdivision of all public affairs relative to justice, finance, and military and naval operations, the details of various branches have necessarily been carried on in other convenient quarters of the metropolis. Such are the Temple, Lincoln's-Inn, Guildhall, the Bank, the Cullom-house, the Excise-office, the Tower, &c.; still it is in Westminster alone that the general arrangement of the whole is continued.

Public Buildings.—Of the ancient residence of the kings of England in the vicinity of the abbey of Westminster, the name, the general position, and a few mutilated apartments, are all now remaining. According to a survey and plan of the whole buildings and vestiges of this palace, it extended along the bank of the Thames from north to south, and then turned westward near to the buildings of the abbey. Of the general arrangement, it is impossible to discover more than that the walls and foundations seem to have been all parallel to the corresponding walls of the present great hall, the only part still remaining in its original state. Composed of parts erected at different periods, no balance or symmetry of plan seems to have been regarded in their distribution.

Westminster Hall, memorable in itself as a building, as the scene of many important transactions, and for the uses to which it is applied, was erected by William Rufus, or William II., about 1067, as an appendage to the old palace, or a part of a new project. Having suffered much from accidental fires, as well as from the lapse of time, the hall, just three centuries after its construction, was completely restored by Richard II., who heightened the walls, altered the windows, adding a new roof, and built a flately gateway. The hall is a vast parallelogram, standing north and south, in length, within the walls, 249 feet, and in breadth 66 feet, not 74, as is generally stated. The walls, although massive and plain, are externally strengthened by buttresses. The roof, rising to a high pitch, is ingeniously and firmly constructed, not of Irish oak, as usually said, but of chef out brought from Normandy. This room is said to be of greater magnitude without pillars than any other known. In this hall parliaments have been held; Richard II. was deposed in it in 1399, and for many ages it has been employed in the coronation-feasts of the sovereigns. In it assembled the court for the trial of Charles I., in January 1649. It is still the place of inquiry, before the house of peers, into the conduct of persons impeached by the house of commons. In the middle of the right or west side of the hall, is an opening into the court of common pleas. The south end of the hall is occupied by wooden structures, to contain on the right-hand the court of chancery, and on the left the court of king's bench; so called because the king in ancient times actually sat, as he is at present averted, by what is styled a legal fiction, actually to sit, on the bench to administer justice. Between these two courts flairs conduct to the apartments occupied by the two houses of parliament. That employed by the peers was towards the south end of the old palace; but on account of the additional number of 32 peers enti-
tled to feats on the union with Ireland, over and above the
unexampled augmentation of the peerage in the present reign,
their meetings were transferred to what was the court of re-
quests; so called because the masters of the court, in ancient
times, received the requests or petitions of the people, and
gave their opinions on the subjects. This room, consider-
ablely larger than the former, is also within the old palace;
and is now ornamented with the celebrated tapestry, represen-
ting the discomfiture of the Spanish Armada, and fleet
and army, defined for the invasion of England in 1588.
At the upper end of the room is the throne, a highly en-
riched arm-chair; and at the lower end is an open space,
termed the bar. The commons of England, when they
formed a separate body from the peers, were, by an agree-
ment with the abbot of St. Peter's, allowed to meet in the
chapter-house already mentioned. But when, at the Re-
formation, the establishment of the collegiate chapel of St.
Stephen in the old palace was suppressed, to that place their
meetings were transferred by Edward VI. This chapel,
originally constructed by king Stephen, was rebuilt by
Edward III. in 1347. The commons, before the union
with Ireland, were accommodated within the chapel; but
their number being by that measure augmented from 558 to
658 members, it became necessary to enlarge the place of
assembly. At the eall, or upper end of the room, is the
speaker's chair; before it is the table with the clerks, and at
the bottom is the bar. The seats for the members ride one
behind another, as in a theatre. Those on the floor, on the
speaker's right-hand, are called the treasury-benches, and
occupied by the members of administration: the bench in front
is usually occupied by the leading members of the opposi-
tion. St. Stephen's chapel, highly adorned by Edward III.,
suffered greatly by its first adaptation for the commons;
but much more by the late alterations. By removing the
wainscot, a great part of the ancient decorations was dis-
closed, and a very important fact in the history of the fine
arts was, for the first time, ascertained. On the 11th of Au-
gust, 1800, was discovered a series of sculpture and painting,
the latter exhibiting portraits, scripture-faces, and other de-
corations, interesting in themselves, and peculiarly so as speci-
mens of the taste of the arts, as they existed nearly five
hundred years ago. It has been usual to ascribe to John Van
Eyck, of Bruges, in Flanders, the invention of painting in oil-colours, in 1410. This opinion has, however, of late
years, been much invalidated; by the discovery in St. Ste-
phen's chapel it is completely overthrown. From original
records of the expenses incurred in the construction and de-
coration of that building, it now appears that the renovation
was begun in the fourth year of Edward III., or about 1329,
and not in 1347, as stated by Stowe and others: that the
painters had not begun in 1345, but were at work in 1350,
and ceased to be mentioned in 1364: that those who painted
on glafs had begun in 1350, and finished in 1352: that the
paintings were unquestionably in oil: and that, of seventy-
five painters employed in the chapel, the whole, with the
exception perhaps of two, and they not the masters, were
natives of England. From these authentic documents it is
therefore fully ascertained, that pictures, in the usual sense of the term (not house-painting), in oil were executed in West-
minster palace in 1350, or sixty years before. Van Eyck's
supposed discovery of the art. But the fame genuine re-
cords go full farther back: they prove oil to have been em-
ployed in painting pictures in the chapel before the rebuild-
ing by Edward III.; that is, in the 20th year of Edward I.,
or in 1272, which was one hundred and eighteen years prior
to Van Eyck. (See Painting.) Under the old house of
lords are the cellars which were prepared for the famous
powder-plot, of the 5th of November, 1605.

Whitehall Palace.—This royal mansion occupied a con-
iderable space on the bank of the Thames, including Privy-
Garden, and extending to Scotland Yard, stretching out in
breadth from the river quite across the street still called
Whitehall into St. James's-park. It was originally the
property of Hubert de Burgh, earl of Kent, and grand
jurisdiction of England under Henry III. The situation
was low and marshy, owing to the concourse of the branch
on the west of Thorney Island with the main channel of
the Thames. In 1248 the palace belonged to the archbishops
of York, who poiffessed it until, on the fall of cardinal arch-
bishop Wolsey, it was, in 1529, feized, with his character-
istic love of justice, by the infatiable Henry VIII. Po-
feffion being obtained, many alterations were made in the
building, of which a portion, commonly called the Cock-pit,
adjoining to the Treasury, still exists. Falling into decay,
James I. resolved to rebuild Whitehall in a suitable man-
er; and for such a design the spacious ground between the
Thames and the park, and commanding both, offered every
facility excepting that of elevation of ground, without a proper
degree of which dignity is hardly attainable in architecture.
Of the magnificent, although in many parts faulty, pro-
ject of Inigo Jones, prepared for the intended work, one
portion only was executed. This is the Banqueting-houe,
so called from its succeeding, in delineation as in fact, to
a part of the old palace appropriated to royal entertainments.
The present edifice, one of the few specimens of noble and
regular architecture in the metropolis, consists of two stories,
on a rustic basement, ornamented with Ionic and Corinthian
columns and pilasters. This edifice, containing seven win-
dows on a floor, was only one of the angular pavilions of
the intended grand structure. It is sufficiently enriched, but
not overloaded with ornament; and being constructed on a
scale of very large dimensions in the parts, had the whole,
even with all the defects of the project, been carried into
effect, no sovereign in Europe could have exhibited a place
of residence to be compared with that of the king of Great
Britain. Magnitude of parts was in that project held to be
indispensable for grandeur of effect. The interior of the
Banqueting-houe has long been converted into a royal, and
lately into a military chapel; adorned, as is still most in-
congruously imagined, with trophies of war. The ceiling
is peculiarly worthy of observation, being the production of
the splendid pencil of Rubens; exhibiting the allegorical
history of his patron, James I. This masterly performance
ought to have diffused the admirers of George I. from con-
verting the room into a place of Christian worship; for
"its contents are in no way akin to devotion; and the work-
manship is so very extraordinary, that, in beholding it, the
spectator must either pollute an uncommon measure of zeal,
or be utterly delirious of skill and taste, who can attend to
any thing besides." From a window of the Banqueting-
houe the unfortunate Charles I., unfortunate in living in
times when the art of managing parliaments was either un-
known, or perhaps thought unworthy of a prince, palled to
the scaffold erected in the public street in front of his
own palace. In a court behind the building stands one of
the small number of public statues of the metropolis me-
ning examination. It is the work of Gubbins, and exhi-
bits James II., indicating, as he would do in his defined
situation, with an air and attitude full of expression, the
spot where his father suffered. At no great distance, on
the former site of the crofts in the village of Charing, is
erected another fine equestrian figure of Charles himself.
St. James’s Palace.—That the sovereign of the British empire was far less suitably lodged in his capital than are numbers of his subjects, has by foreigners been often remarked, and by natives been sometimes converted into a compliment to the sovereign and to the nation. But the fact is, that St. James’s palace was in its origin an hospital, of part of which Henry VIII. availed himself to construct the present buildings, as an appendage to the palace of Whitehall, with which it was connected by St. James’s park. Having been allotted for the residence of the princes, afterwards queen Anne, and her husband George of Denmark, St. James’s has ever since continued to be occupied for court or state purposes. The buildings are neither grand nor regular; the front, overlooking the park, has alone a certain air of dignity; and the state apartments, although they contain nothing peculiarly magnificent in the furniture of the decorations, are commodious and commodious. Connected with this palace is the park of the same name, ornamented with a long canal in the middle, and with broad walks, separated by rows of trees on the sides, the only species of improvement of which its flat situation is well susceptible. Near the centre of the canal, a wooden bridge, in the Chinese style, has been built across the water. On the north-west of St. James’s park is an open space, called the Green-park, capable, from its elevation and variety of ground, of much greater improvement: but its principal recommendation is, that, being in fact a wide extended green field, it furnishes a delightful promenade in all directions, and welcome relief from the hard pavement of the streets.

Buckingham-House.—This edifice, now settled on the present queen in lieu of Somer-fet-house, and hence called the Queen’s palace, possesses peculiar attraction, as much from its unfavourable situation as from its history. It was built by John Sheffield, duke of Buckingham, about the year 1700, and its gardens were adorned with terraces, canals, &c. The building is of brick, and most of the apartments are small. In this palace for several years were held his majesty’s levees, while his health permitted his appearance. Annexed to the palace are an octagon and other apartments, containing the king’s library, rich in various works of value, particularly in early editions of books. Interior views of the chief rooms, with an ample history of this edifice, &c. are given in Pyne’s History of the Royal Palaces.

Carlton House, the residence for a number of years of the prince of Wales, regent of the united kingdom, as formerly of the princes dowager of Wales, his majesty’s mother, occupies a situation in between Pall-Mall and St. James’s park. The chief front towards the street presents the singular incongruity of a lofty and highly enriched Corinthian portico, giving entrance into a low sufficied edifice. Between the house and the street is a court-yard, bounded by a low wall, sustaining an open colonnade, with an entablature. The interior has undergone many changes, and is fitted up in the most costly and sumptuous manner. The library, conservatory, and the armoury, are very fine and splendid. The work just referred to contains several fine prints of the different rooms; also a particular account of the house and its contents.

The ancient palace of Somer-fet-house has now disappeared, being superseded by the magnificent structures composing Somer-fet-place. Of the Savoy a few portions still exist, but much changed from their original delineation; and in a few years, perhaps, even the whole may be effaced. The plan of Somer-fet-place, as formed by sir William Chambers, was to comprehend within one vast edifice pro-
confiding of six of these circular divisions; the whole encompassed with a wall, inclosing 18 acres of ground, and calculated to contain altogether from 1000 to 1200 prisoners. Some of them are already placed, and the beneficial effects of the institution on their general conduct has already been very perceptible. As a part of Middlesex, the proper prisons for criminals are those belonging to the county; but in Tothill-fields is a bridewell for the detention and temporary punishment of petty offenders, under the charge of the magistrates of the city and liberties. The charitable establishments of Westminster for the education and maintenance of youth and the consolation of age, for the relief of disease and accidental calamity, are much more numerous and useful than splendid. St. George’s and the Middlesex hospital, (not, however, properly within the town,) the Westminster infirmary, &c. are excellent institutions, superintended by medical gentlemen of the highest professional reputation. Of the distinguished private mansions of noblemen and others, it is impossible here to do more than point out a few of the most remarkable. Among these are Northumberland-house, the only residence now remaining of our ancient nobility in the Strand; the duke of Marlborough’s in Pall-Mall, erected by the nation for the great duke John; the duke of Norfolk’s, St. James’s square; earl Spencer’s in St. James’s place; Burlington-house; the duke of Devonshire’s and earl of Egremont’s in Piccadilly; the marquis of Lansdowne’s in Berkeley-square; the earl of Cheltenfield’s in South Audley-street; earl Grosvenor’s in Upper Grosvenor-street; the marquis of Anglesey’s in Burlington-street; the marquis of Stafford’s, Cleveland-house. These are some of the best, as far as the exterior is concerned; but many others might be noticed highly deserving of attention, particularly for the admirable paintings by the best masters with which they are enriched.

**Bridges.**—It is a remarkable fact, that, great and important as Westminster is, until the construction of the noble bridge of its own name, of 15 arches, and in total length 1223 feet, completed in 1750, it possessed no other mode of communication across the Thames than by ferries, or by the embarrasmed circuit of London-bridge. The opening of Blackfriar’s-bridge was certainly a great accommodation for an extended portion of the town; but still something more was wanted, in a space between those bridges of no less than 3100 yards, or one mile and three quarters, of a most populous and active metropolis. About mid-way of this interval was opened, on the 18th July, 1817, a new bridge, leading from the Strand between the Savoy and Somerset-place, called the Strand or Waterloo bridge: it is a structure of a novel description in this country. The idea of it is not, however, new, having been frequently suggested, particularly by Gwyn in 1766. (For a particular description of this bridge, and the dimensions of its various parts, we refer to the article Waterloo.) The road-way is strictly horizontal on the level of the street in the Strand, but much above the surface of the Surrey shore, to which it descends by a long and gentle slope. Each pier, as in Blackfriar’s-bridge, is externally ornamented with two Tuscan columns supporting a square projection. The bridge was opened on the anniversary of the horrible carnage of Waterloo, and from this event it has been attempted to give it a name. In this case, however, as the main object was that of a truly solid bridge, the name would be more fitting, as Blackfriar’s and the Strand bridges. This admirable work does great honour to the engineer and architect Mr. John Rennie, and to the judgment of the managers of the enterprise; and it is, all circumstances of position, form, and materials considered, without a parallel in Europe. Besides the Strand-bridge, another of a different kind has lately been constructed over the Thames, just a mile above Westminster-bridge, leading over from Tothill-fields to Vauxhall, and thence properly named Vauxhall-bridge. The architect, Mr. Walker, has divided the breadth of the river into nine apertures, covered by frames of cast-iron, reeling on stone piers. The road is not horizontal, but forms two gently inclined planes, meeting in a very obtuse angle in the middle. The length of this light and elegant bridge is 809 feet. A third bridge, not indeed immediately connected with Westminster, but of great importance to the metropolis, is now in progress. This is the Southwark-bridge, commencing between that portion of the town and the city of London, on the line of Queen-street and King-street to Guildhall. This extraordinary structure, designed also by Mr. Rennie, consists of three grand arches of cast-iron, in segments of very large circles; the centre arch 240 feet in span, and the two others of 210 feet, each. To enable the reader to form a comparative idea of the bridges now mentioned, the following dimensions of some other remarkable bridges are subjoined. London-bridge, (see Bridge,) consists of 19 very unequal arches; Southwark-bridge (the iron part), 730 feet long, and of three arches; Blackfriar’s-bridge, 995 feet long, of nine arches; Strand-bridge, 1280 feet long, of nine arches; Westminster-bridge, 1225 feet long, of 15 arches; Vauxhall-bridge, 809 feet long, of nine arches. On the continent, the most remarkable structures of this description are the celebrated horizontal bridge over the river Loire, at Tours, in the west of France, in length 1335, and consisting of 15 elliptic arches; the bridge over the Moldau, at Prague, in Bohemia, 1700 feet long. These, however, are all far outdone by the antique bridge over the Rhone, at St. Esprit, in the south of France, consisting of a multitude of small arches, supporting a very narrow road-way, extending in all nearly to 3000 feet. This bridge has the peculiarity, that, instead of being straight, it is composed of two lines forming an obtuse angle, turned against the current, as if the water of the Rhone were too strong for it to support a straight line. The literary and scientific institutions.—These have already been noticed in the article London, to which the reader is referred. It will always be a peculiar honour for the British nation in general, and to the metropolis in particular, that, with very few exceptions indeed, all those valuable establishments for the promotion of learning, science, and the arts, which add so much splendour to the capital, owe their origin, their maintenance, and their reputation, to the voluntary exertions, personal and pecuniary, of private individuals. The two principal exceptions in London and Westminster are the British Museum, and the Academy of Painting, Sculpture, and Architecture; but from their nature, without public aid, neither of these institutions might ever have been established. (See Museum.) The British Museum is in regular and rapid progress, in the acquisition of those of high importance in the departments of natural history, literature, and art, to which it is devoted. The Elgin marbles, or the venerable monuments of Grecian sculpture, rescued by the earl of Elgin, during his embassy at the Ottoman Porte, from barbaric neglect and destruction, in their original position in Athens, are objects of attraction and importance unparalleled in Western Europe. Of the British Museum, in general, it is but justice to observe, that, in no familiar
similar establishment, can more attention be shewn to facilitate the researches, literary or scientific persons, of all who resort to the treasures it contains.

The population of Westminster very sensibly fluctuates, according to the season of the year. From October to July, while the parliament is assembled, the courts of law are sitting, and the places of amusement are open, the town is fully inhabited. During the other months, even these whose business is still transacted in town retire to their villas or quarters, in the surrounding villages and country. A hundred years ago, the inhabitants were computed, but surely overrated, at 130,000; but the last returns to parliament in 1811, they amounted to 62,085, occupying 17,555 houses.

The books examined for the foregoing account, and to which the reader is referred for more minute particulars, are, Antiquities of Westminster; the literary part by J. S. Hawkins, eq.; plates from drawings by J. T. Smith; 1 vol. 4to. 1807. The History of Henry VII.'s Chapel, by J. Britton, with plan, views, elevations, &c.; in vol. ii. of Architectural Antiquities of Great Britain. The History and Antiquities of the Abbey Church of St. Peter at Westminster, 4to. 1818, &c., by E. W. Brayley; with numerous plates from drawings by J. P. Neale. The History of the Abbey Church of St. Peter's, Westminster, its Antiquities, and Monuments; in 2 vols. 4to., with 63 engravings; published by Mr. Ackermann. An Inquiry into the Time of the first Foundation of Westminster Abbey, &c., by R. Wildmore, 4to. 1743.

The History, &c. of the Abbey Church, by the same author, 1751. Welfmonasterium, or the History and Antiquities of the Abbey Church of St. Peter, Westminster, by John Dart; 2 vols. fol. 1723. The general histories have been already referred to in the article LONDON.

WESTMINSTER, a town of Malachshhets, in the county of Worcesters, containing 1419 inhabitants; 55 miles N.W. of Boston. Alto, a port-town of Vermont, in the county of Windham, containing 1928 inhabitants; 18 miles N. of Brattleborough. Alto, a town of Maryland, with a post-office; 25 miles N.W. of Baltimore.

WESTMINSTER-Hall, an island in the straits of Magellan, situated to the N.E. of Cape Pillar. S. lat. 52° 34'. W. long. 76° 16'. Alto, an island in the Mergui Archipelago. N. lat. 16° 42'.

WESTMORE, a town of the Isle of Vermont, in Essex county, containing 71 inhabitants; 65 miles N. of Norwich.

WESTMORELAND, Westmorland, or Welfmoreland, a northern county of England, surrounded by parts of Durham and Yorkshire to the N., N.E., and E.; by Lancashire to the S. and to the S.W.; and by Cumberland on the W. and N.W. The greater part of the boundary line is artificial; but at the S. and S.W. rivers and lakes constitute natural lines of demarcation. This district is supposed to have derived its name from being a western moorish country; perhaps it was the land of the moors or lakes in the west. It formed a part of the territory of the Brigantes in that district occupied, according to Richard of Cirencester, by the Pohunites and the Sibunites. The Brigantes were the principal inhabitants of the Roman province Maxima Caesariensis; and during the heptarchy were included in the extensive kingdom of Northumberland. In the time of Edward the Confessor, this kingdom was divided into five shires, of which one was called "Appelbyshire, to which belonged the land of Welfmoreland."

In this division, however, Kendal and its district were not included; for long after the Norman Conquest, they were reckoned to belong to the hundred of Lonsdale, in Lancashire. Of the Roman establishments in Westmoreland, many noticeable vestiges are to be found in flatlands, forts, roads, inscriptions, and other remains. Among the flatlands, or towns, may be mentioned Amboglana, a name supposed to be still preferred in Ambleside, at the N. end of Windermere; but Horley places Diesu at that town. At any rate, bricks, urns, coins, and other relics, sufficiently prove it to have been occupied by the Romans. Verdares, another Roman flatland, was situated where now stand Brough-nader-Stannmore, a name announcing an ancient fortification. Amboglana seemed naturally to have given rise to the modern name of Appleby; but no Roman remains have ever been found at that place, although it be undoubtedly of considerable antiquity. Galacum is by Camden placed at Whelp, but by later writers near Appleby. Brocas is probably Brougham castle, near Penrhys. This flatland has often been confounded with Broconas, of which remains exist in Kirkbythore. This flatland Whelp or Whelp castle lies in the middle of the village, and is commonly called High Burwards. It occupies an advantageous position; the extent from west to east is about 160 yards. The foundations of the wall are very plain. Among the inscriptions found in it is one Fortuna Seruatriis. A branch of the great Roman road, called the Watling-street, passed through the county from Stanmore to Brougham castle; and until the modern turnpike-road was made, the former was very conipicious almost all the way. Between Brough and Kirkby, parts of it are still to be observed; keeping, as was the practice of the Romans, a straight course, regardless of difficulties. This road measured about six yards in width, and is described to have been formed, in many places, by three courses of large square stones. Near the northern border of the county, and not far from Kirkbythore, is a large enclosure, attributed to the Romans, and measuring about 300 yards in length, by 150 in breadth. It is represented as having twelve entrances, with bastions to each; but this is improbable. Some topographers describe a few of the antiquities of the county as of Celtic, or Druidical origin; particularly a "fort of Druidical place of worship near Shap." Maybrough castle, and Arthur's Round Table, near Penrhys, are referred to the British era. There are also several cairns, or heaps of loose stones, in the county. At Kirkbythore, a Roman road, called the Maiden-way, branched off, and passing over the lower end of Crossfell, terminated at Cawvolin, in Northumberland. Roman inscriptions have been found in various parts of the county. In one particular was discovered at Kirkbythore, inscribed Deo Bolatucodo, a local divinity probably of the original Britons. In 1739, at the same place, was found a stone inscribed Jovi Serapiis. In the manor of Milburne was found an altar to Silvanus, within a round fort surrounded by deep ditches, called Green-castle. This county is divided into the two baronies of Kendal and Westmoreland, the latter of which is occasionally called the barony of Appleby; and these again subdivided into the four wards of Eal, West, Kendal, and Kirkby Lonsdale. In ancient times, the Kendal barony was deemed part of the county of Lancashire. In the Domestic survey, an account is taken of some places in the barony of Kendal, with some neighbouring property in Lancashire and Yorkshire; but the Westmoreland district is unnoticed in that record, and hence supposed to have been uninhabited and waste at the time of the Conquest. The Kendal barony is in the diocese of Cheltenham, and consists of two rural deaneries; whereas the other barony is within the diocese of Carlisle, and consists of one
one rural deanship. The whole county contains only thirty-two parishes. According to the census of 1811, these contained 9064 houses, and 45,922 inhabitants.

The general appearance of Westmorland is marked with some of the strongest features in nature; immense tracts of mountains, beautiful but contracted valleys, extensive lakes, and large rocky districts, which contain many high, steep, and bulging crags. The county is not only encircled with mountains, but the greatest part of its interior surface is swelled into hills. A long range of heavy-looking hills bounds the eastern side of the county; in front of which is an extensive tract of tolerably level ground. The rest of Westmorland is almost wholly hill and dale. The farmhouses and those of the small villages, covered with blue slate and whitened with lime, are seated about the bases of the hills, with their small irregular fields spreading up the sides of the mountains, and almost universally divided with stone-walls. This last circumstance gives the county a naked appearance; but the numerous tracts of woodland interpersed tend to enliven the scene. Every dell or hollow has its little brook, and the small plots of these are plentifully supplied with fish. Several low heathy commons are seen towards the eastern side of Westmorland; and the western part is characterized by high rugged prominences, and even some rocky plains, small coppices, and a large extent of low flat peat-moors; on the north, the fine woods about Lowther add a striking feature to the landscape. Such are the brief but general outlines of the picture; we proceed to particularize some of its peculiar characteristics, the most prominent of which are its Mountains. These are provincially called fells, of which the following are the most noted.

Farrington, near the borders of Lancashire, is a very picturesque lime-flone rock; from the Kendal road, near Burton, it is said to have very much the appearance of the rock of Gibraltar.

Whitbarrow-peak is also a very high rock, and in some parts presents a perpendicular face of folio lime-flone. It rises its grizzly front between Minthorpe and Cartmel. The high road leads along its base, whence it presents a grand, and in some places a tremendous aspect.

Langdale-pikes, in the western corner of the county, are conical hills of great height, with pyramidal rocky tops, and are situated in the interior parts of a very mountainous district; their sides and bases are verdant, and have formerly been covered with wood.

Hartfell, High-street, and Kidney-pike, are stupendous heights, within a few miles of the southern end of Haweswater. From the top of High-street, thirteen lakes, and the sea in several directions, may be seen.

The chain of hills on the east, which is continued north and south through other counties, presents a heavy and regular appearance; and they have mostly mellow and healthy tops, except two or three conical green hills opposite Appleby. They are in general picturesque; some with abrupt declivities, or rocky fronts, form high precipices, or in bulging shattered crags project over the vales in a frightful manner; while others show smooth, verdant, and swelling surfaces, beautifully spotted with flocks of sheep and herds of cattle.

There are few Caves in Westmorland; one, however, is to be found at Dun-fell, bordering on Cumberland, and is of considerable extent. So intricate are the different galleries and chambers of this capacious cave, that the Rev. William Richardson is said to have been seven hours in examining its varied parts. He describes the roof in some parts to resemble pointed arches, in others flat surfaces; he found in some places the *flataedite*, and pieces of *rhomboidal spar*. He travelled nearly two miles in a right line, and discovered evident marks of some of the chambers having been filled with water. The highest part of the vault is rather more than 25 yards; the breadth in some places about 150 yards; in other parts there was scarcely height sufficient to creep through the hollow. Some other visitors have mentioned the astonishing height of the pikes, with which these vaults are encroached on. Nicholson and Burn, in their "History of Westmorland," mention three pits, one of which is generally considered unfathomable. In the fasons of salmon smelts, these pits abound with those smelts, when they are to be seen also in the river Kent, which induces a belief that they arrive from thence in subterranean passages.

Rivers.—Although the rivers or streams, (provincially called beck,) are numerous, they are but small, and mostly rise within this district. Only three of these are sufficiently important to retain their original names from their sources to the sea. These are, the Eden, the Lune, and the Kent, or Ken. The first springs in Mallerfield, and runs north, and having received in its course, besides many lesser streams, the conjoined rivers of Lowther and Eamont, enters Cumberland, which county it travesses in its course to the sea, at Rowell. The Lune, or Lyn, hath its source in Ravanstonedale, and passing to the south, through a fine vale, to which it gives name, enters the county of Lancashire, formerly called Joncaster. The Ken, or Kent, has its origin in Kentmere, and runs through a valley, called Kendal; passes the town of Kendal, and empties itself in the sea at Crambo Bay. The different rivulets from the eastern district empty themselves into the Eden, which, during its course through this county, receives its principal supplies. An irregular line, drawn east and west through the centre of Westmoreland, divides the direction of its several rivers; those on the north falling into the Eden, either before or at its entrance into Cumberland, except two or three small branches of the Tees, which rise on the eastern ridge of hills on the borders of the county of Durham. The rivers on the southern parts take a contrary direction, and enter the sea at different places.

The Lowther has its source in the Moors, above Wet-ladda, and passing Upgill-hall, there unites with Swindale-beck, which rises near the large-quiaries; with the augmentation of a few other streams, it joins the Eamont.

The Eamont emerges from Ulls-water, and forms a boundary to parts of this county and Cumberland; and after being augmented by the waters of the Lowther river, which descends from the centre of the county, it joins the Eden as it enters Cumberland.

The Lune, or Lyn, has been described in a previous volume of this work, under Lancashire.

The Crake, a brook or rivulet, descending in several heads from a variety of dells on the side of Brackenthal-fell, passes through a very extensive peat-moss to the Ken, just before its influx to the sea.

The Winter, or Winler-beck, forms the boundary between the lower part of Westmoreland and Lancashire. It rises on the hills about two miles east from Windermere lake, and directs its course southwards, when it discharges itself in an estuary of the sea.

The Trout-beck is a brook issuing from the mountain High-street, and unites itself with Windermere lake.

Rothay springs on the borders of Cumberland, among a number of high mountains; it runs several miles westward, and receives various streams in its progress to Grasmere.

Lakes.—Westmoreland is deservedly celebrated for its fine
fine lakes. Among these, Windermere, or Winandermere, and Ulls-water, merit particular attention for size, and for the picturesque beauty of the scenery which surrounds them. They may be, and are by competent judges, regarded as unequalled in the kingdom.

Winandermere is a large lake of about ten miles and a half in length, by a breadth of from one to two miles; including an area, or sheet of water, of nearly 4534 acres. Its depth is in one place 23 fathoms, in a second 29, and in a third 31 fathoms. Four mountain streams, or rivers, supply this lake, and it is singular that its waters scarcely ever appear to be augmented or decreased. "Even in the most violent rains, when the country is drenched in water, when every rill is welded into a river, and the mountains pour down floods through new channels, the lake maintains the same equal temper; and though it may spree a few yards over its lower shores, (which is the utmost it does,) yet its increase is seldom the object of observation; nor does the severity of the greatest drought make any considerable alteration in its bounds." In this lake are thirteen islands, the largest of which is now called Curwen's island. It contains about 27 acres of land, which are laid out in pleasure-gardens, walks, &c. around a very handsome mansion belonging to Mr. Curwen.

Ulls-water, part of which is known by the name of Ouvel-mer, is a large and long lake, situated at the north-western extremity of the county, and partly in Cumberland. Next to Windermere, it is the largest sheet of water in this part of England. It covers an area of about nine miles in length from N.E. to S.W. by two in the broadest part, though the general width rarely exceeds a mile. Its sides are very irriguous, and from its shores the mountains rise in various bold, picturesque, and romantic forms; occasionally starting abruptly from the lake, and in other places ascending by gradual slopes. Towards the south-western end the mountains are on the grand scale. On the northern and western sides the scenery is mostly rocky and woody. In some places its waters are from 20 to 35 fathoms deep. It abounds with trout, perch, skelles, and eels; also some char, and a large species of trout, some of which have been caught of ten pounds weight. In its highest part are a few small rocky islands.

Haws-water, in beauty and extent, ranks next. This lake is situated between Shap and Ulls-water, in a mountainous district; it is about three miles in length, and in breadth from a quarter to half a mile. The hills on the east side are high and rocky, and partially covered with wood. Those on the west are also high, but have a portion of low cultivated ground along the margin, which is divided into small farms. The narrowest part of the lake is said to be fifty fathoms deep.

Grasmere lake is a small but beautiful sheet of water, about a mile in length, and nearly a mile broad, having its margin indented with numerous small bays with lofty and rocky eminences. Its situation is a few miles north of Ambleside. Near its centre is a small green island. The poet Gray describes this lake and its scenery. He says, "After passing the romantic mountain of Helm-Crag, he says, "opens one of the sweetest land lakes that art ever attempted to imitate. The bosom of the mountains here, spreading into a broad baion, discovers in the midst Grasmere-water; its margin is hollowed into small bays with bold eminences, some of rock, some of turf, that half conceal and vary the figure of the little lake they command. From the shore a low promontory pushes itself far into the water, and on it islands a white village, with the parish-church rising in the midst of it." South of this, in the same vale, is Rydal-water, a small lake nearly a mile in length, and intersected with wooded islands. Its water is slow, and abounds with reeds.

On an elevated situation, nearly two miles west from Ambleside, is a small lake called Elter-water. Broad-water is a small lake half a mile long, and a quarter of a mile broad, situated a few miles above Ulls-water.

Kentmere-tarn, a piece of water upwards of a mile long, and nearly half a mile broad, is situated in Kentmere-dale.

Skeggle-water, a very small lake, three miles north-east of Kentmere-tarn, is embosom'd in the mountains of Longfledg'dale.

Sumbiggen-tarn, and Whin-fell-tarn, are small pieces of water; the former four or five miles east from Orston, well supplied with eels and a red trout, refembling char; and the latter about five miles north-east from Kendal.

The soil of Westmoreland is mostly dry and gravelly; but in the east and north, sand and hazel-mould are found. Clay prevails on a few farms towards the Eden and the eastern hills; and a moist soil appears in some northern districts. Peat-mofs abounds on the tops of some high mountains, consisting of a dry soil upon a hard blue rock, provincially called rag. The soil that lies upon a stratum of lime-flone is esteemed the most profitable.

The roads in Westmoreland, from the rocky nature of the country, are very firm and good. These are generally formed to wind gradually round the sides of the hills and along the vales, in such a manner, that the declivities of the former are mostly avoided. The principal roads leading through this county are those from Scotland and Cumberland to London, and on the southern parts of England. These roads are united through Cumberland, but divide near Penrith, on the confines of Westmoreland: one turns eastwards, over Stainmoore, and through the centre of Yorkshire, to London, &c.; the other proceeds directly south, through Kendal, Lancaster, &c. to Manchester, Liverpool, Wales, the western counties of England, and also to London. A branch from this road goes through Kirkby-Lonsdale to the manufacturing towns in the West Riding of Yorkshire, and other southern districts.

Before the rebellion of 1715, the public roads of this county were almost impassable; but in that year the government planned several new roads: very little, however, was done to them before the more serious insurrection of 1745. This event impelled the government to direct some effectual repairs to be made. In 1774 an act of parliament was obtained to make a turnpike-road from Bowes to Brough. In this year, the first stage-coach from London to Glasgow was established to run this road. A mail began to travel through Kendal, &c. from London in 1786. Since which time the great roads have been kept in very good repair.

With the exception of some trifling veins of lead ore, few minerals have been found in the eastern part of this county. Coal is obtained only in the south-eastern extremity of Westmoreland, except an inferior quality called crown-coal, procured in the neighbourhood of Shap.

The county affords various sorts of valuable flone; particularly lime-flone, marble, gypseum, blue flate, and freestone. There is great abundance of lime-flone, except among the western hills.

Marble of a beautiful kind was discovered a few years ago on the banks of the river Kent, near Kendal, and has been worked with success. The same vein has also been found on the opposite side of the river.

Blue flate of various sorts is dug from the rocky hills on the
the western side of the county; though great quantities are used in the country, yet much of the better sort is sent to London, Liverpool, Hull, and other large sea-ports. Beds of lime-flour are generally incumbent on beds of slate.

The buildings of Westmoreland are distinguished for their neat appearance. The houses are mostly built with lime-flour, or blue rag; thatched roofs are common, but slate is more generally used. In farm buildings, the barn is usually built upon the cow-house and stable, a method which requires the slope of a hill, as carts are carried along a level on one side into the barn. As very little corn or hay is stacked without, the barns are necessarily very spacious. There are many noxious and gentlemen’s feats in this county; and also some pleasant villas which ornament the borders of the lakes.

The commerce of Westmoreland is not extensive. Its exports are chiefly a coarse woollen cloth, stockings, flates, tanned hides, gunpowder, hoops, charcoal, hams, wool, sheep, and cattle.

The manufactures of the county consist of silk and worsted waistcoat-pieces, knit worsted stockings, flannels, tanned leather, and gunpowder.

Formerly the whole county was governed by military tenure, i.e. by homage, fealty, and cornage, which last drew after it wardship, marriage, and relief; and the service of this tenure was military service. Cornage appears to have been peculiar to the border-service against the Scots. Cornage, horn geld, and notgeld, were probably synonymous, and implied annual payments of horned cattle, to provision the garrisons. The lord’s rent was called white rent, probably from its being paid in silver. Scutage, or service of the shield, was another compensation in money, instead of personal service against the Scots.

Some veins of copper ore have been found and worked in different parts of the county; but the product has not been found sufficient to defray the expense of workmanship. Before the year 1704, great quantities of lead were found near Hartley. Some mines at Dunfell have proved very productive of this metal for many years, but latterly there has not been much ore found. At Dunton are some rich and productive lead mines, belonging to the earl of Thanet. There are some considerable mines at Greenhills, near Patterdale, and at several other places in the county. This metal is obtained in various quantities.

Croft-fell, the highest of the chain of mountains which extend along the southern frontiers of the county of Westmoreland and Cumberland, is said by Robinson, in his Natural History of the County, to have been formerly called Fiend’s-fell, from evil spirits which are said in former times to have haunted its summit, and continued their haunts and nocturnal vagaries upon it until St. Auffin, as is reported, erected a croft, and built an altar upon it, whereon he offered the Holy Eucharist, by which he counterchanged those hellish fiends, and disturbed their haunts. Since that time it has been named Croft-fell; and unto this time there is a heap of stones on the summit, which bears the name of Croft-fell.

Upon this and the adjoining mountains occurs the phenomenon called the Helm-wind, which, in spite of St. Auffin’s charms, continues its vagaries on its ancient haunts. It is peculiar to this district, and the confines of Lancashire and Yorkshire, about Ingleborough, Pendle, and Penigent. It also occurs on Wildboar-fell, in Ravendale; and is most prevalent in the months from October to April. The appearances attending it are a whitish cloud hanging half way down the mountains, but keeping an exact parallelism with every plane, depression, and elevation of their tops, which it covers as with a helmet. Above this appears the blue sky, and then a white cloud, called the helm-bar, from an idea that it reproves the fury of the storm; it continues in a tremulous agitated motion till it disperses; and then the hurricane issues forth, roaring along the sides of the hills, and frequently extending two or three miles from their sides. The following are the heights of the principal mountains, as ascertained by Mr. Dalton. Helvellyn is 1070 yards high. A deep drift of snow was seen on this mountain on the 12th of July, 1812. Bowfell and Rydal-head are each 1030 yards in height. The High-fret is 912 yards high. On its summit are annual horse-races, and other sports, on the 10th of July, to which every one brings the sheep that have strayed into their heath-ground, for their owners to challenge.

It appears that different grammar-schools were established in this county previous to the dissolution. Edward VI. was patron of the school at Kendal; and queen Elizabeth founded schools at Appleby, Kirkby Stephen, and Kirkby Lonsdale. From these seminaries many learned men have been distributed over England, some of whom have obtained eminence in the literary world. They have also contributed towards the establishment of other public schools in the county. Seminaries are, therefore, established in nearly every village in Westmoreland.—The History and Antiquities of the Counties of Westmoreland and Cumberland, by Joseph Nicholson, Esq. and Richard Barn, L.L.D. 2 vols. 4to. 1778. An Essay towards a Natural History of Westmoreland and Cumberland, by the Rev. Thomas Robinson, 8vo. 1799. General View of the Agriculture of the County, by Andrew Pringle, 4to. 1794. Observations relative chiefly to Picturesque Beauty of the Mountains and Lakes of Westmoreland and Cumberland, by the Rev. William Gilpin, 2 vols. 8vo. 1788. A Survey of the Lakes, by James Clarke, folio.

WESTMORELAND, a post-township of New York, in Oneida county; 10 miles W. of Utica, and 107 miles from Albany. Its waters are small; its surface very level, but the soil is very rich and fertile. It has a church for Congregationalists, and a competent number of common schools. In 1810, the population was 1135, and the senatorial electors were 141. Allo, a county of Pennsylvania, containing 26,392 inhabitants, of whom 20 are slaves. Allo, a county of Virginia, containing 8102 inhabitants, of whom 4080 are slaves. Allo, a township of New Hampshire, in the county of Cheshire, on the E. bank of the Connecticut, containing 1917 inhabitants; 5 miles N. of Chesterfield.

WEST NANTMILL, a township of Pennsylvania, in the county of Chester, with 1188 inhabitants.

WEST NORTHERN LIBERTIES, a town of Pennsylvania, in the county of Philadelphia, containing 9795 inhabitants. Allo, a township of the same, containing 168 inhabitants.

WEST NOTTINGHAM, a township of Pennsylvania, in the county of Chester, with 642 inhabitants.

WESTOE, a township of Durham, with 2900 inhabitants; 2 miles S. of Shields.

WESTON, a township of Connecticut, in the county of Fairfield, with 2618 inhabitants; S. of Fairfield. Allo, a town of Vermont, in the county of Windor, containing 629 inhabitants; 30 miles N.N.E. of Bennington. Allo, a town of the state of Massachusetts, in the county of Middlesex, containing 1008 inhabitants; 12 miles W. of Boston.

WEST PENNSBOROUGH, a township of Pennsylvania, in the county of Cumberland, with 1264 inhabitants.

WESTPHALIA, a circle of Germany, bounded on
the N. by the Dutch states, on the W. by the Netherlands, and elsewhere by the circles of the Rhine, Upper and Lower. The ancient Saxons were divided into Westphalians, Angrians, and Estphalians. The people inhabiting between the Weser and the Rhine, were called Westphalians, and the tract of country inhabited by them, has from thence been called Westphalia. The duchy of that name, in the electoral circle of the Rhine, constituted a part of this country; but the circle of Westphalia comprised also under it other countries, which never belonged to the above-mentioned Westphalia. And thus we must carefully distinguish from each other the three denominations, which are, the circle of Westphalia, Westphalia itself, and the duchy of that name. Formerly, not only certain states were reckoned in this circle, which at present no longer belong to it, as Utrecht, Gelderland, Zutphen, the bishopric and city of Cambrai; but in other respects, also, the ancient and the modern limits of the countries of the Westphalian circle differ greatly from each. The following appeared to be states of the Westphalian circle before the peace of Lunville, viz. the bishoprics of Paderborn, Munster, Liege, and Osnabruck; the duchy of Verden; the principality of Minden; the abbeys of Corvey, Stablo, Werden, Cornelius Munster, Effen, Thorn, and Hervorden; the duchy of Cleves, with the county of Mark; the dukeries of Juliers and Berg, Naffau Siegen, and Naffau Dillenburg; the principalities of East Frisia and Meurs; the counties of Sayn, Wied-Runkel, Schaumburg, Oldenburg, Delmenhorst, Lippe, Bentheim, Tecklenburg, Hoya, Vinnenburg, Diepholz, Spiegelberg, Rietberg, Pyrmont, Gronsfeld, Reckheim; the bishoprics of Anhalt and Winneburg; the county of Holzapfel; the bishopric of Witten, Blankenheim, Gerboldstein, Gehmen, Gimborn and Neutadt, Wickerad, Mylendonk, and Reichenstein; the county of Kerpen and Lommersum; the bishopric of Schieden, and the county of Hallermund, to which in the matricula are reckoned moreover to belong the bishoprics of Dyck, Severn, Kniphafsen, Keyl, Mechemann, Eyfs, Schlenaken, Wybri, Richold, Dreyz, and Schonau, together with the cities of Cologne, Aix-la-Chapelle, and Dortmund. The summoning princes, and directors of the circle, were the bishop of Munster, and with him alternately the electors of Brandenburg and Palatine, as dukes of Cleves and Juliers, both of whom in this directory enjoyed together but one voice. The dioceses of the circle were usually appointed at Cologne. The archives belonging to it were kept at Duffeldorf. The contribution of this circle in men and money, to the aids of the empire, was made equal to the contributions of Upper and Lower Saxony, Burgundy, and Swabia, and rated at somewhat more than the ninth, but less than the tenth part of the whole farm granted by the empire. With respect to religion, this circle was one of the mixed. Indeed the Catholic states used to nominate two, and the Protestant also the like number of affereors, to sit at the Imperial and chamber court of the empire. By the peace of Lunville, all that part of the circle which lay on the left bank of the Rhine, was ceded to France.

Westphalia, (Duchy of,) a country of Germany, bounded on the N. by the bishopric of Munster and county of Lippe, on the E. by Paderborn, Waldeck, and Helff; on the S. by Wittgenstein, Naffau, and Berg; and on the W. by Berg and Mark; about forty miles in extent from N. to S. and thirty-two from E. to W. Agreeably to its natural situation, this country is divided into three parts. The first of these, called the Hellenge, is low, and produces plenty of corn and other necessaries, with a sufficient breed of cattle and falt-springs. The second is the Haarfrank, which stands somewhat higher, between Hellenge and the Sunderland, and has indeed a good, but not so fruitful a soil as the Hellenge. The third is the Sunderland commonly called the Surland, or Saurland, which consists of hills and vales. This tract indeed is neither of great, nor even a sufficient fertility in corn; but, on the other hand, it has fine woods and meadows, together with a good breed of cattle, game, and fish, in particular trout, as also plenty of iron ore, calamine, lead, copper, silver, and gold. The principal rivers are, the Ruhr, the Lenn, the Dimel, and Lippe. The duchy of Westphalia contains in it thirty-five towns. Henry, duke of Bavaria and Saxony, being put under the ban by the emperor Frederick I. in the year 1180, the latter made a donation of the duchy of Westphalia, as also a part of the duchy of Engern, which belonged to the former, to the archbishopric of Cologne, and invested therewith the archbishop Phillip; concerning which donation, in the same year, a record, or instrument, was executed at Gelmhausen, and the said donation confirmed afterwards in the year 1200, by the emperor Otho IV., as also in the year 1204, by the emperor Philip. In the year 1368, Godfrey, the last duke of Arenberg, and his con- fort Anne, ceded the county of Arenberg to the archbishopric of Cologne; and, in the year 1371, the emperor Charles IV. invested the archbishop Frederick therewith. The county was afterwards added to the share of the duchy of Engern. The archbishops and electors of Cologne governed this duchy, till the year 1442, by marshals, but afterward under the direction of an electoral bailiff. Brilon is the capital. In 1802, the duchy of Westphalia was given to the prince of Hesse-Darmstadt.

Westphalia, a kingdom formed of several principalities, taken from the king of Prussia, after the battle of Friedland, and accorded to at the peace of Tilsit. Westphalia is divided into eight departments. 1. That of the Elbe; consisting of the greater part of the duchy of Magdeburg, with the Old Mark of Brandenburg. Its population is 253,000 souls: the chief place Magdeburg. 2. That of Fulda: the chief place Caelf. It is composed of a part of Lower Hesse, of the counties of Paderborn, Corvey, Minden, &c. Its population 239,502 inhabitants. 3. That of the Harz: chief place Heiligenstadt. It consists of Eichsfeld, of the cities of Muhlhausen and Nordhausen, of the principalities of Hohenstein, Grubenhagen, Blankenburg, &c. Its population is 210,989 souls. 4. That of the Leine: chief place Gottingen. It is composed of a part of the principality of Grubenhagen, and of the counties of Hildenheim, Brunfick, and Helff. Its population is 145,537 souls. 5. That of the Oker: chief place Brunfick. It is composed of the greater part of the duchy of Wolfenbuttel, and the bishopric of Hildesheim. Its population is 267,878 souls. 6. That of Saal: chief place Halberstadt. It is composed of the principalities of Halberstadt, Wernigerode, Quedlinburg, &c. The population is 205,222 souls. 7. That of the Werre: the chief place Marburg. It consists of Upper Hesse, the Hersfeld, &c. The population is 254,000 souls. 8. That of the Wefer: the chief place Osnabruck. It consists of the bishopric of Osnabruck, a part of Schaumburg; and its population is 334,000 souls.

Westphalia-Ham. See Ham.

Westpond plantation, in Geography, a town of the district of Maine, in the county of Kennebec, containing 481 inhabitants.

Westport, a township of Massachusetts, in the county of Bristol, incorporated in 1787, with 2585 inhabitants; 60 miles S. of Boston.
WESTPORT, a sea-port and port-town of Ireland, in the county of Mayo, situated on a beautiful bay, wooded to the water's edge, in the S.E. angle of that large haven called Clew bay, founded by the late marquis of Sligo, whose residence was within half a mile of it. Westport is a neat regular well-built town, 123 miles W.N.W. from Dublin, and 8½ S.W. from Galway. The following account, extracted from a late report to the Linen Board by Peter Bernard, esq., shews what judicious indulgence and liberal protection on the part of a landlord, affiicted by the exertions of an industrious individual, may do. Were the example universally imitated, many squalid and decayed villages would quickly acquire a more comfortable and exhilarating aspect. "The establishment and success of the linen manufacture in Westport, is due to the persevering attention of the marquis of Sligo and Robert Patten, esq. The latter, most fortunately for the neighbourhood, settled here in the year 1787; at that period Westport was a very incalculable town, containing but few houses, and its general market attended only by two or three hundred persons; now it is a beautiful well-built town, with 3000 industrious inhabitants, and many gentlemen of the highest respectability residing in it. Its market at present (1817) is attended by from 4000 to 5000 persons, whole manners, appearance, and dress, bespoke most strongly the happy effects of a well-regulated system of industry." "The first linen-market was held in 1790. For the first five years it produced only eight webs per week, and Mr. Patten was the only buyer; but he, by giving fair and liberal encouragement to the weavers, gradually but firmly advanced the trade, which now stands on a foundation not likely to be shaken. An accession of settlers from Ulster in the years 1797, 98, and 99, who brought their looms, some capital, and their accustomed habits of industry, completed what Mr. Patten had so fortunately begun." At present the market is held every Thursday in a spacious linen-hall built by the marquis of Sligo, where the goods are measured by a machine. The linens are all seven-eighths of three different qualities, and are all brought to market in a brown state. There are sold weekly about 200 webs, the value of which is estimated at above 20,000l. per annum. There are about 150 weavers and about 20 buyers, two of whom have bleach-greens at Westport. Mr. Patten has also successfully introduced at Westport the provision and corn-trade, and also the oil-bufinsels, which is carried on to a considerable extent, and gives employment in the seafaring to a great number of fishermen and boats. In March and April a number of fish appear off the coast, which, from appearing only on a funny day, the inhabitants call fun fish, though they differ from the fish usually so called. The fishermen strike these with harpoons, then cut out the liver, and abandon the rest of the fish, the liver being sufficient to load one boat of four tons burden. A large fish yields eight barrels of oil and two of tallow. This trade amounts to some thousands annually, and Mr. Patten's house has often bought in one year near 3000l. worth. The oil is esteemed as good as spermaceti oil, and is particularly well-suited for lamps, as it has no offensive smell. The price of the present day is five shillings per gallon; the dregs are used by tanners. Bernard's Report to the Linen Board in 1817.

WESTRAY, one of the Orkney islands, terminating the cluster on the N.W. quarter, is situated 20 miles N. from Kirkwall, and 347 miles in the same bearing from Edinburgh. Its shape bears some resemblance to that of a crofs; of which the longer part extends about eight miles, the arms or transverse part not more than five, and comprehends in the whole about fourteen square miles. The island comprises two parishes, St. Mary's and Crofs Kirk; and in the population return of the year 1811 was rated to contain 248 houses, and 1396 inhabitants. The only manufacture is that of kelp, of which are produced on an average 300 tons annually. Much corn is raised, but of an indifferent quality; the grass is excellent for the dairy, and for the pannage of black cattle; and the boisterous seas which surround the island afford great plenty of fish, of a very superior kind. On the eait and north are two bays; but the only harbour that can be depended on is on the north-east, and this is fit for small vessels only: formerly it received ships of much greater burthen; but from the blowing of the land the water has become so shallow, they are now compelled to anchor in a more open road. In two extensive plains near the sea-fide, one on the south, the other on the north part of the island, a multitude of graves have been discovered, all formed in nearly the same manner; and, though tradition is silent, they were probably formed after a singular conflict at some remote period: some of these graves, on the north side, have been opened, and were found to contain skeltons in a reeking posture, with weapons, domestic utensils, and several other articles, the use of which could not be ascertained.—Beauties of Scotland, vol. v. Orkneys, 1808. Carlyle's Topographical Dictionary of Scotland, 1813.

WESTRINGIA, in Botany, was so named by the author of the present article, in honour of Dr. John Peter Wellring, physician to the king of Sweden, member of the Royal Society of Stockholm, and author of several learned papers on the Lichen tribe, published in the Transactions of that body. He has also published several numbers in Svo. on the dyeing properties of many Swedish lichens, comprehending a full history of the modes of applying them to use, and accompanied with most elaborate and complete colour figures, drawn by the celebrated professor Acharius himself.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, somewhat bell-shaped, with five fides and five prominent angles, but no furrows, divided about half way down into five equal, erect, lanceolate, beardless legs, segments, permanent. Cor. of one petal, ringent, twice as long as the calyx: tube the length of the calyx, hairy in the throat; limb two-lipped; the upper lip flat, erect, divided, rather the longest; lower in three oblong, equal, spreading, entire segments. Stam. Filaments four, shorter than the limb, divericated, the two upper ones longest; authors of the two upper flaments roundish, halved, those of the two lower deeply divided, imperfect. Pfi. German in the bottom of the calyx, four-lobed; style thread-shaped, the length of the longer flaments; stigma small, cloven, acute. Peric. none, except the hardened calyx. Seeds four, obovate, naked.

Eff. Ch. Calyx five-cleft half way down, five-fided. Upper lip of the corolla flat, cloven; lower in three deep equal segments. Stamens ditant; the two upper with halved anthers; two lower with divided abortive ones.

A genus of New Holland shrubs, chiefly from the colder parts of that country, having the appearance of our rosemary, delitute of glands, but moily downy. Leaves whorled, entire. Flowers axillary, solitary, on short stalks, with a pair of bractes close to the calyx. Corolla white, sometimes dotted with purple or violet. One species only was, for a long time, known to us, but Mr. Brown has
West

1. W. rosmariniformis. Rosemary-leaved Welfringia. Sm. in Stockh. Trans. for 1797, 175. t. 8. f. 2. Tracts 282. t. 3. Brown n. 1. Ait. n. 1. Donn. Cant. ed. 5. 141. (W. rosmarinacea; Andr. Repof. t. 214. Cumila fruticosa; Wild. Sp. pl. v. 1. 122.)—Leaves four in a whorl, lanceolate, revolute; thin and nearly smooth above; silky beneath. Calyx filiky; its teeth longer than the tube.—Native of New South Wales, near Port Jackson, from whence specimens and seeds were lent by Dr. John White, in 1791. The stem is shrubby, several feet high, very much branched; branches either opposite, or four together, square, silky with white close hairs, densely leafy. Leaves spreading, an inch or somewhat less in length, acute, single-ribbed, entire; dark green, and polished above; white with silky hairs beneath. Footstalks broad and very short, silky, without stipulis. Flowers about the upper part of the branches, shorter than the leaves; their corolla spreading nearly an inch, white, dotted about the mouth with violet spots. Anciis violet. The calyx is filiky on the outside of the tube, its segments naked with revolute margins; they appear to us variable in length. The plant is slightly bitter, not aromatic; nor have the flowers any scent.

2. W. Dampieri. Dampier's Welfringia. Br. n. 2. Ait. n. 2.—"Leaves four in a whorl, linear, strongly revolute; nearly smooth above; hoary and opaque beneath. Calyx hoary and opaque; its teeth half the length of the tube."—Gathered by Mr. Brown on the southern coast of New Holland. Sent to Kew in 1803, by Mr. Peter Good. It flowers in the greenhouse, from May to July. Alton.

3. W. rigid. Rigid Welfringia. Br. n. 3.—"Leaves three in a whorl, linear-lanceolate, divaricated, sharp-pointed, revolute; smoothish above; hoary beneath. Calyx hoary; its teeth half the length of the tube."—Discovered by Mr. Brown, in the fourth part of New Holland.

4. W. cinerea. Grey Welfringia. Br. n. 4.—"Leaves three in a whorl, linear, spreading, pointed, revolute, hoary on both sides. Calyx hoary; its teeth scarcely a quarter the length of the tube."—This was found by Mr. Brown, in the same county as the last species.

5. W. angustifolia. Narrow-leaved Welfringia. Br. n. 5.—"Leaves three in a whorl, linear, spreading, revolute; roughish on the upper side; hoary beneath. Calyx hoary; its teeth half the length of the tube."—Found by Mr. Brown, in the island of Van Diemen.

6. W. longifolia. Long-leaved Welfringia. Br. n. 6.—Leaves three in a whorl, linear, revolute; rough with minute points on the upper side; slightly hairy beneath. Calyx somewhat hairy; its teeth equal to the tube.—Gathered near Port Jackson by Mr. Brown. We have specimens, gathered in that country by Dr. White, whichiffer to the specific character, except that the back of their leaves, as well as the calyx, are rather hoary than, as Mr. Brown says, green, and the leaves are four, or even five, in a whorl. The corolla is externally downy; but this last character is, perhaps, not peculiar to the present species.

7. W. glabra. Smooth Welfringia. Br. n. 7.—"Leaves three in a whorl, linear-lanceolate, flat, smooth on both sides, as well as the calyx."—Gathered by Mr. Brown, in the tropical part of New Holland.

The two last species seem to differ remarkably from all the foregoing, in the flatness and smoothness of their leaves.

West

WEST STRIZ, in Geography, a river of the duchy of Soria, which runs into the Luffnitz, near Furtenfeld.

WESTS, a town of Virginia; 4 miles S.W. of Leeburg.

WEST SALEM, a township of Pennsylvania, in Mercer county, with 666 inhabitants.

WEST SOUTHWARK, a town of Pennsylvania, in the county of Philadelphia, containing 6443 inhabitants.

WEST SPRINGFIELD, a town of Maffachusets, in the county of Hampshire, containing 3169 inhabitants.

WEST STOCKBRIDGE, a town of Maffachusets, in the county of Berkshire, containing 1049 inhabitants.

WEST WHITELAND, a township of Pennsylvania, with 636 inhabitants.

WEST WINDSOR, a town of New Jersey, in the county of Middlesex, containing 1714 inhabitants.

WET AIR. See MOISTURE.

Wet Couch, a term used by the maltsters for one of the principal articles of malt-making.

In the making of malt, the usual way is to soak the grain in water two or three days, till it becomes plump and swelled, and the water is brown; the water is then drained away, and the barley is removed to a floor, where it is thrown into a wet couch, that is, an even heap of about two feet thick.

In this heap the barley spontaneously heats, and begins to grow, shooting out first the radicle, and, if suffered to continue growing, soon after the blade; but at the eruption of the radicle, the prococ is to be stopped short, by spreading the wet couch thin over the floor, and turning it once every four or five hours for two days, laying it thicker each time; after this it is thrown into a large heap, and there suffered to grow hot of itself, and afterwards spread abroad again and cooled, and then thrown upon the kiln to be dried crisp, without scorching. Shaw's Lectures, p. 186.

Wet Dock. See Dock.

Wet-Glover, a dresser of the skins of sheep, lambs, goats, &c. which are slender, thin, and gentle.

WEDA, or Windao, in Geography, a river of the duchy of Courland, which runs into the Baltic, a little below Windau.

WETERFELD, a town of Bavaria, on the Regen; 21 miles N.E. of Ratibon.

WETER-GETTER, among Sheep-Farmers. See RAM.

WETHER-SHEEP, in Rural Economy, a term applied by stock-farmers to a castrated male sheep of more than one year old; but before that time it is called a wether-lamb. The wethers of the improved breeds of sheep, espically those of the new Leicestter fort, are much more early than the old kinds. See SHEEP.

WETHERBY, in Geography, a market-town in the upper division of the wapentake of Claro, West Riding of the county of York, England, is situated on the river Wharfe, 7 miles N.W. from Tadcaster, about the same distance S.E. from Knaresborough, and 94 miles N.N.W. from London. The course of the river forms an angle, whose sides are each about one mile in length; at the point of this angle the town is seated. It affords nothing worthy of notice, but a handsome bridge crossing the Wharfe. Above this bridge the river forms a beautiful cascades, by falling.
falling in a sheet of water over a high dam erected for the convenience of the mills. Over this cascade, the salmon, in their way up the river from the sea, are seen to leap with wonderful dexterity. Wetherby has a weekly market on Thursdays, and three annual fairs. In the population return of the year 1811, the town is stated to contain 1140 inhabitants, occupying 454 houses. In the time of William the Conqueror, this town was possessed by two Norman lords, William de Percy and Ernse de Buron. It was afterwards given to the knights templars; and, together with all their estates in England, was forfeited on the abolition of their order, in the year 1312. In the civil war of Charles I, this town was Garrisoned by Sir Thomas Fairfax, who, in 1642, repulsed Sir Thomas Glenham, in two different attacks. A little below the town is St. Helen's Ford, where the Roman military way crossed the Wharfe. Within a mile of the town is Wetherby Grange, the seat of Richard Thompson, esq. In the park is an heronry, a thing rather uncommon in this part of the country. The herons build their nests in the tops of the highest trees; but seldom take the trouble, when they can get them ready made by the rooks, whom they expel, and enlarge and line the nests, driving away the original poiffessors, should they happen to renew their fruitless claims.

About two miles to the west of Wetherby, is Stockeld park, the seat of William Middleton, esq. His ancestors descended from Hylpomus de Brame, lord of Middleton, who lived in the reign of Henry II. Not far from the house, and near the high road, is a rock of a very singular shape, 65 feet in circumference, and 30 feet high, standing on the margin of a lake.—Hargrove's History of Knareborough, 1809. Beauties of England and Wales, vol. xvi. Yorkshire. By J. Bigland, 1812.

WETHERSFIELD, a town of Connecticut, in the county of Hartford, containing 3561 inhabitants.

WETMORE'S ISLAND, a small island on the coaft of Machias, at the mouth of the river Penobscot.

WETSTEIN, John James, in Biography, was born at Bafle in 1693, and made such proficiency in his early studies, that he was fit to be admitted into the university at the age of eleven years. In his 20th year he was ordained minifter, on which occasion he maintained a disputation on the various readings of the New Testament, in which he defended the authenticity and integrity of the text. To this course of study he was sedulously devoted, and in order to explain the words and pharases of the New Testament, he carefully read the Greek authors, both sacred and profane; and he also consulted the Rabbinical writings, for the purpose of acquainting himself with the opinions and cufoms of the Jews. Richly furnished with this kind of knowledge, he set out, in 1714, on a literary tour to Zurich, Berne, and Geneva. From the latter place he proceeded through Lyons to Paris, where he became acquainted with Montfaucon, Courayer, and other eminent men; and he also visited England, where he was particularly noticed by the celebrated Bentley, and diligently searched for MSS. of the New Testament. During his stay in this country, he was made chaplain to a regiment of Swifs troops, and having obtained leave of abifenee, visited Paris, in order to collate a particular MSS., and, after three months, joined the regiment at Bois-de-duc. Having afterwards visited Holland and Germany, he returned to Bafle in 1717, and became deacon to the church of St. Leonard, which office he held with distinguished approbation for nine years. In purfuance of his main object, he corresponded with Bentley on the subject of various readings; but he was interrupted in his plan by a violent dispute with a divine of Bafle, who had been his intimate friend, occasioned by his publication of a specimen of his various readings in 1718. In the progress of this dispute, the clergy took a part, and presented a petition to the council, requiring that Wetstein's edition of the New Testament might be prohibited; alleging, amongst other objections, that it favored Socinianism. His Prologena, however, were printed in 1730, and a new accusation was preferred to the council against the author. This kind of clamour proving ineffectual, his enemies engaged some of his pupils to appear as witnesses against him; and they produced extracts of his lectures from the MS. copies of these pupils to support their accusation. The result of these dishonourable proceedings was a suspension of his functions in 1729, and this was soon followed by his total deposition. This conduct of the clergy was aggravated by a variety of misrepresentations; the ministers of Mulhausen, Neufchatel, Vallangen, and Geneva, expressed their disapprobation of these measures; and forty heads of families in the parish of St. Leonard presented a petition for obtaining Wetstein's re-establishment. But as this interposition on his behalf was unsuccessful, he left his native country, and removed to Amsterdam, where the Remonstrants elected him professor of philosophy in the room of Le Clerc, requiring, at the same time, that he should justify himself, either by a public apology, or before the council at Bafle. Adopting the latter method, he returned to Switzerland, and in the presence of thirteen commissioners, chosen from the council and body of the professors, he swore that the extracts furnished by his pupils were not worthy of credit; that the witnesses had sworn nothing that could prove the accusation alleged against him; and that the acts of the divines contradicted each other. The council, in March 1733, annulled the decree of condemnation, and restored him to the full exercise of his functions. The Remonstrants at Amsterdam were satisfied, and in 1735 he took possession of his office, the duties of which he faithfully discharged till his death. His character being re-established at Bafle, he was elected in 1744 professor of the Greek language; but the Remonstrants, in order to retain him, nominated him professor of ecclesiastical history, and made an addition to his salary. Amidst the labours of the offices, which he sustained with great honour to himself and benefit to his pupils, he proceeded in collecting and arranging his various readings of the New Testament; grudging no expense, and availing himself of every opportunity that occurred in collating various MSS. Encouraged by a great number of learned men in England, Holland, and Germany, he at length published his first volume in 1751, and the second in the following year; and in order to preclude every objection, he printed the text from that commonly received, and the various readings at the bottom. To the whole he subjoined a commentary, comprehending all the remarks with which he had been furnished by the Hebrew, Greek, and Roman writers whom he had consulted. His attachment to received principles is evinced by his mode of explaining several passages, and particularly those which related to the divinity of Jesus Christ. To his New Testament he added two epistles of St. Clement, now first published, with a Latin version, and a dissertation on their authenticity. His literary reputation being now established, he was made a foreign associate of the Academy of Sciences at Berlin, in 1752; and in the following year elected a fellow of the Royal Society in London. Although Wetstein's constitution was vigorous, his incessant labour accelerated the infirmities of age; and he was seized with a numbness and coldness in his right leg, which threatened a gangrene, and all attempts to check the progress of this malady were ineffectual; so that it terminated his valuable life
in March 1754, in the 61st year of his age. He beheld the approaches of death with tranquillity and resignation. Wet-ten was social, and fond of innocent amusements, though studious. He was an excellent Greek scholar, possessed a retentive memory, and spoke several modern languages. He was affable even to strangers, and kind and condescending to his pupils. His benevolence comprehended all of every nation and communion, and he was prompt in communicating advice and counsel to all who applied to him. His character has been amply vindicated from invidious and degrading charges by Kriigout, in his "Memoria Wett-teniana Vindicata," 4to. Formey's Elog. Gen. Bio!. WETTLESHEIM, in Geography, a town of Germany, in the principality of Anspach; 4 miles N.W. of Treucht-lingen.

WETTENHAUSEN, a princely abbey, founded in the tenth century; 20 miles W. of Augsburg.

WETTER, a town of Germany, in the county of Mark; 6 miles S.W. of Schwert. — Alto, a town of Germany, in the principality of Hesse; 6 miles N.W. of Marburg. N. lat. 50° 54'. E. long. 8° 45'. — Alto, a river of Germany, which rises in the county of Solms, and runs into the Nidda, at Afehnheim.

Wetter Island, an island in the East Indian sea, about 90 miles in circumference, of an irregular form. S. lat. 7° 24'. E. long. 126° 45'.

Wetter Lake, a lake of Sweden, in East Gothland, sixty-five miles long, and from ten to sixteen wide. This lake has but one outlet by the river Motals, though above forty little streams discharge themselves into it. This lake lies much higher than either the Baltic or the North sea, and is deep and clear, but very boisterous in winter. It is supposed certainly to prognosticate the approach of stormy weather. As this lake, like all inland pieces of water, surrounded with hills or mountains, is subject to sudden storms in the slightest weather, superabundance and credulity cooperating, in other cases, have been busy in explaining and attributing causes for this phenomenon; and accordingly it has been reported and credited, that these sudden storms are occasioned by a subterraneous communication with the lake of Constance in Switzerland. It is said, that by a regular series of correspondence and observation it was found, that when the waters of one lake arise, those of the other fell in the same proportion; and frequently the waters of the Wetter were violently agitated without the least wind, or any apparent cause, until information arrived that at the same time the lake of Constance had been disturbed by a tempest. The whole is supposed to be a fable grounded on some antiquated tradition. See WADSTENA.

WETTERAU, or Wetteravia, a country of Germany, bounded between the county of Hesse and the river Maine, which takes its name from the river Wetter. It contains the counties of Siegen, Schaumburg, Dillenburg, Dietz, Hadamar, Weilburg, Idstein, Hanau, Solms, Wetterburg, Ilmenburg, Sayn, Witgenstein, Hohenbeil, Cronberg, and Walemburg, the lordships of Weid, and the imperial towns of Wetzlar, Friedberg, and Gelhausen. The northern part is called Weflerwald.

WETTERINGEN, a town of Germany, in the bishopric of Munster; 7 miles S.W. of Rheine.

WETTING, a town of Weithphalia, in the duchy of Magdeburg, on the Saal, the principal place of a bailiwick, which was formerly a county, in the year 1283 granted to the cathedral of Magdeburg. In the neighbourhood are some coal-mines; 34 miles S. of Magdeburg. N. lat. 51° 37'. E. long. 12° 5'.

WETTINGEN, a town of Switzerland, and principal place of a bailiwick, in the county of Baden, on the Limmat, with a celebrated wooden bridge of one arch over the river, executed by the same person who built the bridge over the Rhine, at Schaffhausen; 1 mile S. of Baden.

WETZ, a river of Germany, which runs into the Lahn, near Wetzlar.—Alto, a town of Germany, in the principality of Solms Braunsfeld; 5 miles S. of Wetzlar.

WETZLAR, an imperial town of Germany, in the circle of the Upper Rhine, situated on the Lahn. The Roman Catholics, the Lutherans, and the Calvinists, have each a church; 45 miles E. of Coblenz. N. lat. 50° 34'. E. long. 8° 33'.

WEWELENSBURG, a town and citadel of Weithphalia, in the bishopric of Paderborn; 8 miles S. of Paderborn.

WEVER, a river of England, in the county of Chester, which runs into the Dee, 7 miles N. of Chester. — Alto, a river of England, in the county of Devon, which runs into the Culm, near Bradninch.

WEWERHAM, a township of England, in Cheshire; 3 miles W. of Northwich.

WEWERY, a river of Wales, which runs into the Wye, near Builth.

WEWER, or WEVER, a town of Weithphalia, in the bishopric of Paderborn; 22 miles S.S. W. of Paderborn.

WEWURZE, a river of Lithuania, which runs into the Minnic, 3 miles S. of Proccus.

WEXEL, a mountain of Stiria; 4 miles N.W. of Friedberg.

WEXFORD, a county of Ireland, in the south-east part of it, which has St. George's Channel on the E. and S., the counties of Waterford, Kilkenny, and Carlow, on the W., and that of Wicklow on the N. It extends from N. to S. 44 Irish miles, and from E. to W. 25; being 56 English miles in length, by 32 in breadth. It contains 342,900 acres, or 535 square miles Irish, equal to 550,888 acres, or 605 square miles in English measure. The number of parishes 142, having 41 churches, all of which, except two parishes with one church, are in the diocese of Ferns. The population was estimated by Dr. Beaufort at about 115,000. Wexford forms almost a peninsula, being separated from Waterford and Kilkenny by the haven of Waterford, and the deep and navigable river Barrow, and from the counties of Carlow and Wicklow by formidable ranges of mountains, which admit of few pannes. Being situated next to the principality of Wales, and nearly opposite to the mouth of the British Channel, it presented great advantages to the English invaders of Ireland in the reign of Henry II., who, after their first victories over the natives, selected this county, from its natural strength, for the residence of the first colonists. The inhabitants of the baronies of Bargin and Forth are supposed to retain traces of their descent from these settlers. (See BARGIE.) Wexford cannot be called hilly or mountainous, except on the frontiers of Carlow and Wicklow. Yet it contains a great deal of coarse cold land, and stiff clay soil, which, with the lime-borne renders it difficult and expensive to improve. The baronies of Bargie and Forth, being of a lighter soil, are well tilled, and produce large quantities of barley. The river Slaney crosses the county from Newtown Barry to Wexford, receiving the Barron from the northward, and affords a perpetual variety of picturesque and romantic views among its wooded and winding banks. This river is navigable to Emmicorothy. The linen manufacture has made no progress in this county, but there is a manufacture of coarse woollens. The chief towns are Wex- ford, New Rofs, and Emmicorothy, of which an account is given.
given under their names. Wexford has been notorious for
the events which took place in it during the rebellion
of 1798. In it the misguided populace was successful
for some time, and the massacres at Scullabogue; and at
the bridge of Wexford, afford a melancholy proof of what
may be expected from an ignorant and almost barbarous pea-
tantry, when they have the ascendency. Their leaders were
unable to control them, and if the king’s troops had not
been successful, there would have been no bounds to their
exterminating phrenzy. Before the Union, Wexford had
eighteen members, but these have been reduced to four, two
for the county, and one each for the towns of Wexford and

WEXFORD, a sea-port and post-town, and also the affize
town of the county of the same name, in Ireland, at the
mouth of the river Slaney. It was originally built by
the Danes, who named it Wexford, and it was formerly con-
dered a place of strength, being enclosed by very thick
walls, some of which are still remaining. There are some
handsome buildings; on the site of the old castle the bar-
acks are erected, commanding an extensive view of the
harbour. The church, situated in the main street, is an
elegant modern structure. The market and court-house are like-
wise new edifices; but the chief ornament of Wexford is its
wooden bridge, thrown over an arm of the sea, 2100
feet long, when an infurmountable difficulty baffled all
efforts to form a stone bridge. This bridge is a favourite
promenade, and is as delightfully calculated for a pleasant
recreation, as it constitutes an useful communication. The
harbour, though spacious, is shallow, and formed by two
necks of land, between which there is an entrance about
half a mile broad, which was formerly defended by two
ports, erected at the extremity of each illus. The
mouth of the harbour is choked with a bar, and there-
fore no vessel drawing more than twelve feet water can
pass to the town. Provisions of all kinds are very plentiful
and cheap here, particularly the finest wild fowl. The chief ex-
port is corn, principally barley and malt. Wexford was
taken from the Danes by the English invaders, after a siege
of four days, in 1170; it was besieged and stormed by
Cromwell in 1649; and on being evacuated by the king’s
troops, it was taken possession of by the rebels in 1798.
The shocking murder of the loyal inhabitants, when 97 un-
offending victims suffered at the bridge, has been already
alluded to. There are seven parishes, but they are all
united, and have only one church in common. Wexford is
67 miles S. by W. from Dublin. Carlyle. Traveller’s
Guide.

WEXIO, a town of Sweden, in the province of Smal-
land, situated on the Helga lake: the site of a bishop, and
residence of the provincial governor; 46 miles N.N.W. of
Carlsbora. N. lat. 56° 22'. E. long. 14° 44'.

WEY, a river of England, which runs into the Thames
at Weybridge. This river is navigable to Guildford and
Godalming, and a canal has lately been made from it to
Basingtloke, in Hampshire.—Allo, a river of England,
which runs into the sea at Weymouth. 

WEY. See WEIG.

WEYBER, in Geography, a lake of Bavaria; 3 miles
W.N. of Konpien.

WEYBRIDGE, a considerable village in the hundred
of Elmbridge, and county of Surrey, England, is situated
on the river Wey, whence it derives its name, not far from
its confluence with the Thames, at the distance of 12 miles
N.E. by N. from Guildford, and 20 miles S.W. by W.
from London. It contains some respectable houses, among
which is a large edifice, called Holteim-house, from having
been the residence of a prince of Holstein, when on a visit
to England; it has for some years been used as a printing-
office. The church is a small, but neat structure, having a
cape and south aisle, at the west end of which is the vault
of the earl of Portmore’s family, built up about four feet
above the level of the pavement, inclosed with iron rails,
but without any inscription. The population return of the
year 1811 states the parish of Weybridge to contain 167
houses, and 918 inhabitants.

In this parish is Oatlands, the seat of his royal highness
the duke of York. This domain came into the possession
of Henry VIII. by an exchange with the family of Rede,
for the manor of Tandridge, in the same county. It was
settled by Charles I. on his queen Henrietta Maria for her
life; and their youngest son, called Henry of Oatlands, was
born here. At the Restoration the queen dowager was
again put into possession of the estate; and after her death
Charles II. granted it to the earl of St. Alban’s. In the
next century it descended to the earl of Lincoln, after-
wards duke of Newcastle, who fixed his residence here,
and enlarged the park, and made considerable plantations. In
the park is a large piece of water, formed by springs which rise
in it. Between the house and garden is a grotto, divided
into three apartments, in one of which is a bath, supplied
by a small spring, dripping through the rock; at the end of
it is a copy of the Venus de Medicis, as if going to bathe.

The duke of York purchased this estate of the duke of
Newcastle, together with the manors and parks of Byfleet
and Weybridge, which he held by leases from the crown.
In 1800 two acts were passed for inclosing the common fields
and waste, under which the duke obtained by allotments
and purchases about 1000 acres of the waste, so that the
domain now comprises about 3000 acres. The mansion
was burned down while the duke was in Flanders, in 1793.
The present house was then erected, from designs by Mr.
John Carter; and in 1843 an act was passed for granting to
the duke so much of this estate as was held of the crown.

In a small park on this elevation is Hartham, an old manion,
formerly the residence of the counts of Dorchelter, mi-
trefles of James II. It is now uninhabited, and in a ruinous
condition. Near it are many large cedars; one, in particu-
lar, measures, at five feet from the ground, about thirteen
feet in circumference, and runs up straight to a great height.

WEYERS, a town of Westphalia, in the bishopric of Fulda; 8 miles E.S.E. of Fulda.

WEYERSHEIM, a town of France, in the department of the Lower Rhine; 6 miles S. of Haguenau.

WEYHER, a town of Austria; 6 miles W. of Bavarian Waldhoven.

WEYHILL, a village of England, in the county of Hants, celebrated for the great annual fair held here for the sale of sheep, hops, &c.; 3 miles W. of Andover.

WEYL, or Wyl, a town of Switzerland, belonging to the abbey of St. Gal, and principal place of a bailiwick; 14 miles S.S.W. of Constance.

WEYLANOOG, a town of Hindoostan, in Guzerat, on the coast; 20 miles S.E. of Putton Summit.

WEYMOUTH, or Weymouth, a borough and market-town in the hundred of Uggecombe, Dorchester division of the county of Dorset, England, is situated on the southern coast of England, at the extremity of a beautiful bay, which forms nearly a semicircle, making a sweep of about two miles. The town is 8 miles S. by W. distant from Dorchester, and 128 miles S.W. by W. from London. It received its name from the mouth of the little river Wey, near which it stands, and communicates with Melcombe Regis, to which it is united by a bridge erected in 1770. That the site of Weymouth was known to the Romans is probable from several circumstances; and Mr. Baxter supposes it to have been the Clavunio, which is mentioned in the anonymous Ravennas. In the Saxon ages, however, it is expressly named in a Saxon charter still extant, by which king Ethelred gave a certain portion of land, called by the inhabitants Weymouth (or Wick), near the site of Portland, to his faithful minister Atleare. In the reign of Edward III. the town had become of some importance, the inhabitants being ordered, together with those of Melcombe and Lyme, to send a certain quota of ships for the king’s expedition to Gascony. In the 21st year of that reign, Weymouth (for Melcombe is not mentioned, though perhaps included) furnished the king with 20 ships, and 264 mariners, at the siege of Calais, according to the roll of his fleet preserved in a manuscript in the Cottonian Library. In the year 1471, Margaret of Anjou, with her son, prince Edward, landed here from France, in order to restore her husband to the throne. In 1507, king Philip of Castile, with his queen, were driven on this coast, and having run into the port, were detained by sir Thomas Trenchard, till an interview took place between the English and Spanish monarchs, from which the former derived some advantages. In 1588, Weymouth contributed six ships to oppose the Armada, one of which was of 120 tons burthen. During the civil war of Charles I., this town was alternately garrisoned and besieged by the king, and by the parliament’s forces. In 1649 the corporation petitioned parliament for an indemnification for the losses they had sustained in the war, and a relief from the burthen of maintaining the garrison; but their request does not appear to have been granted, as a letter was soon afterwards received containing the “refractoriness of the magistrates.” The manors of Portland and Wike, with the ports of Waimouth and Melcombe, and the liberties attached to them, were granted by charter of Henry I. to the monks of St. Swithun, Winton; and Henry II. confirmed the port of Waimouth and the whole land of Melcombe to that establishment, with additional privileges. Weymouth and Melcombe are (as has been observed under Melcombe Regis) too frequently joined in defecits and ancient grants, that some difficulty occurs in separating them with precision. Weymouth is the more ancient borough; though neither sent members to parlia-

ment till the reign of Edward II., since which time each of them returned two. Melcombe, being part of the demeine of the crown, and possessing some peculiar privileges, is principally noticed in succeeding charters. The rivalry which subsisted for centuries between the two boroughs arose, in the reign of Elizabeth, to such a height, that it was judged expedient to unite them; and an act was passed in her 13th year (afterwards confirmed by James I.), by which they were incorporated, and directed hereafter to be called “The united Town and Borough of Weymouth and Melcombe Regis,” the government being vested in a mayor, recorder, two bailiffs, an indefinite number of aldermen, and twenty-four capital burgesses; and they now poll, as one borough, the peculiar right, with the metropolis, of electing four members to parliament. The representatives are elected by the freeholders of Weymouth or Melcombe, whether inhabitants or otherwise. The number of voters is about two hundred. These electors have also votes for the county members. Leland says, “The toment of Weymouth lyeth far from Milton (Melcombe) on the other side of the haven, and at this place the water of the haven is but a small brede, and the trougus is by a bote or a rope bent over the haven; so that in the ferry-bote they use no oars. Waigmouth has certain liberties and privileges, but there is no mair in it. Thar is a kay and wharf for hipples. By this town on a hill is a chapel of ease. The paroch church is a mill off.” The chapel mentioned by Leland was remarkable for its elevated situation; having, according to Coker’s survey of this county, an ascent of eighty stone steps. It was of considerable antiquity, as appears by a patent of Henry VI., granting a licence to found a guild in the chapel of St. Nicholas, in the borough of Weymouth, by the name of the master and wardens of the fraternity or guild of St. George, in Weymouth. This chapel was demolished in the civil war; the site is still called Chapel Hays, and is now used as a bowling-green. Weymouth, since the time of Elizabeth, had, from a variety of causes, been gradually going to decay. The removal of the wool-rotaple to Poole, the loss of the Newfoundland trade, the havoc made by the civil wars, damages by fire, want of public spirit, and other circumstances, had conduced to produce this effect; and till it began to acquire celebrity as a watering place, it was little more than an unconsiderable fishing-town. The late Ralph Allen, Esq. of Bath, about the year 1763, first contributed to bring Weymouth into repute. Having received great benefit from bathing there, he proclaimed its salubrity to the extensive circle of his acquaintance; and his encomium being exceeded by the real beauties of the situation, it soon began to be the resort of the first company from all parts of the kingdom. The reputation thus acquired was extended by the late duke of Gloucester, who, having derived considerable advantage himself, provided a residence for the accommodation of the royal family; and their majesties, accompanied by the three elder princes, in the year 1789, made their first visit to this place. His majesty experienced its beneficial effects, and became so attached to the spot, that he has repeatedly honoured it with his presence. The advantages arising from these visits have proved of the greatest consequence to the town, which has rapidly augmented in size and importance, from the vast concourse of people by which it is now frequented. The chief objects of curiosity to strangers, are the Esplanade and the Bay. The Esplanade, a fine level piece of land, which, but a short time ago, was nothing but a receptacle for all the rubbish of the town, is now converted into one of the most charming promenades in England, and adorned by a range of handsome edifices. This
WHALE, in Astronomy, one of the constellations. See CETUS.

WHALE, Cetus, in the Linnaean system of Zoology, the seventh in the class of mammals. For the characters and distribution of this order, see CETUS.

For the discriminating characters of the genus balana, or whale, and a general account of its species, see BALANA.

The common whale, or balana mysticetus of Linnaeus, with its variations, &c., is described under the article MYSTICETUS. Aristotle is said to have given it the name of mysticetus, poroicus, or bearded whale, from its having in its mouth hairs instead of teeth.

In old time the whale seems never to have been taken on our coasts, but when it was accidentally flung on shore: it was then deemed a royal fish; and the king and queen divided the spoil; the king affixing his right to the head, and the queen to the tail. The reason of this whimsical division, as ascribed by our ancient records, was to furnish the queen's wardrobe with whale-bone.

The anatomy of the bones of the whale has been so little understood, that there have been many very great errors in regard to such of them as have been at times found fossil, or buried in the earth among the teeth of elephants, and the remains of tetracous and other animals. The most frequent and most ridiculous of all the wrong opinions about these, is their having originally belonged to creatures of the human species; yet many, even among the more intelligent part of the world, have taken them for the remains of giants. The vertebræ of a whale have been mistaken for those of a giant, and a part of its fins for a hand, and fo of the rest. While the world, more ready to spread the marvelous, than to enquire into the truth, have made computations of the height of the man to whom bones of that size must have belonged, and from their proportion in regard to those of the common human size, have found the giant who possessed them must have been 90 or 100 feet high; much less pains in comparative anatomy would have taught them, that they never could have belonged to any human body at all. Mem. Acad. Par. 1727.

WHALE, Beaked, Bottle-head, or Noble-haul, Balana Reftrata, the small whale, with taper finout, and adiopoe back fin, or with very long and acute beak or finout. The head, upper part of the back, fins, and tail, are of a dark or blueish-brown; and the sides and abdomen are of a beautiful white, with a flight tinge of pale rofe or fleth colour; and marked for more than half the length of the animal by numerous longitudinal plaits or furrows: the eyes are small, as is also the head, and the finout is more elongated than in any other species, tapering gradually to the extremity, which is slightly pointed; the back fin is small, and situated at no great distance from the tail; the pectoral fins are small and narrow, and the tail is divided into two long and pointed lobes. This is of a more elegant form than that of the larger species. These fish sometimes, but rarely, grow to the length of twenty-five feet; they make little noise in blowing, are very tame, come very near the ships, and will accompany them a great way.

WHALE, Fin-back, Balana Phyalus of Linnaeus, called also fin-fish. See PHYSALUS.

WHALE, Pike-headed, Balana Boops of Linnaeus, is a species which takes its name from the shape of its nose, which is narrower and sharper-pointed than that of other whales. The length of one taken on the coast of Scotland, observed by Sir Robert Sibbald, was forty-six feet, and its greatest circumference twenty; but it sometimes exceeds this length. From the skinny flap at the root of the tongue, as well as from
from the intellines, the Greenlanders prepare windows. See Boops.

**Whale, Round-lipped, or Broad-nosed, or Under-jawed, Balena Musculus of Linnaeus**, is characterized by having the lower lip broader than the upper, and of a semicircular form. See Musculus.

**Whale, Bunchef, Balena Gibbosa of Linnaeus, with one or more gibbous excrescences on the back, and without dorsal fins:** the knoefelfich oder knobbelfich of Anderfon and Crantz. This species is a native of the Northern seas, and though not much known, is said to be of the same general form with the great whale, but of smaller size, and having its back furnished with one or more tubercles. The variety with a single tubercle is found about the coasts of New England; the other with fix tubercles along the back is supposed to swarm about the coasts of Greenland. Their whale-bone is said to be of a pale or whitlil colour.

**Whale Spermaceti.** See Cachalot, Physeter, and Spermaceti.

**Whale-Blubber, in Agriculture,** the fat oily refuse matter left in making the oil from that fish. It is a material which has been used as a manure in some cafes with succes, especially when employed in mixture with clayey loam, sandy loam, or any other common earthy or mouldy substanences. These matters should be blended together in such a manner, it is said by the writer of the "Elements of Agricultural Chemistry," as to expose a large surface to the action of the air, the oxygen of which produces soluble matter from them. It is observed, too, that lord Somerville made use of this oily substanence with great successe on his farm, in the county of Surrey, in which cafe it was made into a large heap with foil, and retained its powers of fertilizing for several successive years.

It is noticed, that carbon and hydrogen abounding so much in this as well as other oily substanences, fully account for their effects; and that their durability is easily explained from the very gradual manner in which they change by the action of the air and water on them, as must obviously be the case.

This fatty material, in this sort of union with earthy matters, may confequently be a very benefical application in many cafes of tillage-land, especially where the superfical bed of mould or foil is rather of the thin kind. It may also be very useful as a top-dressing to grasfs-land, particularly where the fward is thin, tender, and not well fet with grassy herbage, as tending not only to promote the growth of the crops, but the clofemens and firmnes of the surface fwardy covering. See Manure, and Oil Compofit.

It should therefore be prefered and procured as much as poiffible for thefe uses and applications.

**Whale-Bone**, a commodity procured from the whiskers of the whale, used as a stiffening in flays, fans, bulks, fereens, &c. See Whale Spermaceti. Frederick Martens particularly described the whale-bone and the method of procuring it in his "Voyage to Spitsbergen." Within the mouth of the fish is the whale-bone, hairy as a horfe's hair, and hanging down from both fides, all about his tongue. In some whales the whale-bone is bent like a fcymitar, and in others like a half-moon. The smallest whale-bone is before in his mouth, and behind towards his throat; and the middeft is the largest and the longest, being sometimes about two or three men's length. On one side, all in a row, there are 250 pieces of whale-bone, and as many on the other, containing in all 500; and there are still many more, for the cutters let the leaft of all remain, because they cannot easily come at it to cut it out, on account of the meeting of the two lips, where the space is very narrow. The whale-bone is in a flat row, one piece by the other, somewhat bending within, and towards the lips every where like a half-moon. It is broad at the top, where it flicks flat to the upper lip, every where overgrown with hard white finews towards the root, so that between two pieces of whale-bone you may put your hand. These white finews are of an agreeable smell, break very easily, and may be boiled and eaten. Where the whale-bone is the broadeft, as underneath by the root, there growth small whale-bone, the other being greater. The small whale-bone, as Mr. Martens supposes, does not grow bigger; for one end to the other it is equally thick, and full of logs, like horfe's hair. The whale-bone is underneath narrow and pointed, and all overgrown with hair, that it may not hurt that which is young; but without the whale-bone has a cavity, for it is turned like a gutter, in which the water runs, where it lies the one over the other, like the shields or plates of cray-fish, or the pantiles of an houfe, that lie one over the other; for otherwife it might easily wound or hurt the under lip. To cut the whale-bone out is a particular operation, and many iron tools are used for this purpose. Some whale-bone is of a brown, black, or yellow colour, with streaks of several colours. The whale-bones of some whales are blue and light-blue, which latter are fuppofed to come from young whales.

**Whale-Fins,** a name improperly given to whale-bone.

**Whale-Fijbery.** See Fishery.

**Whale-Oil.** See Oil.

Mr. Parkes (Effays, vol. i.) observes, that the dealer in Greenland whale-oil might allo increase the profits of his trade very much, by preparing his oil for sale when the weather is fuitable for the operation. This kind of oil is always purified by paffing it through large flannel bags, which retain the impurities, and suffer the finer parts to percolate through them. When the oil has undergone this treatment, it is called bagged oil, and is then deemed fit for sale. At a low temperature, a coniderable quantity even of this latter kind would concrete, and might be separated by simular means; whereas in a warm atmosphere this diffolves, and, being left inflammable, very much injures the oil for burning.

By proper attention to this circumstance, all the oil which is designed for burning might be very much improved, and the portion thus separated from it, would be worth more to the loaf manufacturer for making yellow loaf, than simular oil which had not undergone this process.

This intelligent chemist conceives, that an oil-merchant would do well always to bag different oils in different feasons; though many experiments might be neccessary before it could be ascertained what was the exact temperature at which the respective kinds would melt copiously depoit this feculence. After obseving that in feveral parts of Germany, and particularly in the neighbourhood of Gottenburgh, ammonia is prepared from the dregs which remain after the expreffion of train-oil, he fuggesfs that whale-blubber might be employed for the diffillation of ammonia. Madder, he fays, might be defived for correcting its offensive smell, and render-

Whale Point, the south-east cape of an island in the straits of Magellan; 6 miles S.S.W. of Paffage Point.

Whale Rock, an under-water rock at the entrance of the Bay of Islands, on which the Endeavour struck in 1769; 4 miles S.E. of Point Pocock.

Whale Sound, a channel in the straits of Magellan, between an island and the coast of Terra del Fuego.

Whalifirth Voe, a bay on the west coast of the island of Yell. N. lat. 60° 58'. W. long. 1° 25'.

Whame, in Natural History, the name given by the people of some parts of England to the barrel-fly, or wringle-tail, a species of bee-fly very troublesome to hones.

Whang-Ho, in Geography. See Hoang-Ho.

Whaplole, a township of Lincolnshire; 2 miles S. of Holbeach.

Whapping's Creek. See Wapping's Creek.

Wharf, a perpendicular building of wood or stone, raised on the shore of a road or harbour, for the convenience of landing or discharging a vessel, by means of cranes, tackles, capstans, &c. See Artificial Ports.

The fee paid for the landing of goods on a wharf, or for shipping them off, is called subarbage. And the person who has the oversight or direction of the wharf, receives wharfage, &c. is called the wharfinger.

There are two legal denominations of wharfs, viz. legal quays and suffereance wharfs.

Legal quays are certain wharfs in all sea-ports, at which all goods are required, by the 1 Eliz. c. 11., to be landed and shipped (except at Hull); and they were set out for that purpose by commissio by the court of exchequer, in the reign of Charles II., and subsequent princes. Others have been legalized by act of parliament; as the London docks, by 39 & 40 Geo. III. c. 47.; West India docks, by 39 & 40 Geo. III. c. 69. and 42 Geo. III. c. 113.; East India docks, by 43 Geo. III. c. 126. and 46 Geo. III. c. 113. (See Docks.) Hull, by 14 Geo. III. c. 56. and 11 Geo. III. c. 197.; Milford, by 50 Geo. III. c. 155.; Bristol, by 48 Geo. III. c. 71.

In some ports, certain wharfs are deemed to be legal quays by immemorial practice, though not set out by commission, or legalized by act of parliament; such as Chepflow, Gloucester, &c.

Suffereance wharfs are places where certain goods may be landed and shipped; such as hemp, flax, raff, and other bulky goods; likewise goods carried coakwise, in Great Britain, by special suffereance granted by the crown for that purpose.

The constituting limits to the ports and legal quays is part of the royal prerogative. Lord Hale's Treatise. Vide Harbrace's Traicts.

Wharf also, in a canal, denotes that wider part of it where boats lie while loading or unloading.

Wharfage, in Commerce, certain rates paid for landing and shipping goods from the quays.

Wharfe, or Wharf, in Geography, a river of England, in the county of York, which runs into the Oule, 7 miles below York.

Wharfinger, the proprietor or farmer of the quays where goods are shipped and landed.

Vol. XXXVIII.

By the 26 Geo. III. c. 40. no goods entitled to drawback or bounty on exportation are to be shipped in Great Britain, but by wharffers licensed by the commissioners of the customs, and in docked lighters. And they are to give bonds not to be concerned in illegally landing, relanding, or shipping goods. They are also liable to certain penalties at contriving or knowing of any fraudulent transfaftion, or landing goods at improper places and times, by 1 Eliz. c. 11., and 13 & 14 Cha. II. c. 11.

Wharton, Henry, in Biography, an English divine of the Established Church, was born in 1664, at Worsfold, in Norfolk, where his father was vicar; and in his sixteenth year admitted a pensioner of Gonville and Caius college at Cambridge, where he assiduously pursued the study of various branches of literature, and particularly of mathematics, under Ifac Newton, Lucasian professor. After taking the degree of B.A. with great reputation, he assisted Dr. Cave in his "History Literaria," contributing almost the whole of the appendix of the three last centuries. In 1689 he took orders, and his degree of M.A. in the following year. He had various literary occupations, chiefly in writing or editing treatises against Popy; until he left priest's orders, when he was presented first to the vicarage of Minter in the isle of Thanet, and in 1689 to the rectory of Chantham. By the advice of Dr. Lloyd, bishop of St. Asaph, he undertook the work which gave some celebrity to his name, intitled "Anglia Sacra, five Collectio Historiarum, partim antiquus, partim recentior. Scriptarum, de Archiepiscopis et Episcopis Anglie a prima Fide Christiana fucceptione ad Annus 1540," 2 vols. fol. London, 1691. An additional part was published after his death in 1695, under the title of "Hisoria de Episcopis et Decanis Londinensibus; neunon de Episcopis et Decanis Alavesibus (St. Asaph); a prima Sedis ururinque Fundatione ad Annus 1540," 8vo. The author's "Anglia Sacra" was the refult of great industriy and labour, and evinces the author's zeal for the church to which he belonged; but it is chargeable with incorrectnec.

In 1692 he published "A Defence of Pluralities;" in the following year he edited some ancient theological pieces; and, under the name of Anthony Harmer, published "A Specimen of some Errors and Defects in the History of the Reformation of the Church of England, by Gilbert Burnet, D.D.;" a work which excited the indignation of the author, and caused him to mention Wharton with afperity in the introduction to the third volume of that work. The last publication of Wharton was "The History of the Troubles and Trial of Archbishop Land;" to which were added Land's diary, and some other pieces. He also edited the Life of Cardinal Pole, by Bacatelli, together with some animadversions on Strype's Memorials of Archbishop Cranmer. Although his constitution was strong, he closed his life, in consequence of intense application, some time prematurely, in March 1694-5, in the 31st year of his age, leaving several MSS., some of which were afterwards printed, as also two volumes of sermons. He was interred in Westminster-Abbey. Biog. Brit.

Wharton, Philip, Duke of, the son of the marquis of Wharton, who was a firm supporter of the Revolution and Hanover succession, was born in 1699; and after having exhibited talents which commanded notice, when he was 13 or 14 years of age, in the course of his education under domestic tutors, contracted a premature marriage with the daughter of major-general Holmes, and thus disappointed his father's views, and hastened his death in 1715.

In the beginning of 1716, Philip set out on his travels, proposing to finish his education at Geneva; but the young marquis, having contracted a taste for gaiety and experence, was
was disguised with the manners of that place, and leaving his governor there, proceeded to Lyons, and wrote to the Pretender at Avignon, accompanying his letter with the present of a fine horse. The Pretender was highly gratified, and receiving the marquis at his court, decorated him with the title of the duke of Northumberland. At Paris he paid his respects to the dowager-queen of James II., and received notice and good advice from the English ambassador, lord Stair. About the end of 1716 he returned to England, and going over to Ireland, where he pollied to a peerage, he was admitted to take his seat in the house of lords of that kingdom. Here, defying the principles and connection which he had lately formed, he defended the established government with all the powers of his reasoning and eloquence; in consequence of which he was advanced to a dukedom, by the style of duke of Wharton, in the county of Westmoreland. Upon coming to age, he took his seat in the English house of lords, where he distinguished himself by an abandonment of his lately avowed principles, in the defence of bishop Atterbury; and he also published a virulent opposition paper, intitled "The True Briton." But such was his boundless extravagance, that his estate was vested, by a decree of chancery, in the hands of trustees, who allowed him an annuity of £200. Having only this pittance, he determined to live abroad, and to enter into the service of the Pretender. Having visited Vienna and Madrid, he formed an acquaintance at the latter place with a young lady of Irish extraction, who was maid of honour to the queen of Spain, and married her; his duchess having died in 1726, without leaving any issue. From Rome, where he appeared under the title of the duke of Northumberland, and decorated with a blue ribbon and garter, he returned to Spain, and obtained permission from the king to go as a volunteer to Gibraltar, which was then under siege by the Spaniards. When this siege broke up, he visited the Spanish court, and was nominated by the king "colonel-aggregate" of one of the Irish regiments. Discouraged in his wishes to be actively employed in the service of the Pretender, he went to Paris, and with singular effrontery paid a public visit to the English ambassador, Horace Walpole; informing him, upon taking leave, that he was going to dine with the bishop of Rochester, though it had been made criminal to hold any communication with that exiled person. At this time a bill of indictment for high treason was preferred against him in England, for having appeared in arms against his majesty's forces at Gibraltar; but a wish to reclaim him induced Sir Robert Walpole to lend two friends to offer him his re-establishment and the possession of his estate, if he would only sue for pardon. This he refused to do, contenting only to accept a pardon if freely granted him. His allowance from Rome was discontinued, and he was overwhelmed with debts abroad. From Rouen, where he had for some time resided, he removed to Paris, living meanly, and providing for himself by various dishonourable expedients. Having obtained a small sum, when all his resources had failed, he took his duchess with him, and went by water to Bilboa. From thence he proceeded to join his regiment, subjecting his duchess to extreme distress, in which state she was occasionally relieved by the bounty of the duke of Ormonde, who was himself an exile. In 1730 his health declined, and he amused himself in composing a tragedy, on the story of Mary queen of Scots; but his end was approaching. In his way to a mineral spring, in the mountains of Catalonia, where he had once obtained relief, he was obliged to stop at a small village, when his condition was so pitiable to ultimate, that the fathers of a Bernardine convent took compassion upon him, and brought him to their house, where by atten-}

Was tolerating with the manners of that place, and leaving his governor there, proceeded to Lyons, and wrote to the Pretender at Avignon, accompanying his letter with the present of a fine horse. The Pretender was highly gratified, and receiving the marquis at his court, decorated him with the title of the duke of Northumberland. At Paris he paid his respects to the dowager-queen of James II., and received notice and good advice from the English ambassador, lord Stair. About the end of 1716 he returned to England, and going over to Ireland, where he pollied to a peerage, he was admitted to take his seat in the house of lords of that kingdom. Here, defying the principles and connection which he had lately formed, he defended the established government with all the powers of his reasoning and eloquence; in consequence of which he was advanced to a dukedom, by the style of duke of Wharton, in the county of Westmoreland. Upon coming to age, he took his seat in the English house of lords, where he distinguished himself by an abandonment of his lately avowed principles, in the defence of bishop Atterbury; and he also published a virulent opposition paper, intitled "The True Briton." In 1730 his health declined, and he amused himself in composing a tragedy, on the story of Mary queen of Scots; but his end was approaching. In his way to a mineral spring, in the mountains of Catalonia, where he had once obtained relief, he was obliged to stop at a small village, when his condition was so pitiable to ultimate, that the fathers of a Bernardine convent took compassion upon him, and brought him to their house, where by atten-
perfectly resembled grains of wheat, and which on being sown in a garden very unexpectedly proved to be wheat of the spring kind, and the usual size, the grains of which being nearly, if not wholly, as large as those of the ordinary wheat of the above fort, that the packet and seeds came either from the peninsula, or from the hilly country, far within land from Bengal, as that province itself is a flat alluvial tract of land, entirely level. That as this hill wheat is, however, no doubt, it is supposed, known to some persons who are now either in India, or who have lately returned from thence into this country, it is certainly a matter of some importance to know what information they can give on the subject of it, especially whether this wheat be a cultivated, or a wild plant; as we shall, it is said, if the latter be the case, ascertain two of the greatest desiderata of cultivators; as those of the country where wheat grows spontaneously, and the nature of the grain in its original state, when unassisted by the sowing hand of man.

It is by no means improbable, from the nature and habits of wheat, that it may have come originally from the hilly country of the east, and been rendered hardy by time and cultivation in this and most other parts of the world.

Wheat is a kind of grain of which there are two different species, in cultivation as crops, in the climate of this country; as the common smooth or polished wheat, and the cone rough or bearded wheat. Of the first of these forms, which is by much the most cultivated in this kingdom, as being the most suited to the nature and quality of the largest part of the soils or lands in it, and as affording the finest kind of flour, there are numerous varieties that are differently preferred in different situations; and the latter species, which is often termed rye wheat, and which has also several varieties that differ little except in the colour of the chaff and the form of the ears, though it does not afford the finest sort of flour, as yielding the largest quantity of produce on loam moist clay lands, and as being less subject to injury and disease from wetness on such soils, as well as leas liable to lodge from its firmness of item, is frequently cultivated and grown on such sorts of land.

It has been observed by an able and intelligent cultivator in the county of Kent, Mr. Boys, that the number of sorts of this grain is annually increasing by importation from foreign countries. But that the old sorts are the brown and yellow lammas, the white flraw, Fulham, and the white or egg-shell. That the brown lammas was the kind chiefly cultivated in that county till within these twenty or thirty years; but that it has now given way to a variety of new kinds, as well as some of the other old sorts: experiment has, however, fhewn it to be the least productive of the several sorts. It is the common brown-flawed wheat that grows with a long jointed ear, the chaff of a dark brown colour, the flour very white, and the corn mellow in grinding, for which reason it is esteemed by the millers as the best of the old sorts for their use; and that the yellow lammas resembles the brown, in every respect, except that the colour of the grain is of a yellow hue, and the chaff of a somewhat lighter colour than the others. A red lammas with a red flraw, red ear, and red kernel, is noticed by Young as being reckoned by many farmers the best of all the sorts hitherto known, as yielding the finest and whitest flour. The first of these writers states, that the white-flawed wheat takes its name from the colour of its ear, and in other counties has the title of the Kentish white flraw. That it sends out a greater number of items from the stook or plant than the other sorts, and in that way is often a very thick crop on the land. That the flraw is generally somewhat shorter than that of many other sorts, and not quite so liable to fall in rainy seasons. That it is on these accounts much found in the eastern parts of that county; but that from its dull colour, its having a thick bran, and often grinding very feely, it is not much approved by the millers of the district. It is remarked, that the Fulham sort produces a white flour, which grows short and coarse; but that it is very productive, particularly on poor land: the grain is however coarse, and the bran thick, which circumstances render it the least valuable to the millers of any of the sorts described above. And that the white or egg-shell wheat is known by its producing a white flour, a smooth white chaff, and very white grain: the bran of which is very thick, but the flour remarkably white. It works mellow in grinding, is very early ripe, and so free in the ear as to blow out in windy weather, which is a disadvantage.

It is noticed, that of the new sorts of wheat in that county, as the hoary white, the nonpareil, the pilbeam, the square ear, the hoary brown, and the hoary white, called by some the velvet-ear'd, the last is by far the most valuable, as being very productive, and the best for the miller's use. It has the flraw white and short, the chaff covered with a thick fine down, somewhat of a brownish hue; the grain remarkably small, and of a dull white colour, the bran very thin, so that the grain in some cafes is almost transparent when held up to the light. It grinds very mellow, and makes a beautiful fine white flour. But from the quantity of the down upon the chaff, and its small ears binding up very close in the flhead, it is apt in a rainy season to vegetate too freely in the field; on which account it is not so proper to cultivate in a moist climate, and in small incloures that are not open to the influence of the sun and winds. That the nonpareil is a sort for the wanton bed to have been brought into this country from America: it has a bright flraw, with a brown ear; and the grain is very white, large, and plump. It is very productive on all sorts, thrashes very free, and yields in that operation the greater part of its chaff; thereby producing a great quantity of horfe-meat. It grinds very mellow, and is well esteemed by the millers in most districts. And that the pilbeam is a brown wheat growing very stif, and is generally thick on the land. The grain is small and plump, somewhat of a yellow-brown. It is accounted very productive on rich lands, and is a valuable kind to mix with others, but will not of itself make good bread, from its not fermenting or working properly in that operation. In regard to the square-ear'd wheat, that it is a very productive sort, but is apt to drop out in the field, before it is ripe, and in gales of wind, on which account it is not so much cultivated. And that the hoary brown is but lately introduced, confentually little known at present. And the hoary white fort, which has a white flraw, ear, and grain, is in much the same situation. That the Clarke-white, which has a red blossom, chaff, and flraw, but white grain, is much cultivated in Suffolk. That the hedge white is also white and very productive. And that the velvet white is distinct from the hoary white, is but white, not weighty, yet affording much flour, being very thin in the skin.

There are also different varieties of cone or bearded wheat, a sort which is named from the form of the ear, as has been seen above. That of the rye flraw, there are two sorts, the white and the brown, neither of which are much cultivated in Kent. They both ripen late in the season, and are fo coarse and feely, as to be unfit for making bread, unless mixed with a large proportion of a better sort of flour. They, however, produce very abundant crops on strong wet lands, as has been noticed. It is remarked, too, by Mr. Young, to be a productive sort on very poor, wet, cold
cold land, though a coarse grain, selling at an inferior price in the markets. And the bearded or rivet kind of wheat is likewise thought, by some cultivators, to be the most adapted to such kinds of rich lands as have been newly broken up, and where there may be danger of the crop lodging from too great luxuriance, as it posses the property of a greater firmness of straw or stem than the common kinds, as suggested above.

The white and the red are the sorts most esteemed in general among the polled kind; the former affording the whitest flour, but the latter has the greater produce in malt casks.

It is observed, that of the several sorts of wheat that are in cultivation in the county of Suff, the velvet-eared is preferred in the weald part of it, as having by much the thinnest skin: they there call it fluffed. It weighs on the average from fifty-nine to sixty pounds the bushel. It is said by the best judges that the white stuff on good land answers best, as being the most valuable: but that on poor land, subject to poppies, the strong-strawed sort that overpowers this weed shou'd certainly be sown.

There is a sort of wheat that obtains much on the Down parts, which is what they call Clark wheat. It is not bearded; has a red blossum, red chaff, and red straw; white grain, as already seen; the sample coarse, being in price under the finest sorts. It is, however, a great yielder, and requires to be cut forward.

The Chidham white or hedge wheat is much in cultivation, being introduced by Mr. Woods of this district. Upon trial, it is found to be a very fine sort: it is white, of a very fine berry, and remarkably long in the straw. It is now much grown in many of the southern as well as northern counties.

In the county of Essex, according to the Corrected Report on the Agriculture of that district, Mr. Kemp of Hedingham compared wheat from Italy, from Scotland, and from Danzig; the last by far the best, and next the Scotch; but the Italian was full of flint in spite of every attention in brining and liming; and sowing it a second time with still more precaution, the result was the same.

About Burnham, some cultivate a sort of wheat from Italy, which they approve of much; the straw is remarkably stilt and stiff. They cultivate also a sort called the Saffodite; red grain, red chaff, and purple straw; this is a very good sort. The Taunton Dean, too, is beautiful, but will not bear rough weather. For two years past the Hamburgh white, with white grain, and white chaff, has been a fashionable sort; the white American wheat is also used.

The sorts most usually sown about Kelvedon are the burrel red chalk, and red grain; and the white rough; white chalk, and white grain, the chalk rough; this straw stands the weather well, and does not shell easily: but is rather difficult to thrash. About Langenhoe they generally sow wheat on heavy land, and rarely rivets, rough chalk. York white, also American red. Some other of the above sorts are like-wise in use.

It is remarked that a few years ago, as a person at Bradfield was walking through his wheat-fields when the corn was in full blossum, he was struck with the variety of hues, or colours, which the blossoms assumed: at first he conceived it might be owing to the different shades of forwardness in the blossum; but on particular examination and more mature reflection concluded that they were certain signs of a specific difference in the quality of the wheat; impressed with this idea, he selected the ears of different hues, and particularly marked eleven distinct numbers; noting very minutely their characteristic qualities and appearances in the field. Thefe he gathered and kept separate when ripe, and planted them apart from each other in his garden: the same characteristic difference was observed to continue upon the several numbers when growing in the garden as was observed in the field the preceding summer, and are as below.

First year in the garden culture.—No. 1. A stiff straw, thick ear, the rows or chefts in which set closer than in any other.
2. Dark straw, full blade, and large open ear.
3. A large long ear, ripened late, and well set.
4. Full foliage, and a long open ear.
5. Straight handsome straw, large well-set ears, flag or leaf small.
6. Red rusty leaf before spindling, red straw with little leaf at harvest and smaller ears than any.
7. Very like No. 6. in straw, the ears small, but well set.
8. Straw leafy at harvest, of a good colour, well eared and handsome.
9. 10. Straw full of flag or leaf at harvest, ears well open.
11. Very like No. 5.
Second year in the garden culture.—No. 1. Short upright stuff straw, thick well-set ears, and later by four or five days than any of the others.
2. Very dark straw, upon which there remained a full dark blade at harvest; long open ears.
3. Strong leafy straw, of a good colour, with a thick long ear, well set, rather later than Nos. 5, 8, and 11.
4. Thick leafy brown straw, with a small ear.
5, 8, 11. Short handsome bright leafy straw; ears long, thick and well set.
6. Long straw with a good deal of flag, ears ill set and open.
7. Straw handsome, but small ears, and subject to root-falling.
9, 10. Long weak straw, very leafy, and subject to root-falling.

It is observed on these, that the lemon-coloured blossum was observed to attend Nos. 5, 8, and 11; but the colour of Nos. 1 and 3, was not particularly remembered. These are the numbers which had been preferred, Nos. 5, 8, and 11, coming to the sickle about a week earlier than Nos. 1 and 3; the produce of which, when compared with the rejected numbers, is an excess of from six to eight bushels per acre, and weighing about three pounds more to the bushel.

At Bradwell, it is observed, a crop of Windsor wheat was had, white grain, white straw, and white chaff, which was a most beautiful sample; the strength of the straw middling.

That of all the different sorts of wheat Mr. Hardy has tried on his farm, the best has been the white egg-shell, and this is the sort most cultivated in Foulness island.

That the red American is a sort which yields remarkably well with some; it is much approved in Mersea isle. Some have had the best success with it. But Mr. Strutt, at Terling, sowed a barrel of remarkably beautiful wheat from New York, in part of a field, the rest of which was sown with English wheat, and the American was so bright and cheerful in the ears as to produce a poor and miserable grain both in quality and quantity. He sowed it again, and the result was the same, and repeated the experiment the third time, the result again the same, though the adjoining English wheat in all the three years produced a fair crop free from all blight. The habit of this wheat, therefore, was not, it is said, changed in three years sowing.

That the rough chalk, a white chalk and white grain, with a velvet
a velvet ear; is found about Burnham to be an excellent
fort; for there they are subject to strong easterly winds, and
it does not shell easily. But fome, however, do not like it
on heavy land, as it has not straw enough; and think that
it should stand till ripe, or it will not thrive well.

And about Hallingburg Rife, and indeed through all the
district of the Roddings, they find the rivet fort a very use-
ful wheat, which is very general, and is found to yield on
that heavy foil much better crops than any common fort;
but on lighter foils the Kentish red.

In Norfolk about Reddlefworth they have an opinion
that red wheat will not anfer on black land, white succeed-
ing to much better advantage. But at Winborough red is
only fown by Mr. Salter, the white forts not anfering fo
well on the heavy foils: it is termed the old red. Some pre-
fer the red chalk, or red wheat to the white, as being les
liable to grow at harveft; white however is a better fample,
and produces a better price.

In Hertfordshire the rivet or bearded fort is the common
fort on the clays and strong loams about Sawbridgworth,
on which it yields more abundantly than the red and white
wheats, four or five quarters per acre not being uncommon
in favourable years. And a fort termed "polled rivets" is also
very productive, one hundred grains having been feen in an
car.

About St. Alban's, Day's stout, which has the ears grow-
ing with four fets of kernels, is much fown; also about
Hitchen, where it was discoered by a poor labourer who
gathered a few ears. It is faid to yield well. It is sup-
pofed to be the pinks of Ellis. The red lamas and Lujefull,
brung from Cambrieghire, are likewise much fown. On
the Albury clays the rivets are grown, yielding largely, but
subject to mildew, and felling badly with indifferent fraw.
They have a blue and white fort; the latter is preferred.

In moft other counties, the fame forts of wheat are like-
wise cultivated and grown with fome other varieties.

In addition to thefe, there is, however, another species or
fort of this grain, which is now much cultivated in fome
cafes, as that which is known by the name of spring-wheat.
This is a fort of wheat that is capable of being put into the
ground at the fame time with other grain crops, in the early
spring months. The cultivation of it has been long prac-
ticed, in fome degree, in both the northern and southern
parts of the ifland; but of late a much greater attention has
been bellowed upon it, and at preftent it is raised and grown
to considerable extent in different districts and places, as in
the fens of Lincolnshire and Cambrieghire, in many parts
of Oxfordshire, in fome iflands in Berkshire, in Hertford-
shire, where it is found to anfer well, and in moft of the
other fouthern counties, as well as in many parts of the
north of England, and even in the lower parts of Scot-
lend, with the greatest fuccefs, where the bottom in the land
is somewhat inclined to be firm and clofe.

In regard to the spring fort of this grain, it would feem
to be capable of being cultivated on the ftrong and heavy,
as well as on the lighter forts of land; but that it is the
most calculated for the latter, where the vegetation and
growth are rapid, particularly fuch fenny lands as have a firm
surfet-earthly bottom. In thefe it fives in a very quick manner,
and they are not by any means well suited for the winter forts
of wheat from their lightnefs, rendering them liable to be
thrown out in that feaon.

Preparation of the Land.—Wheat is a crop that is usually
grown after the land has been prepared by repeated plough-
ning and harrowing or fummer fallowing; but which is often
capable of being raised after different kinds of green crops,
as well as those of the root and other forts with equal or
more advantage. In fome cafes, falk and hemp also afford
a good preparation for this grain; but fome consider beans as
the most favourable preparation: and experiment has fhewn
tares, and clover, to be nearly equal to them in this inten-
tion. In the county of Norfolk, wheat almoft conftantly
succeeds clover, except where pea or bean crops are in-
pofed, the land being fearecly ever fallowed with this view,
except in the infances of what are termed "afflard unmer
ills." It has indeed been well obferved, that if there is one
practice in husbandry proved by modern improvement to be
worfe than another, it is that of fowing wheat on fallows;
it is therefore only flated on this point, that in fome counties
the fallows are ploughed juft before harveft on to two-fout
ridges ready to plough and fow under the furrow in the
fparing method, a feelfman to every plough which reveral
the ridges. In others they lay their lands into ten or twelve
furrow-fitches or ridges, and sowe fome under the furrow,
some under the harrow. That the ridges vary exceedingly,
according to their wetnens; and that in Kent they have by
means of the turn-wrel plough, no lands at all, but a whole
field, one even surface. It would be ufeles to expatiate on the
circumstances of fallow-wheat which ought no where to
be found. If fallows be or are thought necessary, let
them be fown for barley or oats, or with any thing but
wheat. However, in whatever manner or after whatever
crop this fort of grain may be cultivated, the foil
should conftantly undergo that fort of preparation that may
be fufficient, according to the particular circumstances of
the land, to bring it into a flate of coniderable finenesf
mould, efpecially in the more superfical parts, and thereby
prevent as much as pofible the rifing of weeds: for it has
been wef noticed by a late writer, that whoever has attended
to the progres of this fort of crop, in fuch lands as have
been well broken down and reduced, and in fuch as have
been left in a lumpy crude flate at the time of fowing, will
have found the difference to be very coniderable. But it
may be noticed, that when this kind of crop is taken after
clover, the land seldom undergoes more than one ploughing,
which is moftly given immediately before the feed is fown.
However, as the graify matter, in many cafes where this mode
is adopted, is extremly apt to rise and injure the crops in
the more early fages of their growth, it may be better to
follow the practice adopted in some districts of using a skim-
cultered plough, as by this contrivance the remains of the
clover weeds, and graify material on the furface, may be cut
or skimmed off, and turned into the bottom of the furrows,
where they are immediately covered with the leafe mould
from below to such a depth, that little or no inconvenience
can be fubfained by them, while the land is thus rendered
more clean, and capable of being harrowed in a more per-
fect manner than where the common plough only is em-
ployed.
ployed. Besides, perhaps, a better bed of mould is turned up in this way for the feed to vegetate in, provided the furrow is not made of too great a depth and breadth, and remain some time before it is sown; which should constantly be attended to by the agriculturist in preparing this sort of ground for wheat-crops. But it is the custom of some counties, as of Norfolk and Warwick, where the land is often continued for nearly two years in a state of clover, to break them up in the latter end of June; in the second, giving two, and sometimes three ploughings. Where the situation is favourable and the weather turns out suitable for reducing the soil to a proper state of tilth, this may be an advantageous practice, as by such means great benefit may be obtained by cutting the grafts in the beginning of the season, in which it is to be ploughed up; but where circumstances of so favourable a nature do not occur, such a method of preparation must be less beneficial than that of giving only one ploughing. In the preparation of a clover ley for wheat, Mr. Duckett has noticed a singular experiment and practice. He had a field in which wheat rarely escaped being greatly root-fallen; not to lose sowing it with that grain, and at the same time to guard against the experienced malady, he sown it repeatedly, till he had torn up the clover, and also produced tilth enough for drilling it in; then he collected the clover fragments, and carted them into the farm-yard to make dung, and drilled the field; the wheat having a firm bottom in an untilled soil, escaped the disease, and yielded an ample produce. The clover bulbs, which would have secured the dreaded loofenets of foil, had it been turned down, made a large quantity of dung, and therefore was not left to the farm, though the particular field was deprived of it. And it has been stated on the authority of a cultivator of much experience, that in cafes where the clover-crops have been such as to leave the land in a foul condition in respect to weeds, it would be highly improper to sow them with this sort of grain, as from its remaining for such a great length of time upon the ground they may be liable to have their feeds perfectly evolved, and brought into a state of vegetation. In such cafes, it has been suggested as more advantageous to have recourse to such sort of crops as may require the operation of hoeing during the time they are upon the ground. The putting in of wheat after pea-crops, is a practice that may probably be purified with the most propriety and success in those districts that are, from the nature of their situation, sufficiently early to admit of the land being fully cleaned and prepared by repeated ploughings and harrowings, after such crops have been removed, before the proper time of sowing such grain. But where they are so late as to allow of the land being prepared by one ploughing before the period of sowing, it is supposed by some to be an extremely hazardous practice to attempt the culture of wheat after such crops; as unless the ground be in a high state of tilth, there is little chance of a good crop being produced. This is the opinion of the writer of the work on modern agriculture; but the Norfolk farmers are in the constant habit of setting or sowing in wheat upon a pea-flubble with a single ploughing, and confide in it a very safe and excellent husbandry. The pea-crop ought, however, to have been kept clean; and after it is harvested, the haum harrowed off. They never plough a bean-flubble there more than once. In some counties, it is the constant practice to cultivate beans and wheat alternately on the same land for some time. This is the case on the flarger kinds of soil in the county of Kent, on which it is found to answer in a very advantageous manner; and where wheat is only occasionally sown after such crops, it is often found an useful practice; but in all such cafes the beans should be cultivated in drills at from twenty to thirty inches distance, in order that they may admit of being hand and horse loosed in the most perfect manner. If this method has been followed, and the business of hoeing during the growth of the crops effectually performed, the land may be sufficiently prepared for the succeeding wheat-crops by one ploughing, as the soil from being thus kept clean, and in high tilth, can scarcely fail of affording a good produce. It has been remarked, that where the farmer has a bean-flubble intended to be sown with wheat, he should give it the due tillage as early as possible, which should be regulated by the soil, as on some it may be better to trust the skim scuffleers and scariers than the plough. That where the land is very clean, the great skim of the isle of Thanet is capable of cutting through every thing, and loosening the surface sufficiently to enable the harrows to render it as fine as possible, being picked and burned by women. Where not so clean, the Kentish broodthur may be more effective. In other cafes, the scuffle may be sufficient for the purposes. It is noticed that in this cafe, where the farmer has got the surface to his mind, he is to consider whether or not he should plough it, which is advisable if the soil be of a firm, solid tenacious quality, and if he does not intend to drill the wheat: if he should plough such a soil he may not have any apprehension of root-fallen wheat, that is, failing roots, from a loose bottom; but he will bring up a new surface that may drill with difficulty, whereas that which has received the influences of the crop, atmosphere, and of his late operations, will be in exactly the right temper for the drill to work in. If the soil is of a more loose friable quality, and he should plough down the fine surface he has gained, he will give the wheat too loose a bottom, and he will run the chance of a root-fallen crop. In all such cafes, or in any that have a tendency to this circumstance, he should determine not to plough at all, but drill directly; a method in which he faves tillage, and has the probability of a better produce.

This is rather a new practice on strong land, but such successes have been seen in it as leaves no reason for doubting the soundness of its principles. It was done by Mr. Duckett on a sandy soil for years, and with great effect. It should be remembered, that whatever other circumstances may influence the growth of this grain, it loves a firm bottom to root in, and rarely flourishes to advantage where it is loose and crumbly; nor will a depth of such mould do, if the under stratum, in which it will attempt to fix its roots, be from its quality of a repellant nature. The best basis is the cultivable soil, firm from not having been lately disturbed. These observations, as being quite practical, are certainly deserving of the farmer's attention. Where the district is early, and the land is preferred in good order by proper modes of cropping, wheat may be grown after beans, whether cultivated in the drill or broad-cast system, with successes, as there may be sufficient time to give the necessary preparation before the time of sowing, which cannot be done where they are late, and there is only time for one ploughing. But in other situations it is found advantageous when this crop is to be grown after either peas, beans, or tares, to plough the land in as light or shallow a manner as possible; and then harrow and take out the roots and weeds, so that they may be consumed on the ground in heaps; the field being after this formed into proper ridges for the reception of the feed by ploughing again a few inches deeper than the first. And in some cafes, it is even harrowed after the second ploughing, and ploughed a third time for the putting in of the grain.

Wheat, too, may sometimes be cultivated after turnip-crops to advantage on the heavier turnip-soils, particularly
WHEAT.

where they have been kept clean from weeds by repeated hoeings, and fed off upon the land at such early periods as to admit of the ground being prepared by once ploughing, in a light manner. In cases where this kind of crop is intended to be cultivated after potatoes, which, from their having a great tendency to lighten the soil as well as to exhaust it, should never be done on the lighter sorts of land in backward situations, or under any circumstances where a sufficient proportion of manure has not been applied for the potato-crops, one light ploughing immediately before the feed may be in most cases an adequate preparation; and where proper attention has been bestowed in the culture of such crops, the soil is generally left in a sufficiently fine condition for the purpose. It has been remarked, that the cause of wheat not succeeding well after potato-crops, in many instances, is, that besides the land being rendered too light and porous by the growth and cultigation that are requisite for them, the wheat is more exposed to the injurious attacks of the grub, earth-worm, and other insects; and in some exposed situations, from the seed-time being too long protracted, the practice becomes obviously improper. In growing the crop after those of hemp and flax, as weeds are apt to thrive, it is always proper that the soil should be ploughed over two or three times, in order that a fine flate of tilth may be produced. The custom of giving but one earth after such sorts of crops, can seldom or ever ensure full returns of this grain. It has been remarked in "Practical Agriculture," on the best authority, that experience has shown, in the most clear and satisfactory manner, that this sort of crop should never, when it can be avoided, be grown after other kinds of grain-crops, as rye, barley, or oats; and that the manure should not be applied to it, but for such crops as may precede it. That where the contrary is practised, the crop is not only liable to be injured by the rampant growth of weeds, but from its being more apt to be diseased.

On the whole, it may be observed, that whatever the nature or state of the ground may be, or the kinds of crops that precede this sort of grain, it would appear that the preparation for it should always be such as has a tendency to reduce the parts of the soil to a pretty fine flate, as under such circumstances the growth of the crops is not only more regular and perfect, but from the even and compact flate in which the surface is left, it is more fit for affording support and protection to the roots of the wheat-plants, as allowing them to spread and extend themselves with greater readiness in the fine mouldy earth thus provided, as well as by its falling down more closely about them. It has, however, been contended by some cultivators, that a rough cloudy flate of the surface-part of the land is the most proper situation for it of the reception of this kind of crop, as the young wheat-plants are thereby better guarded and secured against the effects of the severe cold that often takes place in the winter season. It is probable, however, that cold is seldom hurtful, in any great degree, to winter wheats, except when accompanied with too much moisture, or where sudden frosts and thaws have the effect of rendering the surface parts of the soil too light and open, as to be incapable of affording proper support to the roots of the young wheat-plants.

In Berkshire they prepare the land for wheat chiefly in three different ways, as by summer fallowing, and manuring with yard-dung, compost, rags, foot, and chalk in some cases; by folding on it with sheep in cases where the ground is not of too deep and wet a nature; and by putting it in on the back of clover-leys, after one or two crops of grass by one or more ploughings.

It is thought by some, however, that manuring for beans or other crops is a much better practice when followed by wheat, than the old custom of fallowing and manuring for this crop, which renders the land too light, and consequently subject to blight.

The farmers in Oxfordshire prepare for wheat by different numbers of ploughings, as the circumstances of the land may be; but the layers are mostly ploughed in a shallow manner, as wheat loves a firm bottom to root in, and which, in sandy land, cannot be too tight. Too loose a bottom is apt to cause a root-fallen crop.

An equally careful preparation of the soil is necessary for the spring crop of this grain, though fewer ploughings will often be sufficient.

Time of Sowings.—In regard to the proper period of sowing this sort of crop, it may, the author of Modern Husbandry observes, be useful to remark, that the earlier the autumnal sowings can be put into the soil, the greater chance the young plants will have of being well established before the frosts take place, which has been seen to be a circumstance on which the welfare of the crop in a great measure depends. Besides, the state of the land and that of the season are much more proper for the processes of vegetation, when the crop is put in at an early period, than when it is delayed till a late one; the state of the weather in the latter case often admitting of only a very languid and imperfect growth till the spring, by which the crop must be exposed to much danger from various causes. Indeed experience has abundantly shewn that late sown wheats seldom succeeds so well, or afford such plentiful crops as those that are put in early. But when sown too early there may notwithstanding be danger of the crop running too much to straw, and consequently of the grain proving light in the ear. From the beginning of September to the middle, or even the end of October, may probably be considered as the most favourable period for this business. This is indeed confirmed by the established practice of the most correct farmers in almost every district of the kingdom where this sort of grain is grown. If sown earlier, especially on the heavy kinds of soils, the land is for the most part in too hard and lumpy a flate to allow of the seed being properly covered by the harrow; and in the lighter ones in too dry a condition for the grain to vegetate in a proper manner; and when delayed later, the ground in one case is apt to become too wet and close by the falling of the autumnal rains, and in the other too loose and porous from the action of the frost upon it. It is remarked by the writer just mentioned, that more than four-fifths of the whole of this sort of grain is sown between the middle of the first and the end of the last of the above months. Mr. Young thinks September the best season for cold backward wet soils, and October for those of the more dry and warm kinds, after which there has been a plentiful rain. There are, however, circumstances, it is farther observed, on the authority of the Synopsis of Husbandry, that may render the times of sowing different from the above; as where the soils are of the rich fertile, loamy, chalky, or gravelly kinds, it may be better to defer it in many instances to a considerably later period; and when such warm sorts of land are cropped too early, they are apt, it is said, to push the plants forward in such a rapid manner, that they become weak and spindling in the early spring months, and at the same time the crops are more liable to be infested with weeds, on account of the season being more favourable to their growth. But that the practice of putting in crops of this sort so late as the latter end of November and beginning of December, frequently depends on the crops that precede them not being capable, from the lateness
of the situation, or other causes, of being taken off so early as that the land may be made for the wheat-crop in the proper time. This is often the case after peas, beans, tares, turnips, and other similar crops. In these cases, on the lighter sorts of soils, and where dress culture is employed, it may often be an advisable practice to sow in the spring, as by such a delay the ground may be brought into a more perfect state of preparation than could be the case in sowing it so late in the winter.

It is indeed remarked in the Corrected Report on Agriculture for Middlesex, that those persons who sow wheat in autumn lose the great advantage of a previous crop of turnips, both as to depleting the weeds and manuring the land; and that they cannot induce the labour of either hoeing, harrow, or otherwise tampering with the weeds and young wheat in the following spring. That a wet seed-time sometimes renders it impossible for the farmer of a clayey soil to sow his usual quantity of wheat in autumn; this should not induce him to sow his grain when the land is too wet for the occasion, but rather let him wait till the first favourable opportunity in the months of February or March, by which time frost will have rendered the land mellow, and then he should sow the residue of his wheat; as the probability is great that wheat sown on a mellow soil, in a dry February, will be more productive than if it had been sown on the same land, in an adhesive state, during a wet November.

That autumnal-sown wheat precludes cultivation for one entire year, which, apart from all other circumstances, gives great encouragement to the growth of weeds; but that in order to appreciate the great mischief done by sowing wheat in that season, its connection with the usual course of crops must be taken into consideration. For instance, first, in the ancient, and still very common course of fallow, wheat, oats, there is seldom any ploughing from the sowing of the wheat until the sowing of the oats, which is one year and a half; secondly, in the course of wheat, clover, spring corn, or pulse, there are two years together in which the plough cannot possibly be put into the ground; thirdly, in the valuable course of turnips, barley, clover, and wheat, the plough is shut out of the ground for two years and a half. That these three courses include most of the arable land in Britain, and they demonstrate the prodigious encouragement which such courses give to the growth of weeds. On the contrary, wheat sown in the spring occupies the ground only half a year; and that when that is placed in a succession with winter tares and turnips every two years, the weeds have not time to grow in such a manner as to do any material injury. There is no period in such a course of more than six months in summer, or eight in the winter, free from the operation of the plough. This degree of tillage keeps the land free of weeds, and, in that manner, prepares it from being exhausted by them; and, by giving the green and root crops to sheep and other cattle, on the land, it becomes doubly manured every other year, which cannot fail to force the growth of the wheat as though it were growing in a hot-bed.

It certainly is not in every possible case advisable to refrain from sowing wheat in the autumn, in order to sow it in the spring. A dry seed-time is of so much importance to the occupiers of adhesive and fenny soils, that they should not let any such time pass without sowing their grain. In the case of a dry autumn, which is the same thing as a fine seed-time, the farmers should sow all such land as is then ready, and thereby ensure the important points of a good seed-bed for their grain, and against the danger of a wet spring. On the other hand, the more rain that falls in autumn, the better chance there is of having a dry spring; and consequently in every wet autumn the wheat-sowing should be postponed until the spring. The proof of the success of one instance of this kind may enable farmers to judge what is capable of being effected, even in an unfavourable situation, by patience in wet seafons, and exertion in such as are dry. A large wheat-farmer, near Haddingston, in Scotland, owing to a wet autumn, delayed fowing his wheat until after the 19th day of February, between that time and the middle of March, feeding one hundred and forty-five acres with wheat, principally the Effex white and Egyptian red. The harvest in this case was about ten days later than usual, and the crop yielded from twenty-four to forty Winchmiller bushels on the acre, which weighed nearly sixty-two pounds each. On examination, the wheat was found a first-rate sample.

Such a successful case of raising fine wheat from the seed sown in the spring may afford reason for putting it in at that season in many cases. Such a practice has never been known to fail, by the writer, when performed early, and on land in good heart. The advantages of the practice are said to be many, and very considerable.

When the sowing is to be done later than the above periods in the spring, the true summer wheat is always to be used.

The exact periods at which this sowing of grain may be put into the ground in different cases with the greatest chance of success, under different circumstances of soil and climate, have not hitherto, however, so far as we know, been fully ascertained and shown by any correct trials; but the above periods of autumn sowing are in very common use by the best farmers.

In the counties of Effex, Suffix, Hertford, Oxford, and many others, most of the best farmers are in favour of early sowing; but more to the east it is done somewhat later. In Berkshire they sow their light lands early, and those that are rich at a later period.

The spring sowing of wheat may be sown from about the middle of March to the end of the following month, in most parts towards the south; but most probably the sooner it is put in after that period of the above month, as the state of the seaso will permit, the better it will be in the crop or produce.

Seed.—In respect to the proportion of feed that is necessary in different cases, it must depend upon and be regulated by a variety of different circumstances, but in general from two to three bushels, according to the state of the soil, the nature of the climate, and the period in which it is put into the ground, may be the most suitable proportion for soils of a medium state of fertility, under the broad-cast method of husbandry; but where the drill system of culture is practised, a considerable less quantity may be sufficient for the purpose. In the drilling and dibbling methods of sowing, however, which are unquestionably the best where they are performed with correctness, six pecks of seed are sufficient; in the latter method two rows being put in on a flag, care being taken to have the land rolled after having been ploughed a fortnight or more, and the seed dibbled in to a sufficient depth, without scattering, covering it in by harrowing.

Where the lands have a known disposition to mildew, a larger proportion of feed should be given, whatever the time or season in which it is put in may be. Much less feed is also necessary in early than late sowings. It is remarked that on the rich soils of Gloucestershire, the quantity generally sown is about seven pecks, while in Yorkshire it is from eight to twelve. Where the lands are in a suitable state of tillage for receiving crops of this grain, ten pecks have been advised by a practical writer as the medium proportion; but
WHEAT.

but much larger quantities are frequently sown in the northern parts of the kingdom. It is obvious, however, that where such large proportions of feed are made use of, the plants must be liable to be drawn up too much, and the crops in consequence to become weak and imperfection fed, as well as smaller in the size of the ears. There may be also disadvantages from making use of too small proportions of feed, from the ground not being properly covered with plants; but where care is taken in the after-culture of the crops, less danger is probably to be apprehended from this than the other extreme; as a great number of plants will be supplied by the lattering or shooting out of new items from the joints about the surface, in consequence of the mould being laid up against them.

In Hertfordshire, in the broad-call method, from two to three bushels are usually sown. But in the county of Norfolk they sow broad-call, from two to two and a half bushels; and in the drilling and dibbling methods, from five to six or seven pecks.

In Essex they sow broad-call about two and a half bushels; and in the drilling and dibbling modes, from seven to ten or more pecks.

In Suffolk they sow a large quantity of feed, some four bushels on ley land, and three upon tillage; others three and a half; but when this crop succeeds peas, only three, if it be early, but if late, more. The medium quantity is about three.

In Berkshire commonly from two and a half to three in the broad-call sowings of this crop.

And in Oxfordshire from two to two and a half, and sometimes three.

In the sowing of the spring fowling of this grain, the quantity made use of is various. Some, for a full crop, sow fourteen pecks to the acre, but with grases-feeds only nine. Eight pecks have produced an abundant crop in some cases, on the same portion of land. Others advise two bushels to the acre; and say that the earlier it is sown the better seed will be required. Sometimes three bushels are sown upon the acre. However, from two and a half to three bushels on the acre may be considered as the most proper quantity. In the dibbling method, four pecks and a half have been found sufficient for an acre and a half.

The broad-call practice of putting this sort of crop into the ground is the most common on the heavier kinds of wheat-lands, as those of the clayey and loamy faw, the feed being harrowed well in by a rather light harrow. But in the lighter faw of wheat-lands, the drilling method is often practised when they are clean, and sufficiently mellow and mouldy on the surface. Sometimes, too, the feed is put in partly by the plough, and partly by the harrow. In some districts it is ploughed in on the fawls, and harrowed in on clover. The clover-leys are also occasionally ploughed in some cases, and have the feed scattered in, and folded upon by sheep. See Sowing, Seed, &c. Also Under-Furrow Sowing.

Some farmers prefer a stale furrow for fowing wheat upon, while others are in favour of the contrary practice. A stale furrow is probably, however, the best in many cases. See Stale-Furrow.

Preparing feed-wheat for fowing is practised in many cases and places in different modes and manners. See Pickling, Steeping, &c. Also Wheat-Seed, Liming of.

The depth of putting the feed in should not probably be more from one to two or three inches.

In some parts of Oxfordshire the last is the usual depth, and the farmers are generally friendly to depositing the feed to a shallow depth.

It is also the practice with many farmers in these different districts to change their feed-wheat frequently.

In the county of Suffex, an intelligent and spirited farmer has found by long and attentive experience that a change of feed-wheat is of essential importance to the cultivator, that feed which has been repeatedly sown over the same ground at length degenerates, and the produce each succeeding year becomes inferior in quality; on which account, wheat that is apt to run to flour is sown on ley-land, and the Hertfordshire white fow upon rice.

In other districts the practice is thought by the best farmers to be always proper; and that the feed-wheat should be brought from a colder soil or land than that on which it is to be sown. See Change of Seed, and Seed.

As soon as the feed has been put into the land, it should constantly be laid as dry as possible by the construction of proper drains and water-furrows, so as in all seasons to keep the water from flagrantly upon it. See Water-Furrowing.

It has been lately suggested as a beneficial practice to have the feed-wheat well trodden in at the time of fowing it by sheep, or fill heavier rocks, on heavy as well as light soils; as by this means the young plants are prevented from dying away in the winter, from the land lying too light and hollow. But more facts are wanting to establish the utility of this method of practice in different cases. See Treading Wheat in, and Plough.

Although under the present practice and management in the cultivation of wheat, the autumn or winter fowling must always necessarily occupy a large extent of the heavier kinds of wheat-lands in this country, and be raised in the manner that has been directed above; yet in a number of cases the true spring fowling is found favorable, grown, and had recourse to with great advantage, success, and profit. But in all such climates, the real summer fowling must always be employed, for though the winter kind may be put into the ground with advantage in many cases to late as after the middle of February, as has been seen above, it is better to have this real fowling last year, as it poises many properties highly necessary for the purpose. By some it has been supposed that it would interfere with winter wheat, and that it may be difficult to find proper courses for introducing it in. However, this sort of wheat should principally be cultivated and grown on soils or lands, and in climates which are not well suited for winter wheat, or in cases where that sort is particularly liable to mildew. But though it may not be suited for universal application, it is most likely to succeed in the lighter, the sandy, and the saltier sorts of soils, where the winter wheat is apt to be thrown out of the earth by frothy seafons. In such cases the courses might be turcks, or rape, according to the nature of the land, spring wheat, clover, and oats, or some such rotations, as in such, if after the clover or other grasses, the land be paroled for one year, the oat crops will be certain, and abundantly productive.

The preparation in some cases might be the rendering the land fine and clean by one or more ploughings and proper harrowing, and in others by ploughing and burning, and fowing cole and other seeds and crops, for being fed off by sheep, or in some other such ways.

In this manner large crops have been raised in many different instances, as thirty Winchester bushels, or more, on the acre, which were ripe and ready at the same time with the other spring-fowling grain. It is a wheat which is said to yield...
yield as much flour in any given quantity as other wheats, and which does not appear to be subject to any disease, nor to have any disadvantages attending the cultivation of it. It does not require more manure than barley or beans, nor does it exhaust the land more. Itanswers extremely well for laying down with clover, in which case the clover-feed should be fown and harrowed in with the last harrowing for the wheat, and the usual quantity of grass-feeds sown. It is to be preferred to all other sorts of corn for raising crops of grass-feeds; owing to the small quantity of leaf which it bears, and which is of short duration, as it fades and falls down almost as soon as it has attained its full size; more air is thus admitted to promote the growth of the clover, or other grasses; and the admixture of more air may also contribute to prevent the mildew with which this sort of wheat is so rarely affected.

There is a further advantage flattered to arise in the cultivation of this sort of wheat in some cases, which is, that on various soils, and in some situations, it often happens that the autumnal-fown crop of wheat may be fown to fall and to go off in patches, from the injury of the wire-worms, or other causes. Consequently, that in the beginning of April, by raking spring wheat into the vacant places, as also where the wheat-plants may appear weak and thin, the uniformity of the crop may be restored, and the spring wheat be ready for the sickle quite as early as the autumnal fown. And that, although such a mixed crop would render its produce highly improper for feed; the miller's use it would afford no objection.

The remarks that are given below are the result of much experience and practice in the cultivation of this sort of wheat. It is found that crops of this kind are ready to cut quite as early as the autumnal-fown wheat in similar soils and situations. That it is highly probable that the succcass of this sort of wheat on clover ley may be found to depend more on the coming feason than autumnal-fown wheat; as if the following feason should prove dry, the crop would be more hazardous in the former than in the latter. In a dry summer it would seem that this wheat would have a better chance upon land that has been longer upon tillage than upon clover ley. That turnip and rape fallows, where the soil is not too light, seem highly proper for spring wheat. That pea and bean fallows may also in many instances prove eligible for spring wheat; and especially after having been ploughed early in the autumn, and benefited by the winter's rains and frosts. That when the spring wheat is sown in, the last light harrowing, clover-feeds, &c. may be fown, the ground will most likely be well set, and the seeds proper equal to any in other cases. That in the application of top-dressings for this sort of wheat, it may seem, that in a long-continued dry feason, the most eligible way would be by applying them at the same time when the wheat is fown. Only once lightly harrowing after may suffice. But that, in a moist and continued rainy season, top-dressing would probably prove to act more powerfully by being sown upon the surface of the soil; because top-dressings are most particularly calculated to invigorate the coronal roots of the wheat-plants, and thereby to cause them to tiller well. And that, when top-dressings are sown on the surface of the soil, the best time of applying them, it may seem, would be when the wheat is grown to the height of three or four inches; because if laid on before the blades of the corn-crop afford a kind of shelter, the finer particles thereof are liable either to be exhaled by the sun, or blown away by high winds, which frequently occur at such seasons. Moist and showery weather, at that critical period, will always be found of the highest importance; therefore, the farmer would do well by having due attention to the state of the weather when employed on this business. And that, as a crop of this sort of wheat is so much more valuable than any other kind of spring-fown corn, there are good grounds for supposing that top-dressings cannot any other way be more beneficially employed.

Trials with this sort of wheat in other unfavourable cases of poor wet cold land likewise shew that this sort of grain may be had recourse to with considerable success in different cases. That five quarters per acre have been had on rich good land in perfect cultivation of excellent wheat of this kind, when put into the foil so late as the 4th of May. It is evident, that this sort of wheat has a rapid growth, being equally forward at harvest with the autumn-fown crops. That on the whole it seems probable, from the successes that has attended this kind of culture in the fenn, in the southern and the more northern districts of the kingdom, that it may be advantageously introduced in many different situations and circumstances of arable land.

We have already considered the history, nature, qualities, and many other properties and circumstances in relation to this sort of grain. See SPRING-WHEAT.

Culture noble growing.—In the culture of wheat after it has been put into the soil, there may be some difference, according as it has been fown, according to the preparation of the land, or other circumstances. But in all cases it should be kept perfectly clean and free from weeds, either by the hoe or hand hoe, as weeds not only injure the crop in its growth, but lessen the value of its sample when brought to the market. And besides, the stirring of the mould on the surface amongst the plants may frequently be useful in other ways, in addition to that of preventing the growth of weed-seeds; for as in the heavy kinds of soils that are moist adapted to this grain, the more superficial parts are liable to become foul and baked as not to be easily penetrated by the new-formed or coronal roots of the plants in the early spring months, especially when they are very dry, and have been preceded by much wet; loofening of the earth, by any means whatever, mull of course be of great utility. This effect is generally shewn to have taken place by the appearance and progres of the crop, which becomes of an unhealthy yellow colour, and advances but little in its growth. In such cases it has been suggested that harrowing once or oftener in a place may be of much service in the early spring months. Where the crops are thin, and of feeble growth, this operation may produce beneficial effects, by affording a sort of earthing up to the weak plants, and thereby promote a more vigorous growth, at the same time that a number of new shoots are sent off from the joints thus covered, and the crop in consequence rendered more full and abundant; and where the grain is too thick upon the ground, it may also be of utility by drawing out and destroying many of the plants. It has likewise been suspected by Dr. Darwin, that many of the root-fibres, by being torn in the operation, may prevent the over luxuriance of the stem and leaves, and by that means promote the more early fructification of the grain.

It has been observed by a late writer, that the practice of fcarifying the young drilled whet-crops should constantly be performed in an effectual manner, and not later than March; but that some have not supposed it to be so very beneficial, from not performing it at the proper time. Mr. Cook has, it is said, contrived two implements for this use, a fixed harrow and scarifier; the former executing its work merely by common tines or teeth, having three rows, which,
by varying its position diagonally, one, two, or three of
them may be brought to act in the space of nine inches,
without injury to the rows of wheat-plants. If two, they
may, it is said, be drawn in a breadth of three inches; if
three, in a space of four inches, and these spaces widened
at pleasure, but still so as to keep quite clear of the rows of
wheat; and that by loading the harrow, the teeth are
forced to a proper depth. Further, that the earlifer has
teeth of various breadths; but for working at this seaso,
between nine and twelve-inch rows, the narrowest are to be
preferred. By the action of these tools the surface mould
is, it is remarked, loofened, and the air admitted, being
performed to the depth of two inches with safety, and
without mould being raised so as to cover or bury the
plants, the earth being only loofened, and not displaced.
By these contrivances much work can be accomplished in
a very short time. This procés is also useful against the
attacks of the worms. They horfe and hand hoe their
wheat-crops repeatedly in Eiflex, and with great advantage,
though very expensive.

But the drilled and dibbled crops, where this method is
not employed, particularly in the latter mode, where only
one row is placed on a flag, must be hand-hoed in the inter-
vals, which should be done the first time in the begining of
the above month, and a second time towards the end of
it, or a little later. Some likewise do it to the broad-cast
wheats, but this has been supponed injurious by many.
The bushels of thilling the wheat-crops should also be
carefully performed in May, or in the very early part of
the following month, in all cafes where it may be necelfary.
The practice of rolling should also be employed without
either having recourse to the harrow, or after it has been
ufed, being highly benefical where the surface is cloddy,
and the operation is executed when the ground possesses
a medium degree of moiture, as well by forcing the roots of
the wheat into the earth, as by cauing the new items to
rise. And in thin light foils, when this fort of grain is
cultivated upon them, much benefit may also be produced in
this way, by the roots of the plants being prevented from
being fo eafily loofened and thrown out of the ground.
And the fame practice is recommended as generally ufeful
by fome where clover or gafes-feeds are fown with wheats-
crops, as a means of rendering the vegetation more fecure
and perfed.

In Berkshire, wheat-crops by the belt farmers are hoed
every where, and sometimes hand-weeded, the former on
frong foils often twice.

By good cultivators in some parts of Oxfordshire, too,
all the wheat-crops are hand-hoed in February or March,
and weeded afterwards.

And in Suffex, the practice most commonly adopted is
to hand-hoe wheat in the spring, sometimes only once, but
frequently twice, as the nature of the preceding crop may
have been. By fome, however, hand-hoeing wheat is dif-
approved of; they never hoe white corn, having given it
up, from a conviction that the crops were never benefited by
the practice; but, on the contrary, that mischief was
always done by it. On which, it is obferved, that fhould
the practice fometimes be right, and fometimes wrong; or
right on fome foils, and wrong on others, thofe contrary
facts may probably depend on the fpring roots, which
are faid to strike into the air, and enter the ground at
fome fmall distance from the item. If a hand-hoeing be
given juft before the appearance of thofe roots, it may, on
a bounden surface, prepare for their easy entrance; but
if given afterwards, it is probable the effeét would be mis-
chievous, would retard the progresfs of the plant, and force
it to do its work over again, perhaps at a worse feaIon. If
this be the cafe, the benefit which results from hitting
the time exactly, may by no means equal the probability of
mifchief upon a fcale of any extent; in which the right
time can fcarcely be taken for the whole of a crop. It has
been heard declared, too, by excellent farmers, that if a
perfon would pay for the hoeing of their wheat, they would
not permit the operation, being convinced that it does more
harm than good.

It has also been recommended, in fuch cafes where the
land is not in a fufficient flate of fertility or preparation to
bring the crops to perfection, to make use of top-dreflings.
Sublubes of both the solid and fluid kinds have been made
ufe of for this pofpose; the firft fectified of the dungs of
differt forts of birds, after being brought into a powdery flate, bone-dift, foot, peat-ashes, and various
faltine matters. The latter are principally the drainings of
dung-hills, and other fimilar liquid materials. The former
should be thinly fown over the crops with as much evennes
as po feasible, as early in the fpring as horfes can be admitted
upon the land without injury; and if it can be done when
the weather is inclined to be moif, it is the better; a roller
may then be paffed over the crop with advantage. Where
the latter sublubes are made ufe of, care should always be
taken that the plants be not injured by having too large a
quantity applied to them. In this practice, the expence
should be a primary confideration, and fmall trials firft made
where dungs are not to be ufed. The proper feaon for
performing the bufines is the beginning of February. See
Manure, and Top-Drefling.

It has been fuggested, too, that the method of transplan-
ting wheat may be had recourse to in particular cafes, with
beneficial confequences, as where there are fome parts of
fuch crops too thickly fet upon the ground, while others
are too thin, irregular, or patchy; as by thinning and set-
ing out the plants of fuch overabundant parts, among
thofe that are deficient, much service may be done to each of
them. The firft will be rendered more capable of admitt-
ing the operation of the hoe, and thereby of supplying
more abundant nourifhment for the luxuriant vegetation of
the plants, and the latter be supplied with the proper num-
er of plants, which could not be accomplished in any other
way. And it has been itated, that when raifed in the gar-
den, one acre would be capable of affording fets for an
hundred, when planted, after being properly divided at the
difance of nine inches from each other; and that as the
bufines of tranplanting is to be performed in the fpring,
it is fuppofed that crops of this grain may be raifed in this
manner on lands that poifefs a greater degree of moiture
than is fitted to the healthy growth of wheat in general.
Besides, clean crops may be produced in this way with
much greater certainty, as where the ground is ploughed
over juft before the plants are fet out, the grain may rife
much quicker from the plants than the weeds from their
seeds, and the crop in this way overpowcr fum noxious
plants. Advantages of other kinds have been itated by
different writers, as the refult of this mode of culting wheats-
crops. It is a practice, which, as well as that of Gribling,
has been had recourse to with fuccefs, both in Norfolk and
Eiflex.

The custom of feeding down wheat-crops, where too
forward or luxuriant in the early fpring months, by means
of fheep, is a practice that has been contended to be benefi-
cial in many cafes. The good effects, in fuch inftances,
according to Dr. Darwin, are fuppofed to arife from the
removal of the upright central item, by which means dif-
ferent new lateral items or root scions are fent off or
brought
brought forward with more vigour, by the acquisition of a larger proportion of nutritious matter from the joints in consequence, that much otherwise have been exhausted in supporting the central items. It is, however, a method which has been found by experience to be the most useful on such strong and fertile lands as are apt to produce a larger proportion of straw than can be properly supported. In which cases, advantage has been said to be derived by feeding off the blade at two or more successive times; but in effecting the business, great care is necessary to see that the whole is completed before the crop begins to spinle, otherwise more injury than good may be produced. And on the lighter and poorer descriptions of soils, the practice must be employed with great caution, as on such lands the growth of the crop may be so retarded, as to become weak and spinly. Besides, on those lands where they are very light, and the crop's thin, injury may frequently be done by many of the plants being pulled up, on account of the clovene of the bite of the sheep. They should, therefore, never be suffer'd to remain upon the crops when the weather is wet, and the surface of the ground much loosened, or after sudden frosts and thaws; as in such cases much harm may be done by the plants being pulled up and destroyed.

The treading of the animals may, however, be of great service in all the light sorts of wheat-land, and where the crops are thin; as by it the earth will not be preflled more closely upon the roots of the plants, but the fexms in many instances forced into the ground and covered up, that new shoots will be fent off laterally, and the crops be thus rendered more full on the land. But where the fexms are very stiff and adhesive, the growth of the crops may be checked and retarded by the practice, and of course the shoots thus caufed become weak, affording only small ears and light grain. Observations and experiments have convinced a writer in the Bath Papers, that wheat ought not to be fed down with sheep, unless it be very rank in January; and that such crops should only be fed as were fown early. And it has been suggested, that though this practice has much similarity to that employed in gardemng, of stopping the growth of the main fexms of fome sorts of plants, as those of the cucumber and melon kinds, by rubbing off or cutting away the central buds, in order to expedite their fruiting; yet in wheat-crops, where the principal items are eaten down, except when they are early, and of very luxuriant growth, the ears of the new shoots may not have time to perfect the feed, and of course become light and thrivell'd in the grain, and the new fexms from their weaknesses be more apt to fall down and be lodged. These are circumstances that have been frequently observed to occur by Mr. Tull, in the feeding down of wheat-crops by means of sheep. And that the fame philosophical obfERVER fupposes, that in the culture of wheat-crops, the most beneficial method is that of promoting, as much as possible, the time of bloflomming, while that of ripening is protracted, as it is for the farinaceous revoorv of nourishment, deposited in the cotyledon of the new seed, in order to support the growth of the corculum, or fresh embryo, that the plant is cultivated; which farinaceous deposition is effected in the interval between the bloflomming and ripening of the corn, either before the impregnation of the pericarp or seed-veffel, or afterwards; and the weight and plumpnefs of the rain are thus augmented.

The practice of feeding down young wheats by sheep may, therefore, be often hurtful, by retarding the period of bloflomming, as well as by restricting the growth of the items of the wheat-plants.

Sheep have likewise been employed on young wheat-crops in other views, as it has been remarked, that as the coronal parts of the roots of such crops are liable to be laid bare and expose'd for some inches in length about the surface of the earth, during severe frosty winters, the turning in sheep upon them in such circumstances when the ground is moist, and keeping them in motion, may tend to press them into the loose foil, and in that way produce new roots, as well as afford covering and protection to such as have been denuded. And, it is added, that some farmers who contend that much advantage is derived from it, turn sheep upon the crops where danger is apprehended from worms, fogs, and other insects; in order that by keeping them constantly in motion, such animals may either be wholly destroyed, or so fixed in the surface mould as to cause their more gradual death. There is a very great variety of these animals, which are suppos'd injurious to wheat as well as other crops; and for the destruction of which, lime, foot, and other faine matters, have been had recourse to with suppos'd advantage. See GRUB, SOOT, &c.

Wheat-crops are suppos'd to be much injured from different ferts of vegetable diseases, as the Blight, Blaff, Mildeuw, Snut, &c. See these different heads.

In the Ellif Report it is mention'd, that a disease which had not before been notice'd or heard of, was met with at Copdock in that district, which is call'd the purdey. The ears affected are perceive'd at once by their colour, a dirty brown mixed with green, as if part were ripe, with some chfts quite green; they feel nearly, but not quite, like blighted or abortive ears, which are brown, while the ears in general of the crop are of a bright red or white; when rubbed in the hand, as if to get the grain, no wheat is found, but apparently the small grains of a flattened indented globular form, and of a darkish purple, greenish or dark hue. It has not the smallest resemblance in appearance or fcent to smutty grains or bladders, and is certainly a distinct distemper. In many of these purpled ears are found some grains of good wheat. In order to discover if all the ears from the same root were affected on trial, in many instances they were found all similar from every root. It is very singular that no account that is recollect'd should have been given of such a strange malady, and so distinct from all others. Smutty ears were found in the same field, under all the common circumstances of that distemper. In Kent, it is faid, this distemper is call'd cockle-ear'd.

It has likewise been notice'd, that particular flutes of the weather have considerable influence on wheat-crops, at particular periods of their growth. As when the feaon is sufficiently dry, there is seldom much injury done to them during the winter months, however severe they may be in other respects, nor in throttle of the summer, provided the weather is not too moist about the time of bloflomming, as where that is the cafe the crops are moftly deficient in their produce.

And several sorts of weeds are injurious to wheat-crops, where they have been fown upon lands in an imperfect state of preparation, as charlock on the light calcareous foils; the corn poppy, on thole of the chalky kind, as well as cockle, oxalis-darling, puckweed, and couch; likewise roll's foot on the rather heavy kinds of lands. See these different heads, and Weed and Weeding.

This fort of crop is fhewn to be ripe and ready for the reaper by its fraw turning of a yellow colour, its ears beginning to bend in the neck and hang down, there being no greenens in the middle of them, and the grain becoming hard and plump. It is remarke'd, in the Ellif Report on Agricul-
Agriculture, that some do not like to cut wheat green, except it be the American white, which is brittle, and must be cut early, to prevent a lot of ears. It rarely lays. In Rochford hundred they do not cut till the wheat is ripe; but some few reap while it is yet green. It is, however, observed by a good farmer, that most rough chaff wheats, if they do not stand till fully ripe, will not thresh well.

It is flatted, too, in the Norfolk Report on Agriculture, that Mr. Parmenter, miller at Ayleham, a considerable farmer also, and a very intelligent man, remarked that the farmers let their wheat stand too long before cutting. They are apt to have a notion, that when millers give this opinion, it is speaking for their own interest; but he cuts his own wheat before it is ripe, and would do so on the largest scale, if he was not a miller. The quality is far superior, and the corn just as good. And Mr. M. Hill prefers cutting green, and never yet commenced harvest but he withheld he had begun three days sooner.

In the first of these Reports on Agriculture, a practice termed flagging is noticed as being for the first time met with. When the wheat-crops are very heavy, with broad luxuriant leaves, men with sickles move regularly through it, strike off many of them, for lightening the top, as a preservative against being beaten down by rain. It should be done carefully, or damage may ensue. See Reaping, Harvesting of Grain, Stacking, and Threshing.

Produce.—In respect to the quantity of wheat produced upon an acre, it must vary considerably, according to the circumstances of soil and preparation, as well as the state of the feaon; for it has been found that in some years the yield is under twenty, while in others it is upwards of thirty bushels the acre, the foil and culture being in every respect the same. And the average return of this crop throughout the whole of the kingdom, is probably not more than from three to three and a half quarters. And Mr. Donaldson has, indeed, flatted it at not more than three quarters the acre. The greatest crop of wheat, of which the author of the Report on Agriculture for Middlesex has any account, is, it is observed, sixty-eight bushels per acre; the least about twelve. The medium between these extremes is forty, which, it is conceived, would be the average of land highly cultivated. But the average produce of Britain does not, it is imagined, exceed one-half of this quantity, and yet, it is thought, that wheat is as certain a crop as any that is cultivated. It is observed, that the yield of several years varies the proportion which wheat bears to the flax in a very great degree, but that the average is about twelve bushels of wheat to each load of flax, weighing eleven hundred weight two quarters and eight pounds. It has been asserted, and probably with truth, that the flax of autumnal-fown wheat is more harsh, and less agreeable to cattle, than the flax of that which is fown in the spring. The weight of wheat by the bushel differs very much in different cases; but in most frowning land districts it is usually about sixty-two or three pounds to that quantity.

The yield of wheat is the greatest at the time of reaping, and becomes successively less and less the longer it is kept, so as ultimately, in many cases, to be a disadvantage to the farmer of not less than nearly one shilling in the bushel.

It may be noticed, that it is necessary, with the view of ascertaining the goodness of a sample of wheat, to determine by the eye whether the berry be perfectly fed or full, plump and bright, and whether there be any adulteration proceeding from sprouted grains, smut, or the seeds of weeds; and by the smell, whether there be any improper impregnation, and whether it has been too much heated in the mow or upon the kiln; and finally by the feel to decide if the grain be sufficiently dry, as when much loaded with moisture, it is improper for the use of the miller and baker. In cases where a sample handles coarse, rough, and does not slip readily in the hand, it may be concluded not to be in a condition either for grinding or laying up for keeping.

Wheat is usually sold by the farmers for being made into flour; and, in some cases, as feed-wheat for other districts, which is very advantageous, as the price in that way is mostly higher. The dealers, who convert it into flour, dispose of that to the different consumers, and the refuse part, as the pollard, to other persons for the food of horses, sheep, hogs, and other animals.

Wheat, Brining of; See Brining.

Wheat, Broyle, that sort of wheat-crop which is grown after oats, barley, or any other such kinds of grain, on light soils of the sandy and other similar sorts.

Broil-wheat crops are common in many of the more northern parts of this country, but the practice of putting wheat-crops in, in this way, is by no means to be much recommended, as they seldom answer any great purpose.

Wheat, Buck. See Buck-Wheat.

Wheat, Buck, in Botany. See Polygonum Fago-

Wheat, Cow, in Botany and Agriculture. See Mel-

Wheat, Cropping of; the practice of putting into the soil in fowing two different sorts of this grain of good qualities, in order to raise a new variety of a hill better kind. The practice of cropping in this manner has been found to answer perfectly, not only in this case, but in those of peas, apples, trees, &c. by Mr. Knight. In his trials, in years when almost the whole wheat-crops of the country were blighted, the varieties procured by croffing alone escaped, though raised on different sorts of land, and in very different situations and circumstances. See Seed, and Varieties.

Wheat, Fallow, that sort of complete naked fallow on which wheat is sown. See Fallow, and Fallowino.

Wheat, Grafs, a sort of grazes met with in land of some kinds. In the trials made on grasses at Woburn, the qualities of it stand as below.

From a rich sandy loam, the produce at the time of flowering was on the acre

Wheat, Grinding and converting of, into Flour, &c., the art and means of reducing it into this state, in which there are much nicety and difficulty in some cases, especially with the thinner-skinned sorts of this grain.

It
It is stated by the writer of the work on Agricultural Chemistry, that in this country the difficulty of grinding thin-skinned wheat is in some measure an objection; but that this difficulty is easily overcome by moistening the corn. And on the authority of John Jeffery, esq., the consul-general at Lisbon, the following observations on the subject are given, as transmitted by Dr Joseph Banks. In order to grind hard corn of this sort with the mill-stones used in this country, the wheat must be well screened, then sprinkled with water at the Miller's discretion, and laid in heaps, being frequently turned and thoroughly mixed together, which will soften the hulk so as to make it separate from the flour in grinding, and, of course, give the flour a brighter colour; otherwise the flinty quality of the wheat, and the thinness of the klin, will prevent its separation, and will render the flour unfit for making into bread.

The writer has been informed by a miller of considerable experience, and who works his mills entirely with the flones from this country or Ireland, that he frequently prepares the hard Barbaric corn of this kind by immersing it in water in close wicker baskets, and then spreading it thinly on a floor to dry; much depends on the judgment and skill of the miller in preparing the corn for the mill according to its relative quality. It is observed, however, that it is not from this previous process of wetting the corn that the weight in the flour of hard corn is increased; but from its natural quality it imbibes considerably more water in making it into bread. The mill-stones must not be cut too deep, but the furrows very fine, and picked in the usual way.

The mills should work with less velocity in grinding hard corn than with soft, and be let to work at first with soft corn, until the mill ceases to work well; then put on the hard corn. Hard wheat always sells at a higher price in the market than soft wheat, on an average of from ten to fifteen per cent.; as it produces more flour in proportion, and less bran than the soft corn.

 Flour made from hard wheat is more esteemed than what is made from soft corn; and both sorts are applied to every purpose.

The flour of hard wheat is in general superior to that made from soft; and there is no difference in the processes of making them into bread: but the flour from hard wheat will imbibe and retain more water in making into bread, and will consequently produce more weight of bread. It is the practice in Lisbon, and which is thought would be advisable to adopt in this country, to make bread with flour of hard and soft wheat, which, by being mixed, will make the bread much better. As the most flinty wheats are capable of being readily and easily ground by these means, much advantage may arise from the mixing of the flour of the thin-skinned wheats with those of the thicker-skinned kinds in the forming of bread, as well as in preventing the objections to the cultivation and growth of the former, on account of their flinty quality, and grinding hard and with inconvenience. By these means many of the well-harvested and well-kept wheats of this country will be found to be equal to those of any other, for most purposes to which the flour is usually put. See Spring-Wheat, and Wheat. Also Vegetables.

In the Middlesex Corrected Report on Agriculture, it is stated, that the best flour is mostly used by the pastry-cooks, and the makers of fine biscuits, and the inferior sorts in the making of bread. These have often the worst kinds of damaged foreign wheats, and other materials, mixed with them in grinding them into flour. And that, if the bread confounded in the metropolis was prepared from the wheat of this country, unmixed with the leaner produce of other nations, the trial detailed below would shew with accuracy the quantity of bread that could be made from a Winchester bushel of that grain.

One bushel of the wheat of this country, which weighed sixty-one pounds, was taken. It was then ground, and the meal weighed 60\$ lbs.; which, on being dried, produced 46\$ lbs. of flour, of the first called seconds, which alone is used for the making of bread throughout the greater part of this country; and of flour and bran \(12\frac{1}{2}\) lbs., which quantity was boiled, and it produced in flour \(3\frac{1}{2}\) lbs., which being sifted produced in good second flour \(1\frac{1}{2}\) lb.

The whole quantity of bread-flour obtained from the

The lack of marketable flour is by law obliged to weigh 240 lbs., which is exactly the produce of five bushels of such wheat; and the lack of flour is constantly supposed to make eighty quarter loaves of bread; and consequently sixteenths of such loaves are made from each bushel of such wheat. It is admitted, however, that two or three loaves more than the above quantity can be made from the lack of flour, when it is the genuine produce of good wheat; that is, in the proportion of about sixteen and a half loaves from each bushel of good grain; and, it may be prefixed, sixteen from a bushel of medium corn. The expense of making the lack of flour into bread, and disposing of it, is about 8s.

WHEAT, Indian. See MAIZE.

WHEAT, Mildew in. See MILDEW.

WHEAT, Mylt of. See MILD.

WHEAT, Rust. See STADDLE, and STAND.

WHEAT, Root. See STADDLE, and STAND.

WHEAT, Rust in. See RUST.

WHEAT-Seed, Liming of, the practice of drying moistened corn of this sort by means of powdery limestone. It is the custom in some places to make it wet over-night, with salt or other water, and to dust it over with the lime the next morning before it is sown, mixing it well together in the operation. By the lime, however, thus remaining for a short time on the grain before sowing, it has no time to penetrate into
into the corn; whereas, by moistening the wheat, and leaving it until the succeeding morning well limed, the lime has a greater power, it is supposed, in destroying the flmutpowder, than when it remains on it only for half an hour, and is then moister rubbed off the corn. Half a bushel of the strongest lime is sufficient for a quarter of wheat, when sifted over and mixed well with it.

In this last mode of drying feed-wheat, with lime, it is found to be very efficient in preventing the crops from being diseased in some districts. See Steeping Seed.

As there is uncertainty whether the effect in this practice is to be ascribed to the washing of the grain or the lime, some merely moisten the corn for the purpose of making the lime adhere to it; while others are extremely attentive to the liquor made use of and the washing of the feed, and simply make use of the lime for drying it for feeding. Lime is, however, considered as a great preventative of disease in the grain by many. It should always be used while fresh and newly flattened.

Wheat, Setting off, the practice of putting it into the soil by the hand. In many parts of the vale of the county of Gloucester, they set wheat by the hand and line; but the difficulty of getting on with the work at the proper season, when on a large scale, in consequence of the want of hands, operates against the more general introduction of this practice. When wheat is set by the hand in this way, not more than three pecks of seed are made use of. On clover-leys wheat is often put in by the hand in small channels made across the beds, which have been formed by the plough to the width of half a ley, dropping the seed into them, and leaving a distance of about seven inches between the different channels. This mode is said to be good for late work; and the expense to be about seven shillings the acre, the seed being usually about six pecks. In some other districts the setting of wheat is said to be practised with much success and advantage; but it is probably too tedious and expensive a mode to be had recourse to on any large extent of wheat cultivation. See Dibbling, and Setting of Wheat.

Wheat, Smyrna, a peculiar kind of wheat that has an extremely large ear, with many lesser or collateral ears coming all round the bottom of the great one.

As this is the largest of all sorts of wheat, so it will diffuse with the nourishment of a garden, without being overfed, and requires more nourishment than common husbandry in the large way can give it. In the common way its ears grow not much larger than those of our common wheat.

This sort of wheat feeds, of all others, the most proper for the new method of horse-hoeing husbandry, as that method feeds capable of giving as much nourishment as the farmer pleases, by often repeating the hoeing. Next to this, the white-cone wheat is best for this sort of husbandry; then the grey-cone wheat.

Wheat-Stubble, Cutting and Collecting of, the useful practice of mowing and raking together the strong stubbles of wheat-crops, and flacking them up in or near the farmyards as additional litter, and for other purposes. It should always be done as soon as possible after the wheat has been taken from the fields. See Stubble.

Wheat, Tillering of, the throwing out of new shoots, items, or flarks, from about the roots, so as to increase the thickness of the crops on the grounds. It takes place much more extensively in the autumnal and winter grown wheats than those of the spring sowings. See Tiller, and Wheat.

Wheat, Transplantation of, the practice of putting into the ground the young plants of wheat that have been raised in other places, or which stand too thick on the land. It is observed in the Middlesex Report on Agriculture, that it is well calculated for increasing the quantity of corn produced from a single grain, and that it may be resorted to for the sake of curiosity when the cultivator has procured a small quantity of some new and very valuable variety of seed; but that a farmer should never extend it to his field culture.

There would be much loss in labour and in other ways, it is supposes, by this practice, and nothing be gained by it. See Transplanting, and Wheat.

Wheat, White-cone, a term used by our husbandmen, to express a peculiar kind of wheat, which is very strong, and has a large ear.

It is the best kind for sowing in fields subject to the blight; for the flarks of it being, for the most part, solid or full of pith, like a rush, not hollow, like those of common wheat; the infects that cause the blight, fothing on the flarks of other wheat, do this no injury, even though they should attack it; the flarks of this kind being often found full of the black specks, which are always the marks of that infect, having been there, and yet the ear full, and the grain good.

This wheat makes very good bread, if the miller does not grind it too small, or the baker make his dough too hard, it requiring to be somewhat larger than other wheat-flour, and somewhats softer in the dough. A bushel of white-cone wheat will make considerably more bread than a bushel of Lammas wheat; but it gives it a somewhat yellowish cast.

Wheat-Bird, in Ornithology, a name given by the people of Virginia to a species of bird, which, after the time of the sowing of the wheat in that country, made its appearance annually at the feast of its beginning to ripen, and was never seen there before. See Migration of Birds.

Wheat-Ear, the English name of the common eanthe, or ovata eanthe of Linnæus, called also the white-tail, and the falloven-finch. See MTACILLA EANTHE.

WHEATEN-BREAD. See Theory of Bread, and Wheat, Grinding of, &c.

WHEATFIELD, in Geography, a township of Pennsylvania, in the county of Indiana, with 1475 inhabitants.

WHEATLY, FRANCIS, in Biography, was born in London in 1747, and received his first instruction as an artist in Shipley's drawing-school. Whilst young he received several premiums from the Society for the Encouragement of Arts, &c. He does not appear to have had any particular instructor in painting, but by his own industry and ingenuity contrived to obtain some knowledge of it; and having formed an intimacy with Mr. Mortimer, whom he assisted in painting the ceiling at Brockett Hall, by that circumstance obtained considerable improvements. He had great employment in painting small whole-length portraits, to which he added landscape back-grounds with considerable taste. After practising some years in London, he went to Ireland, and was much employed in Dublin, where he painted a large picture of the Irish house of commons, with portraits of the most considerable political characters, by which he acquired great reputation. On his return to London he painted a picture of the foldery attacking the rioters in 1785, which was well engraved by Heath.

About this time he appears to have changed his practice, and painted rural and domestic subjects in a manner which evidently exhibits them to have been the offspring of the natural bent of his mind. He was engaged in the Shakespeare Gallery, but failed to excite interest; neither his talent nor his style was suited to the character of the subjects given to him. In the lighter subjects of common life he was at home, and he touched them and composed them in a most agreeable manner, and with a very pleasing tone of colour;
Whee, Whey, Whee, or Qui, in Rural Economy, a term used to signify a young heifer, or heifer-calf, in different places and parts of the country.

Wheang, or Wiang, a provincial term made use of to signify a thong or strap of leather for the harness or gear of farm-teams, or other domestic purposes.

Wheel, Rota, in Mechanics, a simple machine, consisting of a round piece of wood, metal, or other matter, which revolves on an axis.

For an account of the wheel and axis, as a mechanical power, see Axis in Peritrochio, and Mechanical Powers.

The wheel is one of the principal mechanic powers. It has place in most engines; in effect, it is of an assemblage of wheels that most of our chief engines are composed. Windmills, mills, &c.

Its form is various, according to the motion it is to have, and the use it is to answer. By this it is distinguished into simple and dented.

Wheels, Simple, are those whose circumference and axis are uniform, and which are used singly, and not combined. Such are the wheels of carriages, which are to have a double motion; the one circular about their axis, the other rectilinear, by which they advance along the road, &c. in which two motions they appear to have; though, in effect, they have but one; it being impossible the fame thing should move, or be agitated, two different ways at the same time.

This one is a spiral motion; as easily seen, by fixing a piece of chalk on the face of a wheel, so as that it may draw a line on a wall, as the wheel moves. The line it here traces is a just spiral, and still the more curve, as the chalk is fixed nearer the axis.

The fact, however, has been disputed; and it has been alleged, that nothing is more easy than for any one, who will take the trouble to make the experiment, to prove its falsehood. Place the chalk on the face of the wheel, as directed, and you will find that, so far from its describing a just spiral, and still the more curve as the chalk is fixed nearer the axis, the chalk, if placed on the periphery of the wheel, will describe a cycloid, and the nearer it is placed to the axis, the nearer will the line it describes approach to the straight line which is described by the axis itself. Moreover, it is not true, nor pretended to be so, that the same thing moves two ways at once in the rectilinear and circular motion of wheels. The local motion, or motion of the whole wheel, is rectilinear only; that of the parts of the wheel circular. Nor can this latter motion with any propriety be called that of the wheel, unless the same thing could also move quick and flow at the same time, which the different parts of the wheel, in revolving round its axis, evidently do. Jacob's Obf. on the Structure and Draught of Wheel-Carriages, 1773, p. 28, &c.

For a very nice phenomenon, in the motion of these wheels, see Rota Aristotelia.

We shall add, that, in wheels of this kind, the height should always be proportioned to the nature of the animal that draws or moves them. The rule is, that the load and the axis of the wheels be of the same height with the power that moves them; otherwise the axis being higher than the beast, part of the load will lie upon him; or, if it be lower, he pulls to disadvantage, and must exert a greater force. Though Stevinus, Dr. Wallis, &c. shew, that, to draw a vehicle, &c. over wide uneven places, it were best to fix the traces to the wheels somewhat lower than the horse's breast. See Wheels of Coachers, &c.

The power of these wheels results from the differences of the radii of the axis, and circumference. The canon is this: "As the radius of the axis is to that of the circumference, so is any power to the weight it can sustain hereby."

This is also the rule in the axis in peritrochio; and, in effect, the wheel, and the axis in peritrochio, are the same thing; only, in theory, it is usually called by the latter name, and in practice by the former.

Wheels, Dented, are those either whose circumference, or axis, is cut into teeth, by which they are capable of moving and acting on one another, and of being combined together.

The use of these is very conspicuous in clocks, jacks, &c.

The power of the dented wheel depends on the same principle as that of the simple one. It is only that the simple axis in peritrochio, which a compound lever is to a simple lever.

Its doctrine is comprised in the following canon; viz., "The ratio of the power to the weight," in order for that to be equivalent to this, "must be compounded of the ratios of the diameter of the axis of the lathe wheel to the diameter of the first; and of the ratio of the number of revolutions of the last wheel, to those of the first, in the same time." But this doctrine will deserve a more particular explanation.

1. Then, if the weight be multiplied into the product of the radii of the axes, and that product be divided by the product of the radii of the wheels, the power required to sustain the weight will be found. Suppose, e. gr. the weight A (Plate XL., fig. 52, Mechanics,) = 6000 pounds, B C = 6 inches, C D = 34 inches, E F = 5 inches, E G = 35 inches, H I = 4 inches, H K = 27 inches; then will B C X E F X H I = 1201; and C D X E G X H K = 32130. Hence the power required to sustain the weight, will be 6000 X 1201 32130 = 22+ very nearly; a small addition to which will raise it.

2. If the power be multiplied into the product of the radii of the wheels, and the quotient be divided by the product of the radii of the axes, the quotient will be the weight which the power is able to sustain. Thus, if the power be 22+ pounds; the weight will be 6000 pounds.

3. A power and weight being given, to find the number of wheels, and in each wheel the ratio of the radius of the axis, to the radius of the wheel; so as that the power, being applied perpendicularly to the periphery of the lathe wheel, may sustain the given weight.

Divide the weight by the power; resolve the quotient into the factors which produce it. Then will the number of factors be the number of wheels; and the radii of the axis will be to the radii of the wheels, as unity to the several wheels. Suppose, e. gr. a weight of 3000 pounds, and a power of 60, the quotient of the former by the latter is 500, which resolves into these factors, 4, 5, 5, 5. Four wheels are, therefore, to be made; in one of which, the radius of the axis is to the radius of the wheel, as 1 to 4; in the rest, as 1 to 5.

4. If a power move a weight by means of two wheels, the revolutions of the lower wheel are tho' of the swifter, as the periphery of the swifter axis is to the periphery of the wheel that catches on it.

Hence, r. The revolutions are as the radius of the axis FE to the radius of the wheel DC. 2. Since the num-
ber of teeth in the axis $F$ is to the number of teeth in the circumference of the wheel $M$, as the circumference of that to the circumference of this; the revolutions of the flower wheel $M$, are to the revolutions of the swiftest $N$, as the number of teeth in the axis to the number of teeth in the wheel $M$, which it catches.

5. If the factum of the radii of the wheels $G$ $E$, $D$ $C$, be multiplied into the number of revolutions of the flowest wheel, $M$, and the product be divided by the factum of the radii of the axes which catch into them, $G$ $H$, $D$ $E$, &c. the quotient will be the number of revolutions of the swiftest wheel $O$. $E$ gr. If $G = 8$, $D = 1$, $G = 4$, $D = 1$, and the revolution of the wheel $M$ be 1; the number of revolutions of the wheel $O$ will be 8.

6. If a power move a weight by means of divers wheels, the space passed over by the weight, is to the space of the power, as the power to the weight. Hence, the greater the power, the quicker is the weight moved; and vice versa.

7. The spaces passed over by the weight and the power, are in a ratio compounded of the revolutions of the flowest wheel, to the revolution of the swiftest; and of the periphery of the axis of that, to the periphery of this. Hence, since the spaces of the weight and the power are reciprocally as the sustaining power is to the weight; the power that sustains a weight will be to the weight, in a ratio compounded of the revolutions of the flowest wheel, to that of the swiftest, and of the periphery of the axis of that, to the periphery of this.

8. The periphery of the axis of the flowest wheel, with the periphery of the swiftest wheel, being given; as also the ratio of the revolutions of the one, to those of the other; to find the space which the power is to pass over, while the weight goes any given length. Multiply the periphery of the axis of the flowest wheel into the antecedent term of the ratio, and the periphery of the swiftest wheel into the consequent term; and to these two products, and the given space of the weight, find a fourth proportional: this will be the space of the power. Suppose, $e$.gr. the ratio of the revolutions of the flowest wheel, to those of the swiftest, to be as 2 to 3, and the space of the weight 30 feet; and let the periphery of the axis of the flowest wheel be to that of the swiftest, as 3 to 8: the space of the power will be found 280. For $2 \times 3 = 7 \times 3 = 210$.

9. The ratio of the peripheries of the swiftest wheel, and of the axis of the flowest; together with the ratio of their revolutions, and the weight, being given: to find the power able to sustain it. Multiply both the antecedents and the consequents of the given ratios into each other, and to the product of the antecedents, the product of the consequents, and the given weight, find a fourth proportional: that will be the power required. Suppose, $e$.gr. the ratio of the peripheries $8 : 3$, that of the revolutions $7 : 2$, and the weight 2000; the power will be found 2148. For $7 \times 8 \times 3 = 2000 \times 2148$. After the same manner may the weight be found; the power, and the ratio of the peripheries, &c. being given.

10. The revolutions the swiftest wheel is to perform while the flowest makes one revolution, being given; together with the space the weight is to be raised, and the periphery of the flowest wheel; to find the time that will be spent in raising it.

Say, As the periphery of the axis of the flowest wheel is to the given space of the weight; so is the given number of revolutions of the swiftest wheel to a fourth proportional:

Vol. XXXVIII.
wheels would be useful only in overcoming friction; but as they are drawn along roads covered with loose stones, indented with cavities, they are farther useful in serving to depref, or raise the carriage over the one, and in raising it out of the other.

2. The wheels of all carriages ought to be exactly round; and the fellettes should be at right angles to the naves, according to the inclination of the spokes, i.e. the plane of the curvature of the wheel should cut the nave at right angles, though it need not pass through the place where the spokes are intersected into the nave.

3. The spokes, according to Mr. Ferguson and most other writers on mechanics, should be inclined to the naves, so that the wheels may be diving or concave. If, indeed, the wheels were always to go upon smooth and level ground, it would be best to make the spokes perpendicular to the naves, or at right angles with the axes; because they would then bear the weight of the load perpendicularly, which is the strongest way for the wood. But because the ground is generally uneven, one wheel often falls into a cavity or rut, when the other does not, and then it bears much more of the weight than the other does; in which case diving wheels are best, because the spokes become perpendicular to the rut, and therefore have the greatest strength when the obliquity of the road throws most of its weight upon them; whilst those on the high ground have less weight to bear, and therefore need not be at their full strength. Besides, by this form of the wheels, the base of the carriage is extended, and it is thus prevented from being easily overturned, and the fellettes are hindered from rubbing against the load or the sides of the cart. Dr. Brewer, however, is of opinion, that the disadvantages of concave wheels overbalance their advantages. Mr. Anville also, in his "Treatise on Wheel-Carriages," whilst he recommends concave wheels, candidly allows, that some disadvantages attend this construction of them; for the carriage thus takes up more room on the road, so that it is more unmanageable; and when it moves upon plane ground the spokes not only do not bear perpendicularly, by which means their strength is lessened, but the friction upon the nave and axle is made unequal, and so much the more as they are the more dished. Dr. Brewer farther shews, that they are more expensive, more injurious to the roads, more liable to be broken by accidents, and less durable in general, than those wheels in which the spokes are perpendicular to the naves. From these and other considerations, our author is decidedly of opinion, that if wheels are to be compos'd of naves, spokes, and fellettes, the rim should be cylindrical, and the spokes perpendicular to the naves; whereas in concave wheels, the rims are uniformly made conical, which subjects them to a variety of disadvantages. Every cone that is put in motion upon a plane surface will revolve round its vertex, and if force is employed to confine it to a straight line, the smaller parts of the cone will be dragged along the ground, and the friction greatly increased. Now when a cart moves upon conical wheels, one part of the cone rolls while the other is dragged along, and though confined to a rectilinear direction by external force, their natural tendency to revolve round their vertex occasions a great and continued friction upon the lynch-pin, the shoulder of the axle-tree, and the sides of deep ruts.

Dr. Brewer has made some farther observations on the construction of certain parts of the wheels. The iron plates, he says, of which the rims are compos'd, should never be less than three inches in breadth, as narrower rims sink deep into the ground, and therefore injure the roads and fatigue the horses. See the sequel of this article.

4. The axles of the wheels ought to be perfectly straight, and at right angles to the shafts, or to the pole. When the axles are straight, the rims of the wheels will be parallel to each other, and then they will move the easiest, because they will be at liberty to go on straight forwards. But in the usual way of practice, the axles are bent downwards at their ends; which brings the sides of the wheels next the ground nearer to one another than their higher sides are; and this not only makes the wheels to drag sideways as they go along, and gives the load a much greater power of crushing them than when they are parallel to each other, but also endangers the overturning of the carriage when any wheel falls into a hole or rut, or when the carriage goes on a road which has one side lower than the other, as along the side of a hill. Thus, in the hind view of a waggon or cart, let $A$ and $B$ (Plate XL. fig. 9. Mechanics) be the great wheels parallel to each other, on their straight axle $K$, and $C$ the carriage loaded with heavy goods from $C$ to $G$. Then as the carriage goes on in the oblique road $A$ to $B$, the centre of gravity of the whole machine and load will be at $C$; and the line of direction $C$ to $D$ falling within the wheel $B$, the carriage will not overturn. But if the wheels be inclined to each other at the ground, as $A$ and $B$ are (fig. 10.), and the machine be loaded as before from $C$ to $G$, the line of direction $C$ to $D$ falls without the wheel $B$, and the whole machine tumbles over. When it is loaded with heavy goods which lie low, it may travel safely upon an oblique road, so long as the centre of gravity is at $C$ (fig. 9.), and the line of direction $C$ to $D$ falls within the wheel; but if it be loaded high with lighter goods from $C$ to $L$ (fig. 11.), the centre of gravity is raised from $C$ to $K$, which shews the line of direction $K$ to $L$ without the lowest edge of the wheel $B$, and then the load overfalls the waggon. Mr. Beighton has offered several reasons to prove, that the axles of wheels ought not to be straight: for which we must refer to Delagiers' Exp. Phil. vol. ii. Appendix, p. 546. &c. Moreover, if the axle were not at right angles to the pole or shaft, but this was on one side, then the coach or carriage would be drawn on one side, and almost all the weight would bear upon one horse. With some mechanics, it is a practice to bend the ends of the axle-trees forwards, and thus make the wheels wider behind than before. Mr. H. Beighton maintains, that wheels in this position are more favorable for turning; since, when the wheels are parallel, the outer shoe would press against the lynch-pin, and the inner shoe would rub against the shoulder of the axe-tree. In rectilinear motions, however, these converging wheels occasion a great deal of friction, both on the axle and the ground, and must therefore be more disadvantageous than parallel ones. This fact is allowed by Mr. Beighton: but he seems to find his opinion upon this principle; that as the roads are seldom straight lines, the wheels should be more adapted to a curvilinear than to a rectilinear motion.

5. Large wheels are always more advantageous for rolling than small ones, in any case, or upon any ground whatever. If we consider wheels with regard to their friction upon the axles, it is evident, that small wheels must turn as much of the time round the large ones, as their circumferences are less; and, therefore, a wheel which is twice as large as another will have twice the advantage in respect of the friction, the holes of the naves and axles, and the weights upon them, being equal. Again, if we consider the wheels as they sink into the earth, or fall into holes, the bearing of the great wheel being double that of the small one, it would sink but half so deep; and if the small wheel should meet with a hole of the same diameter with itself, it would wholly sink in, whilst only a segment less than half of the great wheel
WHEEL.

wheel would fall in: the same thing would also happen in
marshy ground, where the small wheel would sink wholly in
the same hole which the great one would sink into but in part.
The large wheel would also have the advantage of a
small one in rising over eminences or rubs that occurred; for
that the former would go over rubs much higher than the
latter; and indeed over any eminences, provided their height
be not equal to its semidiameter. Defaguer has reduced
this matter to a mathematical calculation, in his Exp. Phil.
vol. i. p. 171, &c.

A late writer has also proved, that a wheel of eight feet
diameter has somewhat more than twice the advantage in
overcoming obstacles of a wheel of two feet; and he found,
in practice, that if it requires a certain power to draw a
carriage of a certain weight over a certain obstacle, with
wheels of any determinate diameter, it will require wheels
of four times that diameter, to draw the same carriage over
the same obstacle with half that power. This writer also
observes, that, in the draught of carriages ascending inclined
planes, the moving power acts not only against the vis in-
ertia, which is always equal to the absolute gravity of the
load, but also against its relative gravity, which increases
with the inclination of the plane; and with respect to car-
rriages raised on wheels, it is to be observed, that the higher
the axle is removed from the plane, the farther is the centre
of gravity removed out of the perpendicular line of sup-
port; so that the lower the wheel, the less is the relative
gravity of the carriage. Hence he infers, that supposing
the friction of two carriages of equal weight, but of dif-
f erent sized wheels, to be equal, the low-wheeled one would
be drawn up hill, on a smooth plane, much more easily
than the high-wheeled one; though on a smooth, horizontal
plane, the latter would be drawn more easily than the former.
On the contrary, in going down hill, the high-
wheeled carriage will be urged forward, by its relative gra-
vity, more than the low-wheeled one. Jacob, ubi supra,
p. 63, &c.

It appears, therefore, that the larger wheels are, the more
advantageous they are in proportion, provided that they are
not more than five or six feet in diameter; for when they ex-
ceed these dimensions, they become heavy; or if they are
made light, their strength is proportionably diminished, and
the spokes, being long, are more liable to break: besides,
horses applied to such wheels, would be incapable of exert-
ing their utmost strength, by having the axles higher than
their breasts, so that they would draw downwards; as in
small wheels the draught is made more difficult, by the
horses drawing upwards.

It is observed by Dr. Brewster, in the appendix to his
edition of “Ferguson’s Mechanics,” that when the wheels of
carriages either move upon a level surface, or overcome
obstacles which impede their progress, they act as mecha-
nical powers, and may be reduced to levers of the first kind.
In order to elucidate this remark, which is of great import-
ance in the present discussion, let A be the centre, and B C N
the circumference of a wheel 6 feet in diameter, and let the
impelling power P, which is attached to the extremity of a
rope A D P, pulling over the pulley D, act in the hori-
zontal direction A D. Then, if the wheel is not affected
by friction, it will be put in motion upon the level surface
M B, when the power P is infinitely small. For since the
whole weight of the wheel rests on the ground at the point B,
which is the fulcrum of the lever A B, the distance of the
weight from the centre of motion will be nothing, and there-
fore the mechanical energy of the smallest power P, acting
at the point A, with a length of lever A B, will be infi-

weight to be raised, and this will be the case, however small
the lever A B, and however great be the weight of the
wheel. But as the wheels of carriages are constantly meet-
ing with impediments, let C be an obstacle six inches high,
which the wheel is to surmount. Then the spoke C will
represent the lever, C its fulcrum, A D the direction of
the power; and if the wheel weighs 100 pounds, we may repre-
sent it by a weight W, fixed to the wheel’s centre A, or to
the extremity of the lever C A, and acting in the perpendi-
cular direction A B, in opposition to the power P. Now
the mechanical energy of the weight W to pull the lever
round its fulcrum in the direction A E, is represented by
C E, while the mechanical energy of an equal weight P
to pull it in the opposite direction A F, is represented by C F;
an equilibrium, therefore, will be produced, if the power P
is to the weight W as C E to C F, or as the line is to the co-
fine of an angle, whose vertex is equal to the height of
the ob stacle to be surmounted; for E B, the height of the
wheel C, is the verified sine of the angle B A C, and C E
is the sine, and C F the cosine of the same angle. In the
present case, where E B is six inches, and A B three feet,
E B, the verified sine, will be 1666, &c. when A B is 1000
and, consequently, the angle B A C will be 33° 33’, and
C E will be to E F, as 52 to 83, or as 66 to 100. A
weight P, therefore, of 66 pounds, acting in a horizontal
direction, will balance a wheel six feet diameter, and 100
pounds in weight, upon an obstacle six inches high; and a
small additional power will enable it to surmount that ob-
stacle. But if the direction, A D, of the power, be in-
clined to the horizon, so that the point D may rise towards
H, the line F C, which represents the mechanical energy of
P, will gradually increase, till D A has reached the po-
fition H A, perpendicular to A C, where its mechanical
energy, which is now a maximum, is represented by A C,
the radius of the wheel; and since E C is to C A as 53 to
1000, a little more than 53 pounds will be sufficient for
enabling the wheel to overcome the obstacle.

Proceeding in this way, it will be found, by our author, that
the power of wheels to surmount eminences increases with their
diameter, and is directly proportional to it, when their weight
remains the same, and when the direction of the power is
perpendicular to the lever which acts against the obstacle.
Hence we see the great advantages which are to be derived
from large wheels, and the disadvantages which attend small
ones. There are some circumstances, however, which con-
fine us within certain limits in the use of large wheels. When
the radius A B of the wheel is greater than D M, the height of
the pulley, or of that part of the horse to which the rope
or pole D A is attached, the direction of the power, or the
line of traction A D, will be oblique to the horizon as A d,
and the mechanical energy of the power will be only A c,
whereas it was represented by A E, when the line of trac-
tion was in the horizontal line D A. Whenever the radius
of the wheel, therefore, exceeds four feet and a half, the
height of that part of the horse to which the traces shoul
d be attached, the line of traction A D will incline to the
horizon, and by declining from the perpendicular A H, its
mechanical effort will be diminished; and since the load refts
upon an inclined plane, the trams or poles of the cart will
rub against the flanks of the horse, even in level roads, and
still more severely in defceeding ground. Notwithstanding
this diminution of force, however, arising from the un-
avoidable obliquity of the impelling power, wheels exceeding
four and a half feet radius have still the advantage of
smaller ones; but their power to overcome resistances does
not increase so fast as before. Hitherto we have suppos-

Z 2 it
it is evident that when we augment their diameter we add greatly to their weight; and by thus increasing the load, we febibly diminish their power.

From these remarks, we see the superiority of great wheels to small ones, and the particular circumstances which suggest the propriety of making the wheels of carriages less than four feet and a half radius. But even this size is too great; and it may be safely asserted that they should never exceed six feet in diameter, nor ever be less than three feet and a half.

6. Carriages with four wheels, as wagons or coaches, are much more advantageous than carriages with two wheels, as carts and chariots; for in applying horses to a carriage with two wheels, it is plain that the tier carries part of the weight, in whatsoever manner it be kept in equilibrium upon the axle. In going down a hill, the weight bears upon the horse; and in going up a hill, the weight falls the other way, and lifts the horse, by which means part of his force is lost.

Besides, as the wheels sink into the holes in the road, sometimes on one side, sometimes on the other, the shafts strike against the tier’s flanks, which is the destruction of many horses. Add to this, that when one of the wheels sinks into a hole or rut, half the weight will fall that way, whereby the carriage will be in danger of being overturned.

7. It would be much more advantageous to make the four wheels of a coach or wagon large, and nearly of a height, than to make the fore-wheels of only half the diameter of the hind-wheels, as usual in many places. The fore-wheels of carriages have commonly been made of a less size than the hind ones, both on account of turning short, and to avoid cutting the braces. Crane-necks have also been invented for turning yet shorter, and the fore-wheels have been lowered, so as to go quite under the bend of the crane-neck. See an account of an ingenious contrivance for this purpose, under Perch.

Some carriers and coachmen have, indeed, absurdly alleged, that when the fore-wheels are much lower than the hind ones, they serve to push them on. However, many disadvantages attend this construction. A considerable force is lost that would be effectual, if they were large; the carriage would go much more easily, if the fore-wheels were as high as the hind-ones; and the higher the better, because their motion would be so much the slower on their axles, and consequently the friction proportionately diminished. The jolting and uneasy motion occasioned by low wheels, has induced persons to contrive springs, in order to prevent it. But nothing can be more inconvenient, even with this end, than the common method of fixing the braces to the bottom of a carriage. In consequence of this practice, the centre of gravity of the suspended body is so high above the centre of its motion, that it is liable to be continually agitated by the jolting of the carriage, and its danger of overturning increased; whereas if, instead of practising this method, the body were suspended as near as possible to its centre of gravity, the agitation of the carriage, as well as its danger of overturning, would be in a great measure avoided.

The effect of the suspension of a carriage on springs is to equalize its motion, by causing every change to be more gradually communicated to it, by means of the flexibility of the springs, and by confining a certain portion of every sudden impulse in generating a degree of rotatory motion. This rotatory motion depends on the oblique position of the straps suspending the carriage, which prevents its swinging in a parallel direction; such a vibration as would take place if the straps were parallel, would be too extensive, unless they were very short, and then the motion would be some-what rougher. The obliquity of the straps tends also in some measure to retain the carriage in a horizontal position: for if they were parallel, both being vertical, the lower one would have to support the greater portion of the weight, at least according to the common mode of fixing them to the bottom of the carriage; the spring, therefore, being flexible, it would be still further depressed. But when the straps are oblique, the upper one assumes always the more vertical position, and consequently bears more of the load; for when a body of any kind is supported by two oblique forces, their horizontal thrusts must be equal, otherwise the body would move laterally; and in order that the horizontal portions of the forces may be equal, the more inclined to the horizon must be the greater: the upper spring will, therefore, be a little depressed, and the carriage will remain more nearly horizontal than if the springs were parallel. The reason for dividing the springs into separate plates has already been explained: the beam of the carriage, that unites the wheels, supplies the strength necessary for forming the communication between the axles: if the body of the carriage itself were to perform this office, the springs would require to be so strong that they could have little or no effect in equalizing the motion, and we should have a wagon instead of a coach.

The ease with which a carriage moves, depends not only on the elasticity of the springs, but also on the small degree of stability of the equilibrium, of which we may judge in some measure, by tracing the path which the centre of gravity must describe, when the carriage swings.

There is an inconvenience which attends the usual method of loading carriages; for when a carriage is loaded equally heavy on both axles, the fore-axle must endure as much more friction, and consequently wear out as much sooner than the hind-axle, as the fore-wheels are less than the hind ones. However, the carriers commonly put the heavier part of the load upon the fore-axle of the waggons; which not only makes the friction greatest where it ought to be least, but also precludes the fore-wheels deeper into the ground than the hind-wheels, although the fore-wheels, being less than the hind ones, are with so much the greater difficulty drawn out of a hole, or over an obstacle, even supposing the weights on their axles were equal; for the difficulty, with equal weights, will be as the depth of the hole, or height of the obstacle, is to the semi-diameter of the wheel. Moreover, since a small wheel will often sink to the bottom of a hole, in which a great wheel will go but a very little way, the small wheels ought to be loaded with less weight than the great ones; and then the heavier part of the load would be less jolted upward and downward, and the horses tired to much less, as their draught raised their load to less heights. When the waggon-road, indeed, is much up-hill, there may be danger in loading the hind-part much heavier than the fore-part; for then the weight would over-hang the hind axle, especially if the load be high, and endanger tipping up the fore-wheels from the ground. In this case, the safest way would be to load it equally heavy on both axles; and then as much more of the weight would be thrown upon the hind axle than upon the fore one, as the ground rises from a level below the carriage. But as this seldom happens, a small temporary weight might be laid upon the pole between the horses, which would overbalance the danger.

From Mr. Ferguson’s observations on the centre of gravity, it is evident, that if the axle-tree of a two-wheeled carriage passes through the centre of gravity of the load, the carriage will be in equilibrium in every position in which it can be placed with respect to the axle-tree; and
in going up and down hill, the whole load will be sustained by the wheels, and will have no tendency either to press the horse to the ground, or to raise him from it. But if the centre of gravity is far above the axle-tree, as it must necessarily be according to the present construction of wheel-carriages, a great part of the load will be thrown on the back of the horses from the wheels, when going down a steep road, and thus tend to accelerate the motion of the carriage, which the animal is striving to prevent; while in ascending steep roads a part of the load will be thrown behind the wheels, and tend to raise the horse from the ground, when there is the greatest necessity for some weight on his back, to enable him to fix his feet on the earth, and overcome the great resistence which is occasioned by the steepness of the road. On the contrary, if the centre of gravity is below the axe, the horse will be pressed to the ground in going up-hill, and lifted from it when going down. In all these cases, therefore, where the centre of gravity is either in the axle-tree, or directly above or below it, the horse will bear no part of the load in level ground. In some situations, the animal will be lifted from the ground when there is the greatest necessity for his being pressed to it, and he will sometimes bear a great proportion of the load when he should rather be relieved from it.

The only way of remedying these evils, says Dr. Brewster, is to assign such a portion to the centre of gravity, that the horse may bear some portion of the load when he must exert great force against it, that is, in level ground, and when he is ascending steep roads; for no animal can pull with its greatest effort, unless it is pressed to the ground. Now, this may in some measure be effected in the following manner: Let BCD (Plate XL., fig. 12.) be the wheel of a cart, A D one of the shafts, D that part of it where the cart is sustained on the back of the horse, and A the axe-tree; then if the centre of gravity of the load is placed at m, a point equidistant from the two wheels, but below the line DA, and before the axe-tree, the horse will bear a certain weight on level ground, a greater weight when he is going up-hill, and has more occasion for it, and a less weight when he is going down-hill, and does not require to be pressed to the ground. All this will be evident from the figure, when we recollect that if the shaft DA is horizontal, the centre of gravity will press more upon the point of suspension D the nearer it comes to it; or the pressure upon D, or the horse's back, will be proportional to the distance of the centre of gravity from A. If m therefore be the centre of gravity, b A will represent its pressure upon D, when the shaft DA is horizontal. When the cart is ascending a steep road, A H will be the position of the shaft, the centre of gravity will be raised to a, and a A will be the pressure upon D. But if the cart is going down hill, A C will be the position of the shaft, the centre of gravity will be depressed to n, and c A will represent the pressure upon the horse's back. The weight sustained by the horse, therefore, is properly regulated by placing the centre of gravity at m. We have hitherto, however, to determine the proper length of b a and b m, the distance of the centre of gravity from the axle, and from the horizontal line DA; but as these depend upon the nature and inclination of the roads, upon the length of the shaft DA, which varies with the size of the horse, on the magnitude of the load, and on other variable circumstances, it would be impossible to fix their value. If the load, along with the cart, weighs four hundred pounds, if the distance DA be eight feet, and if the horse should bear fifty pounds of the weight, then b A ought to be one foot, which being one-eighth of DA, will make the pressure upon D exactly fifty pounds. If the road slopes four inches in one foot, b m must be four inches, or the angle b A m should be equal to the inclination of the road, for then the point m will rise to a when ascending such a road, and will press with its greatest force on the back of the horse.

When carts are not constructed in this manner, we may, in some degree, obtain the same end by judiciously disposing the load. Let us suppose that the centre of gravity is at O when the cart is loaded with homogeneous materials, such as sand, lime, &c. then if the load is to consist of heterogeneous substances, or bodies of different weight, we should place the heaviest at the bottom, and nearest the front, which will not only lower the point O, but will bring it forward, and nearer the proper position m. Part of the load, too, might be suspended below the fore-part of the carriage in dry weather, and the centre of gravity would approach still nearer the point m. When the point m is thus depressed, the weight on the horse is not only judiciously regulated, but the cart will be prevented from overturning, and in rugged roads the weight sustained by each wheel will be in a great degree equalized.

In loading four-wheeled carriages, great care should be taken not to throw much of the load upon the fore-wheels, as they would otherwise be forced deep into the ground, and require great force to pull them forward. In some modern carriages, this is very little attended to. The coachman's seat is sometimes enlarged so as to hold two persons, and all the baggage is generally placed in the front, directly above the wheels. By this means the greatest part of the load is upon the small wheels, and the draught becomes doubly severe for the poor animals, who must thus unnecessarily suffer for the ignorance and folly of man.

There is another great disadvantage attending small fore-wheels; viz. that as their axle is below the level of the horse's breast, the horses not only have the loaded carriage to draw along, but also part of its weight to bear, which tires them sooner, and makes them grow much flatter in their hams, than they would be if they drew on a level with the forse-axe; and for this reason, coach-horses soon become unfit for riding. So that on all accounts it is plain, that the fore-wheels of all carriages ought to be so high as to have their axles even with the breasts of the horses; which would not only give them a fair draught, but likewise cause the machine to be drawn by a less degree of power.

Mr. Beighton disputes the propriety of fixing the line of traction on a level with the break of a horse, and says it is contrary to reason and experience. Horses, he says, have little or no power to draw, but what they have from their weight; otherwise they could take no hold of the ground, and then they must slip, and draw nothing. Common experience also teaches, that if a horse is to convey a certain weight, he ought, that he may draw the better, to have a proportional weight on his back or shoulders. Besides, when a horse draws hard, he bends forward, and brings his break near the ground; and then, if the wheels are high, he is pulling the carriage against the ground. A horse tackled in a waggon will draw two or three tons, because the point of line of traction is below his break, by reason of the wheels being low. And it is very common to see, when one horse is drawing a heavy load, his fore-feet will rise from the ground; and he will nearly stand on end; in which case it is usual to add a weight on his back, to keep his fore-part down, by a person mounting on him, which will enable him to draw that load, without which he before could not move. The great fires, or main butines of drawing, says this ingenious writer, is to overcome obstacles; for on level plains the drawing is but little, and then the horse's back need be pressed but with a small weight. Most or all of these obstacles may be considered
the line of traction. When the line of traction is horizontal, as $A D$, the lever of resistance is $C F$; but if this line is oblique to the horizon, as $A d$, the lever of resistance is diminished to $C f$, while the lever of the horse's weight remains the same. Hence it appears, that inclined traces are much more advantageous than horizontal ones, as they uniformly diminish the resistance to be overcome.

Whether, however, has investigated experimentally the most favorable angle of inclination, and found, that when the angle $D A F$, made by the traces $A d$, and a horizontal line, is fourteen or fifteen degrees, the horse pulled with the greatest facility and force. This value of the angle of draught will require the height of the spring-tree bar, to which the traces are attached in four-wheeled carriages, to be one-half of the height of that part of the horse's breast to that with which the fore end of the traces is connected.

This height is about four feet six inches, and therefore the height of the spring-tree bar should be only two feet three inches, whereas it is generally three feet.

8. The utility of broad wheels, in amending and preserving the roads, has been so long and generally acknowledged, as to have occasioned several acts of the legislature to enforce their use. See Turnpike.

Several excellent and well-considered experiments have not long ago been instituted by Bouard and Marguron, which have satisfactorily evinced the distinguishing advantage of broad wheels. See a Memoir presented to the Academy of Lyons, in the Journal de Physique, tom. xix. p. 424.

Nevertheless, the proprietors and drivers of carriages feem to be convinced by experience, that a narrow-wheeled carriage is much easier and speedily drawn by the fame number of horses as a broad-wheeled one of the same burthen. Although government allowed them to draw with more horses, and carry greater loads than usual, they were perforce compelled to comply with the requisition of legislation; and methods have been used to evade it. Their principal objection has been, that as a broad wheel must touch the ground in many more points than a narrow wheel, the friction must of course be so much the greater; not considering, that if the whole weight of the waggon, and load in it, bears upon many points, each sustains a proportional less degree of weight and friction than when it bears only upon a few points; so that what is wanting in one is made up in the other, and, therefore, will be just equal under equal degrees of weight, as appears by the following plain and easy experiment proposed by Mr. Ferguson.

Let one end of a piece of packthread be fastened to a brick, and the other end to a common scale for holding weights; then having laid the brick edgeways on a table, and letting the scale hang under the edge of the table, put as much weight into the scale as will just draw the brick along the table. Then taking the brick to its former place, lay it flat on the table, and leave it to be acted upon by the fame weight in the scale as before, which will draw it along with the same ease as when it lay upon its edge. In the former case, the brick may be considered as a narrow wheel on the ground; and in the latter as a broad wheel. And since the brick is drawn along with equal ease, whether its broad side or narrow edge touches the table, it shews that a broad wheel might be drawn along the ground with the same ease as a narrow one, supposing them equally heavy, even though they should drag, and not roll as they go along. Besides, as narrow wheels are always sinking into the ground, especially when the heaviest part of the load lies upon them, they must be considered as constantly going up hill, even on level ground; and their edges must sustain much friction by rubbing

WHEEL.
rubbing against the sides of the ruts made by them. But both these inconveniences are avoided by broad wheels; which, instead of cutting and ploughing up the roads, roll them smooth, and harden them; though, after all, it must be confessed, that they will not do in still, clayey crofs roads; because they would soon gather up as much clay as would be almost equal to the weight of an ordinary load; and also in passing along roads abounding with loose stones and other obfacles, which a narrow wheel may avoid passing over, and a broad one much furround the, the broad-wheel carriage will certainly be drawn less easily and less speedily than a narrow-wheel one, though not on account of any additional friction arising from the pressure of the weight on a greater quantity of surface. Broad wheels are likewise more liable to an inequality of pressure between the axle and box than narrow ones, and consequently to a greater wear and tear.

We shall here subjoin some additional remarks on wheels and axles for carriages. The essential qualities of wheels are strength and durability, and it is defirable that they should be as light as is convenient with strength: for quick travelling carriages lightness is very necessary.

Wheels to four-wheel carriages should be made as near of a height as the construction and appearance will admit; and if not required for heavy work, the lighter they are made the better. The fixtures from whence the draught is taken should be placed rather above the centre of the largest wheel, for advantage of draught.

The members of a wheel are of three descriptions; viz. the nave, or fock, which is the central piece; the spokes, or radii; and the fellies, or circumference. The nave or fock is made of elm, in which all the spokes are fixed, and in which the axletree-box, or wheel-box, is confined, to receive the axl-arms on which the wheel revolves. The spokes are straight timbers made of oak, firmly tenoned in the nave, in the direction of radials, to support the fellies, or wheel-rim. The fellies are made of ash, or beech, and form the rim of the wheel; the whole circumference is usually divided into short lengths, in the proportion of one length to every two spokes. When the fellies are fixed on the spokes, the iron band, or tire, which maintains the wear, is nailed on in lengths, and keeps the fellies together. The diameters of wheels regulate the number of spokes and fellies they are to con-tain: for the larger the circumference of the wheel is, the greater is the number of spokes required in proportion; for they should not in any wheel be more than fifteen inches distant on the fellies, or circumference.

The usual height or diameter of wheels for coaches and travelling carriages extends to five feet eight inches, and are divided into four proportions. Those which contain from eight to fourteen spokes, and only half that number of fellies, are called eights, tens, twelves, or fourteens, which are the number of spokes in such wheels, or of fellies in a pair of wheels. The height which regulates the number is, for an eight-spoke wheel, not to exceed three feet two inches; for a ten, four feet six inches; for a twelve, five feet four inches; for a fourteen, five feet eight inches.

These are the extreme heights for the different numbers of spokes to each wheel, which should be rather more than they are for the fore-wheel of a four-wheel carriage, which receives more pressure than the hind one; and the coach-maker's rule is, when the hind-wheels are of that height to require fourteen spokes, the fore one, if under the necessary height before stated, should have twelve; never allowing the fore-wheels to have but two spokes less than what is needful for the hind ones.

There are three descriptions of wheels; viz. the flanked, the hooped, and the patent rim: the differences of these are only in the rims.

The flanked wheel is made with the fellies in separate lengths or pieces, which are joined together at the ends by dowels; that is, a round pin which enters part into one piece and part into the other, being closely fitted into holes made in each. The iron with which it is plated is called the flake, and is put on in pieces of the same length as the pieces of the fellies, and fastened by nails; the joints of the iron are made to fall over the middle of the pieces of wood so as to unite them firmly together. The hooped wheel is sur-rounded by a hoop of iron in one entire piece. The patent wheel is made with a hoop of wood in one entire piece, by boring or softening the wood until it can be bent into a circle; this is surrounded by a hoop of iron in an entire piece, and fastened by nuts and rivets.

According to the usual method of constructing flanked wheels, their peripheries are composed of a number of pieces or fellies joined together; but these are weak, and subject to several inconveniences. As the joints are the weakest parts of the wheel, they are most liable to yield inward; for which reason the wheelwrights leave them higher than the other parts of the rim, in conformance of which the wheel is not exactly round within the circle of the rim. Besides, the fellies being segments of a circle, fawed or hewn out of straight wood, they are on this account rendered so brittle, from the course direction of the grain near the joints, that they are with difficulty kept together, even though almost twice the quantity of timber is employed that would otherwise be necessary. The strength of such a wheel depends on the thicknees of the iron tire or rim that surrounds it, and hence the carriage is loaded with an uneles weight, both of wood and iron. To obviate these inconveniences, Mr. Viny invented the process for bending timber into a circular form, practised for some time by Messrs. Jacob and Viny, and is now continued by others. In wheels made of timber thus bent, the rim confines either of a single piece of wood, or two fellies only, and is cased with a single hoop of iron. By this mode of construction, the grain of the wood is kept parallel throughout, so that the periphery of the wheel is everywhere equally strong; its thicknees is considerably leffened, inasmuch that though little more than half the usual quantity of timber is employed, the wheel is of itself strong enough to sustain the common burden laid on such wheels, without the assistance of iron tires, which are only applied to them as a safe-guard, to prevent the wood from the injuries to which it would otherwise be necessarily exposed from the roads; and hence a less quantity of iron is sufficient, and even that will be fairly worn out before it becomes useless. Besides, the wheel is rendered much lighter, and at the same time much stronger and more durable, than wheels constructed of detached pieces of wood and iron, in the usual manner. These patent wheels are very superior to the common fort, in their neat light appearance, and in the length of time they wear, as two fets of the former will wear as long as three of the latter: their preservation depends very much on the hoops that the wheels are rimmed with. Some persons still prefer the common fort of wheels, on account of their being more easily repaired than the hoop-wheel; but though the repairing of the latter is more difficult, they are much less subject to need it.

As the rims of wheels wear fonnet at their edges, they should
should be made thinner in the middle, and fastened to the fellies with nails of such a kind, that their heads may not rise above the surface of the rim. The fellies on which the rims are fixed should, in carriages, be three inches and a quarter deep, and in waggons four inches. The naves should be thickest at the place where the spokes are inferted, and the holes in which the spokes are placed should not be bored quite through, as the grease upon the axle-tree would infinate itself between the spoke and the nave, and prevent that close adhesion which is necessary to the strength of the wheel.

The track in which the wheels of every carriage are to run is generally the same, except when intended for particular roads, where waggon and other heavy carriages are principally used, and leave very deep ruts, in which light carriages must likewise run, or be liable to accident, and are also sure to be heavy in draught. All four-wheel carriages should have the hind and fore wheels regulated to roll in the same track. The ordinary width of the wheels is four feet eight or ten inches; that of waggon or carts generally measure five feet two inches; chaise-wheels, as being principally intended for the country, are adapted to this width.

It is immaterial to what width wheels are set if used for running upon stones; but on marly roads, if their exactness is not attended to, the draught is considerably increased. We have seen a carriage of which the iron axle-tree is made in two pieces, overlapping each other in the middle where they are joined, and secured by proper bands to the wood-work of the carriage, so as to admit of sliding in the direction of the axle-tree. These parts are cut with teeth like racks, and a pinion is applied between them; so that by turning this pinion round, the two parts of the axle-tree are made to slide one upon the other; and the wheels which are fitted upon the two extreme ends of the axle-tree can at pleasure be fixed at greater or less distance, as the roads require.

The different heights of hind and fore wheels make also a difference in the length of their axle-tree, agreeable to the proportion they bear to one another; the fore-wheel has the longest axle-tree by one or two inches between the shoulders.

The nave of the wheel is pierced through the centre, with a large hole to introduce the box, or iron tube, for the axle-arm, as this tends to weaken the wood. It has been frequently proposed to make metal naves, or centre-pieces for wheels, which should contain the box for the axis, and the mortises for the spokes of the wheel all cut of one piece of metal. Miers, Dodson and Skidmore had a patent for this in 1799. The objection to it, is, that, if the wood of the spokes shrinks, they become loose in the mortises, whereas a wooden nave shrinks at the same time with the spoke. This defect has been since remedied by making the metal wheel-flock in two parts; one with receffes, or sockets, to contain the spokes, and the other a flat plate to fasten against the former with screw-bolts, and press the spokes into their cavities.

Mr. Plucknett had a patent for a metal wheel-flock of this kind in 1805, which answered extremely well for carts, waggons, and artillery. The spokes were made to fill up all the space in the nave or flock, so that each spoke touched its neighbour. The metal flock was only a flat circular plate, or flanch, projecting from the box which received the axle, and another flat plate fitted upon it, and bound against the former by screw-bolts, one passing through each arm; these rendered the wheel very strong.

Mr. Wilks took a patent in 1813 for a metal flock, in which there are complete cells for each spoke, and the cells are dove-tailed; that is, they are made larger at the central part than at the outside, to prevent them from drawing out, and they are firmly pressed into the dove-tails by the screw-bolts which confine the moveable plate.

Wheels for railway-waggons are made of cast-iron, and usually all in one piece; but this is objectionable, because the unequal contraction of the arms and rim of the wheel in cooling, after the wheel is cast, puts the different parts on a strain, and they frequently break without any adequate force. It is better to cast the rim in one piece and the arms in another, and put them together with screw-bolts, or rivets.

Mr. Hawks had a patent for this in 1807. In this way, the rims may be replaced when worn out.

The Axle-trees for Wheels of Carriages.—The strong iron bar which extends across beneath the wood-work of the carriage, is called the axle-tree; the round parts at each end, on which the wheels run, are called the axle-arms; and the part or item between them, which is fixed beneath the wood-work of the carriage, is also called the axle-tree. In the form of the latter parts there are but two forts, the one made flat, and called a bedded axle-tree, it being sunk all its length in the under side of the timbers of the carriage; the other is made of an octagon form, and flat only at the ends where they are bedded.

The axle-arms on which the wheels turn should be made perfectly round, and somewhat stronger at the shoulder than at the extreme end, which is fixed to receive a nut, through which and the axle-tree the linch-pin passes, to keep them all tight. The nuts are made with a collar at the face; and a temporary collar, or washer, is driven on the back of the arms, which form two shoulders for the wheel to wear against, and helps to prevent the grease from running out, and to prevent dirt from getting in.

As the axle-trees are the principal or only support of the carriage, every attention and care should be fixed in the selection of good iron; and to see that they be well wrought, and of sufficient strength, rather going to the extreme of strength, than risking the life of the passenger by the over-fetting of the carriage, which mostly happens when an axle-tree breaks.

By the bend of the axle-trees, the wheels are regulated to any width at bottom, to suit the track of the roads in which they are to run, and are confined in the carriage by means of clips, hoops, and bolts. The shape of the axle-tree between the shoulders varies according to the situation they are placed in, or the form of the timber of the carriage with which they are united; those are the most firm that are flat, or bedded in the timber. Axle-tree boxes for wheels are of various kinds; those which are frequently called long-pipe, or wheel-boxes, are long tubes fitted accurately to the arms of the axle-trees, and securely fixed in the wheel-rocks, or naves; they are usually made of wrought sheet-iron of a substance proportioned to the weight of the carriage; their use is to contain a supply of grease, and to prevent the effects of friction, whereby the wheels are much afflicted in their motion. These are now used instead of the old cast-iron boxes, which for quick travelling-carriages are totally out of use, being found injurious to the axle-trees, by cutting them at those parts they wear against, so as to occasion a frequent lining of the arms; but with the wrought metal boxes this is seldom necessary.

There are many forts of axle-trees and boxes invented various ways, with a view of attaining the following advantages; viz. To contain a longer supply of grease or oil, to be more durable, to secure the wheels, and to lessen the draught. Those are all certainly great advantages, and though the expense is great, the utility of either of them must be more than adequate to it, and merits more general notice.

Some
Some of these inventors even pretend that all these advantages are combined in one axle-tree; but the generality extend to the advantage only of retaining a supply of oil, and remaining perfect to a considerable length of time. The common form of axle-tree and box, which is most generally used, is simple and cheap in comparison with the others.

Common Axle-tree.—The arms of the axle-tree are made round, but rather of a conical form, strong at the back or shoulders, tapering to the line end, which is screwed for a nut, and also has a small hole for a linch-pin, which prevents the nut from coming off: at the body-end is a washer or collar for the back of the wheel-flock to wear against. The box is made of sheet-iron, proportioned in substance to the weight or size of the axle-tree, having the edges of the plate, of which it is formed, welded in a ridge which projects on the outside; this secures the box in the nave of the wheel, and prevents it turning round therein.

The nut which screws on the end of the axle-arm has a broad face to lie flat against the wheel, and is tapped or screwed to receive the screw-end of the axle-tree. Each of these nuts must turn on the screw the same way the wheel goes, and must have a notch for the linch-pin to pass through, for the purpose of securing the nut from turning off.

The box is what, of the axle-tree, wears most, and is frequently obliged to be refitted to the arms; otherwise they give to the wheel while in use an unsteady motion, and soon exhaust their flock of grease.

Those that are well fitted will contain their supply for about one week with regular use, or a journey of one hundred miles. They wear at the rate of one set of boxes to every two fets of wheels, and require in that time to be twice or thrice taken out of the wheels and refitted to the axle-tree arms.

Axle-trees with Friction-Wheels.—These were invented by Mr. Garnet, at least the best kind, which are made in a very ingenious manner. The wheel-box is made much larger than the axle-tree, in such manner that the space all round between them may receive a number of rollers which fill it up. (See a description in the article Mill-Work.) Mr. Garnet had a patent in 1784, and for some years manufactured great numbers; but being very expensive, they fell into disuse, although very complete. This invention has been lately revived by Mr. Panter.

The Patent Anti-Attrition Axle-tree and Box.—The proposed advantages of this axle-tree are, ease of draft by diminution of friction; the retention of oil to supply a month's use; the ease with which it is replenished without taking off the wheels; the great security for the wheels, which it prevents from coming off, and the carriage from overturning, if even the arm of the axle-tree should break; and their durability, and even improvement by wear. Tho' axle-trees, if made with the securing-collar, for the wheels need no nut or linch-pin, as is generally used, but the wheel may be taken off and put on as easily as tho' on the common principle.

These axle-arms are reduced at the bottom from a perfect round, and grooved, to receive two small rollers, on which the weight of the carriage is borne, and which greatly facilitates the motion, in the same manner as blocks of stone or timber, which require to be removed by the affittance of rollers. These rollers form the outer circumference of the axle-trees at bottom, which are reduced to give a bearing only on them. A circular box or cistern is provided to contain a supply of oil; it is closely fitted to the back of the inner end of the wheel-flock, and fixed by three bolts.

The oil is here contained within three circular recesses, and oozes through small channels on the arm of the axle-tree, which it feeds for a considerable time. This oil-box is made of cast-metal, and has a cap projecting behind the axle-tree, which prevents the dirt from getting into the box. This axle-tree is also provided with what is called the wheel-security, or strap-washer. It is an iron collar, fitted on the external part of the wheel-stock, and confined between the referror and flock, lying as it were in a groove, so that the collar cannot come off. This collar has two lugs or straps extending backwards some distance along that part of the axle-tree which is bedded in the wood-work, where it is fixed by a nut-screw. By means of this strap-washer, the wheel is secured to the bedded part of the axle-tree; and should the axle-arm within the wheel break, the wheel will continue to act.

The cap of this axle-tree is also fixed on the outside part of the wheel-stocks; by the same three bolts which fasten the oil-box, and by means of a screw-plug in the cap, the axle-tree and referror are replenished with oil.

The box is of the same form as the common box, only made of a very hard durable metal, of a considerable thickness, and is made in proportion to the weight of the carriage.

Collinge's Patent Cylinder Axle-tree and Box.—These axle-trees have been a considerable time in use, and their advantages have been proved in the length of time they wear, in the silent and steady motion they preserve to the wheels, in the advantage of retaining the oil to prosecute a journey of two thousand miles without being once replenished; and lastly, they are very durable, and but little subject to be out of order.

The axle-tree arm is made as perfectly cylindrical as possible, and of a peculiar hard substance; the middle of the cylinder is reduced, to contain the oil necessary to feed the axle-trees; so that the two bearings are at the two ends of the axle, which has an internal shoulder, against which the inner end of the wheel-box takes its bearings. Behind this shoulder is a deep groove for a washer to preserve the oil, and prevent noise in its use; also a rim, or hollow box, on the collar of the axle-tree, which overlaps part of the inner end of the wheel-flock to keep out dirt, and anwser the use of a cuttow. The extreme end of the arm is double-screwed, to receive two nuts for securely the wheel: the one screw turns the way of the wheel; the other the reverse, and is meant as an additional security.

The box is made of a-very hard metal, nicely polished, and fitted to the arms, having a circular recess all round at the end nearest the carriage, for containing there a supply of oil. The box is longer than the part which bears on the axle; and the projecting part beyond the bearing at each end is bored out larger than the arm. The back projection fits close to the rim of the collar, which it covers: the fore one projects outwards beyond the surface of the wheel-flock, and is screwed on the inside to receive the screw of the cap.

There are many other patents for axle-trees to wheels; but as few of them have come into use, we shall only notice Messrs. Flight and Brook's patent axles. The axle is fixed fast to the nave of the wheel, by passing through it. This axle turns round within the wheel-box; whereas in others the wheel-box turns round upon the axle.

The axle is cylindrical, and is received into a cylindrical box or tube in the end of the iron axle-tree, which is firmly bolted to the under side of the timber of the carriage. To hold the axle in its place, and prevent it from drawing out of the box, the end of the axle is reduced to a knob or button, which adheres to the end of the axle by a small neck.

Vol. XXXVIII.
neck. This button is fitted and received into a socket, in which it can freely turn round, but cannot draw out endways. It is made in a piece of metal, which is cylindrical on the outside, and of the same fize as the axle. It is made in two halves, which separate longitudinally to introduce or take out the button at the end of the axle; but when the two halves are put together, the socket-piece forms as it were a continuation of the axle. When the axle is put into the box with this socket-piece at the end of it, the two halves of the socket will be confined together, so that they cannot separate; and to prevent them from drawing out of the box, a screw-bolt is put through the box, and passes through both halves of the socket: this holds the socket and the axle in their places.

Mr. Ackermann has recently obtained a patent (1818) for a valuable improvement in the application of the forewheels to four-wheeled carriages. In our article Coach-Making, vol. viii. we have described those methods which were then known of applying the fore-wheels, fo as to make a four-wheel carriage turn with safety, and in a small space. See also Perch.

Mr. Ackermann's improvement consists in this in the most perfect manner. Each of the fore axle-trees is connected with the carriage by means of a vertical axle, formed in the fame piece with the horizontal axle, and upon which the wheel turns, the two halves being situated at right angles to each other. These vertical axles are fitted into sockets, formed at the two extremities of a crofs beam of the frame of the carriage, which is called the fore-spring transom. Upon these axles, as centres of motion, the axle-arms and wheels can be turned about horizontally, in order to place them obliquely to the direction of the hinder-wheels when the carriage is required to turn; but each axle turns upon a separate centre of motion, and these centres are very near to their respective wheels, being at the extremities of the crofs-beam or transom; hence the fore-wheels do not change their place upon the ground when they are placed obliquely.

In a common carriage, the axles of the two fore-wheels are both fixed to one piece of timber, called the axle-bed, which is placed beneath the fore-tranform, and united to it by a vertical pin called the perch-bolt, passing through the middle of the axle-bed. On this pin, as a centre, the axle-bed is turned round. When the wheels are to be placed obliquely, it is evident, that, in so turning upon a single centre, one wheel must advance forwards, and the other must retreat backwards, fo as to diminish the bearing of the carriage-wheels on the ground in a lateral direction, and at the same time the horses are pulling in that direction which tends to overturn the carriage. Another inconvenience is, that one of the wheels will touch the perch of the carriage, if placed very oblique.

In the new improvement, two separate centres of motion being used, and these being removed from each other as far as possible, many defirable properties are attained.

To give the oblique direction to the wheels, each vertical axle has a lever proceeding backwards from it; and these two levers are united together by a connecting-bar, which oblige both axles to move at the same time with a sympathetic action. The pole of the carriage is united to the piece, called the futchel, in the usual manner; and the futchel is united to the spring-tranform by a perch-bolt, in the usual position; also the hinder end of the futchel is joined to the middle of the connecting-bar, between the two levers of the vertical axles. The connecting-bar likewise answers the purpose of a fway-bar.

When the horses move to one side, the pole and futchel turn upon the perch-bolt, as a lever upon a centre of motion; and the extreme end of the futchel acts upon both vertical axles at once by means of the connecting-bar, fo as to place both of the fore-wheels in an oblique direction. This is the invention of M. Lankenperger of Munich.

Wheel, Arifofla's. See Rota Arifotelica.

Wheel, Blowing, a machine contrived by Dr. Defagu-liers for drawing out the foul air of any place, or for forcing in fresh, or doing both successively, without opening doors or windows. See Phil. Trans. N° 437.

The intention of this machine is the fame as that of Dr. Hales's ventilator, but not fo effectual, nor fo convenient. See Defagul. Course of Exper. Philof. vol. ii. p. 553. 568.

This wheel is also called a centrifugal wheel, because it drives the air with a centrifugal force.

Wheels, Baffes or Boxes of; the infide metal linings of the naves. See Wheel.

Wheel, Cutting Roller, in Agriculture, a tool of the cutting and reducing fort, ufed for the purpose of working over crops in some cafes. In Oxfordshire a cutting roller of this fort has been invented, which is composed of twelve wheels, two inches and a half in thickness; and between each of them is a space of two inches and a half. They are three feet in diameter. It is a load in working fo as to be sufficient exertion for a strong team to draw it; it is paved over wheat after it has been fown, or after it is come up; and if dry, crofs and crofs. It has also been ufed in the spring upon wheat; it leaves the surface rough in a fort of diamond forms, which is found very beneficial in some of the wheat-lands of that diftriet. It is also capable of being ufed in breaking down the surface of stiff tillage-land in many other cafes and circumstances.

Wheel, Draining, a wheel constructed for the purpose of cutting or making drains. Wheels differently formed are ufed for this fort of work. In Essex they employ workmen who make use of a cast-iron wheel which weighs about four hundred weight, and which is four feet in diameter; the cutting edge or extreme circumference of the wheel being half an inch in thickness, which increses in this way as it approaches towards the nave or centre; and will, at fifteen inches deep, scour out or cut a drain half an inch wide at the bottom, and four inches wide at the top. The wheel is fo placed in a frame, that it may be loaded at pleasure, and be made to pass to a greater or lefs depth, as the nature of the land may be.

The writer of the Middlefex Report on Agriculture advises the ufe of a common fix-inch cart-wheel, on theelly of which, all round, a fort of ridge-formed addition of wood is to be fixed, and a rim of iron of a triangular shape fastened to the wood. A wheel of this kind put on the axle of a cart, in the usual way, will, of course, reit on the edge of the rim of iron; and which, on driving the horse forward, will make a small indent or depression in the ground merely by the revolution of it; but in order to make it press down to the depth of fix or eight inches, that side of the cart shoild be loaded with stones, iron ballaft, or any other heavy material that may happen to be at hand, until the whole of the parts, if neceffary, sink into the soil. It would however be as well, or better, it is faid, if the rim parts added to the wheel were in one piece of cail-iron; as the increased weight of it would enable it to cut or sink without the aid of ballaft, or with lefs than usual. The cart shoild then be drawn along in such a manner, that the cutting or deprefling wheel may revolve where the drains are intended to be made. In land that is ridges and furrows, it will sometimes be neceffary to draw the wheel along every furrow.
furrow. When the ground is without ridge and furrow, the wheel should be drawn over it in parallel lines, five or ten yards distant from each other. The wheel on the other end of the axle is a common fix-inch wheel, supporting only the empty side of the cart, consequently will not cut or depress the ground.

The advantage of this contrivance is, that it makes an indent or depression in the surface of soft wet clayey grass-lands, sufficient to carry off the water during the famine winter, by prefling down the furrow and herbage without destroying it. In the following spring, these drains will be nearly grown up, and clothed with grass; consequently, there will be nothing taken from the pasturage or the leythe. It is necessary to observe, that the wheel must be drawn over the ground every year on the approach of winter. With it, and two old horses, a stout boy or man may, it is said, drain from ten to twenty acres in eight hours.

It may be found very useful in the grazes and hay land districts about the metropolis and other places. See Surface Draining.

Wheel, Measuring. See Perambulator.
Wheel, Offreyus's. See OFFREEUS.
Wheel, Perian. See PERSIAN.
Wheel, Ploughs, in Agriculture, all such ploughs as are constructed with wheels. See Plough.

Wheel, Potter's, is a round board attached to a lattice, and capable of being moved by it, either rapidly or more slowly, as occasion may require. This round board moves in a horizontal position; and when in use, the clay which is to be fashioned is fixed on the centre of it; and it is put in motion either by a person who constantly attends it when at work, or by means of a treadle which is moved by the foot of the workman himself.

As the clay revolves upon this machine, the workman either models it by his fingers, or forms it, by means of an instrument which he holds in his hand, into any kind of circular shape that he may desire; and when the object is to make a number of vessels exactly similar to each other, the size is generally determined by a gauge fixed without the circumference of the revolving wheel, but projecting over it in such a manner that, whenever the yielding clay is spread out until it touch this gauge, the artist knows that the article which he is making has attained the exact figure which he intends.

The potter's wheel has lately been much improved by adapting a flap to it, which passes over a large taper cylinder of wood, and by means of which the artist is enabled to increase or diminish the rapidity of the motion at pleasure. This contrivance is known to mechanics by the name of the cone pulley. Parke's Elays, vol. iii. See Pottery.

Wheels, Tires of, the iron hoops or bars which are put round the outides of the felly-parts of them.

Wheel, Water. See Water.

Wheel is also a name of a kind of punishment, which great criminals are put to in divers countries.

In France, their affilins, paricides, and robbers on the highway, were condemned to the wheel; i.e. had their bones first broken with an iron bar on a scaffold, and then to be exposed and left to expire on the circumference of a wheel. In Germany, they broke their bones first on the wheel itself.

This cruel punishment was unknown to the ancients; as is observed by Cujas. It is not certain who was the inventor. Its first introduction was in Germany. It was, indeed, but rarely practised any where else, till the time of Francis I. of France; who, by an edict of the year 1534, appointed it to be inflicted on robbers on the highway. Richelet dates the edict in the year 1538, and quotes Brodeus, Miscell. lib. ii. cap. 10.

Wheel, in the Military Art, is the word of command, when a battalion or squadron is to alter its front, either one way, or the other.

To wheel to the right, the man in the right angle is to turn very slowly, and every one to wheel from the left to the right, regarding him as their centre; and vice verfa, when they are to wheel to the left.

When a division of men are on the march, if the word be, wheel to the right, or to the left; then the right or left-hand man keeps his ground, turning only on his heel, and the reft of the rank move about quick, till they make an even line with the faid right or left-hand man.

Squadrons of horse wheel after much the fame manner.

In wheeling, the circle is conceived to be divided into four parts; whence wheeling to the right or left respects only a quarter of a circle; and wheeling to the right or left about, refers to half of the circle. In performing this motion, each man moves more quickly or slowly, according to his distance from the right to the left. See Battalion.

Wheel, or Catherine-Wheel, in Architecture, frequently occurs in the upper part of the north and south transepts of our ancient cathedrals, being divided by mulions, like the spokes of a wheel: it resembles the engine of torture said to have been prepared by the tyrant Maximin to tear the flesh of St. Catherine of Alexandria. The French, who have generally placed a large wheel of this fort by way of a western window to their cathedrals, call it Rèfe du Portail.

Wheel-Animals, Brachionus, in Zoology, a genus of animacules, which have an apparatus of arms for taking their prey. (See Brachionus.) This apparatus has been supposed, by microscopical writers, to be a kind of wheels. This is one of the smaller animacules; and is described by Dr. Hill to be, when at rest, of a plain smooth body, conic figure, obtuse at the posterior extremity, and open at the anterior, of a dull olivine olive, and semi-transparent. When in motion it protrudes from the open extremity a part of its naked body, to the whole of which this outer conic body seems to be but a cafe or sheath; from the end of this exerted part of the body, it thrauls out two proubrances, which give it the appearance of a double head; and in each of these is discovered an apparatus in continual motion, appearing to be a rotatory one, though really a vibratory one very quickly repeated. Each of these protruded bodies has five arms injected into it, which it continually shuts and opens over one another. Each of the arms is furnished with a double series of fibres at its edge, which, being expanded, cause it to spread to considerable breadth. There are several species of this genus.

The wheel animal, described by Mr. Baker, has two seeming wheels, with a great many teeth or notches coming from its head, and turning round as it were on an axis. On the least touch, this animacule draws its wheel into its body into the sheath; but when every thing is quiet, throws them out and works them again.

In order to find these animacules, choose such roots of duck-weed as are long, and proceed from thence old plants, for the young roots seldom afford any; they should not be covered with that rough matter which is frequently found about them, nor any way tending to decay, as they will often be.

In the water found remaining in the leaden pipes, or gutters on the tops of houses, there are also found great numbers
numbers of these wheel-animals. These are of a different species from the former; and when the water dries away, they contract their bodies into a globular or oval figure, and are then of a reddish colour, and remain mixed with the dirt, growing together in a lump as hard as clay. This, whenever it is put in water, in half an hour's time discovers the animals' living again, and as briskly as ever; and they have been found to be living in this manner, after the matter had been kept dry twenty months.

It should seem from this, that as the water dries up, their pores become shut in the manner of those of such animals as remain torpid for the winter; and that when they find water come on again from rain, they then unfold themselves, and live and feed as long as it lasts. Baker's Microscope.

Wheel-Barometer. See Barometer.

Wheel-Boats denote a sort of boats with wheels, to be used alternately on the water and upon inclined planes or roadways.

Wheel-Fire, among Chemists, a fire used for calcining metallic substances; properly called ignis rotus.

It is a fire which only encompasses the crucible, coppel, or melting-pot, around the sides, without touching it in any part.

Wheel-Shaped, in Botany, a term exclusively appropriated to the corolla. See Rotata.

WHEELER, among Brickmakers. See Brick.

WHEELER, in Geography, a river of Wales, which runs into the Clyde, 3 miles N. of Denbigh.

WHEELING, a post-town of Virginia, at the union of Wheeling Creek with the Ohio; 54 miles S.W. of Pittsburgh.—Also, a township of Ohio, in the county of Belmont, with 676 inhabitants.

Wheeling Creek, a river of Virginia, which runs into the Ohio, N. lat. 39° 56'. W. long. 80° 45'.

Wheeling Planks are float planks which the navigators or workmen upon a canal make use of to wheel upon.

WHEELock, in Geography, a township of Vermont, in the county of Caledonia, containing 963 inhabitants; 60 miles N. of Windsor.—Also, a river of Cheshire, which runs into the Dane.

Wheelwright Gut, a creek on the north-west coast of the island of St. Christopher, with a bar before its entrance.

WheeZing and Blowing, in Animals, a sort of affection in the breathing, especially in horses, in which they draw their breath with difficulty and noise.

The generality of people make this and purfiness in horses, the same disease; but the more judicious always distinguishes it, as wholly different from that. Purfiness proceeds always from a stuffing or oppression of the lungs; but this wheezing is only owing to the narrowness of the passage between the bones and gristles of the nose.

The horses that are most of all afflicted with this distemper do not want wind; for notwithstanding that they wheeze excessively when they are exercised, yet all the time their flanks are not moved, but kept in the same condition that they were when the creature stood still. The dealers call this sort of horses blowers, and though there is no real harm in the thing, it is a disagreeable quality, and few people will choose them that have much service for them.

There are some horses which have a natural defect in their breathing, which makes it at all times attended with some difficulty, but not with the wheezing before mentioned; these are called thick-winded horses.

People who are careful in the buying of horses, will purchase neither of these kinds; but there is this caution to be observed in regard to this defect, that it often seems to be in horses where it really is not. When a horse has been kept a long time in the stable without exercise, he will at the first rising be out of breath, and fetch it in a difficult and painful manner, though he be neither a blower nor thick-winded; but all this will go off with a little exercise.

There are some temporary blowers and blazers among horses; these at times rattle, and make a great noise through their noses in taking breath; but the complaint goes off and returns. This is only occasioned by a great quantity of phlegm, for their flanks do not redouble with it at the word of times, nor have they any cough with it; so that there is no danger of their being purgy.

It is probable, that in these cases there is, for the most part, some fort of phlegm or concretion in the chests of the animals, as they are much relieved in moist influences by the use of warm mashes, and by having their fodder made moist.

How far remedies that remove phlegm might be useful has not yet been fully tried, either in these or other forts of animals.

WHELDY-ahad Lake, in Geography, a lake of North America. N. lat. 61° 40'. W. long. 103° 30'.

Gen. Ch. Cal. Perianth inferior, of one leaf, in five deep, roundish, erect, permanent segments, shorter than the corolla. Cor. of one petal, bell-shaped, spreading, in five deep, ovate, acute segments. Nectary somewhat pitcher-shaped, in the bottom of the flower. Stam. Filaments five, awl-shaped, rather longer than the corolla; anthers roundish. There are five other filaments, alternate with the former, and similar to them, but shorter, and defitute of anthers. Pyl. Germen superior, conical, vilious; style thread-shaped, twice the length of the corolla; stigma simple. Peric. Drupa roundish. Seed. Nut large, ovate, of one, two, or three cells.

Some flowers, on the same plant, want the pistil, others the stamens.

This is Schreber's generic description, from which we learn, without difficulty, the natural order of the plant. But it is one of those genera, like his Villaria, (see that article,) which cannot be determined without an examination of the author's herbarium. Such also are his Meyera, already described; his Wolfia, and Xystris, which will occur hereafter. We trust some botanist, who may have the opportunity of clearing up these, the only important obscurities in Schreber's classical work, will favour the world with an explanation of them. Spartina is in the same predicament, except that professor Schrader appears to be acquainted with it. See that article.

WHELKS, Buccina, in Natural History. See Shells, and Trumpet-Shell.

Whelps. See Hound.

Whelps, in a Ship. See Capstan.

Whennuia, in Geography, a small island among those called the Society islands, near Otahe.

WHERLICOTES, a sort of open chariots, of the ancient Britons' invention, used by persons of quality before the invention of coaches.

Whern,
WHERN, in Natural History, a name given by some of our miners to a kind of stone found in Hurra, but of the hardnes and fineness of flint. It is called allo chert and nitrina.

WHERRY. See Vessel, Boat, &c.

Wherry, in Rural Economy, a provincial term applied to a liquor made from the pulp of crabs after the verjuice is exprifed. It has not unfrequently the name of crabwherry. See VERJUICE.

WHERWELL, in Geography, a village of England, in the county of Hants. Here was formerly a convent of nuns, founded by Eftilda, widow of king Edgar, to expiate the murder of her first husband, Ethelwulf, and her fon-in-law, prince Edward; 4 miles S. of Andover.

WHET-SLATE, or Whetstone Slate, and Hone, French novacuité, phible calcite, in Mineralogy, a variety of flate used for sharpening iron and fleel instruments. (See Slate.) The light green coloured variety from the fenerate is confidered as the most valuable. It is brought in maffes to Marfells, and is there cut into pieces of various fizes, and afterwards ground with sand or sand-stone, and then polifhed with pumice and triploli. These whet-planes or hones should be kept in damp places, for when much expofed to the fun, they become too hard and dry for many purpofes. The powder of whet-flate is used for cutting and polishing metals, and is by artifts confidered as a variety of emery. It is neceffary to the perfection of hones, that they should contain no intermixt substances, fuch as quartz, &c. (Jamefon's in Mineralogy, second edition, vol. 1.) Whet-flate, approaching in appearance to foreign hones, occurs in the upper part of Long Sleddale, in Welfmoreland; and at Howe, in Dublin bay.

WHET-STONE, in Rural Economy, the soft flone fecondly made use of in sharpening edge-tools of different kinds.

WHEWER, in Ornithology, a name used in some parts of England for the common figeon. See DUCK.

WHEY, the ferum, or watery part of milk.

In many diforders of the human body, where the fomach will not bear milk, or when it is not proper, for other reafons, whey may be given with great fuccefs.

We have a defcription of Fred. Hoffmann on this fubjed, De Saluberrima feri Laftis Virtute. Oper. tom. vi. p. 9. This author recommends a particular kind of ferum or whey, made by evaporating milk to a drynefs, and mixing the refiduum with water. See MILK.

There are various methods of making whey, vulgarly known. That with oranges is very agreeable, and much recommended by Dr. Cheyne, in his Nat. Method of curing Difeafes.

WHEY, in Rural Economy, a term applied to the ferior part of milk, from which the curd has been separated. There are two forts or colours of whey, the green and white; the latter is by much the richer, and that which chiefly affords the bitter of this kind. See DAIRYING.

WHEY, Alum. Serum Aluminium, a whey made with alum; in the proportion of two drachims of alum to one pint of cow's milk boiled. This whey is beneficial in an immoderate flow of the menses, and in a diabetes, or exceflive discharge of urine. The dofe is two, three, or four ounces, as the fomach will bear it, three times a day.

WHEY-Butter, which is made from the cream of whey. It is commonly made in abundance in the dairy dis- tricts after cheese-making begins. See DAIRYING.

WHEY-Cream, which is collected from off the whey and made into butter of this fort. A dairy cow ufually affords eight or ten ounces of it weekly in some dairies. See DAIRYING.

WHEY, Muffard, is made by boiling of bruifed muffard feed, an ounce and a half, in milk and water, of each a pint, till the curd is perfectly separated, and draining the whey through a cloth. This, says Dr. Buchan, is the most elegant, and by no means the lead efficacious method of exhibiting muftard: it warms and invigorates the habit, and promotes the different fcercrations. Hence, in the low flate of nervous fcercrations, it will often supply the place of wine; it is alfo of ufe in the chronic rheumatism, palfy, dropfy, &c. The dofe is a tea-cupful four or five times a day, which may be sweetened with a little fugar.

WHEY, Scalding, of the heating of it and pouring it over the curd in making cheefe.

WHEY, Scorbutic, is made by boiling half a pint of the scorbutic juices, in a quart of cow's milk. The scorbutic plants are, bitter oranges, brook-line, garden feeru-grafs, and water-crellies.

WHEY Springy Cheefe, the ceyy spongy cheefe of this fort, camed by being improperly made.

WHEY Tub, the vefel in which the whey stands for yielding the cream, &c.

WHICHCOTE, BENJAMIN, in Biography, an eminent divine of the English church, was born in March 1603, 16, of an ancient family at Whichcote-hall, in Shropshire; and having finifhed his education at Emanuel college, Cambridge, in 1626, he pasfed through the common degrees, and became fellow of his college in 1633, and a distinguihed tutor. In 1636 he took orders, and established a lecture at Trinity church, in Cambridge, and continued in it for nearly twenty years. It was his great objeft to subftitute a spirit of fober and rational piety in the university, instead of the enthufiasm and fanaticifm which then prevailed; nor were his efforts for this purpofe unavailing. Being married, and having settled on a living in Somerfifh, his connection with the university was for fome time interrupted; but in 1644 he returned to it, as the successor of Dr. Samuel Collins, the ejected provoft of King's college, allowing to him part of the emoluments that belonged to this office. In 1649 he took the degree of D.D., and was prefented to the rectory of Milton, in Cambridgefhire. He is repreffed by bishop Burnet as a friend to liberty of confeffion, and in order to promote rational and ftimulating ideas of religion, he advised the fudents to perufe the ancient philosophers, efpecially Plato, Cicero, and Plutinus. At the Reformation he was deprived of his provoftship, and re- moving to London, he was chosen minifter of St. Anne's, Blackfriars, in 1662. Afterwards, when his church was burnt down, he retired to Milton, but he was recalled to London to the vicarage of St. Lawrence, Jewry, by prefentation from the crown; and he ferved this church with great reputation till his death in 1683.

After his death, a volume of his "Select Sermons," 8vo. 1698, was published, with a preface by lord Shaftesbury, author of the "Charactefitics," by whom they were valued, becaufe the author recognized that fene of the beauty of virtue which is the foundation of his moral fystem. Two more volumes were afterwards published by Dr. Jeffery, archdeacon of Norwich, who, in 1703, prefented to the public "Moral and Religious Aphorifms collected from Dr. Whichcote's MS. Papers." A fourth volume was published by Dr. S. Clarke in 1707, and reprinted in 1753 by Dr. Salter, with large additions, and eight letters between the author and fome of his friends on impofant fubjefts.
These several publications assigned to Dr. Whichcote a high rank among the rational divines of this country, and particularly at the period in which he lived. Biog. Brit.

WHICKS, in Agriculture, a term sometimes applied to young plants of the white-thorn kind, as well as to couch-grasses. See Quick's and Couch.

WHIDAH, in Geography, a kingdom of Africa, on the Slave Coast; extending about ten miles along the coast, and about seven miles into the land. Europeans who have been in Whidah speak of the country with rapture, and extol it as one of the most beautiful in the world. The trees are straight, tall, and disposed in the most regular order, which preëst to the eye fine long groves and avenues, clear of all brusk-wood and weeds. The verdure of the meadows, the richcnes of the fields, clothed with three different kinds of corn, beans, roots, and fruits, and the multitude of houes, form a most delightful prospect. A perpetual spring and autumn succeed each other; for no sooner has the husbandman cut his corn, than he again ploughs and sows the ground; yet it is not worn out; the next crop puts forth with the same vigour as the former, as if nature here were inexhaustible. Certain it is, that the kingdom of Whidah is so populous, that one single village contains as many inhabitants as several entire kingdoms on the coast of Guinea; and yet they stand so close, that one is amazed how the most fertile land on earth can supply the number of people contained in so small a compass. One may compare the whole kingdom to a great city, divided by gardens, lawns, and groves, instead of streets, the villages in Whidah not being a mufket-shot distant from each other. Some are the king's, some the vicerey's villages, and others are built and peopled by particular private families. The former are the largest and best built; but the latter the best cultivated, if there be any difference in a country so uniformly rich and beautiful. Notwithstanding the small extent of this kingdom, it is divided into twenty-six provinces, which take their names from the capital towns. Thosc small states are distributed among the chief lords of the kingdom, and become hereditary in their families. The king of Whidah, who is only their chief, presides particularly in the province of Sabi, or Xabier, which is the principal province of the kingdom, as the city of the same name is the capital of the whole. Buis, which the French by corruption call bauges, pass frequently for money at their fairs in the country; this is a small white shell, of the fize and shape of an olive. In the kingdom of Whidah and Ardra, these buis serve equally for drefs and money, for ornament and use. They pierce each shell with an iron made for that purpose; forty of them they fling upon a cord, which they call feuze, and the Portuguese toquen: five of these strings compose what the Portuguese call a gallinba, and the Negroes a fore. By the exchange of gold-duft is rated, and the price of slaves determined. The Europeans, the nobility of Whidah, and all the rich negroes, are carried, when they go abroad, in hammocks, or palanquins, on the shoulders of slaves. The natives of Whidah are in general tall, well made, straight, and robust. Their complexion is black, but not so gloomy as that of the people on the Gold Coast, and still less than those of Senegal and the river Gambia. They exccl all other negroes in industry and vigilance. Idlenes is the favourite vice of the Africans in general; here, on the contrary, both sexes are so laborious and diligent, that they never dream till they have finished their undertaking; carrying the same spirit of perseverance into every action of their life. Besides agriculture, from which none but the king and a few persons of the first distinction are exempted, they employ themselves in several kinds of manufactures: they spin cotton-yarn, weave fine cotton cloths, make calabashes, wooden vessels, plates, and dixies; likewise assaguys, and smiths' work in greater perfection than any other people on the coast. Whilft the men are thus employed, the women brew pito, and dress provifions, which, with their husbands' merchandize, they carry for sale to market. As to religion, Bofman is of opinion, that the piety of this country is founded upon no other principles than thofe of interest and superflition. In the latter, they exceed all other nations; for allowing, says he, the ancient heathens to value themselves upon thirty thousand deities, I dare venture to affirm that the natives of Whidah may lay just claim to four times that number. However, he believes that they have a faint idea of the one true God, to whom they attach omnipotence and ubiquity. One of their principal fetiches, or deities, is the snake, which they invoke in extreme wet, dry, or barren feafons, on all occasions relating to their government, civil policy, and cattle; in a word, on all the great difficulties and occurrences of life. This snake has a large round head, beautiful piercing eyes, a short pointed tongue, resembing a dart: its pace flyow and felement, except when it feizcs on its prey, then quick and rapid; its tail fharp andhort, its skin of an elegant smoothness, adorned with beautiful colours, upon a light-grey ground. It is amazincly tame and familiar, permitting itself to be approached, and even handled: they have a mortal antipathy to all venomous serpents: they attack them wherever they find them, as if they had pleasure in delivering mankind from their poison. The Europeans find no difficulty in familiarizing themselves to these inoffensive animals, with which they play without any dread or apprehension of danger. There is no fear of miftaking them for the poisonous ferpents, the colour and size sufficiently distinguishing them. The negroes entertain a notion that the firft progenitor of this race of snakes is still living, and growing to an enormous bulk. When the English firft settled in Whidah, the captain having unhitched his goods on fhore, the sailors foon found at night one of thofe snakes in their magazine, which they ignorantly killcd, and threw upon the bank, without dreaming of any bad confequences. The negroes, who foon discovered the fact, and had it confirmed by the acknowledgment of the English mariners, were not long in avenging the horrid impiy, by a method no lefs horrible. All the inhabitants of the province assembled; they attacked the English, maffacred them all to a man, and confumed their bodies and goods in the fire they had fet to the warehouse. Animals of all kinds are punished with death for injuring a snake. In 1697, a hog having had the precarious to destroy one of these deities, an order was flied for a general slaughter of swine throughout the kingdom, and the deflruction of the whole race was hardly prevented by the interposition of the king.

WHIDAH, a town of Africa, in the country of Whidah. N. lat. 6° 25'. E. long. 1° 24'.

WHIDBY'S ISLAND, an island in the Gulf of Georgia, near the west coast of America; about 36 miles long, and from 2 to 6 broad: fo named from Mr. Whidby, an officer under captain Vancouver. N. lat. 48° 10'. E. long. 237° 40'.

WHIDDY, an island in Bantry bay, in the county of Cork, Ireland, about 2 miles from the town of Bantry. It is a pleafant island of a triangular form, and the foil is exceflent.

WHIFF, in Ichtyology, the name of a fort of scounnder.

WHIFFLER of a Company, in London, a young free-
WHIG, in Rural Economy, a term provincially applied to acidulated whey, which is sometimes mixed with butter-milk and sweet herbs, to give it a flavour, when it becomes a good cooling summer beverage.

WHIGS, a party or faction in England, opposite to the Tories.

The origin of the names of these two mighty factions is very obscure. If some little trivial circumstance or adventure, which escapes the knowledge of mankind, gives name to a party, which afterwards becomes famous, polterry labours in vain to find the original of such a name; it searches the sources, forms conjectures, invents reasons, and sometimes, indeed, meets the truth, but always without knowing it assuredly.

Thus, in France, the Calvinists are called Huguenots; yet nobody was ever able certainly to assign the cause of that appellation. Whig is a Scotch term, and, some say too, an Irish word, literally signifying a bee. Tory is another Irish word, signifying a robber or highwayman.

Under the reign of King Charles II., while his brother, the Duke of York, was obliged to retire into Scotland, there were two parties formed in that country. That of the Duke was strongest, perfecuted the other, and frequently reduced them to fly into the mountains and woods; where those unhappy fugitives had often no other subsistence for a long time but cows' milk. Hence they called those their adversaries tories, q. d. robbers; and the tories, upbraiding them with their unhappiness, from the milk on which they lived, called them swhigs. From Scotland, the two names came over with the Duke into England.

Others give a different origin and etymology of the two words, for which see TORIES.

Bishop Burnet gives another etymology of the term swhigs. The south-west counties of Scotland, he says, are fupplied with currants from Leith; and from a word swigam, used by the carriers in driving their horses, all that drove were called swigmanours, and by contraction, swhigs.

He adds, that in the year 1648, after the news of the defeat of Duke Hamilton, who was charged with being a confederate with the malignants, or royal party, in England, the minifters animated their people to rise, and march to Edinburgh: who came up, marching each at the head of his parish, with an unheard-of fury, praying and preaching all the way as they came. The marquis of Argyle and his party came and headed them. This was called the swigmanour's inroad; and ever after, all that opposed the court were contemptuously called swhigs: and from Scotland the term was brought into England. Burnet's Hist. of Own Times, vol. i. p. 43:

For the distinguishing principles and characters of the whigs, see TORIES.

WHIMBRAL. See Scolopax Guarauna, and Pheopus.

WHIMSEY, Water, a machine consisting of a reservoir, or bucket of water, employed for raising another bucket, filled with coals or other materials, by means of a rope or chain, called round a cylinder or drum, or two drums of different sizes. When the bucket of water in this machine has reached the bottom of the pit or well, a valve is opened by striking against a pin, and lets out the water. In a machine of this kind, used in the Duke of Bridgewater's coal-works, the water descends thirty yards, and raises a smaller quantity of coals from a depth of sixty. In such cases, supposing the action to be single, and the stream of water to be employed during the descent of the reservoir, a considerable preponderance may be advantageously employed in giving velocity to the weights, provided that the machinery be not liable to injury from their impulce.

WHIN, in Botany. See Gorse.

WHIN, in Agriculture, a term sometimes applied to force; which, when cut in the lap and bruised in a proper way by flails, or in other modes, makes an excellent green food in winter for horses, which eat and thrive on it well. It is also useful in some measure to sheep-flock, as well as to bees. Its encroach on land may be safely and readily prevented by proper means being taken for the purpose. See Furze.

WHIN, in Gardening. See Ulex.

WHIN-After, in Agriculture and Planting, the ashes produced in burning whins; which have lately been found of great benefit in planting young trees, as well as on land for other purposes, promoting their growth in a very high degree. If the land to be planted be suitable, they are advised to be carefully spread and plunged in, if of quantity sufficient, over the whole field, otherwise only on the wet or colder spots or parts of it. But if the ground be such that it will not admit of plunging, the ashes should be mixed with part of the bell surface mould, to keep them from blowing abroad; and in the process of pitting, a little of this compound should be intimately mixed with the mould of each pit; previously distributing it in small heaps at convenient distances for facilitating the operation: and this extra trouble will be amply repaid by the progress the plants will make in consequence.

WHIN-Axe, in Agriculture, an instrument employed for extracting whins from land in many places. It is an implement that has one end like a common axe, with four inches of face; and the other like an adze, also with four inches of face; whereby the person using it, continuing in the same position by firmly turning it in the hand, can make cuts at right angles with one another, as circumstances may require. The head of the tool may be about eight inches in length, weighing from three to four pounds; and the handle, of ash, about four feet long.

WHIN, Petty, a name given to a species of ononis, or reed-harrow.

WHIN, Petty, in Gardening. See Genista.

WHINCHAT, in Ornithology, the English name of the Motacilla rubra of Linnaeus.

It is of the common size of the water-wagtail. Its head, neck, and back, are of a reddish-brown, with regular rows of black spots. Over each eye is a narrow white stroke, and beneath that a broad bed of black, extending from the bill to the hind part of the head; the breast is of a reddish-yellow; the belly paler; the quill-feathers are brown, edged with a yellowish-brown; the upper part of the wing is marked with two white spots; the lower part of the tail is white; the two middle feathers excepted, which are wholly black; the upper part of the other is of the same colour.

The colours are very uncertain in this bird, and it often much resembles the stone-chatter; but may always, by an accurate observer, be distinguished from that bird by the white spots in its wings, by the whiteness of the under part of its tail, and the white lines on its head.

The colours of the female are much less agreeable than those of the male; in lieu of the white and black marks on the cheeks is one broad pale brown one; and the white on the wings is in much less quantity than that of the male.

In the north of England, the whinchat is a bird of passage;
fage; in the south he continues the whole year. Ray and Pennant.

WHINE, a hunting term, used in respect of the cry of an otter.

WHINEBACH, in Geography, a town of Africa, on the Gold Coast. N. lat. 5° 30'. W. long. 1° 30'.

WHIN-STONE, in Geology, the provincial name given, in many parts of England and Scotland, to bafaltic rocks: it is also applied by miners to designate every kind of dark-coloured and hard unstratified rock, which refits the point of the pick. Many geologists in this country class all bafaltic or trap rocks under the term whin-stone. See Trap.

The substance which fills very large mineral veins is generally dark bafalt, or green-flone; hence these veins are most frequently called whin-dykes. These veins being harder than most of the rocks which they interfect, remain when the surface on each side of them is washed away, forming enormous walls extending into the sea, or rising above the level of the country in various parts of their course, and may often be traced for many leagues. They occur in the counties of Northumberland and Durham, and on the coasts of Scotland; and when broken down, they form reefs of rock or islands. The Farm îlands, off the coast of Northumberland, are parts of a bafaltic dyke. When whin-dykes cross rivers, they form ledges of rock consisting of fords; or, if very abrupt, they hold up the water on one side and form cascades. The Cleveland bafalt, or whin-dyke, described by Mr. Bakewell's Introduction to Geology, (see Veins, Mineral,) has been traced from the coast of Yorkshire seventy miles into the western part of Durham.

Under the article Mineral Veins, we have observed, that when whin-dykes interfect coal strata, they produce a change in the substance of the coal, and also of the other strata, similar to what might have been expected from a stream of melted lava; and we have recently observed a similar effect produced on primitive rocks of gneifs, in the vicinity of Aberdeen, by contact with a powerful whin-dyke. The whin-stone is also changed near its contact with the gneifs into a reddish horn-flone. In other parts, it is a dark granular bafalt or green-flone. The gneifs have lost its characteristic structure, and becomes porphyritic when near the whin-dyke. Between whin-dykes and the rocks which they interfect, there is sometimes a seam of soft argillaceous earth interposed, which is washed out when they are near the sea-coast, leaving the whin-stone like a wall placed between two perpendicular precipices. Sometimes the internal part of a whin-dyke will be composed of soft iron-clay; in other instances, the dyke will be composed of solid blocks or prisms of bafalt separated by similar clay. In some whin-dykes, the substance which fills them appears a compact and solid mass of whin-stone, which, however, will divide into four, five, or six Prisms, arranged horizontally.

These are perfectly similar to the perpendicular basaltic columns in structure, differing only in their position. There is a dyke traversing the bafaltic strata of the Giant's Causeway, on the coast of Antrim, in which this peculiarity of structure is remarkably displayed. It interfects beds of columnar bafalt, in which the columns are arranged with great regularity, and are perpendicular to the horizon; but the whole dyke is composed of small prisms of bafalt placed horizontally, or at right angles with the former. Some of these prisms do not exceed an inch in diameter, others are much larger; they are for the most part extremely regular, and are articulated or jointed.

It has been supposed with much probability, that the different arrangement of the columnar structure in the beds and in the dyke, is to be attributed to the different circum-

stances under which they were solidified. If the beds have once flowed as lava under the surface of the ocean, the bafalt would begin to cool and crystallize from the upper and lower surface. That this has probably been the case may be inferred from these beds resting on strata that contain marine organic remains, and which must, therefore, have been formed under the bed of the ocean.

The perpendicular dykes intersecting rocks already formed would begin to cool from the sides with which they were in contact, and the process would proceed laterally.

In some instances, we find whin-dykes principally composed of globular masses of stone separated by a large quantity of soft clay, and the globular masses are incrust with ochreous clay: probably the whole of the clay in such dykes has been formed from the decomposition of the basaltic masses by the action of water percolating them.

Whin-stone dykes present so many analogies with volcanic rocks in their composition, and the effects which they produce on the strata that they pass through, that we are led to infer their origin to the action of subterranean fire cracking the upper rocks and strata, and forcing the melted matter into the rent. Under the article Volcano, we have stated many instances of vall rents made in the earth, and filled by eruptions of lava; these rents filled with lava may be considered as whin-dykes of recent formation. This is further confirmed by the observations of M. Cordier, (see Volcanic Productions,) who has shown that the substance which fills both are essentially the same, being principally composed of felspar and augite, with iron-lannd and olivine. Whin-stone not only occupies the cavities of perpendicular dykes; but it appears to have been, in many instances, found laterally between the regular strata, producing singular conlocations and dislocations, and almost always effecting a change in the substance of the rock with which it comes in contact. Sometimes it produces a change in the form of the bed or stratum which it has passed through, breaking it into distinct masses, or bending it in different directions, or enveloping large parts of it in the bafalt or whin-stone. Of this a remarkable instance is described in the third volume of the Transactions of the Geological Society, occurring on the north coast of Ireland, in the county of Antrim. (See Plate IV. fig. 4. Geology.) a a represents a bed of chalk singularly bent, and completely enveloped in the bafalt which forms a part of the basaltic range extending from the Giant's Causeway.

The beds of chalk and the other strata on this coast are frequently intersected by whin-dykes, and a most remarkable change is observed in the structure of the chalk in the vicinity of these dykes. In immediate contact with the whin-stone, and to a considerable distance on each side, the chalk is converted into marble, having the granular texture of primitive lime-flone, or what the French call calcaire facaroid, from its resemblance to the grain of loof-fugar, (see Plate IV. fig. 5. Geology,) which represents two adjoining whin-dykes a b, intersecting the chalk c. The dyke a is thirty feet in width, the dyke b twenty feet, and the intervening mafs of chalk twenty feet. The mafs of chalk between the two large dykes is intersected in a zigzag direction by a smaller dyke. To a certain distance from the whin-stone, the chalk is perfectly crystalline, but it gradually approaches to the character of the chalk at a greater distance from the dyke. In various parts of the world we observe trap or whin-stone occurring in apparently regular beds, either covering stratified rocks, or interposed between them; such have been called by the Wernierian geologists flintz trap-rocks, and their occurrence in this position has been urged as an argument for the aqueous formation of such
such rocks. But it is well known to practical miners, that these beds are much more variable in their thickenss than the regular stratæ, sometimes measuring twenty, thirty, or forty feet or more; and in other parts, the same bed will diminish to a few feet, or entirely terminate. In the isle of Skye, according to the description of Dr. Macculloch, in the third and fourth volumes of the Transactions of the Geological Society, the whin-flone is spread over the regular stratæ in beds, or forms detached conical caps. It is also to be seen interposed between the stratæ, and may be traced for more than a mile in continuous regular beds; but, says Dr. Macculloch, "there are no inclusions where the alternating beds of trap detach veins or dykes from the lower to the upper beds; or the trap, quitting the interval between two given beds of lime-flone or sand-flone, makes its way across the one immediately above or below, and then proceeds with a regularity as great between some other pair of proximate stratæ." And he adds, "I have no doubt, could such extensive exposure of the stratæ be offerent procured, all the inclusions of supposed alternating trap with regular stratified rocks would prove similar to the above." These observations, which might be confirmed by numerous other instances, tend to prove, that whin-dykes, and many of the interposed stratæ of whin-flone, are of posterior formation to the rocks in which they occur, and have been forced between the stratæ in a fluid state, and subsequently consolidated. The whin-dykes, or perpendicular veins, are the channels through which the basalt flowed up; but by superincumbent pressure, it has been driven laterally at different elevations. As beds of whin-flone occur in different rocks, it is probable, and almost certain, that they have had different epochs of formation; and of course some of the beds of whin-flone, which are covered by stratified rocks containing many organic remains, may have flowed as beds of lava under the ocean, and have been again covered with other stratæ, on which again a second torrent of lava burfting from below may have flown and formed an upper bed. It is well known that the beds of toad-flone in Derbyshire, which are interposed between the mountain lime-flone of that district, cut off the metallic veins; but they are found again on sinking through the toad-flone into the lower lime-flone. This flone, which varies from a hard, compact whin-flone or trap, to a soft amygdaloidal wacke, (see Toad-Stone and Wacke,) is supposed, by Mr. Whitehurst, to have flowed between the beds of lime-flone after the formation of metallic veins; and, could we admit the hypothesis, it would satisfactorily explain the cause of their disapperance in the toad-flone. But though there are many inclusions of the vein entirely disapperacing in the latter rock, there are others in which a narrow vein passes through the toad-flone, though it is never productive of ore, being filled with calcareous spar, and a few particles only of galine. The occurrence of these veins in the toad-flone proves that this rock was not found between the lime-flone after the formation of metallic veins. Some softer whin-flone rocks, of the species called by mineralogists wacke, (see Wacke,) contain cavities lined, or partly filled with zeolites, agates, or calcarceous spar; and some of these rocks envelope marine organic remains, particularly a rock of this kind near Berykley in Gloucestershire. The Euganean mountains are composed of a similar rock, and also contain marine remains. These rocks have probably been formed by muddy eruptions of sub-marine volcanoes, similar to what take place from some of the American volcanoes at the present time; and it is not improbable but that these two modes of formation may have given rise to that diversity which we observe in rocks of this class, the softer and more earthy being the products of Vol. XXXVIII.

**W H I**

**Aqueous and muddy eruptions, and the harder and more crystalline the products of igneous fusion. See Trap, and Volcanic Products.**

**WHIP, or Whip-Staff, in a Ship, a piece of timber in form of a strong staff, fastened into the helm, for the steerer, in small ships, to hold in his hand; thereby to move the rudder, and direct the ship.**

**WHIP denotes also a sort of small tackle, formed by the communication of a rope either with a single immovable block, or with two blocks, one of which is fixed, and the other moveable. It is generally used to hoist light bodies, as empty casks, &c. out of a ship's hold, which is accordingly called whipping them up. Falconer.**

To **whip** is to tie a piece of pack-thread, spun-yarn, &c. about the end of a rope, to prevent it from being untwisted and unloosed.

**Whip, in Rural Economy, the lash attached to flexible rods or other substances and contrivances, for the purpose of driving teams.**

**Whip-Grafting, in Gardening, a particular mode of performing the operation. A sort of root-whip-grafting is advised by Agricola, in which a graft or scion is taken from a young tree, and a small piece of the root of another tree of the same kind, or like it; or otherwise, pieces of roots cut off from other trees in transplanting: these are whip-grafted together, taking care that the two but ends of the graft and root be united, and that the resid of the root join that of the graft; then plant the root with the part of the scion underground. See Grafting, and Stocks, Apple-grafting in.**

**Whip-Poor-Will. See Caprimulgus Virginianus.**

**Whip-Rein, in Agriculture, a term used to signify a rein formed of cord or leather, by which a plough or other sort of team is directed in working. See Rein.**

**Whip-Rein-Plough, a term applied to a small plough, drawn by two horses, or oxen, which are guided and directed by proper reins of this sort, and so made as to serve the ploughman in the way of a whip, in driving them while he holds the plough.**

**Whip-Saw. See Whip-Saw.**

**WHIPLADE, in Husbandry, a term used by the farmers in some places for a particular sort of cart, whose hinder part is made up of boards after the manner of a dung-cart, having also a head of boards, and a shamble over the thills; this head being so as either to be taken out or left in. The cart may be indifferently used to carry dung or other things; dung when the head is in, and corn, &c. when it is taken out.**

**WHIPPANY, in Geography, a town of New Jersey; 20 miles W.N.W. of New York.**

**WHIPPER. See Fishing.**

**WHIPPING, a term used by Anglers, when they fasten a line to the hook or rod.**

The word is also taken for the casting in of the hook, and drawing it gently on the water.

**Whipping, in Law, denotes an ignominious punishment inflicted on perfons guilty of petty larceny, &c.**

**Whipping Wheat, in Agriculture, a term applied to the practice in some of the northern districts, by which the wheat-crops are lashed or whipped out on a wooden or wattle frame-work contrived for the purpose. The former is constructed by nailing two or more thick boards in a flaiting manner, to the height of about two and a half, or three feet, on a sort of frame of suitable strengthe, supported by legs, having the upper part a little rounded, and made smooth. This, which is termed the whipping or lashing frame, is placed**
placed in some convenient situation, so as to prevent the grain from flying about during the operation, which is then begun. Where the latter contrivance is made use of, the frame is woven with strong flitches, in the manner of a hurdle, being placed in the same situation when used.

The process is performed by taking large handfuls of the corn in the straw by the butt end, and striking the top or ear-ends over the upper part of the frame, so as to force out the grain from the ears of the top part, without breaking the straw, which in this way becomes much better for thatch, and at the same time the grain is less injured than by the flail method of threshing it out. The butt parts of the straw are sometimes afterwards thrashed over, in order to get out any wheat that may have been left in the short ears. This is an excellent mode of providing feed-wheat, as the finest grain is chiefly procured.

And it is suggested, too, as a particularly good method in cafes where wheat is infected with the smut, as during the operation of threshing, the flail breaks the smut-balls, and reduces them to a powdery flake, which causes the good wheat to have a blacker appearance than would otherwise be the case when ground. It may likewise be used to advantage with other sorts of grain in some cafes.

The above is also a term sometimes applied in the northern districts, to the practice of striking it over a flake or other such contrivance, in order to get out the grain, and leave the straw in an unbroken flake. In this way it is sometimes termed flaking. It is an excellent practice in getting out this sort of grain in many points of view, when on a small scale, but it is not well suited to large concerns. See Thrashing.

WHITTLE-TREE, a term used to signify the bar or wooden part of the contrivance by which a horse or team is attached to a plough, harrow, or any other sort of implement of these kinds. They are of different sizes and forms, according to the nature of the teams and other circumstances. See SWINGLE-TREE, Indented.

WHIPSTITCH, a term not unfrequently used in ploughing to signify a sort of half-ploughing, or what in many places is termed raftering. It is principally made use of for keeping the land more dry and healthy in the winter season. See RAFTERING.

WHIPSTITCHING, the practice of working tillage-land in somewhat the raftering manner. It is a method often employed for turning up flubbles of the wheat and other kinds in the winter time, instead of making a fallow. The best mode of doing it in this intention is first to make what is called a whiplitch, rafter, or sort of half-ploughing of the land; and that when come back again to the same furrow, to turn them both over; the top parts of both furrows being thus turned in the middle, which leaves the space of four inches betwixt each furrow; then ploughing the land across the old furrows. If land lies ever so wet in winter, by ploughing in this manner, it may be kept dry and in a healthy state. It is necessary, too, to strike up the old furrows every day before leaving the ground; and to let the main drains be kept well open to receive the water from the furrows in the land; by this means, the frost will be admitted four inches deeper than in the case of a flat fallow-work.

This mode of tillage is that which is sometimes called double whipstitching in some districts and places.

Some prefer it before all other methods for winter-tillage, as it brings the land into much better condition for cultivation than twice fallowing.

WHIT SYLLABUB. See SYLLABUB.

WHIRL-POOL, an eddy, vortex, or gulf, where the water is continually turning round. See GULPH, EDDY, VORTEX, &c.

These in rivers are very common, from various accidents, and are usually very trivial, and of little consequence. In the sea they are more rare, but more dangerous. Sibbald has related the effects of a remarkable marine whirlpool among the Orcades, which would prove very dangerous to strangers, though it is of no consequence to the people who are used to it. This is not fixed to any particular place, but appears in various parts of the limits of the sea among those islands. Wherever it appears, it is very furious, and boats, &c. would inevitably be drawn in and perish with it; but the people who navigate them are prepared for it, and always carry an empty vessel, a log of wood, or large bundle of straw, or some such thing, in the boat with them; as soon as they perceive the whirlpool, they toss this within its vortex, keeping themselves out; this substance, whatever it be, is immediately received in the centre, and carried under water; and as soon as this is done, the surface of the place where the whirl-pool was becomes smooth, and they row over it with safety; and in about an hour they see the vortex begin again in some other place, usually at about a mile distant from the first. Sibbald's Prod. Hist. Scot.

WHIRLING-TOBE, in Military Antiquities, a machine contrived for exhibiting and demonstrating the principal laws of gravitation, and of the planetary motions in curvilinear orbits. A A (Plate XXI. fig. 13. Astronomy) is a strong frame of wood, B a winch fixed on the axis C of the wheel D, round which is the catgut-fitting F, which also goes round the small wheels G and K, crossing between them and the great wheel D. On the upper end of the axis of the wheel G, above the frame, is fixed the round board d, to which may be occasionally fixed the bearer M S X. On the axis of the wheel H is fixed the bearer N T Z, and when the winch B is turned, the wheels and bearers are put into a whirling motion. Each bearer has two wires, W X and Y Z, fixed and feretive tight into them at the ends by nuts on the outside; and when the nuts are unscrewed, the wires may be drawn out in order to change the balls U, V, which slide upon the wires by means of brass loops fixed into the balls, and preventing their touching the wood below them. Through each ball there passes a silk line, which is fixed to it at any length from the centre of the bearer to its end by a nut-ferew at the top of the ball; the flanks of the screw going into the centre of the ball, and pressing the line against the under side of the hole which it goes through. The line goes from the ball, and, under a small pulley fixed in the middle of the bearer; then up through a socket in the round plate (S and T) in the middle of each bearer; then through a slit in the middle of a square top (O and P) of each tower, and going over a small pulley on the top comes down again the same way, and is at last fastened to the upper end of the socket fixed in the middle of the round plate above-mentioned. Each of these plates, S and T, has four round holes near their edges, by which they slide up and down upon the wires which make the corner of each tower. The balls and plates being thus connected, each by its particular line, it is plain that if the balls be drawn outward, or towards the ends M and N of their respective bearers,
bearers, the round plates S and T will be drawn up to the top of their respective towers O and P.

There are several brass weights, some of two, some of three, and others of four ounces, to be occasionally put within the towers O and P, upon the round plates S and T; each weight having a round hole in the middle of it, for going upon the sockets or axes of the plates, and being fit from the edge to the hole, that it may slip over the line which comes from each ball to its respective plate.

For a specimen of the experiments which may be made with this machine, we shall subjoin the following.

1. Removing the bearer M X, put the loop of the line b, to which the ivory ball a is fastened, over a pin in the centre of the board d, and turn the winch B; and the ball will not immediately begin to move with the board, but, on account of its inactivity, endeavour to remain in its state of rest. But when the ball has acquired the same velocity with the board, it will remain upon the same part of the board, having no relative motion upon it. However, if the board be suddenly stopped, the ball will continue to revolve upon it, until the friction thereof stops its motion; so that matter retains every change of state, from that of rest to that of motion, and vice versa.

2. Put a longer cord to this ball; let it down through the hollow axis of the bearer M X and wheel G, and fix a weight to the end of the cord below the machine; and this weight, if left at liberty, will draw the ball from the edge of the whirling-board to its centre. Draw off the ball a little from its centre, and turn the winch; then the ball will go round and round with the board, and gradually fly farther from the centre, raising up the weight below the machine; and thus it appears that all bodies revolving in circles, have a tendency to fly off from these circles, and must be retained in them by some power proceeding from or tending to the centre of motion. Stop the machine, and the ball will continue to revolve for some time upon the board; but as the friction gradually stops its motion, the weight acting upon it will bring it nearer and nearer to the centre in every revolution, till it brings it quite thither. Hence it appears, that if the planets met with any resistance in going round the sun, its attractive power would bring them nearer and nearer to it in every revolution, till they fell into it.

3. Take hold of the cord below the machine with one hand, and with the other throw the ball upon the round board as it were at right angles to the cord, and it will revolve upon the board. Then, observing the velocity of its motion, pull the cord below the machine, and thus bring the ball nearer the centre of the board, and the ball will be seen to revolve with an increasing velocity, as it approaches the centre; and thus the planets which are nearest the sun perform quicker revolutions than those which are more remote, and move with greater velocity in every part of their respective circles.

4. Remove the ball a, and apply the bearer M X, whose centre of motion is in its middle at w, directly over the centre of the whirling-board d. Then put two balls (V and U) of equal weights upon their bearing wires, and having fixed them at equal distances from their respective centres of motion w and z upon their silk cords, by the screw-nuts, put equal weights in the towers O and P. Last, put the catgut-strings E and F upon the grooves G and H of the small wheels, which, being of equal diameters, will give equal velocities to the bearers above, when the winch B is turned; and the balls U and V will fly off toward M and N, and raise the weights in the towers at the same instant. This shews that when bodies of equal quantities of matter revolve in equal circles with equal velocities, their centrifugal forces are equal.

5. Take away these equal balls, and put a ball of six ounces into the bearer M X, at a sixth part of the distance w z from the centre, and put a ball of one ounce into the opposite bearer, at the whole distance w z; and fix the balls at these distances on their cords, by the screw-nuts at the top: then the ball U, which is six times as heavy as the ball V, will be at only a sixth part of the distance from its centre of motion; and consequently will revolve in a circle of only a sixth part of the circumference of the circle in which V revolves. Let equal weights be put into the towers, and the winch be turned; which (as the catgut-string is on equal wheels below) will cause the balls to revolve in equal times: but V will move six times as fast as U, because it revolves in a circle of six times its radius, and both the weights in the towers will rise at once. Hence it appears, that the centrifugal forces of revolving bodies are in direct proportion to their quantities of matter multiplied into their respective velocities, or into their distances from the centres of their respective circles.

If these two balls be fixed at equal distances from their respective centres of motion, they will move with equal velocities; and if the tower O has six times as much weight put into it as the tower P has, the balls will raise their weights exactly at the same moment: i.e. the ball U, being six times as heavy as the ball V, has six times as much centrifugal force in describing an equal circle with an equal velocity.

6. Let two balls, U and V, of equal weights be fixed on their cords at equal distances from their respective centres of motion w and x; and let the catgut-string E be put round the wheel K (whose circumference is only half that of the wheel H or G) and over the pulley g to keep it tight, and let four times as much weight be put into the tower P, as in the tower O. Then turn the winch B, and the ball V will revolve twice as fast as the ball U in a circle of the same diameter, because they are equi-distant from the centres of the circles in which they revolve; and the weights in the towers will both rise at the same instant, which shews that a double velocity in the same circle will exactly balance a quadruple power of attraction in the centre of the circle; for the weights in the towers may be considered as the attractive forces in the centres, acting upon the revolving balls; which, moving in equal circles, are as if they both moved in the same circle. Whence it appears, that if bodies of equal weights revolve in equal circles with unequal velocities, their centrifugal forces are as the squares of the velocities.

7. The catgut-string remaining as before, let the distance of the ball V from the centre x be equal to 2 of the divisions on its bearer; and the distance of the ball U from the centre w be 3 and a fifth part; the balls themselves being equally heavy, and V making two revolutions by turning the winch, whilst U makes one; so that if we suppose the ball V to revolve in one moment, the ball U will revolve in two moments, the squares of which are 1 and 4; therefore, the square of the period of V is contained 4 times in the square of the period of U. But the distance of V is 3, the cube of which is 27, and the distance of V is 32, the cube of which is 32 very nearly, in which S is contained 3 times; and therefore the squares of the periods of V and U are to one another as the cubes of their distances from x and w, the centres of their respective circles. And if the weight in the tower O be 4 ounces, equal to the square of 2, the distance of V from the centre x; and the weight in the tower P be 10 ounces, nearly equal to the square of 3, the distance
distance of U from \( w \); it will be found, upon turning the machine by the winch, that the balls U and V will raise their respective weights at very nearly the same instant of time. This experiment confirms the famous proposition of Kepler, viz. that the squares of the periodic times of the planets round the sun are in proportion to the cubes of their distances from it; and that the sun's attraction is inversely as the square of the distance from his centre.

8. Take off the rings E from the wheels D and H; and let the rings F remain upon the wheels D and G. Then throw away also the bearers MX from the whirling-board d, and instead of it put on the machine A B (Plate XXI. fig. 14, Aëronomy), fixing it to the centre of the board by the pins c and d, so that the end e may rise above the board to an angle of 30 or 40 degrees. On the upper part of this machine, there are two glass tubes a and b, close stopped at both ends; each tube being about three-quarters full of water.

In the tube a is a little quicksilver, which naturally falls down to the end a in the water; and in the tube b is a small cork, floating on the top of the water, and small enough to rise or fall in the tube. While the board b with this machine upon it continues at rest, the quicksilver lies at the bottom of the tube a, and the cork floats on the water near the top of the tube b. But, upon turning the winch and moving the machine, the contents of each tube will fly off towards the uppermost ends, which are farthest from the centre of motion: the heaviest with the greatest force. Consequently, the quicksilver in the tube a will fly off quite to the end f, occupying its bulk of space and excluding the water, which is lighter than itself: but the water in the tube b, flying off to its higher end e, will exclude the cork from that place, and cause it to descend toward the lowest end of the tube; for the heavier body, having the greater centrifugal force, will possess the upper part of the tube, and the lighter body will keep between the heavier and the lower parts.

This experiment demonstrates the absurdity of the Cartesian doctrine of vortices: for, if the planet be more dense or heavy than its bulk of the vortex, it will fly off in it farther and farther from the sun; if less dense, it will come down to the lowest part of the vortex, at the sun: and the whole vortex itself, unless prevented by some obstacle, would fly quite off, together with the planets.

9. If a body be so placed upon the whirling-board of the machine (fig. 13.) that the centre of gravity of the body be directly over the centre of the board, and the board be moved ever so rapidly by the winch B, the body will turn round with the board, without moving from its middle: for, as all parts of the body are in equilibrium round its centre of gravity, and the centre of gravity is at rest in the centre of motion, the centrifugal force of all parts of the body will be equal at equal distances from its centre of motion, and therefore the body will remain in its place. But if the centre of gravity be not placed over the centre of the board, and the machine be turned swiftly round, the body will fly off towards that side of the board on which its centre of gravity lies. Then, if the wire C (fig. 15.) with its little ball B be taken away from the semi-globe A, and the flat side e of the semi-globe be laid upon the whirling-board, so that the centres may coincide; then if the board be turned over so quickly by the winch, the semi-globe will remain where it was placed: but if the wire C be screwed into the semi-globe at d, the whole becomes one body, whose centre of gravity is at or near d. Fix the pin c in the centre of the whirling-board, and let the deep groove b cut in the flat side of the semi-globe be put upon the pin, so that the pin may be in the centre of A (see fig. 16, where the
trough and balls will go round their centre of gravity, so as neither of them will fly off; because, on account of the equili-

trium, each ball detains the other with an equal force acting against it. But if the ball E be drawn a little more towards the end of the trough at A, it will remove the centre of gravity towards that end from the centre of motion; and then, upon turning the machine, the little ball E will fly off, and strike with a considerable force against the end A, and draw the great ball B into the middle of the trough. Or, if the great ball D be drawn towards the end B of the trough, so that the centre of gravity may be a little towards that end from the centre of motion, and make the machine turned by the winch; the great ball D will fly off, and strike violently against the end B of the trough, and bring the little ball E into the middle of it. If the trough be not made very strong, the ball D will break through it.

12. Mr. Ferguson has explained the reason why the tides rife at the same time on opposite sides of the earth, and consequently in opposite directions, by the following new ex-

periment on the whirling-table. For this purpose, let a b c d (fig. 19.) represent the earth, with its side e turned toward the moon, which will then attract the water so as to raise them from e to g, and in order to show that they will rife as high at the same time on the opposite side from a to e, let a plate A B (fig. 20.) be fixed upon one end of the flat bar D C, with such a circle drawn upon it as a b c d (fig. 19.) in order to represent the round figure of the earth and sea; and an ellipse as e f g h to represent the swelling of the tide at e and g, occasioned by the influence of the moon. Over this plate A B suspend the three ivory balls e, f, g, by the silk lines b, i, k, fastened to the tops of the crooked wires H, I, K, so that the ball at e may hang freely over the side of the circle e, which is farthest from the moon M at the other end of the bar; the ball at f over the centre, and the ball at g over the side of the circle g, which is nearest the moon. The ball f may represent the centre of the earth, the ball g water on the side next the moon, and the ball e water on the opposite side. On the back of the moon M is fixed a short bar N parallel to the horizon, and there are three holes in it above the little weights p, q, r. A silk thread e is tied to the line b, close above the ball g, and passing by one side of the moon M goes through a hole in the bar N, and has the weight p hung to it. Such another thread n is tied to the line i, close above the ball f, and passing through the centre of the moon M and middle of the bar N, has the weight q hung to it, which is lighter than the weight p. A third thread m is tied to the line h, close above the ball e, and passing by the other side of the moon M, through the bar N, has the weight r hung to it, which is lighter than the weight q. The use of these three unequal weights is to represent the moon's unequal attraction at different distances from her, so that if they are left at liberty, they will draw all three balls towards the moon with different degrees of force, and cause them to appear as in fig. 21, in which case they are evidently further from each other than if they hung freely by the perpendicular lines b, i, k. Hence it appears, that as the moon attracts the side of the earth which is nearest her with a greater degree of force than she does the centre of the earth, she will draw the water on that side more than the centre, and cause it to rife on that side; and as she, draws the centre more than the opposite side, the centre will recede farther from the surface of the water on that opposite side, and leave it as high there as she raised it on the side next her. For, as the centre will be in the middle between the tops of the opposite elevations, they must of course be equally high on both sides at the same time.

However, upon the supposition, the earth and moon would soon come together; and this would be the case, if they had not a motion round their common centre of gravity, to produce a degree of centrifugal force, sufficient to balance their mutual attraction. Such motion they have; for as the moon revolves in her orbit every month at the distance of 240,000 miles from the earth's centre, and of 234,000 miles from the centre of gravity of the earth and moon, the earth also goes round the same centre of gravity every month at the distance of 6000 miles from it, i.e. from it to the centre of the earth. But the diameter of the earth being, in round numbers, 8000 miles, its side next the moon is only 2000 miles from the common centre of gravity of the earth and moon, its centre 6000 miles from it; and its farthest side from the moon 10,000 miles. Consequently the centrifugal forces of these parts are as 2000, 6000, and 10,000; i.e. the centrifugal force of any side of the earth, when it is turned from the moon, is five times as great as when it is turned toward the moon. And as the moon's attraction, expressed by the number 6000, at the earth's centre, keeps the earth from flying out of this monthly circle, it must be greater than the centrifugal force of the waters on the side next her; and consequently, her greater degree of attraction on that side is sufficient to raise them; but as her attraction on the opposite side is less than the centrifugal force of the waters there, the excess of this force is sufficient to raise the water just as high on the opposite side.

To prove this experimentally, let the bar D C with its furniture be fixed on the whirling-board of the machine, (fig. 14.) by pushing the pin P into the centre of the board; which pin is the centre of gravity of the whole bar with its three balls e, f, g, and moon M. Now, if the whirling-board and bar be turned slowly round by the winch, till the ball f hangs over the centre of the circle, as in fig. 22, the ball g will be kept towards the moon by the heaviest weight p (fig. 20.), and the ball e, on account of its greater centrifugal force, and the lea weight r, will fly off as far to the other side, as in fig. 22. And thus, whilst the machine is kept turning, the balls e and g will hang over the ends of the ellipse f k. So that the centrifugal force of the ball e will exceed the moon's attraction just as much as her attraction exceeds the centrifugal force of the ball g, whilst her attraction just balances the centrifugal force of the ball f, and makes it keep in its circle. Hence it is evident, that the tides must rise to equal heights at the same time on opposite sides of the earth. See Ferguson's Lectures on Mechanics, lec. 2., and Defag. Ex. Phil. vol. i. lec. 5.

WHIRL-WIND, a wind that rises suddenly, and is exceedingly rapid and impetuous when risen, but is soon spent. In this case, the gusts of wind proceed from different quarters at the same time, and meet in a certain place, where the air acquires a circular, or rotatory, or screw-like motion, either ascending or descending, as it were, round an axis, which axis is sometimes stationary, and at other times moves on in a particular direction. This phenomenon, called a whirl-wind, gives a whirling motion to dust, sand, water, part of a cloud, and sometimes even to bodies of great weight and bulk; carrying them either upwards or downwards, and lastly, scattering them about in different directions.

There are divers sorts of whirl-winds, distinguished by their peculiar names: as, the presser, sphe, turba, exhydra, and ecrephies.

The
The _preyfer_ is a violent wind breaking forth with flashes of lightning. This is rarely observed; scarcely ever without the _euphysis_. Seneca says, it is a _typho_, or _turbo_, kindled or ignited in the air.

The _euphysis_ is a sudden and impetuous wind, breaking out of some cloud; frequent in the Ethiopic sea, particularly about the Cape of Good Hope. The seamen call them _travaden_.

The _exhufia_ is a wind bustling out of a cloud, with a great quantity of water. This only seems to differ, in degree, from the _euphysis_, which is frequently attended with thunderers.

A _typho_, or _vortex_, most properly called a _whirlwind_, or _hurricane_, is an impetuous wind, turning rapidly every way, and sweeping all round the place. It frequently descends from on high. The Indians call it _oruanca_; the Turks, _&c._ _aliphant_. It is frequent in the Eastern ocean, chiefly about Siam, China, &c. and renders the navigation of those parts exceedingly dangerous.

Dr. Franklin, in his Physical and Meteorological Observations, read to the Royal Society in 1756, supposes a whirl-wind and a water-spout to proceed from the same cause; their only difference being, that the latter paffes over the water and the former over the land. This opinion is corroborated by the observations of M. de la Pryme, and many others, who have remarked the appearances and effects of both to be the same. They have both a progressive as well as a circular motion; they generally rife after calms and great heats, and occur most frequently in the warmer latitudes; the wind blows every way from a large surrounding space both to the water-spout and whirl-wind; and a water-spout has, by its progressive motion, paffed from the sea to the land, and produced all the phenomena and effects of a whirl-wind; so that there is no reason to doubt their being meteors arising from the same general cause, and explicable upon the same principles, furnished by electrical experiments and discoveries. See _Hurricane_, and _Water-Spout_.

For Dr. Franklin's ingenious method of accounting for both these phenomena, see his Letters and Papers, &c. vol. i. p. 194, &c. p. 216, &c.

WHISKET, or Whisk, in Rural Economy, a term often used provincially to signify a basket, especially in the northern counties. See _Basket_.

WHISKY, a term signifying water, and applied in the Highlands and islands of Scotland and in Ireland to strong water or distilled liquor. The spirit drank in the North is drawn from barley, and is said to be preferable to any English malt-brandy: it is strong, but not pungent, and free from the repulsive taint or smell.

WHISPERING. See HEARING, ATTENTION, &c.

WHISPERING-PLACE, such as domes and gallerics, depend on this principle, that the voice being applied to one end of an arch, easily paffes by repeated reflections to the other.

Thus, let A B C (Plate XV. _Pneumatics_, fig. 8.) represent the segment of a sphere; and suppose a low voice uttered at D, the vibrations extending themselves every way, some of them will impinge upon the points E, E, &c. and thence be reflected to the points F, F, &c. thence to G, G, &c. till at last they meet in C; where, by their union, they cause a much stronger sound than in any part of the segment whatever, even at D the point whence they first proceeded.

Accordingly, all the contrivance in a whispering-place is, that near the person who whispers there be a smooth wall, arched either cylindrically, or elliptically; in which case he will be heard distinctly by another person, who places his ear pretty near the wall on the opposite side. A circular arch will do, but not so well. It is demonstrated by all the writers on CoNics (which _see_), that if from any point in the circumference of an ellipse two lines be drawn to the foci, those lines make equal angles with one curve at that point. Consequently, the sound which is produced in one focus of an elliptical chamber, and is reflected from the wall to the other focus, makes all the angles of incidence equal to the angles of reflection respectively. Hence that focus is the place where the sound is best heard.

Places famed for the conveyance of whispers are, the prison of Dionysus at Syracuse, which increafed a soft whisper to a loud noise; the elap of one's hand to the sound of a cannon, &c.; the aqueducts of Claudius, which carried a voice sixteen miles; and divers others enumerated by Kircher in his Phosphoria.

The most considerable in England are, the dome of St. Paul's, London, where the ticking of a watch may be heard from side to side; and a very easy whisper be fent all round the dome; this Dr. Derham found to hold not only in the gallery below, but above upon the scaffold, where a whisper would be carried over one's head round the top of the arch, though there be a large opening in the middle of it into the upper part of the dome; and the famous whispering-place in Gloucester cathedral, which is no other than a gallery at the east end of the choir, leading from one side of it to the other. It consists of five angles and fix fides, the middlemost of which is a naked window; yet two whisperers there hear each other at the distance of twenty-five yards. See Birch's Hift. of the Royal Society, vol. i. p. 120. See _Echo_.

WHIST, or Whisk, a well-known game at cards. Mr. T. Matthews, one of the last and moft approved writers on the game of whift, has published (1816) a tenth edition of his "Advice to the Young Whift Player, &c." in which he has comprized, under the detail of 108 maxims, fuch instructions as are neceffary to be observed by thofe who wish to play this game with skill and fuccefs. It would far exceed our limits, if we attempted to follow him in this detail; and an abridgment, if it were practicable, would be of little ufe; nor indeed is it neceffary, as thofe who are defirous of acquiring a knowledge of the minutiae of the game will confer the author, whose "Advice" may be easily and cheaply procur'd. We shall, however, felect fome of thofe instructions that are the moft important, and subjoin thofe laws of the game that ferve to prevent or settle difputes among players.

The following maxims comprehend fome instructions that relate to leads, to which we have annexed fome other directions that are immediately connected with them. It is highly neceffary, fays Mr. M., to be correc in leads. When a good player plays an eight, and then a feven, it may be known that he leads from a weak hand; and the contrary, when he plays the feven firft: the cafe is the fame with a tray or a deuce.

Good players never lead a nine or ten, but for one of these reafons:

1. The safest leads are thofe that are furnished by sequences of threc or more cards; _in which cafe the player is advised to lead the highest, and to put on the lowest to his partner's lead, and to put the highest on his adversary's_; and with a triangle to the king and feveral others, to begin with...
WHIST.

with the knife. If he has no sequences, he is instructed to lead from his most numerous suit; if strong in trumps, to lead rather from one headed by a king than a queen, but with three or four small trumps, Mr. Matthews prefers leading from a single card to a long weak suit. But the players of the old school never lead from a single card without fix trumps. In some cases, Mr. M. observes, this may be occasionally done with very great, though not certain, advantage; e.g., when A has four small trumps, ace, queen, &c. of the second suit; king, knave, &c. of a third; and a single card of the fourth. To lead from three cards, unless in sequences, is bad play, and only proper when you have reason to think it is your partner's suit, and then lead off the highest. Unless, says Mr. M., you have a strong suit yourself, or have reason to suppose that your partner has one, do not trump out unless you have fix trumps. It is generally right to return your partner's lead in trumps, unless he leads a nine or ten, called an equivoque card, because it is led with propriety, both from strong and weak suits.

2. With ace, king, knave, and three small trumps, play the ace and king; with only two, the king, and wait for the finesse of the knave. In other suits, without great strength in trumps, or with the hopes of a particular point, do not wait for the finesse.

3. Ace, king, and five others, lead the ace in all suits. With four or less, the lowest, if trumps. In other suits always the ace, unless all the trumps remaining are with you and your partner; in this case, a small one.

Mr. M. advises not to lead trumps merely because an honour is turned up on your left, nor to be deterred from it if on your right-hand; either, he says, is proper, if the circumstances of your hand require trumps to be led; but neither otherwise.

It is equally advantageous to lead up to an ace as through an ace; not so much fo to a king, and disadvantageous to the queen turned up.

When cards are nearly equal, says this author, the point to which all the manoeuvres of good whist players tend, is to establish a long suit, and to prefer the last trump, to bring it into play, and to frustrate the same play of their adversaries. With an honour (or even a ten), with three other trumps, by well managing them, you have a right to expect succeds. In this case, do not over-trump your right-hand adversary early in the hand; but throw away a losing card, by which, there remaining but twelve trumps, your own hand is strengthened, and your partner has the tenace, in any suit that is led; whereas, had you over-ruffed, you would have given up the whole game, to secure one trick. But there are reasons for breaking this rule: - 1st. If your left-hand adversary has thrown a decided great hand in trumps, (in which case make your tricks while you can,) or 2d. If your partner decidedly means to force you,—to understand if this is the case, you are to observe, if your partner plays the winning or losing card of the suit you have refused. If the former, it is by no means clear he means to force you, and you play your own game. If the latter, you are to suppus he strong in trumps, and depend on this, to protect your long suit: a due reflection on this will convince you of the value of that maxim, which enjoins you never to play a strong game with a weak hand, or vice versa.

It is difficult to judge when to lead trumps. The following situations will affhit the beginner to reason, and in general direct him properly:

1st. With fix trumps, on supposition your partner has a strong suit.

2d. If strong in other suits, though weak in trumps yourself.

3d. If your adversaries are playing from weak suits.

4th. If your adversaries are at the point of eight, and have no honour, or probability of making a trump by a ruff.

With king, queen, ten, &c. in all suits, lead the king; but if it passes, do not pursue the lead, as certain the ace is in your partner's hand, as it is often kept up, but change your lead, and wait for the return from your partner when you have the finesse of the ten, if necessary.

King, queen, and five others, in all suits, the king. With four or less in trumps, lead the lowest. In other suits, always the king, unless you have the two only remaining trumps, if so you may play a small one.

King, knave, ten, &c. in all suits, lead the ten. King, knave, and two or more small ones, the lowest.

You should not lead from king, knave, and a small one, unless it is clearly your partner's suit, in which cases play off your king and knave.

Queen, knave, nine, and others, lead the queen. Queen, knave, with one other, the queen. Queen, knave, with two more, the lowest. Queen, ten, and two others, the lowest. Queen, and three small ones, the lowest. Queen, or knave, with only two, the queen, or knave.

The trump card sometimes occasions a deviation from these rules. A has the ace or king, with sequence from the ten downwards, of the suit of which his left-hand adversary turns up knave, or queen; A should lead the ten. If the knave or queen be put on, you have a finesse on the return with the nine; if not, your partner, with an honour, will pass it, and it is either way advantageous.

That which is denominated under-play, is returning the lowest of your left-hand adversary's lead, though you have the highest in your hand, with a view of your partner's making the third beat, if he has it, and still retaining the commanding card in your hand.

To explain this further, suppose A fourth player, has ace and king of his left-hand adversary's lead; to under-play, he wins the trick with the ace, and returns the small one, which will generally succeeded, if the leader has not the second and third in his own hand. You will see by this, if you lead from a king, &c. and your right-hand adversary, after winning with a ten or knave, return it, you have no chance to make your king, but by putting it on.

The following is another situation to under-play; A remains with the first, third, and fourth cards of a suit, of which he has reason to suppose his left-hand adversary has the second guarded; by playing the fourth, it is often paffed, and A makes every trick in the suit.

When it is at your option to be 8 or 9, it is material always to choose the former score. When at eight, with two honours, look at your adversary's score, and consider if there is a probability they should have their lurch, or win the game, notwithstanding your partner holds a third honour; if not you should not call, as it gives a decided advantage against you in playing for tricks.

Laws of Whist. - 1. If a card is turned up in dealing, the adverfe party on naming it may call a new deal, unless they have looked at, or touched the cards, fo as to have occasioned it; but if any card except the last is faced, it is undoubtedly a new deal.

2. Should any card-player have but twelve cards, and the others their proper number, the deal is good, and he who has the twelve cards pays for any renounce he may have
WHIST.

have made; but if either have fourteen cards, the deal is lost.

3. If the dealer does not turn up the last card, the deal is lost. But if the card is shewn, and falls on its face by accident afterwards, the deal in this case shall stand good.

4. The dealer should leave the last card on the table till he has played; after which nobody can ask for it, though they may inquire what is trumps at any time. Should he leave it on the table after the first round, it may be called, as if thrown by accident.

5. Every person has a right before he plays to call on the players to place their cards before them, which is, in other words, to ask who played them. It is therefore a quibble to say they have no right to make that demand.

6. The partner who reminds his partner to call after the trump is turned up, forfeits a point.

7. If one of the players omit playing to a trick, and remains with a card too many, it is at the option of the adversaries to call a new deal.

8. If A plays out of his turn to his partner's lead, the last player may play before the first: if to his adversary's, his partner may be compelled to, or prevented from winning the trick at their option.

9. Mistakes relative to tricks may be rectified at any time during the game, whether called or not. Also honours, if proved to have been called in time, though not scored; but they cannot be claimed after the trump is turned up.

10. If one party calls at any score but eight, the adversaries may, after consulting, call a new deal: the same, if one calls without two, or the other answers without one honour.

11. If any player calls after he has played, the adversaries may call a new deal; but not consult together.

12. Whoever calls, having only one honour in his hand, should forfeit in proportion to any advantage that actually does or may possibly accrue from the fault. If it should prevent the adversaries from calling, after the hand is played out, the honours shall take place of the tricks.

13. If any person plays out of his turn, the adversaries have the option to call that card at any time, or direct the player whose turn it was, to play any suit they choose.

14. If A, supposing that he has won a trick, leads again before his partner has played to it, the adversaries may oblige his partner to win it, if he can.

15. Any player may call a card from his adversary, if he names it, and proves the separation. Should he name a wrong one, he may have his best or worst card called of any suit played during the deal.

16. Cards thrown down cannot be taken up again; but may be called by the adversaries. They may be thrown down by the player, if sure of every trick.

17. There are in fact four penalties on a revoke, which take place of every other score. The adversaries may take three tricks from the party revoking, or three from their score, or add three to their own; and if there still should remain enough to make the party revoking game, they cannot win it, but remain at nine.

There is often judgment required in taking the penalties of a revoke. Before the score is advanced, if the party revoking has won nine tricks, the least consideration will shew, that the adversaries should take three of them, for if they add three to their own score, they still leave the odd trick to the former; but if the revoking party be at eight, it is better for the adversary to score three points, as the odd trick leaves the former at nine, which is in every respect a worse point than eight. On other occasions, it is only to calculate how the different scores will remain after each mode of taking the penalty; and it will be obvious which will be the most advantageous—never losing sight of the points of the game; i.e. scoring eight or five yourself, or prevent your adversary from doing so.

18. A revoke is not established before the party revoking has played again, or the trick been turned and quitted; but the adversaries, at their option, may call from the highest or lowest of the suit at the time, or the card shewn at any time during the deal.

19. If a revoke is claimed, the adversaries forfeit the penalties of a revoke, if they mix the cards before it is determined.

20. No revoke can be claimed after the cards are cut for the next deal.

21. A cafe having occurred in which A played out of his turn, and B, his partner, was directed to play a trump; but B had another suit, and three or four cards were played before it was discovered that B had a trump in his hand: it was decided, that the cards should be taken up again, and a trump led by B as directed.

22. A cafe occurred in which A called at eight, but his partner did not answer, though he had an honour, because he had a bet on the odd trick. The adversaries contended that the deal should not stand; and reference being made to Mr. M., he decided that the game was fairly won, because there could be no possible advantage made of the circumstance as far as related to the game, though it might as to the trick, if that had been the case referred; and their cafe produced the following law: viz. No one is obliged to answer to his partner's call, even though he has the other two honours in his hand.

23. No player, having three honours in his hand, can be precluded from taking advantage of them at any time previous to his playing a card. This law was grounded on the following cafe; viz. A at the score of eight, on gradually opening his hand, few two honours in it immediately, and told his partner of it, who did not answer: but A continuing to look over his cards found a third honour, and threw them down. It was contended that he had no right to do this, as Mr. M. thought improperly, upon which he proposed the above-mentioned law. We here subjoin a maxim connected with this cafe.

When at eight, with two honours, look at your adversary's score, and consider if there is a probability they should have their lunch, or win the game, notwithstanding your partner holds a third honour; if not you should not call, as it gives a decided advantage against you in playing for tricks.

24. Whoever shall by word or gesture manifestly dis- cover his approval or disapprobation of his partner's mode of play, or ask any questions but such as are specifically allowed by the existing laws of whiff, the adversary shall either add a point to his own score, or deduct one from the party to whom the question was addressed, at his option.

25. It is now settled, that either of the players may insist on the cards being placed at any time previous to their being put together. It is also settled, that where a bet is made, that either of the parties scores two, the bet is won by honour, though the adversary has won the game by cards—supposing it better that A makes two points, if B, his
his adversary, being at seven, makes three by cards, if A has
two by honours, he still wins his bet.
The odds of this game are calculated according to the
points, and with the deal, in the following manner:

Except that 9 is considered as something worse than 8.
It is to 1 in favour of the first game. The odd trick has
been always supposed in favour of the leader; but Mr. M.
is of opinion, that this is an error, as the dealer has the advan-
tage in this, as in every other score.

We shall here subjoin an explanation of two terms that
are universally used, but not generally understood, viz.
tenance and finesse.

"The principle of the tenance is simple. If A has the ace
and queen of a suit, and B, his adversary, has the king and
knave, the least consideration will show that if A leads, B
wins a trick, and vice versa; of course; in every situation it is
the mutual plan of players by leading a losing card to put
it into the adversary’s hand to oblige him to lead that suit,
whereby you prefer the tenace. So far is easily comprehended;
but it requires attention with practice to apply the principle,
so obvious in the superior, to the inferior cards, or
fee that the same tenance operates occasionally with the seven
and five, as the ace and queen, and is productive of the same
advantage. A, last player, remains with the ace and queen
of a suit not played, the last trump, and a losing card: B,
his left-hand adversary, leads a forcing card. Query—How
is A to play?—Answer—If three tricks win the game, or
any particular point, he is not to ruff, but throw away his
losing card, because his left-hand adversary being then
obliged to lead to his suit, he remains tenace, and must make
his ace and queen. But upon a supposition that making
the five tricks gains him the rubber, he should then take
the force, as in these situations you are justified in giving up
the tenace for an equal chance of making any material
point.

"The finesse has a near affinity to the tenace, except that
the latter is equally the object where two, and the former
only where there are four players. A has the ace and queen
of a suit led by his partner, now the dulleft beginner will
see it proper to put on the queen; and this is called finesse
making, and the intention is obviously to prevent the king from
making, if in the hand of his right-hand adversary. Should
it not be there, it is evident you neither gain nor lose by
making the finesse; but few players carry this idea down to
the inferior cards, or see that a trick might be made by a
judicious finesse, against an eight, as a king; but to know
exactly when this should be done, requires more skill than
in the more obvious cases, united with memory and obser-
vation. Another case of finesse even against two cards
frequently occurs, and the reason on reflection is self-
evident.

"A leads the ten of a suit, of which his partner has the ace,
knave, and a small one; B should finesse or let the ten pass,
even though he knows the king or queen are in his left-hand
adversary’s hand, because he prefers the tenace and prob-
ably makes two tricks; whereas, had he put on his ace, he
could make but one—in short, tenace is the game of po-
tition, and finesse, the art of placing yourself in the most
advantageous one.” Matthew’s Advice, &c. ed. 10. 1816.

M. de Moivre has solved this problem: To find the odds
that any two of the partners, that are pitched upon, have
not the four honours? M. de Moivre concludes from this
solution

\[ \frac{476260169700}{15875} = \text{sum} \]

is the common de-
nominator; being
the combinations of
13 in 51.

By the help of these tables several useful questions may be
resolved; as, 1. If it is asked, what is the proba-
bility that the dealer has precisely III trump, besides the
trump card? The answer, by Table I., is \( \frac{4662}{15875} \); and the
probability of his having some other number of trumps is
\( \frac{3}{11213} \).
But if the question had been, what is the probability that some other gamester, the eldest hand for instance, has precisely IV trumps? The answer, Table II., is 104898.

2. To find the chance of the dealer’s not having fewer than IV trumps: add his chances to take o, i, II, which are 39108, 201127, 419592; and their sum 659827 taken from the denominator $1587534$, and the remainder made its numerator, the probability of the dealer having IV or more trumps will be $\frac{659827}{1587534} = \frac{329}{563}$, a little above $\frac{7}{12}$. The wager, therefore, that the dealer has not IV trumps, is so far from equal, that whoever lays it throws away above $\frac{1}{5}$ of his stake.

But if the wager is that the dealer has not V trumps, then $466213$ (the chances of his having IIII besides the trump card) is to be added to the chance for o, I, II; which will make the chance of him who lays this wager to be exactly $\frac{317}{455}$; and that of his adversary $\frac{138}{455}$.

And hence, if wagers are laid that the dealer has not IV trumps, and has not V trumps, alternately; the advantage of him who lays in this manner will be nearly 11½ per cent. of his stakes.

3. To find the odds of laying that the eldest hand has at least III, and at least IV trumps, alternately; the numerator of the one expectation is (by Table II.) $3150119$, and of the other $17514720$, to the denominator $47626017$; whence the advantage of the bet will be $\frac{15}{514}$, or three per cent. nearly.

Again, if it is laid that the trumps in the dealer’s hand shall be either I, II, III, or VI; the disadvantage of this bet will be only $\frac{152.42}{322}$ or about $\frac{1}{3}$ per cent.

In like manner, the odds of any proposed bet of this kind may be computed: and from the numbers in the tables, and their combinations, different bets may be found which shall approach to the ratio of equality; or if they differ from it, other bets may be assigned, which, repeated a certain number of times, shall balance that difference.

4. And if the bet includes any other condition besides the number of trumps, such as the quality of one or more of them; then proper regard is to be had to that restriction.

Let the wager be that the eldest has IV trumps dealt him; and that two of them shall be the ace and king. The probability of his having IV trumps precisely is, by Table II., $\frac{104898}{476200}$; and the different fours in 12 cards are $\frac{12 \times 11}{1} \times \frac{10 \times 9}{3} \times \frac{8 \times 7}{4}$. But because 2 out of the 12 trumps are specified, all the combinations of 4 in 12 that are favourable to the wager, are reduced to the different two that are found in the remaining 10 cards, which are $\frac{10 \times 2}{3}$. And this number is to the former as $1$ to $11$. The probability, therefore, is reduced by this restriction to $\frac{11}{11}$ of what else it had been: that is, it is reduced from near $\frac{1}{5}$ to about $\frac{5}{52}$. De Moivre’s Doctrine of Chances, p. 172, &c. ed. 3d.

WHISTLE, Boatswain’s. See Call.

WHISTLE-Fish, a name given by the people of Cornwall to a species of gadus, with only two fins on the back, otherwise called mulftela fluviatels. See Gadus, and Mustela.

WHISTON, William, M.A. in Biography, an English divine and mathematician, was the son of the rector of Norton near Twycroft, in Leicestershire, and born in the year 1667. He finished his education as a fiater at Clarehall, Cambridge, applying with great diligence to the study of mathematics, and composing devout meditations corresponding to the early bent of his disposition. Having also received the degree of B.A. in 1690, and being elected fellow of his college, he took pupils; and in 1693 became M.A. and entered into holy orders. Soon afterwards he declined the office of tutor, and was appointed chaplain to Dr. More, bishop of Norwich. His acquaintance with sir Isaac Newton commenced in 1694, and produced a change in his philosophical system, from that of Des Cartes to that of Newton. On the principles of this philosophy, he published, in 1696, his "Theory of the Earth," which was refuted by Kell. Having been prelected by his patron, the bishop, to the living of Lowestoft in Suffolk, he resigned his chaplainship, and in order fully to discharge his religious duties procured the affiliation of a curate. Of his invincible and moral scrupulous integrity, he gave an early instance by refusing his vote to a person who solicited a fellowship of Clare-hall, and who had abandoned the bachelorian party with which he was connected, and which he apprehended to be the most powerful, and promised future futility; and giving this reason for his refusal: "Sir, you have conceived that you sacrifices your integrity to your preferment, and thereby have made it impossible for me to serve you." Being obliged to vacate his fellowship by marriage, sir Isaac Newton nominated him his deputy as professor of mathematics, allowing him all the profits of the office; and in 1703 he surrendered to him the professorship itself. Upon this accession, he resigned his living, settled at Cambridge, and was appointed by Dr. More, bishop of Ely, catechetical lecturer of St. Clement’s. Having already published "A Short View of the Chronology of the Old Testament, and the Harmony of the Four Evangelists," and "Jacquet’s Euclid," he presented to the public in 1706 his "Essay on the Revelation of St. John;" and in the following year he preached the Boyle’s lecture sermon on the subject of the Accomplishment of Scripture Prophecies. In the year 1706 he began to entertain doubts concerning the divinity of Christ, and in the prosecution of his inquiries he was led to adopt Arrian opinions, which were further confirmed by the perusal of the "Apostolical Constitutions," reckoned spurious by most writers, but pronounced by Whitton to be "the most sacred of the canonical books of the New Testament." In 1708 he offered an "Essay on the Apostolical Constitutions" to be printed at the University press, but it was rejected; however, in 1709, he published sermons and essays supporting these opinions. His invincible perseverance caused him to be deprived...
deprived of the catechetical lecture, and at the same time he declined receiving the salary which the bishop wished to continue. His situation at the University became very precarious, and in October 1710 he was expelled from it, in conformity to a statute against maintaining doctrines contrary to the established religion. In the following year he also lost his professorship; and having no further employment at Cambridge, he removed to London, and published an account of the proceedings against him, and also books in defence of his sentiments, which he retained without regarding any worldly considerations. His purpotes were fixed, and he declared to two friends, who wished him to pay some attention to his present welfare, "you may as well peruse the fun to come down from the firmament, as turn me from this my resolution." Hoadly and Clarke remonstrated; but all their pleas were unavailing. All his future prospects seemed now to depend on his knowledge of mathematics, and accordingly in 1710 he published his "Prælectiones Physicæ-Mathematicæ; five Philosophia Clarissimi Newtoni Mathematica illustrata." At this time Additon and Steele, and several other persons, exerted themselves in procuring a subscription to his astronomical lectures. But at the close of this year he published the "Historical Preface" to a proposed work on Primitive Christianity, which subjected him to the iniquitous animadversion of the lower house of convocation. Escaping, however, the apprehended consequences of their interference, he persisted in his course, and in 1711 printed this work which he had announced, and which had occasioned an alarm, in 4 vols. 8vo. The convocation, not sufficiently informed with regard to the extent of their power in cafes of heresy, addressed the queen in order to obtain the opinion of the judges, who disagreed upon the subject, and no further measures were pursued by this body. However, in 1713, Whitton was prosecuted in the spiritual court; and as he did not appear to its citation, he was declared contumacious. Difficulties occurring on the part of the lay-judges, the business was deferred, and the prosecution was terminated by an act of grace in 1715. Whitton was at this time a professed member of the established church, and attended its worship, till at length he was refused admission to the sacrament; and therefore he opened an asylum for worship at his own house, and used a liturgy of his own composing. He also established a weekly meeting for the promotion of primitive Christianity, which subsisted for two years. Whitton was thus occasionally engaged, he devoted himself to mathematical and philosophical pursuits; and in concert with Mr. Ditton, who was his colleague in his lectures, published a project for discovering the longitude at sea. But as their speculations were of no use, it will be sufficient to observe, that he published at last a method of ascertaining the longitude by observations of the eclipses of Jupiter's satellites, with tables of such eclipses for four years from the year 1738.

His zeal in religious diffusions and projects remained unabated; and, among other publications in 1716 and the two following years, appeared several pieces founded on the suppositions of gnomonists and authority of the apologetic confutation. In 1719 he published a letter addressed to Finch, earl of Nottingham, on the "Eternity of the Son of God and his Holy Spirit," which received an answer from his lordship, that induced the clergy and universities to return him public thanks, and which caused Whitton's exclusion from the Royal Society, when he was proposed as a candidate in 1720. Sir Isaac Newton, it is said, who was of a very timid temper, took measures for defeating his election. As he was of opinion that the Jews would be speedily restored to their native land, he procured models of the tabernacle of Moses and the temple of Jerusalem, upon which he read public lectures. In 1741 he undertook a survey of the coasts of England, in order to fix the longitude of places, and a chart to this purpose was published in 1745. It was in the year 1747 that he discontinued his attendance on the service of the church of England, and joined a Baptist church, in which connection he continued. In 1749 he published two volumes of memoirs of his own life, to which a third was added in 1750. Having attained to the 87th year of his age, he died at London in 1752, and was interred at Lyndon, where his daughter was married, and where a handsome tomb was erected in honour of his memory. "Fancy," says one of his biographers, "predominating over judgment, a warm head and honest heart, enthusiastic fervour, and disregard to common forms and worldly conceptions, were the leading features of his character." He never hesitated in giving his opinion to all persons on all subjects, freely and without discrimination. Being once asked, in the presence of Additon, Pope, Walton, Craggs, and others, "whether a secretary of state could be an honest man consistently with the duties of his situation?" He gave his opinion that it would be of advantage to such an officer to speak openly what he knew, and declare his intentions without disguise. Mr. Craggs replied, "It might answer for a fortnight, but no longer." "Did you never, Mr. Secretary," returned Whitton, "try it for a fortnight?" When queen Caroline, who honoured Whitton's integrity, and was fond of his conversation, desired him to acquaint her what was particularly found fault with by censurers on her conduct; he replied, that her habit of talking at chapel was mentioned with disapprobation. She promised amendment, and wished him to point out any other faults. "When your majesty," said he, "has amended this, I will tell you of the next." A catalogue is given of Whitton's writings, which are very numerous, at the close of his "Memoirs of Dr. Clarke." He has also given a valuable "English Translation of Josephus," with plans, notes, and illustrations, to which are prefixed eight dissertations. Biog. Brit. Memoirs of his Own Life.

WHITAKER, John, B.D. a divine of the established church, was born at Manchester, about the year 1735, and educated at Oxford, where he became fellow of Corpus-Chrilli college, taking the degree of M.A. in 1759, and of B.D. in 1757. His first work, viz. "The History of Manchester," appeared in 1771, 4to, in which he takes occasion to give a view of the state of the kingdom in general. This work, abounding in literary research and ingenious conjecture, gave reputation to the writer, and was followed in the same year by "The Genuine History of the Britons asserted." However, it is said that Mr. Whitaker's imagination in the progress of his years milled his judgment, of which he gave evidence in the second volume of his "History of Manchester," printed in 1775, though he still maintained his character for deep and learned investigation. As a clergyman, he became morning-preacher of Berkeley chapel, London, in 1773, from which situation he was soon after removed; and he resented his removal with the natural warmth of his temper. Such was his orthodoxy, that he declined accepting a valuable living that was offered to him by an Unitarian patron. In 1778 he succeeded, as fellow of his college, to the rectory of Ruan-Lanyhorse in Cornwall, where his conduct about titles was the occasion of much uneasiness to him. When mutual conciliation took place between him and his parishioners, he published in 1783 a course of Sermons on Death, Judgment, Heaven,
and Hell, which were rendered peculiarly impressive by the fervid eloquence with which he treated the subjéct, naturally awful and interesting. In 1787 he published his "Mary Queen of Scots vindicated," 3 vols. 8vo., in which he fur-
poffed former writers in the zeal with which he vindicated this unfortunate queen, and criminated her enemies, Eliza-
beth, Cecil, Morton, and Murray. He also prefented to the public the fruit of his learned research in "The Course of Hannibal over the Alps ascertained," 2 vols. 8vo. 1794; and in 1795 he advanced the highest monarchical principles in his work, entitled "The real Origin of Government," and also his orthodoxy in his "Origin of Arianism," zealously defending his sentiments in both these refpects by contributions to the English and Jacobin Reviews, and British Critic. At length a paralytic stroke warned him of his approaching end, and after a gradual decline he im-
perceptibly closed life at his rectory in October 1808, at the age of 73, leaving a widow and two daughters. Gen.
Biog.

WHITBREAD, Samuel, an eminent brewer, claims
a place in a work devoted to the record and promotion
of the arts and sciences, on account of the talents which
he displayed and the character which he maintained in his
advancement from small beginnings, to the possession of a
fortune, that set him on a level with some of the first no-
bility of the country. The family from which he sprang
belonged to the class of yeomanry, in the county of Bed-
ford, which possessed some small property, and associated
with that description of moderate dillenents, who occasionally
conformed to the Church of England. Born in the village
of Cardington near Bedford, about the year 1720, and edu-
cated probably with a view to trade, for which his family
designned him, he was bound apprentice at a suitable age, for
the term of seven years, to an opulent brewer in London;
and after the expiration of that period, he remained for
some time unsettled, as he was cautious in commencing bu-
nifies on his own account. At length, however, actuated by
the laudable ambition of tracing the footsteps of those
who, in a similar department, had risen to opulence and
rank, he determined to make trial for himself, how far in-
dustry and activity, aided by economy, would avail to his
success. Having disposed of his own patrimony, which
could not have been very considerable, and deriving affilia-
tion from persons of opulence, who were encouraged to re-
pose confidence in him by his known disposition and habits,
he laid the foundation of a superstructure of fortune and
reputation, which has had few parallels in the history of
commerce. Simple in his manners, he was accustomed to
appear at the corn-market in Mark-lane with a white apron,
as the emblem of his occupation; and liberal in his dispo-
sition, he contrived to secure the attachment and active ser-
\n\sices of those with whom he was connected in his domestic
\arrangements, and in the conduct of his business. He well
\knew that by making those whom he employed partakers
\of his bounty, he gave them a kind of interest in his pro-
\sperity; and therefore on settling the annual balance of his
\accounts, he distributed amongst them donations, correspond-
\ing to their respective ranks and services. Whilft he gave
\50l. to a confidential clerk, he extended his bounty even
to the horfe-feeders, to each of whom he usually gave 5l.

Advancing with sure, but rapid progress, his brew-house
in Chiswell-street became a famous quadrangle, confliting
of an ample dwelling-house, work-houses, stoves, cellars,
and every other kind of convenience both for habitation and
business; while the flock, the plant, the dry-horses that
would have mounted a regiment of cavalry, the eafks, &c.
might in process of time be estimated at nearly half a mil-
lion of pounds sterling. To this immense property, we
might add a floating capital amounting to from 8c to
100,000l. serving to supply the demand of malt, hops, oats,
&c. as well as the payment of clerks and servants. Thus
the direction and superintendence of a single individual,
with the co-operation of a number of coadjutors in various
ranks of subordination, the brew-house in Chiswell-street
became the first establishment of the kind, not only in Lon-
don, but in Europe, depending for its subfinence and fngu-
lar prosperity on the approved quality of the article which
it furnished. To the founder and principal proprietor, it
became a mine of wealth, and an immense feece of supply
for purchases of land and houses, donations and bequests,
which have given distinguished celebrity to the name of Whit-
bread. It is needless to recount the various eftates which
he purchased in his native county; we shall content our-
\selves with mentioning merely the Torrington manors and
eftates, for which he paid the sum of 120,000l., besides
5000l. as a preffent to alderman Skinner the auctioneer,
when the negotiation respecting it was completed. Of
his benefactions and bequests to various objects of public
utility and of private charity, it will be sufficient to say,
that they indicated the liberality of his disposition, and the am-
\plitude of the means which he derived from his fngular
prosperity. Mr. Whitbread was twice married; by his firft
wife he had feveral children; but his fcond wife, who was
d Hust of the firft earl, and fifter of the firit marquis
Carroll's, and to whom he was married August 12,
1769, died December 27, 1770. He was for fome years
one of the repreffatives of the town of Bedford, and
afterwards returned for the borough of St.eyning. For
the abolition of the slave-trade, he was a ready and ardent
advocate; and as fuch he generously undertook from his
private purse to make good all injuries that might be suf-
\fered by thofe who attended to give their testimony for this
purpofe. With this expression of benevolence he clofed a
life, during the progress of which he had amassed landed
and chattel property to an immense amount, without any of
thofe penurious habits, which have been in many inftances
the means of accumulating large fortunes, and of enablin-
gh to die rich who have lived meanly and miserably. His
death happened June 11th, 1796.

In 1799 his fon, the fubject of the next article, erected
a splendif monument to his firft wife, and born in the year
1758. Deflined to the inheritance of a large fortune, and
possifiting talents which by due cultivation would qualify
him for a conspicuous fation in public life, his father spared
no expece in his education. At a proper age he was fent to
Eton, where he also enjoyed the benefit of private tuition,
and where he commenced an intimate acquaintance with
Mr. W. H. Lambton, afterwards M.P. for the city of
Durham, and Mr. now earl Grey, with whose family he
became connected by a double alliance. From Eton he
removed to Chriftchurcb college, Oxford, and from thence
to St. John's college, Cambridge, where he finiflied his ed-
ication, and was graduated B.A. Mr. Whitbread ferior,
fagacious in difcerning the early dawnings of his fon's future
celebrity, liberally offered him all the advantages which might
be
be derived from foreign travel, and selected for his tutor and companion the present archdeacon Coxe, well known by a variety of valuable publications. Having travelled together through France, Germany, and Switzerland, they afterwards separated with professions of mutual regard. Mr. Whitbread, soon after his return, formed, in 1788, a matrimonial connection with Miss Grey, the sister of his Eton associate, who afterwards, by the advancement of her father, general Sir Charles Grey, to an earldom, became lady Elizabeth Whitbread: his sister also, in process of time, married the present sir George Grey, bart., then a captain in the navy. Having acquired every necessary qualification for occupying a seat in the great council of the nation, and interested by an ample fortune either in possession or in prospect, as well as by genuine sentiments of patriotism, in its deliberations and resolutions, Mr. Whitbread offered himself, on the dissolution of parliament in 1790, as a candidate for Bedford, a borough which had been represented by his father, who at the same time offered himself for the borough of Steyning. Both elections were contested; but both father and son finally obtained their respective seats. Mr. Whitbread, junior, commenced his political career in parliament with an animated speech against the unconstitutional doctrine of "confidence," assumed on the part of ministers, who claimed an entire reliance on their wisdom and integrity. The occasion of this claim was a proposed war against Russia, for which the minister (Mr. Pitt) urged the house of commons to vote money, without previous and satisfactory information of the necessity, and much less of the justice or policy of this war, the object of which was the reformation of Oczakow to the Turks. The measure was unpopular; and though the minister obtained a majority, when the question was debated, he thought it most prudent to give up his object, and a pacification ensued, which prevented much calamity to the nation. About this time the abolition of the slave-trade occupied the public attention, and this was a measure to which the member for Bedford had always avowed himself a steady and zealous friend. In parliament he supported it not only by his vote, but by a display of eloquence which commanded universal applause. As an active magistrate, he directed his particular attention to the occurrences that took place in consequence of the scarcity in the year 1795; and in devising means of relief, he proposed that the magistrates were empowered to fix a maximum of wages, so far as respects the husbandman, a minimum should be also preserved by law, in order thus to establish a more accurate proportion between the price of labour and that of the means of subsistence. With this view he introduced into the house a bill, which was approved by Mr. Fox and many other members; but as it was opposed by Mr. Pitt, his efforts were unavailing. The minister was no less unsuccessful in his plan for amending the poor laws, and mitigating the condition of the pauperism and working class. His plan indeed was much more extensive and complicated than that of Mr. Whitbread, which was simply calculated to enable the labourer to maintain himself by his wages, without the degrading as well as dispiriting necessity of seeking parochial relief.

The subject of this article was an undignified and uniform oppressor of the French war in 1793, because he thought it to be unnecessary and unjust; and yet he was a zealous advocate for measures of self-defence against the secret machinations and open attacks of a powerful and vindictive enemy. Accordingly he condemned the negligence of ministers, on occasion of the French attempt at invasion in 1797, by means of a squadron which appeared off Bantry bay, and moved the house for a committee of inquiry into their conduct. His motion was evaded by the previous question. In every stage of the contest with France, and under every varying form of its government, he was anxious for peace, and an advocate for treating with its rulers in order to terminate hostilities, and to put an end to the waste of national treasure and the effusion of human blood. His opinion on the conduct of ministers in the prosecution of this war, and their reluctance to enter into treaty for terminating it, was explicitly avowed in an eloquent speech, which he delivered on occasion of a motion by Mr. Dundas (then secretary of state) for an address to the throne in 1800, for the purpose of approving the conduct of his majesty's government. Anxious, however, as he was for peace, because he disapproved the war from its commencement, and because he thought it essential to the true interest of the country, he was no less solicitous to maintain the honour of the nation in obtaining it. No man in this respect was a more noble-minded patriot than himself; and if he ventured to make any sacrifice, it was because he thought it absolutely necessary to the permanent prosperity of his native country. Whilst he claimed and exercised the privilege of pronouncing his own opinion of public men and political measures, he was a zealous advocate for the liberty of others, and interposed with his most vigorous exertions for the release of those who suffered imprisonment at home or exile to Botany bay, for too freely and imprudently divulging their opinions. During the short interval of the administration of Mr. Addington, (the present lord Sidmouth,) who succeeded Mr. Pitt in the year 1801, and made peace with Buonaparte, several popular measures were adopted, in which Mr. Whitbread cordially concurred; and in the year 1805 he distinguished himself as the public accuser of Mr. Dundas (created lord Melville) for malversations that had occurred, whilst he had occupied the post of treasurer of the navy. His charges against this nobleman were founded on a report of the commissioners of public accounts, from which it appeared that, during the exercise of his office, this noble lord had violated the law, by conniving at mal-practices and participating in unwarrantable emoluments; and that he was responsible for deficiencies amounting to 697,500l. These charges also implicated Mr. Trotter, Wilton, and Spratt; and the former in particular, who was paymaster of the navy department under Lord Melville, and had taken out large sums of money on his own private account. In the investigation of this business, it was discovered, that the sums officially deposited in the Bank had been withdrawn, lodged with private bankers, and applied to other purposes besides those that were properly naval. Mr. Whitbread founded on several facts which he stated, a variety of resolutions which impeached the fidelity and honour of his lordship. To his motion relative to this business, Mr. Pitt moved an amendment, which was negatived by a majority of one (217 to 216), in consequence of the vote of the speaker. In consequence of these proceedings, the vicount resigned his office at the Admiralty-board, and his name was expunged from the list of privy-councillors. Upon the sudden demise of the premier, and a coalition between lord Grenville and Mr. Fox, the two latter came into office; and Mr. Erkine, being raised to the peerage, and appointed lord high chancellor, was deputed to preside at lord Melville's trial. This nobleman having made his defence within the bar of the house of commons was replied to by the member for Bedford; and an impeachment being agreed upon, proceedings commenced in Westminster-hall, April 29th, 1806. The result, after a short trial, was the acquittal of his lordship by a majority, from all the charges alleged against him. Notwithstanding the unexpected termination of this trial, neither the friends
friends nor the enemies of the supposed delinquent attached any blame to the public accuser; but he was allowed to have conducted the business assigned to him with a dignity and propriety suitable to its delicacy and importance. In the case of Lord Melville, as well as in that of Mr. Pitt, he knew how to distinguish between the man and the minister; and to pay a just tribute to the talents and dispositions of the former, whilst he criminated and condemned the latter. Having differed with Mr. Pitt with regard to his political measures almost through the whole of his public life, he took the opportunity which the trial of Lord Melville afforded him of paying a just tribute of respect to his abilities and virtues, when his premature death must have vindicated the eulogy from the slightest suspicion of infirmity and adulation.

Of the new administration, he was a steady supporter; but though he had at an early period enlisted himself under the banners of Mr. Fox, and the Earl Grey, his school-associate and brother-in-law, who was one of its distinguished members; he was their friend as ministers, not from personal and selfish motives, but from a conviction of his judgment that their principles and views were most favourable to the liberty and welfare of the British empire. Indeed he was regarded by many as an impracticable man, because in all great questions he was influenced by principle more than by any private and party attachment. What were his sentiments of the coalition ministry, and what were the grounds of the support which he afforded them, he had an opportunity of stating in the most explicit manner. At this time Sir Francis Burdett offered himself a candidate for the county of Middlesex, and transmitted a circular letter to Mr. W., who had voted for him twice before, soliciting his support. This letter contained reflections on the coalition ministry, which led the subject of this article to decline giving his vote for Sir Francis, and also to express his sentiments of the coalescing parties, which had been feverely cenured. "I have supported the present administration," says Mr. W., "from a conviction that they were united upon principles of real public utility, and for the purpose of carrying into execution plans of great national improvement, both in our foreign and domestic circumstances; and I cannot abandon them, because in a situation more difficult than that in which any of their predecessors have ever flourished, they have not been able to effect what I believe to have been nearest the hearts of them all—I mean a peace with France; seeing such a peace could not have been obtained on terms confident with national honour, and because time has not sufficed to mature and execute the schemes of internal improvement, which they have manifested their determination to pursue," &c. Having stated some other opinions with regard to the union of parties, in which he seems to have disagreed with Sir Francis, he concludes: "These radical differences render it impossible for me to assist you in becoming a member of parliament. Different opinions may be maintained conscientiously with mutual and entire personal respect; such as I unfeignedly profess towards you. The determination you have taken to avoid the expense of conveyance and decorations so conspicuous at your former elections, does you honour; and I with such an example could be followed by all other candidates," &c. The publication of this correspondence threatened a very undesirable termination; but it was happily prevented by the interposition of friends.

During this period, Mr. Whitbread took an active part in public affairs, and distinguished himself on a variety of occasions, guarding on the one hand with vigilant jealousy against an undue exertion of the royal prerogative, and on the other against its infringement by the democratical part of the constitution. In February 1807, he renewed his attention to the existing system of poor laws, as it was his wish and incessant endeavour to improve it, and in doing so to render the peasantry happier, better, and less dependent. It was also an object, which he conceived to be of essential importance, to controul the several branches of public expenditure, and thus to relieve the difficulties of the country. Much depended, he well knew, on peace with France, and to this deliberandum his views and efforts were constantly directed. But he was almost ready to despair of this desirable event, "from the awful moment that death closed the scene upon the enlightened statesman (Mr. Fox) who had first commenced the negociation." When the Grenville administration was obliged to retire, and a new parliament was convoked by its successors, he published a spirited address to his constituents, in which he stated the measures which had been projected and wholly completed or commenced during the existence of the late ministry, and the part which he had taken in the deliberations of the preceding parliament, closing with these memorable words: "I court your inquiry, and if you are satisfied in the result of it, I hope for your votes in the present election. If you do me the honour again to return me, I shall indeed be proud of it, and I will again endeavour to do my duty." The next important object of his attention was the education of the poor, as intimately connected with their morals and religion; but unable to obtain a legislative function to his plan, he was under a necessity of recurring to individual exertions and private subscription. During the important debates that occurred in 1809, with regard to the orders in council, he concurred with those who condemned this measure, and contributed first to their supfension, and at length to their utter discontinuance. With regard to the situation of Spain, he was one of those who conceived the conduct of the French government, and who wished the natives to be stimulated to new exertions in behalf of the independence of their native country. "In 1809," says one of his biographers, "he took an active part in the inquiry and examination into the conduct of the royal duke who preceded over the army, and although he found much to blame on that occasion, yet, at a future season, he feized the first opportunity to afford his testimony in behalf of his royal highness, whose administration as commander-in-chief had contributed not a little to the happy and glorious termination of the late contest. That event did not prevent him, however, after the overthrow of Buonaparte's government, from blaming the conduct of the Congress, and expounding the ambitious views of some of the sovereigns, particularly in respect to Saxony. On the return of the emperor from his exile in the isand of Elba, the member for Bedford (strongly and emphatically) censured the declaration of the allies, more especially that part of it which seemed to recommend the detestable principle of annihilation. He also loudly inferred both on the policy and injustice of a new war, on the ground that the executive power of the enemy was vested in the hands of any one particular person. But above all things he protested against the forcible restoration of the Bourbons by a foreign force, and the assumed right of dictating a government to France. Yet he most cordially joined in a vote of national gratitude to the duke of Wellington, for the memorable victory at Waterloo, although he at the same time boldly avowed that events had not altered his sentiments in respect to the pretended justice of the original contest."
WHITBREAD.

infruction of the poor, Mr. Whitbread was affidious and indefatigable; and whilst he was overwhelmed by a multiplicity of occupations, he voluntarily undertook a more Herculean labour than any other, which was the arrangement of the perplexed concerns of Drury-lane theatre. With every moment of his time thus occupied, and his mental powers unremittingly exerted, it is no wonder that his health should decline, and that his mind itself, though naturally vigorous and ardent, should be impaired by excess and intemperance of application. The consequence that might have been apprehended unhappily occurred, and the world was prematurely deprived of the benefit of his valuable services. "His countenance changed; he became droisy, lethargic, and irritable; and he even supposed himself to have fallen into contempt." These indications of corporeal and mental decay were alas! too soon succeeded by that fatal catastrophe, which occurred on Thursday, July 6, 1815.

"An inquest having been summoned by Mr. Gell, the coroner, at eight o'clock the same evening; at the house of the deceased, No. 35, Dover-street, Piccadilly, and having entered his study, he beheld Mr. Whitbread lying on his back, his arms and legs extended, with a deep incision on his throat from ear to ear, a small part in the front of the throat excepted. A looking-glass was opposite to him; his apparel and the floor were covered with blood; and the fatal razor was found at some distance!"

The verdict of the jury was as follows:—"That the deceased Samuel Whitbread, esq., died by his own hand; but that he was in a deranged state of mind at the time the fatal act was committed." His principles and character have been justly delineated by one of his biographers, and we shall briefly deline them as are consistent with our contracted limits. "In politics he was a Whig; yet a Whig of the old school; one who wished to balance the royal power, by means of a due influence of the popular branch; but at the same time firmly andfeelingly to uphold both. Accordingly, he was always a strenuous, consolant, and uniform advocate for a reform of the house of commons: but this great measure was grounded on the ancient and acknowledged bases, not on the visionary plans of annual parliaments and universal suffrage. As a patriot, he wished for the happiness and prosperity of his country; but these, he deemed most likely to be acquired, and most permanently enjoyed by cultivating the arts of peace, advancing the commerce, cherishing the manufactures, and encouraging the agriculture of his native land. Wars might indeed be popular, successful, glorious; but it was also incumbent and imperative that they should be both just and necessary. It was his firm opinion, that economy was to be as proper for a state as for a private family: he was always, therefore, a decided friend of order, regularity, and good management. He hated jobs; he viewed placemen, courtiers, and contractors, with a jealous eye; and he disliked both unnecessary and excessive pensions, not only on account of the sums thus perverted from the public revenue; but also from their obvious tendency to produce meaner, sycophancy, and dependance.

"Mr. Whitbread was a strenuous advocate for national education, or instruction on a great scale. But finding himself unable to obtain a national sanction to this measure, he contented himself with his assistance and support as a private individual.

"He was an encourager of the fine arts; and always de- flous that they should enjoy protection and applause."—"To agriculture, as a science calculated to advance the interests of the nation, he paid particular attention."—"Horticulture also engaged his notice, and the gardens, and lawns, and groves of Southwell, might have all been exhibited as so many perfect specimens of care, neatness, and propriety.

"Although always doubtful of the justice of the late war, he never hesitated for a single moment as to the propriety of arming and defending his native country against the menaces and attacks of her enemies. He himself raised and commanded a body of sturdy yeomanry; and while he thus excited a martial ardour in his neighbour, he forgot not to enforce his favourite plan of fitting men, by means of education, for their respective stations in life. On this occasion, he instituted a school for the benefit of the non-commissioned officers, and contributed by all the means in his power to render it effectual.

"An only son, born and matured with the expectations of great opulence; it is but little surprising if he occasionally displayed a certain degree of haughtiness in his demeanour. Indeed it cannot be denied, that at times he appeared somewhat haughty and overbearing; but on the other hand, he must be allowed to have been admirably fitted for command; and was seldom known to exceed the bounds of moderation, but when he combated the injustice of power, affixed the influence of office, or endeavoured to expel successful guilt to shame and to punishment.

"His heart constantly glowed with all the social affections. He was zealous in his friendships; while his enmities were transient and short-lived. His ear was ever ready to listen to the tale of the oppressed; his purse always open to succour those who had been reduced to distresses by unexpected calamities. At length, after having lived and acted during the stormy politics of the French revolutionary contest, he was suddenly cut off, at a period when his services might have proved highly advantageous to his country; when the deceitful calm of peace seemed imminent with greater and more formidable dangers than those arising out of a long, widespread, expensive, and destructive warfare!

"On the 11th July, 1815, when the marquis of Tavistock, on moving for a new writ for the borough of Bedford, decanted on the character, worth, and talents of the late member, his encomium was listened to amidst the loud cheers of both sides of the house of commons:

"Acquainted to defend his opinions with warmth and earnestness," said he, "the energies of his ample and comprehensive mind, would never permit the least approach to tameness or indolence. But no particle of animosity ever found a place in his breast, and he never carried his political enmities beyond the threshold of this house. It was his uniform practice to do justice to the motives of his political opponents; and I am happy to feel, that the same justice is done to his motives by them. To those who were more immediately acquainted with his exalted character; who knew the directness of his mind, his zeal for truth, his unshaken love of his country, the ardour and boldness of a disposition incapable of dismay, his unaffected humanity, and his other various and excellent qualities, his loss is irreparable. But most of all, will it be felt by the indigent in his neighbourhood. Truly might he be called the poor man's friend. Only those who, like myself, have had the opportunity of observing his conduct closely can be aware of his unabated zeal, in promoting the happiness of all around him. His eloquent appeals to the house in favour of the unfortunate, will adorn the pages of the future historian; while at the present moment, they afford a subject of melancholy retrospection to those who have formerly dwelt with delight on the benevolence of a heart that always beat, and on the vigour of an intellect which was always employed for the benefit of his fellow-creatures!"
He left behind him by lady Elizabeth, his mourning widow, two sons and two daughters.

The following memorandum of Mr. Whitbread's sudden death was written immediately after the lamentable event was ascertained, in the title-page of a very ancient edition of Cicero's "Paradoxos," by a friend who highly respected the stern virtues both of his public and his private character:

SAMUEL WHITBREAD, armiger:
Vir illusiris iube, quern omnes liberales brevi in tempore appellabant

ANGLICUM CATONEM,
E terra fuit eretus die sexto Julii, anno Chrall 1815.

WHITBY: DANIEL, a learned divine of the church of England, was born at Ruthden, in Northamptonshire, in 1638, and admitted to Trinity college, Oxford, in 1653, where he took the degree of M.A. in 1660, and became fellow of his college in 1662, in which year he first appeared as a writer against popery. In 1668 he was appointed chaplain to Dr. Seth Ward, bishop of Salisbury, and collated to a prebend in his church. In 1672 he took the degree of D.D., and about this time was made rector of St. Edmund's parish in Salisbury. From this time he became a considerable writer in the popish controversy, publishing "A Discourse concerning the Idolatry of the Church of Rome," 1674; "The Absurdity and Idolatry of Holt-Worship proved," 1679; "The Fidelity of the Roman Church demonstrated," 1687; and "A Treatise of Traditions," in two parts, 1689. He also expressed, in common with several other liberal persons at this period, his wishes for an union of all Protestants, in a piece published in 1683, and intitled "The Protestant Reconciler; humbly pleading for Condescension to Difsembling Brethren in Things indifferent and unnecessary, for the Sake of Peace, &c." This publication was too liberal for the times, and called forth a host of adversaries. But the most formidable attack was that of the famous Oxford decree, which passed a cenure on the following propositions contained in it: viz.

"It is not lawful for superiors to impose any thing in the worship of God that is not antecedently necessary:"—"The duty of not offending a weak brother is inconsistent with all human authority of making laws concerning indifferent things:" which propositions were denominated in the decree false, impious and seditious doctrines; and the book was burnt in the quadrangle of the university schools. But it was still more humiliating to the author to be required by his patron, the bishop, to declare his sorrow for having written the work, and to renounce by name the two preceding propositions. This conduct was very unworthy of a Christian bishop, and fixes a permanent stigma on the memory of Ward. It reminds us of the Inquisition and Galileo. (See Galileo.) Dr. Whitby, actuated probably by a desire to conciliate his adversaries, or urged to adopt this meaurence, published in the same year a second part of the book, in which he strongly protests the dissenting laity to join in full communion with the established church, and replies to all the objections of the Non-conformists against the lawfulness of their complying with its rites and ceremonies.

No man could more sincerely rejoice in the Revolution than Whitby, nor more cordially welcome the emancipation of British subjects from all kinds of tyranny. Accordingly he published two tracts in favour of the oath of allegiance required on the accession of king William; and in one of these tracts he maintains the principle in the English government of an original contract between the prince and the people.

His capital work, however, was the result of fifteen years' study, and is intitled "A Paraphrase and Commentary on the New Testament," 2 vols. fol. printed in 1703, several times reprinted, and held in high estimation by biblical students. To the edition of 1710 he annexed a Latin appendix, containing an examination of Dr. Mill's various readings, under an apprehension that they might prove injurious to the authority of Scripture. This great work of Dr. Whitby was followed by several tracts on theological subjects, in which he seems to value himself on that freedom of discussion which, with new times, he was allowed to indulge, more especially as he occasionally strays beyond the fixed boundaries of what has been called orthodoxy. Among these tracts were, "The Necessity and Usefulness of the Christian Revelation;" "A Discourse concerning the True Import of the Words Election and Reprobation;" "The Extent of Christ's Redemption;" "The Grace of God;" "The Liberty of the Will;" "The Perseverance or Defeatibility of the Saints;" "Four Discourses on Election and Reprobation;" "A Treatise on Original Sin," in Latin, in which he denies that the imputation of Adam's sin to his posterity has any fair ground in Scripture. Upon the publication of Dr. Clarke's "Scripture Doctrine of the Trinity," Dr. Whitby adopted his opinion, and wrote a Latin treatise, intended to prove that the controversy respecting the Trinity could not with certainty be determined from fathers, councils, or Catholic tradition. In connection with this subject of controversy, he published "A Discourse from Inquiry into the Doctrine of the Trinity; or, the Difficulties and Discouragements which attend the Study of that Doctrine." In the Bangorian controversy, he was one of the auxiliaries of Dr. Hoadly, and printed several tracts. He also published several sermons. But his last work, which did not appear till after his death, was "The last Thoughts of Dr. Whitby, containing his Corrections of several Passages in his Commentary on the New Testament; to which are added Five Discourses; published by his express Order." In the preface to this work, written at the close of a long life of learned and laborious inquiry, the author says, "when he wrote his Commentaries, he went on too hastily in the common beaten road of other reputed orthodox divines; conceiving first, that the Father, Son, and Holy Ghost, in one complex notion, were one and the same God, by virtue of the same individual essence communicated from the Father; which confused notion (he adds) he is now fully convinced to be a thing impossible, and full of gross absurdities." A short illness closed the life of this eminent biblical scholar, on March 24, 1725-6, at the age of 88. He is represented by a biographer as a man of great simplicity of character, singularly ignorant of worldly affairs, entirely devoted to his studies, but affable, pious, and charitable. He preferred a tenacious memory to the laity, but through a defect of sight was obliged to employ an amanuensis. Biog. Brit.

WHITBY, in Geography, is a considerable sea-port town of the North-Riding of Yorkshire, England, situated between Flamborough-head and the entrance of the river Tees. Considering the ruins of the ancient abbey as the principal object of the town, the latitude of Whitby is 54° 29' 24" N., and the longitude o° 35' 59' W., from the meridian of Greenwich. It is 47 miles N.E. of York, and
WHITBY.

The town is placed at the mouth of the small river Elk, which divides it into two unequal parts. The direction of the river, running nearly due north towards the sea, determines that of the town, which extends along its banks. These banks rise almost suddenly from the river on both sides; particularly on the east, so as to leave but a very narrow stretch of level ground at the bottom, of which, indeed, a great part has, at different times, been gained from the bed of the river. This narrow space is literally covered with houses; but the town ascends the steep banks on both sides, and thus presents a romantic appearance, especially when viewed from the sea; the whole surmounted by the old weather-beaten church, on the verge of the eastern cliff, and the venerable remains of the abbey behind. The eastern half of the town extends about three-quarters of a mile; but the breadth where greatest does not exceed 150 yards. The western division is the largest, the most compact, and the most elegant. Although now of importance, Whitby was but inconsiderable in trade and population, until towards the beginning of the last century. Its origin may, however, be carried back to the foundation of the celebrated monastery in the seventh century. That the Romans, or the original Britons, had any establishment at Whitby, we have no grounds to affirm; although the opening of the river into the sea must have afforded a convenient station for sailing and navigation; of which, had the Romans been a commercial people, they would doubtless have availed themselves, especially on a tract of coast so little furnished with harbours adapted to their shipping. On this part of the coast may, perhaps, be placed the bay mentioned by Ptolemy, under the romanized name Dumum Sinus, of which the most commodious inlet was the mouth of the river, now, by a peculiar appropriation of a generic British name for water, called the Elk. After the establishment of the monastery of St. Hilda in the seventh century, the vicinity began to be inhabited. Under her successor Ætheldea, daughter of Osywy, the port had some share of shipping; for, in 684, the abbess took a voyage, with some monks of the abbey, to the isle of Coquet, on the coast of modern Northumberland, to have an interview with St. Cuthbert. Suffering and again restored with the abbey, after the devastation by the Danes in 867, Whitby obtained its present name, signifying the White town. It was also from the monastery occasionally called Preiftby, or Priesttown. Although unmentioned in Dome-day-book, Whitby, prior to 1189, had become of such importance, that the abbot erected it into a borough, with the customary privileges. Thence privileges were soon after confirmed by a royal charter; and had no unfair means been employed to let them aside, Whitby might now have been a royal borough. But the liberties of Whitby were of short duration: the monks repented of their liberality to the town, and Peter, the succeeding abbot, in 1200, procured from king John a repeal of the charter of his predecessor. About the year 1538, Whitby is described by Leland as a "great fisher town," and nothing more is added by Camden, who mentions the place fifty years later. For many years after the dissolution of the abbey, the vessels of the port were few and small; and the trade was inconsiderable until the establishment of the alum-works at Guisborough, at the close of Elizabeth's reign. A spirit of emulation being excited by the success of these works, a similar establishment was formed in 1615 at Sand's end, within three miles of the town. The vicinity of Whitby abounding with the alum-mineral, other undertakings of the same kind were begun. Hence two important branches of industry were formed in the town; the one to supply the alum-works with coal, the other to export the alum to dilant parts. From these beginnings, the trade of Whitby increased; the schemes of the inhabitants were enlarged; the number of shipping was augmented; and new ships were constructed, for which timber was drawn from the oak-woods of the vicinity. In this manner, the trade and navigation of the town grew up to such a height, that, in the beginning of the present century, Whitby was the seventh in rank for tonnage among the ports of England. In 1816, the number of vessels belonging to the town was 285, carrying 46,341 tons, and navigated by 2674 seamen. Besides the carrying of coal, with the alum trade, and a share of foreign commerce, the number of vessels fitted out from Whitby for the Greenland whale-fithery, begun in 1755, was, in 1800, next to that of those failing from London. As early as the middle of the 16th century, small wooden piers were constructed at the mouth of the Elk, for the protection of the fishing-craft: but in 1632 these piers were begun, through the exertions of Sir Hugh Cholmeley, who, by the favour of the earl of Strafford, his relation, obtained a general contribution over England in aid of the work, when nearly 500 were collected. The navigation of Whitby becoming of importance, acts of parliament were obtained, in 1702 and 1723, for constructing a pier, which now extends above two hundred yards from the cliff on the east side of the harbour, westward to the channel of the Elk. By this work, security was obtained for the town as well as the shipping, both of which were greatly exposed to north-easterly winds. Another pier, on the west side, was afterwards added, running out about an equal distance towards the sea. By subsequent additions and improvements, the harbour has been essentially benefitted. The west pier, now carried out to the length of three hundred and forty yards, is constructed with large blocks of squared stone, and terminates in a circular head, with embrasures for a battery. Within the piers, vessels to the number of five hundred may lie, but all on the ground at low water. The harbour is divided into the outer and the inner by a drawbridge, so constructed as to allow ships of two hundred tons to pass through. In the latter, which is capacious and secure, on both sides of the river are constructed several dry docks, and other accommodations for ship-building. The vessels built for the coal-trade are particularly valued for their strength and durability. One built in 1724 was lost on the Lincolnshire coast in 1810, but did not go to pieces; another, wrecked a few years ago, was above one hundred years old. In neap-tides the water rises from ten to twelve feet at the entrance of the harbour; but in ordinary spring-tides the depth extends from fifteen to eighteen feet. In the equinoctial gales, the depth of water is sometimes increased to twenty-three or twenty-four feet. The trade of the port of Whitby is but small in proportion to its shipping, as many of the largest vessels are employed in time of war as transports, and at other times by the merchants of London, and of other ports. The trade of the town is, however, considerable for its situation, in a country abounding with moors, where few manufactures are carried on. The alum-works in the environs are of great antiquity, and may not improbably be carried back to the Roman times. But the first work established in Britain, in later times, was begun by Sir Thomas Chaloner in 1595, on his eftate at Belman-rock, near Guisborough, twenty miles to the westward of Whitby. Since that period, alum-mineral has been extracted in various other places, particularly at Sand's end, three miles well from Whitby, where the work is still in a prosperous state. Until the year 1789, the alkaline lyes employed

Vol. XXXVIII.
employed in the manufacture were prepared from kelp, or
sea-weed, burnt on the shore: but since that period kelp
has been gradually superceded by black-ashes, made from
the refuse of soap-boilers’ lees. The average annual quan-
tity of alum manufactured in the Whitby district, for the
last twelve years, was 28,400 tons; but in 1816 the quan-
tity was 31,550 tons. Little alum is now exported, nearly
the whole being sent to London. The number of persons, 
including artificers and boys, belonging to the works, is
about 600. (See Alum.) Thin seams of coal have, for
upwards of seventy years, been wrought in the environs of
Whitby, but of a very inferior quality, and used only in
the interior parts of the country.

Whitby contains no public building of note. The town-
hall, erected by the late Mr. Cholmley, is a heavy pile of
the Tuscan order. The poor-house, extensive, and judi-
ciously managed, affords a comfortable refuge for the dif-
tressed, and tends to diminish the heavy burden of the
parish-rates. A dispensary, liberally supported, for distri-
buting advice and medicines to the poor, was established
in 1780. The parish-church stands near the top of a hill,
on the east side of the town, a little to the northward of
the ruins of the abbey, accessible from the bottom by an
inconvenient ascent of 190 stone steps. The architecture
of the edifice is originally what is absurdly styled Gothic;
but it has gone through so many alterations, that little of
its ancient appearance now remains. The church-yard is
exceedingly crowded with grave-stones; but the sea-air of
Whitby is so destructive of stones, that inscriptions are
soon effaced. For the use of the numerous inhabitants,
the spacious chapel of ease has been erected in the lower
depart of the town; and for the country part of the parish,
which is of great extent, three others have been built. 

That at Sleights, four miles from the town, is a handsome edifice. Roman Catholics, Quakers, and various other classes of differents, have their respective places of worship in the town. According to the parliamentary returns of 1811, the houses of this town were 1395, and the inhabitants 6969: but in the spring of 1816, the population was found, by a careful inquiry, to have increased to 10,203.

The inhabitants of the country part of the parish were then estimated at 1477 persons.

The town of Whitby is close, irregular, and unpleasant; but the environs are romantic and beautiful. These are embelished with the country-residences of the opulent in-
habitants, mostly erected on commanding situations: the
most interesting object of all, however, is the celebrated
Abbey, of great antiquity, having been originally founded
in the year 655. Before the fanguinary but decisive battle
of Leeds, on the banks of the Oore, in which he utterly
overthrew and slew his invader foe, Penda, king of the
Mercians, Owfy, king of the Northumbrians, vowed, if
successful, to erect and endow a monastery, and to confe-
crate to the service of religion in it his daughter Ælleda,
then scarcely a year old. In discharge of this engagement,
he founded the monastery of Streonehall, of the Benedictine
order; with this peculiarity, that it was to contain
both monks and nuns, all under the government of St.
Hilda, the first abbess. It is, nevertheless, probable, that
the introduction of the monks, by which the institution
became in all respects similar to that of the celebrated abbey
of Fontevrand, in the well of France, did not take place
till several years after its establishment. The monastery
was begun in 657, and dedicated to St. Peter; but fish
was the veneration entertained for St. Hilda, that it was
always called by her name, and to her was the foundation
ufually ascribed. While Hilda was abbess, the fynod of

Whitby was held in 664, in which, notwithstanding her
opposition, strengthened by that of Colman, the festival of
Easter was directed to be celebrated at the time adopted by
the sovereign pontiff, instead of that which had been in
general observance in Britain. Dying in 682, Hilda’s place
as abbess was filled by Oswy’s daughter, Ælleda. Till
the year 867, the abbey continued to prosper; but it was
then overthrown by the sons of Lodbrog the Dane. In
this state it remained until after the Norman Conquest; the
lands in the neighbourhood were granted to Hugh, the first
earl of Chester, from whom they passed to William de
Percy, ancestor of the Percys of Northumberland. By him
the monastery was restored from its ruins under a prior;
but in the reign of Henry I. it was again raised to the rank
of an abbey. Although pillaged by a Norwegian fleet in
the time of abbot Richard, who died in 1175, its revenues
at the dissolution, under Henry VIII., amounted to 525l.
s. t. a. At this epoch, the seque and lands, partly by grant
and partly by purchase, became the property of Sir Richard
Cholmley, a descendant of the family of Cholmondeley, in
Cheshire.

Of Whitby-abbey, the ruins of the church alone remain;
but by these, which are still considerable and grandly
picturesque, it appears that there have been a magnificent
structure. The exterior length of the church, which is built in
the usual form of a cross, is 310 feet; the breadth at the west
end, including the transepts, is 60 feet by 145 feet by the
length of the nave, 1153 feet. The church probably occupies the site of the Saxon building erected before the Conquest; but of it,
not even the edifice constructed immediately after the
re-erection of the monastery, no vestige now remains. The pres-
ent structure is of different ages, and exhibits different
styles of architecture. The eastern part, or choir, evidently
the oldest, was probably built by Richard de Burgh, who was
abbot from 1148 to 1175, and who rebuilt the chapter-house.
The lower part of the tower, and most of the pillars, which are all clustered, were perhaps erected at the same time: but the north transept and the upper part
of the tower are of a later date. The ornaments of the
windows in those parts, the beautiful range of niches on the
walls within, the tracery of the circular window in the north
end, &c., seem to indicate the work of the clothe of the 13th
or the beginning of the 14th century. The west front is the
latest part of the whole, probably of the time of Edward III.,
or in the end of the 14th century.

The alum-works in the vicinity of Whitby are not less
curious than valuable, from the variety of petrified sub-
stances they contain. Besides the usual petrifications of
shells and other marine bodies, parts of the human skeleton
have been occasionally discovered. In the early part of
the last century, Dr. Woodward, the celebrated naturalist,
dug up on the foar, or cliff, on the east side of the harbour,
the petrified arm and hand of a man, having all the bones
and joints very visible. About 1743 was found, in the alun-
rock, the complete skeleton of a man; but it was broken
by pieces by taking from the bed. A similar discovery is
said to have been made about nine years ago; but the
skeleton was broken without any scientific person having
examined it. In 1758, the bones of a crocodile, as they
were imagined to be, were drawn from the rock, and tran-
ferred to the Royal Society, by Mr. Home, according
them to be published in the 53rd volume of the Philosophical
Transactions. About four years afterwards, the skeleton
of a horse was found in the alun-works at Saltwick, thirty
yards under the surface. Ammonites, or cornua-ammonis,
vulgarly called snake-stones, abound, with other teftaceous
petrifications, in the aluminous schistus in the vicinity of
Whitby;
About nine miles to the northward of Whitchurch is Hawkstone-park, long the residence of the ancient family of the Hills, and a place celebrated for its natural and artificial beauties and curiosities. The mansion, an elegant modern building situated on the north side of a romantic hill, is adorned with a lofty portico of the Composite order. With the beauty of the exterior of the edifice, the interior fully corresponds: the chapel and the faloon are particularly elegant, and the latter is ornamented with valuable paintings. The grounds around the mansion are particularly interesting for their assemblage of naturally romantic scenes, to which art has greatly contributed. The grotto, the view from the cliff, called Poali's-point, the retreat, or hermitage, St. Francis's cave, the Swifs bridge, the terrace, the obelisk, and the widely-extended prospect it presents over the surrounding country, the tower, the artificial river, the cottage, or whim, are among the many attractive features of Hawkstone-park, which owes much of its embellishment to the taste and munificence of the late Sir Richard Hill, bart. The beautiful and romantic scenery of this noble place is fully detailed in T. Roden hurl's "Description of Hawkstone."

WHITCHURCH, a small but ancient borough and market-town in the upper half hundred of Evingar, Kingsclere division of Hampshire, Englad, is situated on the borders of Chute Forest, at the distance of 13 miles N. from Winchester, 24 miles N. by E. from Southampton, and 57 miles W.S.W. from London. It poifeles the rights of a borough by prescription; and has sent two members to parliament since the twenty-seventh year of queen Elizabeth. The borough is the joint property of lord Sidney and lord Middleton; the freeholders, which give the right of voting, being conveyed by them to their respective friends for the purpose of performing the ceremony of an election. The freeholders are nominally about seventy, but the real electors are said to be appointed and influenced by the noblemen before-mentioned. The government of the town is vested in a mayor, annually chosen at the court-leet of the dean and chapter of Winchester, to whom the manor belongs. The town, though small, is remarkable for a variety of religious fefts: there being, besides the church, places of worship for the Independents, Anabaptists, Quakers, Methodists, and Sandemanians. A market is held weekly on Friday, and three fairs annually. The population of the parish, as ascertained by the return of the year 1811, was 1407; the number of houses 281: the labouring classes are chiefly employed in woollen manufactures, and in agriculture.

Adjoining to the western end of Whitchurch is one of the entrances to the earl of Portsmouth's distinguished residence, Hurstbourne-park. Of late years the park has been much enlarged. The grounds contain considerable diversity of surface and scenery; and the conversion of a small stream into a broad piece of water, has tended very much to improve the place. In the old part of the park, trees have attained a size much beyond what might be expected from the chalk and flint which constitute a great portion of the soil of North Hampshire. An old manion-house flood in the bottom near the present parish-church and village: but the late lord Portsmouth pulled it down and erected the present building in a much more eligible and healthy situation. It stands on elevated ground, commanding extended and varied prospects, particularly to the south and the north. This manion, erected by Mr. Meadows from the designs of James Wyatt, eqq. consists of a centre and two correspondent wings connected to it by colonnades. The eastern wing contains the library and a chapel, and in the

Whitby; on which account, probably, the town has chosen three amonites for its arms. "Robin-Hood's Bay," six miles south-east from Whitby, is a noted fishing-lation, frequented for protection by many a vessel palling along that extended tract of inhospitable shore. Among the country-feasts in the vicinity of Whitby, which are not numerous, is Mulgrave castle, the mansion of the earl of Mulgrave, situated five miles westward from the town, on a lofty eminence, commanding a most extensive prospect both by land and sea. Near to the southward stand the remains of the ancient baronial castle of Mulgrave. Manifest evidences of Roman occupation are to be seen in various parts of the surrounding country. The Roman road from Eboracum (York), northwards by the vicinity of New Malton, (perhaps the Derwentine of Antonine,) and apparently terminating at Durnley, near the sea, three miles W. from Whitby, is in many places very perceptible. Along its course still remain traces of Roman encampments, of which the camps at Caulthorpe, 10 miles S.W. from Whitby, supposed to be the Dolgoitia of Antonine, are very perfect. These works are noticed in general Roy's "Military Antiquities of the Romans in Britain," but much more particularly in "The History of Whitby and Streonshahall-abbey, with a Statistical Survey of the Vicinity," by the Rev. George Young, in 2 vols. 8vo. Whitby, 1817.

WHITCHURCH, a populous market-town in the north part of the hundred of North Bradford, and county of Salop, England, at the northern extremity of the country, is situated 20 miles N. by E. from Shrewsbury, and 160 miles N.W. by N. from London. The church, the chief object of notice, seated on the top of the hill over the town, is a spacious modern structure, erected in 1722, with a square tower 108 feet in height. Two recumbent stone figures are preserved from the ruins of the old church; of which one represents the celebrated John Talbot, the first earl of Shrewsbury, and marshal of the realm of France in the reign of Henry VI.: he was called the English Achilles, and was greatly renowned in the wars of France. Shakespeare, in his play of Henry VI., describes Talbot as a most formidable and magnificent character: "the terror of the French,—the scare-crow that affrights their children:—whole grizzly countenance made others fly,—none durst come near him for fear of sudden death." Another effigy represents Christopher Talbot, fourth son of John Talbot, second earl of Shrewsbury, and who was rector of Whitchurch and archdeacon of Chester. The rectorcy of this parish is one of the richest in the county. The cattle has long been in ruins. Whitchurch has a very respectable free-school, in which many persons of eminence have been educated. Here are also meeting-houses for Protestant dissenters, a charity-school for children of both sexes, and six alm-houses for aged women, endowed by Mr. Samuel Higgenson. A weekly market is held on Friday; and here are two annual fairs. The town is a place of much public resort during the horse-races which are occasionally held here. Among the natives of Whitchurch, was distinguished the celebrated linguist Abraham Wheelock, who translated the New Testament into Piscium, and affixed Dr. Brian Walton in the compilation of his polyglot Bible. Wheelock published also an edition of the writings of the venerable Bede. He died in 1654. The population return of the year 1811 states the town of Whitchurch to contain 552 houses, and 2580 inhabitants: but the parish comprehends besides the town, thirteen townships. The whole population is returned as 5532; the number of houses as 1107.

3 D 2
the western are apartments for servants. In the library were preserved a considerable body of the MSS. on various matters, philosophical and theological, of the illustrious Newton. They came into the possession of this family in consequence of the marriage of John, vicount Lymington, (son of the first earl of Portland) in 1745, with Catharine Conduit, great niece and coheir of Sir Isaac. Those papers were examined by the late learned bishop (then doctor) Horley, while preparing his edition of Newton's works. See Newton, Sir Isaac.

A little to the eastward of Whitchurch, near the London road, is Freefolk, noted for the paper-mills belonging to John Portal Bridges, esq., where the paper for the notes of the bank of England has been manufactured ever since the reign of George I. At Laverstoke is the seat of William Portal, esq.; and in the adjoining parish of Overton is a handsome new house, the seat of — Jarvis, esq. In the village a silk-mill has been established. In various spots at no great distance from Whitchurch, are still visible evidences of Roman occupation. The great sows-way, a Roman road leading from Sorbiodunum, or Old Sarum, to Vindonum, or Silchester, passes across the downs two miles to the northward of the town. Near the course of this way, at Egbury, a Roman encampment, forming an irregular quadrangle, may be easily traced, the rampart in most parts is still lofty; the longest side measures about 300 yards. On several eminences within the extent of a few miles from Whitchurch are circular or ring-polls, commonly called beacons; but evidently military stations of the ancient inhabitants of the country, to which they could resort, and on which they could secure their families and property, in the event of hostile affault from domestic or foreign foes. — Beauties of England and Wales, vol. vi. Hampshire; by J. Britton, F.S.A. and E.W. Brayley.

WHITE, GILBERT, M.A. in Biography, an agreeable writer of natural history, was born at Selborne in Hampshire in 1720, and completed his education at Oriel college, Oxford, of which he was elected fellow in 1744. In 1746 he took the degree of M.A., and in 1752 became one of the senior professors of the University. Unambitious in his temper, and fond of rural scenery, he fixed his residence in his native village, and devoted his time to literary pursuits, and particularly to the investigation of those subjects of natural history, which furnished him with lessons of piety and benevolence. The refolt of his observations was communicated to the public in his "Natural History and Antiquities of Selborne," 1789, 4to. the first and principal part of which consisted of letters addressed to Mr. Pennant, and affords a variety of remarks, chiefly in the zoological departments, peculiarly amusing and no less instructive: and the second part treats of the antiquities of the place. Highly esteemed by all who knew him, he died in 1793; but after his decease, the natural history of his work was published separately in 2 vols., 8vo. 1802, with the addition of miscellaneous observations, and a Naturalist's Calendar, extracted from his papers, and of paralleled remarks communicated by W. Markwick, esq., an accurate observer of nature in the county of Suffolk. Gen. Biog.

WHITE, JOSEPH, Regius professor of Hebrew, and Laudian professor of Arabic, in the university of Oxford, was born in Gloucestershire in 1746, and being of humble origin, but devoted to reading whilst he was pursuing his father's occupation as a weaver, attracted the notice of a neighbouring gentleman, who sent him to Wadham college, Oxford. Having graduated M.A. in 1773, and chosen fellow of his college, he directed the main bent of his studies to the oriental languages, under the advice of Dr. Moore, afterwards archbishop of Canterbury. Such was his proficiency in this department of literature, that in 1775 he was elected Laudian professor of Arabic, on which occasion he delivered and printed an oration on the utility of that language in theological studies. By the recommendation of bishop Lowth, he was appointed editor of the Philoxenia Syriac version of the four gospels, which he published in 1778. About this time he was nominated one of the king's preachers at Whitehall; and in a sermon preached before the university of Oxford, he recommended a revision of the English translation of the Old Testament. In 1780 he published a "Specimen of the Civil and Military Institutes of Timour," transliterated from a Persian version of the Mogul original, written by the conqueror himself. He also added a specimen of Persian poetry, and recommended the study of this language. The Institutes having been translated entire by major Davy, were published from the Clarendon press in 1783, under the inspection of professor White, who annexed a preface, indexes, and geographical notes.

As Bampton lecturer, to which office he was appointed in 1781, he preached a course of sermons before the university, which were printed in 1784, and much admired for their learning and eloquence. The general design of these sermons was to evince the excellence of the Christian religion, on a comparison with that of Mahomet. (See Ar. Coran.) It was discovered, however, somewhat to the disgrace of the professor, that he had derived very considerable afurance in the composition of these sermons from the masterly pen of Mr. Badcock, who had been a diffenting minister at South Molton, and afterwards conformed to the church, and that several of them were actually written by him. It was also known, that Dr. Parr, from his ample store of Greek literature, had furnished the materials that had been wrought up into two of these sermons. These facts were investigated and ascertained; and the charge against the professor was sufficiently substantiated, and it was founded, not so much on his want of ability for such productions, as on his impiety, and on certain habits unfavourable to study. His reputation, however, as a defender of Christianity was acknowledged, and he was presented to a prebend of Gloucester, and soon after was graduated D.D. About the year 1790 he married, and accepted a college-living in Suffolk. In this situation he prosecuted his studies, and having set up a press in his house, and furnished himself with oriental types, he and his wife performed the business of compositors, and a man and maid-laborant of that press. Hence originated his "Egyptiaca," relating to the antiquities of Egypt; and an edition, with a version, of an account of that country by an Arabian writer named Abdallah. In 1799 Dr. White published from the Clarendon press his "Diatararion," or the harmony of the four evangelists, in Greek, a work useful to biblical students. He died in 1814, at the age of 68. Gen. Biog.

WHITE, one of the colours of natural bodies. White is not so properly said to be any one colour, as a composition of all the colours; it being demonstrated by sir Isaac Newton, that those bodies only appear white, which reflect all the kinds of coloured rays alike, and that the light of the sun is only white, because it consists of all colours.

From the multitude of rings of colours, which appear upon comprising two prisms, or object-glasses of telescopes together, it is manifest, that these do interfere and mingle with one another at last, as after eight or nine refractions, to dilute one another wholly, and constitute an even and uniform whiteness: whence, as well as from other experiments,
it appears that whiteness is certainly a mixture of all colours; and that the light which conveys it to the eye is a mixture of rays endowed with all those colours.

The same author fliws, that whiteness, if it be most strong and luminous, is to be reckoned of the first order of colours; but if fliws, as a mixture of the colours of several orders: of the former fort, he reckons white metals; and of the latter, the whitenefs of froth, paper, linen, and most other white substances. And as the white of the fliw order is the strongest that can be made by plates of transparent substances, so it ought to be stronger in the denser substances of metals, than in the rarer ones of air, water, and glass.

Gold or copper mixed either by fusion or amalgamation with a very little mercury, with silver, tin, or regulies of antimony, become white; which fliws, both that the particles of white metals have much more surface, and therefore are smaller than those of gold or copper; and also, that they are too opake, as not to suffer the particles of gold or copper to shine through them. And as that author doubts not, but that the colours of gold and copper are of the second or third order, therefore the particles of white metals cannot be much bigger than is requisite to make them reflect the white of the fliw order. See Colour, and Colours from Metals.

Hevelius affirms it as a thing most certain, that, in the northern countries, animals, as hare, foxes, bears, &c. become white in the winter time; and in summer refume their natural colours.

Black bodies are found to take heat sooner than white ones; by reason the former absorb or imbibe rays of all kinds and colours, and the latter reflect all.

Thus, black paper is fooner put into a flame, by a burning glass, than white; and hence black cloths, hung up by the dyers in the fun, dry sooner than white ones. See Black.

White of the Eye, denotes the fliw tunic or coat of the eye, called albuginea and conjunctiva, because it serves to bind together or inclose the refl. See Adnata, and Eye.

White Ale, in Rural Economy, a liquor of the malt kind, which is faid to be prepared somewhat in the following manner. Twenty gallons of malt are mashed with the fame quantity of boiling water; when after flanding the ufual time, the wort is drawn off, and fix eggs, four pounds of flour, a quarter of a pound of salt, and a quart of grout, are well beaten up together, and mixed with the above quantity of wort, which, after flanding twelve hours, is put into a cask, and is ready for ufe the day afterwards.

It is obferved by the writer of the Devonshire Corrected Report on Agriculture, who has supplied the above account, that this liquor is almost exclusively confined to the neighbourhood of Kingfoife, in that county; and that it is a beverage which poifesfes a very intoxicating quality, and which is much admired by those who drink not merely to quench thirst. A mystery, it is faid, hangs over the ingredient called grout, and the secret is faid to be confined to one family in the above district only. No difficulty, however, it is fuppofed, could arife in ascertaining its component parts, by submitting a certain portion of it to the fett of chemical examination. It is plain, it is faid, that this liquor is of confiderable antiquity, from the terrifer of the adwofon of Dobbrook, which expressly calls for the title of white ale.

This mild pleasant liquor may easily be made in other places.

White Antimony Ore, in Mineralogy, Antimoine Oxide, Hauy, generally occurs dillemated and crystallized in veins along with other ores of antimony on primitive rocks. See Antimony.

White Arsenic, and After. See the Sublimatives.

White Bait, in Ichthyology. See Clupea.

White Beam. See Crataegus.

White Bear. See Polar Bear.

White Bear, the Anar Hypeborea. See Duck.

White Bug, in Gardening, an insect of the bug kind, which is often very troublesome and hurtful in vinery, peach-houses, and other such forts of houses for fruit-trees.

It is obferved in the first volume of the Memoirs of the Caledonian Horticultural Society, that the caufe of this insect fo frequently making its appearance in these houses, is much owing to the neglect in not washing the trees properly every day with the engine in many cases. That when a vinery is much overrun with it, in order to its removal, all the old bark should be fript from off the vines, and all the shoots and treills be properly fponged over with black soap and warm water. The writer always makes it a rule, at the time of the winter-pruning, to take off the outer bark, whether infested with them or not, as these bugs lodge between the old and new bark. That in regard to peach-trees, which are infested in this way with the white bug, they should be sponged all over in the fame manner in the winter season; and if any bugs should appear in the spring, it is a good way, it is faid, to tie pieces of mat round the limbs and large branches of the trees; as about these parts these insects take shelter from the heat of the sun. Once every day these portions of mat should be taken off, and thrown away out of the houses. That soon after forcing is begun, the female of these bugs will be observed to be much larger than the male. At which time the infamity goes into some hollow of the trees or bark, and deposits her ova or eggs mothly in some fountains. These are easily capable of being discovered, and may be picked out of such hollows or crevices by means of a large pin, or small piece of sharpened stick; which is an effectual way of getting quit of them, and of preventing their future增进. See Washing Fruit-Trees.

White Campton, in Agriculture, a pernicious perennial weed in corn lands, pastures, and hedges, which is often difficult to destroy, except by good fummer tillage of the ground. See Weed, and Weeding.

White Caterpillar, or Bore, in Gardening, a very destructive fort of insect of this kind, but which is not fo numerous as those of the other kinds, nor does it attack and destroy the fame parts of gooseberry-bulhes, though equally injurious on others. It is of comparatively a fmall size too, in relation to those of the other forts, the black and green, that infest these bulhes; the former of which, the large or black, may be observed, it is flaid in a paper in the Horticultural Transacttions of Scotland, lying during the winter months in large clufers on the under parts, and in the crevices of the bulhes of these forts; and that even in the month of February they have been found in that flaie. But that in the course of eight or ten days after that, if the weather be favourable, they will creep up the bulhes in the day-time, feed on the young buds, and return to their nest during the night. That whenever leaves appear upon the bulhes, they feed upon them until they arrive at maturity, which is generally about the month of June; after which they creep down upon the under sides of the branches, where they lodge until the crust or shell is formed over them. That in July they become moths, and lay their ova or eggs on the under sides of the leaves and of the bark. That the produce
produce of these ova or eggs, which come into life during the month of September, feed on the leaves so long as they continue green, and afterwards collect and gather together in clusters on the under sides of the branches, and in the cracks and openings of the bark, where they abide all the winter, as has been already seen. Consequently that winter is the most proper time for attacking and destroying this sort of these infects with success, as their destruction is then most effectually and completely accomplished by merely the simple operation of sprinkling and pouring a quantity of boiling hot water over and upon them, from a watering-pan or pot, by which no injury, it is said, will thereby be done to the bushes or gooseberry fruit-turfs.

That the latter or green fort are in the shell state in February, when they lie about an inch under the ground. That in the following month they come out small flies, and immediately lay their ova or eggs on the veins and under sides of the leaves. That these ova or eggs produce young caterpillars in the month of May, which feed on the leaves of the bushes until June or the succeeding month, when they crawl off blackish kind of skin, and afterwards crawl down from the bushes into the earth, where a sort of crust or shell grows over them, and in that state they continue until the following April.

The only method which this writer has hitherto found effectual in destroying this sort of these gooseberry-caterpillars, is first to dig the ground all around the bushes very deep during the winter season, by which means the greater part of them are either destroyed, or buried too deep ever to rise to the surface: or, fecondly, in the month of April, when the flies make their appearance, to pick off all the leaves on which any ova or eggs are to be discovered, which is a tedious operation, but may be performed by children. If any of the infects should escape both these operations, they will, it is said, be discernible as soon as they come into life, by their eating holes through the leaves, and may then be easily destroyed, without the least injury to the bushes or fruit.

That this white kind bores the berry, and causes it to drop off from the bush. That they preserve themselves during the winter season in the chrysalis state, about an inch under ground, and become flies nearly at the same time with the latter of the above kinds. That they lay their ova or eggs on the blossoms, and that these eggs produce young caterpillars in May, which feed on the berries until they are fully grown, and then creep down into the earth, where they remain for the winter in the shell state.

This fort of these caterpillars, too, may be best destroyed in the winter season, by having the land well and deeply dug all about the gooseberry bushes at that time of the year, and by preventing them from climbing up the stems of the plants in the early spring season, for the purpose of laying their eggs, by every possible means that can be devised and referred to by the gardener.

These are the best and most effectual methods that have yet been discovered by this writer, for the destruction of this and the other two sorts of gooseberry-caterpillars. For though many other modes of doing it have been tried, none have been found so certain and complete as these; and they have this advantage and consideration to recommend them, that they injure neither the bush nor the fruit. That the same thing cannot be said either of tobacco-liquor, snuff, or soap-fluxes, all which render the fruit constantly bitter and ill-tasted; and which, whatever may be the effect that they may have upon the smaller kind of caterpillars, it is certain, the writer thinks, that they have none upon the larger kinds, and that fruit, lime, and lime-water, do not affect any fort

of caterpillar whatever, as the writer has sufficiently proved by repeated experiments with such substances.

White Ceylon Tea, in Agriculture, an annual weed in woods and other such places; of which animals in general are not fond. It is said to form the balls of the famous Portland powder for the gout. See Weed.

White Cinnamon. See Cinnamon.

White Clover, in Agriculture, a well-known plant of the clover kind, which is perennial, and consequently lasts a number of years in the soil or land. It is said to require a deep free foil to bring it to any degree of luxuriant growth. Consequently but little of the land in many districts suits it; but it is sometimes found with the common clover in about half the quantity. In the Berkshire Report on Agriculture, it is stated, that it is frequently confounded with the Dutch clover, that it affects a light foil, that it is much improved by rolling, and that it yields a very sweet hay when mixed with red clover, rye-grass, and nonfuch. That heep are not very fond of it; and this is, probably, one reason why it is not cultivated than it deserves to be. It appears, it is said, to be the Irish shamrock; and that the powdered flowers of this clover being made into bread, were eaten by the natives of the little island before the introduction of potatoes. It may be noticed, too, that it is capable of bearing flooding, which the red clover is not, and this is a very great advantage in its favour.

It is remarked also, that the real Dutch clover is not unfrequently sown with other granules, in a larger or smaller proportion, as the farmer may think proper. That in some places of the above county it is the common practice to sow of broad clover eight pounds, yellow trefoil, or hop clover, four pounds, and of Dutch or white clover, two pounds, to the acre. If it be sown alone, about eight or nine pounds will be sufficient. It is getting into high estimation in the neighbourhood of Bray, in the above district, and in other places, and is sometimes called honey-fuckle grass, from the sweetness of its smell. That to all sorts of cattle it forms an agreeable pasture, and especially to heep, which thrive on it prodigiously. Even swine will fatten on this grass, the feed of which was imported from Flanders for some time after it began to be cultivated this country, though it appears to be an indigenous plant. It has the excellent property of never wearing out by being close fed. See Tripoli, and Hyb. All CLOVER:

White clover is said, in the Gloucestershire Agricultural Report, to be injurious to cow-rock, by boving them when in abundance after rain in pastures.

White Colours, in Painting, comprehend the following; viz. FLARE White, White-Lead, or Cerussa, calcined or burnt Hars-Horn, the perfection of which depends upon its whitest aff and firmness, distinguishes both by sight and touch, Pearl-White, Troy-White, and Egg-Shell White. (See the several articles.) The most delicate and perfect white in use, in its application to the purposes of painting in water-colours, is the artificial sulphate of barytes. According to Mr. Parker (Ell. vol. ii.), it was first recommended and brought forward by Mr. Hume, of Long-Acre, who has long supplied the public with it under the name of "Permanent White." The same ingenious practical chemist says, that he knows of nothing so well calculated as this for marking bottles in a chemical laboratory, where the gages soon destroy the ink of common labels, and render them illegible. It is equally useful for marking jars, bottles, or boxes, which must be kept in a damp cellar, for it is not only imperishable in such situations, but preserves its extreme whiteness, and consequently the distinctness of the characters. We learn also from Sir Humphrey Davy's
Many’s “Elements of Chemical Philosophy,” that the combination of barytes and carbonic acid, made artificially by pouring a solution of carbonic acid into a solution of nitrate of barytes, forms also a pigment of a very white colour.

**White Colours, in Dyeing. See Colour.**

**White Copper Ores, in Mineralogy.** One of the rarest ores of copper, and has frequently been confounded with copper pyrites, and other ores of that metal. (See Copper Ores.) Its colour is between silver-white and bronze-yellow; it occurs massive and disseminated; it has a metallic lustre. The fracture is fine-grained and uneven; it yields easily to the knife. The specific gravity of this ore is 4.5. It contains about 40 per cent. of copper mixed with iron, arsenic, and sulphur.

**White Copperas, Cordage, Eagle, and Egg-Shell. See the sublimate.**

**White Cofa-Lettuce for Hogs, in Agriculture.** The use of it in feeding these animals. A trial of it in this way is flated to have been made in Sussex, which is particularly deserving of attention: the weaning of young pigs, without much milk and none corn, is often a difficult business; but if this sort of lettuce will do it, which seems to be the case, no farmer should ever be without a stock, or half an acre of this sort of crop for this use.

In this trial, four ounces of this sort of lettuce-seed were sown very thick over two parishes of ground in the beginning of March. A crop of potatoes was in rows at three feet distance; between which a double row of these lettuces was planted in May; both crops being afterwards kept clean by hand-hoeing. In the June following, they were begun to be used for three fows with little pigs, which were kept on these lettuces for six weeks; but these fows had wath in addition: the pigs were then weaned a fortnight earlier than usual; and after the weaning, the great use of the lettuces was found, for the pigs did admirably well upon them, until they all were gone in the middle of August. They were then fed as usual, with cabbage, turnip-tops, and other such vegetable matters, but fell off at once for want of the lettuces. See Lactuca, and Lettuce.

**White Crops, a term applied to all sorts of grain-crops, as wheat, rye, barley, oats, and some others, in contradistinction to those of the green and culmiferous kinds, such as cabbages, turnips, rape, tares, beans, and some others of a similar nature.**

**White Darnel, a very troublesome and prolific weed among corn-crops, especially of the wheat kind. See Weed, &c.**

**White Enamel. See Enamel, and Enamelling.**

**White Face, or Blazes, in the Manes.** A white mark upon a horse, descending from the forehead almost to the nose. It is called in French *chanfre blanc.*

**White Film, or Blindnefs, a difeafe in sheep, which is occasioned by a white film growing over their eyes, in conformance of some sort of inflammation, as arising from different causes, taking place in them.**

The appearances by which it is shown to be present are, according to some, that the animal cannot bear the light, that the white part of the eye is red and inflamed, and that it waters a great deal. That this state is succeeded by a sort of membrane or coat formed by the inflamed veffels, which first covers the white, but gradually extends over the eye, until total blindness is the confequence. That this is noticed to be the cafe, when in folding, the sheep run against dykes, or any other fuch obfacles, and flart when they approach them; that they do not follow the flock, and that they frequently tumble. That when the eye is infpefted, it is generally found, that a blue fliough covers the whole of the eye, without any intermixture of red veffels. That in the worst cafes, the coloured and transparent part of the eye becomes of a reddish-white; by which time, the film on the eye has acquired confiderable thicknefs and hardnefs. That the inflammation is produced in various ways, and by various means; as during the summer feaon by the reflection of heat and light in very funny and dry weather, as it is found to be more frequent when the hilly sheep-walks become fioreched, and on hard rocky fiols, than on the dark-coloured hills which are covered with heather. Others fuppofe, that the difeafe is sometimes caufed by the pollen or dust of flowers irritating the eyes of the sheep, when blown into them, in confiderable quantities, by the wind. That in the winter, the blindnefs is caufed and occurs when the days are very funny, and the evenings frotly and cold; or when the sheep have been long buried under snow, and the ground is still white and glaring when they get out.

But by other others, the blindnefs in sheep is believed to arise from a caufe wholly different from any of these. That it is induced by a continued fatigue for a length of time, which is capable of bringing it on at any feaon of the year. Thus, sheep that are long and hard driven, or such as are daily dragged from one part of the ground to another, eyes that are old, or old, and roughly handled and used by the women in milking, during the operation, where that practice is in use, and hog-sheep which are tired by driving through snow, in order to preferve their fatublence, are all liable to this affection of the eyes. That their eyes at firft become fore, and emit a fort of dry humour; after which a white film fettles over them, and if they continue to be fatigued, it grows thicker, the eyes appearing perfectly white; in which cafes, they are said to be proportionably longer in getting better. The difeafe, too, may proceed from many other caufes of different kinds, as all fuch as tend to caufe local inflammation in the parts, as cold, moisture, and many others of the fame fort.

In the cure of the difeafe, where it is infpefted to arise from the irritating powdery matter of flowers, the sheep should be immediately removed to other proper paturses for a time, until the danger from that caufe is over; and in cafes of snow-blindnefs of this kind, it is always proper to bring them down, as soon as possible, from the high snowly walks, where they occupy them, to the bare grounds below.

The inflamed veffels on the white of the eye, especially those next the nofe, are also sometimes advised to be cut with a lancet or sharp penknife every second morning; while the eyes are to be kept defended against the light, by a shade tied over the head, or a piece of crape over the eyes. The eyes may likewise be bathed two or three times a-day, with a solution of half a drachm of fugar of lead, or of two drachms of alum, and the fame quantity of white vitriol, in a pint of soft-water. At the fame time purgatives may be given internally, fuch as two ounces of some purging falt, or, what is better, a scruple of calomel, once a day for four or five times. When, by these means, the inflammation is got the better of, but the fliough still remains, a little ointment, compos’d of eight parts of some mild unctuous subfance, and one of red precipitate of mercury, made fine by rubbing, may be infuflated into the eyes every morning; or a little finely powdered crytal and leaf fugar be blown into them twice in the day.

With fome, it is at firft the practice to bleed the sheep below the eyes, and to let some of the blood run into each of them; but it is fuppofed that care will infallibly cure the difeafe in a space of time proportioned to the debility that
has induced the complaint without any thing else. The best and most proper means of cure in these cases are, in the first place, local or general bleeding, then the use of some such collusions and internal remedies as the above, after some time having recourse to stronger washes and powders of the same nature, with small quantities of opium, and keeping the animals all the while as much as possible from the light, and the glare of the ground. (See a paper in the third volume of the Transactions of the Highland Society of Scotland.) It is observed, that certain parcels of sheep are very liable to blindness of this sort; and that although it is not a fatal disease in itself, it frequently occasions considerable los by the sheep drowning themselves, or breaking their necks in falling down precipices and other such places.

White Flag, Flats, and Froth. See the substantives.

White Foot, in the Mange, called in French balzana, is a mark that happens in the feet of a great many horses, both before and behind, from the fetlock to the coffin. The horses thus marked are either trembled, crostremelled, or white all four. Some horsemen place an unlucky fatality in the white of the foot behind. See CHAUSSETTE, TREP HANT, and TRAMELLED.

White Friars, a name common to several orders of monks, from their being clothed in a white habit.

Such are, the regular canons of St. Augustine, the Premonstratensians, and Bernardines. See CARMELITES.

White Glaft. See Glass.

White-Hart Silver, candidi corvi argentum, a tribute or mulct paid into the exchequer, out of certain lands in or near the forest of White-hart, in Dorsetshire; which was continued from Henry III. this time, who first imposed it upon Thomas de la Linde, and others, for killing a beautiful white hart, which that king had purposely spared in hunting.

White Herbs. See HELLEBORE.

White Honeysuckle, in Agriculture, a term often applied to the white clover. It is flated, in the Agricultural Report for the County of Gloucester, to be a plant which is brought forward by manure and sheep-lock, and a proof of good land, at least of land in a high state of cultivation; and that, on this account, it has, when it abounds in dairy pastures, a tendency to raise the quality of the milk, and make the cheese more or less which is made from it. See DAIRYING, and WHITE CLOVER.

White Horse-Fish, in Ichthyology, a common English name for the raia alper noistras of Willughby, and the raia fulonica of Rondeletius and Linnaeus. Its back is rough and spiny; the nose is short and sharp; at the corner of each eye are a few spines; the whittling membrane is fringed; the teeth are small and sharp; on the upper part of the pectoral fins are three rows of spines pointing toward the back, and crooked, like those of the fuller's instrument; whence its name fulonica and fuller. On the tail are three rows of strong spines: the tail is slender, and rather longer than the body. The colour of the upper part of the body is cinerous, usually marked with many black spots; the lower part white. This fish grows to a size equal to that of the skate. Pennant.

White Jasper, in Mineralogy, or agate jasper, has a pale yellowish-white colour, and sometimes occurs reddish-white. It is opaque, and has small imperfectly conchoidal fractures. See JASPER.

White Land, in Agriculture, a tough clayey soil, naturally of a somewhat whitish hue when dry, especially when it has lain some time untilled, but becoming blackish after rain: this appears of a light greyish colour when turned up by the plough, and slides off from the plough-share with cafe, and with a smooth glossy surface. It has often a yellowish hue with the grey, and is very leaved with large parcels of a blue marly earth. See CLAY SOIL.

White Lead is a sort of rust of lead, or lead dissolved with vinegar; much used by painters. See LEAD, and CERUSE.

White Leaf. See CRATIGUS.

White Line, among Printers, a void space, greater than usual, left between two lines. See PRINTING.

White Line, in Anatomy. See LINEA ALBA.

White Linen is cloth of hemp, or flax, bleached by divers leys, and waterings on the ground.

White Manganes, in Mineralogy, manganece oxyde carbonaté, Haüy. Red manganece ore of some mineralogists. This ore occurs of various colours, from yellowish-white to rose-red. See ORES OF MANGANESE.

White Meats include milk, butter, cheese, white pots, curdlets, and other foods consisting of milk, or eggs. Some add, also, fish, veal, and chickens.

White Mortar. See MORTAR.

White Mulberry, in Rural Economy, a very fine cider-fruit in field fruit-gounds. This, with the fox-whelp, redscrew, and some others, are fine old fruits, but which are now going off, and afford the better cider, when mixed in the mill: the proportions in which they are to be used have never, however, been defined, but depend probably a good deal on the quantity to be ground at the same time.

White Mulberry, in Agriculture, a sort of plant which is often cultivated in the field for the use of the seed in different places.

The best sort of foil for it is that of the light loam, which should be well broken down and reduced by ploughing and harrowing. Some, on fresh broken up land, make a winter fallow for this crop.

It is mostly put in after a wheat-crop, but may succeed others where the land is clean and well prepared. In Kent, they strike furrows about eleven or twelve inches apart, and then sow the seed, two or three gallons to the acre, in the month of March.

The culture of it while growing is to hoe it, and keep it free from weeds, to set it out in the way of turnips, not too thick on the ground, as that draws up the plants weak. The crop is reaped about July. In some cases, it is laid in gavels or handfuls upon the stubble, in the same manner as cole-see. It is usually threshed out on a sail-cloth in the field.

The produce differs from eight to twenty bushels the acre.

It is a ticklish sort of crop, as one frosty morning will kill it, and it is liable to be injured and eaten by the black caterpillar; but when it turns out well is very profitable.

It is said not to exhaust the land much, which is greatly in its favour.

White Mickel-Crow, a term provincially applied to the rook in some cases.

White Order. See ORDER.

White Paper is that intended for writing, printing, &c., in contradistinction to brown paper, marbled paper, blotting paper, &c.

White, Pearl. See PEARL.

White Pepper. See PEPPER.

White Poplar, in Agriculture, a tree of the poplar kind, in which the wood is soft, but convertible to various uses in husbandry, as it grows quickly and bears cropping well. It is best grown in low situations, where the soil is of a clayey nature. It is sometimes called the ablee tree.
White Poppy, a plant sometimes cultivated in the garden and the field for the use of the opium which is obtained from its juice by means of evaporation. It might be largely cultivated in many situations with great advantage, as it contains this substance or principle in great abundance. See Papaver Album.

White Porcelain. See Porcelain.

White Pot, denotes milk or cream baked with the yolks of eggs, fine bread, sugar, and spice, in an earthen pot. The cooks furnish us with a variety of dishes under this form and denomination: such are, Norfolk white-pot, Westminister white-pot, rice white-pot, &c.

White Pottery. See Pottery.

White Precipitate. See Carbonate of Mercury.

White Pyrites, in Mineralogy; Fr. sulfure blanc, Haüy. The colour of this ore when pure is of a tin-white colour, passing into brads-yellow and steel-grey. It occurs in small octohedral crystals variously modified, also foliated and botryoidal. It is hard, brittle, and easily frangible. It melts before the blow-pipe, giving out a sulphureous vapour; it then acts on the magnetic needle. It decomposes much easier than common pyrites. It contains 46 parts of iron and 54 of sulphur. See Pyrites.

White Rent, in Rural Economy, a rent or duty of 8d. payable yearly, by every tenner in the counties of Devon and Cornwall, to the duke of the latter, as lord of the soil. See Blanch Fermé.

White Salt is common sea-salt dried and calcined by the fire, so as not to leave any moisture therein. The chemists call it decrystallized salt.

There are some salts naturally white, and others that need to be whitened, either by dissolving and purifying them in fair water, which is afterwards evaporated; or by means of fire; or by the sun. See Salt.

White Salt, a term applied to the fine purified salt, in contradistinction to that of the rock kind. The former is said in Cheshire to form a much more important object in the way of commerce than the latter. See Salt.

White Sarsaparilla, a root of fowle made of bleden almonds, and the brest of a capon, pound together with cloves, cinnamon, &c. We also hear of white broth, which is a broth of broth enriched with fack and spices, having blanded almonds feraped into it, and the whole thickened with the yolks of eggs, &c.

White Scour. See Scour.

White Silver Ore, in Mineralogy, an ore of silver always associated with lead and antimony. (See Silver Ores.) Dark white silver contains, according to Klaproth, 9.25 parts in the hundred of silver. Light white silver ore contains 20.40, associated with the same minerals as the dark ore, but in different proportions.

White Soap. See Soap.

White, Spanish, is a kind of fuscus used by the ladies to whiten their complexion, and hide the defects of it, called also magistery of bismuth.

The use of this, as well as of cerusses, is pernicious; and should be particularly avoided during the taking of any sulphureous water, which may change the complexion quite black. Indeed, all phlogistic vapours, and even the fire itself, tend to give both the magistery of bismuth and cerussa a yellow colour: an observation which serves to explain a pallage in Martialis, where a cerused lady is said to fear the sun.

"Cretata timet Fabulla, nimbus,
Cerufata timet Sabella, solem."

WHITE-SWELLING.

When a disease is attended with great varieties, not only with regard to its progress and symptoms, but also its causes, and the disorder which it produces in the parts which are the seat of it, there is as much difficulty in fixing upon a name that will convey an exact idea of it, as in offering a definition or description of it applicable to all the cases which may present themselves to the attentive observer. Such are the circumstances of the disease of which we are about to speak in the present article. Surgeons have given it a variety of appellations, derived from some one particular symptom with which it is accompanied. Thus, it has been called white-swelling, (a name which is still most generally adopted,) because the skin which covers it retains its natural colour, and exhibits no appearance of inflammation. It is also sometimes termed fungus articuli, on account of its softness and elasticity, which allow it readily to yield to pressure, but make it rise up again immediately when the compression is discontinued, like the fungous excrescences which grow upon the oak. The disorder is likewise often named by foreign writers the lymphatic tumour, or sereous swelling of the articulations, in consequence of the great quantity of thick lymph which appears to be effused in the cellular fibres round the ligaments, and upon the ligaments themselves. Sometimes the disease is called spina ventosa. (See that article.) The case is occasionally denominated a false ankylosis, because the diseased surface causes more or less interruption of the motions of the joint. Lastly, the dilatation is often called a rheumatic, or serofulous dislocation of a joint, according as rheumatism, or serofula, is suspected of being concerned in its origin.

White-swellings are usually defined to be chronic enlargements of the joints; circumscripted; without any alteration in the colour of the skin; sometimes hard, and resisting the pressure of the fingers; sometimes less firm, elastic, yielding to pressure, and afterwards rising up again in the manner of a fungus, which grows upon certain trees; sometimes so soft as to present a deceitful feel of fluctuation, although there is no fluid in the part. In particular instances, these swellings are indolent; but, most frequently, they are attended with great pain, especially when the joint is moved, so that the patient either cannot exercise the limb at all, or does it at the expense of considerable suffering, and with imperfect and difficulty. The disease has its seat in the ligaments, cellular fibres, synovial glands, cartilages, and even the bones. All these parts, however, are not affected in every instance; and sometimes the dilatation commences in the bones; sometimes in the cartilages and ligaments, according to the peculiarity in the nature of the case. The foregoing definition is obviously merely an enumeration of the principal symptoms of white-swellings, and is far from giving an exact idea of a disease which presents so many varieties in different individuals, that there are scarcely two patients to be met with in whom the complaint follows precisely the same course, or exhibits altogether similar phenomena.

There is no joint which may not be attacked by this intransite disease; but experience proves, that the ginglymoid articulations are more frequently affected than the orbicular. We are, however, except from this remark the articulation between the femur and os innominatum, in which the disease is very common, and often called by the French surgeons spontaneous dislocation of the femur, because the case generally terminates in a displacement of the head of the thigh-bone. (See Hip-Joint, Dislocation of.) Amongst the ginglymoid joints, the knee is oftener affected than any other. Then come the joints of the elbow, foot, and hand. White-swellings attack the small joints, like those of the fingers and toes, with far less frequency.

White-swellings may occur at every period of life; but they are more common in infancy and youth than in adults and old subjects. It is conceived also by some writers, that these cases begin more frequently in autumn and winter, or when the atmosphere is damp and variable, than in the other seasons. But the disease is on the whole so common in this climate, that it must be difficult to establish the truth of the foregoing conjecture.

The disease sometimes begins with a more or less acute pain in the articulation, usually extending along the fasciae and tendons of the neighbouring muscles. Sometimes the pain is of a dull kind, being superficial, seated in the soft parts, and reaching all round the joint. On other occasions, it is acute, deeply situated, and confined to a small space, which is most commonly the centre of the articulation. In particular examples, the swelling of the joint succeeds a pain which has been experienced in another part of the body, and suddenly ceased. Sometimes the disease begins in an unexpected manner, that the patient, who went to bed perfectly well, rises in the morning with a slight painful knee. Cases of the latter kind are generally rheumatic.

Whatever may be the manner in which the complaint originates, and whatever the circumstances which precede the attack, it always comes on in the form of a tumour, which presents the following characters:—The swelling seldom reaches all round the articulation; but is almost always limited to a more or less extensive portion of the circumference of the part. In the knee, it occurs above the patella, and also below this bone, at the sides of the ligament, which connects it with the tibia. In the elbow, it chiefly occupies the sides of the joint, especially the inner side. In the ankle, it takes place below and behind the malleoli. Lastly, in the fingers, it commonly affects the whole circumference of the diseased joint. Such swelling is circumscripted, immovable, and more or less hard and elastic, not retaining the impression of the finger, as in edema (see EDEMA), but generally communicating, when handled, a sensation of softness, which leads to a suspicion of the presence of a fluid, when none in reality exists. The swelling is more or less painful, especially when compressed. Sometimes, however, it is indolent; the heat of the part is not increased, and the integuments continue of their natural colour. The motion of the joint is impeded, and if the patient will not abstain from moving the part, he is put to an excruciating pain. There are some white-swellings of the knee, in which the leg is fixed in the extended posture; but, most commonly, the limb is bent, even in a considerable degree, and when an endeavour is made to straighten it, great suffering is excited. In white-swellings of the elbow, the forearm is constantly observed in a state of flexion. In those of the wrist, the hand has a strong propensity to fall into the bent position; and in order to prevent this occurrence, and hinder an incomplete luxation of the carpus from taking place backwards, the surgeon is sometimes obliged to support the hand upon a splint.

The constant flexion of the limb produces a considerable retraction of the flexor muscles and their tendons, together with a rigidity which can be felt through the integuments, and which extends far through the muscles and tendons, generally from the bones to the joints, and often further, as far as the skin. The total loss of exercise always arising from this state of the muscles and tendons, generally soon renders the joint stiff and motionless, so that it frequently has the appearance of being in a state of rcal and complete ankylosis. See ARTHRITIS.
WHITE-SWELLING.

The swelling may remain a long while in the condition which has been described; it may even cease to be painful; and it may cause only a serious weakness of the knee, and more or less difficulty in walking. But most commonly it continues to make uninterrupted progress; or, if its advances should happen to be checked, and the disease be for a time stationary, it frequently occurs, that, in consequence of a fall, a bruise, or even without any external cause, and, as it were spontaneously, the complaint afterwards increases again. The articulation swells more and more, and, if it be the knee which is affected, the hollow of the ham also swells up and becomes effaced. The pain likewise augments, being felt sometimes at one point of the circumference of the joint, sometimes at another; occasionally in the ham, and, in other examples, in the very cavity of the articulation. There are, however, some patients who feel no suffer little or no pain of any consequence. The hardness of the tumour is subject to great variety. The older the disease is, the more considerable is in general the degree of induration. Yet there are certain white-swellings which are extremely hard, although they have not existed a long while; and other cases which are very soft, notwithstanding they are of long standing. Boyer thinks, that this difference depends upon the heat of the disease, which is sometimes in the bones; sometimes in the ligaments and surrounding cellular membrane. The skin which covers the swelling grows thin, pale, and shining; the cutaneous veins become dilated and varicose; and the muscles of the leg waste and dwindle away, so that the size of this part of the limb is strikingly diminished. Sometimes, however, it is affected with oedema, and has the appearance of being enlarged. The lower part of the thigh also frequently undergoes a very considerable diminution. This wasting of the limb above and below the disease, makes the joint also seem much more swelled than it is in reality. Sometimes the lymphatic glands in the groin become enlarged and hardened; and when the disease makes much progress, the bones are frequently softened and carious, and the cartilages destroyed. Lastly, abscesses, more or less considerable, are formed in different parts of the tumour; and their formation is attended with a great deal of acute pain, inflammation, and fever. These abscesses are more or less deeply situated, and often communicate with the interior of the joint. When they burst, or are opened, a large quantity of matter is discharged, which is hardly ever of healthy consistence, being mostly a fatty-purulent yellowish fluid, somewhat resembling turbid whey, and containing flakes of albumen. Sometimes, however, it presents very nearly the appearances of healthy pus; but it soon changes into a thin fetid fumes of very bad quality. Its discharge, although very considerable, is followed by scarcely any perceptible diminution in the size of the swelling. The openings by which it escapes sometimes soon close, and fresh collections of matter ensue which burst of themselves, and then heal up like the former; but, in general, the apertures, instead of healing, become converted into incurable fistulae.

Mr. Brodie has paid considerable attention to the several diseases of the joints, which usually go under the name of white-swelling. In particular, he has carefully examined the morbid appearances which are found upon dissection; and his observations have led him to propose a classification of these diseases.

1. The first case which Mr. Brodie describes is, inflammation of the synovial membrane, which may occur as a symptom of a constitutional disease, where the fylene is affected with rheumatism; where mercury has been improperly exhibited, or in large quantities; or where there is general debility from any other cause. But, in these cases, the inflammation is seldom severe; it occasions an effusion of fluid into the joint, but rarely terminates in the extravasation of coagulating lymph, or thickening of the inflamed membrane. Sometimes it leaves one joint to attack another; or, it suddenly subsides without another joint becoming affected.

At other times, says Mr. Brodie, the inflammation occurs as a local affection produced by a sprain, the application of cold, or arising from no evident cause. It is then, for the most part, more severe, and of longer duration; it leaves the joint with its functions more or less impaired, and occasionally terminates in its total destruction. In itself, it is a serious disease; but it is often confounded, under the general name of white-swelling, with other diseases still more serious. In some cases, it assumes the form of an acute; but in the greater number of instances, it has that of a chronic inflammation.

When the case is acute, the skin is in general red, and the joint tender and painful. The pain, which is not confined to any particular point, and aggravated by motion of the limb, is soon followed by swelling. The patient is also affected with inflammatory fever. In a few days, the disease either subsides altogether, or assumes the chronic form.

According to Mr. Brodie, when the inflammation is chronic, the pain and tenderness are less, so that the patient is able to walk about, and often without experiencing any severe distress. There is no fever, and the skin retains its natural colour. The swelling also increases less rapidly than in acute cases. These symptoms are generally rendered worse by exposure to cold and exertions. In the first instance, the swelling of the joint arises entirely from a preternatural quantity of synovia. But when the inflammation has existed some time, the fluid is not so plainly perceptible, because the synovial membrane is now thickened, which likewise augments the stiffness of the articulation. The shape of the swelling is not that of the articulating ends of the bones, but arises chiefly from the distended state of the synovial membrane, and hence depends in a great measure on the situation of the ligaments and tendons, which yield it in certain directions. Thus, when the knee is affected, the swelling is principally observable in the same places where it occurs in cases of hydroptic articular.

After the inflammation of the synovial membrane has subsided, the fluid is absorbed, and, in some instances, the joint recovers its natural figure and mobility; but in the majority of cases, the stiffness and swelling continue. Whenever the patient is exposed to cold, or exercises the limb much, the pain returns, and the swelling is increased. Such cases are of frequent occurrence, and, as Mr. Brodie observes, they form a large proportion of those diseases which are called white-swellings.

2. The same gentleman has favoured the public with a very circumstantial history of another description of cases, where the disease originates in the synovial membrane, which loses its natural organization, and becomes converted into a thick pulpy substance of a light brown colour, intermixed by white membranous lines, and from one-fourth to one-half of an inch, or more, in thickness. As this disease advances, it involves all the parts of which the joint is composed, producing ulceration of the cartilages, caries of the bones, and
bones, waisting of the ligaments, and abscesses in different places. The complaint has invariably proved slow in its progress, and sometimes has remained nearly in an indolent state for many months, or even for one or two years; but Mr. Brodie informs us, that he has never met with an instance in which a real amendment was produced, much less a cure. (See Medico-Chir. Trans. vol. iv. p. 220, &c.) Mr. Brodie also remarks, that the above-described affection of the synovial membrane is rarely met with, except in the knee, and that it generally takes place in young persons under, or not much above the age of puberty. In the origin of this disease, there is a slight degree of stiffness and tumefaction, without pain, and producing only the most trifling inconvenience. These symptoms gradually increase, so that, at last, the joint scarcely admits of the smallest motion, the stiffness being greater than what is the usual result of common inflammation. The form of the swelling bears some resemblance to that in cases of inflammation of the synovial membrane; but it is less regular. The swelling is soft and elastic, and gives to the hand a sensation as it contained fluid. If only one hand be employed in making the examination, the deception may be complete, and the most experienced surgeon may be led to suppose that there is fluid in the joint when there is none; but if both hands be employed, one on each side, the absence of fluid is distinguished by the want of fluctuation.

"The patient experiences little or no pain, until abscesses begin to form, and the cartilages ulcerate; and even then the pain is not so severe as where the ulceration of the cartilages occurs as a primary disease, and the abscesses loco more readily, and discharge a smaller quantity of pus than in cases of this last description. At this period, the patient becomes affected with hectic fever, loses his flesh, and gradually sinks, unless the limb be removed by an operation." See Brodie's Obs. in Medico-Chir. Trans. vol. v. p. 251, &c.

3. Another form of white-swelling described by the same writer, is that which is more particularly characterized by ulceration of the articular cartilages. This change occurs in the advanced stage of several diseases of the joints, and it also exists in many instances as a primary affection, in the early stage of which the bones, synovial membrane, and ligaments, are in a natural state; but which, if neglected, ultimately occasions the entire destruction of the articulation. When ulceration of the cartilages occurs in the superficial joints, it constitutes one of the diseases which have been known by the name of white-swelling. From cases which Mr. Brodie has seen, he is led to conclude, that when it takes place in the hip it is this disease, which has been variously designated by writers, the "morbus coxarius," the "disease of the hip-joint," the "serofulous hip," the "serofulous cartes of the hip-joint," &c. At last, Mr. Brodie conceives, that it is to this disease such names have been principally applied, though he acknowledges that there are probably other morbid affections which have been confounded with it. (Op. Cit. vol. iv. p. 236.) The ulceration of the articular cartilages takes place as a primary disease, chiefly in children or adults under the middle age. "Of sixty-eight persons affected with this disease, fifty-fix (according to Mr. Brodie) were under thirty years of age; the eldest was an infant of about twelve months; the oldest was a woman of sixty-seven." As the knee is more frequently affected with inflammation of the synovial membrane, so is the hip more liable than other joints to ulceration of the cartilaginous surfaces. In general, the disease is confined to a single joint; but it is not very unusual to find two or three joints affected in the same individual, either at the same time or in succession. Sometimes the patient traces the beginning of his symptoms to a local injury; or to his having been exposed to cold; but, for the most part, no cause can be assigned for the complaint. See Medico-Chir. Trans. vol. vi. p. 319.

For a description of the disorder as it occurs in the hip, the reader is referred to the article Hip-Joint, Disease of. At present, we shall merely notice the symptoms which, according to the investigations of Mr. Brodie, particularly characterize ulceration of the cartilages of the knee. They differ from the symptoms of inflammation of the synovial membrane, by the pain being slight in the beginning, and gradually becoming very intense, which is the reverse of what happens in the latter affection. The pain also in the commencement is unattended with any evident swelling, which never comes on in less than four or five weeks, and often not till after several months. It is not to be inferred, however, that every slight pain of the joint unaccompanied with swelling, must of course arise from ulceration of the cartilages. But, says Mr. Brodie, when the pain continues to increase, and at last is very severe; when it is aggravated by the motion of the bones on each other; and when, after a time, a slight tumefaction of the joint takes place, we may conclude that the disease consists in such ulceration. The swelling arises from a slight inflammation of the cellular membrane on the outside of the joint; it has the form of the articulating ends of the bones; and for the most part it appears greater than it really is, in consequence of the muscles being wasted. No fluctuation is perceptible, as where the synovial membrane is inflamed; nor is there the peculiar elasticity, which exists, where the synovial membrane has undergone a morbid alteration of its structure.

Mr. Brodie, however, has explained, that, in some cases, the swelling has a different shape, and communicates the feel of a fluctuation. This happens when inflammation of the synovial membrane, attended with a collection of the synovia of the joint, or abscesses in the surrounding soft parts, or in the articulation itself, occur as secondary diseases. When there has been considerable destruction of the soft parts from abscesses and ulceration, the head of the tibia may become dislocated and drawn towards the ham. See Medico-Chir. Trans. vol. vi. p. 326, &c.

4. There is another species of white-swelling which is peculiarly different from others, in being attended with ulceration of the synovial membrane. As, however, it does not appear to us to need a description in a work not expressly devoted to surgery, we shall only add, that the reader may find Mr. Brodie's account of the cause in the Medico-Chir. Transactions. These white-swellings which are reputed to be serofulous, form a subject, however, on which we cannot be silent. In the serofulous diseases of the joints, the bones are primarily affected, in consequence of which ulceration takes place in the cartilages covering their articular surfaces. The cartilages being ulcerated, the subsequent progress of the disease is, according to Mr. Brodie, the same as where this ulceration takes place in the first instance.

It has been a very prevalent opinion, that, in cases of white-swelling, the heads of the bones are always enlarged. Mr. Ruffell is, perhaps, the first writer who expressed an opposite sentiment, and he absolutely declares, that he had never heard nor known of an instance, in which the tibia was enlarged from an attack of white-swelling. (On Diseases of the Knee, p. 37.) We believe, that a regular expansion of
of the heads of the bones, in cases of white-swelling, is frequently an unusual occurrence, although it may sometimes happen. It is frequent, however, to meet with a sort of enlargement, which arises from spicules of bony matter, deposited on the outside of the tibia, ulna, &c., which alteration is materially different from a regular expansion of the heads of those bones. We have, however, lately seen an instance, in which the upper head of the ulna is considerably increased in size by a regular kind of expansion. The preparation is in Mr. Abernethy's museum; and a few other specimens we have, believe, been occasionally noticed. Yet, as a general fact, we may still remark, that an enlargement of the heads of the bones in the diseased called white-swelling, is far from being the usual state of things. The change which the head of the tibia undergoes in many cases, is first a partial absorption of the phosphate of lime throughout its texture, while a soft kind of matter is secreted into its substance. In a more advanced stage, and, indeed, in that stage which most frequently takes place before the limb is amputated, there are deep excavations in the head of the bone, arising from caries, and its structure is now so softened, that when a probe is pressed against the carious part, it readily penetrates deeply into the bone.

Mr. Brodie also joins in the opinion, that the morbid affection has its origin in the bones, "which," he says, "become preternaturally vascular, and contain a less than usual quantity of earth, while, at first, a transparent fluid, and afterwards a yellowish cheesy substance, is deposited in their cancelli. From the diseased bone, vessels, carrying red blood, shoot into the cartilage, which afterwards ulcerates in spots, the ulceration beginning on that surface which is connected to the bone." Med. Chir. Tranf. vol. iv. p. 272.

With respect to the expansion of the heads of the bones, we ought to have mentioned, that the late Mr. Crowther entirely disbelieved the reality of the occurrence, and every body knows, that he paid very considerable attention to the subject. (See Praef. Obf. on White-Swelling, &c. edit. 2. p. 14.) The event, however, should have been described as unusual, and not as never happening, since, as we have already stated, a few specimens of such a change have now been collected.

Mr. Ruffell has particularly noticed how much the soft parts frequently contribute to the swelling: "the great mass of the swelling," he observes, "appears to arise from an affection of the parts exterior to the cavity of the joint, and which, besides an enlargement in size, seems also to have undergone a material change in structure. There is a larger than natural proportion of a viscid fluid, intermixed with the cellular substance; and the cellular substance itself has become thicker, softer, and of a less firm consistence than in a state of health." (On the Morbid Affections of the Knee, p. 30.) The manner in which the soft parts are affected is also described by Mr. Brodie. "Inflammation takes place of the cellular membrane, external to the joint. Serum, and afterwards coagulable lymph, are effused; and hence arises a puffy elastic swelling in the early and an edematous swelling in an advanced stage of the disease. Scrofula attacks only those bones, or portions of bones, which have a spongy texture, as the extremities of the cylindrical bones, and the bones of the carpus and tarus; and hence the joints become affected from their contiguity to the parts which are the original seat of the disease." Med. Chir. Tranf. vol. iv. p. 273.

All white-swellings which make considerable progress, and occasion fever, pain, long confinement, abscesses, &c. unavoidably bring on that impairment of the general health, which is well known by the name of hectic fever. The patient gradually loses his appetite and natural rest and sleep; his pulse is small and frequent; an obstinate debilitating diarrhea, and profuse nocturnal sweats, ensue. Such complaints are sooner or later followed by dilatation, unless the constitution be relieved in time, either by the amendment or removal of the diseased part. In different patients, however, the course of the disease, and its effects upon the system, vary considerably in relation to the rapidity with which they occur.

Rheumatic white-swellings are very distinct diseases from the scrofulous disfigure of the large joints. In the first, the pain is laid never to occur without being attended with swelling. Scrofulous white-swellings, on the other hand, are always preceded by a pain, which is particularly confined to one point of the articulation. In rheumatic cases, the pain is more general and diffused over the whole joint.

It seems probable, that all cases in which the structure of the bones is found quite undiseased, and in which all the mals of disease appears to be confined to the soft parts, are not scrofulous white-swellings. Few persons who have attained the age of five-and-twenty, without having had the leaff symptom of scrofula, ever experience, after this period of life, a first attack of the white-swelling of the scrofulous kind. All cases, in which the internal structure of the heads of the bones becomes softened, are probably scrofulous.

Mr. Ruffell has noticed the frequent enlargement of the lymphatic glands in the groin, in consequence of the irritation of the disease when in the knee; but, he justly adds, that this secondary affection never proves long troublesome.

When the bones are diseased, the head of the tibia always suffers more than the condyles of the thigh-bone. (Ruffell.) The articular surface of the femur sometimes has not a single rough or carious point, notwithstanding that of the tibia may have suffered a great deal. The cartilaginous coverings of the heads of the bones are generally eroded first at their edges; and in the knee, the cartilage of the tibia is always more affected than that covering the condyles of the thigh-bone. Indeed, when white-swellings have their origin in the bones, and the knee is the seat of the disorder, there is some ground for supposing that it is in the tibia that the morbid mischief first commences.

The ligaments of the knee are occasionally so much weakened or destroyed by this terrible malady, that the tibia and fibula become more or less displaced backward, and drawn towards the tuberosity of the ischium, by the powerful action of the flexor muscles of the leg.

We have seen a curious species of white-swelling, in which the leg could be moved to each side with a very considerable distance, both when the knee was extended and bent. Such a state implies a preternatural looseness of the ligaments of the articulation.

Scrofulous white-swellings, no doubt, are under the influence of a particular kind of constitution, termed a scrofulous or scrofulous habit. In this sort of temperament, every cause capable of exciting inflammation, or any morbid and irritative state of a large joint, may bring on such disorder as may end in the severe disease of which we are now speaking.

In a man of a found constitution, an irritation of the kind alluded to might only induce common healthy inflammation of the affected joint.

In scrofulous habits, it also seems probable, that irritation
tion of a joint is much more easily produced than in other constitutions; and no one can doubt, that when once excited in the former classes of subjects, it is much more dangerous and difficult of removal than in other patients.

The doctrine of particular white-swellings being serofuluous dilates, is supported by many weighty reasons, the opinions of the most accurate observers, and the evidence of daily experience. Wifeman (book iv. ch. 4.) calls the spina ventosa a species of serofula, and tells us, that infants and children are generally thse subjects of this disease. The disorder is said by Severinus to be exceedingly frequent in young subjects. Petrus de Marchetti has observed both male and female subjects affected with what is called rheumatic dilates of the joints, as late as the age of five-and-twenty; but not afterwards, unless they had suffered from serofula before that period of life, and had not been completely cured. R. Lowerus also entertains a similar opinion. Even though a few persons may have serofulous dilates of the joints, for the first time, after the age of twenty-five, this occurrence, like the first attack of serofula after this period, muft be considered as extremely uncommon.

Another argument in favour of the doctrine, which fets down particular kinds of white-swellings as serofulous, is founded on the hereditary nature of fuch forms of disease. Numerous continental surgeons, particularly Petit and Brambilla, have noticed how very fubjeé the English are both to serofula and white-swellings of the joints. We every day fee, that young persons afflicted with the present dilate, are generally manifestly serofulous, or have once been fo. Very often enlarged lymphatic glands in the neck denote this fatal peculiarity of constitution; very often the patients are known to have descended from parents who had ftraneous disorders.

Besides the general emblems of a serofulous constitution, we may often observe a shining, coagulated flaky subfiance, like white of egg, blended with the contents of fuch abfceses as occur in the progress of the dilate. This kind of matter is almost peculiar to serofulous abfceses, and forms another argument in fupport of the foregoing obfervations relative to the fhare which serofula frequently has in the origin and course of many white-swellings. Cooper’s Dict. of Practical Surgery.

The caufes of white-swellings are divided by surgical writers into external and internal. Amongf the former are reckoned mechanical injuries of the joints, fuch as wounds, contusions, sprains, immoderate exercife in cold damp weather, refining continually in a low humid situation, &c. It is certain, however, that these tumours are feldom produced altogether by external caufes; and even when their formation has been preceded by some external violence, this is rather to be regarded only as the determining caufe of the dilate, while the real caufe in this, as well as in other caufes where the complaint begins spontaneously, is of an internal kind. Rheumatifm and serofula are the ordinary caufes of white-swellings; and it may be alleged, without risk of error, that more than three-fourths of these tumours are owing to thofe constitutional dilates. Thofe white-swellings which attack ftrong phlegmatic subjects of adult age, commonly depend upon rheumatifm; while other caufes which happen in children, are almost always caufed by serofula. It is well known that rheumatifm is particularly difposed to make its attack upon the large joints, and that it especially affects the ligaments and neighbouring cellular fubfance, which it thickens and hardens, by caufing an effufion of coagulable lymph. Hence, fays Boyer, in such white-swellings as arife from rheumatifm, thofe parts of the dilate are found difeased in the early stage of the complaint. Traité des Mal. Chir. t. iv. p. 501.

With refpect to serofula, every surgeon is aware that it frequently attacks the heads of the bones, particularly in children, occafioning thofe morbid changes which we have already endeavoured to defcribe. We have likewise mentioned what is now generally admitted, that in white-swellings originating from serofula, the dilate commences in the bones, the foft parts becoming affected only fecundarily. The contrary is faid to happen in all rheumatic dilates, the dilate beginning in the foft parts, and only affecting the bones in a subsequent advanced state of the complaint.

The prognosis in caufes of white-swelling is, generally speaking, unfavourable; but it is more or lefs fo, according to the caufe of the dilate, its duration, the accompanying symptoms, the patient’s constitution, &c. White-swellings arifing from rheumatifm are the leat alarming, especially when they are recent. The progrefs of the complaint may then be often flopped, and fometimes a perfect cure accomplished. In this kind of cafe, the joint fometimes returns to its natural state, and regains the power of freely performing every motion; while in other infanfies, it continues affected with a greater or leffer degree of stiffness. White-swellings, which appear to depend altogether upon an external caufe, in persons in other refpects healthy and found, may terminate well. The worth white-swellings of all are thoé which originate from serofula; for they are very feldom cured, and when they do admit of amendment, the joint is always left in a state of anchylosis.

Whatever may be the caufe of white-swellings, when they are of long standing, severely painful, the bones ftoned and rendered carious, the cartilages ulcerated, the articulation filled with fumanious matter, and abfceses have formed, the openings of which continue fiftful, and emit a more or lefs abundant quantity of a thin fetid discharge, the dilate is in general incurable. In this cafe, the violence of the pain, the hectic fever, the profufe fweats, and colliquative diarrhoea, plunge the patient into a state of marasmus, and foon carry him off, unlefs an attempt be made to fave him by the timely performance of amputation. Yet, as Boyer observes, in some few cafes of this hopeless defcription, nature, skilfully aided by art, has been known to subdue the dilate. The fuppuration then gradually diminishes and affumes a better quality, the low fever, nocturnal perpirations, and weakening diarrhoea, entirely ceafe, the appetite returns, digestion is well performed, the strength is restored, and the patient gets well with an anchylosis. But fuch fortunate cafes are extremely uncommon, and they do not justify us in leaving the dilate to nature, instead of amputating the limb. Traité des Mal. Chir. t. iv. p. 505. 507.

Of all the dilates which fall under the care of the surgeon, there is not one in which a greater variety of remedies has been propofed than in white-swellings. Yet, notwithstanding the numerous means which are occasionally tried, the practitioner feldom has the mortification of finding, not only that he cannot accomplish a radical cure, but that he cannot even palliate the complaint, moderate its violence, or retard its progrefs.

The surgeon, in order to be methodical, fould adapt the treatment to the particular form of the dilate and its different ifates. But, in every ifate, perfect relief of the limb is absolutely indifpenfable, as exercife always has the effect of keeping up pain and irritation, and doing harm, whatever may be the species of the dilate.
WHITE-SWELLING.

Rheumatic white-swellings being invariably accompanied, at their commencement, with an inflammatory character, there can be no doubt, that, at this period of the complaint, the great indication is to take such measures as are best calculated to leffen and subdue inflammation; and bleeding is what should first be practiced. When the patient is strong, robust, and much fever exists, he may be bled once or twice in the arm; but, in other cases, we are to be content with drawing blood from the part affected with leeches, or by cupping. If leeches be used, they should be applied to both sides of the joint, and eight or ten ounces of blood ought to be thus taken away. The application of these animals should also be repeated at proper intervals, more or less frequently, according to the violence of the symptoms, and the strength of the patient. In cases of this description, drawing blood from the diseased part itself is found to be much more efficacious than general blood-letting, which weakens the patient without proportionately lefiening the swelling of the joint.

Blisters are another means, as efficacious as topical bleeding. Boyer recommends beginning with the application of a small one to the front of the joint, where the leeches have not been put; and he says, that it should be kept open, until the bites of the leeches are healed on one fide of the articulation, where a second blister is then to be applied. As soon as this is nearly healed, we are next advised to lay a third blister on the opposite fide of the joint. By thus continually changing the situation of the blister from one fide of the articulation to another, a permanent counter-irritation is kept up, which, says Boyer, in all deeply-seated inflammations, especially those which proceed from rheumatism, is much more effectual, than carefully maintaining a discharge from a single blister.

In conjunction with the foregoing means, the limb should be kept moderately and uniformly warm by covering it with flannel; a low diet is to be observed, cooling beverages preferred, and the action of the bowels regulated by emollients. Thus, the severity of the pain may generally be lefiened, and the inflammation diminished. If the pain, however, should still continue to be violent, Boyer recommends the use of topical anodyne and narcotic applications. He states, that, in this circumstance, he has often employed with success opiate and camphorated liniments; fomentations composed of a solution of the extract of opium in water; a strong decoction of poppies, &c. He thinks, however, that such applications should never be used, unless the pain be very severe.

When the inflammatory flage is over, topical refulent remedies are to be employed, and their effect is to be promoted by exhibiting mild opening medicines at suitable intervals. The most effectual refulent applications, and those which are most commonly tried in these cases, are, dry fritations with a piece of flannel, impregnated with the vapour of benzoin, liniments containing ammonia and camphor, ammonial of salicylic acid; but Boyer affirms, that he has often tried the last application, and that his experience leads him to impute whatever benefit arises from its employment, chiefly to the frictions, which reden and promote the circulation in the skin.

By a perseverance in the judicious use of the means above specified, rheumatic white-swellings may sometimces be cured; but it often happens, that, after the pain and swelling have subsided, the joint remains quite fluff and motionless, and every attempt to move it causes considerable suffering. In the majority of cases, such fluffiness depends almost entirely upon the retraction of the muscles, tendons, and ligaments, and demands the fame treatment as a false ankylosis. See ANKYLOSIS.

When the disease relieves the foregoing treatment, and is of long standing, the cure is more difficult, inasmuch as the thickening of the ligaments, and the effusion of a fero-albunaminous fluid into the cellular subflance around them, are more considerable, and the bones and cartilages are likewise at the fame time affected. In this circumstance, if there be any hope of cure, the surgeon must have recourse to more powerful means, which we shall mention in speaking of the treatment of other descriptions of white-swelling.

In white-swellings, arising from an external cause, such as blows, falls, &c. we must first leffen the inflammation by general and local bleeding, low diet, cooling aperient beverages, fomentations, and emollient anodyne poultries. Afterwards, when the pain and tension have subsided, refulent applications are to be used, and the patient is not to be allowed to move the limb, as long as there is any danger of a renewal of the pain and irritation by exercise.

Serofulous white-swellings in an early stage present different indications, according to the circumstances with which they are accompanied. A fall, or blow upon a joint, being sometimes the exciting cause of these tumours, any accident of this kind in a perfon evidently disposed to fero-albumin. demands the utmost attention and care. No means should be neglected which are at all likely to leffen the pain and irritation in the affected joint, and in particular the limb ought to be kept perfectly quiet for a long time. Serofulous white-swellings frequently come on, as it were, spontaneously, without the concurrence of any external accident, and their attack is attended with a dull, sometimes an acute pain in the very cavity of the joint, which at first is not affected with any manifest degree of swelling. In this circumstance, the surgeon must endeavour to prevent the progres of the disease by enjoining the patient to refrain from moving the joint, and by directing the employment of soothing local applications, which are afterwards to succeed by blisters, or an infus.

In the cases of white-swelling, which appear from Mr. Brodie’s account to depend principally upon inflammation of the synovial membrane, the acute flage of the disea is to be treated by general and local bleeding, aperient medicines, cold topical applications, or fomentations, and emollient poultices. When the affection has become chronic, this gentleman recommends perfect rest, and leeches, or cupping, followed by the application of a large blister. Under this treatment, he says, “the pain is relieved, and, in a few days, the swelling, as far as it depends upon the fluid collected in the cavity of the joint, is much diminished. Even where the tumour is solid, arising from the effusion of coagulating lymph, it will in a great measure subside, and sometimes be entirely diffipated, provided the lymph has not yet become organized. A single blister often produces marked good effects; but, it is generally necessary to repeat both the blister and the blood-letting several times.” Mr. Brodie considers the repeated application of blisters more efficacious, than a single blister kept open with the astringent cerate. When the inflammation has been much jub-ded, he thinks moderate exercise of the joint rather beneficial, and commends the use of a stimulating liniment, composed of 3f of olive oil, and 3f of sulphuric acid. This application, when too irritating, is to be weakened by an additional quantity of oil, and it is not to be used before inflammation.
flammation is subdued, left it aggravate the disease. Iffues
and fetons, which are useful in ulceration of the cartilages,
Mr. Brodie deems ufeles in the prefent difeafe. Plafters
of gum ammoniac, and others of a fimilar nature, are of
little efficacy while inflammation exists, but afterwards they
are of ufe in guarding the joint from the influence of exter-
nal cold, and preventing a relapse. For the removal of a
moderate degree of swelling and iffues, left by the past
inflammation, Mr. Brodie entertains a favourable opinion of
exerifce of the limb, and friction with camphorated mercur-
ial ointment, or by the hand with finely powdered flarch.
When the friction, however, produces inflammation again, it is
to be discontinued, and leeches applied. When the swelling
and iffues are confiderable, Mr. Brodie has never seen friction
do much good, and, as it is in fuch cafes particularly apt to
bring on inflammation again, it is to be employed with much
cautions. According to the fame author, friction is more
efficacious, where the iffues of a joint depends on a con-
tracted flate of the muscles, or tendons of the limb, or on
these being glued to each other, or the surrounding parts,
where it is the confquence of difeafe of the joint itfelf.
In fome cafes, the pumping of warm water on the part,
from a height of ferveral feet, as practifed at fome of the
watering places, is beneficial; but in this plan, the fame
cautions are neceffary, as in the employment of friction.

With regard to the cafes which Mr. Brodie describes as
depending upon a total los of the natural structure of the
fynovial membrane, which is converted into a pulp'y sub-
fance, one-quarter, or one-half, of an inch in thickness, are,
according to this gentleman, quite incurable, and they at
length terminate in ulceration of the cartilages, abfcesses,
&c. Hence, when the health begins to fuffer, he confiders
amputation proper. See Medico-Chir. Tranf. vol. v.

When white-feellings are accompanied with ulceration of the
cartilages, all motion of the joint is extremly hurtful.
Indeed, as Mr. Brodie obferves, keeping the limb in a
flate of perfect quietude is a very important, if not the moft
important circonfstance to be attended to in the treatment.
According to the fame writer, it is in fuch cafes, in which
ulceration of the cartilage occurs as a primary difeafe, that
caucfly iffues are ufually productive of fingular benefit;
but he deems them of little ufe in any other difeafes of the
joints. He thinks fetons, and bliflers kept open with the
famine cerate, may alfo be ufed with advantage in the fame
defcription of cafes. Bleeding can only be proper, when,
from the bad effects of exerifce, the articular surfaces are
infamed, and pain and fever prevail. Mr. Brodie affures
us, that the warm-bath relieves the fymptoms in the early
flate, if it does not flop the progres of the difeafe; but
he condemns plafters of gum ammoniac, embrocations,
liminants, and frictions, as either ufeles or hurtful. Op.
Cir. vol. vi.

The pumping of warm water upon difeafeed joints is a
method which is at prefent very frequently adopted, as
fome conceive, with decidedly benefical effects. The plan
is not altogether modern. Le Drian, and feveral other old
practitioners, recommend throwing warm water upon dif-
eafeed joints, and they prove the advantages of this treatment
by a relation of many ufeeful cafes. In order to derive
the greatest pofible good from the plan, the water fhould
be as warm as the patient can bear it, and it ought to fall
upon the part from a height of feven or eight feet. The
size of the flream muft alfo vary according to the degree of
fenfibilitv in the tumour. When the pain is acute, the end
of the pipe muft be closed with a piece of tin, perforated by
many holes, like the pofnt of a watering-pot. But when
the pain is inconsiderable, the pipe may terminate in a fingle
opening, the diameter of which fhould vary from half an
inch to an inch, according to circonfances. The applica-
tion is frequently to be continued nearly an hour, and when
it is finifhed, the patient ought to go to bed, and the joint
be covered with bladders filled with water as hot as the
patient can bear. Boyer recommends the application of the
bladders to be perforeed in for the space of two hours,
after which they are to be removed, and perfpiration from
the part promoted by covering it with warm cloths, or
flannels. In the evening, the bladders are to be repeated for
fome hours. The dafhing of warm water againft the dif-
eafeed joint is to be praftised every day, or every other day,
according as the patient can bear the plan, without too
much fatigue or inconvenience. This treatment, fays
baron Boyer, is proper in all kinds of white-feellings, and
in every flate of the difeafe; but it is much the moft ufe-
ful in fuch cafes in which the foft parts alone are afccted,
and at an early period, before the complaint has made great
progres. Favourable effects may be expected from this
method, when, after each application of the water, the part
affected perforates copiously, when it grows gradually
lofter, and when, after a certain number of trials, the
feeling begins to diminish. Under thefe circonfances,
the plan is to be continued and repeated very often, as a
long perseverance in it has frequently produced extraor-
dinary cures. When none of the above-defcribed changes
happen, little benefit can be hoped for from the method;
but if the patient fhouid not abandon it, before its ineffi-
cacy has been proved by adequate trials.

When there is no ufitable apparatus for applying the
warm water, it may be injected against the part with a lar-
gaffe, which has a pipe about half an inch in diameter,
made with four or five holes, for the difcharge of the fluid.
The injections may be rendered more or lefs active, by pro-
PELLING the water with more or lefs force.

Thefe affufions operate only by the heat and fhrength of
the current of water. Boyer fates, that their activity may
be augmented by adding to the fluid a quantity of the
mariate of soda or mariate of ammonia, or fome potaffa or
foda; and he thinks it will better to employ a fulphured
mineral water, either natural or faftications. The activity
of the affufions may also be increafed by heating the water
to a high temperature, letting it fall from a confiderable
height, and making the flream large. It is a plan, fays
baron Boyer, adapted to thofe white-feellings which are
fluated in the foft parts on the outside of the joints; and
which are indolent, and unattended with much pain. When
these active affufions are applied to white-feellings which
are painful, and which affect the bones, they often increafe
the patient's fufferings, and accelerate the progres of the

Of late years, furgeons have frequently made trial of dry-
rubbing, as it is termed, or friction of the joint, performed
with the hand, for ferveral hours a day, with the mere
application of a little powdered flarch, or hair-powder, in order
to prevent the part from being chafed. It is a method
which was firft praftised to a confiderable extent at Oxford,
and with great ufccefs. Many poor women there earned
a livelihood by rubbing difeafeed joints at the rate of fifpence
per hour. Indeed, there can be no doubt, that, in indolent
rheumatic white-feellings, fimple friction often removes the
feeling in an expeditious manner, as well as the iffues of
the afccted joint. The plan, however, will not effed a cure
in feroftulous cafes; nor can it be adopted without manifest
harm
In chronic cases, the swelling may also be lessened, and
the complaint sometimes much benefited by pressure, made
either with strips of adhesive plaster, or with bandages.
This method will not do much good in instances where the
bones are diseased, nor is it applicable to cases which are
irritable, or attended with heat and inflammation.

For eczematous white-swelling, and ulcers, which cannot yet be
said to have discovered any effectual or certain means of
relief; and these melancholy diseases frequently compel the
patient to submit to amputation, as the only thing by which a
long train of sufferings can be arrested, and the term of
life extended. The common plan of treating eczematous white-
swellings is, by topical bleeding, fomentations, and cold
applications, when they are attended with much pain, heat,
and inflammation; and by infusions, fomentations, and blisters,
in other periods of the disease. The cautery and moxa have
also been much employed abroad; and as everybody knows,
they were favourite and powerful remedies in the hands of
the ancients. In this country, the use of actual fire in sur-
gery is nearly, if not quite, exploded, on the ground that its
employment is attended with an appearance of cruelty, and
that infusions, made with caustic, are equally efficacious.

Pouteau, an eminent French surgeon, will ever be famous
for having revived in his own country all the ancient part-
tiality to burning iron. He recommended their use for all
white-swellings without discrimination; and the accounts
which he has left of the success of the practice are furi-
posing, if not incredible. In fact, they are in all proba-
bility greater exaggerations; for we find that baron Boyer,
one of the most eminent surgeons at Paris at the present
time, decidedly declares his opinion, that Pouteau's descrip-
tions of the efficacy of the actual cautery in the cure of
white-swellings do not correspond with the results of mod-
ern experience. Boyer himself gives a preference to the
moxa, which is a cone of cotton, burnt upon the diseased
part, so as to produce an effect. We confess, that to us
this plan seems to have no material difference from the
cautery; and, what is it but the application of actual fire
in another form? Indeed, one cannot help thinking, that
Boyer decries the cautery, only for the purpose of after-
wards recommending the moxa, which is now a more
fashionable means employed in French surgery. It is
curious to find Boyer particularly forbidding the use of
infusions, and the moxa in cases of white-swelling, where the
bones and cartilages are diseased; the very cases in which
Mr. Brodie, in common with the generality of surgeons in
England, expressly recommends either infusions or perpetual
blisters. Boyer has never seen much good arise from infu-
sions in any cases, although, as he affirms, he has made exten-
sive trial of them. The time also when he thinks the moxa
useful, is in that stage of the inflammation which intervenes
between the prevalence of inflammatory symptoms, and the
commencement of diseaee in the bones and cartilages.
Sometimes, however, the disorder certainly has its very
origin in the bones themselves.

The late Mr. Crowther introduced the plan of applying
open blisters with the fawine creside, which is a method fre-
quently attended with great success in chronic white-
wettlings, and sometimes appears to check the progress of
the eczematous form of the diseaee. Blisters may be kept
open with this ointment a long time, and with less pain,
than what proceeds from the use of the unguentum cattia;
and other stimulating dressings. It also occasion no risk of
bringing on manmury, or inflammation of the bladder and
stomach, or the upper parts of the body, or the head,
winding organs, like the use of ointments containing can-
Vol. XXXVIII.

tharides. In our opinion, Mr. Crowther had much merit
in making known the eligible qualities of the fawine creside;
and, we believe, no better application for keeping up a dis-
charge from blisters will ever be found. Sometimes, how-
ever, the repeated application of blisters has more effect
upon white-swellings, than a single blister kept open. This
is a circumstance which the practical surgeon ought con-
fantly to remember.

We might enlarge this article with observations on infec-
tions and fester, which are frequently employed in these cases;
but it would be superfluous, as they have been already
described in other parts of the work. See Issue, and
Seton.

It may be supposed, that eczematous white-swellings
will require the exhibition of the remedies usually
administered in cases of fcrupula. (See SCHROFULA.)

Boyer, and some other writers declare, that this is actually
the case. We have never seen these remedies, however, do
any good to diseased joints, if we except sea-air, sea-bathing,
and the use of sea-water lotions and poultices, which some-
times prove useful.

After all, we must acknowledge that white-swellings, we
mean particularly the infusions accompanied with ulceration
of the cartilages, and diseased heads of the bones, are
cases which too generally baffles the utmost skill, and render
a formidable operation unavoidable.

White Tail. See Motacilla Gannike?
White Tartar. See Tartar.
White Thorn. See CRATEEGUS.
White Thorn, or Hawthorn. See HEDGE, and Quick-
set-Hedge.

White-Throat, in Ornithology, the name of a small bird,
very common in our gardens and hedges, and seeming to
have been described under the name of flchipa by Aldro-
vandus and some others, though most approaching to the
fideula claus.

Its beak is black above, and whitish below; its feet of a
yellowish-brown; its neck and back are of a brownish-grey;
its head more grey than either, and the upper part of the
throat white, the rest reddish; its breast and belly are also
a little reddish; but in the female, the breast is perfectly
white. The edges of the long wing-feathers are some
whitish and others brownish, and the tail is variegated
with black and white, and some grey or ash-colour intermixed.
It is extremely common in our gardens and orchards in
summer, and feeds on flies, spiders, and other insects, but
leaves us in winter. It builds in bushes, at a small height
from the ground, with fluffe and horse-hair, and lays five
brownish-green eggs, with black spots. Its note is con-
tinually repeated, and often attended with odd motions of
the wings: it is harsh and displeasing. This bird is shy
and wild, and feeds of a pugnacious disposition. Ray and
Pennant. See Motacilla Sylvia.

White Trefoil, in Agriculture, is said, in the third volume
of the Effays of the Highland Society of Scotland, to be a
humble but sweet plant, which delights in a dry found field,
properly cleaned and limed; and is alone the delight of
sheep. But that a mixture of it, and of the seeds of rye
and rib grafe, constitutes one of the best sheep-pastures
that can be formed by the industry of man. That this sort
of grafe is likewise perennial, and that it enriches instead of
improving the soil or land. This has generally been
noticed
noticed to be the most abundant plant in such rich improved pastures; but that it has seldom been seen in lands remarkable for inducing the rot among sheep. See Rot, Sheep, and White Clover.

White, Troy. See Troy-White.

White, Varnish, and Vitrifi. See the substantives.

White, Vitrifi, in Mineralogy, a natural salt or ore of zinc. (See Zinc, and Zinc Ores.) This ore is a sulphate of that metal, but is frequently combined with a small portion of manganese. It is supposed to be formed naturally by the decomposition of blende or sulphur of zinc.

White, Wadding, Roughcast. See Wash for, &c.

White Water, a disease in Sheep, of the dangerous floramic kind. It is said to be caused by their feeding on rich succulent food in cold frostly seasons, or at other times, and by many other such causes; and is probably an affection of the inflammatory kind.

It is remarked in the Gloucester Report on Agriculture, that the white water is a destructive disorder on the Cotswolds; usually comes on with rapidity, and sometimes terminates with death in three hours. It is supposed to be owing to their licking up the white froth on their green food in spring and autumn. Folding at night on bare ground, giving them dry meat in the morning, and keeping them from the turnips till the froth is gone, is the obvious mode of prevention, if the foregoing cause be well founded.

If, however, the disorder be owing to going themselves with watery food, such as turnips, it is probable that to keep them moving, without suffering them to rest long, nor feed with what they have eaten, will carry off the beginning complaint; and even the white froth has been the occasion, this is the best remedy that reasoning suggests; and it is said to be the practice of the shepherds in Northumberland, in the management of the sheep under this complaint.

It is probable that speedy evacuation, both by bleeding and purging, may be found useful in this disease; and afterwards the use of floramic remedies.

It is found to chiefly attack the young healthy sheep. See Water, Red and Black.

White Water-Lily, in Gardening, a most beautiful plant of this country, which is capable of being propagated in artificial and ornamental pieces of water in gardens and pleasure-grounds, merely by transplanting the bulbous roots of it in the winter season. It is perennial in its nature.

White Wax is yellow wax blanched, and purified by the fun and dew. See Wax.

White upon White, in the Porcelain Manufactory, a name given by the English merchants to a particular china-ware, which is formed of three different white sublunates, the body being one, the flowers of another, and the varnish which covers thee of a third. See Soap.

White Wine is that of a clear, bright, transparent colour, bordering on white. It is thus called to distinguish it from the red wines, or claret.

The generality of white wines are made from white grapes; though there are some from black ones, only the skins are carefully kept from tainting them. See Wine.

Whites, the popular name of a disorder incident to women. See Fluor Albus.

White, in Geography, a county of West Tennessee, with 4238 inhabitants, including 283 slaves.

White Bay, a bay on the east coast of Newfoundland. N. lat. 50° 10'. W. long. 56° 25'.—Also, a bay on the east coast of Kerguelen's Land, south of Point Pringle, so called from some white spots of land or rocks. In the bottom are several smaller bays or coves. S. lat. 47° 53'. E. long. 60° 15'.

White Bear Lake, a lake of North America, said to be the most northerly of those lakes which supply the Mississippi. It is about 60 miles in circumference. N. lat. 45° 50'. W. long. 95° 30'.

White Cliff, or Culver Cliff, a cape of the east coast of the Isle of Wight. North of it is a bay called White Cliff Bay. N. lat. 50° 39'. W. long. 56°.

White Deer, a township of Pennsylvania, in Northumberland county, on the Susquehanna, with 1232 inhabitants.

White Flag Bay, a bay on the west coast of the island of St. Christopher; 2 miles N. of Sandy Point.

White Head, a cape of Ireland, on the coast of Antrim, at the entrance into Belfast Lough, a little to the south of Black Head.

White Hills, a fishing-town of Scotland, in the county of Banff, situated in a creek; 2 miles N. of Banff.

White Horse Vale, a vale of Berkshire, so called from the figure of a horse in a galloping posture, cut in the side of a chalky hill, as is supposed in memory of a great victory gained by Alfred over the Danes in the year 871. The curing the horse is an annual festival, and celebrated by rural games. On the top of the hill is a large Roman intrenchment, called Uffington castle, or Woolton castle. There is likewise another camp in the neighbourhood, with the burial place of the Danish chief, included by stones set on edge, a cromlech, and several barrows.

White Horses, cliffs on the south coast of Jamaica; 20 miles E.S.E. of Kingston.

White-Horse Bay, a bay on the west coast of the island of St. Christopher, a little to the north of Guana Point.

White Inlet, or Boca de Rationes, an inlet on the east coast of Florida. N. lat. 26°. W. long. 86° 20'.

White Island, an island in the South Pacific ocean, near the east coast of New Zealand, north of Cape Run-away, S. lat. 39° 31'. W. long. 182° 36'.—Also, a small island in the Atlantic, near the S.E. coast of Nova Scotia. N. lat. 44° 55'. W. long. 61° 56'.

White Island, or Burnt Island, a small island in the Arabian Gulf, near the coast of Adel. N. lat. 11° S. E. long. 64° 15'.

White, Isle of. See Isle of Wight.

White Keys River, a river of Africa, which runs into the Indian sea, S. lat. 30° 35'.

White Mountains, mountains of New Hampshire, peculiarly applied to the highest part of a ridge, which extends N.E. and S.W.: the whole circumference at least fifty miles. The height of these mountains above an adjacent meadow is reckoned, from observations made by the Rev. Mr. Cutler, of Ipswich, in 1784, to be about 5500 feet, and the meadow 3500 feet above the level of the sea. The snow and ice cover them nine or ten months in the year, during which time they exhibit a bright appearance from which they are denominated the White Mountains. From this summit, in clear weather, is exhibited a view extending sixty or seventy miles in every direction; although they are more than seventy miles within land, they are seen many leagues off at sea, and appear like an exceedingly bright cloud in the horizon. These immense heights, being copiously replenished with water, afford a variety of cascades. Three of the largest rivers in New England receive a great part of their waters from these mountains. Amanoquelle and Isral rivers, two principal branches of the Connecticut, fall from their western sides. Peabody river, a branch of the Amorificogen, falls from the north-east side, and almost
the whole of the Saco descends from the southern side.

The highest summit of these mountains is in about 44° N. lat.

White Oak Creek, a river of North Carolina, which runs into the Atlantic, N. lat. 34° 30'. W. long. 77° 26'.

White Oak Mountains, in the west part of North Carolina. N. lat. 36° 10'. W. long. 82° 30'.

White Point, a cape on the coast of Cape Breton, near Louisburg.—Allo, a cape on the fourth coast of Jamaica; 20 miles E. of Port Royal.—Allo, a cape on the north coast of the island of Cumbava. S. lat. 8° 15'. E. long. 118° 51'.

White River, a river of Louisiana, formerly thought to be a stream of inconsiderable magnitude, but now known to be one of the most considerable in the western country, and likely to become of still greater importance. It rises in the Black Mountains, which separate the waters of the Arkansas from those of the Mifouri and Mississippi. Several of its branches interlock with those of the Ohio river, the Maramek, and the St. Francis. It is navigable about 1200 miles, without any considerable interruption; 800 of which may be made with barges, and the rest with canoes or smaller boats. Its waters are clear and limpid, its current gentle, and even in the driest season, plentifully supplied from the numerous and excellent springs which are every where found. It also receives many considerable rivers in its course, the largest of which is Black river. The country which it waters is described by those who have traversed it as generally well wooded, and abounding in springs and rivulets: the soil is rich, though hilly; and it is said, that on the borders of this river a country may be chosen, at least 100 miles square, not surpassed by the best parts of Kentucky, and one of the best for settlements in the whole world. This river is situated on the S.W. side of the Mifouri, and is 300 miles wide at its mouth.

White River, a river of Guadalupe.—Allo, a river of America, which runs into the Connecticut, 4 miles south of Norwich.—Allo, a river of Jamaica, which runs into the sea, 4 miles W. of Montauk bay.—Allo, a river of Indiana, in the county of Kosciusko, which rises about N. Lat. 40° 45', and W. long. 85° 5'. and runs into the Wabash, N. Lat. 38° 15', and W. long. 88° 20'.—Allo, a river of America, which runs into Lake Michigan, N. Lat. 43° 40'. W. long. 85° 33'.—Allo, a river of Vermont, which runs into the Connecticut, N. Lat. 43° 38'. W. long. 72° 18'.

White Rock, a rocky illet in the East Indian sea, near the south coast of Java.

White Rocks, a range of buildings, accommodated for dwelling-houses, about a mile from Swansea, in the country of Glamorgan, situated on the river.

White's Bay, a bay on the coast of Newfoundland. N. lat. 50° 17'. W. long. 56° 13'.

Whitburn, a town in Scotland, in the country of Linlithgow; 21 miles W. of Edinburgh.

Whiteclay Creek, a hundred of Delaware, in New Castle county, with 1701 inhabitants.

Whitefield, George, in Biography, one of the founders of Methodism, (see Methodists,) was the son of an innkeeper at Gloucester, where he was born in 1714, and where he received the rudiments of literature, so as to be sufficiently qualified for his father's business, for which he was designed. Accordingly he commenced it as drawer at the Bell-inn. At school he is said to have been distinguished by a retentive memory and good elocution. Of his early years, he gives a very unfavourable account, so that there was nothing about him but a fitness to be damned, with occasional glimpses of grace that afforded some indication of his future destination. About the age of 18, he was admitted a servitor at Pembroke college, Oxford, and associated with those young persons whose dispositions and habits resembled his own, and whose conversation and manners contributed to cherish that religious enthusiasm to which he was strongly addicted. As soon as Dr. Benfon, bishop of Gloucester, received information concerning the state of his mind and the course of his general conduct, he made him an offer of ordination, when he was about 21 years of age, and he was accordingly ordained a deacon in 1735. Upon his return to Oxford, after preaching his first sermon at Gloucester, he took the degree of bachelor, and diligently employed himself in communicating instruction to the poor and the prisoners. During the two following years, he acquired a great degree of popularity by his public services in London, Bath, Bristol, and other places; collecting large auditories, and interlacing the attention of his hearers. His voice was strong and musical, his pronunciation clear and distinct, his imagination was lively, and his feelings were warm; and to these natural powers of eloquence we may add his dexterity of subjects, which were adapted to move the inconsiderate, and to comfort those that were awakened to a sense of their guilt and danger: so that we need not wonder that he should command a numerous audience. Upon receiving information that the province of Georgia was likely to open to him an extensive field of usefulness, he determined to visit it, and in May 1738, arrived at Savannah. Here he met with much greater success than his predecessor Wesley; and in order to supply the defect of education which he was concerned to observe in this province, he resolved to found an orphan-house, and in 1739 returned to England in order to collect money for this purpose. In England few of his clerical brethren were disposed to take much notice of him; nevertheless, his original patron, the bishop of Gloucester, gave him priest's orders: but upon afterwards visiting London, none of the churches into which he obtained admission were large enough to accommodate the crowds of people that assembled to hear him. It was about this time that he commenced his practice of preaching in the open fields, and the first scene of his exhibition in this way seems to have been Kingwood, near Bristol, where he collected thousands, chiefly of colliers, who without doubt derived benefit from his discourses. He also preached at Bristol in the open air, when he was refused access to the pulpits of the churches; and he likewise pursued the same practice in Moorfields and Kempton-common, near London, where, amidst the immense multitude that attended him, some persons occasionally treated him with rudenes, but the greater number were commanded by his peculiar power of address into respectful attention. Having succeeded beyond his expectations in soliciting contributions for his projected orphan-house in Georgia, he returned to America in August 1739; and in the following January laid the foundation of the building at Savannah. He then extended his tour as far as Boston, preaching to immense crowds, and collecting considerable sums for the completion of his design; and upon his return to Savannah he found his orphan family comfortably settled in their house; and in January 1741, he embarked for England. His absence had occasioned a declension among his followers; some other circumstances, besides the intermission of his personal labours amongst them, might probably have contributed to produce this effect. Whilf he was in America he had written, as he himself acknowledges, "two well-meant but injudicious letters against England's two great favourites, the Whole Duty of Man, and archbishop Tillottson, who, I said, knew no more of religion than Mahomet." His society had suffered from the influence of the Moravians. Mr. Wesley had
had preached and printed in favour of perfection and universal redemption, and against the doctrine of election. He had written a reply, but he acknowledges that he had used expressions that were too strong in reference to absolute reprobation, which had offended numbers of his spiritual children. His worldly circumstances were embarrassed, and he owed 1000l. for the orphan-house, and some of his bills were returned. He had some enemies who circulated reflections on his integrity in the conduct of his business; but they were never justified, and his state of secular affairs at his death affords a strong presumption that they were groundless.

Dr. Franklin, who lived upon the spot, bears testimony to his honesty. At this time, a separation had taken place between him and Wesley, and this had occasioned a decrease of his auditors. However, his zeal and perseverance overcame these difficulties. In order to counteract Wesley's popularity, he built a shed near his chapel in Moorfields, which he called the Tabernacle; and in process of time this rose from a mean beginning to be a spacious edifice; and he also renewed his field-preaching. At this time, he paid his first visit to Scotland; and though he was a clergyman of the church of England, which excused some prejudice against him, he was invited into the churches, and preached to large congregations, and made collections for his orphans.

On his return by Wales, he married a Mrs. James, a widow lady of Aberavenny. His zeal for doing good, and for making profelytes, induced him, in the spring of 1742, to engage in a contest with the idle people who had booths in Moorfields, and where they frequented for their amusements on holidays. On Whitsunday he collected a party of his attendants, and restored to the spot with a view of conducting a religious service. Although he was much disturbed in this effusion of his piety and zeal, the result, as he says, was so much in his favour, that he received 1000 notes from persons under conviction; and soon after more than 300 were admitted into the society in one day. In 1748 he returned from a second voyage to America; and then commenced his acquaintance with the countesses of Huntingdon, who appointed him her chaplain, and excited the curiosity of some persons of rank to hear him: among these were the earl of Cheltenham and lord Bolingbroke. About this period, it is said, his sentiments became more rational; for on his third visit to Scotland, it was announced to a synod assembled at Glasgow to investigate certain charges against his opinions, that with regard to certain points which were considered as objectionable, his sentiments had been altered for upwards of two years; and that he now seldom preached a sermon without guarding his hearers against impressions, and admonishing them that a holy life is the best evidence of a state of grace. From this time, he was fully employed by a visit to Ireland, two more voyages to America, and his English circuits, till the year 1756, when his chapel in Tottenham-court-road was erected. His labours were incessant for many years; but at length, on a seventh visit to America, he was seized with an athermic complaint at Newburyport, New England, which terminated his life in September 1779, near the completion of his fifty-sixth year.

With regard to his general character, we shall close this article with the reflections of a judicious and candid biographer. "That he had much enthusiasm and fanaticism in his composition is sufficiently evident from his own journal and letters; but whether these were accompanied, as they not unfrequently are, with craft and artifice, is a disputable point. There are, in his narratives, obvious marks of a disposition to represent himself as under the special protection of Providence, and to magnify trifling incidents into little less than miracles in his favour; and much of what is commonly called cant is apparent in his confessions and humiliations. Yet that he was a hypocrite acting a part will fearlessly be believed by any one who looks at his course of life during 34 years. He has been charged with dishonesty and immorality; yet as it is certain that he obtained the eleemos of many persons of worth, it may be concluded that such accusations were defitute of proof. His intellectual qualities were well suited to the talk he undertook; and in the pulpit he occasionally interspersed buffoonery with his veneration, the latter was not less effective on that account. His learning and literary talents were mean, and he is a writer only for his own feet." He published, at intervals, sermons, tracts, and letters, which, after his death, were collected in five vols. 8vo. Middleton's Life. Evangel. Moth. Eccl. Hist. Gen. Biog.

WHITEFIELD, in Geography, a town of America, in the district of Maine, and county of Lincoln, having 995 inhabitants.—Allo, a town of New Hampshire, in the county of Cowes, having 51 inhabitants.—Allo, a town of North Carolina; 40 miles W. of Newbern.

WHITEFIELD, or Wheatfield, a township of Pennsylvania; 156 miles W. of Philadelphia.

WHITEHALL, formerly called Skeneborough, a post-township of Washington county, in the state of New York, at the head of lake Champlain, about 65 miles N.E. from Albany: in mediad length about 10 miles from N. to S., and 7 wide; first erected in 1788, with its present limits. The soil is a tuff clay, and adapted to grass. Wood- creek and Pawlet river unite in this town, and afford facility to navigation and trade, as well as mill-fafts. Marble, limestone, and iron-ore, and also a mineral spring, are found in this township. It has 1 Congregational, 1 Presbyterian, 1 Baptist, and 1 Methodist congregation, and a competent number of common schools; 2 grist-mills, 2 saw-mills, a fulling-mill, and carding-machine.—Allo, an incorporated post-village at the N. end, with considerable trade, situated principally on the W. bank of Wood-creek, at its entrance into lake Champlain; 71 miles N.E. from Albany. About a quarter of a mile from the village is a handsome Presbyterian church, founded by the donation of John Williams, esq., of Salem, who endowed it with a parsonage of 60 acres of land. The whole population, by the census of 1810, was 2119, with 178 electors.—Allo, a township of Pennsylvania, in Northampton county, with 2551 inhabitants; 61 miles N. of Philadelphia.

WHITEHAVEN, a sea-port and market-town in Allerdale ward, in the county of Cumberland, England, is situated between two hills at the northern extremity of a narrow vale, at the distance of 40 miles S.W. from Carlisle, and 305 miles N.W. from London. The rife, progress, and increasing importance of this now rich and flourishing town, strikingly display the effects of trade, industry, and enterprise. From an obscure hamlet, it has advanced, within less than two centuries, to considerable magnitude and commercial importance; and, both in extent and population, far exceeds the capital of the country. In the year 1566, it consisted only of six fishermen's cabins; in 1633, of nine or ten thatched cottages; but in 1695, its buildings were sufficiently numerous for 2222 inhabitants, and have been progressively increasing; till, in the year 1818, the population was returned to parliament as 16,106, occupying 1940 houses. The increase of shipping has been proportionate: in 1685, the whole number of vessels belonging to this port was 46, carrying 1871 tons; they have since gradually increased to 230; the quantity of tonnage is nearly 74,000 tons. The honour of raising this town to its present importance must be attributed to the Lowther family.
family. Sir John Lowther, about the beginning of the reign of Charles II., purchased the lands of the dissolved monastery of St. Bees for his second son, Sir Christopher, who, as coal-owners that period came into general use, conceived the idea of improving his possessions by opening some collieries. No effectual progress was, however, made till after the Restoration, when another Sir John Lowther, who had succeeded to the estate, formed a plan for working the mines on a very extensive scale. To obviate all opposition to his operations, he procured a gift of all the ungranted lands within the district, and also of the whole sea-coast for two miles northward, between high and low water mark. He then directed his attention to the port, which was small and inconvenient; and, by his judicious schemes, laid the foundation of the present haven. Subsequent improvements have been made, particularly during the reign of George II., when an act was passed to perfect and keep it in repair, by a tonnage on shipping. The mines are said to be the deepest in England, and extend a considerable way under the sea: one has been carried 1000 yards out from the shore, at the depth of 112 fathoms under the water. Most of the coal exported from this haven is conveyed to Ireland; the quantity raised annually, on the average, is about 90,000 chaldrons. (See Coal.) The creek on which Whitehaven is built is so deeply seated, that the adjacent lands overlook it on every side. The approach from the north is singular, as the heights are so much above the town, that only the roofs of the houses can be seen till near the entrance, which, on this point, is through an archway of red free-stone. The town itself is one of the most respectable in the whole northern counties; the streets being regular and spacious, and crossing each other at right angles; the houses in general are well built, and even the tradesmen's shops exhibit a degree of elegance.

Here are three chapels, plain convenient structures: they were all erected by subscription of the inhabitants, aided by the benevolence of the Lowther family. St. Nicholas's chapel was built in 1693; Trinity, in 1715; St. James's, in 1752. The latter is neatly fitted up; the roof and galleries are supported by ranges of pillars. Besides the established chapels, here are three meeting-houses for Methodists, two for Presbyterians, and one for each of the following sects, Anabaptists, Roman Catholics, Glaflites, and Sandemanians. The principal manufactures are those of cordage and sail-cloth; the latter was only established in 1786, but already gives employment to several hundred workmen, though much of the business is executed by machinery of great power. A fair is held annually, and there are three weekly markets. The castle, as it is called, adjoining the east side of the town, one of the seats of the earl of Lonsdale, is a large quadrangular building, chiefly erected by the late earl, and containing some good paintings.

St. Bees, in which parish Whitehaven is situated, derives its origin from a religious house founded here by Bega, an Irish saint, about the year 650. On her death, a church was erected to her honour; but both these establishments having been destroyed by the Danes, they were replaced, in the reign of Henry I., by a new foundation for Benedictine monks. The church built at this period had the form of a cross, and great part of it yet remains. The east end is unroofed, and in ruins; the nave is fitted up as the parish church; and the cloisters is used as a burial-place. The whole is of red free-stone. In this village a free-school was founded by a bequest of archbishop Grindal, in the year 1587, under a charter of queen Elizabeth. The endowments were increased by James I., and have been since further augmented by various benefactions.—Beauties of England and Wales, vol. iii. Cumberland, by J. Britton and E. W. Brayley, 1802. Magna Britannia, Cumberland, by Meffrs. Lyfons, 4to. 1816.

WHITEHEAD, William, in Biography, an English poet, was born at Cambridge in 1714-5; educated at Wincleter school, where from his talent in writing verse he acquired the notice of Pope; and upon his return to Cambridge, obtained a scholarship of Clare-hall. As a poet, Whitehead's highest ambition was to resemble the manner of Pope; and of his proficiency he gave a specimen in his "Epistle on the Danger of Writing Verse," 1741. In the following year he was elected fellow of Clare-hall, and pursued his studies with a view to the church; but his poetical talents produced a change in his circumstances and in his purpose. Being recommended to the earl of Jersey as a proper tutor for his eldest son, he removed in 1745 to the earl's house in London, where his treatment was in the highest degree liberal. Having leisure for indulging his taste for literary pursuits, he turned his attention to dramatic composition, and produced a tragedy, entitled "The Roman Father," which was exhibited with applause upon the stage in Drury-lane in 1750. In 1754 he published another, the title of which was "Crepus," which was also favourably received. With the profits arising from these two performances he very honourably discharged the debts of his father, who had died insolvent. In this year he accompanied his pupil, vicount Villiers, and vicount Nuneham, son of Earl Harcourt, on their travels, which continued more than two years; and on his return he published an "Ode to the Tiber," and five elegiac epistles, which were much applauded. Lady Jersey, during his absence, had procured for him the appointment of secretary and regifter to the order of the Bath; and in 1757, on the death of Cibber, he succeeded to the laureat, which he rendered respectable; though in the discharge of the customary duties of the office, he did not escape abuse, and especially that of Churchill, whose popular satire almost overwhelmed the reputation of the laureat. Lady Jersey, in consideration of his services as governor to her son, invited him to take up his residence in her house, where he passed fourteen years, frequently visiting lord Harcourt, much respect ed by his noble host and his former pupils. He still amused himself by presenting to the public occasional productions, one of which was a comedy of the moral or sentimental class, entitled "The School for Lovers." After passing through life tranquilly and pleasantly, and maintaining an estimable character, he died suddenly, April 1785, in his 70th year. Of his works two volumes were published by himself, and to thee a third was added by Mr. Mason, who prefixed memoirs of his life and writings, to which we refer. Gen. Biog.

WHITEHEAD, George, an eminent person among the Quakers, was born in 1636 at Sunbiggs, in Welfmoreland. Attaching himself early in life to this society, and engaging in the propagation of its doctrine, he partook of the sufferings which, in that age, were the ordinary lot of its active members; and was once, simply for having preached at Nayland, in Suffolk, severely whipped by order of two justices as a vagabond; a proceeding which served, as might have been expected, to increase the disposition of the people to hear him. Soon after the Restoration of the monarchy, the Quakers were made the express subjects of a law, the precursor of others of like nature, which imposed on their profession and worship penalties extending to banishment. In the progress of the bill through the house of commons, Whitehead, with three other Quakers, was admitted to the bar of the house, and heard in defence of the society. They pleaded its cause with the freedom of conscious innocence,
cence, and the meekness of men prepared to suffer, but pleaded in vain:—the bill passed, and two out of the four, who had thus advocated the rights of conscience, presently fell victims to the force by which conscience was deliberately oppressed, dying in a crowded unhealthy prison, to which they were dragged from their peaceable religious meetings. Whitehead, who was imprisoned with them, survived to be liberated.

In the year 1672, when Charles II. issued his declaration for suspending the penal statutes against non-conformists, Whitehead solicited and obtained an order under the great seal for the discharge of about four hundred Quakers, many of whom had been for years under close confinement. He records, with expressions of satisfaction, the circumstance that some other diffident ones also partook at this time of the benefit of his exertions. On several other occasions he was concerned in applications on the Quakers' behalf to Charles II. and James II. And after the Revolution, when the Toleration Bill was before parliament, he was particularly serviceable to his friends in that matter; as likewise in taking a part in those representations, which procured the acceptance of their affirmation in lieu of an oath. A profession of faith being proposed for insertion in the above act, in terms which to the Quakers would not have been quite satisfactory, Whitehead and his coadjutors proposed the following, as their own belief on the points to which it relates, and which was adopted as a test for the society accordingly, viz. "I profess faith in God the Father, and in Jesus Christ his Eternal Son the true God, and in the Holy Spirit, one God, blessed for evermore; and do acknowledge the holy scriptures of the Old and New Testament to be given by divine inspiration."

Whitehead lived the greater part of his time in or near London, which accounts for his being one of those Quakers usually concerned in applications to the government. He was well esteemed by his brethren, whom he continued to edify by his ministry and example to the end, dying, after a short confinement, by infirmity, at the age of 86. Besides several writings chiefly controversial, he left some memoirs of his life, which were printed in one volume, 8vo, in 1725.

Whitehead, in Geography, an island in the Atlantic, near the coast of Maine. N. lat. 54° 46'. W. long. 4° 27'.—Also, a cape of Ireland, at the north-east of the bay of Carrickfergus, in the county of Antrim.

WHITELAND, West. See West White lord.

WHITEICK, a town of the flat of Kentucky; 13 miles S. of Stamford.

WHITELOCK, Bulstrode, in Biography, a lawyer and statesman, was born in London in the year 1605, and finished his education as a gentleman-commoner of St. John’s college, Oxford. Being destined for the profession of the law, he pursued the study of it under the direction of his father, Sir James Whitelock, who was one of the justices of the King’s Bench. As he had a taste for the fine arts, he was nominated as one of the chief managers of the royal masque presented by the inns of court to Charles I. and his queen in 1633, of which he has given a florid description. He became soon distinguished in his profession at the bar, and was frequently consulted by Hampden, when he was under prosecution for refuting the impostion of ship-money. In 1640 he was elected as a representative for Marlow in the Long parliament; and though his principles were favourable to the measures which then engaged the public attention, he concurred with Selden and others in depreciating a reformat to arms; but when the house had determined for war, he accepted the post of deputy-lieutenant for the counties of Oxford and Buckingham, and appeared at the head of a gallant company of horse raised among his neighbours. Nevertheless he was always averse from a civil contest; and in January 1642-3, he was one of the commissioners appointed to treat of peace with the king at Oxford; and in 1644 he was one of those who presented to the king propositions of peace agreed upon in parliament; and the king’s answer was, at his majesty’s request, drawn up by him and Holles, for which they were acceded of high treason by parliament, but extricated themselves with honour. As a member of the assembly at Westminster for settling the form of church government, he avowed himself in opposition to the divine right of presbytery. He also opposed the power of excommunication assumed by the Presbyterians; being always, like Selden, an enemy to violent exertions of church power by law and sword; and he was an invariable advocate of legal rights, and an opponent of arbitrary power, assumed or exercised in either house of parliament. When he became suspected by the parliamentary leaders, he joined the army-party, and opposed the measure of disbanded the troops, which was proposed by some of his former associates. When it was determined to bring the king to trial, he was nominated as one of the committee for drawing up the charge; but this was a business in which he did not choose to engage. However, he had no objection against taking an active part under the new government, and he was nominated in February 1648-9 one of the council of state. In some other instances he incurred the charge of inconsistency, as he complied with measures which he did not approve. To Cromwell he was so agreeable, that he was one of the four members of parliament appointed to meet him after his famous victory at Worcester in 1651. White lock avowed himself steadily attached to monarchy, as a part of the flat which could not be dispensed with, and as intertwined with the laws of the country, and he therefore suggested, that the late king’s eldest or second son should be sent for, and enter into terms for securing the liberties of the nation. Upon the dissolution of parliament by Cromwell, though he had previously refilled the attempts of the army to govern without the parliament, he obsequiously performed the functions of his office under the new establishment. The usurper, however, regarded him with distrust, and would not admit him into his first or little parliament. His commission of the seals was superseded by the supersession of the court of chancery; and he was therefore glad to be occupied in a station which would not require his interference in party contentions, which was that of ambassador from England to queen Christina of Sweden. Upon his departure, Cromwell assumed the title and authority of lord protector, and issued his instrument of government, which Mr. White lock had concurred in preparing, and which was afterwards found by Cromwell incompatible with his usurpation. Having concluded an advantageous treaty with queen Christina, who received him in November 1653 with distinction, he returned to his own country, and returned the office of commissioner of the great seal, upon the restoration of the court of chancery; and he was returned as a representative for three counties in Cromwell’s second parliament. Upon Cromwell’s regulation and limitation of the court of chancery, he again resigned the custody of the seal; and as some compensation for his loss, he was appointed a commissioner of the treasury. He was free and faithful in giving faithful advice to the Protector, and nevertheless retained his confidence. Declining the office of ambassador to Sweden, which was offered him, he acted as one of the commissioners to treat with the Swedish ambassador in England. He was returned for Buckinghamshire in Cromwell’s third parliament, and officiated for some time as speaker. Although he would not pretend to parliament the “Humble Petition and Advice,” which was intended to empower Cromwell to assume a higher title than that of Protector, he was chairman of the committee for conferring with him about it; and he concurred in the request that he would adopt the royal title. White lock contracted so decidedly in Cromwell’s interest, that he was one of those who were called by him to the upper house; but he declined being governor of Dunkirk, and also the honour of being created a viscount. During the short protectorate of Richard, White lock acted as one of the keepers of the great seal; and when the army set up a republican government, he was nominated one of the council of state; and as its president, he joined in all the measures that were adopted for upholding the tottering frame of government, on the principle that if no legal authority was acknowledged, the sword alone would probably govern. When Monk proposed to restore the remains of the Long parliament, White lock took a commission from the committee of safety for raising a regiment of horse, and urged Lambert to march against that leader. But the design failing, and the parliament meeting, he at first appeared in pursuance of the speaker’s summons; and as he had reason for supposing a design to apprehend him, he returned to a friend’s house in the country, and sent the great seal by his wife to the speaker,—and thus terminated his public life. Upon the Restoration, he had the good fortune to escape a bill of pains and penalties in the house of commons, only by the negative of a small majority. After having passed fifteen years in retirement, chiefly at Chilton-park in Wiltshire, he there died in January 1676; leaving a numerous family, after having been twice married.

Poculated of considerable abilities, and of distinguished talents for business, he would have claimed a more general and cordial respect, if he had not been a temporizer in his public conduct. His principles of government appear, however, to have been good, and in his temper he was above from every kind of violence and injustice. He was a well-wisher to the law and constitution, and supported them as far as it was consistent with his interest and safety.
private concerns he maintained an estimable character for probity and honour. After his death an anonymous editor, in 1682, published his "Memorials of the English Affairs;" or, an historical Account of what passed from the Beginning of the Reign of King Charles I. to King Charles II. his happy Restoration," vol. i., an improved edition of which appeared in 1733. From his MSS. was published in 1769, "Memorials of the English Affairs from the suppressed Expedition of Brute to this Island, to the End of the Reign of King James I," a chronological epitome of history for his own use. In 1766 Dr. Charles Morton, secretary to the Royal Society, published "Whitelock's Notes upon the King's Wrif forchoosing Members of Parliament, 15 Car. II. being Difpositions on the Government of England by King, Lords, and Commons," 2 vols. 4to. The same editor also published in 1774, "A Journal of the Swedifh Embaffy in the Years 1653 and 1654, from the Commonwealth of England, Scotland, and Ireland," written by the Ambassador the Lord Commiflioner White- 

The commiffioner, amid all his grave affairs, found leisure to cultivate music, of which he was very fond; and seems to have interfected himself in all the remarkable performances of his time. During the happy days of Charles I., mafters were so frequent at court and elsewhere, that in 1635 no less than five mafters were performed at different places before the king and queen. See Masque.

A very circumftantial account of one of these, "The Triumps of Peace," has been left to his family by the commiffioner himself, which was in the possession of the late Dr. Morton of the British Museum. The musical part of this performance seems to have been wholly affigned by the brethren at the Temple to commiffioner Whitelock. For in his narrative he fays, "I made choice of Mr. Symon Ives, an honofable and able muftician, of excellent skill in the art, and of Mr. Lawes, to compofe all the airs, leffons, and fongs for the maftice, and to be matters of all the mufticke under me." See Ives, and Lawes, William.

The commiffioner, besides being a performer, was a bit of a composer; as he fays with great triumph at the latter end of his narrative: "I was fo converfant with the musicians, and fo willing to gain their favour, especially at this time, that I compofed an aier myfelfe, with the affiftance of Mr. Ives, and called it 'Whitelock's Corante,' which being cried up, was fift played publiquely, by the Blackefryar's mufticke, who were then elegant the belt of common muftician in London. Whenever I came to that Houfe (as I did fometimes in thefe days), though not often, to fee a play, the mufticians would preferently play 'Whitelock's Corante'; and it was fo often called for, that they would have it played twice or thrice in an afternoon. The queen hearing it, would not be perfuaded that it was made by an Englishman, because she faid it was fuller of life and spirit than the English aiers ufe to be; but the nobility and the maker of it with her majeflyes roay tall commendation. It grew to that request, that all the common mufticians in this towne, and all over the kingdome, got the compofition of it, and played it publiquely in all places, for above thirtie years after." Among other moral reflections, addreffed to his family, on fuch vanities as he had been defcribing, lord commiffioner Whitelock adds: "Yet I am farre from difcommending the knowledge of this art (muftic), and exercife of this recreation for a diversion, and fo as you fpend not too much of your time in it, that I advise you in this as in other accomplishments, that you endeavour to get to fome per-fection, as I did, and it will be the more ornament and delight to you."

The lord commiffioner inferts his aier, in order to preserve it for the ufe of his family, if any of them should delight in it. This "Corante" may be seen in Burnet's Hist. Muf. vol. iii.; and the whole narrative of the maftice, entitled "The Triumph of Peace," from Whitelock's Labours remembered in the Annals of his Life, written for the Ufe of his Children," MS.

WHITEMARSH, in Geography, a townhip of Penn- 
ylvania, in the county of Montgomery, with 1328 in- 
babitants; 15 miles N.W. of Philadelphia.

WHITEN HEAD, a cape on the north coast of Scot- 
land. N. lat. 58° 37'. W. long. 4° 22'.

WHITENESS, a town of the ifland of Shetland; 
6 miles N.W. of Lerwick.

WHITENING of Bones, for a skeleton. See Bone.

WHITENING of Cloth. See BLEACHING.

WHITENING of Hair. See Hair.

WHITENING of Wax. See WAX.

WHITEMPAINE, in Geography, a town of Pennsyl- 
vania, in the county of Montgomery, with 955 inhabi- 
tants; 20 miles N.W. of Philadelphia.

WHITETOWN, the principal town and half fiire of the county of Oneida, in the state of New York, with 25,330 inhabi- 
tants; 30 miles from New York, and 140 S. of Albany. The whole area of this town is about 84 square miles; and its population, in 1810, was 603, with 68 electors, and 190 tax-able inhabitants. The village of White plains is pleasantly situated on a fine plain, three-quarters of a mile E. of Bronx creek, and contains a court-house, prison, and a handsome collection of houses. The American troops were defeated in this place, by the British under general Howe, in the year 1776.

WHITESAND BAY, a bay on the W. coast of Eng- 
lant, in the county of Cornwall, a little to the N. of the Land's End. N. lat. 5° 6'. W. long. 4° 34'.—Allo, a bay on the W. coast of Wales; 1 mile N.W. of St. 
David's.

WHITESTOWN, the principal town and half fiire of the county of Oneida, in the state of New York, situated on the Mohawk river, 95 miles N.W. of Albany; includ- ing Utica, and having three post-offices. Its form is irreg- ular, and area about 40 square miles. In January, 1785, Mr. Hugh White, from Connecticut, with a young family, became the first settler. In 1788 the town of German Flats was divided, and a new town erected, and named Whitestown, in honour of Mr. White. In 1798 the county of Oneida was establish- ed, by a subdivision of Kerkimer, and Whitestown included within this county. By subse- quent divisions, Whitestown was reduced to a mediate mea- sure of 9 miles by 8. It is situated immediately on the great thoroughfare between Albany and the Western lakes; between Canada and the principal commercial sea-ports of the American states on the Atlantic ocean. This town contains three large post-villages, Utica incorporated, 
Whiteborough, and New Hartford. Whitestown, includ- ing these villages, is unrivalled, in the United States, with regard to wealth, population, trade, and improvements, among inland towns of such recent settlement; and none in this state, of the same area, affords so great a population. It has seven principal churches; one Episcopal, three Pref- byterian, two Baptist, in one of which the service is per- formed
formed in the Welsh language, and one of Welsh Independents, besides some smaller houses dedicated to the same purpose. Here are three grammar-schools, one in each village, and many common schools. It has also a cotton manufactory. This town has been gradually enlarged and embellished. Its population, by the census of 1810, is 49,125, with 53,373 electors.

WHITTING, in Ichthyology, the English name of a common fish of the Aelurus kind, commonly distinguished by the writers in ichthyology by the name of Aelurus mollis, though by some called Aelurus albicollis and merlangus.

The winking, or gadus merlangus of Linnaeus; is a fish of an elegant form; the upper jaw is the longest; the eyes are large, the nose sharp, and the teeth of the upper jaw long,

Vol. XXXVIII.
WHITLOW, in Surgery, called also by surgeons paronychia, pararetum, onychia, &c. is an inflammation affecting one or more of the phalanges of the fingers, and generally terminating in an abscess. These are the parts which are the usual situation of the complaint; but sometimes a diseasae, which is precisely similar, makes its attack upon the toes. It is likewise to be understood, that in fever cases, the disorder extends itself to many other parts besides the finger, the matter making its way upward higher than the writh. Thus, as Callien judiciously observes, the skin, cellular substance, sheath of the flexor tendons, and less commonly that of the extensors, the tendons themselves, the annular and capular ligaments, the periosteum, the very texture of the bone-bones, and the pulpy substance underneath the nail, are all parts to which a whitlow may extend its mischievous consequences.

From what has been already observed, it must be plain that whitlows differ very much in their degree of violence, and in their depth and extent. Hence, surgical authors usually describe four or five varieties of the complaint. The division adopted by Callien comprehends five cases: namely, the cutaneous or superficial paronychia, the subcutaneous paronychia, the paronychia of the tendons, or theca, the paronychia of the periosteum, and the subungual paronychia, or that situated underneath the nail.

The cutaneous paronychia begins with a superficial inflammatory redness of the finger, and, as early as the second or third day from the commencement of the attack, the cuticle of the part affected becomes raised in the form of vesicles, which contain a limpid serum, but sometimes a bloody fluid. (Callien, vol. i. p. 294.) Mr. Pearson describes the cutaneous paronychia as being seated at the end of the finger, immediately below the cuticle, and as sometimes surrounding the finger and root of the nail. The skin, he says, is very little discoloured. The case speedily advances to suppuration; and when this process is completed, the cuticle appears almost transparent. After the contents of this little abscess are evacuated, the ulcer seldom demands any particular attention. Principles of Surgery, p. 88. edit. 2.

The subcutaneous paronychia makes its appearance in the form of an inflammatory tumour, attended with a great deal of acute pain. The symptoms, however, are not alarming, nor do they generally extend beyond the inflamed finger. In severe examples, the whole hand is more or less affected with pain and tension, and uneasiness is felt all up the arm. The severity of the pain, in such cases, frequently prevents sleep, and the whole system is thrown into some disorder. The attack of this kind of whitlow is attended with a more acute and throbbing pain than that of the cutaneous paronychia, suppuration proceeds more slowly, and matter is frequently formed under the nail. The diseasae is particularly situated in the cellular membrane under the cutis.

The more deeply-seated kinds of whitlow are those affecting the sheath of the flexor tendons and the periosteum, which parts, indeed, by reason of their vicinity to each other, are often both attacked together. The diseaasae commences with an intense, burning, throbbing pain in the finger, accompanied with severe febrile symptoms. At first, no swelling whatever can be perceived in the part affected; but afterwards a slight edematous tumour follows, which gradually assumes an inflammatory appearance, and the tumefaction spreads from the finger to the hand, and fore-arm, and even to the axilla. On the inner side of the arm, red hard furlings may also frequently be observed, which are inflamed aborative vesels tending to the axillary glands, which are themselves sometimes enlarged and very painful. The pain of the whitlow is particularly felt shooting up from the affected finger to the inner concdey of the humerus, and thence to the arm-pit. Delirium, and other alarming symptoms, occasionally attend these worst descriptions of whitlows, which are alleged to have proved sometimes fatal.

The matter, which is small in quantity, is either collected within the sheath of one of the tendons, or it is under the periosteum in contact with the bone, which is generally found in a carious state; and sometimes the superincumbent integuments suffer phscalation. See Pearson’s Principles, p. 90.

The subungual paronychia, or that which especially occurs under the nail, commences with inflammatory symptoms, which are, however, much less urgent and dangerous than those of the preceding case; and the situation of the disease renders its nature quite obvious.

The usual exciting causes of whitlows are various external injuries, as pricks, contusions, &c. The lodgement of a thorn or splinter in the part, is another frequent cause of these abscesses. They are, however, much more common in young healthy persons than in others; and they appear in many instances to occur spontaneously, that is to say, without our being able to assign any manifest cause for them. There is one particular sort of whitlow, which Mr. Pearson has thought proper to call veneral, as will be presently noticed.

With regard to the prognosis in ordinary examples of the complaint, it may be laid down that the cutaneous and subcutaneous paronychias are in general unattended with danger. But those whitlows which are formed within the theca of the flexor tendon, if they be not relieved by the timely interference of surgery, very often produce abscesses, extending up the hand and arm, in the course of the corresponding tendon and muscle, which parts become so altered and diseased, that their functions are permanently injured, and the bones of the finger destroyed by necrosis. When also the periosteum is affected, the matter lying underneath, or closely upon it, the neighbouring phalanx of the finger generally perishes. Whitlows beneath the nail frequently occasion a loss and separation of the part.

The indications in the treatment of whitlows are:

1. To endeavour to produce an early resolution of the inflammation; but as this attempt seldom succeeds, and the case almost proceeds to suppuration,

2. The
WHITLOW.

2. The great desideratum is to discharge the matter as soon after its formation as possible.

3. The last thing is to heal the wound.

With respect to the first indication, experience proves, that the inflammation, in a very early stage of the complaint, may sometimes be diffused by the adoption of ordinary antiphlogistic treatment. Here topical bleeding, especially the prompt and repeated application of leeches to the painful part several times in the day, is highly commendable; and the inflamed finger and hand may be covered with a cold, diffusible, fumifhing lotion, together with which some writers advise the whole limb to be bound with a circular roller. Others speak highly of the good effects of an early immersion of the affected finger in very warm water, or in lotions made of alcohol, vinegar, oil of turpentine, &c. and used as hot as can be borne. Callifian flates, that he has also frequently observed great benefit arise from the affusion of such lotions on the part. He even afferts, that the pain and more deeply-seated inflammation of the finger may be sometimes checked by applying caufive or a blifter to the integuments. When the patient's sufferings are very great, the exhibition of opium is indispensable after bleeding has been duly practifed. The fame writer alfo affirms, that electricity has been found ufed of the very commencement of a whitlow.

When two days elapse without any probability of resolution taking place, fuppuration ought to be promoted by the immediate and continued ufe of emollient poultices and fomentations. Nor fhoufl the surgeon wait for the abfeifes to point, but make an opening with lefs fots of time, in proportion as the cafe becomes worfe. In examples where the pain is exceedingly violent, the incision fhoufl not be deferred beyond the fourth day from the beginning of the pain. The opening ought alfo to be made at the part which was firft painful, and thence the cut should be continued longitudinally, and as deeply as the situation of the matter. The lancet, indeed, if requisite, must be introduced down to the bone, by which means a small quantity of deeply-seated confined matter may frequently be voided, and the pain and progres of the difafe at once fopped. Even when no matter is diffcharged from the opening, an early incision fometimes speedily relieves very severe cales of whitlow; probably (as Callifian obferves) on the principle of removing tension, and occafioning hemorrhage from the part. In thofe infances, in which an incifion has not been practifed in due time, and the matter under the tendinous theca has spread extensively up the hand and arm, it is fometimes neceflary to make the opening free and ample, without injuring, however, the annular ligament. The diffcharge of the abfeifes, and the evacuation of blood from the incifion, are followed by a moft immediate relief. When the matter is lodged under the periosteum, the bone is moftly found affected with necroflis. In cafes of this defcription, there are fome practitioners who prefer the removal of the difafeed phalanx, to awaiting a tedious and uncertain cure by the procefses of nature. Callifian, however, informs us, that he has often feen the dead portion of the bone expofed, leaving the reft in a state of prefervation.

When a whitlow under the nail cannot be diffcharged, the matter fhould be let out by an opening, practifed through the tranparent part of the nail, or by the fide of it. Some furgeons adopt the plan of scraping the nail, fo as to render it as thin as poifible, before they cut through it, which is an ingenious and commendable method. See Callifian's Syll. Chir. Hod. t. i. p. 293. 295.

In the fifth volume of the Medico-Chirurgical Tranfac-

tions, Mr. Wardrop has defcribed a very uiterate and troublesome species of whitlow, which, from its malignant character, he has called the onychia maligna. “The commencement of this difafe is marked by a degree of swelling, of a deep red colour, in the soft parts at the root of the nail. An oozing of a thin ichor afterwards takes place at the cleft, formed between the root of the nail and soft parts, and at laft the soft parts begin to ulcerate. The ulcer appears on the circular edge of the soft parts at the root of the nail; it is accompanied with a good deal of swelling, and the skin, particularly that adjacent to the ulcer, has a deep purple colour. The appearance of the ulcer is very unhealthy, the edges being thin and acute, and its surface covered with a dull yellow, or brown-coloured lymph, and attended with an ichorous and very fetid discharge. The growth of the nail is interrupted, it lofes its natural colour, and at some places appears to have but little connection with the soft parts. In this flate (says Mr. Wardrop), I have feen the difafe continue for several years, fo that the toe or finger became a deformed bulbous mass. The pain is sometimes very acute; but the difafe is more commonly indolent, and accompanied with little uneafinefis. This difafe affects both the toes and the fingers. I have only obferved it on the great toe, and more frequently on the thumb, than any of the fingers. It occurs, too, chiefly in young people; but I have alfo feen adults affected with it.”

With regard to the treatment of the species of whitlow named by Mr. Wardrop onychia maligna, all local applications have in many infances proved quite ineffectual, and the part been amputated. The only local treatment which Mr. Wardrop has ever fene relieve this complaint has been the evulcon of the nail, and afterwards the occafional application of efcharotics to the ulcerated surface. We have seen a fimilar plan occasionally Succede, and the applications which appeared to answer belt were, arlenical lotions, Plunket's caufsive, or a very strong folution of the nitrate of silver. Nothing, however, will avail till the nail is removed, and its total separation sometimes takes up a good deal of time, unless the patient submit to the great pain of having it cut away.

Mr. Wardrop tried with fucces the exhibition of mercury in four cafes of the onychia maligna. The medicine was given in small doses at firfl, and afterwards increafed, fo as to affect the gums in about twelve or fourteen days. The fores in general soon afumed a healing appearance when the fyltem was in this flate, and the bulbous swelling gradually difappeared. Wardrop in Medico-Chir. Tranf. vol. v. p. 135. &c.

Mr. Pearfon has published an accoumt of a peculiar fort of whitlow, to which he affixes the epithet venerelial. He obferves, that it generally appears in the form of a smooth, soft, unrefiting tumour, of a dark red colour, and is situated in the cellular membrane about the root of the nail. It is attended with an inconsiderable degree of pain in the incipient flate; but as fuppuration advances, the pain increafes in severity. The progres of the abfeifes to maturaflion is generally low, and is seldom completed.

When the matter is evacuated, the nail is generally found to be loofe, and a very foul but exquifitely fensible ulcer is expofed; and considerable foughs of cellular membrane, &c. come away, fo as to render the fore sometimes very deep. The difcoloured and tumid flate of the skin commonlyextends along the finger, confiderably beyond the margin of the ulcer. In fuch cafes, the integuments of the finger become remarkably thickened, and the cellular membrane is fo firmly
firmly condened, as not to permit the skin to glide over the subjacent parts. The bone is not usually found in a curious state.

According to the same author, this species of whitlow is more frequently seen among the lower classes of people, when they labor under lues venerea, than in the higher ranks of life. It does not appear to be connected with any particular state of the disease, nor is it confined to one sex more than the other. In the Lock Hospital, it is said to occur in the proportion of one patient in five hundred.

In adopting the name of venereal paronychia, Mr. Pearson informs us, that it is not with the design of implying that the cafe is a true venereal abces, the matter of which is capable of communicating lypalis to a found person. Its progress and cure, he observes, seem to be unconnected with the increased or diminished action of the venereal poison in the constitution, and to be also uninfluenced by the operation of mercury. Mr. Pearson considers the venereal disease as a remote cause, which gives occasion to the appearance of this as well as of several other diseases, which are widely different from its own specific nature.

In the incipient state of the venereal whitlow, when no severe symptoms are present, Mr. Pearson thinks it best to use no external applications, and merely cover the part with a bit of fine rag. The disease will then often gradually disappear of itself, without coming to suppuration. When matter is formed, Mr. Pearson says, the abcesses may be permitted to burst spontaneously. Every species of dreeving will frequently be found to give great pain, and disagree with the sore. The same writer, however, states, that one application, composed of equal parts of the bark of copaiva and tinctura thebaica, may sometimes be used with a good effect. The principal object is to keep the patient as easy as possible, by the internal use of opium, until the fluxes are separated, and the ulcer becomes clean. It may then be treated as a common sore; Peruvian bark will also be generally proper. In the thickened diseased state of the integuments, Mr. Pearson condemns amputation, as being likely to produce a tumor, which will change into a sore, resembling that for which the operation was performed. See Pearson's Principles of Surgery, edit. 2.

It is not at all clear to us, that Mr. Wardrop's case, which he terms the onychia maligna, is not actually the same disease as what Mr. Pearson has named the venereal whitlow. The only doubt arises from the former gentleman's recommending the exhibition of mercury as a means of cure; while the latter declares, that the complaint is quite uninfluenced by the operation of this medicine. We confess, that although some hundreds of cases of very bad whitlows have fallen under our observation, we have never met with any instance in which the cure seemed to require mercury.

Whitlow in the Feet of Sheep, in Rural Economy, a disease that takes place in the latter end of summer, and which is more frequent among the long than the short foot of sheep. It but seldom happens in clean sheep-walks, though it is very troublesome on soft, dirty, pasture-lands. It is frequently occasioned in the milking season, by the boughs or folds being dirty, and by the sheep being confined in the old houses. It is of the inflammatory nature, and commonly affects the fore-feet, but sometimes all four. The outer part of the hoof is the usual seat of the disease, and from the cleft a sharp fetid humour exudes, sometimes engendering maggots, and corroding the flesh, may even the bone. All around the hoof there is an inflammation, which turns black, and this part sometimes drops off. It is a very painful affection, so much so, that the animal often crawls.

As the weather gets more cold, it commonly becomes better, but it still walks in a lame manner.

On the appearance of the disease the foot is to be examined, and if diseased, the part opened to let out the acid matter. It is then to be washed well, and dried with mercurial ointment and sulphur in mixture, or tar with red precipitate, binding it up with a flannel bandage, to preserve it warm and clean. In case it does not take on suppuration, but degenerates into a foul and tedious ulcer, such applications as spirit of turpentine and sulphuric acid may be proper. And in all cases the sheep should be kept in a clean, easy, dry pature, until it becomes well. See Foot-Rot.

Whitlow-Grafts, or Mountain Knot-Grafts, in Botany. See Parasychia, or Illecebrum.

Whitlow-Grafts is also a name given to some species of draba.

Whitlow-Grafts, Rue-leaved, a species of saxifrage.

Whitstable, in Geography, a village and sea-port of England, in Kent, near the mouth of the Swale. Here is a considerable oyster-fishery, which employs upwards of 70 boats. Some colliers likewise bring hither coals for Canterbury and the neighbourhood; 7 miles N. of Canterbury. N. lat. 51° 22'. E. long. 1° 2'.

Whitson Island, an island in the South Pacific ocean, discovered by Captain Wallis on Whiton-eve, in the year 1767, about four miles long and three wide, surrounded by a reef. The boat's crew got some cocoa-nuts, and some fcury-graps: they met with none of the inhabitants, but some huts and several canoes building. No anchoring place for the ship could be discovered. S. lat. 19° 26'. W. long. 137° 56'.

Whitson, or Whitson Island, or Pentecost, one of the New Hebrides, in the South Pacific ocean, about thirty miles in length, and eight in breadth. S. lat. 15° 44'. E. long. 168° 20'. See New Hebrides.

Whitson Farthings. See Pentcostals.

Whitsunday's Passage, in Geography, a strait so called by captain Cook, from the day on which he sailed through it, in 1770; between Cumberland island and the coast of New Holland.

Whitsuntide, the fifteenth day after Easter.

The seaman properly called Pentecost, is popularly called Whitsuntide; some say, because in the primitive church, those who were newly baptized came to church between Easter and Pentecost, in white garments.

Whitsuntide Bay, in Geography, a bay on the north coast of the island of Kodiack, west of Cape Whittunday.

Whit-Tower, in Rural Economy, a provincial term applied to a collar-maker for team-horses.

Whittingham, in Geography, a town of Vermont, in the county of Windham, with 1248 inhabitants; 16 miles E. of Bennington.

Whittle, a provincial name applied to a sort of pocket or sheathed knife.

Whittlebury Forest, in Geography, a royal forest of England, in Northamptonshire.

Whittlesea Mere, a lake of England, in the county of Huntingdon, formed by a branch of the river Nen, situated to the S.E. of Peterborough.

Whittlesey, or Whittlesea, a town in the north part of the hundred of Witchford, Isle of Ely, and county of Cambridge, England, is situated on the confines of Northamptonshire and Lincolnshire, at the distance of 10 miles W.S.W. from the town of March, and 5 miles E. by N. from Peterborough. It contains two parishes, St. Mary's and St. Andrew's; but their boundaries cannot be distinctly
WOH

distinctly ascertained, and they are so far consolidated, that, though in separate patronage, the two livings are generally held by the same person; and only one register of births and burials kept for both. Whittlesey formerly had a market; but when or by whom granted, there are no existing records. The market-day was Friday; but it has long been gradually falling into disuse, and since the year 1788 has been wholly discontinued. An annual fair for horses is still held. Each parish has a church, in which are various sepulchral memorials of ancient families. St. Andrew's church was given to the monks of Ely in the twelfth century, by Nigellus, second bishop of that see, for the purpose of augmenting their library: or, as it is expressed by an historian of that time, "making books for the library." At the well end of St. Mary's church is a very handsome tower, surmounted by a tall and elegant spire, which from its height constitutes a very conspicuous object from distant parts of this flat country. The tower is much ornamented with niches, pinnacles, and crocketts; and each angle of the octagonal spire, which connects with the angular pinnacles of the tower by flying buttresses, is adorned with foliated crocketts. There is in the town a charity-school for the instruction of twenty-six children, and several almshouses:

Whittlesey, exclusive of the town, is divided into five districts, named Ellry, Cotes, Eldernal, Willow-hall, and Glaismoor. At Eldernal was a chapel, consecrated in 1525, but long since dilapidated. At Glaismoor were found, in the year 1742, several Roman lamps made of the red ware. The population of the whole, in the return of the year 1811, is stated to be 4245, occupying 729 houses.

WHOLAGUNCE, a town of Hindostan, in Oude; 12 miles N.E. of Fyzabad.

WHOLDYACHUCK, a lake of North America. N. lat. 60° 20'. W. long. 109° 30'.

WHOLE, TOTUM, in Arithmetic, &c. See Part, Division, Partition, &c.

Whole, in Logic, is distinguished into four kinds; viz.

a metaphysical, when the essence of a thing is said to consist of two parts, the genus and the difference; mathematical or integral, when the several parts which go to make up the whole are really distinct from one another, and each of them may subsist apart; physical or essentinal, usually denoting and including the two essentiaI parts of man, body and soul, but more properly including all the essentiaI modes, attributes, or properties, contained in the comprehension of any idea; and logical, called also universal, the parts of which are all the particular ideas to which this universal nature extends. Watts's Logic, p. 117.

Whole Blood, Measure, Number, and Sine. See the Substantives.

Whole Milk-Cheese, in Rural Economy, a term used to signify such cheeses as are made from the whole meal of milk, in contradistinction to those which are made from a part of it only. It is observed in the Gloucester Report on Agriculture, that cowherd-cheese ought to be made of the whole meal of milk; but in a dairy of twenty cows, it is not unusual to let by a pan, of about seven or eight gallons, till the next milking, which is then skimmed, and added to the new meal, from which a similar quantity is taken as before. The cream thus laid by is made into milk-butter. Cowherd-cheeses are either thin, about eight to the hundred; or thick, generally called double Gloucester, about four to the hundred, or even larger. The latter are made in May, June, and July, principally, and even as long as grass continues good in some dairies.

It is noticed, too, in the farm book of report for the county of Peebles, in Scotland, that in the sheep-farms there, where sheep's-milk cheese is made, the whole of that fort of milk is seldom employed; but that the whole of the cow's milk upon the farm is mixed with the sheep's milk. That the butter, during this period, being ill-tasted, is kept for mixing with the tar for lining the sheep; and the milk is afterwards made into cheese. There are, in consequence, very few farms where cheese is made of entire sheep's milk; and that, from the various proportions of the admixture of cow's milk, there are few articles in commerce palling under one common denomination, of which the qualities are so various as those of sheep's-milk cheese. See DAIRYING, and CHEESE.

Whole-Moulding. The impropriety of continuing whole-moulding in the construction of ships, has been pointed out in the article SHIP-BUILDING; but as it is at present continued in the formation of boats; therefore, how far whole-moulding may be used in the construction of boats, we shall endeavour to explain by introducing a boat, which might be whole-moulded from the stem to the stern-post, if part of the midship-bow was approved of for the shape of the tranom; but as there can be no necessity that it should be so far whole-moulded, we shall omit it to the stern-post, but extend it quite forward to the stem.

The length, stem, and stern-post, being determined on in Plate Ship, fig. 1, the next thing is the station of the midship-frame, which is not of material consequence, only let it be before the middle of the boat. Then let off all the stations of the timbers afores and abaft the midship-bow.

The height in the midships being given, draw the shear-line, or top of the gunwale, so that it may have an agreeable appearance. The line below it shews the breadth of the sheer-rame, and the ticked line above it shews the upper edge of the wale-board.

The next thing is the rising-line, which requires some experience to determine at once, so as to answer every purpose; for not only the form of the midship-bow, but likewise the design of the boat must be kept in mind, to know how far we may venture to let the rising-line afores and abaft, without occasioning any hindrance to her flowage.

Having determined the height of the rising-line, dispose of the main height of breadth-line at the midship-bow, at such height as will befri the intended form of the midship-bow, and continue it from thence forward and aft, parallel to the rising-line; for so far as the boat is to be whole-moulded, the main height-of-breadth and rising-line must be parallel to each other in the direction of the square timbers.

In the half-breadth plan, fig. 2, square down from the sheer-plan, fig. 1, when the height-of-breadth line crosses the fore part of the rabat of the stem, and the aft part of the rabat of the stern-post, or aft-side of the tranom. But as this line rises above the tranom abaft, observe where the top of the side crosses the aft part of the tranom, and draw it parallel down from any of the stations of the timbers. Alto square down the station of the midship-bow.

Set off from the middle-line, A B, fig. 2, the half-thickness of the stem, and from thence sweep an arch to the thickness
Then place and faint 9, and move it till each letter on the lower edge of the mould agrees with the middle-line, and the mid-breath on the mould agrees with its corresponding height-of-breath line. Then draw the form of the mould from the head of the timber to the middle-line, as ticked in fig. 3, and draw a straight line from the side of the keel, at the upper edge of the rabbet, to touch the outside of the mould formed by the mould, except where the rabbet of the keel and item rises, as at F, G, H, I.

Set off the half-thickens of the keel from the middle-line, fig. 3, and take the height from the line A, B, fig. 1, to the lower edge of the rabbet at each timber, and fit it from the line A, B, fig. 3, on the line for the half-thickens of the keel or item; then with compasses set to the thickens of the bottom plank, sweep an arch; from the upper side of which draw a straight line to the back of each curve of the mould, which will finish completely the heets of the timbers.

The same method must be observed in the after-body towards perpendicular D, fig. 3, applying the midship-bend mould in the same manner as directed in the fore-body, making use of the mould as far aft as timber 12.

The after-square timber is 9; therefore, to 9 may be finished the heets of the timbers, by drawing a straight line from the back of the whole-moulding curve to the back of the sweep at the rabbet of the keel.

In whole-moulding, but few moulds are necessary to be made to mould all the timbers. Thus the floor-mould is to be made to the midship-bend in fig. 3, a little above the diagonal line, a b or c, which is to be the heads of the floors, and let the lower part of the mould correspond well with the rifting of the midship-bend, as is shown in fig. 4.

When the mould lies well, as in fig. 3, mark the middle-line on the lower edge of the mould, and the head of the floor on the outer edge. Make the inside of the mould to its proper scantling, and let the upper edge correspond well with the cutting-down of the inside of the midship-floors; which cutting-down is so marked in fig. 1.

Then in fig. 2, take the distance of each timber from the line C D to the main-half-breath line, and let them off on the lower edge of the mould, from the middle-line of the midship-bend towards the outer end of the mould, which is the middle-line for each floor.

Now fix the lower edge of the mould in fig. 3, on each rifting-height, in the same manner as the timbers were got in by whole-moulding; and when each mark on the mould is well with the middle-line, and on its proper rifting, describe on the outer edge of the mould the heads of the floors, or the diagonal line a b, or c.

Or, as in fig. 4, square the middle-lines of each timber, and then take the half-breaths of each floor from fig. 3; and let them off square from each middle-line in fig. 4, to intersect the edge of the mould.

The lower futtock-mould, fig. 5, is made to the rifting-height of the midship-bend, and from thence to the top of the floor, but need not be made so long at the heel as the floor-mould. The inside is made to the scantling, and the crof of the middle-line and the floor-head, on the lower futtock-mould, is done in the same manner as on the floor-mould; or the belt way is to lay the floor-mould on the lower futtock-mould, and crofs it by the floor-mould. When the lower futtock-mould is laid in its place to the midship-bend in fig. 3, then mark the main-breath on the mould, which is the main-breath for all the timbers. Then take the distance in fig. 1, from the main-breath line to the top of the floor at each timber, and let it off on the mould, from the main-breath.
breadth upward, which is the heads of all the timbers; and then the crossing of the lower futtock-mould is finished.

To cross the rising Square.—When the boat is whole-moulded, the floors and lower futtocks are generally moulded by the use of the rising-square; which is so called, because when the square is properly placed to mould any timber, one side of the square corresponds with the rising of that timber. When the timbers are moulded by the outside of the mould, and the heels by the rising-square, (which gives the upper edge of the rabate of the keel, or bearding-line,) then there is a button, called a cutting-down button, with the heights of all the floors, from the upper edge of the rabate of the keel to the cutting-down line; which gives the cutting-down or inside of all the floors.

To make the rising-square, let one side of the square be of sufficient breadth to receive the rising and the cutting-down, as may be seen by the square E.

When moulding the floors, or lower futtocks, the lower side of the mould is the rising of the timber; and consequently the edge of the square, which is to be applied to the under side of the mould, is also the same.

Then to mark or cross the square, take the distance from the rising-line in fig. 1 to the upper edge of the rabate of the keel, or bearding-line, at each timber; and set them off from that edge of the square, which is to be applied to the mould, on the other edge of the square, and close to the edge, drawing a margin to put the letters or figures under them. Then take the distance in fig. 1, from the rising-line to the cutting-down line, at the timbers, where the cutting-down is below the rising, and set them off from the edge of the square that is to be applied to the mould on the other edge of the square, but within the rabbet, as may be seen on the square. The other timbers, from A to B, where the cutting-down is above the rising, may be marked on the moulds.

From the edge of the square where the rabbets are placed, set off on the other edge of the square the half-thickness of the keel, which call the middle-line; and then the square is ready for moulding.

To mould the Floors.—The best way for moulding the floors for a whole-moulded boat, is to make two moulds, agreeable to the former directions, made and crossed both alike, but the sides revered. Then lay one on the other, the same as in fig. 4, keeping the lower edges in a straight line, and mooring them till the corresponding middle-lines on the moulds agree. The moulds in fig. 4, are fixed at 9, but the middle-lines on the lower mould cannot be seen; therefore, before the moulds are put together, it is best to mark (in chalk) on the edges of the mould the middle-lines of the timber. When the moulds are placed, fix the middle-line, marked on the edge of the square, to the middle-line on the mould of the timber, and the other edge of the square will represent the side of the keel.

Then apply a straight button to the rising of 9, on the edge of the square, and also to the outside of the floor-mould.

This will give the moulding of the outside of the floor, except timber 9, which is somewhat hollow. Then square the cutting-down for 9, across to the edge of the square, and draw a straight line to touch the inside of the mould.

In the same manner mould the other arm of the floor, by canting the square. But the rising and cutting-down should be marked on both sides.

Before the moulds are moved, mark the heads and firmarks, if any, as a guide to fix the lower futtock when put in its place, if it should not run down to the side of the keel.

To mould the lower Futtocks.—The lower futtock-mould is fig. 5, which is made in the same manner as the floor-mould, but continued as high as the top of the keel. The upper part being straight and perpendicular, and the mould made to the scantling, there is no difference between moulding one side of the floors and moulding the lower futtocks.

The same method of fixing the square for the moulding of the floors will serve to mould the lower futtocks, as on the square in the plate, where the middle-line on the square is put to the middle-line on the lower futtock-mould for G. A straight button applied to the rising for G, on the square, and to the back of the lower futtock-mould, gives the moulding of the outside of the lower futtock; and the cutting-down for G on the square brought to the edge of the square, a straight button from thence to the inside of the mould will also be the inside of the lower futtock.

Mark the firmark, or floor-head, in the same manner as the floors, in order to place the lower futtock to its proper height at the side of the floors, in case they should not be required to run down to the side of the keel.

Likewise mark the main-breadth, and the head for G, before the mould is moved.

That there is no difference between the floors and the lower futtocks in using the rising-square, may be seen more clearly in fig. 4, where the floor-mould is continued up to the top of the side, which makes the lower futtock-mould; so that the form of the lower futtock is seen, as well as the floor.

The two floor-moulds may be made to serve for all the floors, by putting the fore-body on one side of the mould, and the after-body on the other; but observe to cross one mould opposite to the other, so that when it is canted over, it shall then be proper to mould with.

Two rising-squares are sometimes used; one for the fore-body, and the other for the after-body, because the squares must be crossed alike on both sides, to mould the arms of the floors, and likewise to mould the lower futtock for both sides of the boat. Or, instead of this, the fore-body may be put on one side of the square, and the after-body on the other. When the square is wanted on the opposite side, chalk on the edge of the square the rising and the cutting-down for the timber to be moulded, and then cant the square.

Two lower futtock-moulds may also be made, or cross the fore-body on one side of the mould, and the after-body on the other. In order to mould a timber for that side of the ship where the firmarks are at the underside of the mould, chalk the firmarks for the timber wanted on the edge of the mould; or make two margins on the edge of the mould, serving one for the fore-body, and the other for the after-body, and revered on the opposite side.

The lower futtocks for boats generally run about half-way between the floor-head and the side of the keel; but if it were a hoy, or small vessel that was whole-moulded, the lower futtocks might then be required to run to the side of the keel, or dead-wood; wherefore, it is proper to show the moulding of them down to the side of the keel.

Various are the methods used by different artificers in moulding the lower futtocks; and it is evident that the method which has been practised most will appear the best.

Some will make no use of the square, but mark the heels of the lower futtocks on the mould, and provide a button, marked the same as the square; the lower end of the button being long enough to mould the outside of the foremoat and aftermold timbers; and the upper end of the button being long enough to mould the inside of the midship-timber.

Mark
Mark a firmark across the batton, supposed to represent the side of the square, which must always be fitted well to the lower edge of the mould; from which firmark, supposed to be the rising for all the timbers, set off close to the edge of the batton the heels of all the timbers in the fore-body, or the distance in fig. 1, from the rising-line to the upper edge of the rabiet of the keel, or beading-line.

Then draw a margin for the cutting-down of the timbers, and take the distance in fig. 1, from the rising-line of each timber to the cutting-down, and set them off on the batton for the cutting-down, as much above or below the firmark on the batton as the cutting-down is above or below the rising at each timber.

On the other side of the batton may be put the afterbody.

In some boats or vessels, where the rising and cutting-down are farther afield at the midship-bench, then the batton will be as useful as the square; but instead of the middle-lines being marked on the lower footlock-mould, it will be better to mark the side of the keel, or where the heels of the lower footlocks are intended to be, for the better applying the batton.

If the heels of the lower footlocks do not run down to the side of the keel, it will alter the risings on the batton; the heels being marked on the mould short of the side of the keel.

The proper heels of the lower footlocks should be marked on the mould, though moulded by the square; for then the edge of the square might be put to the proper mark on the mould for the heels of the timbers.

The middle-lines marked on the lower footlock-mould in the Plate, were intended only to show that the method of moulding the floors and lower footlocks were alike. The square is the beat to mould the floors, because the middle-lines are the properest to be marked on the floor-mould.

What has been said may suffice to shew that whole-moulding may, in some measure, be used, and yet form a pleasing draught, much more so than that of the boat in fig. 1, if less flowage were sufficient to answer the purpose for which she is designed.

WHOLESOE Ship, in the Sea Language, one that will try, haul, and ride well, without rolling or labouring in the sea. A long ship that draws much water may try, haul, and ride well; but if she draws little water, she may try and ride well, but never haul well; and a short ship that draws much water may haul well, but neither ride nor try well; and such is called an unwieldy ship.

WHORE. See CAmTESEAN, HARLOT, CONCUBINE, &c.

WHORL, in Botany. See VERITILLUS.

WHORLBAT, or HURLBAT, a kind of gauntlet, or leathern strap, laden with plumbers; used by the ancient Romans in their solemn games and exercices; and by them called cebus.

WHORLED PLANTS. See VERTICILATE.

WHORLES OF FLOWERS, among HERBALISTS, are rows of lesser flowers, set at certain distances about the main stalk or spike, as in penny-royal, &c.

WHORTLE-BERRY, BILBERRY, or CRANBERRY, in Botany. See Vaccinium.

The whortle-berry, with one flower upon each footstalk, oval-fawed leaves, which fall off in winter, and an angular stalk, called black subortis, or bilberries, grows very common upon large wild heaths, in many parts of England, but is never cultivated in gardens, it being with great difficulty transplanted; nor will it thrive long when moved thither. The fruit is gathered by the poor inhabitants of those villages which are situated in the neighbourhood of their growth, and carried to the market-towns. These are by some eaten with cream or milk; they are also put into tarts, and much esteemed by people in the North, but they are seldom brought to London.

The shrub on which these grow rises about two feet high, having many branches, which are garnished with oblong leaves, shaped like those of the box-tree, but somewhat longer, and a little fawed on their edges. The flowers are shaped like those of the arbutus, or strawberry-tree, of a greenish-white colour, changing to a dark red toward the top. The fruit is about the size of large juniper-berries, and of a deep purple colour, having a juice upon it when untouched, like the blue plums, which is rubbed off with handling.

The whortle-berry with nodding bunches of flowers terminating the branches, and oval leaves which are entire, turned back and punctured on their under side, called visisidea, and red subortis, is an ever-green shrub, seldom rising above fix or eight inches high, with leaves like those of the dwarf-box, which grows upon moors in several parts of the North, but is not capable of being easily transplanted: the berries are red, and have a more agreeable acid flavour than those of the first fort.

The whortle-berries with oval, entire, refracted leaves, and naked, slender, creeping stalks, called moss-berries, moor-berries, and cran-berries, produce branches small as thread, and trailing upon the mossy bogs, which are garnished with leaves resembling those of thyme, with the upper surface of a shining green, and white underneath. The berries, which grow upon long slender foot-stalks, succeeding the flowers, are round, red, and spotted, of a sharp acid flavour, and much esteemed for tarts, or eaten with milk or cream. This is a native of bogs, and cannot be propagated upon dry land.

There are several other species of this genus, some of which are natives of Spain and Portugal, others of Germany and Hungary, and several of the northern parts of America; from whence those large fruits are brought to England which are used by the pastry-cooks of London, during the winter season, for tarts. But as all these sorts grow naturally in swamps and bogs, they are not easily transplanted into gardens in their native country, so as to thrive or produce fruit; therefore, there can be little hope of cultivating them to advantage. Miller.

WHORTLE-BERRY, African, a species of ROYENA.

WHORTLE-BERRY, Bear’s. See UVA Ulf. WHY, in Falconry, denotes the fluttering of partridges or pheasants as they rise.

WHY-TEA, in Geography, a bay on the east coast of Owbyhee. N. lat. 19° 44'. E. long, 204° 54'.

WHY-MEA BAY, a bay on the north coast of the island of Wunoo. N. lat. 21° 38'. E. long, 204° 51'.

WHY-MEA Road, a road on the south-west coast of the island of Attowas. Captain Vancouver says, this bay is much confined in respect to safe anchorage.

WHYTE, Robert, in Biography, an excellent composer of church-services in the style of Palestrina, which, however, he could not imitate, as he was anterior to him, and a great matter of harmony before the productions of this chief of the Roman school were published, or at least circulated, in other parts of Europe. Whyte was dead in 1581, when his Latin Full Anthems and Services were beautifully transcribed in a set of books, still preferred at Oxford;
WHY

Oxford; as we find by a dithach at the end of a prayer, in five parts, upon a plain song: "Pecucum Sanete Domine."

Maxima omnium nostrorum gloria Whyte
Tu peris; æternum fed tua muta manet.

Whyte preceded Tallis and Bird, and died before their fame was well established. His works seem never to have been printed; but in the library of Christ-church, Oxford, a sufficient number of them has been preferred in the Aldrich collection, to excite not only wonder, but indignation, at the little notice that has been taken of them by musical writers. Morley, indeed, has given him a place in the list of compofer at the end of his Introduction, and ranks him, with Orlando di Lasso, among excellent men, who had ventured to begin a composition with a fourth and sixth; he likewise places him with Fairfax, Taverner, Shepherd, Munday, Parsons, and Bird, "famous Englishmen who have been nothing inferior to the best composers on the continent."

And no musician has then appeared who better defiied to be celebrated for knowledge of harmony, and clearness of style, than Robert Whyte, as is manifested in Burney's Hist. of Mu$. vol. iii. by an anthem for five voices.

But besides this matterly composition, and a great number of others, to Latin words, which we scorcd from the Christ-church books, and which were probably produced at the latter end of Henry VIII.'s reign, or during the time of Queen Mary, when the Romish religion was still in use, we are in possession of a small MS., which, by the writing and orthography, seems of the 16th century, entitled "Mr. Robert Whyte, his Bits, or Three Part Songs, in Partition: with Ditties, 11; without Ditties, 16."

These are short fugues or intonations in most of the eight ecclesiastical modes, in which the harmony is extremely pure, and the answer to each subject of fugue brought in with great science and regularity. Burney.

WHYTHORNE, Thomas, gentleman, in Musical History, author of a book of songs, printed by John Daye, in March 1574, under the following title: "Songes of three, fouer, and five voyces, composed and made by Thomas Whythorne, gentleman, the which songes be of fundrie fortes, that is to say, fome long, fome short, fome hard, fome easie to be fonge, and fome between both; alfo fome folome, and fome pleafant or mery; fo that according to the fkel of the fingers (not being mutifians), and difpoftion or delicte of the heares, they may heare fuch songes to their contentation and liking."

Our secular vocal music, during the first years of Elizabeth's reign, seems to have been much inferior to that of the church, if any judgment can be fairly formed of it from this book, published before the fongs of Bird had appeared, and of which both the words and the music are alike truly barbarous. But we have, in our own time, music-books published in England every day without genius or science to recommend them. And it is not certain that Whythorne's fongs were ever in much public favour. Now, if it should happen that one of these, by escaping the brolm of Time, should reach posterity, and fall into the hands of some future antiquary, critic, or historian, who should condemn all the compositions of the present age by one, that had, perhaps, been never performed or heard of by contemporary judges and lovers of good music, the sentence would very unjustly.

WHYTT, Robert, F.R.S. in Biography, a distinguished physician, was born at Edinburgh in 1714. Educated at St. Andrew's, and studied physic first at Edinburgh, and afterwards at London, Paris, and Leyden. He settled in his pro-

WIB

feftion at Edinburgh, where he became a fellow, then president of the college of physicians, and in 1746 chairman of the institutions of medicine in the university. As a medical practitioner and teacher, and also as a writer, he acquired celebrity. The first of his publications was an "Essay on the Vital and other Involuntary Motions of Animals," 1751, in which he advances a theory different from that of Stahl, as he attributes these motions not to the soul, acting to a foreseen end, but to the power of Julius. In 1755 he published "Physiological Essays, containing an Inquiry into the Causes which promote the Circulation of the Fluids in the very small Vessels of Animals; with Observations on the Sensitive and Irritability of the Parts of Man and other Animals." Here he supposes that the action of the heart is not sufficient to propel the blood through the minute vessels, but that it is assisted by an oscillatory motion of the vessels themselves. Of this work, an enlarged edition appeared in 1761. His other works are, "An Essay on the Virtues of Lime-water in the Cure of the Stone," 1752; "Observations on the Nature, Cause, and Cure of those Disorders which are commonly called Nervous, Hypochondriac, and Hysterical," 1754; and some papers in the Edinburgh "Essays and Observations, Physical and Literary." A posthumous work appeared, entitled "Observations on the Dropsy of the Brain." Having long laboured under a complication of chronic complaints, he died in 1766. His son published an edition of all his works in 1768, 4to, under the inscription of Sir John Pringle. Haller Bib. Anat. Gen. Biog.

WIA, in Geography, one of the small western islands of Scotland, a little to the south of Benbecula. N. lat. 57° 22'. W. long. 7° 11'.—Also, one of the small Western islands, near the east coast of Barray. N. lat. 56° 58'. W. long. 7° 22'.—Also, a small island near the west coast of Skye. N. lat. 57° 21'. W. long. 6° 27'.

WIAMPA, or WINTA, or Sunpa, a town of Africa, on the Gold Coast, in the district of Agonna.

WIANDOTS. See WYANDOTS.

WIAPOCO, or LITTLE WIA, one of the navigable mouths of the Oronoko.

WIBALDUS, in Biography, a person of note in the 12th century, descended from a noble family in the bishopric of Liege, completed his studies at Liege, and became a teacher at Vaffo, and afterwards at Stablo. In 1130 he was elected abbot; and in 1136 he accompanied the emperor Lotharius on his expedition to Italy, by whom he was employed in several important departments, and fixed as abbot in the monastery of mount Caffino. But he quitted this monastery in the following year, and returned to Germany. In 1146 he became abbot of the monastery of Corvei on the Wafer, in which he was confirmed by king Conrad, to whom he was no less an object of confidence than he had been to Lotharius. He was no less a favourite with Frederic I., who had sent him twice as ambassador to Conflantinople; but on his return from his last mission thither, he terminated his life at Bulelia, in Paphlagonia, in consequence, as it is said, of poison, which had been given to him in the month of July, 1158. His Letters, mixed with some other works, one volume of which only remains, throw considerable light on the state of society at that time, and on the ecclesiastical history of Germany. Gen. Biog.

WIBLINGEN, in Geography, a town of Bavaria, with a Benedictine abbey, near the conflux of the Iler with the Danube; 3 miles S.S.W. of Ulm.

WIBORGIA, in Botany. See WIBORIA.
WICBURG, in Geography. See Viborg.

WIBY, a town of Sweden, in the province of Norcia; 18 miles S.W. of Oreb.ro.

WIC, denotes a place on the sea-shore, or on the bank of a river. Though in the original Saxon, it more properly signifies a street, village, or dwelling-place; as also a caftle. See Wyke.

We often meet with wic in the Saxron writers, as a termination of the name of a town which had a complete name without it: as, Londen-wic, that is, London-town; which signifies no more than London. In the Saxon Annals, it is mentioned, that king Ethelbert made Meltius bishop of Lunden-wic. So, Ipswich is written in some old charters, vill de Gippo, and sometimes villa de Gippo wic: which is no variation, but the same thing; for Gippo is the complete name, and the Gipp-wic is Gipps-town.

WICCAKAW, in Geography, a town of the Flate of Georgia; 22 miles N.N.W. of Oakfuksee.

WICHCRA, a river of Saxony, which rises three miles N. of Waldenburg, and runs into the Pleifs, 2 miles N. of Borna.

WICHTIS, a town of Sweden, in the province of Nyland; 27 miles N.N.W. of Helffors.

WICHTRACH, a town of Switzerland, in the canton of Berne; 12 miles S.S.E. of Berne.

WICK, a royal borough, market-town, and the county-town of the shire of Caithness, Scotland, is situated at the entrance of the small river Wick, the effuary of which forms a good harbour, at the distance of 279 miles N. from Edinburgh. The town is small, and the streets narrow and confined; but there are several respectable buildings to ornament the place. The church is an old, dark, and ill-contructed edifice. A weekly market is held on Fridays, and is well supplied. The chief sources of commerce and industry are the fisheries, which are prosecuted with great attention and success. The town and borough-lands of Wick were anciently part of the earldom of Caithness; on the petition of George, then earl, a charter was granted by James VI. of Scotland, Sept. 24, 1589, erecting the town of Wick into a royal borough, under the superiority of that nobleman. In 1672 the whole earldom of Caithness was disposed of to John Campbell, afterwards created earl Breadalbane, by whose successors it was sold to the family of Sinclair, in whom the superiority is still vested. In 1716 the convention of royal boroughs fixed the fett or government of the borough of Wick. By this fett, the old magistrates nominate two persons, out of whom a provost and two bailies are to be chosen by the free burgesses: the provost and two bailies so elected have the right of choosing seven counsellors, a treasurer, and a dean of guild. Wick, in conjunction with the boroughs of Dingwall, Dornock, Kirkwall, and Tain, sends one member to parliament. The parish of Wick is twenty miles long and ten broad; and in the population report of the year 1811 is stated to contain 5980 inhabitants. Carlisle's Topographical Dictionary of Scotland, 4to. 2 vols. 1813. Gazetteer of Scotland, 1806. Beauties of Scotland, vol. v. Caithnessshire.

WICK, a river of Scotland, which runs into the Northern ocean, at Wick, in the county of Caithness.

WICHER, a twig of the osier shrub, fingle or wortich. WICHER-Basket, in Rural Economy, any sort of basket which is made of wicker-work, or the plaited or twisted twigs of the willow, or other such kinds of young shoots. See Basket.

A sort of wicker-basket or braid, too, is made use of in grafting in field, orchard, or fruit grounds. It is observed in the Gloucestershire Report on Agriculture, that the grafts are secured immediately after the compot is put on, with "braid." These are open wicker-baskets in the form of an inverted cone, fitting the stock below the place to which the compot extends, and rising about two feet high, and expanding at the top to nearly the same diameter. This contrivance serves not only to guard the grafts in their early state, but also to keep the shoots to a proper compact form of growth. The practice chiefly prevails on the banks of the Severn, where the oifer (falix viminalis) is grown in great abundance.

In hop-gounds likewise large wicker-baskets are employed for picking the hops into. See Hor.

And wicker-work of the basket kind is made use of for many other purposes of different forts.

WICHER-Tree, a name given by the English to a tree common in China, and described by Kircher and others. It is, as it were, a rope twisted by nature, about an inch thick, and creeps along the earth often for above a hundred paces together, much embarrassing the way, but serving for cables of ships, seats, hurdles, beds, mats, and various other necessary uses. It endures no vermin, and is much valued for being cool and refreshing in the hot seasons.

WICHER-Work, in Agriculture, a sort of basket-work on a large scale, used for defending land from water of the sea or other kinds. It is observed by Mr. Loudon, in his work on "Country Residences," that in some very sandy shores, defences of the embankment kind may be made of wicker-work; and that three or four rows of paling may be made of different heights, and the intervals between them be filled with wicker, brushto, straw, or any other such materials. It is thought that these materials would retain the sand as the tide palled through among them; and that in a very short time a defence or fort of embankment would be formed of the shelving kind, which should then be planted with the upright sea-grafts, in order to bind it. See Embankment, and Water, Sea, Defending Land from Allo Upright Sea Lyme-Grafs, and Elymus Arenarius.

WICHERAD, in Geography, a town of France, in the department of the Marne. It gave name to a lordship, surrounded by the duchy of Juliers; 3 miles N.E. of Erkeleens.

WICKEI', of the French guiche, a little door within a gate; or a hole in a door, through which to view what passes without.

WICKFORD, in Geography, a town of Rhode Island, with a post-office; 10 miles N.W. of Newport.

WICKHAM, commonly called Market-Wickham, to distingiuish it from two other places of the same name in the county, is a village and parish in the hundred of Wilford, and county of Suffolk, England. It has been a place of much greater confluence than it is at present, and had a weekly market and town-hall, where the quarter-seissions were held. The spiritual courts for the archdeaconry of Suffolk are still held here. The parish-church, being built on a hill, constitutes a land-mark for vessels failing by the coast. From the tower, a specktator may see fifty other churches. An aisle, or chapel, on the south side of the church, was built by Walter Fulburn, of this parish, who died, and was buried within its walls, in 1489. The rectories of Wickham, Pettitfree, and Bing, all in the hundred of Wilford, were bequeathed in 1718 by Mr. John Pemberton for charitable uses. According to the population report of 1811, this parish contained 133 houses, and 906 inhabitants. It is 12½ miles N.E. of Ipswich, and
and 81 in the same direction from London. The market, which was formerly held on Saturdays, has long been discontinued.—Beauties of England and Wales, vol. xiv. Suffolk, by F. Shoebler.

WICKHAM Breaux, and WICKHAM Strzyth, the names of two other parishes in Suffolk, England.

WICKLIFISTS, or Wickliffites, in Ecclesiastical History, a religious sect, who had their rise in England in the 14th century, and their name from their leader John Wickhife.

Wickhife, of whose opinions we give some account in his biographical article, (see Wickhiff,) denied that bishops were of a different order from priests, and that by virtue of their office they had any power to do what priests have not; and that in the apostolic times the two orders subsisting in the church were those of priest and deacon. With regard to tithes, he observes, that we do not read in the Gospel where Christ paid tithes, or commanded any man so to do; and that if they were due by God's commandment, there should be every where in Christendom one manner of tithing; and that those things which are due to priests should be given freely, without exaction or constrain ing. In opposition to the papal claims of supremercy and dominion, he maintained that the grants of emperors may be refused; that St. Peter and his successors have no rights conferred upon them of civil or political dominion; that the persons of the clergy and the goods of the church are not exempted from the civil powers; and that bulls of abolution or excommunication are conditional and not absolute, and depend for their effects on the disposition and character of those to whom they pertain.

Wickhife defines hereby to be error maintained against holy writ, and that in life and conversation, as well as in opinion. He ventured to affirm, that children who die without baptism may be saved; that this rite does not confer grace, but only signify that which was before given; and he denied that all sins are abolished by baptism. But in these and some other points, occurring in his various works, which were published at different times, he is not always perfectly consistent; but in all matters of principal importance he is uniform.

He left many followers in England and other countries, who were called Wickliffites and Lollards, and who held their opinions in private without making any public profession of them; though they were generally known by their disparaging the superfluous clergy, whose corruptions were so notorious, and their cruelty so enraged, that it was no wonder the people were much prejudiced against them. Wherever they could be found, they were terribly persecuted by the inquisitors, and other instruments of papal vengeance.—Lewis's History, &c. 8vo. paffim. Moll. Eccles. Hist. vol. iii. 8vo. Burnet's Hist. Reform. vol. i. p. 23.

WICKLOW, in Geography, a maritime county of Ireland, on the east coast, having the county of Dublin on the north, the Irish sea on the east, the counties of Kildare, Dublin, and Carlow, on the west, and that of Wexford on the south. Its extent from north to south is 32 Irish (403 English) miles; from east to west, 26 Irish (33 English) miles; and the superficial contents are 311,600 acres, or 486 square miles, equal to 500,000 acres, or 780 square miles English. Mr. Radcliffe, according to the county map, states the superficial contents at 305,404 Irish acres. There are 58 parishes, which have 20 churches, mostly in the archiepiscopate of Dublin. Dr. Beaufort states the population at 58,000. "A great part of Wicklow is rendered unfit for habitation, and incapable of culture, by mountains intermixed with rocks and bogs. Howe ver, though the heart of the county be a cheerless waste, the hills on the east and west sides, and especially along the coast, are from six to eight miles in breadth, being many of them well wooded, and intermixed with profitable and rolling valleys, form a delightful and various scenery. They are crowded with gentlemen's seats, and are not without small towns and villages." This was Dr. Beaufort's account in 1792. In 1801, captain Frazer published a statistical account for the Dublin Society. This gentleman laments, that "the Wicklow farmers foul the land by repeated corn-crops, and seldom or never lay it down to grass with feeds." He deplores "the total neglect of the improvement of the breed of animals for rock and labour;" and under the head of ploughs he remarks, "the common plough in use in this district is the swing-plough; it is seldom, however, formed on any scientific principles, and is generally very clumsy, and ill-adapted for making clean or regular work." In 1812, however, when the Rev. Thomas Radcliffe published a Report of the Agriculture and Live-Stock of the County of Wicklow, a very great change had taken place. A few extracts from this interesting publication will furnish the reader with the most authentic information on the state of this county, and of what has been effected by the exertions of the Farming Society of Ireland, its own local Farming Society, and the encouragement as well as example of good landlords.

The climate of the county is, in general, mild; but on the easterm side, along the sea-coast, is peculiarly warm, and favourable to vegetation; infomuch that there is almost a perpetual spring; and land of an apparently light quality is known to produce crops equal, if not superior, to those on the richest soils in other parts of Ireland. The crops commonly cultivated are, potatoes, wheat, barley, and oats. With respect to potatoes, the valuable system of drilling is almost universally adopted. The quantity of wheat is inconsiderable: it is generally taken after the potato-crop, sometimes after another white crop, or upon the lea; but the periodical fallow for wheat is fortunately unheard of. The barley-crop is taken after potatoes or turnips, and, like the wheat, is sown under the plough. The oat-crop, by the common practice, is taken upon the lea; but if upon stubble-ground, it is sown under the plough. The crops are not exceeded in quantity or quality in any part of Ireland. Green crops are not in much use among the tenantry. The manure in this county, besides dung, consists of brown, blue, and white marl, lime and lime-flour gravel. In the greatest part of this county, the implements of the bolt construction are in very general use; such as the Scotch plough, as recommended and supplied by the Farming Society, the Scotch harrow, the Scotch cart, drill-machines, and even the threshing-machine. Molt of the improved breeds of cattle have been introduced into this county; but Wicklow cannot be considered as a breeding county. The dairies are numerous; but, on a contracted scale, averaging from eight to fifteen cows, and almost uniformly engaged in the feeding of veal for the Dublin market. In the northern part of the county, much of the milk is consumed in fattening early lamb. The county of Wicklow,though not to be classed as a breeding county with respect to cattle, is very extensively so with respect to sheep, its vall tracts of mountain supplying a wholesome, though not an exuberant, pasturé to that animal. The breed of this county is the mountain kind; and the number of breeding ewes may be stated at 20,000. The South Down are the favourites with the gentlemen; and many flocks of the native mountain have been crossed with South Down. The Merino sheep have also been successfully introduced. The
cotton manufacture is carried on with spirit at Stratford-upon-Slaney. The woollen manufacture is chiefly limited to the flannel-trade. This, however, is carried on largely, and is a source of fair profit and industrious occupation. It prevails on the property of earl Fitzwilliam, and the Flannel-hall at Rathdrum was built at his lordship’s expense. The average annual sale is about 5000 pieces of 120 yards each.

The romantic beauties of this county have been often described. The vicinity to Dublin makes them easily accessible, and few travellers omit to visit them. The antiquities of Glendalough have been noticed in the proper place, under that name. The mineralogy of Wicklow has been noticed in Dr. Fenton’s valuable Notes on the Mineralogy of the Neighbourhood of Dublin; and on this head Mr. Griffith’s Report on the Mountain District of Wicklow should also be consulted. This uncultivated district has many peculiarities, which confit chiefly in the facility of access by means of roads; the vicinity of highly improved lands and industrious inhabitants; the frequent occurrence of beds of lime-Rome, gravel, and marl; the belt manure for the amelioration of mountain soils; and the uncommon mildness of the climate. These uncultivated lands occupy about 200,000 Irish acres, of which about 60,000 consist of black bog; the remainder is moory soil, generally covered by coarse ledgy grays, or grays intermixed with heath. In this district, many rivers have their sources. The Liffey, with its tributary streams, takes a circular course through the county of Kildare, and falls into the bay of Dublin; the Slaney runs southward to the county of Wicklow; the Fartry demibogens itself at Wicklow; and the Ovoca at Arklow. (For an account of the Cronbane mines, see CRONBANE.) At Croghan Kinthela, in the southern part of the county, a quantity of native gold has been extracted by washing from the alluvial soil, of which an account, by Meffrs. Mills and Weaver, may be found in the Tranactions of the Dublin Society. Near 600 ounces of gold, worth above 2000l., were extracted; but the vein could not be discovered, and the search for it was given up. Oxyd of tin was found in the same stream. The county of Wicklow has no large town, and has only the two members for the county to represent it in parliament. —Frazer’s Survey, Beaumont’s Memoir. Radcliffe’s Report. Griffith’s Report, &c.

WICKLOW, the affize-town of the preceding county, which is also a port-town. It is pleasantly situated on a small harbour, and near a beautiful strand abounding in fine pebbles, which is called the Murrough. The ale of Wicklow has been long celebrated in Dublin. It is 24 miles S.S.E. from Dublin.

WICKWA, a small lake of Canada, at the eastern extremity of Lake St. John.

WICKWAR, anciently WICKEN, a market-town in the hundred of Grombald’s Ash, in the county of Gloucester, England, is situated 19 miles S.W. from Gloucester, and 108 miles W. from London, and confines of one long street. The town is incorporated and governed by a mayor and twelve aldermen. It has a weekly market on Monday, and two yearly fairs. In it two courts are held; one for the borough, and another for the tything, or foreign, which have separate confitables. The clothing manufacture, which once flourished here, has long been on the decline; but the lower claffes are still employed in spinning for the clothes of other places. Wickwar contains a well-endowed free grammar-school, which was founded in 1684. The church, a handsome building on an eminence, consists of a nave and north aisle. The rector is valued in the king’s books at 18l. The resident population in 1801 was 764; in 1811 it had increased to 805. —Hilt. of the County of Gloucester, by the Rev. Thomas Rudge, B.D. Gloucester, 1823, 2 vols. 8vo.

WICLLIFF, DE WYCLIFF, WICLEF, or WICKLEFE, JOHN, in Biography, the earliest reformer of religion from Popery, was born about the year 1324 in Yorkshire, near the river Tees, in a parish whence he takes his name. He was educated at Oxford, first as a commorner of Queen’s college, and then at Merton college, peculiarly celebrated at that period for its learned members. His industry and talents soon raised him to distinction; and he is said to have committed to memory the most abstruse parts of Aristotle, and to have excelled in his acquaintance with the subtleties of the school divinity. He was also eminently skilled in civil and canon law, and in the law of the land. But the study which led to his future fame was that of the Scriptures; to which he added a diligent perusal of the Latin fathers, and of the writings of the English divines, Robert Groshead and Richard Fitz-Ralph. In his treatise “Of the Last Age of the Church,” at the early period of the year 1357, he remonstrated against some Papal corruptions; and in 1360 he was active in opposing the encroachments of the Mendicant Friars, who interfered with the jurisdiction and statutes of the university, and took all opportunities of enticing the students from the colleges into their convents. In the following year, such was the credit he had acquired by his conduct and writings, he was appointed master of Balliol college, and was preferred to a living in Lincolnshire. At this time he was held in such esteem by archbishop Simon Fitzlip, that in 1365 he constituted him warden of Canterbury college, which he had just founded; but on occasion of a dispute between the regular and secular priests, Wickliffe and the three secular fellows were rejected; and on an appeal to Rome, the sentence against Wickliffe was confirmed in 1370. His reputation in the university was not at all diminished by his exclusion. In 1372 he took the degree of D. D., and read lectures, which gained him such applause, that whatever he said was regarded as an oracle. The impurities of the monks were the objects to which his first attacks were particularly directed; and the circumstances of the times favoured his design. The court of Rome was now enforcing by menace its demands on king Edward III. of the homage and tribute to the see of Rome, which had been ingloriously stipulated by king John; and the parliament had determined to support the king in his refusal. A monk appeared as an advocate on behalf of the claims of Rome; and Wickliffe’s reply caused him to be favourably regarded at court, and procured for him the patronage of the king’s son, John of Gaunt, duke of Lancaster. In 1374 Wickliffe was joined in an embassy to Bruges, the object of which was to confer with the papal nuncios concerning the liberties of the English church, on which the usurpations of Rome had made unwarrantable encroachments. In the same year the king presented him to the valuable rectory of Lutterworth, in Leicestershire; and in the following year he was instilled in a prebend of the collegiate church of Welbuly, in Leicestershire. Wickliffe, by his foreign mission, had an opportunity of acquainting himself with the corruption and tyranny of the court of Rome; and both his lectures and conversations were amplified with invective against the pope. Whilst he defended the authority of the crown and the privileges of the nobles against all ecclesiastical encroachments, he censured vice and corruption in all ranks of society. This conduct, though it raised his reputation among the people, excited a host of enemies, who selected from his writings nineteen articles, which they deemed heretical, and which,
as such, they transmitted to Gregory XI. In 1377 this pontiff returned three bulls addressed to the archbishop of Canterbury and the bishop of London, ordering the seizure and imprisonment of Wickliffe; or, if this measure failed, his citation to the court of Rome; and also a requisition to the king and government to affill in extinguishing the errors which he had propagated. Edward died before the bulls arrived; and the duke of Lancaster, uncle to the young king, had great influence in the administration. When Wickliffe, therefore, was cited to appear at St. Paul's church before the two prelates, possessing plenitude of power, he thought it necessary to secure himself by the protection of that powerful patron. On the appointed day he appeared at St. Paul's, in the midst of a vast concourse of people, and accompanied by the duke of Lancaster, and lord Henry Percy, earl-marshall. The bishop of London was very impatient, and angry words passed between him and the two lords; so that the whole assembly was tumultuous, and nothing was done. Wickliffe afterwards appeared before the two prelates in Lambeth palace, and delivered an explanation of the articles objected against him. The Londoners, who were apprehensive that he might be severely treated, flocked in crowds to the palace; and a messenger from the queen forbade the delegates to proceed to a definitive sentence. Gregory soon after died, and his commissary expiring with him, Wickliffe escaped, but not without a severe ill-nature, which was the consequence of his anxiety and fatigue. His spirits, however, were unbroken, and he was firm in maintaining opinions which the friars, by all the efforts of intimidation, urged him to renounce.

Upon his recovery, he presented to the parliament, in 1379, a paper against the tyranny and usurpations of Rome; and he also drew up some free remarks on the papal supremacy and infallibility. But his most effectual attack on the corruption of religion was his translation of the Bible into English. This occupied many of the last years of his life, and remains a valuable relique of the age in which it was performed, and a permanent memorial of the talents and industry of the perfon by whom it was accomplished. (See English Bibles.) By way of preparation for his Bible, he published a treatise "Of the Truth of the Scripture," in which, as well as in a prologue or preface to his translation, he held, long before any of our other reformers or advocates for the sufficiency of Scripture, that this is the law of Christ, and the faith of the church; that all truth is contained in it; and that every disputation which has not its origin thence is profane. "The truth of the faith," says he, "shines the more by how much the more it is known—nor are those heretics to be heard who fancy that seculars ought not to know the law of God, but that it is sufficient for them to know what prelates and prelates tell them by word of mouth; for the Scripture is the faith of the church, and the more it is known in an orthodox sense the better; therefore, as seculars ought to know the faith, so it is to be taught men in whatsoever language is best known to them.

D-fides, since the truth of the faith is clearer and more exact in the Scripture than the prelates know how to express it—it seems useful that the faithful should themselves search out and discover the sense of the faith, by having the Scriptures in a language which they understand. The heads which the prelates make are not to be received as matters of faith; nor are we to believe their words or disburse any farther unless they are founded on the Scriptures. Furthermore, with much more to the same purpose, and in the same admirable strain. In this preface, and several other publications and treatises still in manuscript, he reflected severely on the corruptions of the clergy, condemned the worship of saints and images, the doctrine of indulgences, pilgrimages to particular shrines, and confession; and also denied the corporal presence of Christ in the sacrament, inveighed against the wanton exercise of the papal power, and opposed the making of the belief of the pope's being head of the church an article of faith and salvation, censured the celibacy of the clergy, forced vows of chastity, exposed various errors and irregularities in the hierarchy and discipline of the church, and earnestly exhorted all people to the study of the Scriptures.

In his lectures of 1381, he attacked the Popish doctrine of transubstantiation, concerning which he laid down this fundamental proposition; viz. that the substance of bread and wine still remained in the sacramental elements after their consecration, and that the host is only typically to be regarded as the body of Christ; and he deduced from it sixteen conclusions. This attack alarmed the church, which regarded transubstantiation as the most sacred tenet of the Romish religion, and the chancellor of Oxford pronounced a condemnation of these conclusions. Wickliffe appealed from this sentence to the king; but he found himself defrayed by his protector, the duke of Lancaster, who had no further occasion for his services, or who could not avail himself for any political purpose of his theological discussions. This circumstance, he found himself in danger; his resolution failed him, and he humbled himself by making a confession at Oxford, before the archbishop and his bishops, with other clergy, who had already condemned some of his tenets as erroneous and heretical. In this confession, he admitted the real presence of Christ's body in the sacrament, with some explanations and reasons which were not satisfactory to his perceptors. It has been said that he made a public recantation of the opinions with which he was charged; but of this no sufficient evidence appears. The next step in their proceedings against him was a royal letter; procured by the archbishop, addressed to the chancellor and prelates, and directing them to expel from the university and town of Oxford all who should harbour Wickliffe or his followers, or hold any communication with them. These proceedings obliged him to withdraw, and to retire to his recollection at Lutterworth, where he continued to preach reformation in religion, and finished his translation of the Scriptures. Some have said that king Richard banished him out of England; but if that were the case, it was only a temporary exile, and he returned in safety to Lutterworth. In 1383 he had a paralytic stroke, which furnished him with an apology for not appearing to a citation of pope Urban VI.; and this was succeeded by a second attack, which terminated his life on the last day of December 1384.

His remains, however, did not escape the vengeance of his enemies many years after his death; for the council of Constance in 1415, not content with condemning many propositions in his works, and declaring that he died an obstinate heretic, with impotent malignity ordered his bones to be dug up and thrown upon a dunghill. This sentence was executed in 1428, in consequence of a mandate from the pope, by Fleming, bishop of Lincoln, who caused his remains to be disinterred and burnt, and the ashes to be thrown into a brook. "Thus," says Fuller, the church historian, in a figurative strain justified by fact, "this brook hath conveyed his ashes into Avon, Avon into Severn, Severn into the narrow seas, they into the main ocean; and thus the ashes of Wickliffe are the emblem of his doctrine, which now is dispersed all the world over." His doctrine not only survived these impotent attempts to extinguish it, but was perpetuated and diffused by his followers, who were called Lollards; and "this germ of reformation," as one of his biographers
biographers says, "broke forth into complete expansion, when the feason for that great change was fully come." Of his general character, it will be sufficient to say, that he was conffedly learned for his age, and was an acute reasoner. In short, notwithstanding certain errors and imperfections, he may be regarded as a person of extraordinary merit and qualifications, who is entitled to honoured remembrance from every foe to ecclesiastical tyranny and impiety; and we may add that he advanced principles which have not yet produced their full effect.

The number of tracts he wrote and published, both in Latin and English, is very considerable. From two large volumes of his works, entitled "A Theologia, i.e. Truth," and a third under the title of "Trialogus," John Hius is said to have derived most of his doctrines. We have a full and complete "History of the Life and Sufferings, and various Writings of Wickliffe," both printed and MS., published in 1600., at London, in the year 1729, by Mr. John Lewis; who also published, in 1731, "Wickliffe's English Translation of the New Testament from the Latin Version, called the Vulgate." This translation is enriched with a learned preface by the editor, in which he enlarges upon the life, actions, and sufferings of this eminent reformer. Biog. Brit. Mofh. Eccl. Hist. Neal's Hist. of the Puritans. Gen. Biog. For an account of his differing fitting tenets, and of his followers, see Wickliffists and Lollards.

WICOMICO, in Geography, a river which rises in the state of Delaware, enters the state of Maryland, and passes into Fithing bay, on the coast side of the Cheapeap, N. lat. 38° 16'. W. long. 75° 37'.

WICOMOCO, a river of Virginia, which runs into the Cheapeap, N. lat. 37° 55'. W. long. 76° 25'.

WICQUFORT, Abraham, in Biography, was born at Amfterdam in 1508, and having left his own country for France at an early age, he was nominated resident for the elector of Brandenburg at the French court, and held the office for thirty-two years. But being suspected by cardinal Mazarin of communicating secrets to his correspondents in Holland with regard to the amours of Lewis XIV., he was ordered, in 1658, to leave the kingdom; but in the mean time he was arrested, and confined in the Baftile. At length, in 1659, he was releaved and difmissed. However, in three months the cardinal recalled him, and fetted him on a pension. On occasion of the war between France and Holland in 1672, he returned to his own country, and was protected by John de Witt, who employed him in writing a history of Holland to his own time. In 1676 he was arrested and condemned to perpetual imprisonment, under an accusation of carrying on a secret correspondence with the enemies of the state; and after having been confined for three years, he made his ecape by the contrivance of one of his daughters. He then sought refuge at the court of Zell, from which he returned to Holland in 1681, where he lived without moleftation, but without recovering the places of which he had been deprived. In the following year, 1682, he died. The work on account of which Wicqufort is best known, is entitled "L'Ambaffadeur et ses Fonctions," first printed at the Hague in 2 vols. 4to. 1681, and often reprinted. He holds in high estimation the privileges of the order to which he belonged, as we may infer from his cenure of Cromwell's spiritual act of justice in executing the brother of the Portuguese ambaffador for a murder; nevertheless he inculcates found morality with regard to the conduct of diplomatists in the countries to which they are fent. His other works are, "Memoires touchant les Ambaffadeurs et les Miftres;" one volume of his "History of the Dutch Republic," which appeared in French at the Hague in 1719, fol.; and translations into French of the accounts of different embaffies, and also of voyages and travels. More. Gen. Biog.

WIRCANGE, in Ornithology, an English name for the mattagels, or greater butcher-bird, the lanius cinereus major of authors.

WIRCANTUM, in Natural History, a name given by the people of the East Indies to certain fowl bodies, of the nature of the pyrites, of the size of peas, and formed into variously angular figures. They look black and glossy, and much of the nature of blende, or mock-lead; but when put into the fire, they shew us by their smell that they contain Sulphur. They are found in the diamond-mines.

The natives first powder them; and then mixing them with the juices of certain plants, they dry them, and then calcine them again. These proceed in least at least fifty times; but the first calcinations are made with a mixture of divers unres, as that of the horfe, the camel, the cow, and the like.

After this tedious preparation, they are given in coughe and colds, and are said to be a remedy even in consumptions.

WICZENIECZ, in Geography, a town of Poland, in Podolia; 6 miles N.W. of Kamniec.

WIDAWA, a town of the duchy of Warsaw; 22 miles S.W. of Siradra.

WIDDAN, a river of Germany, which joins the Rodau at Rotenburg, in the county of Verden.

WIDDY, in Agriculture. See WITHE.

WIDE, is used in some places to denote a small vale, and also a wide piece of water, or pond.

WIDE-ENDED, in the Mange, is applied to a horse, when the root, or lower part of his ear is placed too low, and the ear itself is too large. The French ufe the term oreillard for a fuch a horfe.

WIDE Bay, in Geography, a bay on the eait coast of New Holland, between Double Island Point and Indian Head.

WIDE Mouth Bay, a bay of England, on the N.W. coast of Cornwall. N. lat. 50° 46'. W. long. 5° 19'.

WIDEKINDI, or WIDICHINDI, JOHN, in Biography, a Swedish historian, was born in the province of Wettland, about the year 1620, and studied at Upsal, where he delivered an oration in 1654, on occasion of queen Christina's accession to the throne; and by her recommendation he was appointed historiographer of the kingdom. In 1656 he proposed printing his "History of Gustavus Adolphus," and measures were taken for this purpose; but he died at Stockholm in 1678, before the work was executed. The first part of this history was published in 1691, fol.; but as it much offended both the Danois and Russians, it was suppressed by the king's command. It is not known whether he completed the work in MS.; but the part published is written in a dull, heavy style, and it has been carelessly printed. The author, however, was a man of learning, well acquainted with history, and reckoned a good Latin poet. He polifhed an excellent library, and was much respected by King Charles Gustavus, who called him his philosopher. The most important of his works, a catalogue of which is given in "Schiller's Scotia Litterata," is the "History of the Russian War," written both in Latin and Swedish, 1672, 4to. Gen. Biog.

WIDERDRIESS, in Geography, a town of the duchy of Stirta; 2 miles S. of Windfield Gratz.
WIDJITZE, a town of Bohemia, in the circle of Czsalau; 8 miles W. of Czsalau.

WIDMINNEN, a town of Prussia; 14 miles N.W. of Lieck.

WIDOW, VIDA, a woman that has lost her husband.

Some also use the term widow, for a man who has lost his wife. Marriage with a widow is a kind of bigamy in the eye of the canon law.

The widow of a freeman of London may use her husband's trade as long as she continues a widow.

Mr. Kerseboom has given us a table, shewing how long our hundred and thirty-two widows lived, and finds, that, as a medium, each lived fourteen years. Philo. Trans. N. 468, sect. 3.

It appears, in Germany, the number of widows lying annually is four times the number of widowers; thus, in Dresden alone, the number of widows who died in four years was 584; the number of widowers 149; i.e. 4 to 1. At Wittenberg, during 11 years, 98 widowers died, and 376 widows. At Gotha, during 20 years, 210 widowers died, and 760 widows. As and widows are certainly, one with another, several years younger than widowers, it may be concluded that the number of the former in life together could not be less than five times the latter.

Thus also, in 1770, the number of widows in life, derived from the whole body of professors and ministers in Scotland, was 380; but the number of widowers among them has, one year with another, been scarcely 90; i.e. not so much as a quarter of the number of widows. Price's Observ. on Rev. Paym. eff. 4.

These facts cannot be accounted for without admitting the greater mortality of males. See Marriage, and Mortality.

There have been many schemes established for providing annuities for widows, for an account of several of which, see Price's Observ. &c. chap. ii. sect. 1, 2, 3.

Among the ancient Greeks, widows had the care of the eternal fire of Velia committed to them; which charge among the Romans could be performed by virgins only, who from their office were called vestals. See Vestal.

Widow of the King, was she, who, after her husband's death, being the king's tenant in capite, was driven to recover her dower by the writ De dote afferenda; and could not marry again without the king's consent.

Widow Benefy, in the county of Suffex, is that share which a widow is allowed of her husband's estate, beside her jointure.

Widow's Chamber, a name given in London to the apparel and furniture of the bed-chamber of the widow of a freeman, to which she is entitled.

Widow-Wall, in Botany. See Cneorum.

WIDURIS, in Natural History, the name of a ftoe found in Java, Malabar, and some other places, and described by Rumphius. Some species of this are all over of a fine white; others are of a dulky colour, with streaks of white; the filmy white ones are semi-pellucid, and look very like the white of an egg. Some also have called this baubula, or acetab vitrea pircficultulis.

WIECK. See WEEK.

WIED, in Geography, a county of Germany, situated to the north of Treves, in the year 1560, divided into two parts: the Lower County, or New Wied; New Wied; and the Upper County, or Wied Runkel. Both had seats in the college of Welfphalia counts.

WIED, New. See Neuwied.

WIE, or Old Wied, a town of Germany, in the county of New Wied; 9 miles N. of Coblenz.

WIEDENBRUCK, a town of Welfphalia, in the bishopric of Osnabruck; 32 miles S.S.E. of Osnabruck. N. lat. 51° 45'. E. long. 8° 18'.

WIEDERAU, a town of Saxony; 5 miles N. of Liebenwerda.

WIEDERSBERG, a town of Saxony, in the Vogtland; 8 miles W.S.W. of Oelsnitz.

WIEDERSPACH, a town of Germany, in the margravey of Anspach; 6 miles W. of Anspach.

WIEGANDSTHAL, or Wiegenthal, a town of Upper Lusatia; 11 miles S. of Lauban.

WIEHE, a town of Thuringia; 26 miles N.E. of Erfurt. N. lat. 51° 18'. E. long. 11° 35'.

WIELAND, Christopher Martin, in Biography, was the son of a Protestant clergyman at Biberach, in Swabia, where he was born in September 1733. Educated by his father, he began at the early age of thirteen to distinguish himself by his Latin and German poems; and he pursued his education at Magdeburg and at Erfurt. Upon his return home he became affectionately attached to Sophia de Guterman, afterwards known by her works under the name of Mad. de la Roche. In the year 1750 he studied jurisprudence at Tubingen; but his time was chiefly devoted to the writing of verses, so that in 1752 he published a didactic poem in six cantos, entitled "The Nature of Things;" "Auto-Ovid, or the Art of Love;" and "Moral Letters and Tales." He also began an epic poem, on the subject of Arminius, the first five cantos of which he sent to the famous Swiss poet Bodmer; and he was thus led to visit Switzerland, and to cultivate a friendship with this celebrated poet, and to reside for some time in his house at Zurich. In this retired and tranquil situation, he applied with great diligence to the study of the belles lettres, and acquainted himself with the principal modern languages, such as English, French, and Italian, to which he afterwards added the Spanish and Portuguese. He also read Plato with great attention, and wrote several works, among which were the "Trial of Abraham," and "Letters of the Dead." After a residence of seven or eight years in Switzerland, he quitted this country, having formed his taste on the models of Euripides, Xenophon, and Shaftsbury, whose writings he had diligently studied; and in 1758 he published his "Araepes and Panthea," a work which manifests the ascendency which judgment and moral sentiment had acquired over his imagination. Upon his return in 1760 to his native city, he was appointed a director of the chancellery, which office he held till the year 1769, referring, however, some leisure moments for the composition of his philosophical romance, entitled "Agathon," and his beautiful didactic poem "Mufarior." About this time he became intimately acquainted with count Stadion, a nobleman who lived with splendideur near Biberach, who had cultivated a taste for literature, and whopossessed an excellent library. He afterwards received from the elector of Mentz an invitation to be professor of philosophy and the belles lettres at Erfurt, and during his residence in this place he became acquainted with Anna Amelia, duches dowager of Weimar, a patroness of polite literature, and in 1772 the appointed him tutor to the two princes, Charles Augustus and his brother Constances, of whose she was guardian. In this situation he occupied himself in preparing a variety of works, both in prose and verse, which have done honour to German literature. He was at this time a live counsellor of the duke of Saxe Weimar, with a pension, and a counsellor of government to the elector of Mentz. Wieland married his favourite daughter Charlotte to a bookeller at Zurich, who was a son of the celebrated poet Solomon Gefner. In 1797 he visited
visited his children at Zurich, and retired with his family in a romantic situation on the border of the lake, where he was visited by the most eminent literati of Switzerland. Conceiving a fond attachment to a rural retreat, he held his house at Weimar, and purchased a small estate in the neighbour-

hood, where he fixed his abode. Although his fortune was small, his disposition was liberal; and he affiliated many distinguished young poets and authors for their contributions to the German Mercury, which he commenced in the year 1783. To the ex-monk Reinhold, who had escaped from Vienna, he was a generous patron, and gave him one of his daughters in marriage. This monk was afterwards professor of philosophy at Kiel. He also supported another monk, who had fled to him from a Cisterian monastery in Swabia, during his residence at Jena, where he studied philosophy. Wieland had married in 1765 a person of good family at Augsburg, of whom he expresses himself in the highest terms of respect and affection; and by whom he had thirteen children; "found," he says, "in body and mind; with their mother, they form the happiest of my life." In 1807 this venerable poet was elected a member of the floral order at Nurem-

berg; and in 1808, Buonaparte sent him the crofs of the legion of honour. After the battle of Jena, he was protected by a special order of that conqueror. He died in January 1813, in his 80th year. For the delineation of his talents and character by Kuttner and others, and an account of his works, which were very numerous, we must refer to his article in the General Biography, observing that his original works have been published in thirty-six large 4to volumes, and six supplementary volumes. Leipzic, 1794—1802.

WIELAS, in Geography, a town on the easter coast of the island of Gdino. N. lat. 1° 9'. E. long. 128° 30'.

WIELCZYNY, a town of Lithuania, in the palatinate of Novogrodjeck; 40 miles S.E. of Slomnitz.

WIELDEMANN. See Wilde-man.

WIELSEN, a town of the Duchy of Warsaw; 46 miles N.W. of Posen.

WIELICHOW, a town of the Duchy of Warsaw; 25 miles S.S.W. of Posen.

WIELICZKA, a town of Austrian Poland, celebrated for its salt-mines, which produce a great revenue to the em-

peror, to whose lot it fell in the year 1773. The inhabitants reside chiefly in the mines, and the church is under-

ground; 8 miles S. of Cracow. These salt-mines, with the territory belonging to them, were assigned to the em-

peror of Austria by the treaty at Vienna in 1815.

WIELON, a town of Samogitia; 20 miles S. of Roifenne.

WIELUN, a town of Poland, in the palatinate of Siradja; 16 miles S. of Siradja.

WIEN, a river of Austria, which runs into the Danube at Vienna.

WIENNERHORBEK, a town of Austria; 12 miles W. of Brug.

WIENNERWALD, or The Forest of Vienna, the south part of the arch-duchy of Austria, bordering on Hungary.

WIEPERZ, or WIPZ, a river of Poland, which runs into the Viftula, near Stericza, in the palatinate of San-
domirz.

WIER, John, in Biography, a physician, was born in 1515, at Grave on the Meuse; and being domiciliated with the famous Cornelius Agrippa, adopted his opinions with regard to the occult sciences. After having studied at Paris and Orleans, he took the degree of M.D. about the year 1534.

In the course of his travels, he visited the court of the duke of Cleves, and was appointed his physician. He died at Tecklenburg, in Westphalia, in 1586. He was a man of considerable learning; and though participating in a great degree the credulity of the age, he incurred the en-

mity of the monks by ascribing to deception and imposture the forcery, witchcraft, and magical practices, which they supported, to the operation of natural caules. The turn of his mind is discernible in his book "De Daemonum Pref-
tigatis et Incantationibus." In his treatise of medical ob-

servations he has given an account of the putrid fore throat, under the name of "Angina pestilentialis." Among his other writings are enumerated "De Iter Morbo, et ejus Curatione Philosophica, Medica, et Philosophica; "Trac-

tatus de Commentitiis Jejuiniis; "De Tulli Epidemica, Anno 1580; "De Varenis, Morbo endemio Westphal-

in which case, they are absolutely and entirely his own: and shall go to his executors or administrators, or as he shall bequeath them by will, and shall not revest in the wife. But if he dies before he has reduced them into possession, so that at his death they still continue chesf in action, they shall survive to the wife.

Thus in both the species of property the law is the same, in case the wife survives the husband; but, in case the husband survives the wife, the law is very different with respect to chattels real and choses in action; for he shall have the chattel real by survivorship, but not the choses in action; except in the case of arrears of rent, due to the wife before her coverture, which in case of her death are given to the husband by the statute 32 Hen. VIII. cap. 37:

As to chattels personal (or choses in possession), which the wife hath in her own right, as ready money, jewels, household goods, and the like, the husband hath therein an immediate and absolute property, devoted to him by the marriage, which can never again revest in the wife or her representatives.

The wife also, by marriage, acquires a property in some of her husband's goods, called her parenomata, which shall remain to her after his death, and shall not go to his executors. These, signifying the apparel and ornaments of the wife, suitable to her rank and degree, the husband cannot devise by his will; though during his life perhaps he hath the power (if unkindly inclined to exert it) to sell them or give them away. But if she continues in the use of them till his death, she shall afterwards retain them against his executors and administrators, and all other persons, except creditors where there is a deficiency of affects. And her necessary apparel is protected even against the claim of creditors.

The wife can make no contract without her husband's consent; and, in all law-matters, sue vro respondere non potest.

The husband is bound to provide his wife with necessaries by law, as much as himself; and if the contracts debts for them, he is obliged to pay them; but for anything besides necessities, he is not chargeable. Also if a wife elopes, and lives with another man, the husband is not chargeable even for necessities, at least if the person who furnishes them is sufficiently apprized of her elopement.

If the wife be indebted before marriage, the husband is bound afterwards to pay the debt. If the wife be injured in her peron or property, she can bring no action for redress without her husband's concurrence, and in his name as well as her own; neither can she be sued, without making the husband a defendant. There is indeed one case where the wife shall sue and be sued as a semp sola, viz. where the husband has abjured the realm, or is banished; for he is then dead in law. See Custom of London.

In criminal prosecutions, the wife may be indicted and punished separately; for the union is only a civil union. But in trials of any sort, they are not allowed to be evidence for or against each other. However, where the offence is directly against the person of the wife, the rule has been usually dispensed with; and, therefore, by Stat. 3 Hen. VII. cap. 2. in case a woman be forcibly taken away and married, she may be witnesses against such her husband, in order to convict him of felony. See FORCIBLE ABDUCTION.

In the civil law, the husband and wife are considered as two distinct persons, and may have separate estates, contracts, debts, and injuries; and, therefore, in our ecclesiastical courts, a woman may sue and be sued without her husband.

But, though our law in general considers man and wife
WIG

as one person, yet there are some instances in which she is
separately considered; as inferior to him, and acting by his
compulsion. And, therefore, all deeds executed, and acts
done by her during her coverture, are void; except it be a
fine or the like matter of record, in which case she must be
solely and secretly examined, to learn if her acts be voluntary.
She cannot by will devise lands to her husband, unless
under special circumstances; for at the time of making it
she is supposed to be under his coercion. And in some
d felonies, and other inferior crimes, committed by her
through consent of her husband, the law excuses her;
but this extends not to treason and murder. See FEME-
Covert.

The husband also, by the old law, might give his wife
moderate correction; but this power of correction was con-
fined within reasonable bounds, and the husband was pro-
bited from using any violence to his wife. The civil law
gave the husband the fame, or a larger authority over his
wife; allowing him, for some misdemeanours, flagellis et
futibus acriter verberare uxorem; for others, only modicum
calligationem addibere. But, with us, in the politer reign of
Charles II., the power of correction began to be doubted;
and a wife may now have security of the peace against her
husband, or, in return, a husband against his wife. The
courts of law will still permit a husband to restrain a wife of
her liberty, in case of any gross mischief. Blackf.
Com. book i. book ii.

If a wife bring forth a child during her husband’s absence,
though of many years; yet if he lived all the time inter
quater maria, within the four, he must father the child;
and the child, if first born, shall inherit. See BASTARD.

If a wife bring forth a child begot by a former husband,
or any other person, before marriage, but born after mar-
rriage with another man; this latter must own the child,
and that child shall be his heir at law.
The wife, after her husband’s death, having no jointure
settled before marriage, may challenge the third part of his
yearly rent of land, during her life; and, within the city
of London, a third part of all her husband’s moveables for
ever. See DOWER, INTESTATE, and CUSTOM OF LONDON.

The wife partakes of the honour and condition of her
husband; but none of the wife’s dignities come, by mar-
rriage, to her husband.

Yet, the husband, who marries a woman seised of lands
in fee-simple, or fee-tail, i.e. of any estate of inheritance,
and has by her issue born alive, which was capable of her
estate, shall, on the death of his wife, hold the lands for his
life, as tenant by the curtesy of England.

The English laws are generally esteemed by foreigners as
very hard, in respect to the women; and yet Chamberlayne
is of a very different opinion, asserting, that the condition
of wives in England is better than in any other country.

The dispositions to which the wife is subject are for the
most part intended for her protection and benefit. So great
a favourite (says judge Blackstone) is the female sex of the

Tertullian has two books, on the ornaments, and attire of
wives. In the second, he labours to prove that a Christian
wife cannot, in conscience, endeavour to please by her
beauty, which she knows to be naturally liable to ratie loose
defiles; and that she ought not only to avoid all affected
beauty, but even to conceal and cover her natural beauty.

WIFE, Mid. Offeries. See DELIVERY.

WIFFLISBORG, in Geography. See AVENCHES.

WIGAN, a borough and market-town in the hundred of
Welf-Derby, and county of Lancashire, England, is
feated near the rise of the river Douglas, the banks of which
are noted for a celebrated battle fought between king Arthur
and the Saxons, when the latter were defeated. In
the time of Henry VIII., Wigan is described by Leland as a
“paved town, as big as Warrington, but better built,
and inhabited by some merchants, artificers, and farmers.”
In its present state, it has a neat though irregular appear-
ance; and has been lately much improved by the opening of
two new streets, and the erection of several handsome
buildings. An extensive trade is carried on in the manufac-
ture of coarse home-made linens, checks, calicoes, fustians,
and other cotton goods. Here are also large brazes and
pewter works.

Wigan is a borough by prescription, and has had its pri-
ileges confirmed by the several charters of Henry III.,
Edward II., Edward III., Richard II., and Charles II.
Its corporate body consists of a mayor, recorder, twelve
aldermen, and two bailiffs. Two members are returned to
parliament; and the right of election is vested in the free
burgesses, in number about 200. The representation of
this borough has occasioned some very expensive contests;
and it is said to have cost George Byng, esq. 10,000l.
in his opposition to the interest of sir Fletcher Norton, and
Simon Luttrell, esq. Returns appear to early as the 23d
and 35th Edward I., after which the privilege was suffered
to be dormant for 240 years; no other return being made
till 17 Edward VI.

The parish-church is ancient, and considered to be a
handsome structure; it consists of a nave, a spacious chancel,
and two side-aisles. Among the monuments in the church
there is one to the memory of sir Roger Bradlaugh, and another
to sir William and lady Mabel Bradlaugh. The remains
of George Hole, rector of this church and bishop of
Chefter, are deposited within the communion-rails. He
died August 23, 1668. The rectorcy is one of the best en-
dowed in the kingdom, and the incumbent is always lord of
the manor. In the town is a chapel of ease, three chapels
for dissenters, and one for Roman Catholics. A town-hall
was built in 1721, at the joint expense of the earl of Barry-
more and sir Roger Bradlaugh, the then representatives of
the borough. A free-school was erected, and liberally en-
dowed, about the beginning of the last century, by volun-
tary contribution; and upwards of 30 years ago, the same
liberality established a blue-coat school for 30 boys. A
commodious workhouse has been also built at the expense of
the inhabitants of the town, where the necessitous and super-
annuated poor are comfortably accommodated; industri
in the more able are furnished with the means, and the meri-
torius are encouraged and rewarded. A dispensary has
been erected, and is supported by the benevolence of the in-
habitants of the town and its vicinity.

At the north end of the town is a monumental pillar,
erected in 1679 by Alexander Rigby, esq., then sheriff of
Lancashire, to commemorate the valour and loyalty of sir
Thomas Dyleley, who was slain on this spot in 1651, in
the action wherein the earl of Derby was defeated by colonel
Lilburne.

In a field near Scholes-bridge, contiguous to this town,
a spring was lately discovered, which has obtained the name
of Wigan Spa, or New Harrowgate, as the water resem-
bles that of Harrowgate in Yorkshire.

The population of Wigan, which has been progressively
increasing, was, in the year 1801, according to the return
to parliament, 10,989; the number of houses, 2236. In
1811, the former had increased to 14,460, and the latter
to 2686.

The parish of Wigan contains twelve townships, in three
of which, besides that in the town, are chapels of the esta-
blishment,
The first manufactories establisht here were for different kinds of coarse linens; but since the year 1783, this busi-
ness has received a confiderable check by the encouragement
given to the various branches of the cotton trade, which
flourish in great vigour. In 1790 a manufactory for print-
ing calicoes was establisht at Spittle, about a quarter of a
mile from the town, and seems likely to become an im-
portant undertaking, as the goods are in high repute, and
the situation extremely convenient for extending the works.

The present church was erected in 1758; its neatness is
eminentiy contrasted with the ancient fabric, which was a
dark gloomy structure, built, according to the Chronicon
Cumbriae, by Odoard de Logiz, to whom the barony was
given by Waldef, son of earl Gofpatrick. The materials
it was constructed with were procured from the Roman sta-
tion at Old Carlisle, as appears from the stones being marked
in a similar manner to those that may yet be obtained there.
In removing the foundations of the old tower, two Roman
episcopal inscriptions were discovered. The streets are
tolerably spacious, and many of the buildings are handsome
and modern. In the year 1723, an hospital was founded
here, under the will of the Rev. John Thomlinson, A.M.
for five indigent widows of Protestant beneficed clergymen,
episcopally ordained; and incorporated by the name of
"The Governors and Sifters of the College of Matrons,
or Hospital of Chrift in Wigton." The endowment has been
augmented by some small benefactions: the allowance to
each widow is about eight pounds annually. A free-school
was also establisht here in 1750; chiefly by the contribu-
tions of the inhabitants, aided by the benevolence of Dr.
Thomlinfon's brother. In this town, observes Mr. Gough,
was anciently an hospital or free chapel, dedicated to St.
Leonard, to which, Mr. Pegge is of opinion, belongs a seal
found in Pickering-castle, Yorkshire: it is of wood, and
has the representation of the Deity, with the crucifix, cir-
cumfcribed Sigilcom Wighton.

About one mile south from Wigton are the ruins of the
considerable Roman ftation, now called Old Carlisle, but
generally suppos'd to have been the Olancum of the Noti-
tia, where the Alae Herculae were in garrison. Vestiges
of ancient buildings are very conspicuous; the foundations
of numerous ruined edifices being scattered over many acres,
as well within the vallum as on every fide, without excepting
to the westward, where the ground descends precipitously
to the brook Wifa. The ftation itself occupied an elevated
ftice, and commanded an extensive view north and north-west.
Its form is an oblong fquare 170 paces in length and 150
broad, with obtufe angles, defended by a double ditch and
vallum, and having an entrance near the middle of each fide.
The military way, on which it flands, is very broad and
ficient, and leads immediately to Carlisle and the Wall.
Within the vallum, a well was discovered a few years ago,
about three feet in diameter, and regularly lined with ftones.
Various inscriptions, defiguring instruments, coins, altars,
small images, statues on horse-back, urns, and other veftiges
of antiquity, have been found at this ftation.

Several antiquities, discovered near this place in the
course of the laft century, have been described in different
volumes of the Gentleman's Magazine, particularly in thofe
for the years 1748, 1756, and 1757.

Clea-hall, a feat of Sir Henry Fletcher, bart., whole fa-
family obtained it by an intermarriage with the female heir of
a branch of the Muirgraves, ftands on a cultivated spot in
the midst of an elevated and dreary moor.—Beauties of Eng-
land and Wales, vol. iv. Cumberland, by J. Britton and
E.W. Brayley.
WIGTOWN, a royal borough, market-town, and the capital of the shire of the same name, Scotland, is situated on the side of a hill near the confluence of the river Bladnock, at the distance of 105 miles S.W. by S. from Edinburgh. It is of very high antiquity, and appears to have received its charter of incorporation from King Robert Bruce. The civil government is vested in a provost, two bailies, and twelve councillors. Wigtown unites with the boroughs of Whitehorn, New Galloway, and Stranraer, in sending one member to the British parliament. The church is in good repair. A well-supplied market is held weekly, and five fairs annually. Being the shire-town, the sheriffs' courts are held here. A grammar-school is established, and well conducted. The parish of Wigtown is in the form of an oblong-square, extending five miles in length and four in breadth, and comprehends about 5500 acres. The climate is cold, but remarkable for producing health and longevity. A great diversity prevails in the soil and surface; towards the south it is intersected with hills, which are almost entirely arable, with a dry, light, and fertile mould; the north-west corner is more varied and less productive; and the north-west part is principally covered with mosses, and appears to have been formerly an arm of the sea. The greater part is inclosed; and the spirit of agricultural improvement is much encouraged. Particular attention is paid to the repairs of the roads and bridges. The population of the parish, at the enumeration of the year 1811, amounted to 1711. In the western part of the parish is a large circle of stones, called "The Standing Stones of Torhouse," which is supposed to have been a temple of the Druids.—Beauties of Scotland, vol. ii. Wigtownshire. Gazetteer of Scotland, 1806. Carlile's Topographical Dictionary of Scotland, 2 vols. 4to. 1813.

Wigtown Bay, a bay of the Irish sea, on the S. coast of Scotland, at the mouth of the river Cree, between the counties of Wigtown and Kirkcudbright.

WIGHTONSHIRE, the western part of the district of Galloway, forms the south-western extremity of Scotland. It is bounded on the E. by Kirkcudbright, on the S.E. by Wigtown bay, on the S. and W. by the Irish sea, and on the N. by Ayrshire. It is of an irregular figure, of which the greatest length is about thirty miles, and the breadth nearly twelve. The superficial contents are 460 square miles, or 238,721 Scotch acres. The thre comprehends three royal boroughs, Wigtown, Stranraer, and Whitehorn; also the town of Portpatrick, and thirteen other parishes. By the population return of the year 1811, the number of houses is found to be 3402; that of the inhabitants 26,891; namely, 12,305 males, and 14,586 females. The thre sends one member to the imperial parliament, and the three boroughs unite to send another. Wigtownshire is one of the most level counties in Scotland; and the hills are in general free from projecting rocks, and very accessible to the plough. The navigation along the coast is so uninterrupted, that it may be regarded as one of the most eligible situations in the island, in point of natural advantages, for a trading district. The richest lands lie upon the coast, where the means of improvement are to be met with in the greatest abundance: the inland and more elevated parts have a considerable mixture of heath and moss, but are all in a greater or less degree susceptible of improvement. There are few mountains in Wigtownshire. The Cairnpit, near Portpatrick, is one of the most considerable: it rises 820 feet above the level of the sea. The furmint bears all the marks of having been a military station, being surrounded by three stone walls, with very ample spaces between them; and commands a prospect of Loch-ryan, and Luce bay, which by advancing inland form the peninsula, called the Rhynns of Galloway, in which Portpatrick is situated.

The rivers of this county are of no great importance. The Cree forms part of its eastern boundary. The next stream to the westward is the Bladenoich, which rises from a lake called Loch Macbeary, situated mostly between the two parishes of Kirkowen and Penningham. There are several small islands in it; upon the largest of which are the remains of a considerable building and small garden. The river Bladenoich, which has its source in this lake, runs in a south-easterly direction for about two-thirds of its length; after which it takes a more easterly course, and empties itself into the bay of Wigtown: its whole length is about twenty-four miles. Tarff is a stream which rises in the precincts of Ayrshire, and after a course of twelve miles, in a south-westerly direction, falls into the Bladenoich in the parish of Kirkowen. Luce-water is a small river, which runs into the great bay of that name. Salmon are caught in it; and it is observed that the skin of the salmon, when it first goes up the river, which is deeply tinged with mosses, is of a filthy colour, but after remaining some time, it becomes of a brownish-yellow.

Wigtownshire has several fresh-water lakes, but none of particular importance. In the parish of Sorbie is one of three miles in circumference, well floored with pike, perch, and eels. It is called Dowalton lake, because the ancient powerful chiefs, the Macdowals, had their residence near it.

In the parish of Luce are fifteen lakes, of different degrees of extent, abounding with fith of several kinds, and frequented by a variety of water-fowls. Swans emigrate from Ireland, particularly in severe winters, and continue in these lakes till spring. The thre of Wigtown is deeply penetrates by navigable bays. Wigtown bay and Luce bay advance in a direction nearly parallel far into the country towards the north. At the same time, from the northern part of the county, the long and narrow bay called Loch-ryan advances southward towards the bay of Luce, and penetrates an extensive territory, which appears to have long remained divided from the rest of Scotland. Loch-ryan is a beautiful as well as a safe and commodious bay for shipping. It is about ten miles in length from north to south; the entrance into it is near two miles broad. It is bounded on the east by the parish of Balantrae, in Ayrshire, and on the west by Millar Point, a headland in the parish of Kirkholm. About three or four miles from the mouth of the loch, on the east side, is the little village of Cairn; contiguous to which is a commodious bay with good anchoring ground, and depth of water sufficient for ships of any burthen; and all vessels entering into or coming out of the Firth of Clyde seek this bay in stormy weather. King William's fleet anchored here in their passage to Ireland. Before the Cairn bay, there are several other good anchoring bays in the loch. Luce bay, which advances from the south towards Lochryan, is far more extensive. In dark and hazy weather, vessels often mistake Luce bay for the Irish channel, and when keeping a northerly course, sometimes run on shore, before the error is discovered. The bay of Luce contains a great variety of leffer bays, some of which are capable of being converted into convenient harbours; and mariners acquainted with them find anchoring places, in which they are in safety from almost every wind. The coast around the bay of Luce is very various: in some places it consists of a fine gravel beach; at other points steep rocks project into the sea, forming a bold inaccessible shore. The most southern point of the coast, or rather of Scotland, is called the Mull of...
of Galloway: in the western side of it rises a very elevated coal; it is about the extent of a mile, and projects itself as the boundary between the Irish sea and the bay of Luce. In a high, wet, winds create a prodigious swell of the sea, rolling round the point, and is then awfully grand. Here the sea has formed caverns, which are rendered dreadful by a setting-in tide and a strong, running wind. The noise is like loud claps of thunder. Ships pass and repass this point from England, Ireland, and the west of Scotland.

Though the agriculture of this country is yet but in an inferior state, great exertions are making to bring the soil under the best management of which it is capable. Still, however, the defects of the soil, added to the imperfect state of the husbandry which has hitherto existed, greatly depress the value of the territory. The earl of Stair's estate is paid to extend to about 55,000 acres, but produces an annual rental of no more than 11,000. sterling. There are in this county great tracts of land, of that soft confidence which renders it almost inacceivable, and of no utility either for agriculture or pastoral use. Little hopes are yet entertained of the practicability of improving this fort of territory. But it is confidently asserted, that an immense field of mofs of this description below Newton Douglas might by proper management be floated into the sea, leaving some thousand acres of rich clay behind. The great trunks of trees that are found in the mofes of this county, afford full proof of its having been formerly covered with wood. The renewal of the forests, however, proves a very arduous task; and in certain exposures on the coast has repeatedly baffled the hopes of the most ingenious and attention; planters. Wood, corn, and potatoes, in this exposure, are more or less injured, according to their vicinity to the sea; whereas, when protected from it, they are found to grow with their usual vigour. Shelter, therefore, either natural or artificial, must be had on this coast before wood can be planted with any chance of success. Scottish firs, which serve to nurse up plantations in many other parts of the country, are unfortunately found to thrive worse here than any other species of wood. Under this difficulty, the earl of Galloway fortunately discovered the valuable properties of the piny West Coast, or maritime pine, which he observed to grow with a degree of luxuriance superior to any other in his plantations. He has since increased the propagation of that tree, and now finds that under its protection, almost any other wood may be planted with success. Attempts are making to introduce dairy-farms into this country, for the purpose of supplanting the universal practice of breeding cattle. One farmer, upon this plan, has no less than eighty milking cows: he uses his whole milk in the manufacture of cheese, which he exports to the Clyde. A remarkable breed of small white-faced sheep, peculiar to the coast of this county, deserves notice. It is called the Mochrum breed. These are said to be of Spanish extraction, an idea the more readily adopted, from the quality of their wool, which is of the fine English sort, of a texture superior to wool in Scotland, and but little inferior to real Spanish. This breed, which is at present of an under size, is well-shaped, hardy, and found by proper attention to improve much, both in weight of carcass and wool.

The mineral productions of the country are but few: the parish of Kirkmaiden, which forms the southern part of the peninsula that bounds the bay of Luce on the west, contains valuable quarries of slate, of which considerable quantities are wrought and sent to market. Here are several natural caverns, in one of which is a petrifying water, dropping from the roof. In the parish of Inch, situated upon Loch-ryan, are several mineral springs: one, with a fulphurous impregnation, has been found useful in stomatie and scurvy complaints. There is also a chalybeate spring. Some appearances of coal have been thought to exist here; but that valuable mineral has hitherto been sought in vain. In this quarter, towards Ayrshire, is a bold rocky shore, containing several natural excavations or caverns, extending eighty or an hundred yards under ground. The parish of Whitehorn, in the south-eastern part of the county, produces very fine variegated marble, and also slate of a strong quality. The chief natural defect incidental to this county is the want of coal, a defect common to it with almost the whole of the southern border of Scotland. Was it not for this check to the establishment of manufactures, it might be likely to assume some share of commercial importance. Though of small extent, it has an ample coal-foothold, which affords great facility for exporting the produce of its agriculture and dairies. This facility is so great, that the inhabitants of Wig-townshire are sometimes in dread of scarcity, in consequence of the greater part of their produce being carried to Glasgow, Paisley, or Liverpool, where a market is always to be obtained.—Beauties of Scotland, vol. ii. Wigtownshire, 1805. Gazetteer of Scotland, 1806.

WOOLWORM Point, a cape on the coast of Patagonia, in the thirty-sixth parallel of Magellan; 3 miles W. E. of Cape Providence.

WHACIS, or WHATS. See BHAIS.

WHENALS, a town in Sweden, in the province of Savolax; 40 miles N. of Childa.

WIHI, or WYER, a town of France, in the department of the Upper Rhine; 6 miles W. of Colmar.

WHIRBACH, a river of France, which runs into the Rhine, 7 miles above Germersheim.

WIKES, in Agriculture, a term used to signify temporary boundaries or marks, set up in order to divide the fields to be mown; such as the bounds of trees, in the common fields and meadows in different districts; as well as such bounds which set upon hay-cocks and flouks of corn for the taking of tithe, and other such purposes.

WIKINISH CREEK, in Geography, a river of Pennsylvania, which runs into the Susquehanna, N. lat. 40° 32'. W. long. 77° 1'.

WILAF, a river of Wurtemberg, which runs into the Rems, near Schorndorf.

WILBESSEN, or WILDADESSEN, a town of Westphalia, in the bishopric of Paderborn; 8 miles S.E. of Dringenberg.

WILBRHAM, a township of Massachusetts, in the county of Hampshire, with 1776 inhabitants; 10 miles N. of Springfield.

WILBURG, a citadel of Austria; 8 miles E.S. of Ips.

WILBY, JOHN, in Biography, one of our best madrigalists of Queen Elizabeth's reign. In his first set, the following are well-known: "Lady, when I behold the roses sprouting;" and "Flora gave me fairest flowers." But, "Hard by a crystal fountain," which, according to Hearne, (Lib. Neg. Scacc.) used annually to be sung by the fellows of New college, Oxon, we are unable to find. Those words are adjusted to the music of Giov. Croce, in the second book of Musica Transalpina, and are set by Morley in the Triumphs of Oriana; but appear not either in the first or second set of Madrigals published by Wilbye, and we know of no other.

WILD ALBEH, in Geography, a mountain of the duchy of Sturia; 7 miles N. N. W. of Muertzenfchlag.
Wild Angelica, Basil, Briar, Campion, Carline Thistle, Carrot, Cherries, Cistus, Climber, Lettuce, Liquorice, Marjoram, Mela, Mint, Mulberry, Oak, Radish, Rape, Rocket, Tare, Thyme, and Vine, in Agriculture. See Weed.

Wild-Fire, or Erysipelas, a disease in sheep, which affects the skin, and which, if not well attended to, is liable to spread very quickly among the flock. It is attended with considerable inflammation in many cases, though but seldom with blisters over the body. It commonly takes place towards the latter end of summer, and does not continue more than eight days at a time, although such sheep as are once affected with it are very liable to have it again. It was formerly a practice with shepherds to bury the sheep that were affected with this disease in the ground at the door of the fold, with their feet upwards, which, they believed, acted as a charm to drive it from the flock. But this folly is now done away with.

In the cure of this affection of the skin, recourse may be had to evacuations from the bowels by the use of calomel, or purging-farts, dissolved in warm water, for three or four days; then sulphur with nitre may be given in pretty full doses, cooling washes being used at the same time. Strengthening remedies should afterwards be employed, such as oak, or other barks of the same nature.

During the cure, the sheep should be kept from being too much exposed to cold, and in a dry found pasture, being well fed when necessary.

Wild-Fire, Ignis Gregalis, or Græca. See Wild-Fire.

Wild-Fire Arrows, such as were trimmed with wild-fire, and shot burning, to drive the flocks or rigging of ships in a fight. See Fire-Arrow.

Wild-Fowl. See Water-Fowl, and Decoy.

Wild-Goof. Anas Anser. See Duck.

Wild-Goose Chase. See Chace.

Wild-Honey. See Honey.

Wild-Land, Reclaiming of, in Agriculture. See Reclaiming Lands.

Wild-Olive. See Eleagnus.

Wild Service-Tree, in Agriculture and Gardening, a deciduous tree of considerable growth, which is much cultivated in the field and pleasure-ground. It has been observed, that this tree is sometimes planted in orchard-grounds among fruit-trees, but that it should be put in pleasure-grounds, plantations, or on lawns, for its ornamental effect in the autumnal season.

If trained up with straight clean stems, service-trees will grow to the height of thirty or forty feet; in that case, they should be planted among forest-trees, or in the back parts of large shrubberies. But those who wish to plant them as flowering shrubs must head them down when young, to make them throw out horizontal shoots; they may then be planted among the middling-sized shrubs, which will make a beautiful variety, both when in flower, and when bearing fruit. These trees grow to a considerable size when properly managed, and are very much used by wheelers and others, on account of the wood being all, what they call, heart-wood.

The fruit has been found excellent for feeding game, and other sorts of birds and fowls.

Wildau, in Geography, a town of the duchy of Slesia, on the west side of the Muchr; 12 miles S. of Gratz.

Wildbad, a town of Wurttemberg, celebrated for its warm-baths; 30 miles N.E. of Strafsburg. N. lat. 48° 40'. E. long. 8° 26'.

Wildberg, a town of Wurttemberg, on the Nagold; 3 miles N. of Nagold. N. lat. 48° 33'. E. long. 8° 48'.—Also, a town of Prussia, in the province of Oberland; 12 miles S. of Ortelburg.

Wildberg, or Wylbergen, a town of the Middle Mark of Brandenburg; 20 miles N. of Brandenburg. N. lat. 52° 55'. E. long. 12° 38'.

Wilde, James, in Biography, a Swedish historian, was born in Courland in 1097, and educated at Riga; and having quitted that city in 1095, he fought farther improvement in several German academies, graduating M.A. at Grieswald. At the age of 21, such was his proficiency in various branches of literature, he was appointed co-rector of the cathedral school at Riga, and soon after teacher of politics, history, and eloquence, in the royal gymnasium of that place. Qualified by his talents and acquirements for a higher rank in the department of instruction, he was invited, in 1703, to be professor of history in the academy of Pernau; but declining this office, he was, in the following year, nominated by Charles XII. to fill the chair of Latin eloquence and poetry, which he occupied for five years. During his stay at Aix-la-Chapelle, which he visited in 1709 for the recovery of his health, the Russians made an irruption into Livonia, and he lost his library, with all his documents and papers. From hence, instead of returning to his native country, he proceeded to Stockholm, and offered his services to the senate. Such were the exciting troubles at that time, that it was not till the year 1713 that government appointed him to be professor of eloquence and poetry at Grieswald. But he preferred a humble and more private situation as tutor to the two sons of count Cronhelm, with whom he made a tour to England, Holland, France, and Germany. Pursuing a similar tour with a young Holstein count, and becoming acquainted with the duke of Holstein, he was appointed his cabinet-secretary, in connection with the professorship of the law of nature and nations at Kiel. And in the same year his friend Frederick made him historiographer to the kingdom; on which office he entered at Stockholm in November 1719. His works were numerous and learned; but his constitution was feeble, so that he sank under his labours, and died in 1755. Although he was more than thirty years old when he went to Sweden, he obtained a thorough acquaintance with the Swedish history; he was also well acquainted with the public law of Germany; and in his earlier years he had raised himself by writing Latin poetry. He was also a good philosopher, and a theologian, and often preached. His memory was singularly retentive; and this served him in various works which he composed after having lost his sight in 1741. Many of his works were lost at the capture of Pernau. During his tour with the sons of count Cronhelm, he published at Frankfort, in 1717, "Diatriba de Jure et Judice Legatorum à Stephano Callio;" "Suecic História Pragmatica, qua vulgo jus publicum dicitur, &c." Holm. 1731, 40.; "The Foundation, Nature, Origin, and Antiquity of the Swedish Laws," with an Account of the Changes and Alterations which have been made in them," ibid. 1736, 40.; "Puffendorf's Introduction to the History of Sweden, with Additions, Proofs, and Notes," by J. Wilde; "I. Part," ibid. 1738, 40.; "II. Part," ibid. 1743, 40.; "Preparatio hodegetica ad Introdutcionem Puffendorfii in Sveclici ratus Historiam, &c.," ibid. 1743, 40. Gen. Biog.

Wilde, in Geography, a river of Prussian Lithuania, which runs into the Russe.
WILDEBERG, a town of Pomerelia; 2 miles S. of Marienburg.

WILDEMAN, a town of Welthphalia, in the principality of Grubenlagen, near which are some mines of silver and lead; 6 miles S.W. of Goslarn.

WILDENBERG, or WILDENBERG, a town of the duchy of Berg; 10 miles E. of Homberg. WILDENBERG, a town and castle of France, in the department of the Rhine and Moselle; 10 miles W. of Kirn.

WILDENBRUCH, a town of Hinder Pomerania; 5 miles S. of Bünau.

WILDENFELD, a town of Saxony, in the circle of Erzgebirg; 5 miles S.E. of Zwicau.—Also, a citadel in the territory of Nuremberg; 3 miles W.S.W. of Bezenstein.

WILDENBURG, or WILDENBURG, a town of the circle of Neufristadt; 2 miles N.N.E. of Weyda.

WILDENHOF, a town of Prußen, in Natangen; 23 miles S. of Brandenburg.

WILDENS, John, in Biography, was born at Antwerp in 1584. He became an admired painter of landscapes, but under whom he acquired the art is unknown. He appears to have been a diligent observer of nature, and to have indulged much in the open air; as his studies of forests, fields, &c. are numerous. When he had obtained considerable reputation, his talents introduced him to the notice of Rubens, who employed him to assist in executing the landscape parts of back-ground, which he did with so great felicity, that there appears no diffimilarity in artists in the pictures on which they both took their respective parts. Two of his best pictures are in the chapel of St. Joseph at Antwerp, embellished with figures by Lang Jan; the subject of one is the Flight into Egypt, and of the other a repose. He died in 1644, aged 60.

WILDENSCHWERT, in Geography, a town of Bohemia, in the circle of Chrudim; 9 miles E. of Hohenhain.

WILDENSCHWERT, in Geography, a town of Germany, in the margraviate of Anspach; 7 miles S.E. of Creilheim.

WILDENTHAL, a town of Saxony, in the circle of Erzgebirg; 7 miles S.S.W. of Schwartenberg.

WILDENSCHWERT, in Geography, a town of Bohemia, in the circle of Chrudim; 9 miles E. of Hohenhain.

WILDENSCHWERT, in Geography, a town of Germany, in the margraviate of Anspach; 7 miles S.E. of Creilheim.

WILDENTHAL, a town of Saxony, in the circle of Erzgebirg; 7 miles S.S.W. of Schwartenberg.

WILDERNESS, in Gardening. There is nothing so great an ornament to a large garden as a wilderness, when properly contrived, and judiciously planted. The wilderness should always be proportioned to the size of the garden, and should never be situated too near the house; because the trees perish for a large quantity of watery vapours, as makes the air very unhealthy; though vegetables serve, as modern experiments have sufficiently ascertained, to purify and temper the air. See AIR.

The wilderness should never be placed as to block up a good prospect; but where the view naturally ends with the verge of the garden, or little more, nothing terminates it so well as a fine plantation of trees. The size of the trees should be considered, and tall growing ones should be planted in larger places; smaller, in less extensive; evergreens also should be kept by themselves, and placed most in fight, not mingled confusedly among the trees which call their leaves. The walks should be large and not numerous; the large walk is best made perpendicularly, and this should not be entered upon in the grand walks of the garden, but by some private walk.

It is too common a method to dispose the trees in wilder-nes, in form of regular squares, triangles, &c. but this is faulty; for as nature should be studied in these works of fancy, the most irregular is the most pleasing plantation. The walks for the same reason are much more pleasing when they run in wild meanderer, than when they intersect one another in studied and regular angles. The winding walks should be made to lead to an open circular piece of grass, with a statue, an obelisk, or a fountain: or, if an opening large enough for a banqueting-houfe be contrived in the middle, it will afford a very pleasing scene. The trees should gradually rise from the sides of the walks and openings, one above another, to the middle of the quarters, where the larger trees should stand, by which means the heads of all the trees will appear in view, but their items will not appear in fight.

Not only the growth of trees is to be considered in the planting of a wilderness, but their nakedness are to be considered and hid. The larger growing trees are allowed a proportionable distance, and their items hid by honey-fuckles, roses, spiræas, and other low-flowing shrubs. These may also be planted next all the walks and openings; and at the foot of these, near the walks, may be set rows of primroses, violets, and daffodils, with other the like flowers; behind the first rank of lower flowing shrubs should be planted those of a somewhat higher stature, as the althaea-frutices, the cytisides and guelder-roses; and behind these may be rows of the taller flowering shrubs, as the lilacs, laburnums, and the like; and behind these, the heads only of the lower growing trees will appear, which should be backed gradually with those of higher growth to the centre of the quarter; from whence the heads of the trees should descend every way to the walks, or openings. The grand walks and openings should always be laid with turf, and kept well mowed; but, before these, there ought to be smaller serpentine walks through the feveral quarters, where persons may retire for privacy; these should be left with the bare earth, only kept clear of weeds, and laid smooth.

These walks should be made as winding as possible, and a few wood-flowers planted along their sides will have a very good effect. The ever-greens should be allotted a peculiar part of the wilderness, and such as fronts the house; and in the planting of these, the fame regard is to be had to their growth, that the taller trees be planted hindmost, and their items hid by shorter ones, and so on, down to the verge; as in the first row may be planted laurusines, boxes, spurge, laurels, junipers, and fias; behind these, laurels, hollies, and arbutus; next behind these, yews, alaternus, phileraya, cypress, and Virginian cedars; behind these, Norway and silver firs, and the true pine; and finally, behind these, the Scotch pine and pinaster. These will have a very beautiful appearance, as their tops will only be seen, and make a sheet of green, which may also be very beautifully varied, from the artful admixtures of the several shades of green which the various plants have. In all these plantations, the trees, however, should not be set in formal lines, but in a loose variety, proportioned to their manner of growth. Miller.

WILDERSDORF, in Geography, a town of Austria; on the Zeya; 8 miles W.S.W. of Zitterdorf.

WILDESCHAUSEN, a town of Welthphalia, with a district formerly belonging to the archbishopric and duchy of Bremen, and afterwards to the duchy of Brunswick, in which it is intufated. It is situated on the Hante, and contains about 312 house. The inhabitants are partly Roman Catholics; in the bailiwick are 50 villages; 20 miles S.S.W. of Bremen. N. lat. 52° 52'. E. long. 8° 27'.
WILDING, in *Rural Economy*, a four autiere fort of apple, often used with others that correct these qualities, for making home cyder. See Cyder.

WILDING, *Royal*, an excellent cyder-apple. It is said, in the Gloucester Report on Agriculture, to be a native of Dimock; that it is a fine, clean, and handsome grower; makes excellent cyder, is a great favourite among the planters in the upper part of the forest-distri t of that county, and is much introduced in the vale, on the east side of the Severn. See Cyder.

WILDS, a term used by our farmers to express that part of a plough by which the whole is drawn forwards. The wilds are of iron, and are of the form of a gallows, whence they are by some called the gallows of the plough, but improperly; the gallows of the plough being properly that part formed by the crown-plies, and the transverse piece into which they are mortised at the top. The wilds consist of two legs, and a transverse top-piece: one of the legs, and the top-piece, are all of one piece of iron; and the other leg, which is loose, has a hole in the top, into which the end of the transverse piece is received: both these legs pass through the box of the plough, which is that transverse timber through which the pinples of the wheels run. These legs are pinned behind the box with iron pins: the holes through the box at which these legs pases, are not made at right angles, but flanting upwards, so that the part of the wilds is higher than the hinder part; were it not for this, the upper part of the crown-plies would lean quite back when the plough is drawn.

The use of the notches in the wilds is to give the plough a broader or narrower furrow; if the legs are moved to the notches on the right-hand, it brings the wheels toward the left, which gives the greater furrow; and, on the contrary, a smaller furrow is made when the legs are moved to the notches on the left. The legs of the wilds should be nineteen inches, and their distance eight inches and a half; they must be made strong, and the legs must be placed in different notches, that the front of the plough may be kept steady, and the wheels not be drawn one before the other. These legs are of iron also, and are each six inches and a half long, and to these are fastened the chains of the harness, by which the whole plough is drawn along.

WILDAUBACH, in Geography, a river of Germany, which runs into the Elbe, 6 miles below Dresden.

WILDEE, a lake of the duchy of Sturia; 8 miles E. of Neumark.

WILDSHUT, a town and castle of Bavaria; 5 miles N.N.W. of Lauffen.

WILDSTADT. See WILSTADT.

WILDUNGEN, a town of Germany, in the county of Waldeck; 7 miles S.S.E. of Waldeck. N. lat. 51° 7'. E. long. 6° 8'.

WILEHENGEN, a town of Switzerland; 9 miles W. of Schaffhausen.

WILEIA, a town of Samogitia, on the Niemen; 25 miles S.S.E. of Rofienne.

WILF, in Agriculture, a term used provincially to signify the white willow. See Willow.

WILFERSDORF, in Geography, a town of Austria; 4 miles W. of Brugg.

WILHELMSDORF, a town of Prussia, in Oberland; 13 miles S. of Holland.

WILHELMSHAOF, a town of Germany, in the duchy of Anhalt Bernburg, near Hartzgerode.

WILHELMSPURG, a town of Austria; 8 miles S. of St. Polten.

WILHELMSTEIN, a town of France, in the department of the Roer; 7 miles S.W. of Juliers.

WILHELMSTHAL, or Neustadtel, a mine-town of Silicia, in the principality of Glatz; 15 miles S.E. of Glatz. N. lat. 50° 3'. E. long. 16° 42'.

WILLA, a river of Lithuania, which runs into the Niemen, near Kowno, in the palatinate of Troki.

WILINGO, a town of Sweden, in the province of Schonen; 7 miles N. of Helsingborg.

WILITZ, a town of Bohemia, in the circle of Kauzim; 5 miles N.N.W. of Kauzim.

WILKES, JOHN, in *Biography*, was born in London in 1727, and finished his studies at the university of Leyden. Soon after his return to England, he married a Miss Mead, who was a lady of large fortune, and settled at Aylesbury. This lady, though highly respectable both in her character and connections, and belonging to a diffenting family as well as himself, was older than he, and in other respects an unattractive wife, so that the attachment was originally formed, on his part, from lucrative motives: one daughter was the fruit of this connection. Mr. Wilkes, thus furnished with the means of profusion, lived in an expensive style, and being little anxious about domestic happiness, associated with the gay and licentious, to whose habits and manners his principles and character were sacrificed. Urged by his partial friends who thought him qualified for public life, he offered himself, in 1754, as a candidate for the town of Berwick, but his views were disappointed. In this and in several other instances, he counteracted the inclinations and wishes of his wife, so that their continued connection was a source of disquietude, and they determined to separate. In 1757 he was returned as a member for the borough of Aylesbury, the consequence of which was an increase of expenditure, that involved him in pecuniary embarrassments, and led him to dishonourable practices, and particularly to an attempt of freeing himself from the obligation of paying his wife’s annuity, in which he failed of success. His parliamentary patron was earl Temple, by whose influence he was chosen representative for Aylesbury; and from whose interest he expected to obtain some place under government, which the perplexity of his circumstances rendered particularly desirable. But he was once and again disappointed; and he ascribed his failure to the interference of lord Bute. In 1762 he brought himself, as a political writer, with lord Temple and Mr. Pitt, and defended them, whilst he exposed the ministry, on occasion of the rupture with Spain, in a pamphlet entitled “Observations on the Papers relative to the Rupture with Spain.” This publication was followed in 1763 by an ironical dedication to lord Bute, of Ben Jonson’s “Fall of Mortimer,” in which he indulged unrestrained levity against the “favourite,” as he was called, and his antipathy to the Scottish nation; which was further manifested in a periodical paper called “the North Briton,” commenced in 1762, and intended to counteract “the Briton,” which Smollet conducted in defence of lord Bute’s administration. The North Briton, however, was written with a spirit so contemptuous to the sentiments of the public at that period, that it probably contributed to the re-election of that nobleman in April 1763. The 45th number of this periodical work was published on the 23d of April, and contained so severe and sarcastic a comment on the king’s speech, that his ministers, under the direction of the crown lawyers, determined upon a prosecution: and the home secretary of state, lord Halifax, issued a “general warrant,” i.e. a warrant, in which no particular names were specified, for the apprehension of the authors, printers, and publishers of that paper. As soon as it was discovered that Wilkes had
had given orders for the printing, he was taken into custody, and brought before the two secreries of state. Perfectly self-poifled, and avowing the illegality of his arrest, he refued to answer any interrogatories; and a habeas corpus which had been fued out for him being evaded, he was clofeely confined in the Tower. However, he was soon after brought by habeas corpus before the court of common pleas, when lord chief juftice Pratt declared the opinion of that court against the legality of his commitment, fo that he was difcharged amidit the acclamation of the audience and of the populace. In the course of these proceedings he was deprived of his commiffion as colonel, by the king's order; and his patron, lord Temple, loft his poit of lord-lieutenant of the county. This nobleman, at his own expense, availed himself of the legal decifion againft general warrants, and commenced actions against the king's meffengers, the secrearies, the under secreary, and the folici- tor of the treafury; in all which the profecutors obtained damages, which were paid by the crown, in confequence of an express order of council. Thus the doctrine of the illegality of fuch warrants was establiifhed, and for this accefion to the caufe of liberty the public were indebted to John Wilkes, lord Temple, and lord chief juftice Pratt, afterwards lord Camden. Wilkes, not fatisfied with this triumph, proceeded, againft the advice of friends, to fet up a prefs in his own houfe, and to reprint the North Briton; for which he was again prosecuted to conviction. Having withdrawn to France in 1763, he was expelled from the houfe of commons, because he did not appear to answer the charges that were produced againft him. The next attack that was directed againft him was occasioned by his printing an indecent and profane piece, called "Eflay on Woman," and faid to have been written by Mr. Potter, fon of the abifhop of the fame name; and as fome scandalous reflexions on a bishop were introduced in this piece, complaint of breach of privilege was made in the houfe of lords; and on a profecution, he was found guilty of both the crimes of blasphemy and libel. By his continued abfence, he incurred the penalty of outlawry. Upon a change of ministry he returned to England, and delivered himfelf to cuftody; and confiding in his popularity, he offered himfelf as a candidate to repre- fent the city of London; but failing in this objeft, he was immediately elected for the county of Middlefex. Al- though his fenfence of outlawry was reversed as illegal, he was condemned for his two libels to an imprisonement of 22 months, and a fine of 100l. In 1769 he was charged with being the authour of a pamphlet relating to the riots, occa- fioned by his imprisonement, and expelled from the houfe; and being immediately re-elected, he was declared incapable of a seat in the houfe during the excifing parliament. He now became popular as the farty of liberty, and large fums were collected towards the payment of his debts. He was again re-elected, and his election was declared void. At the next election, the court-candidate, colonel Luttrel, whole votes were about a fourth of thofe of Mr. Wilkes, was de- clared the fitting member. This meafure caufed diffaft- fication and complaint through the country, and produced petitions for the difsolution of parliament. Wilkes, though excluded from parliament, was chosen an alderman of the city of London; and in the excifing of his office as a magiftrate, he refited with his ufual spirit exafciions of authority which he considered as illegal; and actually libelled one of his printers of newfpapers in which the fpeeches of members of parliament were detailed, and who had been arrested by royal proclamation. Two others were released by lord mayor Crofby and alderman Oliver, who being members of the houfe were committed to the Tower. Wilkes was ordered to attend at the bar of the houfe; but in a letter to the speaker, he objefted, that in the order for attendance, no notice was taken of his being a member of the houfe, and his attendance in his place had not been defired, which forms, he faid, were effential: he also demanded his fet, and then he would give a full account and juftification of his conduct. The houfe, fenfible of the difficulty to which it had objefted itfelf, faved its authority by adjourn- ing for the day on which Wilkes was ordered to attend. In 1772 Wilkes was chofen one of the sheriffs for London and Middlefex, and in 1774 lord mayor of London. Having conducted himself with propriety and reputation in his pub- lic offices, he was re-elected in 1776 a reprefentative for the county of Middlefex; and was allowed to take his seat without oppofition. In parliament, he oppofed the meafures that occasioned the American war; and on the accelfion of the Rockingham administration, he carried his motion for refeding the decifion of the houfe of commons, which gave Luttrel a seat by a majority of votes. In 1779 he suc-ceeded in his application for the office of chamberlain in the city of London, and retained it during the remainder of his life. Tired of political conflicts, the latter years of his life paflf off with much notice, fo that, to adopt his own expreffion, he was an "extinguiflied volcano;" and he ex- peired at the houfe of his daughter in 1797, in the 73d year of his age. His private letter affords no memorial that is either amusing or instructive. The early errors of his con- duct call a fhade over his character. His literary talents and attainments, devoted as he was to pleafure, and engaged in bufinesf, never attracted much notice; though as a com- panion he knew how to render himfelf agreeable. Although his patriotism might possibly originate in difappointed views and expectations, he was cofitent and fteady in maintaining the caufe to which he was attached; and he was, either intentionally or incidentally, and by an intrepidity and self-poiflion which he poifioned in an eminent degree, the in- strument of gaining some important advantages to public and private liberty. Alm. Mem. of Wilkes. Ann. Reg. Gen. Biog.

WILKES, in Geography, a town of Ohio, in Gallia county, with 187 inhabitants.—Alfo, a county of the flate of Geor- gia, bordering on South Carolina, containing 7066 inhab- itants. Tobacco is the chief produce, of which 3000 hogheads were exported in 1788.—Alfo, a county in the N.W. corner of North Carolina, with 7247 inhabitants, including 790 slaves.—Alfo, a town of North Carolina; 50 miles W. of Salem.

WILKESBARRE, formerly Wyoming, called also Wilkesburg, a town of Pennsylvania, and chief town of Luzerne county; situated on a plain, bounded on one fide by the Susquehanna, and on the other by a range of mountains, and containing about 150 wooden dwelling-houfes, a church, court-houfe, and gaol, with 1225 inhabitants. A dreadful maffeacre was committed in this place, during the American war, by the Indians under the command of colonel Butler, which is recorded in most histories of that war, and which will ever remain a blot on the English annals. Several of the houfes, to which the unfortunate victims retired to defend them- felves on being refued quarter, are still standing, perfor- rated in every part with balls; the remains of others that were fet on fire are alfo still to be feen, nor will the inhab- itants on any accountuffer them to be repaired. N. lat. 45° 13', W. long. 75° 59'; Weld's Travels, vol. ii.

WILKINS, David, in Biography, a learned antiquary, was born in 1685, and in early life more than once made the tour of Europe, acquiring a knowledge of most modern languages. In 1715 he was appointed by archbishop Wake keeper
keeper of the Lambeth library, of which he made a catalogue, and for his three years' labour in this way he was recommended with several preferments, such as the rectories of Hadley and Monk's Ely, the archdeaconry of Suffolk, and a canonry of Canterbury. Among his principal publications we may reckon "Novum Testamentum Copticum," Oxon, 1716, 4to.; an edition of "Leges Saxoniae ecclesiasticæ et civiles," with many valuable additions, 1721, fol.; "Joannis Seldeni Opera omnia," 1726, 3 vols. fol.; "Pentateuchus Copticus," 1731, 4to.; "Concilii Magne Britanniae," 4 vols. fol. 1736; and a learned preface to bishop Tanner's "Britannico-Hibernica." He married the eldest daughter of Thomas, lord Fairfax, settled in Scotland, and died in 1745, in his 60th year. Nichols's Lit. Anecd. Gen. Biog.

WILKINS, JOHN, D.D., an English prelate, was born near Daventry, in Northamptonshire, in 1624, and finished his education at Magdalen-hall, Oxford, where he graduated M.A. He afterwards took orders, and became chaplain, first to lord Say, and then to Charles, count palatine of the Rhine. At the commencement of the civil war he joined the parliament, took the solemne league and covenant, and became warden of Wadham college. In 1649 he graduated D.D., and in 1656 married the sister of Oliver Cromwell. In 1659 he was nominated head of Trinity college, Cambridge; but being ejected on the restoration of king Charles II., he became preacher to the society of Gray's-Inn, London, and rector of St. Lawrence, Jewry; about which time he was introduced into the Royal Society as fellow and one of the council, and advanced to the fee of Chetter. He was distinguished by his moderation, and was reproached on this account by his enemies, who represented him as wavering in his religious principles. Several bishops cenfured him with uncandid severity, among whom were archbishop Sheldon, bishop Fell, and archbishop Dolben, making no allowance for the favourable disposition which he was led to manifest towards the dissenters by his education under Mr. John Dod, his grandfather, a truly pious and learned man, who disapproved many things in the church of England long before the grand separation which took place on account of Laud's impositions and severities. After the Restoration he was a moderate conformist, and disposed to be indulgent in many things, for the sake of preventing religious divisions. On this account he incurred hatred and obloquy. He at length fell a victim to the flame,occasioned by his fedentary habits, and close application to study; and died, with a tranquillity andfirmnessbecoming a wise man and a Christian, at the house of his friend Dr. Tillotson, in Chancery-lane, London, in November, 1672. Bishop Wilkins was not only an able divine, but a good mathematician and astronomer; and well skilled in mechanics and experimental philosophy. As a writer he was judicious and plain; and he studied more to be useful than to please. Generous in his disposition, he neither sought honour nor riches. The revenues which he received from the church he spent in its service; and while he was secure from want, he did not wish to be richer. His character is thus delineated by Dr. Burnet: "He was a man of as great a mind, as true a judgment, as eminent virtues, and of as good a soul, as any he ever knew; and though he married Cromwell's sister, yet he made no other use of that alliance but to do good offices, and to cover the university of Oxford from the fournefs of Owen and Goodwin. At Cambridge he joined with those who studied to propagate better thoughts, to take men off from being in parties, or from narrow notions, from superfluous conceits, and fierce and rash opinions. He was also a great observer and promoter of experimental philosophy, which was then a new thing, and much looked after. He was naturally ambitious, but was the wiseffel clergyman I ever knew. He was a lover of mankind, and delighted in doing good." He also professed, according to this historian, "a courage which could stand against a current, and against all the reproaches with which ill-natured clergrymen studied to reproach him." His principal works are the following: viz. "The Discoveries of a New World; or, a Discourse tending to prove that it is probable there may be another habitable World in the Moon," London, 1638, 4to., written when he was only twenty-four years of age; "Discourse concerning the Possibility of a Passage to the World in the Moon;" "Discourse concerning a new Planet, tending to prove that it is probable our Earth is one of the Planets," ibid. 1640, 8vo.; "Mercy; or, the Secret Messenger: shewing how a man may with privacy and speed communicate his thoughts to a friend at any distance," ibid. 1641, 8vo.; "Mathematical Magic; or, the Wonders that may be performed by Mechanical Geometry," in two books, ibid. 1648 and 1680, 8vo. These latter five, composing his mathematical works, were printed at London in one volume, 8vo. 1708. "Essay towards a real Character and a Philosophical Language," ibid. 1668, fol.; "Of the Principles and Duties of Natural Religion," in two books, ibid. 1675, 8vo. published by Dr. Tillotson. Also, "Sermons preached on several Occasions," and some others. Life prefixed to his Philosophical and Mathematical Works.

WILKINSON, in Geography, a county of Georgia, with 2154 inhabitants, including 318 slaves.—Alfo, a county of the Missipppi, with 5068 inhabitants, including 2630 slaves.

WILKOMIERS, a town of Lithuanja, in the palatinage of Wilna, on the Swienta, near its union with the Wilna; 44 miles N.N.W. of Wilna.

WILKS, a county of North Carolina, with 9054 inhabitants.

WILKUSCHEK, a town of Prussia; 5 miles N.N.E. of Ragnoitz.

WILL, VOLUNTAS, is usually defined a faculty of the mind, by which it embraces or rejects any thing reprented to it, as good or evil, by the judgment.

Others will have it to be the mind itself, considered as embracing or refusing; adding, that as the understanding is nothing else but the soul, considered as perceiving; so the will is nothing else but the soul, considered as willing, &c.

Mr. Locke more intelligibly defines the will, a faculty which the soul has of beginning or forbearing, continuing, or ending, several actions of the mind, and motions of the body, barely by a thought or preference of the mind, ordering, or as it were commanding, the doing, or not doing, such and such a particular action. This power which the mind has, to order the consideration of any idea, or the forbearing to consider it; or to prefer the motion of any part of the body to its rest, and vice versâ, is what we call the will. See Power.

The actual exercise of that power, is what we call volition, or willing; and the doing or forbearing of any action consequent on such order of the mind, is called voluntary. So far, according to this writer, as a man has a power to think or not to think, to move or not to move, according to the preference or direction of his own mind, so far he is free; and hence liberty, he says, is not an idea belonging to volition or preferring, but to the perfon having the power of doing, or forbearing to do, as the mind shall choose or direct. On the other hand, wherever any performance or forbearance is not equally in a man's power; wherever doing or not doing will
WILL.

will not equally follow upon the preference of his mind; there he is not free, though perhaps the action may be voluntary. Accordingly, where thought is wholly wanting, or the power to act or forbear according to the direction of thought, there necessity takes place; this, in an agent capable of volition, when the beginning or continuation of any action is contrary to the preference of his mind, is called compulsion: when the hindering or stopping of any action is contrary to his volition, it is called restraint. Agents that have no thought, no volition at all, are in every respect necessary agents.

Father Malebranche lays it down, that the will is that to the soul, which motion is to the body; and argues, that as the Author of nature is the universal cause of all the motions in matter, so he is of all the inclinations in the mind; and that as all motions are direct, unless their course be diverted and changed by some foreign cause; so all inclinations are right, and could have no other end but the enjoyment of truth and goodness, were there not some foreign cause to determine the natural impression to evil ends. Accordingly, he defines will to be the impression, or natural motion, which carries us towards good indeterminately, and in the general; and the power the mind has, to direct this general impression towards any particular object that pleases it, is what he calls liberty.

Aristotle distinguishes two kinds of acts of the will, viz. belon to willing, volition: and propriety, election. The first, that employed about the ultimate end; the latter, about the means.

The schoolmen also distinguish the actions of the will into elicit and commanded. Elicit acts, ationes elicitae, are those immediately produced by the will, and really inherent in it; such are willing and willing. Commanded acts, ationes im- perate, are effects produced by other powers; v. gr. the sentient, intellective, or locative powers, at the command or instigation of the will. As to follow, stay, fight, fly, &c.

But others will have the former kind properly to belong to the understanding; and only the latter to the will.

The word will is taken in three senses:

1. For the power or faculty of willing, in which sense it is, we have considered it above.

2. For the act or exercise of this power; as, when we say, No man wills his own destruction.

3. For a habit, or a constant disposition and inclination to do anything, in which sense justice is defined a constant will to give every one what belongs to him: Juftitia est confitans et perpetua voluntas justi faum unicique tribuendi. Inflit. Justin.

WILL, Antecedent. See Antecedent.

WILL, Free. See Liberty, and Freedom.

WILL, Last Will, or Testament, in Law, a solemn act, or instrument, by which a person declares his mind and intention as to the disposal of his goods, effects, &c. after his death. See Testament.

This act or instrument is emphatically styled the will of the deceased, because it directs the disposal of the whole or part of his property, by written or oral instructions properly witnessed and authenticated, according to his pleasure. Some have distinguished between a testament and a will; a will being properly limited to land, and a testament only to chattels, requiring executors, which a will only for land doth not require: so that every testament is a will, but every will is not a testament. However, the words have been commonly used indiscriminately.

WILLS, History of. Wills or testaments, says judge Blackstone, are of very high antiquity. We find them among the ancient Hebrews; not to mention what Eusebius and others have related of Noah's testament, made in writing, and witnessed under his seal, by which he disposed of the whole world, a more authentic instance of the early use of testaments occurs in the sacred writings (Gen. chap. xlvii.), in which Jacob bequeaths to his son Joseph a portion of his inheritance double to that of his brethren; which will we find executed many hundred years afterwards, when the posterity of Joseph were divided into two distinct tribes, those of Ephraim and Manasseh, and had two several inheritances assigned them; whereas the descendants of each of the other patriarchs formed only a single tribe, and had only one lot of inheritance. Solon was the first legislator that introduced wills into Athens; but in many other parts of Greece they were totally discomfited. In Rome they were unknown, till the laws of the Twelve Tables were compiled, which first gave the right of bequeathing; and among the northern nations, particularly among the Germans, testaments were not received into use. Hence it appears, that the right of making wills and disposing of property after death, is merely a creature of the civil state, which has permitted it in some countries, and denied it in others, and subjected it to various restrictions and regulations, where the law allows it.

With us in England, this power of bequeathing is coeval with the first rudiments of the law; not indeed, that it extended originally to all a man's personal estate. See RATIONABILIS parte bonorum.

It is also sufficiently clear, that, before the Conquest, lands were devisable by will. But, upon the introduction of the military tenures, the restraint of devising lands naturally took place, as a branch of the feudal doctrine of non-alienation without the consent of the lord. By the common law of England since the Conquest, no estate, greater than for term of years, could be disposed of by testament; except only in Kent, and in some ancient boroughs, and a few particular manors, where their Saxon immunities by special indulgence subsisted. But when ecclesiastical ingenuity had invented the doctrine of use, as a thing distinct from the land, uses began to be devised very frequently, and the devisee of the use could in chancery compel its execution. However, when the statute of uses, vis. 27 Hen. VIII. cap. 10. had annexed the possession to the use, these uses, being now the very land itself, became no longer devisable; whereupon the statute of wills was made, vis. 32 Hen. VIII. cap. 1. explained by 34 & 35 Hen. VIII. cap. 5. which enacted, that all persons being feigned in fee-simple (except feme-coverts, infants, idiots, and persons of nonfane memory) might by will and testament in writing devise to any other person, except to bodies corporate, two-thirds of their lands, tenements, and hereditaments, held in chivalry, and the whole of those held in fagace; which now, through the alteration of tenures by the statute of Charles II. 12 Car. II. cap. 25. amounts to the whole of their landed property, except their copyhold tenements. As for copyhold and other customary lands, these are devisable or not, according to the custom of the respective manors. And generally, a devise of copyhold will not pass, without a surrender to the use of the will. In the case of a child or widow, a court of equity, in favour of these, will supply a defect of surrender (2 Vez. 582. 5 Vez. 557,); so also, when there is a general devise of real estate to pay debts, and there is no real estate but copyhold: also where a copyhold is in the hands of trustees, the person for whom the lands are held in trust may devise the same without surrender. (4 Atk. 38. 1 Vez. 489.) And though the court will supply the defect of a surrender for the benefit of children, yet the rule doth
doth not extend to grand-children, or to a natural child, and consequently not to any more distant kindred. (2 Vez. 582. 1 Willon, 161. 6 Vez. 544.) And if a man, feized of copyhold lands, surrenders the same to the use of his will, and executes a will, not attested by any witnesses, yet it shall direct the uses of the surrender: for the clause in the statute, which requires the testator’s signing in the presence of three witnesses, is confined only to such devises as pats by the statute of wills of 34 & 35 Henry VIII., which doth not extend to copyhold. (2 Atk. 37. 7 Earl’s Rep. 299.) See Mortmain.

By 29 Car. II. cap. 5, any estate pur auter vie shall be devisable by a will in writing, signed by the party devising the same, or by some other person in his presence and by his express directions, attested and subscribed in the presence of the devisor by three or more witnesses; and if no such devise thereof be made, the same shall be chargeable in the hands of the heir, if it shall come to him by reason of a special occupancy, as affets by descent, as in case of lands in fee-simple; and in case there be no special occupant thereof, it shall go to the executors or administrators of the party who had the devise thereof by virtue of the grant, and shall be affets in their hands.

One that hath money to be paid him on a mortgage may devise this money when it comes. God. O. L. 391.

And if the feoffee in mortgage, before the day of payment which should be made to him, maketh his executors and die, and his heir entereth into the land as he ought; it feemeth in this case, that the feoffor ought to pay the money at the day appointed to the executors, and not to the heir of the feoffee: but yet the words of the condition may be such, as the payment shall be made to the heir; as if the condition were, that if the feoffor pay to the feoffee or to his heirs such a sum at such a day, there after the death of the feoffee, if he dieth before the day limited, the payment ought to be made to the heir at the day appointed. 1 Inst. 209, 210.

And hereby it appeareth, that the executors do more represent the person of the testator, than the heir doth that of the ancestor; for though the executor be not named, yet the law appoints him to receive the money, but so doth not the law appoint the heir to receive the money unless he be named. 1 Inst. 209, 210.

A person may devise by his will the right of presenting to the next avoidance, or the inheritance of an advowson. And if such devise be made by the incumbent of the church, the inheritance of the advowson being in him, it is good, though he die incumbent; for though the tendment hath no effect but by the death of the tementor, yet it hath an inceptive in his life-time: and so it is, though he appoint by his will who shall be presented by the executors, or that one executor shall present the other, or doth devise that his executors shall grant the advowson to such a man. Watf. c. 10.

But where an advowson was devised to the first or other son of B, that should be bred a clergyman and be in holy orders, and if B should have no such son, to C; both devises were held by the court of common pleas to be void, as depending on too remote a contingency; for the rule of law is, that the contingency on which such an executionary devise hinges must take effect within some life in being, or 21 years afterwards; but it was uncertain that the son of B, if he ever should have any, would take, or be able to take orders within 21 years of the death of his father. Proctor v. the Bishop of Bath and Wells, and others, 2 H. Bla. 358.

If upon articles for a purchase, the purchaser die, having devised the land before a conveyance executed, the land will pass in equity; for the testator had an equity to recover the land, and the vendor sold trustee for the tementor, and as he should appoint, till a conveyance executed. 1 Chan. Ca. 39. 2 Vern. 679.

For the vendor of the estate is, from the time of his contract, considered as a trustee for the purchaser; and the vendor, as to the money, is considered as a trustee for the vendor. 1 Atkyns. 573.

So if a man covenant to lay out a sum of money in the purchase of lands, generally; and deviseth his real estate before he hath made such a purchase: the money to be laid out will pass to the heir. Id.

But if a man, having made his will, afterwards contracts for the purchase of lands: the lands contracted for will not pass by the will, but descend to the heir at law. Id.

But if a good title cannot be made of the lands; as the heir in such case cannot have the lands, so he shall not have the money intended to be laid out. Id.

If a man have a lease for ever so many years, determinable upon life or lives, that is, if such or such live so long; this estate may well enough be given and dispofed by will, because it is but a chattel. Went. 19.

A lease for years may also be devised to A for life, remaining to B. And if the lease be renewable, and A renew, B shall contribute to the fine for taking of the benefit of the renewal.

If the testator, by his last will and tendment, do give or bequeath to another any debt due unto him, or a thing in action belonging unto him, the legacy is good and effectual in the law, and may be recovered in this manner, that is to say, if the testator do make the legatary executor of that particular debt or thing in action bequeathed, then the legatary as executor thereof may commence suit in his own name, and recover the same to his own use, against him by whom it was due; but if the testator do not make the legatary executor of the debt or thing in action bequeathed, then his remedy lieth in the ecclesiastical court, where he may convene the executor, and compel him either to sue for that debt in a court competent, and upon recovery and payment thereof to pay it over to the legatary, or else to make a letter of attorney to the legatary for the recovery of the debt or thing in action bequeathed in the name of the executor to the use of the legatary. Swin. 187, 188.

Albeit the testator have no such thing of his own as is bequeathed, yet nevertheless the legacy is good in law; therefore, if the testator do bequeath a horfe or a yoke of oxen, the legacy is good in law, though the testator have neither horse nor ox of his own. But who shall make choice, in this case, of the thing so bequeathed, is a question not to be neglected: and the solution is this; that if the words of the devise be directed to the legatary, as if the testator shall thus say, I will that A B shall have a horse, the choice doth belong to the legatary; but if the words be directed to the executor, as if the testator shall thus say, I will that my executor give to A B a horse, the election doth belong to the executor. Provided nevertheless, that to whomsoever the election doth belong, whether to the legatary, or to the executor, they must not be unreasonable in their election, but frame themselves according to the meaning of the testator; otherwise the legatary might make choice of the best horse in the country, and the executor of the worst, contrary to the meaning of the deceaseth. Swin. 188.

If there be two joint-tenants of lands, and one of them deviseth that which to him belongs, and dieth; this is no good devise, and the devisee takes nothing, because the devise
WILL.

doth not take effect until after the death of the deviseur, and then the surviving joint-tenant takes the whole by prior title, to wit, from the first feoffment. Gilbert on Wills, 120.

And although the jointure is severed before the testator’s death, yet if the will be made before the severance, it will have no effect; unless there is a republication of the will after the partition. Bur. Mansf. 1496.

So also a man cannot give or bequeath by will any of those goods or chattels which he hath jointly with another; for if he should bequeath his portion thereof to a third person, this bequest is void by the laws of this realm; and the survivor, which had those goods or chattels jointly with another, shall have that portion so bequeathed, notwithstanding the said will. Swin. 189.

But otherwife it is with the tenants in common (God. O. L. 131.) and coparceners. For there is no survivor between coparceners, but the part of each is descendible, and consequently may be devised. (Co. Lit. 185. 6.) And a deed of partition is not a revocation of a devise of his moiety by tenant in common. Luther v. Ridley, cited in 3 F. Wms. 160.

By 20 Hen. III. cap. 2. widows may bequeath the crop of their ground, as well of their dowers, as other their lands and tenements; saving to the lords of the fee all such services as be due for their dowers and other tenements. And this is only in affirmation of the common law. (2 Inft. 80.) But by 27 Hen. VIII. cap. 10. a married woman, having a jointure made, shall not have any dowry of the residue of her husband’s lands.

By 28 Hen. VIII. cap. 11. if the incumbent before his death hath caufed any of his glebe land to be manured and fown, at his proper costs and charges, with any corn or grain; he may make and declare his testament of all the profits of the corn growing upon the said glebe land so manured and fown.

But if the testator be leflee for years, and fow the land a short time before his leafe expires, and then dies, before the corn can possibly be ripe within the term, in this cafe a devise thereof is void, because he himself could not, have reapèd it after the expiration of the term, if he had lived. Swin. 191.

Not only that thing may be devised or bequeathed by the testator, which is truly extant, or hath an apparent being at the time of the making of the will or death of the testator; but that thing also which is not in rerum natura, whilst the testator liveth: therefore, it is lawful for the testator to bequeath the corn which will be fown or grow in such foil after his death, or the lambs which shall come of his flock of sheep the next year, depauperizing in such a field. But if there be no such corn growing in that foil, nor any lambs arising out of that flock, then the legacy is defeitute of effect, becaufe no fuch thing is extant at all as was bequeathed. But if the testator devise a certain quantity of grain or number of lambs, as for the purpose, twenty quarters of corn or twenty lambs, and doth will and devise, that the same shall be paid out of the corn which shall grow in such a field, or arise out of his sheep depauperizing in such a ground; though not fo much or no corn at all there grow, or not any or not fo many lambs there arise, yet nevertheless the executor is compellable by law to pay the whole legacies entirely; becaufe the mention of the foil and of the flock was rather by way of demonstration than by way of condition, rather showing how or by what means the faid legacy might be paid, than whether it should be paid at all yea or no. Swin. 186.

Those things which after the death of the testator defend to the heir of the deceafed, and not to his executor, cannot be devisèd by testament, except in fuch caíes wherein it is lawful to devise the lands, tenements, or hereditaments.

If a man be seiz’d of a house, and possessed of divers heir-looms, that by custom have gone with the house from heir to heir, and by his will deviseth away thefe heir-looms; this devise is void; for the will taketh effect after his death; and by his death, the heir-looms by ancient custom are vested in the heir, and the law prefers the custom before the devise. And fo it is, if the lord ought to have a heiriot against his tenant, and the tenant deviseth away all his goods; yet the lord shall have his heiriot for the reason aforesaid. 1 Inft. 185.

The testator may devise all goods and chattels which he hath in his own right, but not those which he hath in the right of another as executor. Swin. 185.

An administrator cannot make a testament of those goods which he hath as administrator to any person dying intestate; because he hath not any such goods to his own proper use, but ought therewithal to pay the debts of the dead person, and to distribute the rest according to law. Swin. 189.

The husband cannot devise fuch goods as his wife hath as being executeur to another, nor fuch things as are in action, as debts due to her before marriage by obligation or contract, unless he and his wife recover the fame during marriage, or that he renew the bonds, and take them in his own name; otherwise after his death they remain to her. 1 Inft. 351.

But the husband may, at any time during the couverture, release a bond given to his wife. And where the husband makes a settlement, the bonds to his wife, being part of her fortune, will notwithstanding his death in the life-time of his wife, before the security be changed, be decreed in equity to his executor; he being considered in that cafe as a purchafer for a valuable consideration. Cafes in the time of L. Tabl. 168.

A man may by his will dispose of his chattels and personal estate that he shall for the future acquire, any time after the making his will, to the time of his death. And this is necessary from the reason of the thing; because the chattels and personal estate are in a continual fluctuation; and if the law were not fo, it would create very great confusion, or else would render it unnecessary for a man to make a new will every day. Gilb. 122.

But it is not so with lands, for they are fixed and permanent: and, therefore, if a man maketh his will, and deviseth therein all the lands which he shall have at the time of his death; and after that, he purchaseth lands, and dieth without republication or making a new will; in this case, though his intent to the contrary is very apparent, yet it is a void devise: for a man cannot devise any lands but what he hath at the time of making his will. And this was adjudged upon great deliberation, by Holt chief justice and the court, in the cafe of Bunker and Cook: and the judgment was affirmed afterwards upon a writ of error in the house of lords, Feb. 24, 1707. Gilb. 122.

But, by Holt chief justice: If he republished his will, in such manner, as well as such circumstances, as are necessary to complete execution of an original will; then the purchased lands will pass as by an original will. (11 Mod. 127.) And in truth this seeming to make it a new will, to all intents and purposes; and not a republication of the old one.

But a codicil, which concerneth only personal legacies, will not amount to a republication of the will, fo as to pass lands purchased after the making of the will. 2 Vern. 625.
WILL.

If a man devieth all his lands for payment of his debts, and purchaseth lands afterwards: the lord keeper faid he would decree a sale, though there were no precedent articules.

2 Cha. Ca. 144.

If a man hath a lease, and dispofeth of it specifically by his will; and after surrenders it and takes a new leave, and after dies; the devisee shall not have this last leave, because this was a plain countermand of his will. Goldf. 93.

But in the case of Sterling and Lydiard, Nov. 21, 1744, where a man devised all and singular his leafhold estate, goods, chattels, and personal estate whatsoever, and afterwards renewed a leave; it was held by the lord chancellor Hardwicke clearly, that the leafhold estate paffed by the will.

If a man devieth a term for years, which he hath not at the time of the devise, but purchaseth some time before his death; Holt chief justice doubted whether this would be good. But Mr. Peere Williams says, that notwithstanding the doubt which the court of king's bench seems to have had in that case, it hath been clearly held to pass by such a will. 3 P. Wms. 169.

WILLS, Persons capable of making. Every person hath full power and liberty to make a will, that is not under some special prohibition by law or custom: which prohibitions are principally upon three accounts; for want of sufficient libration; for want of sufficient liberty and free will; and on account of criminal conduct.

In the first class are to be reckoned infants, under the age of fourteen if males, and twelve if females; which is the rule of the civil law. By statute 34 & 35 Hen. VIII. cap. 5. wills or testaments made of any dames, lands, tenements, or other hereditaments, by any person within the age of twenty-one years, shall not be taken to be good or effectual in law; for until that time, by the common laws of this realm, they are accounted infants. (Swinb. 74.)

But by custom in particular places, they may devise lands before the age of twenty-one. (Gom. L. 21. Wentw. 24.) But no custom of any place can be good, to enable a male infant to make any will before he is fourteen years of age. (Law of Exec. 153.) If the testator is not of sufficient discretion, whatever be his age, that will overthrow his testament. Accordingly, madmen, or otherwise non competes, idiots or natural fools, person known childishly by age or delirium, such as have their senses betossed with drunknness; all these are incapable, by reason of mental disability, to make any will as long as such disability lasts. To this class may also be referred such persons as are born deaf, blind, and dumb; who, as they have always wanted the common inlets of understanding, are incapable of having animus testandi, and their testaments are therefore void. It has been maintained that persons deaf and dumb, who understand what a testament meaneth, and that are defirous of making one, may by signs and tokens declare their testament; and that a blind person may make a nuncupative testament, by declaring his will before a sufficiency number of witnesses; and that he may make his testament in writing, provided the same be read before witnesses, and in their presence acknowledged by the testator for his last will. (Swinb. 95, 96.

Persons of the second description are by the civil law of various kinds; as prisoners, captives, and the like. But the law of England does not make such persons absolutely intellible; but only leaves it to the discretion of the court to judge, upon the consideration of their peculiar circumstances of dures, whether they could be supposeth to have liberum animum testandi. With regard to feme-covets, our laws differ still more materially from the civil. Among the Romans, a married woman was as capable of bequeathing as a feme-fole. But with us, a married woman is not only utterly incapable of devising lands, being excepted out of the statute of wills, 34 & 35 Hen. VIII. cap. 5. but also she is incapable of making a testament of chattels, without the licence of her husband, who frequently, upon marriage, covenants with her friends to allow her that licence; his assent, therefore, must be given to the particular will in question, without which it will not be a complete testament. Her will, therefore, operates in the nature of an appointment, the execution of which the husband by his bond, agreement, or covenant, is bound to allow. The queen-confect is an exception, for the may dispof of her chattels by will, without the consent of her lord; and any feme-covert may make her will of goods, which were in her possession in auter droit, as executrix or administratrix; for these can never be the property of her husband; and if she has any pin-money or separate maintenance, it is said she may dispof of her savings thereout by testament, without the control of her husband. But if a feme-lole makes her will, and afterwards marries, such subsequent marriage is effeemed a revocation in law, and entirely vacates the will.

Persons of the third class are, first, all traitors and felons, from the time of conviction; for then their goods and chattels, and all such lands, tenements, and hereditaments, as they shall have in their own right, nse, or possession, of any estate or inheritance, at the time of such treason committed, or at any time after, are forfeited to the king. The testament before made doth, by reason of the same conviction, become void both in respect of goods, and also in respect of lands, tenements, and hereditaments. But if a person, attainted of treason, obtain the king's pardon, and be thus restored to his former estate, he may make his testament, and his former testament is good. (Swinb. 97.) Neither can a feo de je make a will of goods and chattels, for they are forfeited by the act and manner of his death; but he may make a devise of his lands, for they are not subjected to any forfeiture. (3 Inf. 55.) Outlaws also, though only for debt, are incapable of making a will, so long as the outlawry subsists, for during that time their goods and chattels are forfeited; but he that is outlawed in an action personal, may make his testament of lands, for they are not forfeited. (Swinb. 107.) An outlaw in a personal action may in some case make executors; for he may have debts upon contract, which are not forfeited to the king; and those executors may have a writ of error to reverse the outlawry. (Cru. Eliz. 851.) Coke observes, that an excommunication (meaning the greater excommunication) is worse than an outlawry; for if a plaintiff, who is an executor, be outlawed, his outlawry cannot be pleaded to disbar him from proceeding in the suit, because it is in the right of another; but if he is excommunicated, it is otherwise, because every man that converses with such a person is excommunicated himself (1 Inf. 134.); that is, after he is denounced excommunicate, and they are admonished not to converse with him. (Ayl. Par. 266.) As for perons guilty of other crimes, short of felony, who are by the civil law precluded from making testaments, (as usurers, libellers, and others of a worfe stamp,) by the common law their testaments may be good.

WILL, Nature and Incidents of a. Wills or testaments are divided into two sorts, viz. written and verbal or nuncupative: of which the former is committed to writing; the latter depends merely upon oral evidence, being declared by the testator in extremis before a sufficient number of witneses, and afterwards reduced to writing. A codicil is a supplement to a will.
As _nuncupative_ wills and codicils are liable to great im-
positions, and may occasion many perjuries, the statute of
frauds, 29 Car. II. cap. 3, hath laid them under many restric-
tions; except when made by mariners at sea, and sol-
diers in actual service. As to all other persons, it enacts,
1. That no will shall be revoked or altered by a sub-
sequent nuncupative one, except the same be in the life-
time of the testator reduced to writing, and read over to him and
approved; and unless the same be proved to have been so
done by the oaths of three witnesses at least; who, by 4 &
5 Ann. cap. 16, must be such as are admissible upon trials
at common law.

2. That no _nuncupative_ will shall be good, where the
estate bequeathed exceeds 30l, unless proved by three such
witnesses, present at the making of it, and unless they or
some of them were specially required to bear witness to it
by the testator; and unless it was made in his last sicknes,
in his own habitation, or where he had previously resided
at least ten days, except he be surprised with sickness on a
journey, or from home, and dies without returning to his
dwelling.

3. That no _nuncupative_ will shall be proved by the wit-
nesses after six months from the making, unless it were put
in writing within six days; nor shall it be proved till four-
teen days after the death of the testator, nor till procès
hath first issued to call in the widow, or next of kin, to
contest if they think proper.

As to _written_ wills (viz. those that concern not the de-
vise of lands), they need not any witnesses of their publication.
A testament of chancellors, written in the testator’s own hand,
though it has neither his name nor seal to it, nor witnesses
present at its publication, is good; provided sufficient proof
can be had that it is his hand-writing. (Swib. 353-
Gilb. Rep. 262.) And though written in another man’s
hand, and never signed by the testator, yet if proved to be
according to his instructions, and approved by him, it hath
been held a good testament of the personal estate. How-
ever, it is the safer and more prudent way, and leaves lefs
in the breath of the ecclesiastical judge, if it be signed or
sealed by the testator, and published in the presence of wit-
nesses. It is said in 3 Salk. 396, that by the canon law,
and also by the common law, two witnesses are requisite to
prove a will of goods; for one witness by the civil law, unto
which the other laws are conform in this matter, is as no
witnesses at all. 1 P. Wms. 13.

The statute of frauds and perjuries, 29 Car. II. cap. 3,
directs, that all devises of lands and tenements shall not only be
in writing, but signed by the testator, or some other per-
son in his presence, and by his express direction; and be
subscribed, in his presence, by three or four credible wit-
nesses. In the construction of this statute, it has been ad-
judged that the testator’s name, written with his own hand
at the beginning of his will, as “I John Mills do make this
my last will,” &c. is a sufficient writing, without any
name at the bottom; though the other is the safer way.
(3 Lev. 1.) It hath been said, that if the testator only
put his seal to the will, without signing it, this is a sufficient
writing within the statute; because signing is no more than
a mark to distinguish a man’s act, and sealing is a sufficient
mark to know it to be his will. (Gilb. 93.) Others,
however, have held that sealing without signing was not
sufficient. (1 Wilfon, 313. 2 Vezey, 459.) Signing
being only mentioned in the statute, sealing is not necessary.
(God. O. L. 5. 1 Wentw. 29.) It has also been deter-
mined, that though the witnesses must all see the testator
sign, or at least acknowledge the signing, yet they may do
it at different times. But they must all subscribe their
names as witnesses in his presence, lest by any possibility
they should mistake the instrument. In one case determined
by the court of king’s bench, the judges would not allow
any legatee, nor consequently a creditor, where the legacies
and debts were charged on the real estate, to be a com-
petent witness to the devise. This determination occasioned
the statute 25 Geo. II. cap. 6, which restored both the
competency and credit of such legatees, by declaring void
all legacies given to witnesses, and thereby removing all
possibility of their interest affecting their testimony. The
same statute likewise established the competency of creditors,
by directing their testimony to be admitted; but leaving
their credit (like that of all other witnesses) to be con-
sidered, on a view of all the circumstances, by the court
and jury before whom such will shall be contested. And in
a much later case, M. 31 Geo. II. the testimony of three
witnesses, who were creditors, was held to be sufficiently
credible, though the land was charged with the payment of
debts. By 48 Car. II. cap. 3, all declarations or
creations of trusts or confidences, of any lands, tenements,
or hereditaments, shall be manifested and proved by some
writing signed by the party who is by law enabled to de-
clare such trust, or by his last will in writing, or else they
shall be utterly void, and of none effect. And all grants
and assignments of any trust or confidence shall likewise be
in writing, signed by the party granting or assigning the
same by such last will or devise; or else shall be utterly
void, and of none effect.

No testament is of any effect till after the death of the
testator; and, therefore, if there be many testaments, the
last overthrows all the former; but the republication of a
former will revokes one of a later date, and establishes the
first again. Although no man can die with two testaments,
because the latter doth always infringe the former; yet a
man may die with divers codicils, and the latter doth not
hinder the former, so long as they be not contrary. (Swib. 15.)
All codicils are part of the will; therefore, a codicil
merely for a particular purpose, as to change an executor,
and confirming the will in all other respects, does not revive
a part of the will revoked by a former codicil. If two
testaments be found, and it doth not appear which was the
former or latter, both testaments are void; but if two
codicils be found, and it cannot be known which was the
first or last, and one and the same thing is given to one per-
son in one codicil, and to another person in another codicil,
the codicils are not void, but the persons therein named
ought to divide the thing between them. Swib. 15.

If codicils are regularly executed and attested, they may
be proved as wills are. So if they are found written by the
testator himself, they ought to be taken as part of the will,
and to be proved in common form by the oath of the ad-
ministrator with the will annexed; and in case of opposition,
by witnesses to the hand-writing and finding; and it hath
been usual to exhibit an affidavit of the hand-writing and
finding, before a probate or administration passes even in
common form.

But in case of a real estate, a codicil cannot operate, unless
it be executed according to the statute. 1 Aik. 426.

By 48 Car. II. cap. 3, no devise in writing of lands,
tenements, or hereditaments, or any clause thereof, shall be
revocable, otherwise than by some other will or codicil in
writing, or other writing declaring the same, or by burning,
cancelling, tearing, or obliterating the same by the testator
himself, or in his presence, and by his directions and confent;
but all devises and bequests of lands and tenements shall re-
main and continue in force, until the same be burnt, can-
celled, torn, or obliterated by the testator, or by his direc-
tions.
tions in manner aforesaid, or unless the same be altered by some other will or codicil in writing, or other writing of the devisor, signed in the presence of three or four witnesses declaring the same.

And no will in writing concerning any goods or chattels or personal estate shall be repealed, nor shall any clause, devise, or bequest therein be altered or changed, by any words, or will by word of mouth only, except the same be in the life of the testator committed to writing; and after the writing thereof read unto the testator, and allowed by him, and proved to be so done by three witnesses at the least.

A will which will pass personal estate is not a sufficient revocation of a former will, by which a real estate is devised. Comyns, 451.

Although the statute says, that no will in writing concerning personal estates shall be repealed by word of mouth only, except the words be put into writing, and read to and allowed by the testator, and proved to be so done by three witnesses; yet where a man by will in writing devised the residue of his personal estate to his wife, and the dying, he afterwards by a nuncupative codicil bequeathed to another all that he had given to his wife, this was resolved to be good: for by the death of the wife, the devise of the residue was totally void; and the codicil was no alteration of the former will, but a new will for the residue. 1 Abr. Ca. Eq. 408.

Also, the statute hath not taken away revocations of wills by act of law; as if the testator afterwards make a feoffment, or do any other act inconsistent with the will: but such revocation remains as before the statute. Carth. 81.

If a man devises lands to one and his heirs, and afterwards mortgages the same lands to another for years or in fee; though a mortgage in fee is a total revocation at law, yet in equity it shall be a revocation pro tanto only. 1 Abr. Ca. Eq. 410.

And the reason is, because a mortgage is not considered as a conveyance of the estate, but only as a charge upon it; being merely a security, and in the consideration of equity carries only a chattel interdict, the creditor gains nothing real, it affords no dower, and goes to executors. Sparrow and Hardcastle, May 6, 1754. 3 Atl. 798.

But if lands be devis'd to one in fee, and afterwards mortgaged to the same devisee; this is a revocation in toto, being inconsistent with the devise: but if the mortgage had been to a stranger, it had been a revocation quoad the mortgage only. Prec. Ch. 514.

If a man seised in fee devises it to one in fee or for life, and afterwards makes a lease to another for years; this, even at law, shall not be a revocation but during the years. 1 Roll's Abr. 616.

So if a husband poissessed for forty years devises it to his wife, and after leases the land to another for twenty years, and dies; this lease is not any revocation of the whole estate, but only during the twenty years, and the wife shall have the residue by the devise. Id.

But where a man seised of a lease for lives devises it, and afterward surrendered the old lease, and took a new one to him and his heirs for three lives; it was decreed, that this renewal of the lease was a revocation of the will as to this particular. For by the surrender of the old lease, the testator had put all out of him, had divested himself of the whole interest; so that there being nothing left for the devise to work upon, the will null and, the new purchase, being of a freehold descendable, could not pass by a will made before such purchase. 3 P. Wms. 166. 170.

But where the testator devised all and singular his leasehold estate, and afterwards renewed a lease; it was held by lord Hardwicke clearly, that this leasehold estate pass'd by the will: for that this is not a specific legacy, but only an enumeration of the several particulars of the personal estate, but yet is a general devise of the whole. 3 Atl. 199.

Though a covenant or articles do not at law revoke a will; yet if entered into for a valuable consideration, amounting in equity to a conveyance, they must concludingly be an equitable revocation of a will, or of any writing in nature thereof. 2 P. Wms. 642.

A woman's marriage is alone a revocation of her will. Id.

A man made a will, and appointed one (who was no relation) to be his executor. He afterwards went abroad, where he became a governor of one of the plantations, and went over for an English woman of his acquaintance, whom he married, and had children by; and died, without an actual revocation of his will. Yet it was determined, that this total alteration of his circumstances was an implied revocation. 1 P. Wms. 304.

It is an established maxim, that wills should be construed favourably. Accordingly, the intention of the testator is called by lord Coke the polar-star, to guide the judges in the expounding of wills. In divers instances, relating to the interpretation of wills, collateral evidence hath been admitted in the court of chancery to explain the testator's intention. But notwithstanding these cases, the courts have been very unwilling to admit of parol evidence in relation to any thing that appears on the face of a will; and it is certain that too much caution cannot well be used in this particular, especially when it is considered that the statute of frauds and perjuries, which was made to prevent perjury, contrariety of evidence, and uncertainty, binds the courts of equity as well as the common-law courts; as also that little regard ought in many cases to be had to the expressions of the testator, either before or after the making his will, because possibly these expressions might be used by him, on purpose to conceal or disguise what he was doing, or to keep the family quiet, or for other secret motives and inducements which cannot after his death be found out. 2 Bac. Abr. 310.

Notwithstanding that wills are generally favoured by the law; yet where the testator endeavours to establish a settlement against the reason and policy of the common law, the judges will reject it. Gilb. 110. 2 Bac. Abr. 79.

Also where the testator by his will maketh no other disposition of his estate than the law itself would have done, had he been silent; there such a will is useless, and shall be rejected: and, therefore, if a devise be made to a person and his heirs, which person is heir at law to the devisor; this is a void devise, and the heir shall take by descent as his better title; for the devisee strengthens his title, by taking away the entry of such as may possibly have right to the estate; whereas if he claims by devise, he is in as by purchase. Gilb. 110. 2 Bac. Abr. 79.

Also devises are void and rejected, where the words of the will are so general and uncertain, that the testator's meaning cannot be collected from them; and, therefore, where a man by will gave all to his mother, the general words did carry no lands to his mother; for since the heir at law hath a plain and uncontested title, unless the ancestor divinherits him, it would be severe and unreasonable to fet him aside, unless such intention of the testator is evident from the will; for that were to fet up and prefer a dark and at best but a doubtful title to a clear and certain one. Gilb. 112. 2 Bac. Abr. 81.

The clause of "perfect mind and memory" is more usual than necessary in a will, and yet not hurtful. (Swinb. 7.) But
WILL.

But in case of contellt, it is necessary to prove the sanity of the testator. 2 Atk. 56.

For the different modes of devise, and the legal meaning of the appropriate terms by which they are expressed, we refer to Burn’s Ecclesiastical Law, ubi infra.

From the above accounts it follows, that testaments may be avoided three ways: 1. If made by a perfon labouring under any of the incapacities before mentioned. 2. By making another testament of a later date. And, 3. By cancelling or revoking it.

The Romans were wont to set aside testaments, as being inofficiales, deficient in natural duty, if they disinterested or totally passed by (without assigning a true and sufficient reason) any of the children of the testator. But if the child had any legacy, though ever so small, it was a proof that the testator had not left his memory nor his reason, which otherwise the law presumed. Hence probably, says Blackstone, has arisen that groundless vulgar error of the necessity of leaving the heir a shilling or some other express legacy, in order to effectually disinherit him; whereas the law of England, though the heir or next of kin be totally omitted, admits no quareia inofficiales, to set aside such testament.

Wills of Seamen and Marines. By the statute 26 Geo. III. c. 63, no will made by any petty officer or seaman in the king’s service, whereby any wages, pay, prize-money, or allowance of money of any kind due for such service is bequeathed, shall be valid, unless, if made while the party is in the service, it be signed before and attested by the captain, or the officer then commanding, and one of the signing officers of the ship to which the party belongs, and unless it specify in the body thereof the name of the ship, and the number at which the maker of the will立unds upon the ship’s books, and contains a full description of the reference, profession, or business of the person in whose favour it is made, and the day of the month and the place where it was executed, or by the agent of any of his majesty’s hospitals or quarters appointed to receive sick and wounded seamen, in which the party may be at the time; or if made by such officer or seaman discharged from the service, within the bills of mortality, unless it be attested by the officer appointed by the treasurer of the navy to inspect such wills, or if made at any of the ports where seamen’s wages are paid, unless it be attested by the treasurer of the navy, chief or second clerk there; or if made at any other place, unless it be attested by the minister and churchwardens of the parish in England or Ireland, or by two elders of the parish in Scotland. In order to obtain a probate thereof, the will must be sent to a proctor by the inspector of wills appointed by the treasurer of the navy.

If any such petty officer or seaman should die intestate, the peron claiming administration must apply by petition to the said inspector, who is to grant a certificate directed to a proctor, that letters of administration may pass in favour of the petitioner, if entitled thereto by law.

If any proctor, registrar, or other officer of any ecclesiastical court shall be aiding and abetting in procuring probate of a will, or letters of administration, for the purpose of enabling any peron to receive such wages, pay, prize-money, or allowance of money of any kind, without first obtaining the certificate from the inspector of seamen’s wills, or peron authorized to officiate for him, every such proctor, registrar, or other officer, shall forfeit 500l., and for ever after be incapable of acting in any capacity in any ecclesiastical court in Great Britain or Ireland.

And by the 32 Geo. III. c. 34. after the 1st day of Au-
gust 1792, no letter of attorney or will of a non-commissioned officer of marines or marine shall be valid unless made according to the 26 Geo. III. c. 63.

All are to be deemed petty officers, seamen, marines, &c. except such as are rated upon the books of such ship, admirals or flag officers, and their secretaries, captains, and lieutenants, masters, second masters, and pilots, physicians, surgeons, chaplains, boatswains, gunners, carpenters, and purlers, captains of marines, captain lieutenants of marines, lieutenants, and quarter-masters of marines.

Every lieutenant, on board any of his majesty’s ships, shall upon a page of every mutter book of such ship sign his name for the purpose, and for the purpose only, that the inspector of seamen’s wills, or such person as shall be appointed by him, may have an opportunity of comparing the name with the name of any such lieutenant attesting the will, &c. executed by or in favour of any petty officer, seaman, non-commissioned officer of marines or marine.

And all captains of ships shall, upon their monthly mutter books or returns, specify which of the men, mentioned in the said returns, have granted or issued any will or testament during that month or space of time from the preceding returns, by inferting the date thereof opposite to the party’s name. The mutter books, &c. in case of failing from any foreign station, at a time when no opportunity shall offer of transmitting them to the navy-board, to be left with the naval officer of the place, if any, or with some respectable merchant, with directions to forward the same to the commissioners of his majesty’s navy by the first safe opportunity, and in case of the removal of the commander, to be delivered over to his successor and a receipt given for the same.

Provided that it shall be lawful for the minister of any parish, to whom the inspector of seamen’s wills shall transmit his check of any letter of attorney or will, passed and allowed by him, to deliver the said check to the attorney or executor in the said letter of attorney or will named and appointed. And all seamen’s letters of attorney, and wills made prior to the 1st of Augst 1786, and those of marines prior to the 1st of Augst 1792, shall be examined and inspected by the inspector of seamen’s wills for the purpose of preventing frauds, forgeries, or impositions of any kind therein; and if such inspector shall fee no cause to suspend the authenticity of the same, he shall affix the stamp of his office, and issue checks for the same, but if he shall fee good cause to suspend the truth and authenticity of such letter of attorney or will, he shall report the same to the treasurer, or to the paymaster of the navy, and shall enter his caveat against such letter of attorney or will, which shall prevent any money from being had or received thereof until the same shall be authenticated to the satisfaction of the said treasurer or paymaster.

The wages, pay, prize-money, or allowances of petty officers or seamen, non-commissioned officers of marines, and marines dying intestate, are to be paid only upon letters of administration obtained in the following manner:

The person claiming such administration shall fend or give in a note or letter to the inspector of seamen’s wills, flating the name of the deceased, the name of the ship or ships to which he belonged, and that he has heard or been informed of his death, and requiring the inspector to give such directions as may enable him to procure letters of administration to the deceased, or to the like effect, upon receipt whereof the inspector of seamen’s wills shall deliver or send to the person claiming such administration, a paper in a peculiar form of words, which paper being duly filled up and certified shall be returned to the treasurer, or to the paymaster of his majesty’s navy, London, who upon receiving the
the same shall direct the inspector of seamen's wills to examine the same, and make such inquiry relative thereto as may appear to him necessary on that behalf; and being satisfied, he shall forthwith make out a certificate for obtaining letters of administration, and pursue the course minutely described in Burn's Ecclesiastical Law, art. Will.

By 32 Geo. III. c. 34, the following sums are to be paid for the seal, parchment, writing, and finishing forth of probates of wills and letters of administration granted in pursuance of this act, for the purpose of receiving wages, or pay, or allowances of money of any kind, which shall remain due to the deceased, viz.

And no more than 5l. are to be taken for the suing forth of the probate of any will or letters of administration granted to the widow, children, father, mother, brother, or sister of any such seaman or marine, &c. and 5l. for commissions or requitions to swear such widow, &c. unless the goods amount to 100l.: which half-mentioned charge of 5l. must be understood to be demandable where the probate or letters of administration are not for the purpose of receiving wages, or pay, or allowances of money remaining due, but for general purposes, as to obtain administration of the goods and chattels of the deceased.

A bill of the expenses of obtaining letters of administration to creditors, is to be laid before and taxed by one of the registrars of the prerogative court of Canterbury, or their deputies, who are entitled to a fee of 3l. 4d. for the same; and the proctor is to transmit such letters of administration with the bill of expenses so certified, to the treasurer or paymaster of his majesty's navy. Proctors taking more than the preferred sums forfeit 50l., and registrars and other officers of any ecclesiastical court, procuring letters of administration or probate contrary to this act and the 26 Geo. III., to be incapacitated to act, and forfeit 500l.

WILL, Qualification and Office of the Executor of a. See Executor, Executor de Jure Tort, and Joint-Executors. See also Debts, Debtor-Executor, Inventory, and Legacy.

WILL, Probate of a. See Probate.

WILL, Estrate at, in Law, is where lands and tenements are let by one man to another, to have and to hold at the will of the lessor; and the tenant by force of this lease obtains possession. Every estate of this kind is at the will of both parties, landlord and tenant: so that either of them may determine his will, and quit his connection with the other at his own pleasure, under certain restrictions. For, if the tenant at will fows his land, and the landlord, before the corn is ripe, or reaped, puts him out, the tenant shall have the emblements, and free ingrefs and egress to cut and carry away the profits. But where the tenant himself determines the will, the landlord shall have the profits of the land. The law is careful, that no such sudden determination of the will by one party shall tend to the manifest and unforeseen prejudice of the other. This appears in the case of emblements put mentioned; and also, the lease after the determination of the lessor's will shall have reasonable ingrefs and egress to fetch away his goods and utensils. And if rent be payable quarterly or half-yearly, and the lessor determines the will, the rent shall be paid to the end of the current quarter or half-year. Upon the same principle, courts of law have of late years inclined as much as possible against construing demises, where no certain term is mentioned, to be tenancies at will: but have rather held them to be tenancies from year to year, so long as both parties please, especially where an annual rent is referred: in which case they will not suffer either party to determine the tenancy even at the end of the year, without reasonable notice to the other. Blackl. Com. vol. ii.

WILLACH. See Villach.

WILLAERT, Adrian, in Biography, the disciple of John Mouton, and master of Zarlin, has been long placed at the head of the Venetian school of counterpoint by the Italians themselves. He was born at Bruges in Flanders, and during his youth studied the law at Paris; if with the view of making it his profession, there must have been an early conflict between legislation and music, which having a powerful advocate in his own heart gained the cause; for by his own account (see Josquin) he went to Rome in the time of Leo X., where he found that his motet, "Verbum bonum et suave," was performed in the pontifical chapel, as the work of that renowned composer; he therefore must have been a contrapuntist some time, before any of his works could have travelled to Rome.

The account which Zarlin gives of this motet (P. i. p. 175.) having palled for a work of Josquin, excited our curiosity to see it; and finding it among the Motetti della Corona, in the British Museum, we feared it; but discovered that the predilection for a great name had operated too powerfully in favour of this composition while Josquin was imagined to be the author of it; for it is neither written with the clearness, dexterity, nor even correctness of that wonderful contrapuntist: there is not only confusion in the
the parts and design, in many places, but something very harsh and unpleasing in the harmony, particularly in the closers without a sharp seventh, both in the key-note and in the fifth. The motet is in fixed parts, sopranos, two counter- tenors, tenor, baritone, and bafe. Some of these sevens would doubtless have been made sharp in performance by the finger of those times, in obedience to a rule for sharpening ascending sevens in minor keys, and flattening them in defcending.

The list of his works, in Walther's Dictionary, though ample, is far from complete. The motet Verbum bonum, just mentioned, was published at Fosfombrone in 1519, forty- three years before Zarlin made him an interlocutor in his dialogue (Ragionamente), at Venice; and it can hardly be imagined that no others of his compositions appeared till 1542, when, we are told, that his motets for fix voices were published. In the Flor di Motetti, lib. 1, Venice, 1539, there is a Pater-noster, in four parts, by Adrian; and in the same year the first book of his motets, for four voices, was republished in the same city. by Ant. Gardano, in folio, under the following pompous title: "Famofifimi Adriani Willaert, Chori Divi Marii illufrifsimi Reipublicae Venetiarum Magiftri, Mufica Quatuor Vocum (quæ vulgo Motetica nuncupatur) novior omní iudio, ac diligentia in lucem edita." This edition, which, we find by the title, was not the first, is preferred in the British Museum. Indeed, for near fifty years after his name first appeared, hardly a collection of motets or madrigals was published to which he did not contribute; but the most splendid and curious work of this author, that we have seen, is preferred in the British Museum. It was published at Ferrara, 1558, by his scholar and friend, Francesco Viola, another of the interlocutors in Zarlin's Ragionamente, under the title of Mufica Nova, in three, four, five, fix, and seven parts. In the dedication of this work to Alfonso d'Este, duke of Ferrara, the editor, his maestro di capella, calls Adrian (the name by which he is always mentioned by the Italians) his master, and says, that he is strongly attached to him, not only for his wonderful abilities in music, but integrity, learning, and the friendship with which he has long honoured him. Zarlin, in like manner, omits no opportunity of exalting the character of his master. These are honourable testimonies of regard, which seem the more worthy of being recorded, as, either from the worthlessness of the master, or ingratitude of the scholar, they are but seldom bestowed.

In the canzon part there is a wooden cut of the author: "Adrian Willaert Flandr. Effigies." And indeed the compositions are of that kind for which he was most renowned, and such as the editor thought would constitute the most durable monument of his glory. In the tenor part there are many canons of very curious construction; some with two and three clefs, and a different number of flats and sharps for the several parts, which are moving in different keys at the same time; and one particularly curious, in seven parts, "Præter rerum fieriem," of which three are in strict canon of the fourth and fifth above the guide; the tenor leading off in C, the fustus following in C, and the femina pars in D, while the rest move in free fugue.

Zarlin (P. iii. p. 268.) affirms to Adrian the invention of pieces for two or more choirs; and Pecetoni (Guida Armonica) says, that he was the first who made the bates in compositions of eight parts, move in unisons or octaves; particularly when divided into two choirs, and performed at a distance from each other, as they had occasion for a powerful guide. The dexterity and resources of this author, in the construction of canons, are truly wonderful, as is, indeed, his total want of melody; for it is scarcely possible to arrange musical sounds, diatonically, with less air or meaning, in the single parts. But there are many avenues through which a musician may travel to the temple of Fame; and he that pursues the track which the learned have marked out, will perhaps not find it the most circuitous and tedious; at least theorists, who are the most likely to record the adventures of passengers on that road, will be the readiest to give him a chart. A learned and elaborate style conceals the want of genius and invention, more than the free and fanciful productions of the present times.

Adriano lived to a great age, and filled a very high musical station, maestro di capella of St. Mark's church at Venice. His works and scholars were very numerous; and among those to whom he communicated the principles of his art, there were several who afterwards arrived at great eminence, such as Cipriano Rose, Zarlin, and Cofitano Porta. In the title of a book, published at Venice, 1549, there are "Fantasia," or "Ricercari," composed dallo excellenzissimo Adrian Vuilgart, and Cipriano Rose, suo discepolo. P. Martin, in his Saggio di Contrappunto, p. ii. p. 266. calls Adrian Willaert the master of Cofitano Porta: Burney, WILAFANS, in Geography, a town of France, in the department of the Doubs; 3 miles S.E. of Orans. WILAKALA, a town of Sweden, in Finland; 48 miles E. of Biernorge.

WILLAWARY, an Indian town on the N.W. coast of lake Michigan. N. lat. 47° 45', W. long. 87° 10'.

WILLDENOVIA, in Botany, received its name from professor Thunberg, in honour of Dr. Charles Lewis Willdenow, late professor of botany at Berlin, well known as the author of many learned botanical writings, but especially by his Species Plantarum, of which the immortal work of Linn€us, bearing the same title, is the basis. The addition of essential characters, and of many new species, besides those accumulated in profusion, with great intelligence and discrimination, from authors subsequent to Linneus, might entitle this to rank as an original work; were not the Linnean part of it too servile a transcript, not only of mistakes, of remarks contradicting each other, and of evidently false synonyms; but in general of errors of the press, and wrong citations of plates and pages, which prove that the respective books, though in every body's hands, were not consulted. The learned editor happily lived to complete the first part of the fifth volume, comprising the order of Ficus, in which he was well verified. That he left the rest of the Cryptogamia unattempted, is perhaps rather fortunate than otherwise. The Mucl, Lichen, and Fungi, each form a study by themselves, and are treated of separately by different authors. They would have added enormously to Willdenow's work, and could, after all, have proved but a compilation. If the science goes on as it has done, an universal botanist will be nearly as impossible a character as an universal naturalist is at present.

Another genus (see Schlechtendaia) was dedicated to Willdenow by Cavanilles, which is retained in Lamarck's Illustrations, t. 685, by the name of Willdenovia. The change of orthography at the conclusion we readily adopt, instead of the uncouth Willdenovia, or Willdenovia, and it is now likewise followed by Thunberg himself, in his Flora Capensis.—Thunb. in Stockh. Trans. for 1790, 26. Prodr. 14. Fl. Capens. v. 1. 312. Willd. Sp. Pl. v. 4. 717. Poiret in Lamarck Dict. v. 6. 177.—Clfs and order, Dioe- cia Triandra. (Triandra Monogyna; Thunb.—Nat. Ord. Tripetaloides, Linn. Junci, Julit, Rejilenses, Brown Prodr. v. 1. 243.

Gen. Ch. Male, Cal. Perianth inferior, of numerous, imbricated, membranous, pointed, permanent glumes, longer then
than the fruit. Cor. Petals fix, equal, erect, oval, membranous, permanent. Stam. Filaments three, capillary, shorter than the corolla; anthers ovate-oblong.

Female, Calyx and corolla as in the male. Tip. German superior, roundish; style very short, two or three-crested, stigmas two or three, downy. Peric. Drupa dry, roundish, smooth. Seed. Nut solitary, of one cell.

Female, Calyx and corolla as in the male. Style one. Stigmas two or three. Drupa with one seed.

Obi. This genus differs from Restio (see that article), chiefly in having a single-leaved drupa instead of a capitulum, opening by valves, and containing several seeds. We have here merely altered the phraseology respecting the calyx, which in Restio is termed, rather improperly, a catkin.

1. W. fritata. Striated Willdenovia. Thunb. in Stockh. Trans. for 1790, 27. t. 2. f. 1. Fl. Cap. v. 1. 312. Wildl. n. 1. Poiret n. 3. —Stem leafless, round, flattened. —Native of the Cape of Good Hope, as are likewise the two following species. The stem is two feet high, or more, erect, rusty, hard and rather shrubby, branched, usually simply forked, rarely three-forked, round, jointed, flat, smooth; the branches also round, flattened. Sheaths at each joint and subdivision solitary, ovate, close, brown, smooth. Leaves none. Flowers terminal, solitary, erect, the fize of a pea. Scales of the calyx about ten, rarely fewer, or more, loosely imbricated, equal, oblong, pointed, brown, smooth, the length of the nail, membranous at the edges. Petals ovate, acute, as long as the fruit. Style undivided. Stigmas three, feathery. Drupa ovate, compressed, obtuse, grey. Thunberg.

WILLERBROD, in Biography, the apothecary of Frieland, was an Anglo-Saxon, and born in Northumberland about the year 658, and educated in the abbey of Rippon, where he engaged in the religious profession. At the age of 33, he accompanied eleven of his countrymen into Batavia, and employed himself for three or four years in converting the Frisians who were under the French domination; and having met with great success, he went to Rome, and received from pope Sergius the pallium, ordaining him archbishop of Frieland. Pepin gave him a residence at Wilteburg, now Utrecht, of which he was the first prelate. Embarking from Frieland for the north, he penetrated into Denmark, and in his return was cast by a storm on an island called Fofeland, supposed to be the same with Heligoland. He afterwards baptized Pepin, son of Charles Martel, and spent the rest of his life in propagating Christianity among the Batavians. His colleague and assistant was Visfrid, his countryman, surmounted Boniface, the apostle of Germany. He died in 740, at the age of 82; was buried at his abbey of Eflernac, in the diocese of Treves, and honoured with canonization. His life was written by the celebrated Alcuin. Mosheim. Moreri.

WILLENSTADT, or WILLIAMSSTADT, in Geography, a strong town of Holland, situated upon that part of the Meuse called Buttermel, built in 1584, by William I., prince of Orange, from whom it receives its name. This fortress is one of the keys of Holland, and defended with seven bastions and double fosse; it has also a good harbour, but which is sometimes dangerous for vessels to enter at certain times of the year. It was besieged by the French in the year 1753, but by the brave resistance of the governor and garrison, aided by the English, with gun-boats, &c. the besiegers were compelled to retire with great loss; 12 miles S.W. of Dort. N. lat. 51° 41'. E. long. 4° 18'.

WILLERNBERG, or WILDBERG, a town of Prussia, in the province of Oberland; 93 miles S. of Königberg. N. lat. 53° 11'. E. long. 20° 53'.

WILLERING, a town of Austria, on the Donabe; 4 miles W. of Lintz.

WILLERSDORF, a town of Bavaria, in the bishopric of Bamberg; 5 miles S.W. of Forchem. WILLET'S Bay, a bay on the north-west coast of the island of St. Christopher, about a mile to the south-west of Dieppe Bay.

WILLIAM I., called "the Conqueror," king of England, and duke of Normandy, in Biography, was the natural son of Robert, duke of Normandy, by Arlotta, the daughter of a tanner, and born in 1024. When his father went on a pilgrimage to Jerusalem, and his son was only nine years of age, he caust the fates of the duchy to swear allegiance to William, as his heir. On his return in 1033, Robert died; and the conquefs was a variety of diftinctions among the barons of the duchy, in which Henry I. of France took a part; so that when William arrived at majority, he found his dominions in a low and disaffected state. But his vigour and exertions soon restored order and submission, and general tranquility through his duchy. Edward the Confessor, at this time king of England, had no children; and the archbishop of Canterbury, who was a Norman, recommended his adopting William as his successor, and he was commissioned by the king to inform the duke of his intention. However, as he had not publicly divulged his purpose, Harold, the son of earl Godwin, ascended the throne without opposition, on his decease.
in 1066. Harold, however, had previously taken a solemn oath to assist William in accomplishing the purpose of Edward respecting the succession; and his perjury excited the indignation of William, and induced him to prepare for disappointing Harold of the English throne by force of arms. His intentions were not sooner announced than he was joined by a great number of military adventurers; and upon an appeal to Rome, the pope sanctioned the contest, and sent him a consecrated banner. Thus encouraged, he assembled a fleet of 3000 vessels, and an army of 60,000 men; and determining on invading England, landed on September 28, 1066, at Pevensey, in Sussex. Harold, as soon as he received this intelligence, marched from York, and having recruited his forces at London, hastened to encounter the Normans, who were encamped near Hastings. On the 14th of October the two armies engaged, and after a severe battle, which lasted during a whole day, the English were defeated, with the loss of Harold and his two brothers. William lost no time in availing himself of this victory; but having reduced the town and castle of Dover, and received the submission of the Kentish men, proceeded towards London. In his way he was met by Edgar Atheling, who had been proclaimed legal heir to the monarchy, Stigand, archbishop of Canterbury, and some of the principal nobility, who made an offer to him of the crown; and on Christmassday, 1066, after a kind of tumultuous election, he was crowned at Westminster-abbey by the archbishop of York, and took the coronation-oath. Having adopted measures for conciliating his subjects, and overawing those who were adverse to him, he re-crossed the sea to Normandy, taking with him hostages Edgar, the primate, and several of the principal nobility. Soon after his departure, the English were treated contumeliously and oppressively by the Normans, whose conduct excited insurrections, and led to a conspiracy for the massacre of all who remained in the country. This intelligence occasioned William's return in December 1067; and among other measures of a more conciliatory nature, he improvidently renewed the tax called "dangelt," which excited insurrections through various parts of the kingdom. As soon as these insurrections were suppressed, his queen, Matilda, was crowned at Westminster; but new troubles arose from the union of the two principal nobles, Edwin and Morcar, with the kings of Scotland and Denmark, and the prince of North Wales, which threatened an extensive revolt. The conspiracy for this purpose was discovered and crushed, and measures were taken for preventing the evils that were likely to result from it. From this time William's government became daily more and more despotic; and the nobility of the country, perceiving that their ruin was the object of his contemplation, prepared to leave the kingdom. Insurrections broke out in various parts of the country, and the means which he adopted for suppressing them were in the highest degree rigorous and destructive. As a measure of future prevention, he brought from Normandy the feudal constitution into England, and divided most of the lands into baronies, which he granted to the most considerable of his followers, under the condition of certain services and payments; and these subdivided their shares on similar tenures, among others, chiefly foreigners, of inferior rank. The ecclesiastical property of the kingdom was regulated upon a similar footing; and under various pretences, the Normans superfed the English in the possession of all church dignities. In order to favour this expulsion of the English dignitaries, a legate from the pope was, for the first time, admitted into this country, and a reverence for the fee of Rome, similar to that which subsisted on the continent, was inculcated on all British sub-
jects; whilst the king took care, by referring certain powers to himself, to guard the civil sovereignty against papal usurpations. In order further to subjugate the minds of the English, and reduce them to the state of a conquered people, the king projected the abolition of their language; and by admitting at court no other language besides the French, he caused all the youth in the schools of the kingdom to be instructed in it, and the laws to be drawn up in that language, which was also used in all judicial pleadings and writings.

Having suppressed an insurrection which broke out in 1071 by the instigation of the earls Edwin and Morcar, and in the following year negotiated a peace with Malcolm, king of Scotland, he was called to Normandy in 1073, on occasion of a revolt in that country. In 1075 his presence was necessary in England to check a conspiracy among the Norman barons, whom he had distinguished by his favour, and who were joined by Waltheof, an English nobleman, on whom he had bestowed his niece Judith. Waltheof, in this conspiracy, fell a sacrifice to the treachery of his wife. In the following year, viz. 1076, the haughty and ambitious Hildebrand, who was now pope Gregory VII., required William to do homage for his kingdom to the holy see, alleging a promise to this purpose, and also to pay the accustomed English tribute. William denied his promise of homage, which he refused to render, but remitted to Rome the Peter-pence, and whilst he would not allow the English prelates to attend a general council summoned by Gregory, he permitted the pope's legate to convene a synod at Winchester for establishing the celibacy of the clergy. On his return to Normandy in this year, he found the country engaged in a civil war, in consequence of a rebellion excited by his son Robert. On this occasion the father and son had a personal encounter; but when the son discovered that he was thus engaged, he was struck with horror, fell at his father's feet, and implored forgiveness. The father was at first unrelenting; but they were afterwards reconciled. About the year 1081, William ordered that survey of the landed property of the kingdom to be made which is recorded in Domesday-book. (See DomEesy.) For an account of the impolitic as well as cruel manner in which he indulged his passion for the chase, we refer to the article Forest.) The latter years of his life furnished various occasions of affliction and disquietude. The death of his queen Matilda, to whom he was affectionately attached, was an event that took place in 1083, and was the cause of undiluted sorrow and lamentation. The preparations made by the king of Denmark and the earl of Flanders for an invasion of England occasioned to him no small degree of anxiety; and when he was rescued from this danger by the death of the Danish king, he was called into Normandy in 1086, to repel the incursions of some French barons; and suspecting that the king of France had instigated them to these acts of hostility, he commenced a war against him in 1087, in the prosecution of which he even laid waste the country at the approach of harvest by the most cruel devastation. But an accidental injury which he received in mounting his horse stopped his career, and terminated in his death. Alarmed by the near prospect of dissolution, his mind was harassed with remorse in the review of the atrocious conduct with which he was chargeable, and he sought relief by donations to the church, to which person of his characters have commonly referred, and by the pardon and release of some of his enemies. By his last testament he bequeathed to his eldest son Robert the counties of Normandy and Maine, and to his second son William, the crown of England, and to his third son, Henry, the property of his mother. He expired at the abbey of St. Gervais, near Rouen,
On but and very general. But his passions were strong, his disposition was severe and merciless, and his ambition and love of rule caused him to disregard all restraints of justice and humanity. There never was a more fortunate usurper of a throne, which he transmitted to a long and still fulfilling line of descendants; and the establishment of his dynasty is the most conspicuous era of English history." — Ralph Hume. Henry Lyttleton. Gen. Biog.

**WILLIAM II.** Furname Rufus, second son of the Conqueror, and king of England by his father’s nomination, was crowned at Westminister in September 1087, and recognized as king when he was about 27 years of age. His brother Robert succeeded to the dukedom of Normandy by the deposition of his father, which proved the occasion of much discontent and contention; partly because the great barons possessed estates both in England and Normandy, and under separate governments; and partly because Robert was the eldest son, and the most popular. A conspiracy was formed by the maternal brothers of the late king, in which many nobles concurred for deposing William. But William,possessing a certain portion of his father’s vigour, took measures for defeating them. With this view he conciliated the native English, took possession of the castles and persons of the unfortunate barons, banished them to Normandy, and bestowed their estates on his faithful adherents. When he was firmly seated on the throne, he forgot his promises of relieving the English from oppression, and even enhanced the severity of the forest laws. The death of Lanfranc, whom he respected, left him at liberty to seize vacant bishoprics and abbeys, and to bestow church lands on his captains and favourites. In 1099 he visited Normandy with hostile intentions respecting his brother; but a negotiation took place, and they were reconciled. Robert accompanied William to England, and commanded an army which was sent against Malcolm, king of Scotland. But a variance soon took place between the brothers, occasioned by the encroaching and treacherous disposition of William, which led him to excite the Norman barons to rebel against Robert. Whilst William was prosecuting hostile measures against his brother, he was recalled to England in 1095, to suppress a conspiracy among the barons in the north, whom he speedily defeated and severely punished. The spirit of crusading having at this time pervaded Europe, Robert was seized with the mania, and mortgaged his dukedom to William for 10,000 marks, in order to enable him to unite with the crusaders in 1096. William, having gone over to the continent to take possession of Normandy and Maine, was taken extremely ill, and apprehending danger, resolved to repair the injury which he had done to the church, and to supply the vacancy of the archbishopric of Canterbury, which had continued from the death of Lanfranc. The ecclesiastic nominated on this occasion was Anfelm, who, notwithstanding the disinclination he had manifested against accepting the appointment, was afterwards a zealous defender of the rights of the church, and of ecclesiastical authority in general. The king and the primate then disagreed; and though a synod was assembled for the deposition of the archbishop, the king failed in the attempt. But when Anfelm defined permission to leave the kingdom, he obtained leave; but his temporalities were seized, and the pope received him as a confessior in the cause of religion. William’s French acquisitions were the occasion of trouble to him; for whilst he was hunting in the New Forest, he received information that the citadel of Maine was besieged, and he therefore hastened to Dartmouth, and determined to embark without delay. As the weather was tempestuous, the mariners expressed some apprehension of danger; the king, however, was resolute and persevering, and asked them if they had ever heard of a king who was drowned. Having accomplished his object, he was applied to by the duke of Guienne, who was under the influence of the passion for crusading, for the loan of a sum of money, as a mortgage on his rich provinces of Guienne and Poitou. William accepted the proposal; but whilst he was preparing to carry over the money, and to take possession of the provinces, he was accidentally killed in the New Forest. Having alighted from his horse after a chase, a flag sprang up near him; and a French gentleman, Walter Tyrell, perceiving the animal, shot off an arrow, which glanced from a tree, entered the king’s breast, and penetrated to the heart. Tyrell immediately fled, and embarking for France, joined the crusaders. The king’s body was found by the country people, and interred without ceremony at Winchester. This happened on August 2, 1100, when the king was in the 40th year of his age, and the 13th of his reign. The character of William Rufus has been unfavourably represented, both on account of the depredations which he committed in the church, and of his indifference to religion. "The incidents of his reign," says a biographer, "prove him to have possessed vigour and decision, courage and policy; but to have been violent, pernicious, and rapacious, and void of all sense of justice and honour. One of his best public acts was the sending Edgar Atheling into Scotland, to restore prince Edgar, son of Malcolm, to the throne of that kingdom, of which he was the lawful heir. He deserves to be regarded as a promoter of the useful arts by his still-remaining erections of the Tower, London-bridge, and Westminster-hall." — Gen. Biog.

**WILLIAM III.** King of England, prince of Orange, and stadtholder of Holland, was the posthumous son of William II., prince of Orange, and of Mary, daughter of Charles I., king of England, and born on November 14, 1650, at a very interesting period. His guardianship was divided between the prince’s-royal his mother, the princes-dowager his grandmother, and the elector of Brandenburg. During the negotiations that succeeded the naval war between the English and Dutch republics, Cromwell, the protector, stipulated, that the prince of Orange, who was a branch of the house of Stuart, should be for ever excluded from the stadtholderate; but on the event of the Restoration, the prince’s-royal petitioned, in 1662, that her son might be invested with the offices and dignities which belonged to his ancestors; and soon after the act of exclusion against him was annulled. Although the states of Holland would not admit, as a condition of peace in the succeeding war between England and the United States, the preliminary proposed by Charles II. of elevating the prince to the stadtholderate, they formally adopted him as "a child of the state," and placed him under the care of persons who should inspire him with principles suited to his situation under a free government. After some subsequent debates concerning the rank which should be assigned him, he was raised in 1670 to the dignity of first noble of Zeeland, and then admitted into the council of state. On occasion of the war, which was declared by Lewis, and his pensioner Charles, against the United States in 1672, the public voice obliged the magistracy of Holland to revoke the perpetual edict procured by De Witt for abolishing the stadtholderate,
ate, and to confer that dignity with all its prerogatives upon William. Thus authorized by the States to change the regency in all the most considerable towns of Holland and Zealand, party opposition was extinguished, and every proposal for the defence of the country was unanimously adopted. The prince, at this early age, fully justified the confidence that was reposed in him by the firmness and elevation of his mind. At an extraordinary assembly of the states, he pointed out, in an elaborate speech, the pernicious consequences that must result from the “peace proposed by the French king, who was in possession of three of the provinces; he shewed the possibility of raising supplies for a war in defence of their religion and liberty; and by the cool intrepidity of his manner and force of his arguments, he produced such an effect upon his before-defending audience, that they concurred in the resolution of making every sacrifice, rather than defer the cause of their country. Vigorous measures were entered upon; foreign alliances were formed; fortunate circumstances prevented the further advance of the French, who evacuated the province of Utrecht; Charles II. was obliged by his parliament to make peace, in 1674, with the Dutch, who in the same year signed separate treaties with the bishop of Munster and the elector of Cologne; and at length the three conquered provinces were re-united to the States General, and the conduct of the prince of Orange so much ingratiated him with the states of Holland, that the offices of stadtholder and captain-general were declared hereditary in his male line.” In all his military actions, he displayed both courage and wisdom; so that the prince of Condé testified in his favour, that at the battle of Steen, “he had in every point acted like an old captain, except in venturing his life too like a young follower.” The humiliation of the French king seems to have been his favourite object; and with this view he wished to fix the English court in the same interest. This was one motive which induced him to connect himself more closely with the royal family, by a marriage with Mary, eldest daughter of the duke of York. Accordingly he came into England in 1678, and then the nuptials took place which were so satisfactory to the nation, and which were afterwards followed by the most important consequences. Without enlarging on the measures pursued by the prince on the continent, we shall direct our attention to those in which our own country was more immediately interested. The succession of the prince’s father-in-law to the crown of England in 1685, instead of strengthening the bonds of affinity by which they were attached to one another, served only to separate them more widely. The king was a bigotted papist, and the prince was regarded as a great supporter of the Protestant cause on the continent, and therefore they could not cordially concur in their views and operations. King James, whose object was to render the Catholic religion predominant, began with endeavouring to procure for it a free toleration in Great Britain, by a repeal of the penal laws and the test-act; and in order the more effectually to accomplish his purpose, he strongly solicited the prince of Orange to express his concurrence and that of the princely, but as they knew how unpopular the design was in England, they refused to grant it. About this time Lewis XIV., under the influence of his own bigotry, and that of those with whom he acted, repealed the edict of Nantes, which had secured the privileges of his Protestant subjects; and by his harsh treatment of them, drove numbers of them out of his dominions, and thus excited a dread and hatred of popery through all Protestant countries of Europe. The effect of this measure with regard to the prince of Orange was, that it supported all party opposition to him in Holland, and gave him additional importance in Europe, as the determined foe of French ambition. The arbitrary proceedings of king James alarmed all the friends of civil liberty, and of the established religion in England; and apprehensive of danger, they directed their views to the prince of Orange as their deliverer. Accordingly conferences were held with a confidential envoy whom he sent over to ascertain the public opinion; applications were made to the prince by several persons of rank; and at length, when the birth of a prince of Wales disappointed all hopes of a Protestant succession, the leading men of different parties concurred in actually inviting him to come over, and to undertake the protection of the church and constitution from threatening ruin. The prince consented, and with consummate prudence and secrecy prepared for the interesting expedition; and as exiling circumstances afforded a prospect of a breach between the United States and their allies, and the king of France, he was thus enabled to augment the Dutch forces by sea and land without suspicion. Having previously dispersed through the kingdom a declaration, stating the grievances of the reign, and announcing his intention of bringing over an armed force to defend the nation from tyranny, and to procure the assembling of a free parliament, he put to sea in October 1688, with a fleet of about 500 vessels, and an army of 14,000 men. He was once driven back by a storm, but a second attempt succeeded, so that he gained the English coast without opposition, (the king’s fleet being wind-bound,) and on the 5th of November disembarked his troops at Torbay. Of the causes, progres, and termination of the Revolution, we have given an account under the articles JAMES II. of England, and REVOLUTION. King William feated on the throne became sovereign of a powerful kingdom; but his tranquill possession of the crown depended on a variety of circumstances which he could neither directly nor controul. The conflict of different parties was not easily restrained; nor were his disposition and manners, which were cold and reserved, notwithstanding all his excellent qualities, adapted to unite and conciliate the partisans of the old and new government. Amongst those who had taken an active part in the late measures, or who had acquiesced during their progress, some were dissatisfied with the total exclusion of James and his infant son; and others could not approve the transfer of the crown by the will of the people. In Scotland, the appointment of William was the act merely of the whigs; and in Ireland, where the population was chiefly Catholic, the interest of James was predominant. The church zealots in England were not pleased with the tolerant principles manifested by king William, and with the wishes he expressed for the comprehension of the dissenters. Thus circumstances, the commencement of his reign was embroiled by the open opposition and secret intrigues of his enemies, and in the progress of it the collision of parties was the occasion of much personal disquietude both to him and to the queen. His attention was for a considerable time distracted by the state of his native country, when war with France was renewed in 1689, by James’s invasion of Ireland in the spring of that year, when his interest with the Catholics was powerful, and in which he was aided by the French king, and also by an insurrection of the Jacobite party in Scotland. Ireland feemed at this time to demand his principal exertions; for though marshal Schomberg had been sent over in 1689 to oppose the progress of the late king, little had been done to any important purpose. Accordingly in the summer of 1690, he embarked with a reinforcement for this country, and by the battle of the Boyne, in which Schomberg was killed, he
he routed the Irish army, and totally dispersed it. James abandoned the contest, and fled precipitately to France, leaving the reduction of the island to William, which was completely effected in the following year. Whilst he was thus engaged in military operations, a party spirit agitated his domestic government. The convention parliament, consisting of wigs, who were his decided friends, dreaded monarchical power, and refused to settle upon him the crown reversion for life. Hence he was led to dissolve the parliament in disgust; but he soon found that the new parliament, in which the influence of the Tories preponderated, though it readily indulged his desires with regard to the revenue, and voted liberal supplies for the Irish war, was composed of persons that were not real friends to the principles which placed him upon the throne. We shall leave to the details of history the events that occurred on the continent in the prosecution of the war against France; and proceed to observe, that in the year 1663 he suffered a severe loss by the death of queen Mary, who had proved herself an affectionate wife, and both faithful and zealous in promoting his interest; nor was his attachment to her less ardent and sincere. The decease of Mary revived the hopes of the Jacobites, and they were busy and active in forming conspiracies, not scrupling to concert the atrocious plan of assassinating the king. In 1667 peace with France was concluded at Rytwick, and Lewis was reduced to the necessity of acknowledging William as the lawful sovereign of Great Britain, and to make no future attempts for dispossessing him of his throne. The next contest, that engaged political parties at home related to the reduction of the military establishment. King William, attached to a military life, and not very confident with respect to his own security on the throne, wished to retain a greater force than parliament was disposed to allow; which was no more than 7000 men, who were to be all natives; so that he was under a necessity, though with great reluctance, of parting with his favourite Dutch guards. The next political object that engaged the king's attention was connected with the balance of power in Europe, and that was the succession to the crown of Spain, upon the death of Charles II., who was in a declining state of health, and who had no issue. In 1701 the king of Spain died, and left a testament in favour of the grandson of Lewis XIV., which will was accepted by the French king; and of course preparations were made by William and the Dutch for renewing the war with France. This measure was further rendered necessary by the death of James II., in the same year, and Lewis's acknowledgment of his son as king of Great Britain. On the meeting of the parliament at the end of this year, William made a speech on the state of affairs, on his own proposed conduct, and on the necessity of mutual confidence between the crown and people. This speech was much applauded, and was answered by a very loyal address. Thus was his reign, which had been distinguished by its vicissitudes and trials, and by the extensive and permanent benefits that resulted from it, drawing to its termination. A fall from his horse gave a shock to his enfeebled constitution, and brought on a fever, the issue of which he tranquilly expected; and he expired on the 8th of March, O.S. 1702, in the 52d year of his age, and 13th of his reign.

The character of king William has been variously delineated by political writers of different sentiments and dispositions. All allow that he possessed considerable political talents, and though in his military operations he was often unsuccessful, few persons exceeded him in his ability for repairing losses, and making a good close of a campaign. Although, as we have before said, his manners were cold and reserved, he was not destitute of sensibility. The partisans of James, and those who disapproved of the Revolution, have cenured his conduct in deposing his father-in-law; but public liberty and the welfare of a nation must be ever regarded as paramount to private duties. He never fought power otherwise than for accomplishing the important and beneficial ends to which his views were directed; and therefore he cannot be justly charged with a culpable degree of ambition. Whatever may be the opinion of erroneous and interested individuals of the Jacobites and Tories of more ancient or modern times, "he will ever be gratefully remembered," as one of his biographers says, "by the United Netherlands; as the great founder of their freedom and independence; and will be honoured as the deliverer of the British isles from tyranny, civil and religious, as long as a due sense of the benefits of that deliverance subsists among their inhabitants."

There are few more conspicuous instances of the power of the cultivated mind in the promotion of public affairs than William of Nassau, prince of Orange, and founder of the Dutch republic, who was born in Germany in 1533, and descended from Lutheran parents, though, being introduced into the service of Mary queen of Hungary, and afterwards of Charles V., he conformed to the Catholic religion. He was trained to military and civil employments of high rank; and as he had ample possessions in the Low Countries, he attained to the dignity of governor of the provinces of Holland, Zeeland, and Utrecht, under the Spanish government. His character is very highly drawn, and is said to have combined magnanimity, prudence, bravery, equanimity in all fortunes, singular penetration and sagacity, retentive memory, popular eloquence, and the art of conciliating men's affections. Upon the introduction of the inquisition by the bigotry of Philip II., a flame broke out in the Netherlands; and the prince of Orange, with the counts Egmont and Hoorn, did everything in their power to restrain the severity exercised on a religious account, and to induce the Spanish court to recall cardinal Granvelle, to whose influence solely they were owing; and in this effort they succeeded in 1564. On occasion of the faininary measures proposed in the councils of Philip, and carried into execution by the duke of Alva, the prince of Orange, the moderation of whose temper caused him to be suspected, surrendered his employments, and retired with his family, in 1567, to his brother at Nassau. Alva, having arrested counts Egmont and Hoorn, and occasioned them to be condemned and executed, cited the prince of Orange to answer charges of sedition and treason that were preferred against him; and on his non-appearance, his estates were confiscated, and his eldest son, a studen at Louvain, was carried off into Spain. William, who about this time seems to have declared himself a Protestant, levied an army with a view of penetrating into Brabant; but Alva's military skill defeated his purpose, and he was under a necessity of disbanding his troops. Still determined on relieving his country, he made another application in 1571 to several Protestant powers for succour, but they were all averse from encountering the power of Spain. At length he obtained from the court of France some supplies of money, and was then enabled to fit out a small squadron, which,
in 1572, took possession of the port of Brill. This trivial
successes routed the spirits of the Netherlanders, and several
places in Zealand and Holland declared for the Orange
party. At length a convention of nobles and deputies from
the principal towns in Holland took place at Dordrecht,
and forming themselves into an independent state, chose
William for their chief. Convinced by the massacre of
the Protestants in France, that it was in vain to expect
affiliation from that quarter, he dismissed his troops, and retired to
Holland; and whilst Alva was exercising his usual severity,
the people of Holland and Zealand alone remained in
arms against the Spanish government; and the preference of
William gave order and stability to the new republic. Altho-
ough the duke of Alva was recalled from his government
in 1573, the cause of independence was in a very precarious
state. However, in 1574, the states of Holland and Zea-
land conferred on William the sovereign authority over
the war, and formed a treaty of union and alliance with each
other. Peace with the court of Spain could not be obtained
otherwise than on terms which could not be accepted; and
the aspect of affairs in 1576 was very discouraging. At
length, however, the death of Requesens, who had succeeded
Alva as governor, and the deprivations to which the towns of
Brabant and Flanders were exposed, favoured William
in his efforts to accomplish a general union of the provinces of
the Low Countries for mutual defence; and this was
effected by the treaty, called the pacification of Ghent.
William was now justly regarded as the true patron of
public liberty. At the beginning of the year 1579, the
duke of Parma being the Spanish governor, the union of
Utrecht was signified, which was the basis of the confedera-
tion of the Seven United Provinces, all of which, by their
deputies, concur in forming it. When the separation of
the Catholic and Protestant Netherlands took place, the
latter, being distressed, sought the affiance of France, by
nominating, in 1580, the duke of Anjou, brother to
Charles IX. king of France, for their sovereign, and
re-nouncing their allegiance to Philip; but the administration
of Holland and Zealand was still entrusted with the prince
of Orange. Philip, desiring this measure to William, promised
an edict of proscription against him; in consequence of
which his life was in danger, and an attempt was made to
assassinate him. At length he fell a victim to the fanaticism
of a native of Franche-Comte, who was urged forward by a
Cordelier and a Jesuit, who, under pretense of business,
obtained access to him, and shot him through the body.
He fell, and ejaculating "My God! have mercy upon me
and thy poor people," instantly expired, on July 10, 1584,
having nearly completed his 52d year. He was interred
with great honour and solemnities of respect, at Delft. He
was four times married, and had issue by each wife. His
second son, Maurice, succeeded to his authority in the
United Provinces. (See Maurice.) William, having
been educated in a court, acquired the manners and habits
of a statesman, and was charged with diffimulation and proud
ambition. But his objects were always pure and patriotic,
and he zealously preserved the liberties of his country; and,
though he has been traduced by the advocates of despotism,
his remains have the highest tokens of respect from a people
who gratefully acknowledge him as the principal author
of their freedom and independence. 

William of Wykeham, an English prelate, was born in
1324, at Wykeham in Hampshire, and by the liberality
of a patron, educated at Winchester school, and afterwards
recommended to Edynsgord, bishop of Winchester, who intro-
duced him into the service of king Edward III. about his
23d year. Acquiring extraordinary skill in architecture, he
was appointed in 1356 clerk of the king's works in two
mansions, and surveyor of the royal works at the castle and
in the park of Windsor. The king was so highly satisfied
with his conduct in these similar departments, that he recom-
pended him by several preferments, civil and ecclesiastical.
In 1359 he was nominated chief warden and surveyor of the
royal castles of Windsor, Leeds, Dover, and Hadiam, and
of several other castles, mansions, and parks. Whilst he had
only the clerical tenure, he enjoyed many ecclesiastical
dignities; and, in order to his further advancement in the
church, he was ordained priest in 1362. In the following
year he was made warden and jurenoary of the royal forests
south of Trent, and in 1364 keeper of the privy-veal. He
was also chief of the privy-council, and governor of the
great council; and besides other civil preferments which he
enjoyed, he succeeded Edynsgord, in 1366, as bishop of Win-
chester, which paved the way for his elevation to the post of
high-chancellor in 1367, of which latter dignity, however,
he was divested in 1370. Thus possiably ample means of
municibns in a state of celibacy, and a liberal spirit, his pro-
fession as an architect led him to repair and erect numerous
buildings in his fee at an expense of no less than 20,000
marks. He also directed his attention to the improvement
and proper discipline of the religious houses comprehended
within his diocese. For the better education of his clergy,
he laid the foundation of a college in Oxford, which was to
be supplied with students from a feminary at Winchester. He
was interrupted, however, in his liberal designs of general
utility by an impeachment for misconduct in the administra-
tion of public affairs, occasioned by the influence of the duke
of Lancaster, who had conceived a prejudice against him;
and, in consequence of this impeachment, his temporalities
were feized to the king's use, and he was banished from court.
The clergy, however, interfered, and the people regarded
him as a sufferer from the duke's exorbitant power; so that
a tumult ensued, that procured the restoration of his tem-
poralities, and his recovery of the royal favour, a little while
before the king's death. During the turbulent reign of
Richard II. Wykeham conducted himself with caution, and
succeeded in the establishment of his two colleges. For that
alone he obtained a patent in 1370, and it was completed
in 1386. It is now known by the name of the New
college. His college or school at Winchester was finished
in 1393. He also undertook the repair of the cathedral,
which was a Saxon edifice of the eleventh century, and in
the course of ten years rebuilt in the Gothic style. (See Win-
chester.) In 1384 he was induced, against his inclina-
tion, to accept the office of high-chancellor, which he
resigned again in 1391, after having restored the public
tranquility. When the king recovered his authority, he
procured a parliament in 1397, which impeached several of
the commissioners, who had almost divested him of his au-
thority, of high treason; but Wykeham, who was one of
them, escaped with a forced loan of 1000l. He attended
the first parliament of Henry IV. in 1399, which depo-
sed Richard, but was not present at the council, which adjudged
him to perpetual imprisonment. As his health declined, he
was disabled from performing the duties of his office; and
therefore nominated coadjutor in his bishopric, settled all his
temporal and spiritual concerns, and with tranquility spent
his dismission from the world. This happened in September
1404, when he had finished his 80th year. His remains
were interred in his own chapel or oratory in Winchester
cathedral, where a tomb of white marble was erected to
his memory. Lowth's Life of William of Wykeham.

Biog. Brit.

3 M
WILLIAMS, Daniel, D.D. in Biography, an eminent non-conformist divine, was born at Wrexham, in Denbighshire, about the year 1643 or 1644. The disadvantages of his early education were counterbalanced by the natural vigour of his mind, and by future application. Devoting himself to the ministry among Protestant dissenters, he was one of the first who had resolution to engage in it, after the privations and sufferings which followed the Act of Uniformity in 1662. At the age of 19 years he was admitted a preacher among the Presbyterians, and for several years officiated occasionally in several parts of England. Being here in danger of persecution, he accepted an invitation to become chaplain to the countesses of Meath in Ireland, where dissenters enjoyed a greater degree of liberty; and some time afterwards he became pastor to a respectable congregation in Wood-lreet, Dublin. Here he continued for nearly twenty years, exercising his ministry with acceptance and usefulness, and conducting himself so as to maintain harmony with his brethren in the ministry, and to secure respect and esteem from the Irish Protestants in general. During his residence in Dublin, he married a lady of an honourable family, with a considerable estate. Towards the close of the reign of James II., his opposition to popery rendered his situation in Ireland unpleasant to him, and he therefore came over to England in 1687, and settled in London. Here he joined those ministers who opposed an address to the king on occasion of his dispelling with the penal laws; and by his firmness and intrepidity contributed in no small degree to their unanimous rejection of it. Out of his own funds, and by his wealthy connections, he procured relief for those Irish Protestants who sought refuge in London from the tyranny and persecution of Tyrconnel. After the Revolution in 1688, which was an event that gave him and his brethren inexpressible satisfaction, he was often consulted by king William on Irish affairs; and his reports concerning the abilities and character of Irish refugees, who were capable of serving the government, were duly regarded.

On occasion of his visit to Ireland, in the year 1700, for settling his own affairs, his conduct in the influences now specified was gratefully acknowledged. Towards the latter end of the year 1688, he was unanimously chosen pastor to a numerous congregation of Presbyterians in Hand-alley, Bishopsgate-street; and in this connection he spent the remainder of his days, devoting to charitable purposes the salary which he received from his congregation. With the famous Richard Baxter he cultivated an intimate acquaintance; and at his death, in 1691, he was chosen to succeed him at the Merchants' Tuesday lecture in Pinners' hall. Some of his fellow-leachers advanced what he conceived to be Antinomian tenets; and these dangerous notions he thought it to be his duty to oppose. Hence arose a suspicion of his orthodoxy, and an attempt to exclude him from the lecture. Their design was frustrated by a majority of the subscribers; but as their opposition was inveterate, it was thought most advisable to separate and to establish another Tuesday lecture at Salters' hall. Three of the most respectable of the old lecturers, viz. Dr. Bates, Mr. Howe, and Mr. Allop, succeeded with Williams.

Upon the publication of the works of Mr. Crisp, who avowed himself the champion of Antinomianism, Mr. Williams undertook to refute them; and in 1692 published his "Gospel Truth stated and vindicated, &c." 8vo.; a work which, though now almost forgotten, was deservedly approved by the principal London ministers of that period; and as it is distinguished by great clearness and strength of argument, as well as a truly Christian temper, it served to check the pernicious errors which were then indifferently circulated. It was defended by the author in his "Defence of Gospel Truth, &c." 8vo., and in a "Prefcript" to a new edition of his work, and also in other pieces. Against the charge of Socinianism, an appeal was made to Dr. Stillingleet, then bishop of Worcester, and Dr. Jonathan Edwards of Oxford, who were deemed masters and judges in this controversy; and they, honourably acquitted the author, with many expressions of respect for him. Disappointed in their efforts to induce a suspicion of his orthodoxy, his enemies indulged their malignity further by arraigning the purity of his morals. Indignant as he well might be at this attack, he submitted his conduct to the investigation of the United London Ministers, who concurred in the report of their committee, "that he was entirely clear and innocent of all that was laid to his charge." The attachment of his congregation, it should be observed, was not in the least degree diminished by the malignant misrepresentations of his enemies.

In the year 1701, Mr. Williams, after having been for some time a widower, married a second wife of considerable fortune and distinguished worth, who survived him.

During the reign of queen Anne he exerted himself, though ineffectually, in opposing the bills against occasional conformity, and for imposing the sacramental toll upon the dissenters in Ireland. In 1707 he used all his influence with his friends in Scotland in promoting the union between the two kingdoms; and in the year 1709 he was honoured with the degree of D.D. by the universities of Edinburgh and Glasgow. Availing himself of his long acquaintance with the earl of Oxford, he took the liberty of remonstrating against the political measures which he was purifying. The doctor's frankness did not please the statesman; and his remonstrance against him for declaring unfavourable sentiments of the ministers of his administration, and communicating them to his friends in Ireland, was deep and permanent. Upon the accession of king George I., he had the honour of presenting an address of congratulation to his majesty, at the head of the Protestant dissenting ministers of the different denominations residing in London and its vicinity; and it has been ever since the custom for the body of such ministers to present addresses on all public occasions, and they have the honour, as a body, of being received on the throne, and by their committees in the closet, and of receiving a written answer. Soon after the accession of George I., the health of Dr. Williams began to decline; and at length an apoplectic disorder terminated his life on January 26, 1715-16, in the 73rd year of his age. In the sequel of this article we shall take advantage of literally transcribing the well-written account given of Dr. Williams by the Rev. Mr. Morgan, the highly respectable and much esteemed librarian of the excellent institution which he has established; under whose inspection and care this library is gradually rising into a reputation, which, by the contributions of its friends in books and money, and by the annual appropriation of a small sum out of the surplus of its founder's bequests, will vie with the principal establishments of a similar nature in the city of London.

"He had been blessed by nature," says our biographer, "with a strong and vigorous constitution, and possessed a sound penetrating judgment, and great strength of memory. The subjects of his pulpit performances were always practical and useful; his sentiments solid, pertinent, and distinguished by an uncommon variety; and his manner of enforcing them powerful and impressive. He was remarkable for his boldness and courage in avowing and defending what he
he conceived to be truth of importance, and 'pursued what he thought right with a blunt integrity and unshaken resolution.' At the same time his candour towards those who differed from him, his kind treatment of persons who had endeavoured to injure his own reputation, and his conscientious tender regard for that of others, were prominent features in his character. He was a steady non-conformist upon principle; yet he maintained a charitable dispositions towards the established church, and at the Revolution was very desirous of promoting the scheme of a comprehension.

Though he possessed an ample fortune, he exercised great frugality in his personal expenses, for the noble purpose of being more useful to others who stood in need of assistance, and of more effectually serving the great interests of truth and virtue. The same laudable views governed him in the final disposal of his property. By his last will, besides liberal benefactions to numerous benevolent and charitable institutions in London and Dublin, he provided for the support of an itinerant preacher to the native Irish, of two persons to preach to the Indians in North America, and of several charity-schools in England and Wales. He directed that a certain fixed sum, from the income of his estates, should be appropriated to the assistance of poor ministers, the widows of poor ministers, students for the ministry, and to other benevolent purposes. He also left estates to the university of Glasgow, which at present furnish handsome exhibitions to fix students for the ministry among Protestant dissenters in South Britain, who are to be nominated by his trustees. The laft grand bequest in his will was for the establishment of a library in London, for the benefit of the public. Having formed this design, he purchased Dr. Bates's curious collection of books, which he added to his own, and directed his trustees to provide a proper building for their reception. Such an edifice was erected by them in Red-Cross-street, Cripplegate, where the library was opened in 1729, and admission to it is easily obtained by persons of every description, without any exception, upon application to one of the trustees. Since it was first established, very considerable additions have been made to it by legacies, as well as gifts of money and books; and it now contains upwards of 16,000 volumes, many of which are very valuable and rare, in the various departments of literature and science. The founder's works were collected together, and printed at different periods, in 6 vols. 8vo.; the last consisting of Latin versions of several of his tracts, which he directed to be published in that language for the use of foreigners.' Memoir prefixed to his Works.

WILLIAMSON, in Geography, a township of Pennsylvania, in Northampton county, with 1243 inhabitants; 60 miles N. of Easton.

WILLIAMSON's Port, a town of Maryland, on the Potomack; 5 miles S.W. of Hagers Town.

WILLIAMSON's River, a river of Vermont, which runs into the Connecticut, N. lat. 43° 10', W. long. 72° 24'.

WILLIAMSBOROUGH, a poll-town of North Carolina, on a creek which falls into the Roanoke; 48 miles N.E. of Hilliborough.

WILLIAMSBURG, a county of the state of South Carolina.—Alfo, a county of the state of Virginia.—Alfo, a town of Virginia, situated on an isthmus between York river and James river, a creek from each river coming up within a mile of the town, but not navigable for large vessels. It was at one time the seat of government and residence of the governor, now removed to Richmond. It contains about 200 houses, and 1200 inhabitants. The principal buildings are a college and town-hall, an episcopal church, and an hospital for lunatics; 50 miles E.S.E. of Richmond. N. lat. 37° 13'. W. long. 76° 50'.—Alfo, a town of Massachusettts, in Hampshire, with 1122 inhabitants; 8 miles N.W. of Northampton.—Alfo, a town of New York, on the Genesee; 288 miles N.N.W. of Philadelphia.—Alfo, a town of the state of Ohio, on the Little Miami, in the county of Clermont, with 1251 inhabitants.—Alfo, a town of Maryland; 4 miles N. of Talbot.

WILLIAMSBURG, or Jones-town, a poll-town of Pennsylvania; 23 miles E.N.E. of Harlirgton.

WILLIAMSON, a township of Ontario county, in New York, 266 miles from Albany, bounded N. and W. by lake Ontario. In 1810 the whole population consisted of 1139 persons, and it had 55 senatorial electors. A red oyx of iron is found in this town, which is a good pigment for painting.

WILLIAMSON, a county of West Tennessee, with 13,153 inhabitants, including 3085 slaves.

WILLIAMSPORT, a poll-town of Pennsylvania, on the west branch of the Susquehanna, in the county of Wyoming, with 344 inhabitants.

WILLIAMSTOWN, a township of the state of Vermont, in Orange county, with 1553 inhabitants; 60 miles N. of Norwich.—Alfo, a poll-town of New York, on the Mohawk; 55 miles W. of Cleveland.—Alfo, a town of Massachussetts, in the N.W. corner of the state, in the county of Berkshire, with 1843 inhabitants; 132 miles W.N.W. of Boston.—Alfo, a poll-township of Oneida county, in New York, erected in 1825, from a part of Mexico, and consisting of two townships of Scriba's patent, each being six miles square. The population in 1810 consisted of 562 persons, and 82 senatorial electors. The post-office was established in 1812.

WILLICHA, in Botany, was so called by Mutis, after Dr. Christian Lewis Willich, a physician at Clathual, in Lower Saxony, who published at Gottingen, in 1747, 1762, and 1766, various observations and illustrations of Botany, of more or less importance, chiefly relating to the determination of species and their synonyms, with cursory remarks on variations or irregularities of structure, exceptions to received characters, &c. The author died in 1776.

WILLIAMSTOWN, a township of the state of Vermont, in Orange county, with 1553 inhabitants; 60 miles N. of Norwich.—Alfo, a poll-town of New York, on the Mohawk; 55 miles W. of Cleveland.—Alfo, a town of Massachussetts, in the N.W. corner of the state, in the county of Berkshire, with 1843 inhabitants; 132 miles W.N.W. of Boston.—Alfo, a poll-township of Oneida county, in New York, erected in 1825, from a part of Mexico, and consisting of two townships of Scriba's patent, each being six miles square. The population in 1810 consisted of 562 persons, and 82 senatorial electors. The post-office was established in 1812.

crescent, hairy, an inch in diameter; reddish underneath. Flowerstalks very long, hairy, thicker than the stem. Flower-flax axillary, in pairs, single-flowered, thread-shaped, hairy, the length of the flowerstalks. Flowers small, rose-coloured, with a hairy calyx.

There is no specimen in the Linnean herbarium.

WILLISTON, in Geography, a post-town of Virginia; 242 miles S.S.W. of Washington.

WILLIMANTIC, a river of Connecticut, which runs into the Shattuck at Windham.

WILLINK, a large township of New York, at the S. end of Niagara county, erected in 1808; 315 miles W. of Albany. It comprises about eighteen townships of the Holland company lands. The general character of the soil is, that it is good land for farming. In 1810 the population consisted of 2028 persons, and there were 260 senatorial electors.

WILLING's CREEK, a river of West Florida, which runs into the Mississipii, N. lat. 30° 49'. W. long. 91° 21'.

WILLINGBOROUGH, a town of New Jersey, in Burlington county, with 619 inhabitants; 14 miles N.E. of Philadelphia.

WILLINGTON, a town of Connecticut, in Tolland county, with 1161 inhabitants; 6 miles E. of Tolland.

WILLIS, BROWNE, in Biography, an eminent antiquary, the grandfather of Dr. Willis, a celebrated physician, was born at Blandford in 1662, and was removed from Westminster-school in the year 1692 to Oxford, where he was admitted a gentleman-commoner of Christ-church; and after leaving the university he prosecuted his studies for three years under Dr. Wotton. When he came into possession of the family estate, he was returned in 1705 as a representative for the town of Buckingham. In 1715 and 1716 he published two parts of a work, intitled "Notitia Parliamentaria; or, a History of the Counties, Cities, and Boroughs in England and Wales, with Lists of all the Knights, Citizens, and Burgesses," 8vo., to which in 1750 he added a third part, being an appendage to the journals of the house of commons, then printed. On the revival of the Society of Antiquaries in 1717, he was chosen a member; and he sustained his reputation as an antiquary by various writings, amongst which are, "Surveys of the Four Welsh Cathedrals;" "History of the United Parliamentary Abbeyes and Conventional Cathedral Churches;" "Survey of the Cathedrals of England, with Parochial Anglicanum," 3 vols. 4to.; "History and Antiquities of Buckingham." In 1723 he received, in consideration of his literary merit, from the university of Oxford, the degree of A.M. by diploma. He manifested his attachment to the church by expending considerable sums in repairing those in the country, and thus injured his own fortune. But frugality in his personal and domestic expenses compensated this injury. He possessed a fine cabinet of English coins, which in 1741 he presented to the university of Oxford; the university, in consideration of his family, liberally paying for those of gold by weight, and conferring upon him the degree of L.L.D. With many peculiarities in his character, he claimed respect as a man of moral worth from those who knew him. To him belonged the honour of having first placed the English ecclesiastical history and antiquities upon the firm basis of records and registers, which he assiduously sought. He died in 1760, in the 76th year of his age. Biog. Brit.

WILLIS, THOMAS, an eminent physician, was born in 1622-3, at Great Bedwin, in Wilts; and in 1656 admitted into Christ-church college, Oxford, where he took the usual degree with a view to the clerical profession. But he changed his purpose, and studied physic, taking his bachelor's degree in 1658, and commencing medical practice at Oxford. He distinguished himself by his steady attachment to the church of England, and also by his love of science, so that he became one of the first members of that philosophical society at Oxford, which laid the foundation of the Royal Society of London. As a chemist, which was the character under which he was ambitious of excelling, he published in 1659 a work, intitled "Diatribe de quinacria; prior agit de Fermentatione, altera de Phæbus. His accedidit Differtatio Epistolica de Urinis." The recompense of his attachment to the cause of episcopacy and loyalty was the Sedleian professorship of natural philosophy at Oxford, conferred upon him after the Restoration, by the recommendation of archbishop Sheldon, soon after which he received the degree of doctor. Upon the establishment of the Royal Society, he was one of its first members. In the year 1664, when he was on the point of being discovered, and brought into use, the mineral water of Attop in Hampshire, he published his "Cerebri Sanequ; quic accedent Nervorum Defertitio et Ufina." This work, on which his reputation principally depends, was followed in 1667 by his "Pathologia Cerebri et Nervi Generis, in qua agitur de Morbis convulsivis, et de Scorbuto." Before this year he was settled in London, and being nominated a physician in ordinary to the king, was advancing to the first rank in practice. His next publication was intitled "Adfcriptionem quanti dicaturus Hypherae et Hypochondriacae Pathologia Spafmodica, vindicata contra refpoumonem epistolarem Nanth. Highrneri. Cui acceduerunt Exercitationes Medicas, Phycicae de Sanguinis Accensione, et Motu muculari," 1670. On occasion of the loss of his wife, a daughter of dean Fell, he amused himself by writing his work "De Animae Brutorum que Hominis Vitalis ac Senitiva et Exercitationes duce," 1672, in which he considers the soul of brutes as the same with the vital principle in man, corporeal in its nature and perishing with the body. After his second marriage, he began to print in 1673 his "Pharmaceutica Rationalis, sive Diatribe de Medicamentorum Operationibus in Humano Corporis;" but he did not live to publish this work, as he was carried off by a pleurisy in 1675, at the premature age of 54, in the full vigour of his faculties and zenith of his reputation. Dr. Willis had no powers for appearing with advantage and brilliancy in society; but he was intent on science and practice, frugal, pious, and charitable. His works engaged great attention on their first publication; but in consequence of modern improvements, they have sunk in the public estimation, though they are not altogether neglected. They are written in a rich and elegant Latin style. Haller. Biog. Brit.

WILLIS, in Geography, a town of the state of New Jersey; 33 miles S.E. of Burlington.

WILLIS's CREEK, a river of Virginia, which runs into James river, N. lat. 37° 40'. W. long. 78° 18'.

WILLIS'S ISLAND, a small island in the South Atlantic ocean, near the north-west coast of the island of Georgia, so named by captain Cook, from one of his crew who discovered it in the year 1775. S. lat. 54°. W. long. 38° 25'.

WILLISAU, a town of Switzerland, and capital of a bailiwick, in the canton of Lucerne; 15 miles W. of Lucerne.

WILLISTON, a post-town of the state of Vermont, in the county of Chittenden, with 1195 inhabitants; 25 miles N. of Newhaven.

WILLISTOWN, a township of Pennsylvania; 15 miles S.W. of Philadelphia.

WILLMAR, a town of the county of Hesseberg; 7 miles S.E. of Meinungen.
WILLOBOCKE, a river of Yorkshire, which runs into the Swale.

WILLONGTALYS, a lake of Vermont. N. lat. 44° 45'. W. long. 71° 58'.

WILLSHAW, a town of England, in the county of Warwick, situated on a navigable canal, on the borders of Northamptonshire; 14 miles S.E. of Coventry.

WILLSHAW Bay, a bay on the south-east coast of the island of Antigua. N. lat. 17° 10'. W. long. 61° 25'.

WILLSHAW Lake, a lake of the state of Vermont.

WILLOW, &c., in Botany. See SALIX.

Our common willows in the spring season, when they are in flower, produce a quantity of cottony matter, which might be put to some use.

The Chinese are industrious enough to collect this cotton as it falls from their willows; and the women and children, among the poorer people, card it, and pick out the seeds, and render it fit for many uses in the place of cotton.

The poor people, in some part of the Indies, make a fort of liquor of the flowers of their willows before they are opened, which intoxicates them very suddenly; and the dry hulls of the same tree remaining after the flowers and seeds are fallen, are wholesome as food, people in time of famine having lived upon them, boiled in water.

The wood of the willow, though in itself very light and fpongy, is yet of a nature to bear the injuries of wet better than almost any other kind. It is used by the Chinese on this occasion, in the making of their wells, and on all other occasions where wood is to stand under water, and succeeds perfectly well. Observ. sur les Coutumes de l'Asie. For the uses to which willow-bark and wood are applied, see SALIX, and GUNPOWDER.

WILLOW, in Agriculture, a well-known tree, of which there are several different species or kinds; but those mostly cultivated for farm purposes are, the common white willow, the purple or red willow, the fallow, and the broad-leaved or Huntingdon willow.

The first is a tall-growing tree, of the deciduous kind. It has a fine silvery appearance in the leaves; is quick of growth, and the wood is very useful where lightness and cleanness of the grain is beneficial, as for hurdles, gates, hop-poles, &c.

The second is a free-flowering willow; but its wood is inferior for many uses, especially those of the farmer.

The third fort delights in a rather dry soil, being a tree below the middle growth. It has numerous branches, of a smooth appearance, and dark green colour. Its wood is very useful for hurdles and other similar purposes of the farmer.

It has two varieties, the long-leaved, and the striped fallow, both which are very useful.

The fourth, or red-hearted willow, is supposed by some as the best fort for planting, for the use of the farmer, as growing quickly; but the great use to which they are applied is that of making hurdles, stakes, gates, and farming implements, being a wood uncommonly tough and light, owing, as is conceived, to a new method used in planting them close to the ground. If it is the design of the planter to let them grow into timber, (which would be far superior to deal for the purpose of flooring, or other light work, particularly as it will neither splinter nor fire; and if suffered to remain for twenty or twenty-five years, would make good masts for small craft, as they shoot up perfectly straight, and without any collateral branches,) it is necessary, at the first or second year's growth, to observe which pole is the strongest, as the remaining poles must be cut away. In about fifteen years' time it is supposed they will want thinning; of course the inferior must be taken out and the superior be suffered to remain.

In cultivating them on walle moist lands, laying out the ground into lands, like hop-lands, as from three to four yards wide, with a ditch on each side; three feet wide at the top, one foot at the bottom, and two and a half deep, is advised by a late writer as the best mode from much experience. The earth that comes out of the ditch should be thrown on the land. But if there is not fully sufficient fall for the water to get off, the ditch should be deeper and wider, till there is near a yard of earth above the level of the water. As soon as this is done, the ground must be double ploughed, that is, trenched two spades' depth, except it be very boggy, which will afford room for the plants to shoot, and will save the expense of weeding, which otherwife must be incurred in the first summer after the plants are set; for if they are not kept clear of weeds the first year, the hopes of the planter will certainly be destroyed.

In respect to the times of planting, they must be from January to the end of March; but the fets for that purpose should be cut from December to the end of February, when the sap is down. And the reason is, that if poles are cut in the spring (the sap being up), the fow will at least be weakened by bleeding, if not killed; and of course prevented from shooting so vigorously as if cut at the preceding time.

In regard to the fets or truncheons, they may be cut from twenty inches to two feet long; particular care should be taken in the cutting, that the bark be not friged or bruised, or in any other respect injured; for in that case the fow will be weak and puny.

The poles have been sold at eight years' growth for 214l. per acre, net-money; the kids or brushwood pay for the felling. Had they been suffered to have fow two years longer, they would, it is said, have produced 300l. per acre.

The plantation of the balket and cooper's willow is an object of importance in those walle and neglected corners which are to be found upon every estate and farm.

The refuse dwarf willows or offal, as it is termed, are used in the fisheris and balket-work, and will pay, comminibus annis, for the labour. The cooper's willow differs from the common or balket-willow; the former is known by a single bud or eye throughout the rod, which simply throws out a leaf; the latter by a double or flattened eye, which produces a branch or sprig. The former is applicable to every purpose; the latter the cooper rejects: of course the former should be propagated.

Plantations of the willow kind have been vastly increased, indeed, in many parts of the country within these few years.

WILLOW-GALLS, in Natural History, the name given by authors to certain protuberances found very frequently on the leaves of the several species of willow, which are properly galls, each containing the worm of a fly, and owing its existence to that insect.

The galls are usually of a roundish or oblong figure, and are equally protuberant on each side of the leaf: they are of a pale green at first; but they afterwards become yellowish, and finally reddish. The surface of these is seldom perfectly even, but usually has several little prominences and cavities in it. When this gall is opened, there is found in it a worm resembling a caterpillar in figure, having a smooth annulated body, a hard brown head, and twenty legs; and by Reaumur called falfe or ballard caterpillar. This creature, when the gall is young, is blue; it afterwards becomes greenish; and finally, when the gall becomes red, it is white. This insect seems to eat in its prison more voraciously than any
any other gall-infect whatever; for while the gall grows in size, it becomes also thinner in every part; so that the creature, at the proper time, has but little difficulty to get out. Foraum. Hift. Insect. vol. vi. p. 211.

When the time of the last change of this infect draws nigh, it leaves the tree, and defending to the earth makes its way into it in a proper place, and then becomes a nymph, out of which at a proper time issues a four-winged fly.

The flies which are produced in April copulate almost as soon as freed from their exuviae of the chrysalis state, and the females soon after lodge their eggs in the leaves of the willows. This is all done before the end of April, and the young ones hatched from these eggs live but a short time before they pass into the chrysalis state, and flying flies are hatched from these in June. The young ones of this brood pass their chrysalis state in the earth, and appear not during the whole winter, till the spring fun enlivens them again. There is, beside these, another kind of galls of the willow-leaves, which are of the class of those, each of which contains several cells; in each cell of these there is found a small white maggot, the offspring of the egg of a two-winged fly, which, after passing the chrysalis state in the earth, also comes out in the form of its winged parent. The cells in the galls are different in number in the several galls, and are from four or five to twenty: they have no communication with one another, but each worm lives in its own cell.

Beside these there is also sometimes found in these galls a worm of a brownish-white colour, having two hooks in its head, and no legs at all. This has all the appearance of a carnivorous animal, and probably was deposited there in the egg-state by its parent, not to feed on the gall, but on its defenceless inhabitant. This worm finally becomes a small blue-colored beetle, and is often found alone in the cavity of the gall, often in company with its proper inhabitant, feeding on its juices as it feeds on those of the plant. There seem to be several species of these devourers common to these galls; since Vallisneri observed, in the boxes where he kept these galls to produce the animals from thence, many species of small beetles, and several distinct kinds of flies, which were probably the last state of several kinds of carnivorous worms, which had preyed upon the proper inhabitant of the galls. Vallisneri, Dialog. des Insect.

EPILOBII, or French Willow, in Botany. See EPILOBIUM.

WILLOW, or French Willow, in Botany. See EPILOBIUM.

WILLOW-HERB, or French Willow, in Botany. See EPILOBIUM.

WILLOW, Sweet, Dutch Willow, Gale, or Candle-Berry MYRTLE, in Botany. See CANDLE-BERRY TREES, and CANDLE-BERRY MYRTLE.

WILLOW-WOOD, in Agriculture, a term provisionally applied to smart-weed, or percirica, which is a troublesome weed on many places in the corn-fields and other tilage-lands. See WeED.

WILLS, in Geography, a town of Ohio, in the county of Guernsey, with 659 inhabitants.

WILLSBOROUGH, a post-township of Essex county, in New York, with a post-office, 530 miles from Walling- ton, erected in 1778, then in Clifton county, and very extensive; from which several towns have been since created. It is bounded N. by Chesterfield, E. by lake Champlain, in the state of Vermont, S. by Essex, and W. by Lewis. Along the lake the land is level and tolerably productive. A small well-drain affords many fites for water-works; and iron ore of the best quality is found in great abundance. The population consists of 668 persons, and the senatorial electors are 57. Here are, one distillery, a forge for making bar-iron, an anchor-shop, a carding-machine, and a clothier, besides a considerable number of grain and saw mills.

WILLSBOROUGH, a township of New York, near Crown Point.

WILLSTADT, a town of Sweden, in the province of Smaland; 50 miles W. of Wexio. — Also, a town of Germany, in the county of Hanau Lichtenberg; 7 miles S.E. of Strafsburg.

Gen. Ch. Cal. Perianth inferior, of one leaf, fleshy, in five deep acute segments, very small. Cor. of one petal, faver-shaped: tube cylindrical, enlarged at the bottom: limb horizontal, in five deep, oblique, acute, wavy, segmental, more dilated at one side than the other, lying over each other at the base. Stam. Filaments five, very short, inserted into the tube just above the base; anthers arrow-shaped. Fl. German superior, roundish: style quadrangular; Stigma capitata, ovate, thick, fringed, double-pointed, subtended by a flat orbicular disc. Peric. Berry ovate, coated, of one or two cells. Seeds numerous, angular, compressed, imbedded in pulp.

1. W. acida. Acid Willughbea. Willd. n. 1. (Amelabia acida; Aubl. Guian. 266. t. 104.)— Stem erect. Flower-flakes the length of the foot-flakes.—Native of extensive forests in Guiana and Cayenne, bearing flowers and fruit in September. The trunk of this tree is feven or eight feet high, and seven or eight inches in diameter, with a greyish bark, and soft white wood. The seed-flakes of very numerous, straight, knotty branches, subdivided in an opposite manner. Leaves opposite, on short flaxes, elliptical, somewhat pointed, entire, wavy, smooth and shining, with one rib, and many transverse parallel veins; their greatest length seven inches, by three in breadth. Flowers axillary, three or four together on one common inflorescence, which is hardly so long as the adjoining foot-flake. Bracteas scaly, solitary, at the base of each general as well as partial flake. Corolla whitish, scarcely so large as that of Vinca minor. Fruit yellow-coloured, oval, succulent, or warty, two inches long, separated by a longitudinal fleshy partition, into two cells, filled with acid viscid pulp, and containing many brown rough seeds. This fruit, though milky, is wholesome. After the rind is taken off, the remainder is foaked for a while in water. The flavour is agreeably acid, notwithstanding a great degree of viscidity, by which the pulp adheres to the lips and teeth. The fruit with or without its rind, is preferred in fugar. In the latter flate it is cooling, slightly acid; in the former moderately purgative, and efficaciously useful in dysenteries. The whole plant when wounded discharges a milky, very tenacious juice.

WIL

Native of woods about the mouth of the creek of the Galbis in Guiana, bearing flowers, as well as fruit, in May. The trunk is about three inches in diameter, fending long, knotty, trailing branches, which twine round the neighbouring trees to their very summits, from whence the extremities hang down, clothed with opposite, oval, smooth, entire leaves, not unlike the foregoing, and about as large, on short flanks; their rib, as well as lateral veins, are prominent and reddish. The flower-flanks are axillary, solitary, wavy, alternately branched, refembling tendrils, terminating in several long tufts, or umbels, of yellow flowers, rather smaller than the first species. Fruit roundish or obovate, the size and colour of a guinée, of an agreeable scent when ripe, pulpy, yielding but a small quantity of milky juice if cut, though all the other parts of the plant contain a great quantity of the same kind of glutinous milk as the preceding. Aublet does not mention any use to which this species, or its fruit, is applied.

WILLUGHBY, Francis, in Biography, was born in 1635 of a good family in Lincolnshire, and educated in Trinity college, Cambridge, under the tuition and in habits of friendly intercourse with the excellent philosopher and natural historian, John Ray. They were intimate associates, and made a foreign tour together in the years 1663 and 1664. To birds and fishes Willughby paid particular attention, and he formed a rich museum of animal and fofile productions. In 1668 he married the daughter of Sir Henry Bernard, and his family residence at Middleton, in Warwickshire, was the place of Ray's frequent refor, where he and his host prosecuted their philosophical experiments and observations, the result of which they communicated to the Royal Society, of which they were both members. This instructive and pleasant intercourse was, however, prematurely interrupted by the death of Willughby in 1672, at the age of 37. His confidence in Mr. Ray was manifested by appointing him one of his executors, and committing to him the charge of educating his two infant sons, bequeathing to him an annuity for life as a compensation. Ray acquires to him, without any trace of adulation, singular moral excellence and high mental endowments. His polished and elegant writings, published under the inspection of Mr. Ray, was entitled "Francisci Willughbi Arm. Ornithologiae Libri tres; in quibus Aves omnes haecetenus cognitae, in methodum natura suis convenientem redactae, accuratim describuntur. Descriptiones iconibus elegantissimis et vivarium avium similiis æxi incisulis illustrantur. Totum Opus recognovit, digestit, supplevit Johannes Raus," Lond. fol. This work was also translated into English by Ray, and published in 1671 with large additions. Mr. Ray also collected and arranged Willughby's papers on Ichthyology. He added the two first books, and with the assistance of the Royal Society published them in 1686 under the following title: "Franc. Willughbi Arm. de Historia Fisium, Libr. quatuor, jussu et fumptu Soc. Reg. Lond. editi. Totum Opus recognovit, coacapit, supplevit librum etiam primum et secundum integros adjuncti J. Raus." Oxon. fol. The papers of Willughby in the Phil, Trans. relate to vegetation, plants, and insects. The collection of Ray contains none of his letters. Biog. Brit. Pulney's Sketches of Botany.

WILLY, in Geography, a river of England, which runs into the Avon, near Salisbury.

WILLYKA, a town of Lithuania, in the patinate of Wilna; 60 miles E. of Wilna.

WILMANSTRAND. See Wilmanstrand.

WILMANTON, a town of New York; 50 miles N. of New York.

WILMINGTON, a sea-port town of the State of Delaware, on Brandywine Creek; 22 miles S.W. of Philadelphia. N. lat. 39° 45'. W. long. 75° 34'.—Also, a sea-port town of North Carolina, with about 250 houses, on a branch of Cape Fear river. In January 1781, this town was taken by the British troops; 76 miles S.S.W. of Newbern, N. lat. 34° 11'. W. long. 78° 5'.—Also, an island near the coast of Georgia, at the mouth of the Savannah. N. lat. 32°. W. long. 81° 6'.—Also, a town of Vermont, on Deerfield river, in Windham county, with 1193 inhabitants; 10 miles E.-S.E. of Bennington.—Also, a town of Massachusetts, in the county of Middlesex, with 716 inhabitants; 16 miles N. of Boston.—Also, a town of New York; 53 miles N. of New York.

WILMOT, John, in Biography, car of Rocheller, was the son of Henry, earl of Rocheller, an eminent loyalty in the reign of Charles I., and was born in 1647, at Ditchley, in Oxfordshire. In 1659 he was entered at Wadham college, Oxford, and afterwards travelled into France and Italy under a tutor, who is said to have reclaimed him from his early licentiousness; but upon his return to the profligate court of Charles II., in which he was a gentleman of the bed-chamber, he relapsed into his former intemperance. In 1666 he went to sea, and, as it is said, behaved with great intrepidity in the attack of a castle at Bergen, in Norway, which character for courage he also maintained when he afterwards served under Sir Edward Spragge. In some of his domestic adventures, however, he forfeited this kind of reputation. Welcomed in all companies on account of his wit and vivacity, he became habitually intemperate, inso much that, on a subfrequent review of his conduct, he acknowledged that for five successive years he was never free from the inflaming effects of wine. His various adventures, in his real, or in a disguised character, have furnished many anecdotes, that have been circulated in conversation, or in books of mere amusement, but which are not worth recording in graver publications. His wit furnished in the societies which he frequented a kind of apology for his profaneness and licentiousness; and as for his poetical compositions, they were for the most part lampons or amatory effusions, the titles of which would flain the page of biography. "In all his works, (says Dr. Johnson, meaning probably those which can be read,) there is sprightliness and vivacity, and every where may be found tokens of a mind which study might have carried to excellence." The justice of Walpole's sentence, in his "Catalogue of Noble Authors," will be generally allowed: "Lord Rocheller's poems have much more obscurity than wit, more wit than poetry, more poetry than politeness." His course of debauchery was of no long duration; for soon after the age of 30 he sunk into a state of debility and diseae, which induced him to study physic, and this study permitted him to reflect on the course of his past life, the irremediable effects of which he learnt from experience. Towards the close of his short life, he became acquainted with bishop Burnet, who convinced him of the truth both of natural and revealed religion, and his mind was then impressed to such a degree, that he is said to have become a sincere penitent. His life terminated in July, 1689, soon after he had commenced his 33d year. He left a son and two daughters. Biog. Brit. Johnson. Burnet.

WILMOT, in Geography, a town of Nova Scotia, near Annapolis.—Also, a town of New Hampshire, in the county of Hillsborough, with 298 inhabitants.

WILNA, a city and capital of the duchy of Lithuania, on the Wilna, founded in the year 1305. This city lies in a mountainous country, on several little eminences. It is very
very large, and has two considerable suburbs, called Antokolla and Rudaifzka. In the old ruined royal palace is the arsenal, and the hall where the court of justice is held; and over-against it is the magnificent church belonging to the castle, which was built in the year 1386. The treasury belonging to this church is very rich; and it is also remarkable for the elegant marble chapel of St. Casimir, whose silver shrine is said to weigh thirty quintals. There are upwards of forty churches in this city, and among these are, one Lutheran and one Calvinist church, a Jewish synagogue, a Tartarian church, and a Greek church; but all the rest are Popish churches. Not to mention the devastation which Wilna formerly suffered from the Russians in the years 1610 and 1655, and from fire in 1737, it was destroyed by a dreadful conflagration in the year 1748, when 13 churches, the Jewish synagogue, 25 palaces, 460 stone edifices, consisting of private houses, hospitais, inns, baths, convents, and mills, with 146 tradesmen's shops, and dispensaries, besides a great number of granaries and warehouses, were consumed to ashes. In 1749 another fire happened by lightning, which consumed 6 churches, the council-houfe, 8 palaces, and 277 other stone buildings. The chapel of St. Casimir was also burned, and the loss sustained by the destruction of this edifice only amounted to a vast sum. The churches have been since rebuilt at a very great expense, and some of them in a more elegant manner than before; but the city has not recovered its former grandeur. Wilna is the seat of a bishop, founded in 1387. The university was founded in 1570. It gives name to a palatinate. In 1794 it was taken by the Russians, and with its territory annexed to that empire; 168 miles E. of Königsberg. N. lat. 54° 36'. E. long. 25° 18'.

WILRE, a town of France, in the department of the Ourthe; 4 miles E. of Fauquemont.

WILS, a town of the county of Tyrol, on the borders of Bavaria; 5 miles N.N.W. of Reutten.

WILSCHOE, a river of Brandenburg, which empties itself into a large lake, communicating with the Rega, 4 miles S. of Treptow.

WILSDEN, a township of England, in the West Riding of Yorkshire, near Halifax.

WILSDORF, or WILSDORF, a town of Saxony, in the margravate of Meissen; 9 miles W. of Dresden. N. lat. 51° E. long. 13° 8'.

WILSELM, a town of Austria; 3 miles W. of Brugg.

WILSNACH, a town of Brandenburg, in the Mark of Prignitz. This town was anciently famous, there being no less than three hofts worshipped at this place, which hofts they fay, in 1383, remained untouched in the church when it was burned down, and upon each of them was feen a drop of blood. To thefe hofts numerous pilgrimages were made from the remotest countries; by which means this place rofe from a village to a mall town. At length the hofts were burned in the year 1552, by the Lutheran preacher, Joachim Ellesfildt; 8 miles S. of Perleberg.

WILSON, Richard, in Biography, the moft eminent landscape-painter of the English school, was the fon of a clergyman, and was born at Pineses, in Montgomeryshire, in 1714.

Having received from his father a good classical education, in the course of which he had evinced a decided disposition for drawing, he was sent to London at the age of 15, and placed as a disciple with an obscure portrait-painter, named Wright. After a lapse of six years, he commenced professor, and under the patronage of Dr. Heyter, bishop of Norwich, he soon afterwards had the honour to paint portraits of his present majesty and his brother, the late duke of York; both at that time under the tuition of the bishop. He continued to pracitife portrait-painting some time in London, but with no great successes, and at length went to Italy to cultivate his taste. Even there he continued to pracitife it, still unacquainted with the genuine bias of his genius, although occasionally exercising his talents and employing his time in studies of landscape. At Venice Wilfon painted a portrait of the late Mr. Lock, of Norbury-park, one of the moft creditable of his performances in that branch of the art; and it was there that accident opened his eyes to his own peculiar gratifications, and led him into that path, by pursuing which he has obtained a name among the worthieft in art.

As a matter of relaxation and amusement, he had painted a landscape, which being seen by Zuccarelli, so warmly excited that eminent artist's admiration, that he advised Wilfon to pursue that line of art exclusively. From this time it is believed that he abandoned portraiture, and followed the judicial advice of a rival artist; and soon after he left Venice in company with Mr. Lock, and travelling slowly to Rome, made numerous studies on the way, which are still preferred at Norbury-park. On his arrival at Rome, the advice of Zuccarelli was confirmed by Vernet and Mengs, both then in high repute. So much were they delighted with Wilson's landscapes, that they each offered to exchange a picture with him; a proposal far too flattering for refusal. This liberality, as commendable as it is unusual, was followed by Vernet in the handomest manner, as he hung the picture by the Englishman in his exhibition-room, and recommended him to the particular attention of the connoisseurs.

His progress in landscape-painting must have been very rapid; indeed it must have had the character of being almost intuitive, since he obtained a very great degree of reputation during his stay in Italy, and painted many pictures there of known celebrity. He travelled with the late earl of Dartmouth to Naples, and made a number of very fine drawings for that nobleman, now preferred by his grandson; and for him also he painted two pictures, one a very fine one, a view of Rome, which has been beautifully engraved by middiman. He was also employed by the late duke of Bridgewater to paint a landscape with the story of Niobe; but his grace had the bad taste to employ Placido Constanza to re-paint the figures. To preserve his reputation, Wilson painted another of the same subject, and both are now in England. He returned from Italy in 1755, and occupied apartments over the north piazza of Covent-Garden. He had merited, and here he also obtained celebrity, and for a while employment. Many of his principal performances appear to have been painted about this time, most of which are known by the fine prints engraved from them by Woollett, and others; in which the grandeur, breadth, and purity of composition in maps and in line, contend for admiration with the talents conspicuous in the engravings.

Hitherto the life of Wilfon was honoured as his talents deferred; the remainder of it exhibited a gradual declension, not so much of power as of patronage. 'Tis true he was often too free in his pencil, and too much mannered in his style; repeating himself, perhaps, till it became irksome; 'tis said, also, that he was not of the most tractable humour, and was low in his pursuits and associations. Whencesoever it arose, he was doomed to undergo indifference and neglect, and consequently the inconveniences of lowness of purse. Sometimes he was employed to paint views of gentlemen's seats, but probably the occupation suited the artist as little as the result gratified the patron. Wilson's view of nature was far too broad for suitable adaptation
adaptation to such a purpose, and consequently there are not many pictures of this class to be met with which have proceeded from his pencil. The great characteristic of his works is grandeur, resulting from breadth, purity, and simplicity, united in fullness of colour and mellowness of touch. He was perfectly original in feeling and execution, more grand in general conception than Claude, though infinitely less perfect in detail; and far from travelling through his career in art, with so even a pace as his great predecessor and only rival in the more exalted style of landscape-painting before our time. Now a third shines in the same hemisphere, and Claude and Wilton find no ill-fated associate in the name of Turner.

At the institution of the Royal Academy, Wilton was chosen one of the founders; and after the death of Hayman he was made librarian. That station he sustained till his death, which happened in May 1782, in the 68th year of his age.

WILSON, Thomas, an English prelate, was born in 1663, at Burton-in-Wirral, Cheshire, and finished his education in Dublin college, where he took his degree of arts. In 1689 he was ordained priest, and in 1692 became domestic chaplain to the earl of Derby, and attended his son, lord Strange, who was his pupil, on a tour to the continent. Upon the death of the young gentleman, he returned to England, and in recompense of his faithful services, was nominated to the bishopric of the Isle of Man, by the earl of Derby, who then possessed sovereignty of the island. The nomination was approved by king William, and he was consecrated in January 1697-8, having received at Lambeth the degree of LL.D. The revenue of the bishopric did not amount to more than 360\text{\$/a} a year; but by some collateral advantages the bishop was enabled to exercise hospitality and charity, to repair his ruined palace, and to found a new chapel at Castletown. He also established parochial libraries, which he furnished with religious books, among which was a small tract, the first that was ever printed in the Manx language. He improved the agriculture of the island by introducing into it corn, borches, cattle, and sheep, from England; and he studied physic with a view of administering to the relief and comfort of the islanders. He published ecclesiastical constitutions, which were so much approved, that lord chancellor King laid them of, that "if the ancient discipline of the church were left, it might be found in all its purity in the Isle of Man." Bishop Wilton, chiefly with a view to the interest of religion and morality, was anxious to maintain a due regard to episcopal authority, and this anxiety led him in two instances to exceed the bounds of prudence and propriety. When some copies of the "Independent Whig" had found their way into the island, he ordered them to be seized, apprehending that they incited sentiments hostile to Christianity and the established church. He also involved himself in difficulties and incurred reproach by excluding from the communion the wife of the governor, on account of an act of defamation, for which the refused to ask pardon of the injured party. This led to a serious altercation with the governor, who fined both the bishop and his two vicars-general, for suspending his chaplain for disobedience in admitting the wife to communion, and who arrested them for refusing to pay the fine. Accordingly they were kept close prisoners in the castle for nine weeks, till the bishop, by application to the council in England, obtained their release. The pious and mild-tempered bishop afterwards declined prosecuting the governor for damages. From his piety and attachment to the church, he was honoured in 1707 with the degree of D.D. from the university of Oxford, in full convocation, and in which he was afterwards aggregated at Cambridge.

Such was the bishop's zeal for doing good, that he would not quit the sphere assigned him for this purpose, though he was offered an English bishopric; in reference to which circumstance queen Caroline, directing her attention to Wilton, among a number of other prelates who happened to be at court at the same time with him, said to them, "Here, my lords, comes a bishop whose errand is not to apply for a translation, nor would he part with his spouse because she is poor." His character was in such estimation with the French minister, that he procured an order that no French privateer should commit ravages on the Isle of Man. In this retired situation his life was prolonged to his 93d year, when he calmly expired in March, 1755, leaving one surviving son, known in the political world as lord St. Stephen's, Walbrook, and patron of the celebrated historian Mrs. Macaulay. After his death a collection of his works was published in two vols. 4to. 1781. His notes to Cruikshank's Bible, which was published under the bishop's name in three vols. 4to. 1785, are of little value. The translation of the New Testament into the Manks language, which he had undertaken, was completed by his successor, Dr. Mark Hillelsey. Biog. Brit. Life prefixed to his Works. Gen. Biog.

WILSON, Dr. John, a native of Feverham, in Kent, was a gentleman of Charles the First's chapel, and servant in ordinary to his majesty, in the character of chamber-musician. His instrument was the lute, upon which he is said to have excelled all the Englishmen of his time; and, according to Ant. Wood, his royal master was so pleased with his talents, and had even such a personal regard for him, that he not only listened to him with the greatest attention, but frequently condescended to lean or lay his hand on his shoulder, while he was playing.

For the excellence of his performance we must now wholly depend on tradition, as the compositions he has left behind him for the lute are but feeble testimonies of a great hand. Nor will his vocal productions, or Fantasias, either in print or manuscript, generate very exalted ideas of his genius or abilities as a compositor. That he was admired by his majesty, and by the lovers of music at Oxford, where he was honoured with the degree of doctor in music, 1644, and where he long resided, proves more the low state of the art at this time, before the ears of the public were rendered discriminative, by a variety of great and rival talents, than his own perfections. Little had been heard, but but little was expected. Swift says, "we admire a little wit in a woman, as we do a few words spoke plain by a parrot;" and it might more seriously be said, that the best music, during times of ignorance and inexperience, is perhaps more admired than the most exquisite productions and performance of a more enlightened period. Nothing can prove this more clearly than the unbounded and hyperbolical praises bestowed in France on the operas of Lulli, of which, at present, the whole nation is ashamed.

Dr. Wilton, indeed, seems to have set words to music more clumsily than any composer of equal rank in the profession; but as he was respected by his contemporaries, and held an exalted rank in his art, a lift shall here be infected of his works; not so much for their intrinsic worth, as to enable curious enquirers to judge for themselves of the progress which music had made in this kingdom, when such productions were in high favour, not only with the greatest personages but principal professors of the times.

"Psalterium Carolinum, the devotions of his sacred majesty.
jealous in his solitude and sufferings, rendered in verse, set to music for three voices and an organ or theorbo.” Folio, 1667.

“Cheerful Aires or Ballads, first composed for one single voice, and since set for three voices.” Oxon. 1660.

“Aires to a voice alone, to a theorbo or bafs viol,” these are printed in a collection entitled “Sele&aire and Dialogues.” Folio, 1653.

“Divine Services and Anthems,” the words of which are in Clifford’s Collection. Lond. 1663.

He also composed music to several of the odes of Horace, and to some select passages in Aufonius, Claudian, Petronius Arbiter, and Statius; these were never published, but are preserved in a manuscript volume curiously bound in blue Turkey leather, with silver clasps, which the doctor presented to the university, with an injunction that no person should be permitted to peruse it till after his decease. It is still among the archives of the Bodleian library.

The compositions of Dr. Wilfon will certainly not bear a severe scrutiny either as to genius or knowledge. It is, however, not easy to account for the ignorance in counterpoint which is discoverable in many lutenists of these times; for having harmony under their fingers, as much as the performers on keyed instruments, it facilitates their study, and should render them deeper contrapuntos than the genericity of flute-players, whose flimsy compositions are proverbial.

On the surrender of the garrison of the city of Oxford, 1646, Dr. Wilfon left the university, and was received into the family of Sir William Walter, of Sarfen, in Oxfordshire; but, in 1656, he was constituted music-professor, and had lodging assigned him in Balliol college, where, being assisted by some of the royalists, he lived very comfortably, exciting in the university, according to A. Wood, such a love of music, as in a great measure accounts for that flourishing state in which it has long subsisted there, and for those numerous private music-meetings, of which this writer, in his own life, has given such an amusing relation. At the restitution of his kingdom, Dr. Wilfon was appointed chamber-musician to Charles II. ; and, on the death of Henry Lawes, 1663, was again received into the chapel-royal, when, quitting the university, he resided constantly in London, till the time of his decease, at near 78 years of age, in 1673. Burney.

**Wilson**, in *Geography*, a town of South Carolina; 15 miles S.W. of Queenborough. — Also, a town of Scotland, in the county of Lanark, founded in the latter end of the 18th century, by Melfes. Wilfon of London, to accommodate the workmen employed in an iron foundery there; 5 miles E. of Lanark.—Also, a county of West Tennessee, with 11,952 inhabitants, including 2397 slaves.

**Wilsonia**, in *Botany*, received that appellation from Mr. R. Brown, who commemorates it by the remarkable zeal and perseverance of Mr. John Wilson, an inhabitant of Kendal, Westmoreland, author of a “Synopsis of British Plants in Mr. Ray’s Method,” published at Newcastle-upon-Tyne in 1744. This work, however, is incomplete, the grasses, trees, shrubs, and all the cryptogamic tribe, except ferns, being omitted. The author, whom Dr. Pulteney supposes to have died about the year 1750, is said to have left these clafses unfinished in MS.; but they were never published. His performance indeed is now altogether oblolete, being chiefly translated from Ray and Tournefort; though with some alterations of the system of the former, and much additional matter, respecting the situations of rare plants; all which evinces a considerable portion of practical knowledge. Copious medical information is interspersed, and a botanical dictionary is prefixed. But the botanists of whom we are speaking is principally worthy of memory, for that indefatigable love of science, which even the most humble situation, and the most limited circumstances, could not counteract. Whether he was employed in the manufacture of knitted stockings, formerly very extensive in his native town, or whether he made shoes, his biographers are not agreed; but he contrived to attain more knowledge, and cultivation of mind, than perhaps a great majority of the gentry around him. He must have had a competent acquaintance with Latin, and he may rank as an English writer among the most respectable, upon scientific subjects, in his time. We cannot commend his prudence, if we commis- sionate his difficulties, when he would have sold his only cow, the support of his wife and family, to buy a copy of Morison’s work. But we may be allowed to regret that his mental application did not tend to so ample a pecuniary reward, as that of the famous sir Richard Arkwright, who repeatedly incurred the cenfure of many a prudent friend, for neglect of business, while he was planning a scheme of unbounded profit for himself and family. We rejoice to read that the book so much defired, was presented to Wilson by a benevolent lady, who lived near him, and who by this act has afforded a lasting testimony to the worth of his character. An honest man may always hope for indulgence and affluence, if he smooths the path of hard duty with a little mental excursion, instead of mere unprofitable recreation or dilipation, whatever may be his situation in life. Many a cow has been sold in consequence of evil propenities; few have been sacrificed to procure food for the mind. — Brown Prodr. Nov. Holl. v. 1. 490. Clas and order, *Pentandra Monogynia*. Nat. Ord. Convolvul., Juff. *Convolvulaceae*, Brown.

Eff. Ch. Calyx pitcher-shaped, five-sided, many-toothed. Corolla funnel-shaped, of one petal; imbricated in the bud. Gernn with two seeds. Style clawn. Stigmas capitate. Capule...

1. *W. humilis*. Humble Wilsonia. Br. n. 1.—Disco- vered by Mr. Brown, in the fourth part of New Holland. A little, dwarf, shrubby, prostrate, much branched, downy plant. Leaves small, sessile, thickish, imbricated in two ranks. Flowers axillary, solitary, sessile, without bracteas. Mr. Brown remarks, that the natural affinity of this genus must be uncertain while its fruit continues unknown. He met with the plant after the flowers were faded, before the seed-coffle was formed, nor is he certain whether the germen consisted of one cell, or of two. He ranges Wilfonia next after *Cepha*, of whose place in the natural system Linnaeus had formed no opinion, but which Juffien well refers to *Convolvul.,* notwithstanding the solitary seed.

**Wilsger**, a town of the duchy of Holstein, on the river of the same name; 8 miles N. of Glückstadt.

**Wilsum**, a town of Germany, in the county of Berchtes; 11 miles W.N.W. of Nienhaus.

**Wiltzer**, a town of the Tyrol, on the Inn; 3 miles above Innsbruck.

**Wilton**, an ancient market, borough, and county-town of Wilshire, England, derives its name from the river on which it was originally built. By old writers, it was called Wile, or Wily-Vilodanum and Ellandanum; and according to Baxter it was a chief seat of the British prince, Carvilius, and thence denominated Caer-Guilou. Henry of Huntingdon says, it afterwards became the capital of the West-Saxon dominions; but Leland and Dr. Milner con-
Wilton, a town of the district of Maine, in the county of Kennebec, containing 770 inhabitants; 60 miles N.N.E. of Portland.—Also, a town of New Hampshire, in Hillsborough county, with 1017 inhabitants; 30 miles E. of Cheltefield.—Also, a town of Connecticut, in the county of New London.
of Fairfield, with 1728 inhabitants.—Also a town of South Carolina; 27 miles S.W. of Charleston.

WILTOWN, a town of South Carolina; 21 miles W.S.W. of Dorchester.

WILTPERG, a town of Austria; 8 miles S.W. of Freystadt.

WILTSHIRE, an inland county, situated towards the south-western division of England, derives its name from the town of Wilton, which, according to some ancient historians, was the metropolis of the Anglo-Saxon kingdom of Wessex. On the north and north-west it is bounded by Gloucestershire, on the south-west by Dorsetshire, on the south and east by Hampshire, and on the north-east by the county of Berks. These boundaries are in general artificial, and form a figure approaching that of an ellipse. Concerning the extent and superficial area of this county, various are the statements of different writers. In the Magna Britannia it is said to be thirty-nine miles in length from north to south, and thirty in breadth from east to west. Gough, in his additions to Camden's Britannia, estimates its length at forty-one miles, and its breadth at thirty-four. Its circumference, according to the same author, is one hundred and fifty miles, and the number of acres it contains 876,000. Mr. Davis, whose authority on this subject is highly respectable, in his Agricultural Report on the County states it to be in length forty-five miles, and in breadth thirty-four. The same writer computes the superficial area to be 1372 square miles, or 878,000 acres.

The county of Wilts is a district peculiarly interesting to the topographer and antiquary. To the latter, indeed, it offers a wider and more varied field for research than perhaps any other county in England. The grand and mysterious monuments of Stonehenge and Avebury, and the numerous barrows which cover its plains, are relics of an age anterior to historical record, and of which the annals of the world do not furnish a parallel example. Like the proud pyramids of Egypt, the former were calculated by their construction to have remained entire to almost endless futurity, if the agency of the elements had not been affliated by the destructive influence of man. In the Wantdyke, Bokerly-ditch, and Grimshilly, and in the simpler intrenchments with which the county abounds, we behold the remains of British towns, and perceive the mode adopted by the Britons to mark boundaries and for communication. The cattles of Old Sarum, Scratchbury, Battlesbury, and Bratton, display the efforts of a more advanced period; and many other of the Wiltsire intrenched works bear marks of successive occupation by the Romans, the romanized Britons, the Saxons, and the Danes. This part of the kingdom, indeed, seems to have been the principal theatre of the military and civil events which were consequent on the Saxon and Danish invasions. Here the far-famed Arthur and the still more illustrious Alfred contended at different periods for the liberties of their country, and checked for a time the tide of invading conquest. At Ludgerhall, Devizes, Malmsbury, and Marlborough, the vestiges of Norman fortresses may yet be traced; and in Clarendon-park flood a magnificent palace, erected by king John. Malmsbury yet preserves the ruins of a magnificent abbey; and in the cathedral of Salisbury, we behold an edifice surpassing every familiar ancient structure in uniformity of style and symmetry of parts. Many of the parochial churches in the county are objects worthy the examination of the antiquary, as specimens of architectural skill and science; and in Wilton-house, Longford-castle, Font-hill, Corsham-house, Bowood, Tottenham-park, Charlton-park, Stourhead, and Longleat, we are presented with monuws ake celebrated for magnificence and beauty of scenery, and for popular attractions to the connoisseurs and artists of the country.

At the period of the invasion of our island by Julius Cæsar, a people called the Belgæ inhabited a portion of this county. The Hedui are said to have occupied its north-western division, near the source of the Avon and near Cricklade. Another district is mentioned by Carte, in his History of England, as being subsequently poftelled by the Carvili, so named from their prince Carvilius; but whether these people were some of the Belgæ, or a distinct tribe, does not appear. Other authors suppose that the Cangi inhabited the northern parts, if not at this era, at least soon after it.

When the Romans, after the lapse of nearly a century, from the final departure of Cæsar, again invaded Britain in the reign of Claudius (A.D. 44.), they found the political condition and relations of its several tribes very materially altered. The opinion of Camden, in his Britannia, is, that the Belgæ had subdued the whole of Wiltsire, and also had poftelled themselves of all the territories of the Hedui.

It is very generally admitted, that the Belgæ were the most powerful people in the south-western division of England at the era of which we are now speaking; and no doubt is entertained of their having occupied all the southern district of this county, as far as the Wantdyke, which is therefore designated by the appellation of 'The Great Belgic Boundary.'

Under the Romans, Wiltsire formed part of Britannia-Prima, and many stations, encampments, and other military vestigia of that people can be traced in different parts of it.

Subsequent to the departure of the Romans, the earliest event of political importance which occurs in history relating to Wiltsire is the massacre of three hundred British nobles, on the spot where Stonehenge is situated, by the orders of Hengist (leader of the first Saxon expedition to England), who had invited them here to a banquet under the pretence of effecting a reconciliation between the Britons and himself. The truth of this dreadful catastrophe, however, is extremely doubtful, as it does not appear to be mentioned by any of the Saxons writers, and seems to rest solely upon the authority of Nennius, and a few of the British or Welsh bards, who were evidently interested in the propagation of stories calculated to excite feelings of enmity and revenge in the breasts of their countrymen, against a people, once their allies, but afterwards their inveterate and barbarous enemies. Carte says, that this story was borrowed from Witukind, who relates it of the Thuringians, who were murdered by the Saxons on a like occasion, and upon a signal given in the same words made use of by the British writers. Turner, in his History of the Anglo-Saxons, regards it as an incident which can neither be authenticated nor disproved; and Whitaker, in his History of Manchester, afferts, that the conquests of Hengist never extended beyond the limits of Kent; a circumstance which, if fully established, would give no doubt tend to invalidate our belief of the transaction. Hume, in his History of England, calls it a story inverted by the Welsh authors, in order to palliate the weak resistance made at first by their countrymen, and to account for the rapid progress and licentious devastations of the Saxons. About the year 520, Cerdic, founder of Wessex, having received considerable reinforcements from Saxony, and cut off a body of Britons which had been dispatched to intercept them, collected all his disposable forces, and advanced to Mount Badon, Badbury-castle, a British post then
then considered of great strength and importance, on account of its commanding situation, and its proximity to the confluence of the Roman roads, which intersect the northeastern division of this county. The distinguished Arthur, who so long upheld the falling fortunes of his country, relieved the garrison with a large army formed under his own inspection: Cerdic, apprized of his intention, abandoned the siege, and waited the approach of the enemy. The conflict was severe: the genius of Arthur, however, ultimately prevailed over the superior science of the Saxon general, and the more steady conduct of his veteran troops. The subjugation of Wiltshire was not again attempted till the year 952, when warfare was once more renewed. Kenric, the son of Cerdic, and his successor in the Wilt-Saxon monarchy, again faced the frontiers of his dominions, and threatened the fortified towns of Old Sarum.

The British army took a position to secure its safety, and fought with their usual intrepidity, but were defeated by the superior discipline of the Saxons. At "Barbury Castle," near Marlborough, another decisive battle was fought, in which the invaders were again the conquerors; and Wiltshire in consequence became incorporated in the kingdom of Wessex.

After several skirmishes, a decisive battle was fought at Woodbury, in which the usurper of Wessex was defeated. The Danes made a descent on the island in the thirty-second year of Egbert's reign, and effectually ravaged Wiltshire. King Alfred afterwards attacked the Danes near Wilton, and routed them; but elated by successes, he incalculably suffered them to rally when they gained a victory.

Alfred engaged them in several battles with varied success, and ultimately compelled them to sue for peace, which was granted; yet in the following year, regardless of their recent engagements, they suddenly advanced to Chippenham, then a royal residence, and established themselves in that town. They had gained such considerable reinforcements, that the king, with a part of his army, retired into Somersetshire. Here he remained several months, occasionally falling out upon the enemy, destroying their magazines, and carrying off their provisions. Having mustered a considerable army, Alfred quitted his retirement, and advanced to Athelney, where the Danish forces lay encamped, attacked them by surprise, and gained a complete victory. No other particular event occurred in Wiltshire until 976, when a fyndow was held at Calne, in which the respective rights of the regular and secular clergy underwent solemn discussion: the secular clergy would not relinquish their pretensions; another council was, therefore, convened the same year at Amesbury, in which it appears the canons were unsuccessful.

The next historical occurrence in Wiltshire happened in 1009, when the towns of Wilton and Sarum were plundered and nearly burned to the ground by the Danish monarch.

In 1006 another army of Danes visited Wiltshire, and retreating to the coast through Wiltshire, when some of its natives attacked it in the vicinity of Kennet; the Saxons were, however, defeated, and purchased peace by submitting to the tribute called Danegeld.

England now remained tranquil five years, when in 1014 King Swein and his son Canute again landed on the south coast, and entering this county, levied heavy contributions on the inhabitants. King Edward at this time being indisposed at Corsham, his son Edmund took the field, and put the invaders to flight. An obstinate battle was fought, about this time, at "Sceatland," or Sheridon, on the northwestern verge of the county, by Edmund (who had just succeeded his father, Edward) against the Danes; the decision of the battle turned in favour of King Edmund by the unexpected flight of Canute. Subsequent to the Norman Conquest, Wiltshire retained a considerable share of political interest.

In the year 1086, the conqueror held a great council at Sarum; "where," says Blackstone, "all the principal landholders submitted their lands to the yoke of military tenure, became the king's vassals, and did homage and fealty to his person." Thus was the feudal system formally introduced into this country.

Clarendon, in this county, is remarkable for the laws passed there in the reign of Henry II.; "whereby," says Blackstone, "the king checked the power of the pope and the clergy, and greatly narrowed the total exemption they claimed from the secular jurisdiction," thus "the completion of his wishes was prevented by the murder of the proud and arrogant prelate, archbishop Becket. These laws are still familiar to the antiquary, by the appellation of the 'Constitutions of Clarendon.' At Marlborough, in 1207, Henry III. held a parliament, or a general assembly of the 'Estatists of England,' to provide for "the better state of the realm, and the more speedy administration of justice," and here were conterminously enacted those statutes for the suppression of tumults, which have ever since been denounced, 'The Statutes of Marlbridge.' In the contests between the houses of York and Lancaster, the inhabitants of Wiltshire were conspicuous for their attachment to the fortunes of the Henries. Many of them were present at the battle of Tewkesbury, an event which tended to fix the crown on the brows of Edward.

In the deplorable events of the 17th century, this county was equally distinguished. Many actions between the parliamentary and royal forces were decided within its boundaries; particularly at Malmesbury, at Ludgerhall, and at Round-a-way-hill, in the neighbourhood of Devizes. Wadbour and Longford castles were alternately besieged and taken by both parties within one year.

The returns of antiquity in Wiltshire, first entitled to notice in a collective view, are the stupendous monuments at Avebury and Stonehenge, both of which are regarded as druidical temples. In these structures we are prescient of the most wonderful works of a rude but powerful people; works in which the bodily strength of associated numbers, with the science and cunning of their age, are strongly manifested, and which are calculated not only to excite the transported gaze and amazement of the multitude, but also to rouse curiosity and awaken inquiry in the minds of antiquaries and historians. See Avebury, and Stonehenge.

Next to these immense temples, because resembling them in relative magnitude, though totally dissimilar in kind, the Wansdyke may properly claim attention. This vast earthwork, which is supposed to have originally intersected the whole country, is now only distinctly visible in detached places, throughout the range of hills to the south and west of Marlborough, where it still remains tolerably entire, and in one place is seen in a bold and connected line for the space of ten or twelve miles.

**Barrows, or Tumuli.—** Of corresponding antiquity to the monuments already named, are the artificial hillocks or mounds of earth which abound in this county, and which appear to have an intimate connection with these temples, as they are more numerous around Stonehenge and Avebury than in any other places. These memorials were undoubtedly appropriated to sepulchral purposes. By the researches of Mr. Cunnington, Sir Richard C. Hoare's 'Ancient Wiltshire,' the Rev. James Douglas's 'Nennius Britanniae,' and a few other enlightened antiquaries, we are made
made familiar with the contents of these sacred depositories. See Barrow, and Tumuli.

The Roman stations mentioned in the Itinerary of Antoninus, as being situated within the county, are three in number, Sorbiodunum, Verulamium, and Cunetio. The first of these is placed by all antiquaries at Old Sarum; but the situation of the other two has been much disputed. Camden fixes Verulamium at Welbed; Horley, at Lackham; and Stukeley, whose opinion is the most probable, in the neighbourhood of Heddington. Cunetio was formerly supposed by some writers to be at the village of Kennet, and by others at the present town of Marlborough; but it is now generally allowed to have been situated at a short distance east of the latter place, near the north-eastern boundary of Savernake forest. Besides these, the Romans had several other settlements in this county; particularly at Eallon-Grey, at Wanborough, at Pitmed at Heytesbury, and at Littlecote, at each of which places tessellated pavements and other Roman remains have been found. Of the Roman roads which passed through Wiltshire, the principal was a continuation of the Julia Strata, which entering the county from Bath, left it near Hungerford on the east. The Fosse road branched off from the Julia Strata at Bathford, at the north-west corner of the county, where in many places it is still conspicuous. Several other roads connected Sorbiodunum with neighbouring stations; and of these, three are traced with considerable certainty: first, one which led to Durnovaria, or Dorchester; secondly, that to Venta-Belgarum, Winchester; and thirdly, another to Vindonissa, or Silchester.

The numerous encampments and other intrenched earthen works with which Wiltshire abounds vary not only in size and shape, but in method of construction and peculiarity of situation. Some of these are doublets the works of the Britons, others of the Belgae, of the Romans, of the Saxons, the Danes, and the Normans. Many of them, however, have been in all probability successively occupied and altered by the armies of one or more of these nations, at different periods subsequent to their original formation. The immense fortifications of Old Sarum, Chidbury-hill, near Warmington, and Vephanian's camp, near Amesbury, constitute the most distinguished monuments in these classes of antiquities.

Castles.—That this county, at an early period, contained a number of those baronial fortified structures, which are usually designated by the term castles, and which are supposed by several writers to have been first introduced by the Normans, is undoubtedly. Most of them, however, are now totally demolished, so that it is even difficult to ascertain their actual sites; and the rest have been so much altered in later times, as almost to efface every vestige of the original building. The more celebrated of these edifices, and those which most frequently occur in the ancient historians, are the castles of Marlborough, Devizes, Lodergham, Wardour, Combe, and Malmbury.

General Aspects.—In a geographical arrangement, Wiltshire may be said to be naturally divided into two portions, by an irregular range of hills, which extends transversely through the greater part of the county in a direction inclining from the north-east to the south-west. These districts are usually denominated South and North Wiltshire, and differ very materially from each other, not only in appearance, but in almost every distinguishing quality.

South Wiltshire, which claims priority of notice on account of its superior extent, forms the western division of a vall tract of chalk-hills, which extends into Hampshire, and having for its boundaries the rich lands of Berkshire, and the extreme verge of the Marlborough hills on the north; the broken ground of Somerfetshire on the west; the new forest of Hampshire on the south; and the heaths of Surrey and Suffolk, together with the Weft Downs of the latter county, on the east. The surface of the higher down, to use the words of Gilpin, is "spread out like the ocean, but it is like the ocean after a storm; it is continually heaving in large swells." In some parts, the hills assume the form of round knolls, and are separated by smoothly-fided hollows, which vary considerably both in depth and extent. At other places they range along for a short distance in connected ridges, flowing on one side of the range rather a rapid declivity, from the top of which, on the other side, the hills sink in irregular gradation, till at length they frequently delve into a perfect flat. This effect, says Marshall in his "Observations on," what he terms the "Western District" of chalk hills, is of course more particularly distinguishable, "where the range of hills is narrow, single, than where a congeries of such ranges are crowded together disorderly." The whole of this district, generally speaking, is separated into two divisions, the one called Marlborough-Downs, and the other Salisbury-Downs or Plain.

The principal valleys in this division of the county lie along the banks of the rivers, the most remarkable of which diverge like irregular radii from the country around Salisbury and Wilton. These display rich meadow and corn lands, intermixed with fields and villages, and finely covered in various parts with plantations of wood.

North Wiltshire differs entirely from the southern division of the county in its general appearance. Instead of a constant series of "chalky waves," the aspect of this district, which extends from the verge of the Downs to the hills of Gloucestershire, is nearly that of a perfect flat; the few deviations from the ordinary level being so gradual as scarcely to be perceptible, on a cursory view. The country here is so close and well wooded, that when viewed from any of the surrounding hills, it appears like one vast plantation of trees. If examined in detail, however, it is found also to contain many extensive tracts of rich pature land, situated on the banks of the Lower Avon and the Thames, and of smaller streams which flow into both of those rivers.

Rivers.—Wiltshire abounds with rivers, which either take their rise within the county, or on its immediate confines. Two of these, the Thames and the Lower Avon, are unquestionably important streams. All the others are much inferior both in extent and confluence; but several of them deserve to be particularly noticed, viz. the Upper or Salisbury Avon, the Nadder, the Willey, the Bourne, and the Kennet. See Thames.

The Lower Avon rises in the hilly district of North Wiltshire, at a short distance from the town of Wootton-Bridge.

The Upper Avon is formed by the confluence of several smaller streams, which take their rise among the hills near the centre of the county. The Kennet rises near Avebury, and running in an easterly direction, unites with the Thames at Reading. The Willey and the Nadder join their streams at Wilton, and unite with the Avon at Salisbury.

The chief of North Wiltshire has long been devotedly celebrated; though for some time after it became the staple commodity here, it was sold in the London market as the manufacture of Gloucestershire. See Cheese.

Waste Lands.—It is a common idea that the Wiltshire downs consist entirely of "waste land." This notion, however, is completely erroneous; for if the correct appropriation of land is to be estimated by its comparative utility in
WILTSHIRE.

in different conditions, the application of the grounds in the chalk district cannot be very easily improved, or materially altered for the better.

In North Wiltshire the number of common fields is very great, but none of them are of any considerable extent. It is subject of regret, however, that they should exist at all, as many of them are deserted over the richest foil in the district; and if brought under regular cultivation would be extremely productive.

The chaises within Wiltshire are suppos'd to have been numerous formerly, but only three woodland districts now retain that peculiar appellation: these are Cranbourne-chen, Vernditch-chen, and Aloubn-chen. The first and second join each other, and occupy a long narrow track of country on the southern confines of Wiltshire. There are three canals which intersect parts of this county: first, the Thames and Severn; secondly, the Kennet and Avon; and thirdly, the Wiltshire and Berkshire. See CANALS.

The manufacturies of Wiltshire are various, and of great extent. Salisbury is noted for its flannel and fancy woollen; and besides carries on a considerable manufactory of cutlery and steel goods, which are probably superior in workmanship to any in the kingdom. Wilton was celebrated for a large manufactory of carpets, and Mere for another of fancy woollens; and in its neighbourhood a great quantity of linen is made, chiefly dawlas and bed-ticks. Broad cloths, kerseymeres, and fancy cloths, are the principal produce of the towns of Bradford, Towbridge, Warminster, Weftbury, Melksham, Chippenham, and all the adjacent towns and villages from Chippenham to Heytesbury. At Albourn is an excellent manufactory of cotton goods, of which fustians and thickets form the most valuable portion. Swindon and its vicinity has been long famed for its manufactory of gloves.

Ecclesiastical and Civil Division and Government.—The whole of this county is situated in the province of Canterbury; and, with exception of the parish of Kingwood, is in the dioceze of Salisbury. It comprehends two archdeaconries, Sarum and Wilts; the former comprising the deaneries of Salisbury, Amesbury, Chalk, Potter, Wilton, and Willy; and the latter, with the annexed rectory of Minety, thofe of Avebury, Cricklade, Malmbury, and Marlborough.

As in the other counties of England, the chief civil magistrates of Wiltshire are, the lord lieutenant, the mayor of Salisbury, and the mayor of each of the following boroughs; Chippenham, Calne, Cricklade, Devizes, Heytesbury, Hindon, Downton, Great Bedwin, Marlborough, Malmbury, Ludgerhall, Wiltbury, Wilton, Wootton-Baffet, and Old Sarum. At an early period the whole county was divided into twenty-nine districts, called hundreds; and these again subdivided into two hundred and ninety-five smaller districts, called parishes; with parts of fourteen others. In the county is one city, Salisbury; and twenty-three market-towns, viz. Amesbury, Bradford, Calne, Chippenham, Cricklade, Devizes, Downton, Great Bedwin, Heytesbury, Hindon, Ludgerhall, Melksham, Marlborough, Market-Lavington, Swindon, Towbridge, Warminster, Wiltbury, Wilton, and Wootton-Baffet.

The government, provincial management, number, and rate of the poor in this county, as laid before parliament in the year 1803, and published by authority of the House of Commons, are detailed in the following particulars. It is stated, "that returns were received from three hundred and thirty-six parishes, or places, in the county of Wilts, in the year 1803; in 1785, the returns were from three hundred and thirty-six; and from three hundred and twenty-five, in 1776." It is then further stated, "that forty-one parishes, or places, maintain all or part of their poor in workhouses; the number of persons so maintained, during the year ending Easter 1803, was one thousand six hundred and seven; and the expense incurred therein amounted to 14,547l. 2s. 0d., being at the rate of 8l. 19s. 8d. for each person maintained in that manner. By the returns of 1776, there were forty workhouses capable of accommodating two thousand and seventy-nine persons. The number of persons relieved out of workhouses was forty thousand five hundred and eleven, besides four thousand five hundred and thirty-six, who were not parishioners. The expense incurred in the relief of the poor, not in workhouses, amounted to 113,888l. 17s. 9d." A large proportion of those who were not parishioners appear to have been vagrants; and, therefore, it is probable the relief given to this class could not exceed 2s. each, amounting to 453l. 12s. od. This sum being deducted from the above 113,888l. 17s. 9d., leaves 113,435l. 5s. 9d., being at the rate of 3l. 6s. 8d. for each parishioner relieved out of any workhouse. The number of persons relieved in and out of workhouses was forty-two thousand one hundred and twenty-eight, besides those who were not parishioners. Excluding the expense suppos'd to be incurred in the relief of this class of poor, all other expenses relative to the maintenance of the poor amounted to 131,864l. 19s. 9d., being at the rate of 3l. 2s. 7d. for each parishioner relieved. The resident population of the county of Wilts, in the year 1801, appears from the population abstract to have been one hundred eighty-five thousand one hundred and seven; so that the number of parishioners relieved from the poor's rate appears to be twenty-three in a hundred of the resident population. The number of persons belonging to Friendly Societies appears to be fixed in a hundred of the resident population. The amount of the whole total money raised by rates is 16s. 0d. per head on the population. The amount of the whole expenditure on account of the poor appears to average at 14s. 7d. per head on the population. The expenditure in suits of law, removal of paupers, and expenses of overseers, and other officers, according to the present abstract, amounts to 962l. 15s. od. The amount of such expenditure, according to the returns of 1785, was then 250l. 13s. 4d. The expenditure in purchasing materials for employing the poor, according to the present abstract, amounts to 849l. 8s. 7d. The amount of such expenditure, according to the returns of 1785, was 434l. 11s. 9d. It does not appear from the returns received, that the poor of any parish or place in this county are farmed or maintained under contract. The poor of six parishes are maintained and employed under the regulations of special acts of parliament. Thirty-six Friendly Societies have been enrolled at the quarter-seessions of this county, pursuant to the act of 33 & 35 Geo. III.—Beauties of England and Wales, Wiltshire, by J. Britton, F.S.A. 8vo. 1814. Ancient Wiltshire, by Sir Richard C. Hoare, bart., folio, 1815.
Wiltshire of Eleven-shafted PloUGH, in Agriculture, an
implement of this kind invented and used in that district.
In Oxfordshire it is employed for many different purposes ;
as for cleaning the land, and with shaves contrived for fur-
rowing the land previous to sowing. The crops principally
own, or put in after the use of this implement, are those of
tamed wheat and turnips. See PLOUGH.
WILIZ, in Geography, a town of France, in the depart-
ment of the Forets; 6 miles N.W. of Diezicr.
WILZBURG, a fort of Germany, in the principality of
Anspach; 2 miles S.E. of Anspach.
WIMACK, a town of New York, in Long
Island; 44 miles E. of New York.
WIMBA, or WINIPA, a town of Africa, on the Gold
Coast; 20 miles S.W. of Accra.
WIMBLE, in Rural Economy, a term provincially made
use of to signify a boring auger. See AUGER.
WIBDON, in Geography, a village of England, in the
county of Surrey; supported by Camden and others to be
the place where Ethelbert king of Kent was defeated by
Cæolin king of the West Saxons. According to histroy,
the battle was fought in the year 586, at Wibdone. At
the south-west corner of Wimborne common is a circular
encampment, with a single ditch, containing a space of about
seven acres; 9 miles S. of London.
WIMBORN or WINEBORN Minster, a market-town
of remote antiquity, in the hundred of Badbury, Shafton
division of the county of Dorset, England, is situated on the
river Allen, near its confluence with the Stour, at the distance of 28 miles E.N.E. from Dorchester, and 100 miles S.W.
by W. from London. It was called by the Romans Vindol-
gladus, alluding to its situation on a river. The appellation of Wimborne is Saxon, derived from Bourne, a vale, and
Wim, a small river which flows near the town. The term
Minster, from the church, was added to distinguish it from
other places of the same name. Camden states this town to have been a place of great confluence in the Saxon times,
and that it then retained many marks of Roman grandeur.
The present appearance indicates no vestiges of its former
prosperity, though large and populous, it has little to re-
commence it to notice; the streets being irregular, and the
houses deficient in uniformity. The trade carried on is
chiefly confined to the woollen manufactury and the knitting
of hosiery. The great object whence Wimborne derived its
ancient reputation, and to which it is solely indebted for its
modern celebrity, is the Nunnery, which was founded
among the earliest of its kind in the kingdom. It was
erected, as Leland informs us, in the beginning of the eight
century, by St. Cuthburga, daughter of Kenred, and
sister of Ina, king of the West Saxons. In the reign of Ed-
ward the Confessor, or of one of the Edwards his predece-
sors, this edifice being destroyed by the Danes, the
establishment was dissolved, and converted into a college of
several canons, consisting of a dean, four prebendaries, three
vicars, and other inferior officers. This college subsisted till
the year 1547: on the dissolution the revenues were vested
in the crown. Great part of the lands was granted to
Edward, duke of Somerset; and part was by queen Elizabeth
vested in the corporation of the college towards the founda-
tion of a grammar-school. In the reign of Charles I., all
the possessions of the church and school were granted, in
trust, to twelve governors, who, among other conditions,
were to find for the service of the collegiate church three
priests, three clerks, and subordinate members. This esta-
blishment, with some temporary obstructions, has been kept
up ever since. The revenues at present amount to between
three and four hundred pounds. The church merits parti-
cular notice for its age and venerable appearance, and for
the peculiarities of its architecture. Mr. Gilpin says, its
form dates its antiquity, being of the heaviest and earliest
Saxon style. Dr. Stukeley, however, and other antiquaries,
were of opinion, that the eastern tower, and most part of
the church, were built soon after the Conquest. Many
parts are of early Norman architecture, particularly the
femicircular arches in the eastern tower, the sable windows
in the south transept, and several others. The church is
cruciform, with two quadrangular towers, one standing
on the middle of the roof, and the other at the west end; the
former was anciently ornamented with a spire, said to be of
an extraordinary height. The whole edifice consists of a
chancel, nave, choir, and side aisles, a transept, and three
porches. Its length, from east to west, is 180 feet. Both
chancel and choir are supported by eight pillars, over which
are five windows on the north and three on the south side.
The nave is supported on each side by six massive pillars of
an irregular form, above which are pointed arches, with zig-
zag mouldings: the whole enlightened by a similar number
of windows, apparently of a more modern style. Many
royal and noble persons have been interred in this church,
most of whom were anciently commemorated by suitable
monuments. Of these time has destroyed many, and the
hand of violence more. Among those remaining, the most
conspicuous is that of king Ethelred, who, as the inscription
states, was slain by the Danes April 23, 872. This tomb
stands in the choir on the north side of the altar. On the
opposite side is that of the duke and duchess of Somerset
(parents of Margaret, countess of Richmond, mother of
Henry VIII.), with their effigies in alabaster. Within this
church were once standing ten altars for the celebration of
divine service, all of which were composed of alabaster and
other costly materials, and suitably ornamented. The fur-
ture of the high altar was particularly splendid; consisting of
a variety of croffes and images, and other objects of
worship, of silver-gilt, and adorned with precious stones.
Exclusive of the church, the public buildings of Wim-
borne are few and uninteresting. The town-hall was suf-
ered to fall to decay; near its site is an open space, called
the Square. Here are two meeting-houses for Presbyterian
ians and Anabaptists; and large commodious workhouses.
Two annual fairs are held, and a weekly market on Fridays.
The north part of the town has been long styled a borough,
and consists of two streets, East Borough and West Borough.
It was never incorporated, but is governed by two
bailiffs annually chosen. The south part of the town, in-
cluding all that is not in the borough, comprises the tything
of Wimborne Minster. The population of the whole, by
the return of the year 1811, was enumerated at 3,158; the
houses at 791. About a quarter of a mile from the town
is an hospital, or almshouse, with a chapel adjoining,
called St. Margaret's hospital. The time of its foundation
is entirely unknown; but by several curious deeds preserved
in the chapel, it appears to be at least as old as the time of
king John, when it was set apart for the relief and support
of poor persons afflicted with the leprosy. "It does not ap-
ppear to have had any endowment, but to have been sup-
ported by voluntary donations, for which pope Innocent IV.,
in the year 1245, granted special indulgences. Since the
year 1688, the alms-people are not required to have the
original qualification of leprosy, but only to be poor aged
people. A second hospital, or almshouse, was founded and
endowed by Gertrude Courtney, marchioness of Exeter, for
the maintenance of six poor men and women; and a patent
was
WIN.

was procured from queen Elizabeth for incorporating the "governor and poor persons:" they were invested with a common seal and other corporate privileges. But notwithstanding this parade, the charity has dwindled to nearly nothing; the fix persons now on the foundation having only each a room, and the poor pittance of fifty-two shillings yearly.—Hutchins's History of Dorsetshire. Beauties of England and Wales, vol. iv. Dorsetshire. By J. Britton and E. W. Brayley.

WIMBREL, in Ornithology, the English name of a bird of the curlew kind, the 

*Scolopax phasianus* Linnaeus, and known among authors by the name of *arguta minor*, or the lesser curlew, and called in the Venetian markets *taraniola*.

It is much of the shape of the common curlew, but is not more than half its size. Its beak is about three fingers' breadth long, dusky above and red below; its feet are greenish; the feathers on the head and neck brown tinged with red, marked in the middle with an oblong black spot; the upper part of the back, coverts of the wings, scapulars, and farthest quill-feathers, of the same colour with the neck, but the black spots spread out transversely on each web; the quill-feathers dusky, their shafts white, and their exterior webs marked with large semicircular white spots; the breast, belly, and lower part of the back, are white; the coverts of the tail are of a pale whitish-brown, crossed with black bars. Its haunts and food are much the same with those of the curlew, but it is much less frequent on our shores. Pennant.

WIMES, in Geography, a town of France, in the department of the Straits of Calais; 9 miles S.S.W. of St. Omer.

WIMMERBY, a town of Sweden, in the province of Smaland; 62 miles N. of Calmar.

WIMMIS, a town of Switzerland, in the canton of Berne, on the Sihun; 18 miles S. of Berne.

WIMPPEL, of the Dutch *wimpel*, a muffer, a plaited linen cloth, which nuns wear to cover their necks and breasts.

The word is also sometimes used for a streamer, or flag.

WIMPFEN, in Geography, a town of Germany, on the Neckar, near which it is joined by the Jaxt. This place consists properly of two towns, the most considerable of which is called Wimpfen-sulz-demburg, or Wimpfen on the hill; and the other Wimpfen-in-thal, or Wimpfen in the vale. In the former of these are a Lutheran parish-church and a grammar-school, as also a Roman Catholic hospital; but in the latter is a Roman Catholic abbey, with a convent of monks. The magistrats here are wholly Lutherans. The Huns are said to have ravaged this town; but an instrument of donation by king Henry VII. bearing date in the year 1288, shews it to have entirely recovered from that calamity. On the failure of the dukedom of Swabia, it gradually procured its freedom, and the emperors Charles IV. and Wenceslaus promised to maintain it in its immediate dependency on the empire. In the years 1645 and 1688, it was taken by the French. In 1802, it was given to the duchy of Baden; 8 miles N. of Heilbronn. N. lat. 49° 15'. E. long. 9° 15'.

WIN, at the beginning or end of the names of places, signifies that some great battle was fought, or a victory gained there. The word is formed from the Saxon *winnan*, to win, or overcome.

WINANDER MERE, or Winder Mere, in Geography, a lake of England, in the county of Westmoreland, in which is an island, with a village. This is one of the largest lakes in England, being 15 miles long, and two broad, and from 90 to 200 feet deep, well furnished with fish of several sorts, but especially char; 17 miles S.S.E. of Keswick, and 270 N.N.W. of London.

WINBERG. See Winterberg.

WINCANTON, or Wincanton, a market-town in the hundred of Norton-Ferris, and county of Somerset, England, is situated on the western slope of a hill near the river Cale, at the distance of 108 miles W. by S. from London. It is a place of remote antiquity; and was probably occupied by the Romans, as numerous coins of that people were discovered here in the early part of the last century. The Saxons were long in possession of it; and it is recorded in Domesday-Book to have been held by one Elf in the reign of Edward the Confessor; but when William came to the throne he gave it to Walter de Doucer. It afterwards passed to the Lovells, lords of Castle Cary, and through the families of St. Maur and Zouch, till by attainder it was given to the crown, 1 Henry VII., who granted it to Giles, lord Daubery. The town, in its present state, consists of four principal streets. A fire which occurred in 1747 opened a way towards the improvement of the buildings. The turnpike-road from Taunton to Salisbury runs through it. A considerable market is held on Wednesdays for cheese, butter, pigs, and flax-yarn for the linen manufactures, which are chiefly thofe of dowlas and ticking, in which most of the poorer inhabitants find employment. Here are also three annual fairs. The town-hall is a respectable brick building, with a rustic stone basement: here is likewise a small old market-house, with a few stalls. At the west end of the town, in the road to Castle Cary, is a stone bridge of two arches over the Cale: there is another of one arch over the same stream in the road to Bruton. Wincanton church is a spacious edifice, and consists of a nave, chancel, and two aisles. The church is ancient; but the chancel was rebuilt, and the church new-roofed and windowed in the year 1748. At the west end is a plain square tower. The parih extends nearly seven miles from north to south, and three miles from east to west: it includes, besides the town, five small hamlets. The population return of the year 1811 states the whole to contain 380 houses, and 1850 inhabitants. Within this parish, at the distance of about three miles north-east from the town, are the remains of the priory of Stavordale, founded in the reign of Henry III., by Richard Lovel, then lord of the manor, for canons of the order of St. Augustine. The priory is now converted into a farm-house and barn, in which several arches and other parts of the original structure still remain.—Collinson's History of Somersetshire, vol. iii. 4to. 1791.

WINCH, a popular term for a windlass.

WINCH also denotes the crooked handle for turning round wheels, grind-foones, &c.

WINCH, a small windlass, with an iron axis, hung in hodings or gudgeons, abaft some vessels' masts to hoist the main-fall, &c. with a conical piece of timber at each end without the checks. It is hove round by two iron handles, formed by cranks or winches, from whence it takes its name.

WINCHES, the large iron handles by which the main-pumps in ships are worked.

WINCH, used by rope-makers, is made of wood, having four spokes at each end, connected together by four blades, to form the body. Through the centre of the spokes is a hole to receive an iron bolt, on which it turns by a handle in one of the spokes. Its use is to wind the yarn on as it is spun.

WINCH, to twill or make spun-yarn with, is similar to the former, but much less. The motion given to this winch is by the hand in twilling the yarn: on the edges of the spokes is a small iron hook to flot the yarn in twilling, after

Vol. XXXVIII.
after which the spun-yarn is wound round the body of the winch.

WINCHCOMBE, in Geography, a market-town in the lower division of the hundred of Kilfrate, Gloucestershire, England, is situated on the Cotswold-hills, 15 miles N.E. by E. from the city of Gloucester, and 95 miles W.N.W. from London. It was anciently a town of considerable importance, was written Winclcumbe in Domesday-Book, and was there styled a borough when only Gloucester and Bristol, in the same county, were dignified with that title. It was the seat of a castle, and of a mitred abbey sufficiently capacious for the reception of 500 monks; but every vestige of these buildings has long been levelled with the dust, and the places where they stood are only conjectured. By whom the castle was erected is unknown; but the abbey was founded in 798, by Kenulph, king of Mercia, and was consecrated with great solemnity in the presence of three kings, and a great number of prelates and nobles. Being destroyed by the Danes, it was rebuilt in 981 by Olaf, bishop of Worcester, who converted it into a college of seculars, and restored it to great splendour. It was largely endowed; and in the reign of the Conqueror nineteen mansions in this county were annexed to it, independently of Winchcombe itself. In 1265 its abbots were dismissed to parliament, and the privilege was continued to all the succeeding abbots. The twenty-eighth abbott, Richard Ancelm, surrendered his abbey and its possessions to Henry VIII. in 1539. The edifice was soon after totally destroyed. Tradition reports it as very magnificent; but no description of it is now extant. Winchcombe, with a small territory adjoining, is said to have been, in the Anglo-Saxon time, a sherrifdom or county of itself; but in the reign of Canute, it was divested of its independence, and annexed to Gloucestershire. The town now consists chiefly of two streets, intersecting each other; the houses are low, and principally of stone. The difficulty of approaching it, through the badness of the roads, has prevented it from being much visited; but the new turnpike-roads have now opened a short and easy communication. The church is a spacious structure, with a nave, chancel, two aisles, and an embattled tower: the body of the church is also ornamented with battlements and pinnacles. The old church stood on the west end of the town; but having fallen to decay, the present fabric was begun in the reign of Henry VI. by the abbott, William Wincombe, who completed the east part: the remainder was finished by the parishioners, assisted by the munificence of Ralph Boteller, lord Sudeley. The government of the town, which is a borough by prescription, is vested in two bailiffs and ten aldermen from the latter, the bailiffs are annually chosen. A weekly market is held on Saturdays, and here are three annual fairs, which are well attended; but from the decline of the town very little trade is carried on, a papermill and a tan-yard being the chief sources of employ. The workhouse is an ancient irregular building, in which the poor are employed in spinning and weaving linen. Here are also an almshouse for twelve poor women, and three charity-schools. The population of the town in the year 1811, according to the return to parliament, was 1536, occupying 399 houses: the parish extends twelve miles in circumference, and includes nine hamlets; the enumeration of the whole was 56 houses, and 1536 inhabitants.

About a quarter of a mile to the south-east of the town are the ruins of Sudeley-castle, erected by Ralph, lord Bote- ller, an eminent state-man in the reign of Henry VI., on the site of a more ancient castle which appears to have been the residence of Harold, son to Radulf, earl of Hereford, in the time of the Norman conqueror. In this family, which assumed the name of Sudeley, the manor continued till the 41st of Edward III., when it was conveyed by marriage. Sudeley was attached to the crown till the reign of Edward VI. when it was granted to Sir Thomas Seymour, who settled there with Catharine Parr, the queen-dowager, whom he had married, and who died here in child-bed, not without suspicion of poison. Seymour being afterwards attained, Sudeley was granted to William Parr, marquis of Northampton, who forfeited it soon afterwards. It now belongs to the marquis of Buckingham. Of this once-famed fortress, very little remains: parts of the tower, the hall, and the chapel, serve to shew the style of architecture and character of the buildings. — See Williams’s History, &c. of Sudeley Castle, folio. Also Beauties of England and Wales, vol. v. by J. Britton and E.W. Brayley.

WINCHELSEA, a borough and market-town on the coast of Sussex, England, situated about 3 miles W. from Rye, 8 E. from Halling, and 67 from London. It is a member of the Cinque Ports, and an incorporated town, the officers of which consist, according to its charters, of a mayor and twelve jurats; but these are seldom composed of more than four or five persons. Winchelsea is a place of antiquity; but by the ravages of the sea, the sites of its houses, at different periods, have totally changed. The epoch of the rapid though gradual overthrow of the original town is fixed by Leland between 1280 and 1287. During that time the inhabitants petitioned Edward I. for ground to found another town, who accordingly granted them the site of the present town, which he surrounded with walls, and to it the inhabitants gradually removed. The new town afterwards fell into decay, from a cause just the reverse of that which ruined the old; for the sea deserted its neighbourhood, and left in its place a dreary marsh. This began to be feebly felt in the end of the reign of queen Elizabeth. The channel leading to the harbour was choked, the coast was deflected, and the town, abandoned by the trader, soon declined. The houses and churches fell to ruin, so that a town, once covering a surface two miles in circuit, is now reduced to comparatively a few houses in the centre of an ancient site, now a mile and a half from the sea. Of the ancient church, the lofty and spacious chancel, now used for divine service, and three aisles, alone remain entire. It is in two monuments, with effigies of knights templars. Some fragments of the walls and of three gates of the town still exist. From the situation of Winchelsea, and the spacious vaults frequently discovered, it is probable that the town was the principal mart for French wines, imported into England before the wine-trade with Portugal was established. Winchelsea sends two members to parliament, who are elected by about forty freemen. The houses in this parish, in 1811, were 126, containing 131 families, and 652 persons.—Beauties of England, vol. XIV. 1813.

WINCHELSEA, an island in the Pacific ocean; 30 miles S.E. of Sir Charles Hardy’s island.

WINCHENDON, a town of the state of Massachusetts, in the county of Worcester, with 1732 inhabitants; 56 miles N.W. of Boston.

WINCHESTER, an ancient and eminent city in Hampshire, or the county of Southampton, in England, 11 miles N.N.E. from Southampton, and 62½ W.S.W. from London. The buildings are disposed on the eastern declivity of a low hill, which gently slopes to the valley of the river Itchen, the chalky cliffs of which, and the chalky foil of the surrounding heights, in the opinion of Camden, occasioned the ancient name of the city, Caer-Gwent, signifying the ‘white city.’ The latter portion of the name,
under the Romans, became Venta, with the addition of Belgarum, from its situation in the country occupied by the Belgae, by which it was distinguished from Venta Silurum, now Caerwent, in Monmouthshire, and Venta Icenorum, now Caistor, near Norwich, in Norfolk. From Gowen or Venta we have the first part of the name, and chester, the last part, is a corruption of castrum, the Roman term for encampments of different kinds; a frequent name, or appellation of a name, of various places in England, and perhaps invariably an indication that such places owe both their origin and their primitive form to the military stations of the earliest conquerors of Britain.

Historic Events.—The origin of Winchester, remote as it unquestionably is, has been carried back to an epoch far beyond belief, even a century and half anterior to the foundation of Rome. Without referring to such remote and uncertain time, we may safely infer that this spot was occupied by the Belgæ, a Germanic tribe, who passing from Gaul, took possession of the country bordering the southern coast of England. (Cæsar's Bel. Gal. ii. 4.) Previous to their occupancy, it is conjectured that Winchester was the Caer-Gwent, or white city, of the aboriginal Britons. After the Romans had subdued the Belgæ and the Britons, they took possession of this town, and fortified it with ramparts and walls. These were disposed on the sloping side of a hill, and in the usual form of a parallelogram. Within this inclosure the town was constructed and arranged; and from the importance of this station, and its connection with other stations by military roads, there can be little doubt that Venta Belgarum, the Roman name, was a place of considerable importance. Among the antique relics of the Romans, which have been discovered at Winchester, are several coins, urns, &c.; also some fine coins of Caracallus, called the first British emperor. After the Romans left the island in 446, Gortheryn, or Vortigen, was elected chief of the western district, and he fixed his seat of government at Winchester. This town, as well as the whole island, was soon defined to experience a total change of polity, customs, and manners, by the introduction and domination of the Saxons in 519. On this occasion, the name of the city was changed from the Britih Caer-Gwent and the Roman Venta to another of equal import, Wintan-ceaster, from which the modern name, Winchester, has gradually been formed. In 635 an important event occurred in Winchester, the arrival there of Birinus, deputed by pope Honorius to preach the gospel in those parts of the country still involved in paganism. Favoured by king Cynegils, Birinus's apostolic labours were eminently successful: for the king founded a new cathedral on the site of that destroyed by Diocletian, which was consecrated under his son and successor, Kenewalch, in 648. Egbert, king of the West-Saxons, succeeding in the subjection of all the other Saxon princes, was in 827 crowned king of all England in the cathedral of Winchester, thus created or confidered to be the metropolis of the whole kingdom; and there, about 854, Egbert's successor, Ethelwulf, granted his famous charter, establishing a general synod of tythes. About this period the commerce of the city is recorded to have greatly increased, and the principal inhabitants are stated to have constituted a guild, under the royal protection; the earliest association of the kind, by a century, recorded in history. During the greater part of this and the succeeding reign, the see of Winchester was filled by the celebrated St. Withun, by whose advice king Ethelbald raised fortifications for the defence of the cathedral against the Danes. Landing at Southampton, they advanced to Winchester, where they committed horrible excesses; but the cathedral escaped their fury. About 871, however, that greatly suffered by them, and all the clergy belonging to it were massacred. On the ultimate success of the great Alfred, Winchester resumed a portion of its former splendour; it became again the seat of government; there the public records of the kingdom were deposited, in particular the general survey, called, from this circumstance, Codex Wintoniensis; afterwards imitated by William the Conqueror in 1086, in the famous Roll of Winchester, or Domesday-book. (See Domesday.) The succession of Edgar the Peaceful increased the importance of Winchester. Among the judicious laws which he established was one to prevent frauds arising from the diversity of measures used in the country, by providing a standard legal measure for the whole of his dominions. This was the origin of the established Winchester measures; the standard vessels for measurement made by Edgar's orders being deposited in that city, where the original bushel is still preserved. In the reign of this prince, in 980, the cathedral, having been partly rebuilt, was solemnly re-consecrated. About the same time the married canons of the cathedral were, at the suggestion of St. Dunstan, removed, to make room for Benedictine monks. In Winchester, in 1002, and in the reign of Ethelred, famous the Unready, commenced the general massacre of the Danes, in merciless vengeance for the atrocities they had committed on the inhabitants of the country. Thence arose the noted lock-tide sports, of which some traces may still be observed in remote corners of England. But this vengeance remained not long unrewarded by Swayne the Dane, who obtained possession of Winchester eleven years afterwards. St. Ethelph II., then bishop, is said to have first introduced organs into the cathedral. Canute, obtaining the sovereignty of England by the death of Edmund Ironside in 1016, chose Winchester for his capital, and, with other rich gifts, bestowed on the cathedral his crown, which was placed over the crucifix on the high altar: for Canute had vowed never more to wear that ensign of royalty, from the day when, by commanding in vain the flowing tide not to approach his feet, he proved to his flatterers the emptiness of their adulation, in hailing him lord of the ocean. Winchester cathedral is described to have been the scene of a legendary tale relating to queen Emma, mother of Edward the Confessor, who is said, but very improbably, there to have established the purity of her character, by walking unshrunk over nine burning plough-shares. In the reign of the same Edward, the broad seal of the chancellor of England was first made and kept in Winchester.

The Norman invasion produced many changes in the state of the city: there king William I. founded a castle, as he did in many other parts of the kingdom, with the view of overawing, under the pretence of protecting, the inhabitants. It continued, however, to be a principal royal residence, although London then began to assume the pre-eminence. The politic monarch knew the influence of the clergy over the people; he consequently assigned all or most of the chief offices in England to his relatives, dependants, and oftentimes friends. Councils were held in Winchester, in which the new clergy, with the primate Lanfranc at their head, drew up canons or laws levelled at the Saxons, and framed to protect or justify themselves. Winchester, the residence of the court, was of course filled with the prelates, the officers, and the followers of the king. The curfew (courve feu), or eight-o'clock-bell, was first rung in Winchester. The year 1079 is memorable in the history of Winchester, for then was commenced the present spacious and magnificent cathedral church. In the reign of Henry I. a singular transaction
transactiion is recorded to have taken place in Winchester. The current coin of the realm having been greatly debased by the different mint-masters, the king in 1125 assembled them in this city, when all, except three who dwelt in Winchester, were found guilty and severely punished. The bills were cried down, and an entirely new coinage ordered to be made by the three masters who had preferred their honesty. About the same period Henry caused to be made a standard yard, from the length of his own arm, in order to prevent frauds in the measurement of cloth. This standard is supposed to have been deposited with other measures, &c. in Winchester. The city suffered greatly in the ensuing conflagration on the death of Henry, by the struggle between his nephew Stephen and his daughter, the empress Matilda, or Maud. Stephen's party held the bishop's palace, the cathedral, and adjoining quarters, while Maud's possessed the castle and the remainder of the city. By fire from Stephen's party, the whole north portion, then the most populous, the royal palace, the abbey of St. Mary, and twenty churches, the magnificent monastery of St. Grimbald, the suburb of Hyde, &c. were destroyed.

Many privileges were conferred on Winchester by Henry II., in particular, in 1184, that of being governed by a mayor, with a subordinate bailiff. His successor, Richard Courte-ducion, was solemnly re-crowned in the cathedral in 1194, on his return from captivity under the duke of Austria. To the end of 1207 was born in Winchester Henry III.; and four years afterwards his father John, for the sum of 200 marks paid at once, and 100 marks per annum, conferred on the city all the great and unprecedented privileges of a corporation. Thus Winchester became the first of all the corporate cities or towns in the kingdom, nearly two years before London had even obtained the privilege of being governed by a mayor. The dignity of the city was in some measure reftored by the residence of Henry III. during his minority; but it again severely suffered in the contests between the king and the barons. A heavy blow on Winchester proceeded from the removal of the royal residence, in the reign of Edward I.; who nevertheless held several parliaments there. Under Edward III. it was constituted one of the fixed markets, or staple for wool; but by the removal of the staple in 1363, the decline of Winchester from commerce and wealth was sensibly uniform. In this reign the rebuilding of the nave of the cathedral was begun by bishop Edington; but the honour of completing it, with material alterations, was reserved for his celebrated successor, William of Wykeham. To Winchester Henry VI. was a considerable benefactor; for in his reign it was restored in trade and population, that the inhabitants, in a petition to the king, represented 997 houses to be unoccupied, and 17 churches shut up. The see of Winchester was held for a short time by cardinal Wolsey; but in the time of his successor, Gardiner, the final dissolution of the monasteries, and the consequent destruction of religious houses, reduced the city to be little more than the skeleton of what it had formerly been. It revived for a short time in the reign of Mary, who restored her union with Philip of Spain, and restored to the see many lands which had been alienated by her father and brother. The city itself, however, had, as appears by a charter of Elizabeth, fallen ‘‘into great ruin, decay, and poverty.’’

The commencement of 1623 was distinguished by the proclamation of James I. in Winchester, by the sole authority of the sheriff of the county, without waiting for the orders of the privy council in London, who had passed several hours in deliberation on the subject. In the civil wars of Charles I.'s time, Winchester was successively held by the opposite parties; but after the fatal battle of Naseby in 1645, it was finally reduced by Cromwell. The works of the castle were blown up, the fortifications of the city were destroyed, together with the bishop's castle of Wolvesey, and several churches, and other public buildings. During the latter part of the reign of Charles II. Winchester had a prospect of recovering some portion of its former splendour; for he chose it for his usual residence, when not required by presence in the capital. In imitation of his example, many of the nobility and gentry likewise erected mansions in the city; but by Charles's death in 1685, the project was laid aside; the palace was left unfinished; and so completely has its original definition since been changed, that, after being frequently used as a prison of war, it is now converted into military barracks for the district.

Fortifications: Palace.—The ancient walls of Winchester form an irregular parallelogram, inclosing a portion of the slope of the western hill, and of the level valley watered by the Itchen. But the walls are now nearly destroyed, and the foss in many places filled up. The four gates seemed to have been constructed where those of the Roman intrenchment were opened. Through two of them, on the north and south sides, passed the great Roman road communicating between Vindonum, now Silchester, and Clausentum, near Southampton. Through the gate in the west side of the inclosure, corresponding to the Praetorian gate of the intrenchment, ran the road communicating with Serdiodunum, where now stand the remains of Old Sarum. This gate still exists, but much altered from its ancient state: part of it is suppos'd to be coeval with the city walls, but the whole western face displays workmanship of much later date. The east or Decuman-gate opened access to the lively and wholesome waters of the Itchen.

The castle, now entirely destroyed, overlooking the city from the west, owes its origin to the system of dominion adopted by William of Normandy. Within its boundary, of an elliptic form, 850 feet from north to south, and in its greatest breadth 250 feet from west to east, stands the original chapel dedicated to St. Stephen, and apparently erected by the king of that name. It is in length 110 feet, divided into a nave and side-aisles. At the east end is suppos'd the antique curiofity called king Arthur's round-table; but with more accuracy attributed to king Stephen, and probably introduced by him to prevent disputes for precedence, during their entertainments, among the chivalrous valiant of that age. It is 18 feet in diameter, composed of stout oak planks, painted with the figure of the renowned Arthur, and the names of his twenty-four knights, as collected from the romances of the 14th and 15th centuries. The costume is, however, of the time of Henry VIII., when the table was painted. This chapel was, in Cromwell's time, converted into a county-hall, a destination to which it continues to be applied. In the year 1792, several thousands of French ecclesiastics fought refuge on the British shores. In their distressful situation, they were generously succoured by the state and the people; and at one time one thousand of them were accommodated with lodgings, and all other necessaries, in this deferted abode of royalty.

Winchester possessed also another fortrefs at the opposite end of the city: this was Wolvesey castle, the episcopal residence erected by the powerful bishop Henry de Blois, brother of king Stephen.

Cathedral.—The grand object of attraction in Winchester is its cathedral, one of the most interesting structures of its kind in England, whether considered with respect to the antiquity of its foundation, to the importance of the trans-
WINCHESTER.

sections of which it has been the scene, or to the characters of the personages whose mortal remains it contains. This magnificent and venerable structure has been called, and not without some propriety, a school of ecclesiastical architecture; for it displays to the student an interesting and varied series of examples of the ancient architecture of England, from an early age down to a recent period. If the student fail to satisfy himself as to Roman remains, or genuine Saxon work; if, after careful examination, he retire either doubtful or persuaded that no such architecture is there to be discovered; till he will have ample evidence and examples of Norman works. The plans and magnificent designs of those proud invaders and innovators are in that fabric amply displayed. There he will see that the Normans built not for themselves only, but for posterity; that their edifices were solid and substantial, simple in their forms, and large in their parts; that as their system of religion was intended to awe, terrify, and terrify the mind, to its primary temple in England was calculated most essentially to promote these ends.

The cathedral of Winchester is of great extent, its extreme external length being 556 feet, that of the crofs or transepts 230 feet; the external breadth of the whole body and choir 118 feet, and that of the transepts 88 feet. The body of the church is divided by ranges of clustered columns into a nave and two side-ailes, as are also the transepts, with the usual addition of aisles at the extremities. The great central tower rises upon four piers of great solidity, and rises 140 feet from the pavement. The present fabric may be considered as the foundation of bishop Walkelyn, a chaplain and relative of William of Normandy, who began it in 1279, constructing the crypts, the transepts, and tower; also the internal parts of the piers and walls of the nave. The work was continued under succeeding prelates, in particular by bishop de Lucy, who built part of the east end; by Edington, who erected the west front about 1330; and above all by Wykeham, who, between 1370 and 1400, brought the nave to completion. The exterior of the cathedral presents but few beauties, or attractive features. Its length of nave, plainness of masonry, shortness and solidity of tower, width of east end, and boldness of transepts, furnish, however, so many peculiar and specific characteristics. The interior of the cathedral will amply compensate for any defects or deficiencies of the outside. While the fine and sublime architecture of Wykeham, in the nave and aisles, produces the most impressive effect, and claims general admiration; the large, plain, and substantial works of Walkelyn, in the tower and transepts, are simply grand and imposing. The transepts and tower are entitled to attention, as unrivalled specimens of Norman architecture. The choir and eastern end are elevated above the nave and aisles, by an ascent of several steps; the choir itself occupying the space molily beneath the Norman tower, and fitted up with flails of elaborate workmanship. On the north side stands the pulpit, curiously carved in the time of Silkreade, who became prior in 1408. On the same side of the choir is placed the organ, in an unusual situation, under one of the lofty arches of the tower. The choir is separated from the nave by a screen of the Composite or Roman order of architecture, said to have been designed by Inigo Jones. The lofty stone screen erected behind the high altar is an elaborate and sumptuous work, covered with niches, canopys, buttracres, pinacles, crockets, pediments, &c.; and when in its original colour and condition, with statues and costly ornaments, must have been peculiarly splendid and beautiful. On entering the church by the well door, the attention is first arrested by the vast and lofty columns of the nave, which have been made to affimilate with the pointed style, by surrounding them with clustered shafts and other ornaments. Between the fifth and sixth columns, on the south side, stands the chantry or mortuary chapel, containing the tomb of bishop William of Wykeham, erected in his life-time, or prior to the clofe of the year 1404. On an altar-tomb within the chapel is the marble effigy of the founder. On the same side of the nave is the chantry of bishop Edington, who died in 1366; within an open screen is an altar-tomb supporting his effigy. Immediately behind the altar-screen in the south aisle is placed the sumptuous chantry of bishop Fox, containing neither tomb, flatue, nor inscription, to commemorate the founder, or to explain his works in the church. In a recess beneath is the effigy of an emaciated human figure, the head ornamented with a mitre, but the feet reposing on a skull. Opposite to this chantry in the north aisle stands that of bishop Gardiner, who died in 1555.

Towards the eastern extremity of the church are the chantries of cardinal-bishop Beaufort on the south side, and of bishop Waynflete, the magnificent founder of St. Mary’s college, Winchester, and Magdalen college, Oxford, on the north side; each containing the tombs and figures of the respective prelates. The eastern extremity of the church is terminated by the spacious Lady-chapel, with a smaller inlaid on each side. In the middle of the presbytery, between the choir and the altar, lies a coffin-tomb, said to cover the remains of William Rufus, who was killed while hunting in the New Forest, and buried in this cathedral in 1100.

On the top of the side-screens, between the present choir and the ailes, are placed six wooden canopies, the work of bishop Fox, containing memorials and relics of Saxon monarchs, princes, and other illustrious personages, former protectors and benefactors of the cathedral. Another object of undoubted antiquity is the curious font, now placed between two columns on the north side of the nave. It is a large square block of black marble, charged on each side with sculptures, the whole supported by small columns at the corners. The subject of the sculptures is a matter of dispute; and although as productions of art they are beneath criticism, yet as representations of costume, manners, implements, &c. they deserve particular attention.

Episcopal Castle, or Palace.—Of this structure, better known by the name of Wolvesey castle, the ruins shew it to have been an imperfect parallelogram of about 250 feet by 150. What still remains belonged to the keep. Much was removed to make way for the new palace erected by bishop Morley, under the superintendence of Sir Christopher Wren, after its destruction by Cromwell. The front of Morley’s palace was pulled down by the present bishop, who never occupies the present house.

College.—One of the most celebrated institutions of Winchester is the college, founded by bishop Wykeham, and completed in 1393, on the site of an ancient grammar-school; intending it as preparatory for its establishment of New college, Oxford. The establishment in Winchester consists of a warden, 70 scholars, 10 secular priests, who are perpetual fellows, 3 priests’ chaplains, 3 clerks, 16 choristers, and a first and a second master. So judicious and complete were the statutes drawn up by Wykeham for the government of his college in Winchester, as to be adopted, with very little alteration, by Henry VI., for his own splendid institutions at Eton and King’s college, Cambridge. On the confirmation, by Edward VI., of the general dissolution of colleges, &c. introduced by his father, Winchester college, with that of Eton and the universities, were specially excepted. The buildings of the college occupy a considerable extent of ground, and consist principally
principally of two courts, with a cloister. The entrance to the first court is under a spacious gateway, having the mutilated buls of a bishop and a king, to represent the founder and his royal patron, Edward III. The second court is also entered by a tower gateway. The chapel and hall form the south wing of the quadrangle, and are enlightened by lofty windows. The interior of the chapel has a fine and lofty vaulting, ornamented with traceried. In the centre of the cloister is the library, originally constructed for a chantry in 1439, but converted to its present use in 1627. In the south-west corner of the second court is the hall or refectory, between which and the passage to the chapel is the school, a plain brick building, erected by subscription in 1687; over the door is the statue of the founder in bronze, by Cibber.

City.—The present city of Winchester consists chiefly of one main street, extending from the west to the east, with a number of collateral streets and lanes branching off on each side. Towards the middle of the High-street stands the city cross, an elegant specimen of the style of the age of Henry VI., consisting of three stories adorned with open arches, niches, pinnacles, and small croffes. The ecclesiastical buildings in Winchester, and its suburbs, were once very numerous, and, according to some writers, amounted to upwards of ninety. Scarcey twelve now remain. St. Laurence's church, near the cross, is considered as the mother-church of the city, and by a solemn entry into it the bishop takes possession of his see; but the principal parochial church is now that of St. Maurice. The town-hall, or more properly the hall of the guild of merchants of Winchester, rebuilt in 1713, occupies the place of one erected about 1112. There the city archives, the original Winchester bulwark of king Edgar, and other measures of length and capacity fixed as standards by succeeding princes, and various curious memorials of antiquity, are now preferred. The front of the building is ornamented with a statue of queen Anne. A neat market-house was erected in 1772. The ancient building on the north side of the High-street, called St. John's House, was originally founded as an hospital, apparently fo early as in the 10th century; but falling into the possession or the administration of the knights templars, or of St. John of Jerusalem, it was on the suppression of their order granted by Edward II. to a citizen of Winchester, who re-founded the institution for the sick and lame. soldiery, pilgrims, and wayfaring men, to have their lodging and diet there gratis for one night or longer, as their inability to travel might require. At the general dissolution of hospitals and monasteries, the revenues and moveable property were seized by Henry VIII. St. John's, but the corporation of the city referred the building itself to be used for municipal business. In 1554 it again became a charitable foundation, being endowed by Richard Lamb, Esq., for the support of six widows. The principal chamber or hall, which is 62 feet in length, 38 in breadth, and 28 in height, has been handsomely fitted up, chiefly by a donation from the late colonel Brydges of Avington. Among the decorations of this hall, in which public feasts, music-meetings, and assemblies are held, is a whole-length picture of Charles II. by Lely, presented to the city by that king himself. In the adjoining council-chamber are suspended the city tables, as they are called, containing a chronological arrangement of the most remarkable occurrences relating to Winchester. The ancient chapel of the hospital is now used as a Free-school. The celebrated monastery founded by the great Alfred, called the Newen Mynstre, and afterwards Hyde abbey, occupied nearly the whole space between the cathedral and the High-street. Completed under his son Edward, it was first filled by canons regular, who, in 963, gave place to Benedictine monks. Alwyn, the eighth abbot, with twelve of his monks, fell in the battle of Hatfield, in supporting the cause of his nephew, Harold, which drew upon the abbey the vengeance of William of Normandy. But the position being unhealthy and inconvenient, a new and magnificent church and monastery were erected without the north wall of the city, on the spot called Hyde-meadow, to which the monks removed in 1110, carrying with them the remains of several illustrious personages who had been buried in the former abbey, among which were those of Alfred himself and some of his descendants. The annual revenues of Hyde abbey, of which the abbot was in parliament, were at the dissolution valued at 865l. 18s. The church and monastery were soon afterwards demolished, and even the tombs of Alfred and other eminent personages were defiled. What now remains of this institution is the small and mutilated parish-church of St. Bartholomew. Precisely on the place occupied by the abbey-church was some time ago erected a bridge, or house of correction, on the plan of the benevolent Howard. In digging the foundations, stone coffins, rings, and vessels for the service of the church, were disinterred, together with fragments of architectural sculpture. But between fifty and sixty years ago, among the remains of the buildings, was found a bronce with this inscription in Saxon characters, 'Alfred Rex DCCCCLXXXI.' Another remarkable religious establishment in Winchester was the Nunna Mynstre, or abbey of St. Mary, founded by Alfred's queen, Alfswitha, and the place of her retirement after his death. Scarcely any vestige of the conventual buildings now remain, excepting in a modern mansion built out of the ancient materials, and the name of the abbey still applied to the inclosure where it stood.

Winchester, besides the numerous churches of the establishment, contains meeting-houses for dissenters of various denominations, among which the principal building is the Roman Catholic chapel, rebuilt by Dr. Milner in 1792, on the foundations of one more ancient. A large and commodious county-gaol, from the designs of Mr. Mouncey, has been lately erected on the north side of the city.

Many privileges have at various times been bestowed on Winchester by English sovereigns. Its chief magistrate, as was before noticed, received the title of mayor in 1384, some years before the title was granted to the chief magistrate of London. The first charter was conferred by king John; but that under which the city is now governed was the gift of Elizabeth, "in consideration," as it is stated, '"of the city of Winchester having been most famous for the celebration of the nativities, coronations, feuphreus, and for the preservation of other famous monuments of the queen's progenitors.' By this charter, the government is vested in a mayor, recorder, six aldermen, a town-clerk, two coroners, two constables, and a council of twenty-four of the "better, discreet, and more honest" inhabitants. The first return of representatives to parliament for Winchester took place in the twenty-third year of Edward I. The right of election is vested in the corporation.

Winchester possesses very little trade but what arises from its situation in the centre of an extensive and populous county. An ancient wool-combing manufacture, however, is still in existence, and of late years the silk manufacture has been introduced. All the public business of Hampshire is transacted in Winchester, which occasions a frequent and ample influx of strangers from all quarters. The cathedral and the college secure to the city the residence of a number of superior clergy. When in the height of its prosperity, and poifting the benefit of the wool-staple, the wealth of the inhabitants was greatly increased by the multi-
itudes referring to its fairs, the principal of which was held on the neighbouring hills of St. Giles and St. Mary Magdal.

St. Giles's fair was, at one time, by far the greatest in England. By a grant from William the Conqueror, it was originally to be held for one day only; but by Henry II. its duration was enlarged to sixteen days; and in that time no mercantile business was permitted to be transacted in Southampton, nor in any other place within seven leagues of St. Giles's hill. This fair has long become very insignificant; that of St. Mary Magdalen is still, however, much frequented. Since the year 1770, various improvements have been made in the general appearance of the city, by paving, repairing, and cleaning. As early as 1736 was established in Winchester an hospital or infirmary for the county, a very useful institution, conducted on a plan judicious in itself, and honourable to those entrusted with its administration. According to the parliamentary returns of 1811, the number of benefactions comprising the city and suburbs was 1134, and the inhabitants 6705.

Hospital of St. Cross.—About a mile south from Winchester, in the valley watered by the Itchen, stands the venerable hospital of the holy cross; an institution still retaining more of its original character. "The lofty tower," observes Dr. Milner, "with the grated door and porter's lodge beneath it, the retired ambulatory, the separate cells, the common refectory, the venerable church, the flowing black drapery, and the silver cross worn by the members, the conventual appellation 'brother' with which they address one another, the silence, the order, the neatness, in short, that reign here, seem to recall the idea of a monastery to those who have seen one, and will give no imperfect idea of such an establishment to those who have not had that advantage." But this establishment was never a monastery, being only an hospital originally founded by bishop Henry de Blois, between 1132 and 1136, for the residence and maintenance of thirteen poor men, and the relief of a hundred others of the most indigent of the city, but of creditable character. Each of these was to be provided daily with a loaf of bread, three quarters of small beer, and two melleys for his dinner, in a hall appointed for the purpose. In the hospital was an endowed place for a master, a clerk, four chaplains, thirteen clerks, and seven choristers. Before the time of William of Wykeham, bishop of Winchester in 1366, the revenues of St. Croes had been employed in a way very different from the intentions of the founder; but that munificent prelate succeeded, after long litigation, in restoring the institution to its original uses, re-establishing it on a secure and well-ordered foundation. The plan was afterwards refumed and enlarged by cardinal-bishop Beaufort, for the additional support of two priests and thirty-five religious poor men; he also rebuilt a considerable portion of the hospital. The present establishment of St. Croes is but the wreck of its ancient institutions, having been severely fleeced, though not quite destroyed, like many other charitable establishments, at the Reformation. Instead of seventy residents, clergy and laity, entirely supported in the place, and one hundred out-pensioners, the institution at present confits of but ten refiding brethren, and three out-pensioners, with one chaplain and the master. Certain doles of bread, it is true, continue to be distributed to the poor of the neighbourhood; and, as perhaps the only vestige remaining in the kingdom of the simple hospitality of ancient days, the porter is daily furnished with a certain quantity of good bread and beer, of which every traveller, or other person whatever, who knocks at the lodge and calls for relief, is entitled to partake gratuitously. The buildings of the hospital once composed two courts; but the fourth side of the interior quadrangle has been of late years pulled down. On the east side of the outer court is the 'hundred-menne's hall,' about forty feet long, now converted into a brewhouse; on the south side is the handsome tower-gateway, with the statue of the founder, Beaufort, in the upper part. In the second, or inner court, is the church, built in the cathedral form, with a nave and transepts, and a low massive tower at their interfrontion. The architecture of the edifice is singularly curious, as it throws some light on the progress, if not on the origin, of the pointed, or English style. The whole edifice seems to be a collection of architectural essays, with respect to the form and the disposition, of both the essential parts and the subordinate ornaments. It presents the ponderous pillar of a height equal to its circumference, but supporting an incipient pointed arch. The lower part of the nave contains massive Norman pillars; and the portal of the west front is an elegant specimen of the time of King John, or beginning of that of Henry III. The west wing of the remaining buildings contains the apartments of the Brethren, each of whom has for his own use three chambers and a separate garden. Adjoining to the hall on the north side are the apartments of the master, which are spacious and convenient; and on the east side is the ambulatory or open portico for exercise.

St. Catherine's Hill, or College Hill, separated from the meadows of St. Croes by the branches of the Itchen, is remarkable for the intrenchment carried round its summit: the former name it acquired from an ancient chapel on it, deprived of its endowments by cardinal Wolsey; the latter, because it is a frequent place of resort for the students of the college.

About three miles north-east from Winchester lies Avington, anciently Abingdon, a seat and manor of the present marquis of Buckingham, in conformance of his marriage with the sole daughter and heir of James, the late duke of Chandos. The manor, originally a royal demesne, was granted, in 1561, by king Edward to the monastery of St. Swithun, in Winchester; but in conformance of the diolution, it became, in the reign of Elizabeth, the property of the ancient family of Bruges, or Brydges, first settled in Shropshire at the Conquest. Inter-marrying with the family of lord Chandos, renowned in the wars in France under Edward III., the honours of the two families have ever since continued united. Avington is situated in a secluded valley, well planted and nearly inclosed by high downs. The present mansion is of brick, and has been greatly improved by the present possessor, having been previously dismantled by the late duke, for the purpose of adding two wings. Some of the apartments are fitted up with great elegance, and enriched by a selection of excellent paintings. The park formed by the late duke, about three miles in circumference, contains a piece of water supplied by the river Itchen.—History, &c. of Winchester, by the Rev. John Milner, D.D. F.S.A., 2 vols. 4to. 2d edit. 1809. Beauties of England, vol. vii. Hampshire, by J. Britton and E. W. Brayley. History, &c. of Winchester Cathedral, by J. Britton, 1 vol. 4to. with 30 Prints.

Winchester, a town of New Hampshire, in the country of Cheshire, with 1478 inhabitants; 13 miles S.E. of Chesterfield.—Allo, a town of the state of Connecticut, in Litchfield county, with 1466 inhabitants; 22 miles N.W. of Hartford.—Allo, a town of the state of Kentucky, with 4 churches, and 2000 inhabitants.

Winchester, or Fredericktown, a town of Virginia; 56 miles W.N.W. of Washington. N. lat. 39° 15'. W. long. 78° 27'.

Winching, in the Manges, is said of a horse when he kicks, spurs, or throws out his hind feet.
WINCKHEIM, in Geography, a town of the duchy of Wurzburg; 4 miles N.N.W. of Lauringen.

WINCRANTUM, in Natural History, a name given by the people of the East Indies to a sciolie substance resembling, in some degree, the plated lead ores of Europe, but containing very little of that metal; it is properly a species of blende, or mock-lead, of a tacky appearance; it is confiderably hard, and is usually found in other stones. It is given in medicine in the Indies as a provocative to venery, being first calcined and beat to powder.

WIND, VENTUS, a fenfible agitation of the air, by which a large quantity of it flows in a current or stream out of one place, or region, into another. See Meteorology.

The winds are divided into perennial, flated, and variable. They are also divided into general and particular.

WINDS, Perennial or Constant, are such as always blow the same way.

Of these we have a very notable one between the two tropics, blowing conftantly from east to west; called the general trade-wind.

WINDS, Stated or Periodical, are such as constantly return at certain times. Such are the sea and land breezes, blowing from sea to land in the evening; and from land to sea in the morning.

Such also are the shifting or particular trade-winds, which, for certain months of the year, blow one way, and the reft of the year the contrary way. See Trade-Winds.

WINDS, Variable or Erratic, are such as blow now this, now that way; and are now up, now hufhed, without any rule or regularity, either as to time or place.

Such are all the winds observed in the inland parts of England, &c. though few of these claim their certain times of the day. Thus, the west wind is moft frequent about noon; the south wind in the night; the north in the morning, &c.

WIND, General, is such a one, as at the fame time blows the fame way, over a very large tract of ground, almoft all the year. Such only is the general trade-wind.

But even this has its interruption: for, 1. At land it is scarcely fenfible at all, as being broken by the interpoftion of mountains, valleys, &c. 2. At sea, near the shore, it is disturbed by vapours, exhalations, and particular winds, blowing from landward; fo that it is chiefly confidered as general, only at mid-sea: where, 3. It is liable to be disturbed, by clouds driving from other quarters.

WINDS, Particular, include all others, excepting the general trade-winds; which fee.

Those peculiar to one little canton, or part, are called topical or provincial winds. Such is the north wind, on the western side of the Alps, which does not blow above one or two leagues lengthwise, and much less in breadth: such also is the pontias in France, &c.

WINDS, Physical Cause of: Some philosophers, as Des Cartes, Rohault, &c. account for the general wind, from the diurnal rotation of the earth, and from this general wind derive all the particular ones. The atmopherfe, fay they, invelling the earth, and moving round it; that part will perform its circuit fooneft which has the fmalleft circle to defcribe: the air, therefore, near the equator, will require a fowemwhat longer time to perform its course in, from west to eaf't, than that nearer the poles.

Thus, as the earth turns eastward, the particles of the air near the equinoctial, being exceedingly light, are left behind; fo that, in refpect of the earth's surface, they move eastwards, and become a confiant eaf'terly wind.

This opinion seems confirmed by this, that these winds are found only between the tropics, in thofe parallels of latitude where the diurnal motion is fweeter. But the confant calms in the Atlantic sea near the equator, the wefterly winds near the coast of Guinea, and the periodical wefterly monfoons under the equator in the Indian seas, declare the infufficiency of this hypothesis.

Besides, the air, being kept close to the earth by the principle of gravity, would, in time, acquire the fame degree of velocity that the earth's surface moves with, as well in refpect of the diurnal rotation, as of the annual, about the fun, which is about thirty times fweeter. See Trade-Winds.

Dr. Halley, therefore, substitutes another cafe, capable of producing a like confant effect, not liable to the fame objections, but agreeable to the known properties of the elements of water and air, and the laws of the motion of fluid bodies. Such a one is the action of the sun's beams upon the air and water, as he paffes every day over the ocean, confidered together with the quality of the fand, and the situation of the adjoining continents.

According to the laws of statics, the air, which is lefs rarefied or expanded by heat, and confequently is more ponderous, muft have a motion towards thofe parts of it which are more rarefied, and lefs ponderous, to bring it to an equilibriwm; alfo, the preience of the sun continually shifting to the wef'tward, that part towards which the air bends, by reafon of the rarefation made by his greateft meridian heat, is, with him, carried wef'tward; and, confequently, the tendency of the whole body of the lower air is that way.

Thus a general eaf'terly wind is formed, which being impressed upon the air of a vaf't ocean, the parts impel one the other, and fo keep moving till the next return of the fun, by which fo much of the motion as was loft is again restored; and thus the eaf'terly wind is made perpetual.

From the fame principle it follows, that this eaf'terly wind fhould, on the north fide of the equator, be to the northward of the eaf't, and in fouth latitudes to the fouthward of it; for, near the line, the air is much more rarefied than at a greater diftanee from it; becaufe the fun is twice in a year vertical there, and at no time distant above 23½ degrees; at which diftanee, the heat, being as the fane of the angle of incidence, is but little short of that of the perpendicular ray; whereas under the tropics, though the fun ray longer vertical, yet he is a long time 47 degrees off, which is a kind of winter, in which the air is cooler, as that the fummer heat cannot warm it to the fame degree with that under the equator. Wherefore, the air towards the north and fouth being lefs rarefied than that in the middle, it follows, that from both fides it ought to tend towards the equator.

This motion, compounded with the former eaf'terly wind, accounts for all the phenomena of the general trade-winds, which, if the whole surface of the globe was fweeter, would undoubtedly blow quite round the world, as they are found to do in the Atlantic and the Ethiopic oceans. But feeing that fo great continents do interpofe, and break the con tinuity of the ocean, regard muft be had to the nature of the fand, and the poftition of the high mountains, which are the two principal caufes of the variations of the wind from the former general rule; for if a country lying near the fun prove to be flat, sandy, and low land, fuch as the deferts of Lybia are ufually reported to be, the heat occasioned by the refexions of the fun's beams, and the retention of it in the fand, is incredible to thofe who have not felt it; by which the air being exceedingly rarefied, it is neceffary that the cooler and more dense air fhould run thitherwards, to reftore the equilibrium. This is supposed to be the caufe, why, near
near the coast of Guinea, the wind always sets in upon the land, blowing westerly instead of easterly, there being sufficient reason to believe that the inland parts of Africa are prodigiously hot, since the northern borders of it were so very intertemperate, as to give the ancients cause to conclude that all beyond the tropics was uninhabitable by excess of heat.

Mr. Clare, in his Motion of Fluids, p. 302. mentions a familiar experiment, that serves to illustrate this matter, as well as the alternate converse of land and sea breezes. Fill a large dish with cold water, and in the middle of it place a water-plate, filled with warm water: the first will represent the ocean, the other an island, rarely the air above it. Then holding a wax-candle over the cold water, blow it out, and the smoke will be seen, in a still place, to move toward the warm plate, and ribbing over, it will point the course of the air (and also of vapour) from sea to land. And if the ambient water be warm, and the plate filled with cold water, and the smoking wax-candle of a hook held over the plate, the contrary will happen. (See Breeze.) For the phenomena of the wind observed by Dr. Halley, and explained by his theory, see Wind, in Navigation.

From the same cause it happens, that there are more constant calms in that same part of the ocean, called the rains; for this tract being placed in the middle, between the westerly winds blowing on the coast of Guinea, and the easterly trade-winds blowing to the westward of it; the tendency of the air here is indifferent to either; and so stands in equilibrium between both; and the weight of the incumbent atmosphere being diminished by the continual contrary winds blowing from hence, is the reason that the air here holds not the copious vapour it receives, but lets it fall in frequent rains.

But, as the cold and dense air, by reason of its greater gravity, presses upon the hot and rarefied, it is demonstrable that this latter must ascend in a continued stream as fast as it rarefies; and that, being ascended, it must disperse itself, to preserve the equilibrium; that is, by a contrary current, the upper air must move from those parts where the greatest heat is, fo, by a kind of circulation, the north-east trade-wind below will be attended with a south-westerly wind above; and the south-east, with a north-west wind above.

That this is more than a bare conjecture, the almost instantaneous change of the wind to the opposite point, which is frequently found in passing the limits of the trade-winds, seems strongly to assure us; but that which above all confirms this hypothesis, is the phenomenon of the monsoons, by this means most easily solved, and without it hardly explicable. See Monsoons.

Supposing, therefore, such a circulation as above, it is to be considered, that to the northward of the Indian ocean there is everywhere land, within the usual limits of the latitude of 30°; viz. Arabia, Persia, India, &c., which, for the same reason as the Mediterranean parts of Africa, are subject to insufferable heats when the sun is to the north, passing nearly vertical; but yet are temperate enough when the sun is removed towards the other tropic, because of a ridge of mountains at some distance within the land, said to be frequently, in winter, covered with snow, over which the air, as it paffes, must needs be much chilled. Hence it happens, that the air coming, according to this general rule, out of the north-east, to the Indian sea, is sometimes hotter, sometimes colder, than that which, by this circulation, is returned out of the south-west; and, by consequence, sometimes the under-current, or wind, is from the north-east, sometimes from the south-west.

Which these winds set, viz. in April; when the sun begins to warm these countries to the north, the south-west monsoons begin, and blow, during the heats, till October, when the sun being retired, and all things growing cooler northward, and the heat increasing to the south, the north-east winds enter, and blow all the winter till April again. And it is, undoubtedly, from the same principal, that to the southward of the equator, in part of the Indian ocean, the north-west winds succeed the south-east, when the sun draws near the tropic of Capricorn. Phil. Tranf. No. 185. or Abrig. vol. ii. p. 139.

Some philosophers, dissatisfied with Dr. Halley's theory above recited, or not thinking it sufficient for explaining the various phenomena of the wind, have had recourse to another cause, viz. the gravitation of the earth and its atmosphere towards the sun and moon, to which the tides are confessedly owing. See Tides.

From the laws of universal attraction it has been inferred, that these celestial bodies must act upon the atmosphere, or that they must occasion a flux and reflux of the atmosphere, as well as of the ocean. Hence it has been alleged, that though we cannot discover aerial tides, of ebb or flow, by means of the barometer, because columns of air of unequal height, but different density, may have the same pressure or weight; yet the protuberance in the atmosphere, which is continually following the moon, must, they say, of course produce a motion in all parts, and fo produce a wind more or less to every place, which, conspiring with or counteracted by the winds arising from other causes, makes them greater or less. Several dissertations to this purpose were published, on occasion of the subject proposed by the Academy of Sciences at Berlin, for the year 1746.

Although the atmospheric air is much more variable than water, and the action of the sun and moon upon it becomes much less apparent to us, because they must frequently counter with or be counteracted by the much more powerful effects of heat and cold, of dryness and moisture, of winds, &c. so that their action upon the barometer has been long disputed and even denied, (see Moon, Influence of) yet that the moon in particular, as well as the sun, has such an action has been for a considerable time surmised; and of late years it has been in a degree observed and rendered sensible by means of very accurate and long-continued barometrical observations, and perceived only by taking a mean of the observations of many years.

Toaldo, the learned astronomer of Padua, after a variety of observations made in the course of several years, found reason to assert, that, ceteris paribus, at the time of the moon's apogee, the mercury in the barometer rises the 0.105 of an inch higher than at the perigee; that at the time of the quadratures, the mercury stands 0.008 of an inch higher than at the time of the syzygies; and that it stands 0.022 of an inch higher when the moon in each lunation comes nearest to our zenith, (meaning the zenith of Padua, where the observations were made,) than when it goes farthest from it. Journal des Sciences Utiles.

In the seventh volume of the Philosophical Magazine, there is a paper of L. Howard, esq., which contains several curious observations relative to this subject. This gentleman found, both from his own observations, and from an examination of the Meteorological Journal of the Royal Society, which is published annually in the Philosophical Transactions, that the moon had a manifest action upon the barometer. "It appears," he says, "to me evident, that the atmosphere is subject to a periodic change of gravity, by which the barometer, on a mean of ten years, is depressed at least one-tenth of an inch while the moon is passing from the 3 P quarters
WIND.

quarters to the full and new; and elevated, in the same proportion, during the return to the quarter. A great fall of the barometer generally takes place before high tides, especially at the time of new or full moon.

The canes, it is said, which render the diurnal tide of the atmosphere sensible to us, may be the elasticity of the air, and the interference of the much more powerful effects of heat, cold, vapours, &c.

It has been calculated by D'Alembert, from the general theory of gravitation, that the influence of the sun and moon in their daily motions is sufficient to produce a continual east wind about the equator. So that, upon the whole, we may reckon three principal daily tides, viz., two arising from the attractions of the fun and moon, and the third from the heat of the sun alone; all which sometimes combine together, and form a prodigious tide.

In corroboration of the opinion of the influence of the sun, and principally of the moon, in the production of wind, we must likewise mention the observations of Bacon, Gaffendi, Dampier, Halley, &c.; namely, that the periods of the year most likely to have high winds are the two equinoxes; that storms are more frequent at the time of new and full moon, especially those new and full moons which happen about the equinoxes; that, at periods otherwise calm, a small breeze takes place at the time of high water; and that a small movement in the atmosphere is generally perceived a short time after the moon and the midnights of each day.

M. Mučhenbroek, however, will not allow that the attraction of the moon is the cause of the general wind; because the east wind does not follow the motion of the moon about the earth; for in that case there would be more than twenty-four changes, to which it would be subject in the course of a year, instead of two. Intro. ad Phil. Nat. vol. ii. p. 1103.

Some action in the production of wind may also be derived from volcanoes, fermentations, evaporation, and especially from the condensation of vapours: for we find that, in rainy weather, a considerable wind frequently precedes the approach of every single cloud, and that the wind subsides as fast as the cloud has passed over our zenith.

Wherever any of the above-mentioned causes are constantly more predominant, as the heat of the sun within the tropics, there a certain direction of the wind is more constant; and where different causes interfere at different and irregular periods, as in those places which are considerably distant from the torrid zone, there the winds are more changeable and uncertain.

In short, whatever disturbs the equilibrium of the atmosphere, viz. the equal density or quantity of air at equal distances from the surface of the earth; whatever accumulates the air in one place, and diminishes it in other places, must occasion a wind both in disturbing and in reestablishing that equilibrium, as above stated.

Mr. Henry Eales, apprehending that the sun's rarefying of the air cannot singly be the cause of all the regular and irregular motions which we find in the atmosphere, attributes them to another cause, viz. the ascent and descent of vapour and exhalation, attended by the electrical fire or fluid; and on this principle he has endeavoured to explain at large the general phenomena of the weather and barometer. Phil. Trans. vol. xvi. art. 25. p. 124.

M. Brilhon (Principes de Physique) also is of opinion that electricity is the principal and more general cause which produces winds; but Mr. Cavallo is of a different opinion.

After making various observations on the nature and theory of winds, Dr. Darwin recapitulates his opinions in the following manner. 1. The north-east wind consists of air flowing from the north, where it seems to be occasionally produced; and has an apparent direction from the east, owing to its not having acquired in its journey the increasing velocity of the earth's surface. These winds are analogous to the trade-winds between the tropics, and frequently continue in the vernal months for four or six weeks together, with a high barometer, and fair and frosty weather. They sometimes consist of south-west air, which had passed by us or over us, driven back by a new accumulation of air in the north; and they continue but a day or two, and are attended with rain.

2. The south-west wind consists of air flowing from the south, and seems occasionally absorbed at its arrival to the more northern latitudes. It has a real direction from the west, owing to its not having lost in its journey the greater velocity it had acquired from the earth's surface from whence it came. These winds are analogous to the monsoons between the tropics, and frequently continue for four or six weeks together, with a low barometer, and rainy weather. They sometimes consist of north-east air, which had passed by us, and which becomes retrograde by a commencing deficiency of air in the north. These winds continue but a day or two, attended with heavy frosts, with a sinking barometer; their cold being increased by their expansion as they return into an incipient vacancy.

3. The north-east wind consists of air flowing from the north, which have been passed over, been blown down, and driven back towards the south by newly-generated northern air. They continue but a day or two, and are attended with rain or clouds. They consist of north-east winds blown down from the higher parts of the atmosphere, and having there acquired a greater velocity from the earth's surface than frosty and fair. They consist of north-east winds formed into a vertical eddy, not a spiral one, with frost or fair.

4. The north winds consist of air flowing slowly from the north, so that they acquire the velocity of the earth's surface as they approach it; they are fair or frosty, but seldom occur. They consist of retrograde south winds; these continue but a day or two, are preceded by south-west winds, and are generally succeeded by north-east winds, cloudy or rainy weather, the barometer rising.

5. The south winds consist of air slowly flowing from the south, losing their previous colder velocity by the friction of the earth's surface as they approach it; they are moist, but seldom occur. They consist of retrograde north winds; these continue but a day or two, and are preceded by north-east winds, and are generally succeeded by south-west winds, colder, and the barometer sinking.

6. The east winds consist of air brought hastily from the north, and not impelled farther southward, owing to a sudden beginning absorption of air in the northern regions; they are very cold, the barometer high, and are generally succeeded by south-west winds.

7. The west winds consist of air brought hastily from the south, and checked from proceeding farther to the north, by a beginning production of air in the northern regions; they are warm and moist, and generally succeeded by north-east winds. They consist of air bent downwards from the higher regions of the atmosphere; if this air be from the south, and brought hastily, it becomes a wind of great velocity, moving perhaps 60 miles in an hour, and is warm and rainy; if it consists of northern air bent down it is of less velocity, and cooler.

Various other interesting remarks and reflections on winds may be seen in the notes to the Botanic Garden, by the same writer.
The industry of some late writers having brought the theory of the production and motion of winds to somewhat of a mathematical demonstration; we shall here give it the reader in that form.

WINDS, Laws of the Production of. If the spring of the air be weakened in any place, more than in the adjoining places; a wind will blow through the place where the diminution is.

For, 1. Since the air endeavours, by its elastic force, to expand itself every way; if that force be less in one place than another, the effort of the more against the less elastic, will be greater than the effort of the latter against the former. The less elastic air, therefore, will refill with less force than it is urged by the more elastic: consequently, the less elastic will be driven out of its place, and the more elastic will succeed.

If, now, the excess of the spring of the more elastic above that of the less elastic air, be such as to occasion a little alteration in the baroscope; the motion both of the air expelled, and that which succeeds it, will become sensible, i.e. there will be a wind.

2. Hence, since the spring of the air increases, as the compressible weight increases, and compressed air is denser than air less compressed; all winds blow into rarer air, out of a place filled with a denser.

3. Wherefore, since a denser air is specifically heavier than a rarer; an extraordinary lightness of the air in any place must be attended with extraordinary winds or storms.

Now, an extraordinary fall of the mercury in the barometer, fleeing an extraordinary lightness of the atmosphere, it is no wonder if that foretold storms. See Barometer.

4. If the air be suddenly condensed in any place, its spring will be suddenly diminished; hence, if this diminution be great enough to affect the barometer, there will a wind blow through the condensed air.

5. But since the air cannot be suddenly condensed, unless it have before been much rared, there will a wind blow through the air, as it cools, after having been violently heated.

6. In like manner, if air be suddenly rared, its spring is suddenly increased; wherefore, it will flow through the contiguous air, not acted on by the rarefying force. A wind, therefore, will blow out of a place, in which the air is suddenly rared; and on this principle, in all probability, it is, that,

7. Since the sun’s power in rarefying the air is notable, it must necessarily have a great influence on the generation of winds.

8. Mott caves are found to emit wind, either more or less. M. Mufchenbroek has enumerated a variety of causes that produce winds, existing in the bowels of the earth, on its surface, in the atmosphere, and above it. See Intr. ad Phil. Nat. vol. ii. p. 1116, &c.

The rising and changing of the wind are determined experimentally, by means of weather-cocks, placed on the tops of houses, &c. \[ \text{But these only indicate what passes about their own height, or near the surface of the earth: Wol-} \]
\[ \text{fius affords us, from observations of several years, that the} \]
\[ \text{higher winds, which drive the clouds, are different from the} \]
\[ \text{lower ones, which move the weather-cocks. And Dr.} \]

WIND, Laws of the Force and Velocity of. Wind being only air in motion, and air being a fluid subject to the laws of other fluids, its force may be regularly brought to a pre-
cise computation: thus, ‘The ratio of the specific gravity of any other fluid to that of air, together with the space that fluid, impelled by the preffure of the air, moves in any given time, being given: we can determine the space through which the air itself, acted on by the same force, will move in the same time.’ By this rule:

1. As the specific gravity of air is to that of any other fluid; so, reciprocally, is the square of the space, which that fluid, impelled by any force, moves in any given time, to the square of the space which the air, by the same impulfe, will move in the same time.

Supposing, therefore, the ratio of the specific gravity of that other fluid to that of air, to be \( \frac{b}{c} \); the space described by the fluid to be called \( s \) and that which the air will describe by the same impulfe, \( x \). The rule gives

\[ x = \sqrt{\frac{b}{c}} s. \]

Hence, if we suppose water impelled by the given force, to move two feet in a second of time, then will \( s = 2 \); and since the specific gravity of water to the air is as 800 to 1, we shall have \( b = 800c \) and \( c = 1 \); consequently, \( s = \sqrt{800 \times 4} = \sqrt{3200} = 57 \) feet nearly.

The velocity of the wind, therefore, to that of water, moved by the same force, will be as 57 to 2; i.e. if water move two feet in a second, the wind will fly 57 feet.

2. Add, that \( x = \sqrt{\frac{c}{b}} s \); and therefore the space any fluid, impelled by any impression, moves in any time, is determined, by finding a fourth proportional to the two numbers that express the ratio of the specific gravities of the two fluids, and the square of the space the wind moves in, in the given time. The square root of that fourth proportional is the space required.

Mr. Mariotte, \( a, gr. \) found, by various experiments, that a pretty strong wind moves 24 feet in a second of time, which is at the rate of 1440 in a minute; \( i.e. \) at the rate of somewhat more than 16 miles in an hour: wherefore, if the space which the water, acted on by the same force as the air, will describe in the same time, be required; then will \( c = 1, s = 24, b = 800 \); and we shall find \( x = \sqrt{\frac{576}{800}} = \frac{24}{5} \) nearly.

Derham estimated the velocity of the wind in very great storms at 66 feet per second; and de la Condamine at 904 feet per second.

3. ‘The velocity of wind being given, to determine the preflure required to produce that velocity,’ we have this rule. The space the wind moves in one second of time, is to the height a fluid is to be raised in an empty tube, in order to have a preflure capable of producing that velocity, in a ratio compounded of the specific gravity of the fluid to that of air, and of quadruple the altitude
WIND.

Altitude a body descends in the first second of time, to the
aforeaid space of the air.

Suppose, \( r \), gr. the space through which the air moves
a second, \( a = 24 \) feet, or 288 inches; call the alti-
itude of the fluid \( x \); and the ratio of mercury to air,
\[
\frac{b}{c} = \frac{800 \times 14}{1} = \frac{11200}{1};
\]
and the altitude through which
a body descends in the first second of time, 16 feet 1
inch; then, by the theorem, we shall have \( 288 : x ::
11200 \times 762 : 288 \), and consequently
\[
x = \frac{11200 \times 762}{288} = 11200 \times 762
\]
= .01, &c. of an inch. Hence we see why a small
but sudden change in the barometer is followed with
violent winds. See an account of the principle upon
which these calculations are founded under the article WATER.

When the direction of the wind is not perpendicular, but
oblique to the surface of the solid, then the force
of the former upon the latter will not be so great as when the
impulse is direct, and that for reasons which are easily derived
from the theory of the resolution and composition of forces,
and from the theory of direct and oblique impulses. In
short, the general proposition for compound impulses is, that
the effective impulse is as the surface, as the square of the
air's velocity, as the square of the sine of the angle of inci-
dence, and as the sine of the obliquity of the solid's motion
to the direction of the impulse, jointly; for the alteration of
every one of those quantities will alter the effect in the same
proportion. But these general rules, as we have already
more than once observed, are subject to great variations; so
that their results seldom coincide with those of actual
experiments.

Philosophers have used various methods for determining
the velocity of the wind, which is very different at different
times. The method used by Dr. Derham was that of
letting light downy feathers fly in the wind, and accurately
observing the distance to which they were carried in any
number of half seconds. This method he preferred to that
of Dr. Hooke's mola alata, or pneumatica. (See Phil. Tran.
No. 24, and Birch's Hill. Roy. Soc. vol. iv. p. 225.)
He tells us, that he thus measured the velocity of the wind
in the great storm of August, 1705, and by many experi-
ments found, that it moved at the rate of thirty-three feet
per half-second, or of forty-five miles per hour: whence he
concludes, that the most vehement wind (as that of Novem-
ber, 1703) does not fly at the rate of above fifty or sixty
miles per hour, and that at a medium the velocity of wind is
at the rate of twelve or fifteen miles per hour. Phil. Tran.
No. 313, or Abr. vol. iv. p. 411.

Mr. Brice observes, that experiments with feathers are
subject to uncertainty: as they seldom or ever descibe a
straight line, but describe a sort of spirals, moving to the
right and left, and rising to very different altitudes in their
progress. He, therefore, considers the motion of a cloud,
or its shadow, over the surface of the earth, as a much more
accurate measure of the velocity of the wind. In this way
he found, that the wind, in a considerable gale, moved at
the rate of 62.9 miles per hour; and that, when it blew a
fresh gale, it moved in the same time about twenty-one
miles; and that in a small breeze, the wind moved at the

But it has been observed by Cavallo and others, that this
method is very fallacious, partly because it is not known
whether the clouds do or do not move exactly with the air
in which they float; and partly because the velocity of the
air in the region where the clouds float is by no means the
fame with that of the air which is nearer to the surface of
the earth, and is sometimes quite contrary to it, as indicated
by the motion of the clouds themselves. Others have esti-
mated the velocity of the wind by the changes affected by
it upon the motion of found, which must of course be very
inaccurate. A very simple method of determining the ve-
locity of the wind is that which M. Coulomb (Mem. de
l'Acad. Roy. 1781, p. 70.) employed in his experiments
on wind-mills, because it requires neither the aid of instru-
ments nor the trouble of calculation. Two persons were
placed on a small elevation, at the distance of 150 feet from
one another, in the direction of the wind; and, while the
one observed, the other measured the time which a small
and light feather employed in removing through this space.
The distance between the two persons, divided by the num-
ber of seconds, gave the velocity of the wind per second.
The best method, says Cavallo, of measuring the velocity of
the wind, is by observing the velocity of the smoke of a
low chimney, or by estimating the effect it produces upon
certain bodies, and thus may be determined its force as well
as its velocity. We shall here observe, that from the concurrence
of experiments made with various instruments, and different
modes of calculation, it has been inferred, that in currents of
air, of the denomination which are expre sued in the 4th
column of the annexed table, the air moves at the rate of
so many feet per second as are expressed in the 2d column,
or of so many miles per hour as are expressed in the 1st
column.

A Table of the different velocities and forces of the
winds, constructed by Mr. Roule with great care, from a
considerable number of facts and experiments, and
communicated to Mr. Smeeant, and first published by him in
the 5th volume of the Philosophical Transaotions.

| Miles in one Hour. | Feet in one Second. | Perpendicular Force on one Square Foot, in Air and Atmos- 
| Common Appraisals of the | | Pounds. |
| per Hour. | | |
| 1 | 1.47 | .005 | Hardly perceptible. |
| 2 | 2.93 | .020 | Soft perceptible. |
| 3 | 4.40 | .044 | Gentle pleasant wind. |
| 4 | 5.87 | .079 | Pleasant brisk gale. |
| 5 | 7.33 | .123 | Very brisk. |
| 10 | 14.67 | .492 | High wind. |
| 15 | 22.00 | 1.107 | Very high. |
| 20 | 29.34 | 1.698 | A storm or tempest. |
| 25 | 36.67 | 3.075 | A great storm. |
| 30 | 44.01 | 4.429 | A hurricane. |
| 35 | 51.34 | 6.027 | A hurricane that tears up trees, and carries |
| 40 | 58.68 | 7.873 | buildings, &c. before it. |
| 45 | 66.01 | 9.653 | |
| 50 | 75.35 | 12.300 | |
| 60 | 88.02 | 17.715 | |
| 80 | 117.36 | 31.490 | |
| 100 | 146.70 | 49.200 | |

The force of the wind is as the square of its velocity; as
Mr. Ferguson has shown by experiments on the whirling-
table; and in moderate velocities this will hold very nearly.

On
Upon this principle the numbers in the third column are calculated. The proposition upon which this column has been formed seems to be, that the impulse of a current of air, striking perpendicularly upon a given surface, with a certain velocity, is equal to the weight of a column of air which has that surface for its base, and for its height the space through which a body must fall, in order to acquire that velocity of the air.

It is observed, with regard to this table, that the evidence for those numbers, where the velocity of the wind exceeds fifty miles an hour, does not seem of equal authority with that of those of fifty miles, or under. Phil. Trans. vol. i. p. 165.

Dr. Hales found (Statistical Eff. vol. ii. p. 326.) that the air rushed out of a pair of smith's bellows, at the rate of 68.73 feet in a second of time, when compressed with a force equal to the weight of one inch perpendicular depth of mercury, lying on the whole upper surface of the bellows. The velocity of the air, as it paffed out of the trunk of his ventilators, was found to be at the rate of three thousand feet in a minute; which is at the rate of thirty-four miles an hour. Dr. Hales says, that the velocity with which impelled air paffes out at any orifice may be determined by hanging a light valve over the nose of a bellows, by plant leathern hinges, which will be much agitated and lifted up from a perpendicular to a more than horizontal position by the force of the rushing air. There is another more accurate way, he says, of estimating the velocity of air, viz. by holding the orifice of an inverted glass fiphon full of water, opposite to the stream of air, by which the water will be depressed in one leg, and raised in the other, in proportion to the force with which the air is impelled by the air. Descritp. of Ventilators, 1743, p. 12, &c.

The velocity and force of the wind are determined experimentally by a peculiar machine, called an anemometer or wind-measurer. Of these there have been many, variously constructed. See ANEMOMETER, ANEMOSCOPE, and WIND-CAGES.

WIND, Qualities and Effects of. 1. "A wind blowing from the sea is always moist; in summer, it is cold; and in winter, warm, unless the sea be frozen up." This is demonstrated thus: there is a vapour continually rising out of all water, (as appears even hence, that a quantity of water, being left a little while in an open vessel, is found sensibly diminished,) but especially if it be exposed to the sun's rays; in which case, the evaporation is beyond all expectation. By this means, the air incumbent on the sea becomes impregnated with a quantity of vapour. But the winds, blowing from off the sea, sweep these vapours along with them; and consequently they are always moist. Again, water in summer, &c. conceives less heat than terrestrial bodies, exposed to the same rays of the sun, do; but in winter, sea-water is warmer than the earth covered with frost and snow, &c. Wherefore, as the air contiguous to any body is found to partake of its heat and cold, the air contiguous to sea-water will be warmer in winter, and colder in summer, than that contiguous to the earth. Or thus: vapours raised from water by the sun's warmth in winter, are warmer than the air they rife in, (as appears from the vapours condensing, and becoming visible, almost as soon as they are got out into air.) Fresh quantities of vapour, therefore, continually warming the atmosphere over the sea, will raise its heat beyond that of air over the land. Again, the sun's rays reflected from the earth into the air, in summer, are much more than those from the water into air: the air, therefore, over the earth, warmed by the reflection of more rays than that over water, is warmer. Hence, sea-winds make thick, cloudy, hazy weather.

2. "Winds, blowing from the continent, are always dry; in summer, warm; and cold in winter." For there is much less vapour arising from the earth, than from water; and, therefore, the air over the continent will be impregnated with much fewer vapours. Add, that the vapours, or exhalations, raised by a great degree of heat out of the earth, are much finer, and less sensible, than those from water. The wind, therefore, blowing over the continent, carries but little vapour with it, and is therefore dry.

Farther, the earth in summer is warmer than water exposed to the same rays of the sun. Hence, as the air partakes of the heat of contiguous bodies, that over the earth in summer will be warmer than that over the water: therefore, the winds, &c.

After the like manner it is shewn, that the land-winds are cold in winter. Hence, we fee why land-winds make clear cold weather.

Our northerly and southerly winds, however, which are commonly esteemed the caules of cold and warm weather, Dr. Derham observes, are really rather the effect of the cold or warmth of the atmosphere. Hence it is, that we frequently see a warm southerly wind, on a sudden, changed to the north, by the fall of snow or hail; and that in a cold frosty morning, we see the wind north, which afterwards wheels about toward the southerly quarter, when the sun has well warmed the air; and again, in the cold evening, turns northerly, or eartherly. See Darwin's Observations supra.

For the manner in which north-easterly winds contribute to blights, see BLIGHT. For the effect of winds on the barometer and thermometer, see BAROMETER, &c.

The utility of winds has been universally acknowledged. The ancient Perians, Phoenicians, Greeks, and Romans, sacrificed and erected temples to the winds; as we learn from Voifius, Theolog. Gentil. lib. iii. part i. cap. i. Besides their use in moving bellows, mills and other machines, applied in various ways to the service of mankind, and the benefits resulting from them to navigation and trade, they serve to purify and refresh the air, to convey the heat or cold of one region to another, to produce a regular circulation of vapours from the ocean to countries remote from it, and to supply by wafting them in their progres against hills, &c. springs and rivers.

Wind has been, by many authors, made the basis of many different diseases: among others, Dr. Reyn has given it as his opinion, in a Treatise on the Gout (De Arthritis.), that flatulences, or wind inflowed between the periosteum and the bone, are the true caule of that disea; and accordingly, that all the methods of cure ought to tend to the expelling of that wind.

He is also of opinion, that head-aches, palpitations of the heart, tooth-aches, pleurisy, convulsions, colics, and many other diseases, are originally owing to the same cause, and only differ in regard to the place affected, and to the various motions and determinations of the wind. The moveableflens of the pain in gouty persons from one part to another, he looks on as a proof of this, and thinks that the curing of the gout by burning moxa, or the cotton of the mugwort leaves, upon it, is owing to its giving way to the wind in the part to evaporate itself.

That these winds are cold, appears from the shivering fits which generally precede a paroxysm of the gout; and that the shiverings in the beginning of fevers, and before all fits of agues, are owing to the same cause, is supposed by this
WIND.

The author makes a natural conclusion from the former observations.

Their differences, he says, principally proceed from the various fermentations producing in us a variety of sensations; which acting upon one another, do in their effects produce winds of various effects, and denote different faces from the places which are the foci of their action. It is on this account that the acupuncture, or prickings with long needles, among the Chinee, is of use: the Japanese, and other neighboring nations, having no other cure for most diseases than the prickings with the needle, and the burning of the moxa on the part.

The husbandman often suffers extremely by high winds in many different respects. Plantations of trees, at a small distance from the barns and houses, are the best safeguard against their suffering by winds; but they must not be planted too near as that they fall, if it should happen, would endanger them. Jews grow very slowly, otherwise they are the best of all trees for this defensive plantation. Trees suffer by winds, being either broken or blown down by them; but this may be in a great measure prevented by cutting off great part of the heads and branches of them, in places where they stand most exposed.

Rocks are the most subject to be injured by winds of any crop; but this may be in a great measure prevented by a high pale, or very thick thorn-hedge; this will both keep off the spring wind, which nips the young buds, and be a great safeguard against other winds that would tear the plants from their poles. The poles should always be very firm in the ground; and the best security to be added to this, is a row of tall trees all round the ground.

Winds, attended with rain, do great injury to the corn, by laying it flat to the ground. The best method of preventing this, is to keep up good enclosures; and if the accident happens, the corn should be cut immediately, for it never grows at all afterwards. It should be left on the ground, in this case, some time after the cutting, to harden the grain in the ear. Mortimer's Husbandry, p. 302.

Wind, in Navigation, is the same agitation of the air, considered as serving for the motion of vessels on the water.

If the wind blows gently, it is called a breeze; if it blows harder, it is called a gale, or a stiff gale; and if it blows very hard, it is called a storm.

The following observations on the wind have been made by skilful seamen, and particularly by Dr. Halley.

1. Between the limits of 60°, viz. from 30° of north latitude to 30° of south latitude, there is a constant, or almost constant, easterly wind through the year, blowing in the Atlantic and Pacific oceans, called the trade-wind; which see.

2. The trade-winds, near their northern limits, blow between the north and east; and near their southern limits they blow between the south and east.

The trade-wind seems to depend principally upon the rarefaction of the air, which is occasioned by the heat of the sun progresively from the east towards the west. The air which is rarefied, and, of course, elevated by the heat of the sun immediately over it, is condensed, and descends as soon as the sun is gone over another place to the west of the former; then the air of the latter place is rarified, and the condensed air of the former rushes towards it, &c. From the northern and southern parts of the world, the air likewise runs to the place which is immediately under the sun; but those directions, combining with the easterly wind, which blows nearer to the equator, form the above-mentioned north-easterly and south-easterly winds on the borders of the trade-wind.

3. These general motions of the wind are disturbed on the continents, and near their coasts.

In places that are farther from the equator, the rarefaction which arises from the heat of the sun, and from the attraction of the sun and moon, is less active; and is besides influenced by a variety of local and accidental circumstances, such as extensive continents, mountains, rains, islands, &c. which disturb, interrupt, or totally change the direction of the wind. Hence, in those latitudes north and south, which are beyond the limits of the trade-wind, or near the coasts, the winds are very uncertain; nor has any good theory been as yet formed respecting them.

4. In some parts of the Indian ocean there are periodical winds, which are called Monsoons; which see.

For the explanation of these, it is said, that as the air, which is cool and dense, will force the warm rarefied air in a continual stream upwards, there it must spread itself to preserve the equilibrium. Therefore the upper course or current of air must be contrary to the under current; for the upper air must move from those parts where the greatest heat is; and so, by a kind of circulation, the N.E. trade-wind below will be attended with a S.W. above; and a S.E. below, with a N.W. above.

5. In the Atlantic ocean, near the coasts of Africa, at about a hundred leagues from the shore, between the latitudes of 28° and 10°, feamen cautiously meet with a fresh gale of wind blowing from the N.E.

6. Those bound to the Caribbean islands, across the Atlantic ocean, find, as they approach the American side, that the said N.E. wind becomes calmer; or seldom blows more than a point from the east, either to the northward or southward. These trade-winds, on the American side, are extended to 30°, 31°, or even to 32° of N. latitude; which is about 4° farther than they extend on the African side; also to the southward of the equator, the trade-winds extend three or four degrees farther toward the coast of Brazil, on the American side, than they do near the Cape of Good Hope, on the African side.

7. Between the latitudes of 4° N. and 4° S., the wind always blows between the south and east; on the African side, the winds are nearest the south; and on the American side, nearest the east. In these seas, Dr. Halley observed, that when the wind was easterly, the weather was gloomy, dark, and rainy, with hard gales of wind; but when the wind veered to the southward, the weather generally became serene, with gentle breezes, approaching to a calm. These winds are somewhat changed by the seasons of the year; for when the sun is far northward, the Brazil S.E. wind turns to the south, and the N.E. wind to the east; and when the sun is far south, the S.E. wind gets to the east, and the N.E. winds on this side of the equator veer more to the north.

8. Along the coast of Guinea, from Sierra Leone to the island of St. Thomas, under the equator, which is above five hundred leagues, the southerly and south-westerly winds blow perpetually; for the S.E. trade-wind, having passed the equator, and approaching the Guinea coast within eighty or a hundred leagues, inclines toward the shore, and becomes south, then S.E., and by degrees, as it comes near the land, it veers about to south, S.S.W., and in with the land it is S.W. and sometimes W.S.W. This tract is subject to frequent calms, violent sudden gusts of winds, called tornadoes, blowing from all points of the horizon.

The westerly wind on the coast of Guinea is probably owing
WIND.

owing to the nature and situation of the land, which, being greatly heated by the sun, rarefies the air exceedingly; hence the cooler and heavier air from over the sea will keep rushing in to reful the equilibrium.

9. Between the fourth and tenth degrees of north latitude, and between the longitudes of Cape Verde, and the easternmost of the Cape Verde isles, there is a tract of sea subject to perpetual calms, attended with frequent thunder and lightning, and rains; whence this part of the sea is called ‘The Rains.’ Ships in sailing these four degrees are said to have been sometimes detained whole months.

The cause of this seems to be, that the wetterly winds setting in on this coast, and meeting the general easterly wind in this tract, balance each other, and cause the calms; and the vapour carried thither by the hottest wind, meeting the coolest, is condensed, and occasions the very frequent rains.

The three last observations account for two circumstances which mariners experience in sailing from Europe to India, and in the Guinea trade.

The for is the difficulty which ships, in going to the southward, experience, especially in the months of July and August, in passing between the coast of Guinea and Brazil, although the breadth of this sea is more than five hundred leagues. This happens, because the S.E. winds at that time of the year commonly extend some degrees beyond the ordinary limits of four degrees north latitude; and besides coming to much fether, as to be sometimes fouth, sometimes a point or two to the west; it then only remains to ply to windward; and if, on the one side, they fleer W.S.W. they get a wind more and more easterly; but there is a danger of falling in with the Brazilian coast, or shoals; and if they fleer E.S.E. they fall into the neighbourhood of the coast of Guinea, from whence they cannot depart without running easterly as far as the island of St. Thomas; and this is the constant practice of all the Guinea ships.

Secondly, With regard to all ships departing from Guinea for Europe, their direct course is northward; but on this course they cannot go, because the coast bending nearly east and west the land is to the northward; therefore, as the winds on this coast are generally between the S. and W.S.W., they are obliged to fleer S.S.E. or S., and with these courses they run off the shore; but in so doing they always find the winds more and more contrary; so that when near the shore they can lie fouth, at a greater distance they can make no better than S.E., and afterwards E.S.E.; with which courses they commonly fetch the island of St. Thomas and Cape Lopez, where, finding the winds to the easterly of the fouth, they wait easterly with it, till coming to the latitude of four degrees fouth, they there find the S.E. winds blowing perpetually.

On account of these general winds, all thofe that ufe the West India trade, even thofe bound to Virginia, reckon it their beft course to get as soon as they can to the southward, fo that they may be certain of a fair and free gale to run before it to the westward; and for the fame reafon, thofe homeward-bound from America endeavour to gain the latitude of thirty degrees, where they first find the winds begin to be variable; though the molt ordinary winds in the North American ocean come from between the fouth and weft.

10. Between the southern longitudes of ten and thirty degrees in the Indian ocean, the general trade-wind about the S.E. by S. is found to blow all the year long in the fame manner as in the like latitude in theEthiopian ocean; and during the six months from May to December, thofe winds reach to within two degrees of the equator; but during the other six months, from November to June, a N.W. wind blows in the reft, lying between the third and tenth degrees of southern latitude, in the meridian of the north end of Madagascar; and between the second and twelfth degree of south latitude, near the longitude of Sumatra and Java.

11. In the reft between Sumatra and the African coaft, and from three degrees of south latitude quite northward to the Asiatic coasts, including the Arabian sea and the gulf of Bengal, the monfouns blow from September to April on the N.E., and from March to October on the S.W. In the former half the year the wind is more freftly and gentle, and the weather clearer than in the latter six months; and the wind is more freftly and steady in the Arabian sea than in the gulf of Bengal.

12. Between the island of Madagascar and the coaft of Africa, and thence northward as far as the equator, there is a reft, in which, from April to October, there is a conftant fresh S.S.W. wind; which to the northward changes into the W.S.W. wind, blowing at that time in the Arabian sea.

13. To the easterly of Sumatra and Malacca on the north of the equator, and along the coasts of Camboya and China, quite through the Philipinas as far as Japan, the monfoons blow north ery and fouthery; the northern setting in about October or November, and the southern about May; thofe winds are not quite fo certain as thofe in the Arabian seas.

14. Between Sumatra and Java to the weft, and New Guinea to the eaf, the fame northery and fouthery winds are obferved; but the firft half-year monfouns inclines to the N.W., and the latter to the S.E. Thofe winds begin a month or fix weeks after thofe in the Chinefe seas let in, and are quite as variable.

15. Thofe contrary winds do not shift from one point to its opposite all at once; in fome places, the time of the change is attended with calms; in others, by variable winds; and it often happens on the fhores of Coromandel and China, towards the end of the monfouns, that there are molt violent ftrorms, greatly rehmbeling the hurricanes in the Weft Indies; in which the wind is fo very ftrong, that hardly any thing can refund its force.

All navigation in the Indian ocean muft necofarly be regulated by these winds; for if mariners fhould delay their voyages till the contrary monfoun begins, they muft either fail back, or go into harbour, and wait for the return of the trade-wind.

16. The irregularities of the wind in countries which are farther from the equator than thofe which have been men- tioned above, or nearer to the poles of the earth, are fo great that no particular period has as yet been discovered, excepting that in particular places certain winds are more likely to blow than others. Thus at Liverpool the winds are said to be wefterly for near two-thirds of the year; in the fouthern part of Italy, a north-eaft wind (called the fibriacco) blows more frequently than any other wind, &c.

17. The temperature of a country with refpeft to heat or cold is increafed or diminished by winds, according as they come from a hotter or colder part of the world. The north and north-eaftly winds, in this country and all the western parts of Europe, are reckoned cold and drying winds. They are cold, because they come from the frozen region of the north pole, or over a great tract of cold land. Their drying quality is derived from their coming principally over land, and from a well-known property of the air; namely, that warm air can difsolve, and keep diffolved, a greater
greater quantity of water than colder air: hence the air which comes from colder regions, being heated over warmer countries, becomes a better solvent of moisture, and dries up with greater energy the moist bodies it comes in contact with; and, on the other hand, warm air coming into a colder region deposits a quantity of the water it kept in solution, and occasions mists, fogs, clouds, rains, &c. "In short," says colonel Roy, "the winds seem to be drier, denser, and colder, in proportion to the extent of land they pass over from the poles towards the equator; but they appear to be more moist, warm, and light, in proportion to the extent of ocean they pass over from the equator towards the poles. Hence the humidity, warmth, and lightness, of the Atlantic winds to the inhabitants of Europe. On the east coasts of North America the severity of the N.W. wind is universally remarked; and there can scarcely be a doubt, that the inhabitants of California, and other parts on the west side of that great continent, will, like those on the west of Europe, feel the strong effects of a N.E. wind."

18. In warm countries, sometimes the winds, which blow over a great tract of highly-heated land, become so very drying, scorching, and suffocating, as to produce dreadful effects. These winds, under the names of Blooms, Samiel, and Solano, are often felt in the deserts of Arabia, in the neighbourhood of the Persian gulf, in the interior of Africa, and in some other places. There are likewise in India, part of China, part of Africa, and elsewhere, other winds, which deposit so much warm moisture as to soften, and actually to diffuse glue, salts, and almost every article which is soluble in water.

19. It is impossible to give any adequate account of irregular winds, especially of those sudden and violent gales as come on at very irregular periods, and generally continue for a short time. They sometimes spread over an extensive tract of country, and at other times are confined within a remarkably narrow space. Their causes are by no means rightly understood, though they have been vaguely attributed to peculiar rarefactions, to the combined attractions of the sun and moon, to earthquakes, to electricity, &c. They are called in general hurricanes, or they are the principal phenomenon of a hurricane, that is, of a violent storm. Almost every one of those violent winds is attended with particular phenomena, such as droughts, or heavy rains, or hail, or snow, or thunder and lightning, or several of those phenomena at once. They frequently visit suddenly from one quarter of the horizon to another, and then come again to the former point. In this case they are called tornades.

In mountainous countries, the wind sometimes rages with extreme violence, and the mountains generally exhibit signs of the approaching storm. Thus, at the Cape of Good Hope, there are four remarkable mountains, called Table Land, or Mountain; Sugar-Leaf, or the Lion's Head; James Mount, or the Lion's Rump; and Charles Mount, called also the Devil's Tower, or Devil's Head, from the violent squalls of wind which come from it. In the summer season Table Mountain is sometimes suddenly covered with a white cloud, called the Table-cloth; when this cloud seems to roll down the steep face of the mountain, it is a sure indication of an approaching gale of wind from the S.E., which generally blows with great violence, and sometimes continues a day or more, but in common is of short duration. On the first appearance of this cloud, the ships in Table bay begin to prepare for it, by striking yards and top-masts, and making everything as snug as possible. If, in the morning, the cloud extends from the Table to Mount Charles, or the Devil's Tower, which are almost contiguous, it is a general saying among seamen, that the old gentleman is going to breakfast; if in the middle of the day, that he is going to dinner; and if in the evening, that the cloth is spread for supper.

There are various other periodical winds; of these, however, that generally known by the name of Limbat, which is common in the island of Cyprus, shall only be mentioned here. The period of this wind is five days: on the first day, it begins to blow at eight in the morning, and increases till noon; from thence it gradually weakens, and ceases entirely about three P.M. On the second day, it arises at the same hour; but it does not attain its greatest strength till about one in the afternoon, and ceases at four. On the third day, it begins as before; but it falls an hour later. On the remaining days, it follows the same progression as on the third; but it is remarked, that a little before it ceases, it becomes extremely violent. Upon the N.W. side of the above island, this wind is considered as a sea-breeze; and upon the S.E. as a land-breeze. See Wind, Qualities of, supra. See also Hurricanes, Tornadoes, and Whirl-Wind. See Phil. Trans. N° 183, or Abr. vol. ii. p. 133, &c. Robertson's Elem. of Nav. b. vi. f. 6. Cavallo's Philos. vol. ii.

The winds are divided, with respect to the points of the horizon from which they blow, into cardinal and collateral.

Winds, Cardinal, are those blowing from the four cardinal points; east, west, north, and south.

Thus, a wind that blows from the E. towards the W. is called east wind; when it blows from the W. towards the E., west wind; when it blows from the N. to the S., it is called north wind; and when it blows from the S. towards the N., it is called south wind.

Winds, Collateral, are the intermediate winds between any two cardinal winds. The number of these is infinite, as the points from which they blow are; but only a few of them are considered in practice; i.e. only a few of them have their distinguishing names.

Those winds which deviate a little from the cardinal points are called northerly, easterly, southerly, and westerly winds. But for the sake of greater dilution, the space or arch which lies between any two contiguous cardinal points, is supposed, by the mariners, to be divided into eight equal parts, or points, and each point into four equal parts, called quarter-points. So that the horizon is supposed to be divided into thirty-two principal points, which are called rhumbs, or winds, to each of which a particular name is assigned; and those names are derived from the names of the adjacent cardinal points. See Compass.

The ancient Greeks, at first, only used the four cardinal ones; at length they took in four more. Vitruvius gives us a table of twenty, besides the cardinals, which were in use among the Romans.

The moderns, as their navigation is much more perfect than that of the ancients, have given names to twenty-eight collateral winds, which they range into primary and secondary; and the secondary they subdivide into those of the first and second order.

The English names of the primary collateral winds and points are compounded of the names of the cardinal ones, north and south being still prefixed.

The names of the secondary collateral winds of the first order are compounded of the names of the cardinals, and the adjacent primary one. Those of the second order are compounded of the names of the cardinal, or the next adjacent primary; and the next cardinal, with the addition of the word by. The Latins have distinct names for each; all which are expressed in the following Table.

Note.—The ancient names are here, after Ricciolus, adapted to the modern ones; not that the winds formerly denoted by those were precisely the same with these, (for the ancient number and division being different from the modern, the points they refer to will necessarily be somewhat different,) but these are what come the nearest. Thus, Vitruvius, only reckoning twenty-four winds, disposes the points they refer to in a different order; as in the following Table.
WIND.

The following Table shews the angles which every rhumb or point of the compass makes with the meridian; by means of which the direction of the wind, &c. may be determined.

For the use of the winds in navigation, &c. see Sailing.

WIND, a disease in sheep of a very dangerous and distressing kind.

It is observed in the Shepherd's Guide, that in this complaint, the sheep, immediately after being clipped or shorn, appear to be in violent pain, their sides are somewhat extended, and their breathing very short, the head is hung down drooping, and they have a great aversion to moving or walking. These symptoms continue to increase until the sheep dies, which is in a very few hours, unless a violent purging comes on, which generally gives immediate relief. On inquiring for the name of this affection, the writer says, he found it was called the wind, but where the seat of it lay few could tell him; some thought it was in the head, others in the lungs; and the remedies they applied were as various as their opinions of the nature of the disease.

Not being satisfied with these accounts, he endeavoured, by inspecting the carcasses of sheep that died of the disease, to discover the cause and seat of the complaint. On opening four sheep that died of the disease, he found all the intestines rather distended with flatus, but not in any great degree. Their blood-vessels were very turgid, and of a deep red, particularly those of the large intestines, excepting the rectum, or what is called the bum-gut, which had a healthy appearance, as likewise had the stomach, small intestines, liver, heart, lungs, and in short all the viscera contained in the cavity of the trunk. From these appearances he ventures to say, that the disease in question is a violent inflammation of the intestines, perhaps in some measure arising from bruises in shearing, but more from losing a warm clothing, and being suddenly exposed to cold air and cold feeding.

He therefore recommends to farmers, that on the first appearance of the complaint they put the sheep into a flake or other warm place, and immediately bleed it freely. Then to bruise a quarter of an ounce of some carminative seed, such as cumin, anise, cummin, or fennel, and to mix thele with two ounces of Glauber's purging salts, in a pint of water, placing it on a fire, and making it boil for a few minutes, then to strain it off. Then to add a quarter of an ounce
ounce of powdered jalap, and while lukewarm to give the sheep a quarter of a pint of this liquor, well shaken together, every half hour till it dung. It should have no food or cold water until recovered, but a little warm water might be of service in some cases.

This is a disorder which is in general so suddenly fatal, that recours should be instantly had to any remedy that may have been found beneficial; but bleeding is probably that on which the greatest dependence may be placed, with calomel in some infirmities.

Wind, among Animals, is another name for the breath, or rather for the power with which the lungs are endowed in the exercise of their functions, which in many cases is a sort of morbid affection of them, especially in horfes, swine, calves, and some others. Horses are often thick-winded and purvey, which is this flate, and require much exercife and management, and the other two are sometimes affected in much the same way.

Wind, in Rural Economy, a term applied to a winch or wince in some places.

Wind. Freh. See FRESH.

Wind, To haul the. See HAUL.

Wind, Large, in the Sea Language. See LARGE.

Wind, Quarter, at Sea. See QUARTER.

Winds Reigning. See REIGNING.

Winds, Tropic. See TRADE- WINDS, and WIND FUPRA.

Wind, Side, at Sea, that which blows on the side of the ship.

To Wind a Ship or Boat, in Sea Language, is to change her position, by bringing the stern to lie in the situation of the head, or directly opposite to its former situation.

Wind, in the Mange. A horfe that carries in the wind, is one that toffies his nose as high as his ears, and does not carry handomely.

The difference between carrying in the wind and beating upon the hand is, that a horfe who beats upon the hand shakes his head, and refills the bridge; but he who carries in the wind, puts up his head without faking, and only sometimes beats upon the hand. The oppofite to carrying in the wind is arming and carrying low.

Wind, Whirl. See WHIRL-WIND.

Wind, Coll. See COLIC.

Wind-Droffen. See TYPANITIES.

Wind-Eggs. An addle egg, or an egg that has taken wind. See EGG.

Wind-Fall denotes fruit blown off the tree by the wind.

Wind-Flower, in Botany. See ANEMONE.

Wind-Furnace. See FURNACE.

Wind-Gage, in Pneumatics, an instrument serving to determine the velocity and force of the wind. See ANEMOMETER, ANEMOSCOPE, and Laws of the Force, &c. of the Wind fupra.

Dr. Lind, of Edinburgh, has contrived an apparatus of this kind, which is fimple and easy of conftruction, and which feems to be well adapted for measuring the force of the wind with a fufficient degree of accuracy. This instrument confifts of two glafs tubes A, B, C, D, (Plate XV. Pneumatics, fig. 9.) five or fix inches in length, and about four-tenths of an inch in bore; which are connected together like a fiphon, by a small bent glafs tube a, the bore of which is one-tenth of an inch in diameter. On the uppe: end of the leg A B there is a tube of latten brafs, which is kneet or bent perpendicularly outwards, and has its mouth open towards F; on the other leg C D is a cover, with a round hole G in the upper part of it, two-tenths of an inch in diameter. This cover and the kneet tube are connected together by a flip of brafs, e d, which ftrengthen the whole instrument, and ferves to hold the scale H I. The kneet tube and cover are fixed on with hard cement, or felling-wax. To the fame tube is foldered a piece of brafs, e, with a round hole in it, to receive the fheel fpindle K L, and at f another fuch piece of brafs is foldered to the brafs hoop g b, which furronds both legs of the instrument. There is a small shoulder on the fpindle at f, upon which the instrument reffes, and a small nut i, to prevent it from being blown off the fpindle by the wind. The whole instrument is easily turned round upon the fpindle by the wind, fo as to prevent the mouth of the kneet tube toward it. At the end of the fpindle there is a fcrew, by which it may be fwered to the top of a pole or fland; it has also a hole at L, to admit a fmal lever for frewing it into wood with greater facility. A thin plate of brafs k is foldered on the kneet tube, about half an inch above the round hole G, fo as to prevent rain from falling into it. There is also a crooked tube A B (fig. 10.), to be put occasionally upon the mouth of the kneet tube F, in order to prevent rain from being blown into the mouth of the wind-gage, when it is left exposed to the rain.

This instrument ferves to afsertain the force of the wind, by filling the tube half full of water, and pushing the scale a little up or down, till 0 upon the scale, when the instrument is held perpendicularly, be on a line with the furface of the water, in both legs of the wind-gage. The instrument being thus adjufled, hold it up perpendicularly, and turning the mouth of the kneet tube toward the wind, obferv how much the water is defreffed by it in one leg, and how much it is raised in the other. The fun of the two is the height of a column of water, which the wind is capable of difpofing at that time; and every body that is oppofed to that wind, will be preffed upon by a force equal to the weight of a column of water, having its base equal to the furface that is oppofed, and its height equal to the altitude of the column of water defpofed by the wind in the wind-gage. Hence the force of the wind upon any body, where the furface oppofed to it is known, may be easily found; and a ready comparifion may be made betwixt the strength of one gale of wind, and that of another, by knowing the heights of the columns of water which the different winds were capable of difpofing. The heights of the column in each leg will be equal, provided that the legs are of equal bores; but unequal if their bores are unequal. For fuppose the legs equal, and the column of water defpofed by the wind to be three inches, the water in the leg which the wind blows into will be defpofed 1 ½ inch below 0, and rafed as much in the other leg. But if the bore of the leg which the wind blows into be double that of the other, the water in that leg will be defpofed only one inch, while it is rafed twice as much, or two inches, in the other, and vice verfa.

The force of the wind may likewife be meafured with this instrument, by filling it till the water runs out at G. For if it be then held up to the wind as before, a quanitity of water will be thrown out; and if both legs of the instrument are of the fame bore, the height of the column defpofed will be equal to double the column of water in either leg, or the fun of what is wanting in both legs. But if the legs are of unequal bores, none of these will give the true height of the column of water which the wind defpofed. For, obtaining in this cafe the true height, Dr. Lind has fubjoined the requisite formule. The use of the small tube of communication a b (fig. 9.), is to check the undulation of the water, fo that the height of it may be read off from the scale with ease and certainty; and also to prevent the water
water from being thrown up to a much greater or less altitude than the true height of the column which the wind is able at that time to sustain. The author has calculated a table, by means of which, having the height of the column of water sustained in the wind-gage, the force of the wind upon a foot square may be determined.

When the height of the water is not exactly mentioned in the table, then that height may be separated into such parts as are mentioned in the table, and the sum of the forces answering to such parts will be the force of the wind correspondent to the height in question: thus, if the height of the water be 4.6 inches; then this height is equal to 4 + 0.5 + 0.1, which parts are all in the table; therefore,

The sum is 23.958, which expresses the force of the wind when the height of the water in the gage is 4.6 inches.

Any alteration that can usually take place in the temperature of the water, makes no sensible difference in this instrument.

In frothy weather this gage cannot be used with common water. At that time some other liquor must be used, which is not so subject to freeze; and, upon the whole, a saturated solution of common salt in water is the most eligible: but in that case, (since the specific gravity of a saturated solution of salt is to that of pure water, as 1.244 to 1,) the forces which are stated in the preceding table must be multiplied by 1.244. Thus, if in the preceding example the saturated solution of salt had been used instead of water only, the force of the wind on a square foot would have been 29.8 pounds.

When salt-water is used, the force of the wind, which is stated in the table, must be increased in the proportion of the specific gravity of salt-water to that of common water; thus, using the preceding example, we must lay, as 1 : 1.244 : : 23.958 to a fourth proportional, which must be found by multiplying the second term by the third, and then dividing the product by the first term; but, the first term being unity, we need only multiply 23.958 by 1.244.

On the 9th of May, 1775, Dr. Lind observed, that the wind supported a column of water in his wind-gage 6,570 inches in height; and from his table it appeared, that the force of the wind in this hurricane, which did great damage to the gardens in his neighbourhood, was equal to 34,921 pounds avoidups, on every square foot.

If the velocity and density of the wind in any particular case were accurately determined, this instrument, which gives its force or momentum, would enable us to ascertain the velocity in every other case, the density being known: for the force of the wind is as the square of its velocity. Phil. Trans. vol. lv. part ii. art. 34 p. 353, &c.

Mr. Martin, from a hint first suggested by Dr. Burton, contrived an anemoscope, or wind-gage, of the following construction. A B C D E F G H I (fig. 11.) is an open frame of wood, firmly supported by the shaft or pollern I. In the two cross pieces H, K, L, M, is moved an horizontal axis Q M, by means of the four stays a, b, c, d, e, f, g, h, in a proper manner, exposed to the wind. Upon this axis is fixed a cone of wood M N O, upon which, when the shaft moves round, a weight S is raised by a string on its superficies, proceeding from the small to the largest end N O. Upon the great end or base of the cone is fixed a ratchet-wheel i k, in whose teeth falls the click X, to prevent any retrograde motion from the depending weight.

From the structure of this machine, it is easy to understand, that it may be accommodated to estimate the variable force of the wind, because the force of the weight will continually increase, as the string advances on the conical surface, by acting at a greater distance from the axis. And, therefore, if such a weight be put on, on the smallest part of M, as will just keep the machine in equilibrio with the weakest wind; then as the wind becomes stronger, the weight will be raised in proportion, and the diameter of the base of the cone may be increased in comparison of that of the smaller end or axis at M, that the strongest wind shall but just raise the weight to the great end.

Thus, for example, let the diameter of the axis be to that of the base of the cone N O as 1 to 28; then if s be a weight of one pound on M, on the axis, it will be equivalent to twenty-eight pounds, or 1/5 of an hundred, when raised to the greatest end. If, therefore, when the wind is weakest, it supports one pound on the axis, it must be twenty-eight times as strong to raise the weight to the base of the cone. Thus may a line or scale of twenty-eight equal parts be drawn on the side of the cone, and the strength of the wind will be indicated by that number therein from which the string shall at any time hang.

Furthermore, the string may be of such a size, and the cone of such a length, that there shall be fourteen revolutions of the string between each division of the scale on the cone; so will the strength of the wind be expressed in pounds and ounces. And if greater exactness be required, let the periphery of the cone’s base be divided into fourteen equal parts; then whenever the equilibrium happens, the string will leave the conical surface against one of those divisions, and thus shew the force of the wind to a drachm avoidups weight. Martin’s Phil. Brit. vol. ii. p. 211, &c.

M. Bouger contrived a very simple instrument, by means of which we may immediately discover the force which the wind exerts upon a given surface. This is a hollow tube A B B A (fig. 12.), in which a spiral string C D is fixed, that may be more or less compressed by a rod F S D, passing...
pafting through a hole within the tube at AA; then having observed to what degree different forces or given weights are capable of compri{ing the spiral, mark divi{ions on the rod in such a manner, that the mark at S may indicate the weight requisite to force the spring into the situation CD; afterwards join at right angles to this rod at F, a plane surface E F E of a given area, either greater or less, at pleasure; then let this instrument be opposed to the wind, so that it may strike the surface in the directions V E, V E, parallel to that of the rod, and the mark at S will shew the weight to which the force of the wind is equivalent.

The ingenious professor Leslie (Enquiry into the Nature and Propagation of Heat) having found, in the course of his experiments on heat, that the refrigerating, or cooling power of a current of air, is exactly proportional to its velocity, derives from this principle the construction of a new and simple anemometer. "It is in reality nothing more," says he, "than a thermometer, only with its bulb larger than usual. Holding it in the open still air, the temperature is marked: it is then warmed by the application of the hand, and the time is noted which it takes to sink back to the middle point. This shall term the fundamental measure of cooling. The same observation is made on exposing the bulb to the impression of the wind, and shall call the time required for the bisection of the interval of temperatures, the occasional measure of cooling. After these preliminaries, we have the following easy rule: Divide the fundamental by the occasional measure of cooling, and the excess of the quotient above unit, being multiplied by \( \sqrt{\frac{\text{distance}}{\text{velocity}}} \), will express the velocity of the wind in miles per hour. The bulb of the thermometer ought to be more than half an inch in diameter, and may, for the sake of portability, be filled with alcohol, tinct, as usual, with archil. To simplify the observation, a sliding scale of equal parts may be applied to the tube. When the bulb has acquired the due temperature, the zero of the slide is set opposite to the limit of the coloured liquor in the limb; and after having been heated, it again flands at \( 2^\circ \) in its defcent, the time which then ceases takes until it sinks to \( 1^\circ \) is measured by a stop-watch. Extemporaneous calculation may be avoided, by having a table engraved upon the scale for the series of occasional intervals of cooling."

Wind-Gall, a disease in horses and some other animals. It is a puffy kind of swelling or tumour, which yields to the pressure of the finger, but upon removing the pressure recovers itself, and pushes out as before. These swellings have been thus named from a false notion of their containing nothing but air or wind. These tumours are often seated on both sides of the back of a horse above the fetlock on the fore-legs, but mostly frequently on the hind-legs. They are quite loose and detached from the parts on which they grow, and exhibit the same signs wherever they are met with, whether in the hooves or about the knees; for these swellings are not confined to the lower limbs only, but appear in any of those parts of a horse's body where the cellular membrane can be easily separated; and they exist, for the most part, without occasioning any pain. They are usually caused by riding on very hard roads, or on dry billy grounds. Sometimes travelling horses, when they are worked too young, before its limbs are grown firm and vigorous, will have them. And Gibbon observes, that they sometimes proceed from constitutional weaknesses, especially in bulky horses, that are somewhat under-limbed and hefty about the fetlock-joint. These, it is said, have been known to have wind-galls without any strain, hard riding, or other ill usage of any kind.

It has been observed too, that when these tumours appear upon the hind-legs they never cause lameness, though such horses are often stiff behind after riding. When on the fore-legs they always make a horse go lame at first; but afterwards their lameness goes off in a great measure, and they seldom go lame, but stiff, and inclined to stumble. They generally recover, however, with a day or two. Those flatulent swellings indeed that come in the ligaments of the hocks are always troublesome, disfigure the animal, and, unless speedily affixed, will cause incurable lameness. At first they are but small, but in time they grow to the size of a pullet's egg, perhaps, and push out on each side of the hollow of the hock. Swellings of the same kind also appear before the knee, where they often precede a diseased joint. Very small similar swellings under the fore part of the knee, in the interstices of both sides of the joint, are also dangerous; but these seldom happen, and are usually caused by some violent strain, especially when a horse falls down upon a leant with his whole weight upon his knees. The other flatulent swellings which horses are subject to seldom cause lameness, but are, for the most part, easily cured. We mean those that arise in the interstices of the large muscles of the hips and thighs, which are distended like little bladders filled with air. These come by strains and over-exertion; for draught-horses are the most subject to them.

Wind-galls that proceed from mere weaknesses are seldom curable, unless the constitution can be improved; but we often see horses that were subject to wind-galls when young, get the better of them as they advance in age. The methods of cure in these cases is by means of blistersing, firing, and the use of astringent applications.

As there are enlargements of the capvules, or horse-surface, situated between the tendons, that contain an oily lubricating fluid for the prevention of friction and to facilitate motion, arising from long exertion producing inflammation of them, and an increased secretion of the contained fluid, they are capable of being easily removed in their beginning stages, by reft and the use of blisters to the parts composed of cantharides and corrosive sublimate with olive oil; afterwards turning the animals out to graze or the straw-yard. Or where this cannot be permitted, the parts may be strengthened by the use of a flannel roller, made and continued wet by a wash composed of equal parts of strong vinegar and Goulard water, or the latter alone in some cases. If, however, the disease may have been neglected, recourse must be had to the hot iron; after which the blistersing should be practiced as before advised.

Wind-Gun. See Air-Gun.

Wind-Hatch, in Mining, a term used to express the place at which the ore is taken out of the mines.

The word hatch is the general term used by the miners to express an opening from the surface into the mine, or in the attempting to find a mine.

Thus the word effay-batches signifies the openings made in search of the veins of such veins; and the tin-batch in Cornwall is the name of the opening by which they descend into a tin-mine.

The word wind-batch seems to be a corruption of winder-hatch; for at these places they have a winder conveying two buckets, the one continually up, the other constantly down; the man below fills the bucket that descends; and when that which ascends is emptied at the mouth of the hatch, the person who has the care of that part of the work, delivers it empty to go down again. Phil. Trans. No 09.

Wind-Hover, in Ornithology, the name of a species of hawk,
WIND-MILL.

A windmill, called also by some the flannel, but more usually the kestrel, and known among authors by the names of the tinunculus and cencerit.

WIND-Instruments, in Music, are instruments played by wind, chiefly by the breath; in contradistinction to stringed-instruments, and instruments of the pulsative kind.

The wind-instruments known to the ancients were, the tibia, fluitula, or syrinx of Pan, consisting of seven reeds, joined to a reed pipe; also organ, tubes, cornus, and the litus. Those of the moderns are, the flute, bagpipe, hautboy, trumpet, &c. See Instrument, and Music.

WIND-Mill, in Mechanics, a machine which is put in motion by the force of the wind. Wind-mills are in general applied to the purpose of grinding corn, but are occasionally used to give motion to machines for raising water, sawing-mills, or for other purposes. We shall in this article consider the wind-mill as a first mover, or primus mobile, which may be applied to many purposes.

The invention of wind-mills is not of very remote date. According to some authors they were first used in France in the sixth century; while others maintain that they were brought to Europe in the time of the crusades, and that they had long been employed in the East, where the scarcity of water precluded the application of that powerful agent to machinery.

The wind-mill, though a common machine, has some things in it more ingenious than is usually imagined. Add, that it is commonly allowed to have a degree of perfection, which few of the popular engines have attained to, and which the makers are but little aware of; though the aid of mathematics has furnished ample matter for its improvement.

The vertical wind-mill, which is the kind most common in use, consists of an axis or shaft A B (Fig. 1, Plate II. Wind-Mill) placed in the direction of the wind, and usually inclined a little upwards from the horizontal line. At one end of this, four long arms or yards, S, T, V, W, are fixed perpendicular to the axis, and crofs each other at right angles; into these arms small crofs-bars are morticed at right angles; and other long bars are joined to them, which are parallel to the length of the arms; so that the bars intersect each other in the manner of lattice-work, and form a surface, on which a cloth can be spread to receive the action of the wind. These are called the sails; they are in form of a trapezium, and are usually nine yards long and two wide.

The circular motion is produced by the obliquity of the planes of these surfaces, from the plane in which all the four arms are situated; by these means, when the wind blows in the direction of the axis, it does not impinge upon the sails at right angles to their surfaces, but strikes obliquely; hence the effect of the sail to recede from the wind, causeth it to turn round with the common axis, and the four sails are all made oblique in the same direction, so as to unite their efforts for the common object.

That the wind may act with the greatest efficiency upon the sails, the wind-shaft must have the same direction as the wind. But as this direction is perpetually changing, some apparatus is necessary for bringing the wind-shaft and sails into their proper position; this is done by turning the axis and sails round in an horizontal direction. There are two methods of effecting this. In the old mills, like Fig. 1, the whole of the mill or building on which the machinery is fastened upon a vertical post, firmly fixed as a stand or foot, upon which the whole machine can be turned by a lever, to prevent the sails to any quarter of the horizon from whence the wind blows; and hence these are called post wind-mills, and are necessarily made of wood. The other kind, Fig. 2, is called a smock-mill, in which only the dome-cap or head, which contains the axis of the sails, and covers the great cog-wheel, turns round horizontally; the other parts of the machinery being contained in a fixed building, which rises up in form of a conical tower of masonry, and is surmounted by this moveable cap or dome, which is supported on rollers, so as to turn round easily.

As both the common methods of adjusting the wind-shaft require human assistance, it would be very desirable that the same effect should be produced solely by the action of the wind. This may be done by fixing a large wooden vane or weathercock at the extremity of a long horizontal arm, which lies in the same vertical plane with the wind-shaft.

By these means, when the surface of the vane and its distance from the centre of motion are sufficiently great, a very gentle breeze will exert a sufficient force upon the vane to turn the machinery, and will always bring the sails and wind-shaft to their proper position. This weathercock, it is evident, may be applied either to machines which have a moveable roof, or to those which revolve upon a vertical axis. This method is practised in small machines; but a vane of sufficient power to turn a large mill about would be unwieldy. A much better method is therefore practised in the best mills, as we shall soon describe.

In a post-mill the building must necessarily be of small size, and it can only contain one pair of mill-joiners. For this purpose, a large cog-wheel is fixed upon the main-shaft or axis of the sails; the cogs are placed in the face or flat surface of the wheel, and act upon the teeth of a pinion, which is fixed upon the horizontal axis or spindle of the mill-joiners. The mill-house is of a rectangular figure, but narrow in the direction which is perpendicular to the wind; it is two stories high, the main-shaft and mill-joiners being in the upper chamber, whilst the lower is used to contain the sacks of flour, and also to receive the pole on which the mill turns round, horizontally to face the wind. This pole is a very strong tree, and is held perpendicularly by fixing it upon the middle of long timbers, which form a large cross on the ground, and are the baum of the whole mill.

The pole is fixed perpendicularly by means of several oblique braces, extending from the ground-cros to the middle part of the pole; but ten or twelve feet from the upper end of the pole, the brace must be round, and clear from the obstruction of the braces. This part of the pole rises up through the middle of the lower chamber, in the floor of which a circular collar is formed, to surround the lower part of the pole exactly. At the upper end of the pole is a pivot or gudgeon, which enters into a socket fixed in the middle of the upper floor, and to one of the strongest crossbeams, because this beam must sustain the whole weight of the mill. In this manner, the whole mill can turn about upon the vertical pole, but remains always in equilibrium. To make it firm, and prevent it from turning about at every moment, a strong framing is united by joints to the back part of the mill-house, and defends in a sloping direction till it touches the ground; it is furnished with leps, so that it serves as a broad ladder to ascend to the mill; but another use is to steady the mill, because the end of this frame, which is very heavy, rests on the ground, and the shorter poles are fixed in a circle round the mill at regular intervals, to which the end of the ladder is fastened with cords. In order to turn the mill about, a rope is fastened to the end of the sloping ladder, and is carried up to the top of the mill in an inclined direction. By means of a strong lever, or a tackle of pulleys, this rope can be shortened, so as to lift up the ladder clear of the ground; and then, by pulling it like a long lever, the whole mill is turned round. To obtain more force, a small capstan is often provided to draw a rope.
WIND-MILL.

A rope attached to the end of the ladder. This capstan is moveable, and is fastened at pleasure to any one of the poits which are fixed in the ground.

The internal mechanism of a poit wind-mill is exhibited in fig. 3. Plate II. Wind-Mil. A B O is the upper room; H O the lower room; A B the axis passing through the mill; S, T, V, W, the sail, covered with canvas, let obliquely to the wind, and turning round in the order of the letters in fig. 1; C the cog-wheel, having about forty-eight cogs, which carry round the lantern E, having eight or nine rounds, together with its spindle G N; K is the upper mill-stone, and L the lower room; Q is the bridge supporting the axis or spindle G N; this bridge is supported by the beams e and X Y, wedged up at e and Q; X Y is the lifting-tree, which stands up right; a b and c d are levers, whose centres of motion are a and a; f g h i is a cord, with a flone, j; it goes about the pin g and b, to wind it up and raise the flone at pleasure. The spindle t N is fixed to the upper mill-stone K, by a piece of iron called the yoke, and fixed in the lower side of the flone, which is the only one that turns about, and whose whole weight rests upon a flone fixed, in the bridge Q R at N. The trundle E, and axis G t, may be taken away; for it rests by its lower part at t by a square socket, and the top runs in the edge of the beam w. By bearing down the end f of the lever e, b is raised, which raises x y, and this raises X Y, which lifts up the bridge Q R, with the axis N G, and the upper mill-stone K; and thus the flones are set at any distance. The lower immovable flone is fixed upon strong beams, and is broader than the upper one: the flour is conveyed through the tunnel n o into a chest; P is the hopper, into which is put the corn, which runs along the fpout r into the hole s, and so falls between the flones, where it is ground. The axis G t is square, which shaking the fpout r, as it goes round, makes the corn run out; r s is a string going about the pin s, and serving to move the fpout nearer to or farther from the axis, so as to make the corn run faster or slower, according to the velocity and force of the wind. And when the wind is great, the falls S, T, V, W, are only in part or one side covered; or perhaps only one half of the two opposite falls. Toward the end B of the axis another cog-wheel may be fixed, with a trundle and mill-stones, like that already described; so that the same axis moves two flones at once; and when only one pair is to grind, the trundle E, and axis G t, are taken out from the other; s x y l is a girr or grisse of pliable wood, fixed at the end s; and the other end l is tied to the lever k m, moveable about k; and the end m being put down, draws the grisse s x y l close to the cog-wheel; and thus the motion of the mill is flapped at pleasure; p q is a ladder for ascending to the higher part of the mill; and the corn is drawn up by means of a rope, rolled about the axis A B, when the mill is at work.

The structure of the mill-stones, or grinding parts, is the same as the water-mills. See Mill.

It is plain that this construction confines all the machinery to the two chambers, or that part of the mill which is poited upon the vertical pole; hence this kind of windmill is unfit for any other purposes than that of grinding corn, and for expressing oil, because there is so little room for the machinery. The Dutch, who are famous for windmills, make them sometimes with a very large poit, which has a hole down through the centre of it, like a trunk, and through this, a perpendicular axis passes to convey the power of the mill down into a building below, and upon the top of which, as a roof, the foundation-beams of the poit are fixed. (See fig. 4.) In this way, the mill is applied to saw wood, or to make paper, or any other purpose; but the construction is complicated, and less effective than the other kind of mill, in which only the head or top turns round, as we shall now describe.

The Smock-Mill.—This is the best kind of mill, because the building which contains the machinery may be made of any required dimensions, the falls and turning cap being all at the top of the house. Fig. 3. in Plate I. Wind-Mill, is a vertical section of one of these mills. K K are the walls of the house, and O O strong timbers forming a roof to it; upon these eight principal timbers H are erected, to form an octagonal pyramid of carpentry, the sides of which are filled up by diagonal bracing, and small uprights to nail the boarding to.

The four falls are fixed on an iron axis B N, by screwing them to an iron cross formed at one end of it. Two of these falls are marked A A; but the other two are endways, and cannot be seen. Upon the axis within the mill the cog-wheel C is fixed; and this turns a trundle or lantern D, fixed on the upper end of a strong vertical shaft, E E, extending from the top to the bottom of the mill, to turn the machinery; on the lower end of it is a large wheel, f g, which are two pinions, g g, upon the spindles of the mill-stones b b. These are on the same conduction as those described in our article Mill, to which we refer. At l is a wheel upon the main axis, giving motion to a pinion on a horizontal shaft or roller, k, which has a rope wrapped upon it, to wind up the tacks of corn. The wheel k also turns a similar horizontal axis with several wheels, to receive endless ropes for turning the bolting and dressing machines.

We will now enter more fully into the mechanism of the upper part of the mill, which is called its head or cap, marked G, and contains the axis B N. This is supported upon bearings, one being near its falls, and the other at its extreme end, as is shown in fig. 5. Plate II. Wind-Mill, which is an horizontal fection of the head, shewing the circular kirb, or wooden ring, K, and the framing which is bolted upon it to support the axis.

The construction of the axis is shewn in fig. 6. of the same plate. It consists of an octagonal iron shaft with two cylindrical necks at e and d, where it rests upon its bearings. At the end it has a kind of box, which has two mortises, e and f, through it in perpendicular directions to receive the falls. At the back of one of these mortises, and the front of the other, a projecting arm is left in the cutting to receive screw-bolts, which hold the falls fast in the mortises. The cog-wheel is fixed on by bolting its arms against a flanch C, cast on the axis. The falls are braced by a rope-stray to each arm, proceeding from the end of a pole, which is fixed at the end of the cafl-iron axis. Each fall is formed of a fall-cloth, spread upon a kind of lattice-work or framing, composed of rails mortised into the arms of the falls. The plane of this frame is inclined to the plane of the falls' motion at such an angle, that the wind blowing in the direction of the axis acts upon the falls as inclined planes, and turns them about with a power proportionate to the size of the falls and force of the wind. It is necessary, as the wind changes its direction, to turn the falls about, that the axis may be always in the direction of the wind. (See fig. 3. Plate I.) This motion is effected by turning the head of the mill round upon the fixed part, on a circle or kirb at the top of the frame composing the house of the mill. At the bottom of the frame of the wood-cap is a circular or moveable kirb, between which and the fixed kirb a number of rollers are placed; and the moveable kirb of the cap lies upon these rollers, which are kept equidistant
equidistant from each other by their centre-pins being fitted into a circular hoop: by these means, though the head of the mill with the wheels and sails weighs several tons, they can be made to turn round to face the wind by a slight power.

The head is contrived to turn itself about whenever the wind changes in the following manner:—A small pair of fans, or fads, M, are fixed up in a frame L, projecting from the back of the head: it has a pinion of ten leaves upon its axis, engaging in a wheel of 62 teeth upon an inclined axis b; and this has a pinion of 172 teeth upon a vertical iron axis, at the lower end of which is a pinion of 11 teeth: this works in a circle of 120 cogs, fixed round on the outside of the fixed kibb. By these means, whenever the fan M is turned, it moves the head of the mill slowly round, and with proportionate power.

Now if ever the wind varies in the leaf from the direction of the main shaft of the sails, it acts obliquely upon the vane of the fan, and turns them round, at the same time setting the head right again, so that the axis points to the wind. But when the axis is in this situation, the wind blows in the planes of the vane of the fan, and has no effect upon them. The head of the mill is kept firmly in its place when it turns about by rollers; the axles of which are bolted to the inside of the framing of the head, and the rollers apply to the inside of the fixed kibb: there are four of these rollers. The pivot at the upper end of the vertical shaft is supported in a bearing bolted to a cross-beam in the framing of the head of the mill; and this is fixed precisely in the centre of the head, so that it may not vary in its situation as the head turns round. Many other things are so evident in the drawing as to need little farther explanation; such as the different floors of the building, and the circular gallery, I I, all round the mill, for the miller to go round to take the cloth off the sails in high winds, or when the mill is to stop. This is done by untying the cloth at the extremity of the sail, and twisting it up like a rope; then tying the end of it again to the lattice, in which state it presents no surface to the wind. At l is a roller turned round by a wheel I, fixed on the middle part of the vertical shaft: it is used to draw up the sacks of corn from the bottom of the mill into the upper part, which is used as a storehouse for the corn, being divided into as many compartments as the miller requires.

The mill-floines are made the same as those used in water-mills. A pair of regulating balls are attached to the upper part of the mill-floine spindle, to regulate the velocity of the mill. The manner of applying this regulator is explained in fig. 5.

Plate II. Wind-Mill. The lower end of the iron spindle F is fitted to a square, formed on the top of the mill-floine axis, and the pinion g g is fixed on the upper end, to give motion to the floines: immediately beneath the pinion two rods are jointed, hanging downwards, having a heavy iron ball, I, fixed fast on the lower end of each: two links are jointed to the arms at m, and suspend a collar, which is capable of sliding freely up and down upon the spindle F. It is evident that when the balls fly out from the spindle by their centrifugal force, that the collar will be elevated, and the contrary when the balls approach the spindle. The sliding collar is embraced by a fork formed at the end of a beelyard, lying horizontal, and suspended by the rod p as a fulcrum; an iron rod q descends from the extreme end of the beelyard, having its lower end jointed to a hook, by which it is connected with a lever, r, whose fulcrum is s; this, by an iron rod t, suspends one end of the beam called the bridge, on which the lower pivot of the mill-floine axis rests, the other end bearing on a fulcrum or centre. Now it follows from this arrangement of levers, that by elevating the forked end of the beelyard, or the sliding collar, that the spindle of the floines will be suffered to descend a very minute quantity. This regulates the velocity of the mill, because when the wind increaseth, and the motion of the mill is accelerated, the balls fly out by the centrifugal force; this lets the upper floine down nearer to the lower, thereby increasing the resistance to the mill, and counteracting the increased force of the wind. On the other hand, if the wind falls, and the mill moves more slowly in consequence, the balls fall together, and let down the sliding collar; this raises the floine up, and increases the distance between them, thereby diminishing the resistance; for this purpose, a weight o (fig. 5.) is hung upon the beelyard, sufficient to elevate the floine whenever the closing of the balls and consequent descent of the collar will permit it to do so. There are several notches made in the beelyard for different positions of the fulcrum p and rod q; by means of these the quantity of the regulation can be adjusted to the following rule. If when the wind blows stronger the mill goes slower, contrary to the effect expected, it shews that the regulation is too active; then increase the leverage of the balls by shortening the distance between the fulcrum p of the beelyard and the suspension of the rod q, by shifting either of them into different notches. On the contrary, if the mill goes much faster when the wind increases, it shews that the regulation does not act sufficiently; then increase the distance between the rod q and the fulcrum p. If the whole limits of the notches in the beelyard should not be sufficient to effect this, the adjusting length of the lever r s must be increased or diminished by removing its fulcrum s to a greater or lesser distance from the suspending-rod t; by means of this converse the miller is enabled, without much inconvenience, to regulate the velocity of the floines to that degree which is found best for reducing the greatest quantity of grain to flour, without damaging it by heating, as is the case when the floines move too quick.

Theory of the Motion of a Wind-Mill, with the Position of its Sails or Vanes.—The angle which the surfaces of the sails are to make with their common axis, that the wind may have the greatest effect, or the degree of weathering, as the millwrights call it, is a matter of nice inquiry, and has much employed the thoughts of the mathematicians.

To conceive why a wind-mill moves at all, the theory of compound motions must be supposed. A body moving perpendicularly against any surface, strikes it with all its force. If it move parallel to the surface, it does not strike it at all: and if it move obliquely, its motion, being compounded of the perpendicular and parallel motion, only acts on the surface, considered as it is perpendicular, and only drives it in the direction of the perpendicular. So that every oblique direction of a motion is the diagonal of a parallelogram, whose perpendicular and parallel directions are the two sides. Add, that if a surface, which, being struck obliquely, has only received the perpendicular direction, be fastened to some other body, so as that it cannot pursue its perpendicular direction, but must change it for some other; in that case, the perpendicular itself becomes the diagonal of a new parallelogram, one of whose sides is the direction which the surface may follow; and the other, that which it cannot.

Thus, a rudder fastened obliquely to the keel of a vessel, being struck by the current of water parallel to the keel, and, of consequence, obliquely with regard to itself; it will appear, by drawing the line of perpendicular impulse, that it tends to tear the rudder from the keel, and to carry it away: and that this direction, perpendicular to the rudder,
wind-mill.

The rudder, then, would be carried off in an oblique direction; but as, in reality, it is so secured, that it cannot be torn and carried off, we are only to consider, in this compound motion, that of the two directions wherewith it can move without being torn from the keel; and leave the other, which would tear it off, as useless.

Now, the direction in which it can move without parting from the keel, is that which carries it circularly about its extremity, as about a centre. So that the effect of the oblique impulse of the water on the rudder is reduced, first to a perpendicular impression, which is again reduced to the mere turning of the rudder round; or, if the rudder be immovable, to the turning of the vessel. Now, in an oblique and compound motion, where only one of the directions is of service; the greater ratio the other has to it, the less effect will the motion have, and vice versâ. In examining the compound motions of the rudder, we find, that the more obliquely it is to the keel, the ratio of the direction that serves to turn it to the other is the greater. But, on the other hand, the more obliquely it is to the keel, and, of consequence, to the course of the water which is suppos’d parallel to it, the more weakly it strikes. The obliquity of the rudder, therefore, lies, at the same time, both an advantage and a disadvantage; but as they are not equal, and as each of them is still varying with every different position of the rudder, they become complicated variously; so that sometimes one prevails, and sometimes the other.

It has been a point of inquiry to find the position of the rudder, in which the advantage should be the greatest. M. Renan, in his famous theory of the working of ships, as found, that the best situation of the rudder is, when it makes an angle of fifty-five degrees with the keel. Seeudder.

If, now, a wind-mill, exposed directly to the wind, should have its four fails perpendicular to the common axis in which they are fitted, they would receive the wind perpendicularly; and it is visible that impulse would only end to overturn them. There is a necessity, therefore, to have them oblique to the common axis, that they may receive the wind obliquely.

For the greater ease, let us only consider one vertical fall. The oblique impulse of the wind on this fall is reducible to a perpendicular impulse; and that direction, as the fail cannot absolutely keep to it, is compounded of two; one of which tends to make it turn on its axis, and the other to fall backwards. But it is only the first of these directions that can be obeyed. Of consequence, the whole impulse of the wind on the fall has no other effect but to make it turn from right to left, or from left to right, its acute angle turns this way or that. And the structure of the machine is so well contrived, that the three other fails are determined, from the same causes, to move the same way.

The obliquity of the fails, with regard to their axis, has precisely the same advantage and disadvantage with the obliquity of the rudder to the keel. And M. Parent, seeking, by the new analysis, the most advantageous situation of the fails on the axis, finds it precisely the same angle of fifty-five degrees.

For the farther illustration of this point, let A B (Plate II. Wind-Mill, fig. 7.) be the axis of the mill, C D a fail, and its angle of obliquity (viz. that which it makes with the axis) E C G; then if G C be the force of the wind in the direct position of the fail, G E (the force of the angle of incidence G C E) will be the force of the wind in its oblique situation; but the force of G E is resolvable into two others, E F and G F; of which the latter, being parallel to the axis, avails nothing in turning the fails about it; but the other, E F, being perpendicular to it, is wholly spent in compelling the fail to turn round. The force of the wind on the fail will be as the square of the force of incidence, or as G E^2; and if the area of the fail, and the velocity of the wind, be suppos’d constant, the force of the wind in the direct position will be to that in the oblique one, as G C to G E^1; but when G E is the whole force, that part which turns the fail is represented by E F; and G E : E F (: G C : C E) :: G E^2 : G C

= to the force which turns the fail, when the whole force is represented by G E^3. This expression begins from nothing, when the angle of incidence begins to be oblique, and increases with the obliquity of the said angle to a certain number of degrees; because that part of the force which is parallel to the axis, becomes less in proportion to that which is perpendicular to it; but after it has passed this limit, it again decreases, and becomes nothing, when the angle of incidence vanishes. There is, therefore, one certain position of the fail, in which the force of the wind upon it is a maximum. In order to find this, put radius G C = a, E C = x, and we have G E^3 = a x x, and consequently the force \[
\frac{C E \times G E^2}{G C} = \frac{a x x - x x x}{a},
\]
which must be a maximum: therefore its fluxion \(a x x - 3 x x x = 0\): whence \(a = 3 x, \) and so \(x = \sqrt{\frac{a a}{3}} = (\text{in logarithms}) 20.000000 - 0.477121 \cdot \frac{2}{\pi} = 9.761439,\) which is the logarithmic sine of the angle 35° 16' = C G E; and therefore the angle \(E C G = 54° 44',\) when the force of the wind is a maximum. Thus, also, if \(l m (\text{fig. 7.})\) parallel to the axis Q M, be equal to a, and represent the whole force of the wind on the fail; this force is reduced to \(l n,\) and this again to \(n o,\) which acts perpendicularly to the axis, and turns the fail. This force, putting \(m n = x,\)

is expressed by \(\frac{a x x - x}{a},\) and thus, as before, when it is a maximum, \(x = \sqrt{\frac{a a}{3}} = a \sqrt{\frac{1}{3}};\) and the angle \(l m n = 54° 44'.\) Martin’s Phil. Brit. vol. i. p. 220, vol. ii. p. 212.

This angle, however, is only that which gives the wind the greatest force to put the fall in motion, but not the angle which gives the force of the wind a maximum upon the fail when in motion; for when the fail has a certain degree of motion, it yields to the wind; and then that angle must be increased, to give the wind its full effect. Mr. Maclaurin, in his Fluxions, vol. ii. p. 734, has shown how to determine this angle.

It may be observed, that the increase of this angle should be different, according to the different velocities from the axis to the extremity of the vane or fail. At the axis it should be 54° 44', and hence continually increase, giving

3 R

the
the vane a twist, and so causing each rib of the vane to lie in a different plane.

It is observed, that the ribs of the vane or fail ought to decrease in length from the axis to the extremity, giving the vane a curvilinear form; so that no part of the force of any one rib be spent upon the rest, but all move on independent of each other. The twist above-mentioned, and the diminution of the ribs, are exemplified in the wings of birds. As the end of the fail nearest the axis cannot move with the same velocity which the tips or farthest ends have, although the wind acts equally strong upon them, Mr. Ferguson (lect. on mechanics, p. 52.) suggests, that perhaps a better position than that of stretching them along the arms directly from the centre of motion, might be to have them set perpendicularly across the farther ends of the arms, and there adjusted lengthwise to the proper angle. For, in that case, both ends of the fails would move with nearly the same velocity; and being farther from the centre of motion, they would have so much more power, and then there would be no occasion for having them so large as they are generally made; which would render them lighter, and, consequently, there would be so much less friction on the thick neck of the axle, when it turns in the wall.

M. Parent considered what figure the fails of a wind-mill should have, to receive the greatest impulse from the wind; and he determined it to be a sector of an ellipse, whose centre is at the axis, or arbor, of the mill; and the little semi-axis the height of thirty-two feet: as for the greater, it follows necessarily from the rule that directs the fail to be inclined to the axis, in an angle of 55 degrees.

On the foundation he assumes four such fails, each of which is one-fourth of an ellipse; which, he shews, will receive all the wind, and lose none, as the common ones do. These surfaces are multiplied by the lever with which the wind acts; one of them, expresses the whole power the wind has to move the machine, or the whole power the machine has when in motion.

The same manner of reasoning, applied to a common wind-mill, whose fails are rectangular, and their length about five times their breadth, shews, that the elliptic wind-mill has about seven times the power of the common one.

A wind-mill with four elliptic fails, he shews, would have more power than one with only four. It would only have the same surface with the four, since the four contain the whole space of the ellipse as well as the fix. But the force of the fix would be greater than that of the four, in the ratio of 245 to 231. If it were desired to have only two fails, each being a semi-ellipse, the surface would be something the same; but the power would be diminished by near one-third of that with fix fails, because the greatest of the sectors would much shorten the lever with which the wind acts.

**Bent Form and Proportion of rectangular Wind-Mills.**—As elliptical fails would be something so new, that there is little room to expect they will come into common use, the fame author has considered which form, among the rectangular ones, will be the most advantageous. And by the method de maximis et minimis, he finds it very different from the common ones.

The result of this inquiry is, that the length of the rectangular fail should be nearly double its length; whereas the length is usually made almost five times the width. Add, that as we call length the dimension which is taken from the centre of the axis, the greatest dimension of the new rectangular fail will be turned toward the axis, and the smallest from it; quite contrary to the position of the common fails.

The power of a wind-mill with four of these new rectangular fails, M. Parent shews, will be to the power of four elliptic fails, nearly as 13 to 23; which leaves a considerable advantage on the side of the elliptic ones; yet will the force of the new rectangular fails be considerably greater than that of the common ones.

M. Parent likewise considers what number of the new fails will be most advantageous; and finds, that the fewer the fails, the more surface there will be, but the less power. The ratio of the power of a wind-mill with six fails will be to another with four, nearly as 14 to 15. And the power of another with four will be to that with two, nearly as 13 to 9.

For a variety of curious experiments and observations concerning the construction and effects of wind-mill fails, by the ingenious Mr. Smeaton, see Phil. Trans. vol. ii. p. 138. &c.

Mr. Smeaton's experiments did not realize M. Parent's theory; for he found the fails fixed at the angle of 55 degrees with the axis, to be the least advantageous of any which he tried; but if the fails are included from 72 to 75 degrees from the axis, or 15 to 18 degrees to the place of their motion, the greatest effect will be produced that can be when the fails are plane surfaces.

He also found, that the elliptical fails, which intercept the whole cylinder of wind, do not produce the greatest effect, for want of proper interlaces for the wind to escape.

The following maxims, deduced by Mr. Smeaton from his experiments, contain the most accurate information upon the subject:

**Maxim 1.** —The velocity of wind-mill fails, whether unloaded or loaded, so as to produce a maximum effect, is nearly as the velocity of the wind, their shape and position being the same.

**Maxim 2.** —The load at the maximum is nearly, but somewhat less than, the square of the velocity of the wind, the shape and position of the fails being the same.

**Maxim 3.** —The effect of the same fails at a maximum are nearly, but somewhat less than, the cubes of the velocity of the wind.

**Maxim 4.** —The load of the same fails at a maximum is nearly as the squares, and their effects as the cubes of their number of turns in a given time.

**Maxim 5.** —When fails are loaded, so as to produce a maximum at a given velocity, and the velocity of the wind increases, the load continuing the same: 1st, The increase of effect, when the increase of the velocity of the wind is small, will be nearly as the squares of those velocities 2dly, When the velocity of the wind is double, the effects will be nearly as 10 to 27.5. But, 3dly, When the velocities compared are more than double of that where the given load produces a maximum, the effects increase nearly in the simple ratio of the velocity of the wind.

**Maxim 6.** —In fails where the figure and positions are similar, and the velocity of the wind the same, the number of turns in a given time will be reciprocally as the radius or length of the fail.

**Maxim 7.** —The load at a maximum that fails of a similar figure and position will overcome, at a given distance from the centre of motion, will be as the cube of the radius.

**Maxim 8.** —The effects of fails of similar figure and position are as the square of the radius.

**Maxim 9.** —The velocities of the extremities of the fails, in all their usual positions, when unloaded, or even loaded
led to a maximum, are considerably quicker than the velocity of the wind.

Rules for modelling the Sails of Wind-Mills.—Fig. 4.

Plate II. Wind-Mill, is a front view of one of the four sails of a wind-mill. The letters of reference will serve to explain the terms made use of in the following description.

1. The length of the arm or whip A A, reckoned from the centre of the great shaft B, to the outermost bar 19, governs all the rest.

2. The breadth of the face of the whip, A, next the centre, is one-thirtieth of the length of the whip; its thickness at the same end is three-fourths of the breadth; and the back-side is made parallel to the face for half the length of the whip, or to the tenth bar; the small end of the whip is square, and as its end is one-sixtieth of the length of the whip, or half the breadth at the great end.

3. From the centre of the shaft B, to the nearest bar of the lattice, is one-seventh of the whip; the remaining space of fix-sevenths of the whip is divided into nineteen spaces, so as to make nineteen bars; one-ninth of one of these spaces is equal to the mortise for the bars, the tenons of which are made square where they enter and go through the whip, and consequently the mortises must be square also.

4. To prepare the whip for mortising, strike a gage-score at about three-fourths of an inch from each end, and the gage-score, on the leading side 3, 5, will give the face of all the bars on that side; but on the other side the faces of all the bars will fall deeper than the gage-score, according to a certain rule. To find the space to be set off for this purpose for each bar, construct a scale in the following manner.

5. Extend the compasses to any distance at pleasure, so that the distance of the arms may be greater than the breadth of the whip at the seventh bar; let those fix spaces off upon a straight line for a base, at the end of which raise a perpendicular; let off three spaces upon the perpendicular, and divide the two spaces that are farthest from the base line into fix equal parts each; so that this quantity of two spaces may be equally divided into twelve spaces marked out by thirteen points; from each of these points draw a line to the opposite end of the base, as so many rays to a centre, and the scale is finished.

6. To apply this scale to any given cafe, set off the breadth of the whip at the last bar, (that is, the bar at the extremity of the sail,) from the centre of the scale along the base towards the perpendicular; and at this point raise a perpendicular to cut the ray nearest to the base; also set off the breadth of the whip at the seventh bar in the same manner, and at this point erect another perpendicular to cut the thirteenth radius. From the intersection of the perpendicular (drawn upon the breadth of the last bar) with the first of the thirteen radii, to the intersection of the other perpendicular with the thirteenth radius, draw an oblique line cutting all the rest, and the distances of each of these last-mentioned points of intersection from the base line is the space which the face of each bar is distant from the gage-line on the driving side.

7. These distances give a different set-off for each bar till the seventh, which fame must be set off for all the rest to the first.

8. The mortises must be square to the leading side of the whip.

9. When the mortises are cut, let the face of the whip be flopped off so as to agree with the face of the bars in every part.

10. Two-fifths of the whip are the length of the last or longest bar.

11. Five-eighths of the longest bar must be on the driving side of the whip, and three-eighths on the leading side, each being reckoned from the middle of the whip.

12. The proportion of the mortises already given determines the size of the bars at the mortises, but their thickness must be diminished each way, so as to be only one-half at the ends; but the face must be kept of equal breadth all the way.

13. The leading side goes no farther than the fourth bar, and there only projects one-third of the projection of the last bar.

14. All the bars on the driving side are made hollowing in the arch of a circle, which begins to spring one-third of the length of the bars on the driving side from the whip; and the sweep is such, that if a straight line is applied to the face of the bar from the whip to the end, the face of the bar should leave the straight line about the breadth of the bar.

15. There ought to be three uplongs, as 3, 2, 19, fig. 4, to the driving, and two to the leading side, as at 5, 4, to strengthen the lattice.

Self-regulating wind-mills are those which adapt themselves to the irregularities of the wind, by diminishing or increasing the surface on which the wind can act, to turn them round. If the wind increases in force, the surface exposed to its action is diminished; on the contrary, if it decreases in force, the surface will be increased in the same proportion, so as in some measure to render their motion uniform.

The following self-regulating wind-mill is stated as the invention of Mr. Andrew Mickle in 1772, the inventor of the threshing-machine. The length of the sail was divided into eleven compartments, by the bars forming a number of oblong openings, which were, each filled up by a square frame of wood covered with canvas, and mounted on pivots at their ends; one pivot turning in a hole in the whip, and the other in the bar which lies parallel to it, in the manner of a Venetian blind: the pivots were not placed in the middle of the breadth of the frames, but at one-third from that edge, towards the shaft or axis of the fails. On the end of each pivot which enters the whip a small roller is fixed, round which a chain passes, and its end is attached to a flax spring, placed at right angles to the whip, and in the direction of the length of the canvased frames. Now, if the wind blows too hard, it acts to turn the frames edgeway, in which case the flax passes through the fails, and exerts less force to turn them round; but as soon as the wind becomes moderate, the flax spring brings the frames into a plane, presenting their whole surface to its action. A rod of iron extends the whole length of the whip, and is connected with the several springs, to afford the means of strengthening or diminishing their action, according to the season of the year. This rod was formed into a screw at its outer extremity, and a nut put on to enable the miller to adjust the strength of the springs conveniently, from the circular gallery surrounding the outside of the mill.

Mr. William Cubitt of North Waltham, in the county of Norfolk, took out a patent, in 1807, for a method of equalizing the motion of wind-mill fails. It is similar to Mr. Mickle's, in the fails being made like a Venetian blind; but instead of the springs, he applied racks and pinions on the ends of the blind pivots, and a sliding rod, which passed in a small hole made through the length of the axis of the fails; the end of this rod within the mill was made...
made into a rack, working in a wheel upon which a weight was hung. By this means, when the wind blows too hard, the blinds turn upon their pivots, and by the racks draw out the rod which passes through the axis, and raise the weight; but as soon as the wind abates, the weight brings the blinds to their former position.

A patent was granted in 1804 to Mr. John Bywater of Nottingham, for a method of clothing and unclothing the fails of wind-mills while in motion. The invention consists in a manner of rolling or folding up, and unfolding again, the cloths of common wind-mill fails while in motion. It is effected by placing a long roller in the direction of the length of the whip round which the cloth is rolled; the inner end of the roller is furnished with a pinion, which engages in the teeth of a circular ring of cogs fixed to the shaft-head, close behind the back-rocks, with the liberty of turning round independent of the shaft. Another roller is placed at the back-side of the fail, round which several cords pass, and are conveyed over pulleys at the edge of the fail, and then made fast to the cloth at different distances along its length. The object of this second roller is to clothe the fail, in the same manner as the first-mentioned roller uncloathed it. The inner end of the back roller is furnished with a bevelled pinion, which acts in the teeth of a ring of cogs placed concentric with the one before described, which has also the liberty of turning round independent of the shaft. Suppose the fails to be completely clothed, and turning round by the wind, the two rings of cogs revolve with the axis, and therefore produce no effect on the pinions; but if the wind blows too violent, and it becomes necessary to partly unclothe the fails, the miller pulls a cord which is connected with a lever in the head of the mill. This lever comes in contact with a projection on the ring of cogs belonging to the rollers, upon which the cloth wounds. Now it is evident, that if the ring of cogs is held fast, and the fails continue to revolve, it will cause the pinions to turn round and roll up the cloth upon the rollers; on the contrary, if the wind falls, the fails will require to be more clothed, which is effected by the lever being moved farther, so as to quit the ring of cogs it held before, and hold the other fail, which will put the rollers at the back of the fails in motion, and by winding the cords upon them, draw the cloth off the tail-roller, which increases the surface for the wind to act upon. We have not entered into the minute details of this invention, as given in the patent, for it would have exceeded our limits, but only given a sufficient description to enable a person to understand the means of effecting the regulation.

**Horizontal Wind-Mills.**—These are of various kinds; but only one kind that we know of has been put to any valuable use.

Horizontal wind-mills were a favourite speculation a century ago; and the Theatrimum of the celebrated Leopold contain a great variety, but they are all upon one or other of two principles. In one of these, a very large wheel, like a water-wheel, is mounted with its axis in a perpendicular direction. It consists of several circular wheels fixed upon the axis; and it has large boards or vanea fixed parallel to its axis, and arranged at equal distances round the circular wheels. Upon these vanea the wind can act to blow the wheel round; but if the wind were to act upon the vanea at both sides of the wheel at once, it would have no tendency to turn the wheel round; hence one side of the wheel must be sheltered from the wind, whilst the other is submitted to its full action. For this purpose, the whole wheel is inclosed within a large cylindrical framing of wood, which is furnished with doors or shutters on all sides to open at pleasure, and admit the wind, or to shut and stop it. If all the shutters on one side be open, whilst all those on the opposite side are shut, the wind, acting with undiminished force on the vanea at one side, whilst the opposite vanea are under shelter, turns the mill round; but whenever the wind changes, the disposition of the open vanea must be altered, to admit the wind to strike upon the vanea of the wheel in the direction of a tangent to the circle in which the vanea move. A horizontal wind-mill is thus described in Leopold's Theatrimum Machinarum for grinding corn with one pair of fleses. A strong upright axis is fo poized on a pivot at the lower ends, and furnished in a collar or bearing, as to turn round. Into this several long arms are fixed, in the manner of radii, and at the extreme ends of each arm a vane is fixed, to receive the action of the wind. These vanea are made of two or more moveable leaves, which close up flat like a book, when they are at that side of the circle which moves in a direction to advance towards the wind; so that only the edges of the boards are opposed to the wind; but when these vanea arrive at the opposite side of the wheel, so that the wind blows upon them, the leaves fly open, and expose their full surfaces to the wind, and receive the impulse thereof.

A horizontal wind-mill is described by Dr. Hooke in the Philosophical Collections for 1681. It consisted of four vanea mounted upon vertical axes, and arranged round in a circle by the upper and lower pivots of the vanea being received into holes in the rims of two horizontal wheels fixed upon the same vertical shaft. The vanea were disposed in such a manner, that on one side of the wheel each vane presented its surface to the wind, whilst the one on the opposite side edgways, so as to move through the air without much resistance. This was effected by cog-wheels placed on the lower pivots of the vanea, and so arranged, that as one vane turned round upon its pivots, the whole number moved together, and the motion was given to them by a cog-wheel fixed fast to the framing over the wheel, but concentric with it. This wheel communicated, by means of an intermediate wheel, with the wheels on the axes of the vanea.

The action of this machine is as follows:—Suppose the wind blowing at the wheel; it acts against that vane which is at right angles to its motion, to turn the wheel round upon its axis. The opposite vane presenting its edge to the wind opposes very little resistance. The motion of the wheel upon its axis turns the vanea round upon their pivots, by means of the fixed cog-wheel before described; so that by the time that one has passed out of the direction of the wind, another arrives in the same perpendicular position; and when the wheel has made half a revolution, the vane which stood edgways will be perpendicular to the wind, and the one which before stood perpendicular will be edgways; thus a continued motion is produced without the wheel being caged up.

Horizontal wind-mills, which are inclosed in a house with blinds on all sides, are very fully described in Jacob Leopold's Theatrimum Machinarum, 1724; but we believe they were first practised in this country by captain Hooper, who erected one at Margate, and another at Battersea. The latter is upon a very large scale, and is used for grinding corn; but at present it does not work with much advantage, as the repairs are more considerable in proportion to the power it exerts, than in the mills with falls constructed in the common manner.

In Plate Wind-Mill. fig. 1, is an upright section, and fig. 2, a plan
WIN

This apparatus answers the purpose of the brake or grapple used in common wind-mills to stop their motion. By pulling the fall of the purchase $o$, it causes the iron strap to embrace the great wheel, and produce a resistance sufficient to stop the wheel. The mill can be regulated in its motion, or stop entirely, by opening or shutting the blinds $F$, which surround the fan-wheel. They are all moved at once by a circular ring of wood situated just beneath the lower ends of the blinds upon the floor $I$, being connected with each blind by a short iron link. The ring is moved round by a rack and spindle, which descend into the mill-room below, for the convenience of the miller.

A sort of wind-mill has been long much employed in Portugal, in which, from the difference in the construction of the fails, it is supposed by some, as Lord Somerville, who has inspected it when working, to possess a superiority in having the broad part of the fall at the end of the levers or booms; in consequence of which equal resistance is overcome with less length of branches; and that from this shortness a considerable saving is made in the timber of both the booms and spindles, as well as in the height, first coat of the mills, and their future repairs.

The advantages of making use of these sorts of wind-mills in preference to others are, that as there are four booms, as well as four masts for the falls, they are capable of being more easily braced out to the wind, and in case of a sudden gale or gulf of it, are more easily cast loose than in those of the common construction; and that as the fails in these mills are placed in the best possible direction by the booms, it is presumed that a wind-mill built on this plan and principle will do more work than any common wind-mill with an equal quantity of canvas.

These sorts of mills have also lately been very much improved by constructing and disposing those surface parts upon which the wind is intended to act, in such a particular manner, as that by alternately opposing a refilling and non-refilling surface, the whole force or impulse may operate in a direct manner upon the refilling side of the fall or vane, in proportion to its extent; and that when the non-refilling side is returning against these powers, the mill being so contrived that there is very little refilling, however large the surface. These improvements, when applied to horizontal wind-mills, the power of them, even with the same quantity of fall, or acting surface, may too be increased or diminished at pleasure, which is a circumstance of very great utility and convenience in many cases.

Wind-Pump, that sort of pump which is so contrived and formed as to be driven by the wind. These kinds of pumps are very useful for draining and lifting water in many cases, as where the depth of it is too great to admit of cutting drains, or the superficial too loose for forming them, and when the height to which the water is to be raised is great. See Surface-Draining.

Wind-Row, in Agriculture, a term signifying the green parts or borders of a field, dug up, in order to carry the earth on another land to mend it; so called because it is laid in rows, and exposed to the wind. It also signifies a row of peats set up to dry for fuel. Likewise a row of hay exposed to the wind and sun to get dry. And also of turfs or swart cut up in paring and burning.

The peats are set up in these rows in an open manner, to the height of two or three feet or more, that the wind may pass between and dry them. The rows of hay of this kind are either single or double, the former for that which is in the more gravelly soil, and the latter for that which has been more made; and the work is performed by different persons.
raking the spread hay in opposite directions towards themselves, and by such means forming a row between them of double the extent of that of the single wind-row. See Hay-Making.

The turf or sods for burning are set up in these rows, in leaning directions against each other, so as to let the wind readily pass among and dry them in a quick manner for burning.

Whins are sometimes, too, formed into wind-rows for being burnt for the ashes. See Whin-After.

WIND-Sail, or Ventilator, in a Ship, is made of canvas, and used for circulating fresh air between the decks, and is in the form of a cylinder, or an obtuse-ending cone, and is adapted to the size of the ship. Four breadth of canvas are sewed together, and the outer selvages are joined with an inch seam, leaving one cloth four feet short of the top. A three-inch tabling goes round the top and bottom. It is kept distended by circular hoops, made of ash, fowed to the inside, one at top, and one at every interval of fix feet. The upper part, or top, is covered with canvas, and a small rope fowed round the edge; into which are spliced, at the quarters, the ends of two pieces of rope, that are fowed up to the middle, and an eye formed by seizing the bights. The length of a wind-sail is taken nine feet above the deck, to three or four feet below the lower hatchway; the quantity of canvas is obtained by multiplying the number of cloths by the length.

These, of which there are generally three or four in our capital ships of war, have the advantage of taking little room, of requiring no labour in working, and of a simple contrivance, so that they can fail in no hands. But their powers are said to be small in comparison with those of Dr. Hales's ventilators: they cannot be put up in hard gales of wind, and are of no efficacy in dead calms, when a refresment of air is most wanted. See Ventilator.

WIND-Seed, in Botany. See Arctotis.

WIND-Stop, a name given by our farmers to a dillertemperature to which fruit-trees, and sometimes timber-trees, are subjected.

It is a sort of brulée and diver throughout the whole substance of the tree; but the bark being often not affected by it, it is not seen on the outside, while the inside is twilled round and greatly injured.

It is by some supposed to be occasioned by high winds; but others attribute it to lightning. Those trees are most usually affected by it, whose boughs grow more out on one side than on the other.

The best way of preventing this in valuable trees, is to take care in the plantation that they are sheltered well, and to cut them frequently in a regular manner while young.

The winds not only twit trees in this manner, but they often throw them wholly down; in this case, the common method is to cut up the tree for firing, or other uses; but if it be a tree that is worth preserving, and it be not broken but only torn up by the roots, it may be proper to raise it again by the following method:—Put a hole be dug deep enough to receive its roots, in the place where they were; let the fragglag roots be cut off, and some of the branches, and part of the head of the tree; then let it be raised, and when the turn-up roots are replaced in the earth in their natural situation, let them be well covered, and the hole filled up with rammed earth; the tree will, in this case, grow as well, and perhaps better, than before. If nature be left to herself, and the tree be not very large, the pulling off the roots will raise it. Mortimer's Husbandry, vol. ii. p. 79.

WIND-Tackle Blocks, in a Ship. See Winding-Tackle.

WIND-Taught, in Sea Language, denotes the name as fliff in the wind. Too much rigging, high masts, or any thing catching or holding wind aloft, is said to hold a ship wind-taught; by which they mean, that the floors too much in her failing in a stiff gale of wind.

Again, when a ship rides in a main fires of wind and weather, they strike down her top-masts, and bring her yards down, which else would hold too much wind, or be too much diffused and wind-taught.

WIND-Throw, in Ornithology, a name given by some to the red-wing, and supposed to be given from their generally first appearing with us in windy seasons; but it appears more probably to be derived from the German name wint-throffel, or vine-thrush, from its doing great mischief there in the vineyards, by eating and destroying the grapes. Ray. WIND-Tumours. See TUMOUR.

WIND-Word, in Sea Language, denotes any thing towards that point from whence the wind blows, in respect of a ship.

WIND-Word, Sailing to. See Sailing.

WIND-Word Tide denotes a tide which runs against the wind.

WIND, in Geography, a river of America, which runs into the Connecticut at Windfor.

WIND Gap, a pass in the Blue Mountains of Pennsylvania.

WINDAGE of a Gun, is the difference between the diameter of the bore and the diameter of the ball.

The windage is not the same in England as it is abroad. With us, if the diameter of the shot is divided into twenty equal parts, then the diameter of the bore is twenty-one of these parts. The French suppose the diameter of the shot divided into twenty-six parts, and the diameter of the bore to be twenty-seven. Mr. Müller observes, that the less windage there is, the truer the shot will go, and having less windage to bounce from one side to another, the gun will not be spoiled so soon. Accordingly, he divides the diameter of the shot into twenty-four equal parts, and makes the bore twenty-five, which is a medium between the English and French method. Artillery, p. 84.

Dr. Hutton observes, that if the windage be one-twentieth of the caliber, which is the usual fize, no lefs than one-third or one-fourth of the powder escapes, and is lost. As the balls are often smaller than the regulated size, it frequently happens, that half the powder is lost by unnecessary windage.

Dr. Hutton also recommends the diminishing of the windage. See Gunnery.

WINDALA, in Geography, a town of Sweden, in East Bothnia; 65 miles E. of Walf.

WINDALL, a town of the slate of Vermont; 22 miles S. S. W. of Windfor.

WINDASS, WANASS, or WAXASS, an ancient term in hunting. Thus, to drive the windas signifies the chasing of a deer to a stand, where one is ready with a bow, gun, or to shoot. This is one of the customary servives of hies.

"—Omnes illi qui nunnuntur in bondagii tenitura, solebant vocari custumarii: & quotque nunc dominus ad venandum venerit, illi custumarii solebant fugare windassum, ad flabulum, in venatione ferorum belliarum secundum quantitatem tenenra fumeu." MS. de Confluet. Manier de Sutton Colfield, an. 3 Ed. II.

WINDAU, in Geography, a sea-port town of the duchy of Courland, near the mouth of the Wera, on the Baltic. It was the capital of a palatinate, and has a castle, once the residence of the Livonian knights; the states of Courland likewise held their assemblies here, which made it populous; but it is now much decayed, and chiefly supported by ship-building, and exporting pitch, tar, wax, &c.; 8 miles N. N. E. of Piltyn. N. lat. 57° 10'. E. long. 21° 32'.
Windeau. See Weta.

Windauk, a town of France, in the department of the Scheldt; 9 miles S.S.E. of Ghent.—Also, a town of the duchy of Berg; 21 miles E. of Bonn.

Windeken, a town of Germany, in the county of Hanau Munzenburg; 4 miles N. of Hanau.

Windelsbach, a town of the margravate of Anspach; 22 miles N.W. of Anspach.

Winder, in Agriculture, a term used provincially to signify to clean corn with a fan-machine. See Fan-Machine.

Winder-Meb, in Ornithology, the name of a bird of the larus, or gull-kind, the larus cinereus of Linnæus, moderately large, and described by Aldrovandus under the name of larus major.

Its head is remarkably large and thick, and is of a mottled colour of white and grey; its breast and belly are also variegated with the same colours, but they are somewhat paler; its beak is thick and strong, of a yellow colour, and very sharp, and the opening of its mouth very wide; its wings are variegated with white, grey, and chestnut colour, and both the tail and the four tail in black in them; the feet are webbed and yellow, the claws are sharp, and the hinder toe longer than in most birds of this kind. Ray's Zoology, p. 267.

Winders of Wood. See Wood-Winders.

Windham, or Wymondham, in Geography, a town of England, in the county of Norfolk, with a weekly market on Friday. The chief trade of the place is making wooden ware. In 1549, William Ket, one of the Norfolk insurgents, was hanged on the steeple of the church; 9 miles W.S.W. of Norwich. N. lat. 51° 34'. E. long. 1° 7'.

Windham, a large post-township of Greene county, in New York, comprising all that part of the country on the S. and W. of the summit of the Catskills or Catskill mountains; bounded N. by Durham, Cairo and Catskill, E. by the northern angle of Ulster county, S. by Ulster and a part of Delaware counties, and W. by Delaware county. It has a post-office, and is about 24 miles in length, its median breadth being about 12 miles.

It is mountainous, with much good pasturage-lands that yield excellent dairy. It is watered by the Schoharie creek, which has several mill-feats and small branches. Along these streams are some alluvial lands, which are rich and fertile. The view from the Catskills, over which is a road, is very grand and interesting. The W. part of Windham is about 35 miles W. from Catskill, its principal market. The population consists of 3965 persons, and the senatorial electors are 267.

Windham, a town of the state of Connecticut, on the Thames. It is the chief town of a county, to which it gives name. The county contains 28,611 inhabitants, and the town 2,176; 63 miles S.W. of Boston. N. lat. 41° 38'. W. long. 72° 11'.—Also, a town of the state of Vermont, in the county of Windham, with 782 inhabitants; 20 miles E. of Bennington.—Also, a county in the S.E. part of the state of Vermont, bordering on the Massachusetts. It contains 26,760 inhabitants.—Also, a post-town of New Hampshire, in Rockingham county, with 743 inhabitants; 40 miles S.W. of Portmouth.

Winding, twirling from an even surface, or not a direct plane.

Winding a Call, in Sea Language, denotes the act of blowing or piping upon a boatman's whistle, so as to communicate the necessary orders of hoisting, heaving, belaying, slackening, &c. See Call.

Winding-Engine, in Mining, a machine employed to wind or draw up cores or barrels out of a deep pit or shaft. There are several different machines employed for this purpose, and each has a different name.

The most simple winding-machine is a roller placed horizontally over the pit, to wind up the rope, by which the bucket is suspended; the roller is turned round by a handle at each end. This simple machine, which is called a wind-lafs, wind-up, or roller, is commonly used for well-digging, and formerly was the common machine for mines; but for mining on the present system more powerful machinery is required. In Derbyshire it is called a bowie, and the construction is very minutely directed in the ancient mining-laws of the district, called 'The King's Field.' A small model or effigy of a bowie, constructed according to law, and fixed up "in fight of all men," is still the sign of legal possession of a lead-mines, and one of these must be constantly maintained at every thirty-nine yards in length of the vein of ore; by these laws no man may work more than thirty-nine yards, and it is supposed that each one of these is a separate working and drawing up of the ore from the mine.

With this simple machine a man can work continually to draw up a weight of 7750 pounds, at the rate of one foot per minute, or any smaller weight with a proportionably quicker motion. This is a fair average of the strength of man, which has been determined by a number of experiments, as shewn in our article Water. The radius of a winch or handle should not be above fourteen inches, which describes a circle of 75 feet circumference; a man can turn this round twenty times per minute with convenience, and the motion of his hands will therefore be 14 feet per minute, at which rate a man can exert a force of 25 pounds according to our standard. To apply a man's force to the greatest advantage, we must not depart much from these proportions; but the load which is drawn up at one time may be varied according to the diameter of the roller or barrel on which the rope winds: for instance, if this barrel is seven inches diameter, it will draw up the weight only one-fourth as fast as the man moves the handle; and in consequence the weight may be $4 \times 25\frac{1}{2} = 102$ pounds, and this he will be able to wind up at the rate of thirty-seven feet per minute. It is best to employ two men, and make the two handles at right angles to each other; the roller may then be 14 inches diameter, and they can draw up the 102 pounds at the rate of 74 feet per minute. The roller should have two ropes wrapped upon it in opposite directions, and a bucket being suspended from each, one bucket will be drawn up as the other is let down, and no time will be lost.

The next machine is the horse-gin: it has a large drum or barrel to wind up the rope; the barrel is mounted on a vertical axis, which is provided with one or more long levers, to the extreme ends of which a horse is harnessed, and by walking round in a circle, the barrel is turned round, and the rope which descends into the pit or shaft, is wound up by wrapping round the barrel. The gin is placed at a convenient distance from the mouth of the pit, and the rope is conducted over a pulley at the top of the pit, to change the direction from horizontal to vertical. The horse-gin usually has two ropes wrapping round the barrel in opposite directions, and one winds up as the other unwinds. The two buckets or cores which are suspended in the pit at the same time, go up and down alternately, one full and the other empty, and the weight of the empty core, which is depending, tends in some measure to balance that which is coming up full.

The barrel must be turned in a contrary direction every time a barrel is drawn up, and for this purpose the horse is turned
A perfect equal motion is not necessary for horse-work, and if it is not so much in extremes as to strain the horse in one part of his journey, whilst he has nothing to do in another, he will work very well. Gentle ascents and descents in a road are found as advantageous to the action of horses as a road upon a perfect flat. The following is the construction recommended by Mr. Smeaton for a two-horse gin for a lead-mine. — The horse-track 36 feet diameter, and two horses are employed at once; the diameter of the drum is 14 feet; the weight to be drawn at once 54 cwt. or 644 lbs. exclusive of the bucket, because there are two, and the one serves as a balance for the other; depth of the pit 45 fathoms, or 270 feet; the girt of the rope 6½ inches. The counterbalance for the unequal weight of the great rope is constructed as follows: — Above the drum or rope-wheel, a smaller one, or balance-drum of one-fourth the diameter of the great drum, or 3 feet 6 inches, must be firmly fixed to the upright axis; also a little shaft or pit-muff be funk at a convenient distance from the machine; if this is opposite the great pit, it will require less bracing to keep the fixed parts of the framing at their proper distances. A hole must be made in the circumference of the small wheel, or balance-drum, through which the end of a rope is passed, and secured by a knot. This rope, which is for the counter-weight, is to pass over a pulley of 3 feet or more diameter, such as is used to direct the great ropes down the main shaft; but it must be strongly and substantially fixed, because there will be a greater strain upon it. Over this pulley the balance-rope goes down into a little pit funk for the purpose, and a balance-weight is hung to it, which must be double the weight of 4½ fathoms of the main pit-rope, and it will act as a counter-weight to the great pit-rope. The counter-weight must not, however, go down so as to touch the bottom of the little pit; and it must be so regulated as to be at the lowest point when the two buckets are at their meetings, half way down the main pit. Hence, whichever way the main drum turns round, the counter-weight will be drawn up, and will arrive at the top when either of the buckets arrive there; by this means, whatever be the weight of the rope, though it exceeds the weight of matter in the bucket, yet the horse will always have something to draw; whereas in the old horse-gins made at Newcastle, they had no other method than turning the horses at the point of equilibrium; and after that letting them draw the backward way, which obliged them also to walk backwards, till the bucket arrived at the top.

As a 6½-inch rope is far more than equivalent to the weight required to be drawn, the fame fort of rope will do for the counter-weight also; but as there will be a great deal of chafing at the hole where it is fixed to the little drum-wheel, in consequence of its bending alternately one way and then the other, it will be proper to fortify it there with the white leather made of horses' skins, and the hole itself should be rounded off on each side, so as to make the rope bend easily.

In the sinking of the little shaft, if there is any particular advantage or obstacle, the depth may be greater or less than a quarter part of the main shaft; but then the size of the little drum and counter-weight must be proportioned accordingly. If practicable, the pit had better be deeper; and if it was half the depth, then the little drum might be half the diameter of the large one, and the counter-weight would be no more than the weight of the rope in the great pit. On account of the expense of the balance-pit, the double conical drum, which requires no counter-weight, is much preferable to any machine with a counter-weight.

In our article Water we have given the experiments on the strength of horses; from which it appears that a proper load...
load for 1 horse to work eight hours in a day is 22,000 lbs. avoirdupois, to be raised one foot in a minute, or any smaller weight to be drawn quicker in proportion; hence the weight of 644 lbs. may be drawn by two horses at the rate of 71 feet per minute, or the whole depth of 45 fathoms in 3½ minutes. The horses will then walk in their circle rather more than three miles per hour; but 2½ miles is the best pace. Horses are frequently loaded much more than this, and indeed one strong horse may work this machine; but as he could only work a short time each day, it is better to employ two.

When mines were sunk to very great depths, the drawing of the ore by horse-gins became too expensive, particularly for coal-mines, and more effective winding-machines were introduced. The water-gin was the first of these. The most simple of these is called a whimsey, and consists of a bucket, which is let down full of water, and by its descending force, draws up a loaded basket or corve from the bottom of the pit. (See WHIMSEY.) This machine requires a very considerable fall of water, and it can rarely be less than one-fourth or fifth of the whole depth from which the coal or ore is to be drawn.

In cafes where the fall is smaller, an over-shot water-wheel is employed; and in order to make the wheel turn at pleasure either way round, so as to wind up or let down, the wheel is made double; that is, with two rows of buckets, one row adapted to receive the water from a spout, which will cause it to turn round in one direction, and the other row of buckets is supplied with water from a different spout, and will turn the wheel in the opposite direction. Each spout is provided with valves to stop the stream at pleasure, and when one is open the other must be shut, and thus the wheel may be made to turn either way round. This is a very old invention, and is fully described by Agricola in his De Re Metalllica, 1551. It was at one time in very common use in the collieries, and they raised up the supply of water for it by a pump applied to the beam of the fixed steam-engine, or sometimes by an engine on purpose.

Mr. Smeaton made a machine, in 1774, for drawing coal at Griff, in Warwickshire, by a water-wheel, in which the motion of the wheel is always continued in the same direction; and by a change in the communication of the wheel-work, the barrel is made either to draw up or to let down. In 1777 Mr. Smeaton made a larger machine for Long Benton colliery, at Newcastle, which is worked by the water raised by a steam-engine on Newcomen’s principle.

The water-wheel and machinery are represented in Plate Winding-Engine, in several different elevations. X is the over-shot water-wheel, which is 30 feet in diameter; it is mounted on a cast-iron axis, which is clearly represented in the drawing. The water is delivered upon the wheel by a spout from a trough or chitter, which is supplied by the pump of the steam-engine. This trough is supported on tall piers of masonry, one of which is shown in the sketch. Upon the axis of the water-wheel are fixed two cog-wheels, U, V, of 88 cogs each, and the cogs are turned towards each other; W is a trundle, which is situated between the two wheels, and is turned round by either of them, according as it is placed; but it is smaller in diameter than the space between the two wheels, so that it cannot engage with both wheels at the same time. The trundle is fixed at the extremity of a long shaft, as shown in the plan, fig. 1; and the opposite end of this shaft is connected with the barrel on which the ropes are wound: this barrel is composed of two cones, joined together at their bases. The ropes from the barrel are conducted over pulleys at the top of the pit, as flown in the elevation, fig. 2, and descend into the same. The baskets, or corves, in which the coals are brought up, are hooked to the ends of the two ropes; so that by the motion of the water-wheel one basket is drawn up whilst another is let down.

To regulate the motion of the machine, two brakes or gripes are applied: one encompasses the great cog-wheel U, which is fixed on the axis of the water-wheel, in the same manner as the brake of a wind-mill; and in like manner, the fixed circle or brake is provided with a lever, as shown in fig. 4, by means of which the brake can be drawn tight round the wheel, and will then cause such a friction as to stop the water-wheel and all the machine.

The other brake-wheel DC (fig. 1) is fixed near the end of the long axis, and has clogs or pieces of wood applied at the top. This piece of wood is supported by a lever A B, as shown in fig. 2, A being the centre; and to the other end, B, a box E is suspended, and contains as much weight as will press the clog upon the wheel, with the force necessary to retain the corve from descending when it is full loaded. To enable the man at the mouth of the pit to lower down the corve, a cord is fastened to the lever A B, and is conducted over the pulleys, g k and k, to the mouth of the pit, where it hangs down in a knot, which the man can always reach, and by pulling it, he raises up the lever, and releases the wheel from the clog. To prevent accidents, if the clog and lever A should fail to stop the machine, another clog and lever F G are applied beneath the wheel; this lever is drawn upwards by a cord and a block of pulleys O, which are attached to the lower part of the weight for the upper lever. This cord is conducted to the pit’s mouth, and hangs down, so that the man can always reach it, and by pulling this, he compresses both the upper and lower clogs upon the wheel at the same time, which will be certain to stop it even if it be in a rapid motion; but he only refers to this lower clog on occasion, as the curb-rein is used for a horse; the weight of the upper lever, like a horse’s bridles, being a sufficient check for common use.

To make the machine wind either up or down, the trundle W must be changed from one of the wheels, U or V, to the opposite one, and this will cause the barrel to turn in an opposite direction. The pivot of the trundle W is supported by the long upright beam shown in fig. 3, which is moveable on a centre at the lower end, so that by inclining it to the right or left, the trundle may be engaged with either of the wheels U or V. The requisite motion is given to the upright beam by two tackles of pulleys applied to the upper end of the beam, as shown in fig. 3.

The ropes of both these tackles are fastened together, and hang down in a loop in reach of a boy, who can pull it either way, and make the trundle engage with either wheel, so as to wind up or let down the corves at pleasure. This boy is always stationed in a small room immediately over the wheels U V, so as to have the brake-lever, as well as the upright lever, always at his command; likewise the shuttle of the water-wheel, which is fixed, as is shown in fig. 3. A lever is made to communicate with it, and from the opposite end of the lever a rod descends into the room, so that the boy, by pulling it, can open or shut the shuttle at pleasure. This he must do whenever the corve comes up, or rather before; and notice of the proper time is given by a large knot in the main rope. The water being then shut off, the wheel will continue to turn by its momentum until the corve comes fully up, but by that time will have diminished its velocity, so that the application of the brake will stop it without any strain; the man at the mouth of the
the pit also applies the brake on the wheel CD. Immediately the motion ceases, the boy pulls the tackle, which disengages the trundle W from the wheel, but without engaging it with the opposite one, and in consequence the barrel is detached from the water-wheel. A man now feizes the corve with a long hook, like a shepherd's crook, and draws it aside; then another man releases the clog or brake on the wheel CD, and the wheel and the corve immediately descend upon the ground at the side of the pit. The pulley over the pit is raised up to a considerable height, because the machine cannot be stopped exactly at the precise spot; but if the corve should be drawn up a few feet higher than necessary, no harm can ensue as soon as the full corve is landed and exchanged for an empty one; and the same is done at the bottom of the pit. The boy throws the trundle in gear with the opposite wheel, then draws the shuttle to let the water flow upon the wheel, and the wheel refines its motion.

For the facility of stopping the machine at the proper moment, Mr. Smeaton applied a piece of machinery, which he called a count-wheel. This received its motion from a pinion of 15 teeth, fixed upon the extremity of the pivot of the lantern W; the pinion gave motion to a small cog-wheel of 60 teeth, situated between the two great cog-wheels UV, being fixed at one end of a horizontal spindle; and at the opposite end of it was a pinion of eight teeth, which gave motion to the count-wheel. This wheel had 80 teeth, and was fixed in a vertical position. It had affixed to its plane two projecting pieces of iron, which operated upon a lever that was connected with the lever which lets down or draws up the shuttle to regulate the flow of water upon the wheel. These projections were fixed to the wheel as to be capable of regulation in such manner, that when the machine had worked long enough to have brought up the corve to the top of the pit, the projection of the count-wheel would seize the lever, and let fall the shuttle so as to stop the water-wheel at the proper moment, without any attention on the part of the boy. This could be easily regulated by the position of the projection on the count-wheel, and when once adjusted always operated correctly; for as the count-wheel turned only once for forty turns of the barrel, the machine would therefore draw up a corve from the bottom of the pit before the count-wheel made a complete turn.

As the two corves in the pit ascended and descended mutually, they must pass each other at half the breadth of the pit; and it sometimes happens that they strike together, and overheat the coals. The best remedy for this is to divide the pit in two, or make two separate pits, and the barrel may be situated between the two. As it is frequently impracticable to do so, a smaller projection was applied in Mr. Smeaton's machine upon the count-wheel, which acted in the middle of the course upon the lever, and raised it up so as to diminish the opening of the water-shuttle, and make the machine move slowly at the moment when the corves met and paffed each other; this prevented accidents.

The principal dimensions of this machine were as follows:—The cylinder of the steam-engine 20 inches diameter, and 5 feet 8 inches the length of stroke. It made 14 strokes per minute. It was on the principle of Newcomen, i.e., atmospheric, with injection into the cylinder. The pump was 18 inches bore, and 5 feet 8 inches stroke; it raised the water 33 feet high. This water, being conveyed in a trough to the machine, was delivered upon the water-wheel, which was 30 feet diameter, with 72 buckets; its cast-iron axis was 7 inches diameter; the great cog-wheels 12 feet diameter, with 88 cogs; the trundle 20 cogs, so that the barrel turned 4½ times for once of the water-wheel. The barrel was 5 feet 3 inches diameter in the middle, and 2 feet 1½ inches diameter at the ends; the whole length being 10½ feet. Upon the circumference of the barrel a spiral line is traced, and a groove, which receives half of the rope, to prevent the rope from slipping on the barrel.

The depth of the pit was 165 yards; and it was found, on a long course of experiments, that the total consumption of coals was one corve of coals to draw up 8½ corves from that depth. The machine would draw 18 score of corves, each containing 20 pecks and weighing 5½ cwt., every 12 hours.

The more modern winding-engines by steam are upon a much more simple construction. The power of the steam-engine is applied at once to the barrel which wins up the rope, with only one pair of cog-wheels; viz., a large wheel fixed on the axis of the barrel, and a smaller one on the axis of the fly-wheel of the steam-engine. These engines are frequently made on Newcomen's principle, as the consumption of coals is a small object, but Mr. Watt's engines are more manageable. As the steam-engine with a crank will turn either way, according as it is set in motion, it is very well adapted for winding-machines; the boys who manage them are very dexterous in stopping and turning them the contrary way. See Steam-Engine.

There are many ingenious contrivances for facilitating the landing of the corves when they come up to the pit's mouth. The bed is a platform, which runs upon wheels, and can be pushed over the pit's mouth, when the corve is drawn up, by means of a light carriage with one horse, which is backed on the platform beneath the corve, and pushes the platform over the pit by the same motion. The corve is lowered down upon the carriage, and then the horse draws the corve away; the same motion withdraws the platform from the pit's mouth, ready to let down an empty corve and draw up another full one.

In many modern pits, conductors are fixed in the pit. These are perpendicular rods, and the baskets have projecting parts which embrace the conductors, and guide the corve regularly up or down the pit.

In many collieries flat ropes are used. These are composed of four small ropes placed flat, side by side, and fastened together by a packthread, which pieces all the four ropes. These flat ropes are used, a barrel or drum of small size is used, and the coils of the rope wind upon the other, so as to form a spiral, and increase the diameter of the effective barrel as the rope winds up, so as to balance the weight of the rope. This was invented by Mr. John Curr, of Sheffield, who has several patents for machinery for manufacturing such flat ropes, as they are extensively used in Yorkshire.

In others, iron chains are used instead of ropes, and are found to answer extremely well.

Winding of Cotton. See Cotton Manufacture.

Winding of Silk. See Manufacture of Silk.

Winding-Screw Chefs-Prefis, in Rural Economy, a contrivance of this sort, in which the weight is paid, in the Gloucestershire Report on Agriculture, to be capable of being gradually let down on the vats. It is thus described:—A strong platform, or sill, is raised on four legs, about a foot from the floor; near the edge is made a channel all round, to carry off the whey as it is expressed, by a lip, into the pan or receiver. Two strong side-poles are morticed into the sill, reaching about six feet high; across which, about four feet high, is firmly fastened a strong bar, with an aperture in the centre large enough to let in the screw with ease. This screw is fixed, at the lower part, into a heavy cubical stone
WIN  

of two feet dimensions, or nearly: the upper part of the sere, having passed the perforation in the cross-bar, enters a nut or female sere, large in the middle, but worked off at the two ends fine enough to be grasped by the hand: by turning this nut, the weight is raised or let down on the cheese-vats underneath.

Where stones of the required weight and dimensions are not to be had, a wooden frame of the same size is used, which is filled with sand, pebbles, or rubble-stones.

The screw part of the press has, in many dairies, been lately superceded by the adoption of an apparatus less simple in its construction, though more easily worked. In which, on the right side of the press, a third upright is raised from the floor, and connected by two cross-bars, about a foot long, with the upright post parallel with it. About four feet high, a cylinder of wood, from five to six inches diameter, is inserted, passing quite through the additional upright, but kept to its place by a shoulder. To the end are fixed four spokes, or levers, or an iron handle, to which manual power is applied. A strong rope is fastened to and cooled round the cylinder, which passing over a pulley let lengthways into the upper bar, proceeds horizontally to another pulley, fixed directly over the centre of the weight, and by an iron hook attached to it. Very moderate strength will raise the weight, which in this construction slides with grooves fitted to the side-posts. The mechanical powers are varied in some presses by the use of a wheel of a foot or eighteen inches diameter, instead of the pulley; but the effect is similar. In either way of working the weight, there is a superiority over the old press, and little difference in the expense.

WINDING STAIRS. See STAIR.

WINDING OF WOOL, in Rural Economy, the practice of putting it up into fleeceves. There is some nicety required in this operation; all the loose ragged parts are to be turned inwards, so as to form a neat fold of fleece, and all the dirty parts removed. The work is done on a large table or bench for the purpose. In some cafes of expert winders, four hundred fleeceves can be wound in the course of the day.

WINDISCH FEISTRITZ, in Geography, a town of the duchy of Stieria, on the river Ptucka; 40 miles S. of Graz. N. lat. 46° 30'. E. long. 15° 28'.

WINDISCH Gram, a town of the duchy of Stieria; 18 miles N.W. of Cilley. N. lat. 16° 35'. E. long. 14°.

WINDISCH Landberg, a town of the duchy of Stieria; 12 miles E. of Cilley.

WINDISCH Mark, a part of Carniola, bordering on Hungary and Croatia.

WINDISCH Mainz, a town of the archbishopric of Salzburg; 54 miles S.S.W. of Salzburg. N. lat. 46° 55'. E. long. 12° 36'.

WINDISH, a village of Switzerland, near Konigsfelden, at the confluence of the Aar and the Reuss, in the canton of Berne, in which are found the ruins of the ancient city of Vindonifia, a fortress mentioned by Tacitus, which the Romans made a place of arms to frop the irritation of the Germans, and is said to have been the site of a hilltop. It was destroyed in the 7th century; 3 miles W. of Baden.

WINDISHGARTEN, a town of Austria; 16 miles S.W. of Austrian Aichlawn.

WINDLASS, or WINDLACE, a machine used for raising heavy weights, as guns, lances, anchors, &c. It is very simple, confiting only of an axis, or roller, supported horizontally at the two ends by two pieces of wood and a pulley. The two pieces of wood meet at top; being placed diagonally, so as to prop each other. The axis, or roller, goes through the two pieces, and turns in them. The pulley is fastened at top, where the pieces join.

Lastly, there are two flaves, or handspikes, which go through the roller, by which it is turned; and the rope, which comes over the pulley, is wound off and on the same.

WINDLASS, an horizontal machine, composed of timber, &c. and most used in merchant-ships for heaving up their anchors in lieu of a capstan. The body of the windlafs is octagonal, and is tapered from the middle to the ends by given dimensions. It is fawn from oak-timber of the finest quality, and the length between the cheeks is in one piece. But when fitted with an iron axle or spindle in the middle, it must be in two pieces. The ends without the cheeks are fitted with iron spindles, and have a hoop driven over their ends. The spindles must be very accurately let into the ends and middle of the body, that the axis of each may exactly agree in a right line. A bolt is driven through the body of the windlafs and each end of the spindles. On each end of the body is let on and securely bolted an iron pulley, with teeth or notches at every two or three inches. The pull, which are iron, are fixed against the sides of the pulleys, and fall into the teeth or notches of the pull, fo as to prevent it turning backwards when charged by the effort of the cable, &c. Holes or mortises are cut through, along the middle of the windlafs on each square, to admit the handspikes, and each square of the body is covered with elm or fir facings between the cheeks, on the working side of the windlafs. It is suspended by its axles or spindles in brafs hodings, or gudgeons, which are let in and bolted into a frame of oak-timber called the cheeks, which are let down the deck and bolted and pulled to the pull.

There are other methods of fitting windlafs, but this is recommended as the best.

WINDLASS-CHEEKS, pieces of oak or elm fastened to the sides of small vessels, and by which the ends of their windlafs are suspended.

WINDLE, in Geography, a township of England, in Lancashire; 10 miles N.E. of Liverpool.

WINDLESTRAW, in Agriculture, a term applied to the naked stems of the crested dog's-tail, and other natural grasses.

It is observed in the third volume of the Transactions of the Highland Society of Scotland, that the common poa there sometimes goes by the name of windelstraw-grafs. See Grass, and POA.

WINDMANNIA, in Botany. See WEINMANNIA.

WINO, in Geography, a sea-port town of Sweden, in the province of Smaland; 85 miles N. of Calmar.

WINDORS, a town of the bishopric of Passau; 10 miles W. of Passau.

WINDOT CREEK, a river of America, which runs into the Ohio, N. lat. 37° 39'. W. long. 80° 48'.

WINDOW, q. d. WIND-DOOR, an aperture, or open place, in the side of a house, to let in the air and light.

Before glass windows came into use, (for the antiquity and first introduction of which, see GLASS,) the window caturements were commonly made of a transparent stone, called speckulis lapicis, and thence called speckula; and before the speckula, veils were the only defence they had against the weather. Pitic. Lex. Antiq. in voc. Specularia.

We have various kinds and forms of windows; as glass-windows, wire-windows, horn-windows, &c. Arched windows, circular windows, elliptical windows, square and flat windows, round windows, oval windows, Gothic windows, regular windows, sultic windows; to which add light.
The chief rules with regard to windows are.

1. That they be as few in number, and as moderate in dimensions, as may conduce to other respects; inasmuch as all openings are weakenings.

2. That they be placed at a convenient distance from the angles, or corners of the building; because the parts ought not to be opened and eaves, whose office is to support and strengthen all the rest of the building.

3. That care be taken the windows be all equal one with another, in their rank and order; so that those on the right-hand may answer to those on the left, and those above be right over those below; for this situation of windows will not only be handsome and uniform, but also, the void being upon the void, the full upon the full, it will be a strengthening to the whole fabric.

As to their dimensions, care is to be used to give them neither more nor less light than is needful; therefore regard is to be had to the bigness of the rooms which are to receive the light. It is evident, that a great room needs more light, and, consequently, a greater window, than a little room; and e contra.

The apertures of windows, in middle-sized houses, may be four and a half or five feet between the jams; and in the greater buildings, six and a half or seven feet; and their height may be double their length at the least. But in high rooms, or larger buildings, their height may be a third, a fourth, or half their breadth, more than double the length.

Such are the proportions for windows of the first story; and, according to these, must those in the upper story be for breadth; but, as to height, they must diminish; the second story may be one-third part lower than the first, and the third story, one-fourth part lower than the second.

Windows, Arched. See Architrave.
Windows, Dormer, or Letherns. See Letherns, &c.
Windows, Scenography of. See Scenography.
Windows, Transept. See Transept.

Window and House Tax, is one of the assessed taxes transferred to the commissioners for the affairs of taxes. The duties charged annually with respect to the windows or lights in every dwelling-houses, (for which, see Tax,) are subject to the following regulations.

All skylights, and all windows or lights, however constructed, in flairecas, garrets, cellars, offices, and all other parts of dwelling-houses, to what use or purpose soever applied, and whether such windows or lights shall be in the exterior or interior parts of such dwelling-houses, to be charged to the said duties.

Every window or light in any kitchen, cellar, cellaret, buttry, pantry, larder, wall-house, laundry, bakehouse, brewhouse, and lodging-room, belonging to or occupied with any dwelling-house, whether the same shall be within or contiguous to or disjoined from the body of such dwelling-house, shall be charged to the said duties.

The said duties to be charged yearly upon the occupier or occupiers of the houses, cottages, or tenements, in respect whereof the said duties shall be charged, and to be in force for one whole year, from the 5th day of April in the year in which the same shall be charged, to be levied on them, or on their respective executors or administrators, except as hereinafter provided.

Where any change in the occupation of any house, cottage, or tenement, shall take place after the affinment shall be made, then the said duties shall be levied upon and paid by the occupier, landlord, or owner, for the time being, or on both or all of them, according to their times or pollion thereof, without any new affinment, notwithstanding such change in the occupation for the year that such house shall have been affinmed; provided, that where a tenant shall quit the same, on the determination of the lease or demise after an affinment made, and shall have given notice thereof to the assessor, the duty shall be discharged by the commissioners for this act for the remainder of that year, in case it shall appear to them at the end of such year, that such house, &c. shall have continued wholly unoccupied during the remainder of such year.

Where any dwelling-house is or shall be let in different apartments, tenements, lodgings, or shop, and shall be inhabited by two or more persons or families, the same shall nevertheless be charged as if inhabited by one person or family only; and the landlord or owner shall be deemed and taken to be the occupier, and shall be charged with the said duties: provided, that where the landlord shall not reside within the limits of the occupier, or the said house remain unpaid by him for twenty days after the same is due, the duties so charged may be levied on the occupier or occupiers respectively, and such payment shall be deducted and allowed out of the next payment on account of rent.

Every house, of which the keeping is left to the charge of any person or servant, shall be subject to the like duties as if it were inhabited by the owner or by a tenant; and, if such person or servant shall not pay rates to the church and poor, the said duties shall be paid by the respective owners or tenants of the said house.

Every distinct chamber or apartment in any of the inns of court, or of chancery, or in any college or hall in either of the universities of Oxford or Cambridge, or any public hospital, being severally occupied, shall be subject to the same duties as if an entire house, which shall be paid by the respective occupiers; provided, that every such chamber or apartment, which shall not contain more than seven windows or lights, shall be charged at the rate of 3d. for every such window or light.

All dwelling-rooms in any hall or office whatsoever, belonging to any person, or to any body politic or corporate, or to any company, lawfully charged with the payment of any other taxes or parish-rates, shall be subject to those hereby payable, and be respectively charged as dwelling-houses; and the tenant, &c. to whom the same shall belong shall be charged as the occupier or occupiers thereof.

When a partition or division between two or more windows or lights, fixed in one frame, is of the breadth of space of twelve inches, the window or light on each side of such partition or division shall be charged as a distinct window or light.

Every window extending so far as to give light into more rooms, landings, or stories than one, shall be reckoned and charged as so many separate windows as there are rooms, landings, or stories enlightened thereby.

Every window or light, including the frame, partitions, and divisions thereof, which by due admeasurement of the whole, or the window, or light, shall exceed in height twelve feet, or in breadth fourteen feet nine inches, except being less than three feet six inches in height, shall be reckoned and charged as two windows or lights, except such windows or lights as shall have been made of greater dimensions at any time prior to April 5, 1785; except also the windows or lights in such parts of dwelling-houses as are used for shops, workshops, and warehouses, and except the windows or lights in the public room of any house licenced to sell wine, or other liquors by retail, shall be used for the entertainment of guests; and the windows or lights in farm-houses especially exempted from the duties.
duties in the schedule marked (B.), or in any dwelling-house not chargeable to the duties mentioned in the said schedule.

Where any dwelling-house shall be divided into different tenements, being distinct properties, every such tenement shall be subject to the same duties as if the same were an entire house, which duties shall be paid by the respective occupiers; provided, that every such tenement, which shall not contain more than seven windows or lights, shall be charged at the rate of 3s. 6d. for every such window or light; and every such tenement in Scotland, which shall not contain more than seven windows or lights, shall be charged at the rate of 3s. for every such window or light.

The cafes in which windows are exempted are the following.

1. Any house belonging to his majesty, or any of the royal family, and every public office, for which the duties heretofore payable have been paid by his majesty or out of the public revenue.

2. Any hospital, charity-school, or house provided for the reception and relief of poor persons, except such apartments therein as are or may be occupied by the officers or servants thereof, which shall severally be assessed, and be subject to the said duties as entire dwelling-houses.

3. The windows in any room of a dwelling-house, licensed according to law as a chapel for the purposes of divine worship, and used for no other purpose whatsoever.

Provided that every such hospital, charity-school, house for the reception and relief of poor persons, or room licensed as a chapel aforesaid, shall be brought into charge by the aforesaid or aforesaid, or in their default, by the surveyor or inspector, and shall be rated on the certificate of assessment as such; and on due proof of the facts before the commissioners by the aforesaid, it shall be lawful for the commissioners for executing the said act to discharge such hospital, &c. from the said duties, or such part thereof as is hereby intended to be exempted, in like manner as they are authorized to discharge the assessment on poor persons by this act, but not otherwise.

4. The windows or lights, in any dairy or cheese-room, belonging to and occupied with any dwelling-house, chargeable with the said duties, although the same shall be part thereof, which shall be used by the occupiers for the purpose of keeping butter or cheese, being their own produce, for sale or private use; provided, that the windows or lights in such dairies or cheese-rooms shall be made with tiles or wooden laths, or iron bars, or wires, and wholly without glass, and that the occupiers of the dwelling-houses to which such dairies and cheese-rooms belong shall cause to be painted on the outer door thereof, or on the outside of the windows, or one of them, in large Roman letters, the words, "dairy, or cheese-room," as the case may require, and shall keep such words so painted distinctly legible, during all such time as such exemption shall be claimed; and provided, that such dairies or cheese-rooms shall not be ever used to dwell or to sleep in by any person, but shall be wholly kept for the several purposes hereinbefore mentioned; and provided also, that an assessment of all such windows or lights shall be duly made, and the fact be truly returned in the manner directed by this act, in other cases of exemption from the said duties, so that the number of windows so to be exempted may be ascertained, and the exemption be allowed by the commissioners for executing this act.

The provisions that respect the exemptions of windows from assessment by 43 Geo. III. c. 161 are as follow.

Windows are to be stopped up with stones or brick, or the same kind of materials as the outside of the house; allowing being made for those in the roof made of the same materials with the outside of the roof, or stopped up before the commencement of this act; or windows are not to be made, restored, or stopped up without six days' previous notice given to the surveyors, under a penalty of 10l. ; and surveyors are to charge windows newly made or restored, and omitted in the assessment; and the penalty on stopping up windows to elude payment is a charge on the occupier of the tenement, at the rate of double the sum by which the assessment shall be augmented, by reason of such certificate, subject to appeal, provided it is proved to the satisfaction of the commissioners for executing this act, that the same windows or lights were respectively stopped up according to the directions of this act, previous to the commencement of the year on which the said assessment shall or ought to have been made.

The duty on dwelling-houses (for which, see Tax) comprehends every coach-house, stable, brewhouse, washhouse, laundry, woodhouse, bakehouse, dairy, and all other offices, and all yards, courts, and curtilages, and gardens, and pleasure-grounds, belonging to and occupied with any dwelling-house, within the limits of one acre.

All shops and warehouses which are attached to the dwelling-house, or have any communication therewith, shall, in charging the said duties, be valued together with the dwelling-house and the household and other offices aforesaid thereunto belonging, (except such warehouses and buildings upon or near adjoining to wharfs which are occupied by persons who carry on the business of wharfers, and who have dwelling-houses upon the said wharfs for the residence of themselves or servants employed upon the said wharfs.)

And also except such warehouses as are distinct and separate buildings, and not parts or parcels of such dwelling-houses, or the shops attached thereto, but employed solely for the purpose of lodging goods, wares, and merchandise, or for carrying on some manufacture (notwithstanding the same may adjoin to or have communication with the dwelling-house or shop.)

Every chamber or apartment in any of the inns of court, or of chancery, or in any college or hall in any of the universities of Great Britain, being severally occupied, shall be charged thereto as an entire house, and on the respective occupiers thereof.

Every hall or office whatever belonging to any person or to any body politic or corporate, or to any company lawfully charged with the payment of any other taxes or parishes, shall be subject to the duties as inhabited houses; and the person, &c. to whom the same shall belong shall be charged as occupier.

Where any house shall be let in different stories, tenements, lodgings, or landings, and shall be inhabited by two or more persons or families, the same shall nevertheless be charged to the said duties as if inhabited by one person or family only, and the landlord or owner shall be deemed the occupier, and shall be charged to the said duties; provided, that where the landlord shall not reside within the limits of the collector, or the same shall remain unpaid by such landlord for the space of twenty days after the same is due, the duties so charged may be levied on the occupier or occupiers respectively; and such payment shall be deducted and allowed out of the next payment on account of rent.

No dwelling-house, or other such premises as aforesaid, shall be estimated or rated at any less annual value than the rent or value at which the same premises stand charged in the last rate made on or before the time of making the
affeſſment for the relief of the poor in the same parifh or place, under certain specified restrictions with regard to the poor rate.

Where any dwelling-house shall be divided into different tenements being diſtinct properties, every such tenement shall be subject to the fame duties as an entire house, which duty shall be paid by the occupiers respectively.

The cafes of exemption are the following.

1. Any house belonging to his majesty, or any of the royal family, and every public office for which the duties heretofore payable have been paid by his majesty, or out of the public revenue.

2. Every dwelling-house, being a farm-house occupied by a tenant, and bona fide used for the purposes of husbandry only.

3. Every dwelling-house, being a farm-house occupied by the owner thereof, and bona fide used for the purposes of husbandry only, which, together with the household and other offices aforesaid, shall be valued under this act at 10l. per annum, or any lefs sum.

4. Any hospital, charity-school, or house provided for the reception or relief of poor persons.

5. Every house whereof the keeping is committed to the care of any perfon or ſervant, who doth not pay rates to the church and poor, and who refers therein for the purpose only of taking care thereof: provided, that an affeſſment shall be duly made in every ſuch cafe, and the fact be truly returned in the manner directed by this act in other cafes of exemption from the ſaid duties, and the exemption be allowed by the commissioners for executing this act.

Any perfon inhabiting a dwelling-house, containing not more than fix windows in the whole, ſhall be exempted from the duties in schedule (A.), in ſaid ſuch perfon ſhall be upon the books of ſuch parifh or place as receiving parochial relief; and ſhall not be affeſſed, or liable to be affeſſed to any of the duties contained in schedules (B.), (C.), (D.), or (E.); which several exemptions ſhall be proved or claimed in the manner hereinafter mentioned.

And, in order to relieve ſuch perſons who may be charged to the several duties ſet forth in the schedules (A.) and (B.), or either of them, it is enacted, that where any ſuch house, cottage, or tenement, as is deſcribed in the preceding clause, ſhall be brought into charge, and the occupier thereof ſhall be entitled to the ſaid exemption by reaſon of poverty, in every ſuch cafe, the affeſſors ſhall, on the certificate of affeſſment, fet oppoſite the ſum charged on the occupier thereof, the fact of his or her being poor, and ſhall return the ſame, together with the affeſſment and a certificate, as hereinafter mentioned, to the commissioners for executing this act in the diſtrict where ſuch affeſſment ſhall be made; who, before allowing any ſuch affeſſment, or making any order thereupon, ſhall examine the affeſſors, who ſhall reſpectively attend them for that purpoſe, at ſuch time as they ſhall appoint, touching the return so made; and if the ſaid commissioners ſhall, from ſuch examination, and from the certificate hereinafter mentioned, be ſatisfied that ſuch occupier is entitled to ſuch exemption, they may, after ſuch proof, strike out the charge, leaving his name, and the number of windows and rent of ſuch house in the affeſſment, and ſuch occupier ſhall be exempted accordingly; which exemption ſhall, in the like cafes, extend to, and ſhall be allowed on all affeſſments on ſuch poor perſons, of the duties payable at the time of paſsing this act, ſuch ſhall have been, or ſhall be made, at any time after the commencement of the preſent year.

But before any ſuch exemption or abatement ſhall be allowed, the affeſſors ſhall produce to the commissioners a certificate under the hands of five or more ſubſtantial householders of ſuch parifh or place, in ūſtrry ſealed, of whom the ſaid minister ſhall be one; but in cafe there ſhall be no ſuch minister ſaid therein, then at leaſt two or more churchwardens and overeers of the poor of ſuch parifh or place ſhall concur with ſuch ſeholders in ſuch certificate, ſertifying thereby, that they have carefully examined the affeſſment of theſe duties, and the allegations therein made by the affeſſors, touching ſuch perſons who ſhall be therein ſlated to be poor, and that in their judgment and belief the perſons therein ſertified to be poor are entitled to be exempted by reaſon of their poverty, and are wholly unable to pay the duties affeſſed upon them; provided, that if in any parifh or place there ſhall not be five ſubſtantial householders, then ſuch certificate may be made by the ſubſtantial householders thereof reſiding; or if there ſhall be no churchwardens or overeers, then the fame may be granted by the ſaid minister, or by any two churchwardens or overeers of any adjoining parifh or place, who can certify the truth of ſuch allegations, concurring therein with the ſubſtantial householders ſeiding in the parifh or place where ſuch affeſſment ſhall be made.

And where the occupier of any ſuch, cottage, or tenement, containing more than the number of windows or lights before ſpecified, ſhall be brought into charge, and the occupier thereof ſhall, at the commencement of the year for which ſuch affeſſment is made, be poor and indigent, or ſhall become so during that year, in every ſuch cafe, ſuch occupier may give notice thereof in writing, rating the caufes to the affeſſor, or to the ſurveyor of the diſtrict in which ſuch house is ſituate, annexing thereto a certificate, under the hands of ſuch perſons as aforesaid, ſertifying that, in their judgment and belief, ſuch perſon is juſtly entitled to relief on account of poverty for the caufes mentioned in ſuch notice; and every affeſſor ſhall deliver the notices by him received to ſuch ſurveyor: and if ſuch ſurveyor ſhall be ſatisfied of the truth thereof, after due examination of the caufes and circumstances, and that ſuch perſon is unable to pay the duties charged on him or her, and has no probable means of bettering his or her condition within that year, he is hereby required to certify the fame to the commissioners; and if ſuch ſurveyor ſhall not be ſatisfied, then, on notice thereof to ſuch occupier, he may appeal from ſuch charge to the commissioners, giving ten days' previous notice thereof to the ſaid ſurveyor.

And in every cafe where the ſurveyor ſhall certify to the ſaid commissioners that he is ſatisfied of the truth of the claim made by any ſuch occupier, and that he is, and will be unable to pay the duties charged on him or her within that year; or if, upon appeal, it ſhall appear to the ſatisfaction of the major part of the ſaid commissioners, preſent, on the oath of ſuch appellant, or by other lawful evidence on oath produced by ſuch appellant, that he or she is entitled to maintain ſuch appeal, and wholly unable to pay the duties charged on him or her, the ſaid commissioners may give ſuch relief, either by striking off the whole of the duty so charged, or diminishing the same, as to them shall seem meet and neceſsary; and which appeals, for the caufes in this clause mentioned, may be heard and determined, either on the days mentioned in this act for hearing appeals in other cafes, or at the end of the year, or any days to be appointed by the respective commissioners for executing this act; which exemption ſhall, in the like cafes, extend to, and ſhall be allowed on all affeſſments on ſuch poor perſons of the duties payable at the time of paſsing this act, which ſhall have been or ſhall be made at any time after the commencement of the preſent year.
Unoccupied houses are to be inlurled in the affection, and the affellors, or the surveyors and inspectors, are to certii when they become occupied, and the person occupying shall give notice to the affeiler, surveyor, or inspector, within twenty days after occupation, under a penalty of 5/-, and be liable to be charged for the rent of the preceding quarter; and houses becoming unoccupied after affection are to be charged for the whole year, unless notice is given. Notices are also to be given by occupiers of houses or managers of hospitals, charity-schools, poor-houses, or licensed chapels, entitled to exemptions; and the exemptions are to be allowed by the commissioners after examination. Burn’s Justiciary, vol. v. See Tax and Communication.

WIND, in Anatomy, &c. See Fenestra.

WINDRUSH, in Geography, a river of England, in the county of Oxford, which runs into the Thames, 5 miles S.S.W. of Witney.

WINDSCHACH, a town and citadel of Germany, in the principality of Ansbach; 10 miles S.E. of Ansbach. N. lat. 47° 15’. E. long. 10° 46’.

WINDSHEIM, a town of Bavaria. The inhabitants are chiefly Lutherans. This town was imperial till 1602, when it was given to the Elector of Bavaria; 28 miles S.W. of Wurzburg. N. lat. 49° 34’. E. long. 10° 26’.

WINDSOR, commonly called New Windsor, to distinguish it from a parish called Old Windsor, a market and borough town of Berkshire, England, is eminent in the historic annals of the kingdom, on account of containing one of the palaces of the sovereigns, and from the many distinguished events which are identified with the place. Some of our most eminent military and chivalrous sovereigns have made the castle, or palace of Windsor, their chief residence, and consequently the scene of various celebrated festivities, tournaments, and national assemblies. In the annals of the castle, this is fully verified. When the Domeday-book was compiled, the castle, which had been then lately built by William the Conqueror, was within the manor, and it is probable within the parish of Clewer, of which Windsor was formerly a chapelry; it afterwards became the seat of an extensive honor.

We are told by the Saxon Chronicle, that William the Conqueror kept his Whithuntide at Windsor in 1071; and that a synod was held there in 1072, wherein the province of York was made subject to Canterbury. It is probable, that William Rufus kept his Whithuntide at Windsor in 1095, his Christmas in 1096, and his Easter in 1097: but in all probability all these festivals were held at the palace at Old Windsor. Windsor-castle seems to have been intended by William the Conqueror more for a military poll, for which by its situation it was well adapted, than for the residence of himself and his successors.

Several monarchs kept their Christmas and other festivals at Windsor; on some of which occasions there were tournaments and other chivalrous fetes performed. After the contenstions between Stephen and Maud, Windsor-castle, as the second fortres of the kingdom, was committed to the custody of Richard de Lacy.

It appears that a new barbican, or out-work, was built to the castle by king Henry III. In 1265, during the wars between that monarch and his barons, prince Edward Garrisoned Windsor-castle with foreigners, who nearly destroyed the town, and did much injury to the surrounding country. The same year it was given up to the barons, and the king made an order that Eleanor, wife of prince Edward, with her daughter, and all her household, should, without delay, retire from the castle.

A great tournament was held in Windsor-park on the 9th of July, in the fifth of king Edward I. That monarch and his successor, king Edward II., resided frequently at Windsor, where several of their children were born.

John, king of France, and his son Philip, were prisoners in Windsor-castle. David, king of Scotland, is also said to have been prisoner there at the same time.

All historians agree, that Windsor-castle owes its magnificent fabric to the affection which king Edward III. bore to the place of his nativity. Wallingham relates, that in 1334, he built a chamber, which he called the round table, 200 feet in diameter: this, by other accounts, appears to have been only a temporary furniture. Holinshad says, that in 1359, the king set workmen in hand, to take down much old buildings belonging to the castle of Windsor, and caused divers other fair and sumptuous works to be set up in and about the same castle, so that almost all the masons and carpenters, that were of any account within the land, were sent for, and employed on the same works.” But it appears that various commissions for appointing surveyors and impriying workmen had been issued some years before; and that in 1356, William of Wykeham, then one of the king’s chaplains, was made clerk of the works with ample powers, and a fee of one shilling a day whilst at Windsor, and two shillings when he went elsewhere upon business: his clerk had a salary of three shillings a week. In 1359, the architect’s powers were further enlarged, and he was appointed keeper of the monars of Old and New Windsor. The next year 360 workmen were impriying to be employed on the buildings at the king’s wages, some of whom having clandestinely left Windsor, and engaged in other employments for greater wages, were ill-used to prevent persons employing them, on pain of forfeiting all their goods and chattels, and to commit such of the workmen as should be apprehended to Newgate. The plague having carried off a great number of the king’s workmen in 1352, new writs were issued to the sheriffs of several counties to imprison 302 masons and diggers of stone to be employed in the king’s works. The counties of York, Salop, and Devon, were to furnish sixty men each. Glaziers were imprisoned in the year 1363; very few commissions were issued after the year 1369, and none after 1373, so that it may be presumed that this noble work was then completed; compiling the king’s palace, the great hall of St. George, the lodgings on the east and south sides of the upper ward, the round tower, the chapel of St. George, the canon’s houses in the lower ward, and the whole circumference of the walls, with the towers and gates.

The appeal of high treason, brought by the duke of Lancaster against Thomas Mowbray, duke of Norfolk, in 1508, was heard by king Richard II., on a scaffold erected within the castle at Windsor, when, it being found impossible to reconcile the opponents, a day of combat was appointed to take place at Coventry. The castle continued to be the occasional residence of our monarchs, who from time to time made various alterations in the buildings, particularly king Henry VII. Windsor-castle was garrisoned by the parliament, soon after the breaking out of the civil war between Charles and his subjects; and colonel Venne, who was afterwards one of the king’s judges, was appointed the governor. Prince Rupert made an unsuccessful attack upon it in the autumn of 1642. The castle continued under the jurisdiction of parliament during the war, and in the year 1648 became the prison of its unfortunate monarch. Judge Jenkyns was also a prisoner here for several years; whence he was removed to Wallingford, in 1656.

Upon the Restoration, king Charles II. finding the buildings
ings of the castle much dilapidated by plunder and neglect, caused it to be thoroughly repaired and richly furnished. During the greater part of his reign, he made Windsor his summer residence. King James II. in 1687 received the pope's nuncio at Windsor-castle. Queen Anne, when princes of Denmark, lived in a small house adjoining the little park, and was very partial to Windsor.

During the reign of his present majesty, Windsor-castle has undergone considerable improvements, under the direction of the late James Wyatt, esq. surveyor-general of his majesty's works.

The castle consists of two courts, between which is the keep, or round tower. The upper court contains on the north side the state apartments, chapel, and the hall of St. George. The east and south sides have been lately fitted up for the residence of their majesties and the royal family. Our limits will not allow us to enter into a detail of the magnificent rooms which constitute the state apartments, or of dwelling on the valuable collection of pictures therein contained.

St. George's hall, on the north side of the upper ward, was built by King Edward III., as a refectory for the knights companions of the garter: it is a noble room 108 feet in length. The ceiling and walls are painted by Verrio; the subjects are the triumphs of the warlike founder, and his brave son, Edward the Black Prince.

In the area of the upper court is a bronze statue of King Charles II. on horseback, executed by Stada at the expense of the munificent Tobias Rustat.

On the north side of the castle is the terrace made by Queen Elizabeth, which was extended by King Charles II. along the east and south sides: its whole length is 1350 feet, and it may be regarded as the noblest walk of the kind in Europe, as well as the most interesting in situation.

The chapel of St. George is situated on the north side of the lower court of the castle. King Henry I. built a chapel at Windsor, dedicated to St. Edward the Confessor, and placed in it eighty canons, who were maintained out of the king's exchequer. This chapel appears to have been rebuilt, or considerably enlarged and decorated, by King Henry III.: that monarch, in the year 1243, intrusted a commission to Walter de Gray, archbishop of York, to expedite the works at the king's chapel at Windsor, directing that the workmen should proceed as well in winter as in summer, till the whole was completed; that a lofty wooden roof, like the roof of the new work at Lichfield, should be made to appear like flute-work, with good ceiling and painting: that the chapel should be covered with lead, and four gilded images be put up in it, where the king had before directed images of the same kind to be placed; and that a fluted turret should be made in front of the chapel of sufficient size to hold three or four bells. Some remains of Henry III.'s buildings, as may be presumed by the style of the arches and architectural decorations, may be seen on the south side of the dean's cloisters, and at the east end of the chapel behind the altar.

King Edward III., who had been baptized at Windsor, rebuilt St. Edward's chapel there, and dedicated the new structure to the Virgin Mary and St. George. In the year 1349, he augmented the number of canons to twenty-three, besides a warden; and appointed 24 poor knights, for all of whom he built habitations, and granted land for their support. In 1351, the bishop of Winchester made considerable alterations in the college; and Henry IV. changed the title of warden to that of dean.

The present splendid and truly interesting chapel of St. George may be regarded as the most perfect and most beautiful pile of ecclesiastical architecture in the kingdom. It was commenced by King Edward IV. and committed to the superintendence of Richard Beauchamp, bishop of Salisbury. The work was not completed till the reign of King Henry VIII.: the beautiful roof of the choir was put up in the year 1508. Sir Reginald Bray, prime minister to King Henry VII., and one of the knights companions of the order of the garter, who died in 1502, succeeded Bishop Beauchamp in the superintendence of this great work, and was a liberal contributor to the building of the choir and other parts of the fabric: his cognizance is frequently repeated on the roof of the choir, as are the royal arms and those of several noble families with the order of the garter. The roof roof and lantern were erected in 1516; the present organ-gallery and screen at the end of the choir are of Coade's artificial stone. The halls of the knights companions, which are very richly carved in wood, exhibit the names and arms of the several illustrious and noble persons by whom they have been respectively filled. The altar-piece, which represents the Last Supper, is by Mr. Wett, from whom designs the east window, representing the Resurrection of our Saviour, was executed in painted glass by Jarvis and Foreit, and put up in 1788: the expense of the latter was about 4000I. Another window by the same artists display the angels appearing to our Saviour. Many of these improvements, as well as several others in the chapel and castle, have been executed under the patronage, and partly at the expense, of his present majesty. Beneath the choir repose the remains of Henry VIII., his queen, lady Seymour, and king Charles I. Henry VI. was also interred in this chapel; also his rival and successor, Edward VI.

At the east end of the south aisle is the Lincoln chapel, which contains the monument of Edward, earl of Lincoln, lord high admiral of England for thirty years, who died in 1584. Sir Henry Clinton, bart., a descendant of the earl of Lincoln, was buried in this chapel in 1705. In the same aisle is an elegant chantry chapel, built by John Oxenbridge, canon of Windsor. Further west is a chapel built by Dr. Oliver King, bishop of Bath and Wells, who died in 1492.

In the middle of the south aisle is a spacious chapel, founded by Sir Reginald Bray, who died in 1502, and is here interred: his arms and crest appear in several parts of the chapel, particularly in the beautiful screen which separates it from the aisle.

At the west end of the south aisle is the Beaumont chapel, in which is an altar-tomb with the effigies of the founder, Charles Someret, earl of Worcester, who died in 1536, and his lady; and a splendid monument, supported by Corinthian pillars, to the memory of Henry, the first duke of Beaumont, who died in 1699.

Near the south door of the choir is interred Charles, duke of Suffolk, a favourite minster and brother-in-law of King Henry VIII., who died in 1543.

On the west side of the choir-door in the north aisle is a chapel built by Elizabeth, wife of William, lord Hatfield, who is buried here.

At the east end of the chapel is a distinct though attached building, called the tomb-house, which was commenced by Henry VII. and intended for his burial place. It was granted by Henry VIII. to cardinal Wolsey, who began a magnificent monument for himself within its walls. This was destroyed in the civil wars. James II. fitted up the building as a Roman Catholic chapel; and publicly attended the celebration of masses. After that monarch's decease the chapel was deserted; but in 1800 his present majesty gave orders
orders for it to be repaired, beautified, and appropriated for the interment of his family. The princes Mary and the princes Charlotte of Wales have been committed to its vault. On the north and east sides of the chapel are houses and lodgings for the dean and canons. The south and west sides of the lower ward are occupied by houses appropriated to the poor knights.

Between the two wards or courts of the castle is the keep, or round tower, for the residence of the governor of the castle. It consists of a lofty, artificial, conical mount, surrounded by a moat, and surmounted by a strong fortified tower, which is approached by a flight of 100 steps. The circumference of the whole castle is 4180 feet; its length from east to west 1480 feet; and the area, exclusive of terrace walks, is about twelve acres.

On the south side of the castle is a modern mansion, called the Queen's-lodge, where the royal family resided for several years; but it is now unoccupied. About half a mile S.E. of the castle is Froome, a modern fest built to the queen. It is principally noted for its beautiful garden.

To the south and west of the town is Windsor Forest, which formerly was computed to measure 120 miles in circuit. At present it is about 56 miles. A part of this, called the great park, consists of 3800 acres. The little park, on the north and east sides of the castle, contains about 500 acres.

Windsor is a large irregular town, disposed on the sides of a hill, and at its base, on the southern banks of the Thames. In 1276 it was declared a free borough by King Edward I., who granted to the burgesses a mercantorial guild, and various privileges and exemptions. He constituted it the county-town. King Edward IV. incorporated the burgesses by the name of mayor, bailiffs, and burgesses. By the later charter of King Charles II., the corporate body is made to consist of twenty-eight or thirty members. A weekly market is held by royal grant, as well as three annual fairs. Near the centre of the town is a guildhall or town-house, which was built in 1666.

This borough sent two members to parliament in the reign of Edward I.; but omitted making any return from 1340 to 1446. The right of election has frequently been contested, but was finally settled to be vested in all the inhabitant householders not receiving alms. Windsor has continued to increase in population for the last 300 years. In 1553, there appears to have been 1000 persons; in 1801, they amounted to 3461; and in 1811 to 6155, who occupied 1051 houses. The parochial church is a spacious building, and part of it ancient, though it was formerly only a chapel subordinate to the church of Clewer. In it are several old monuments. On the west side of the town are extensive barracks, and an hospital for sick soldiers.

Windsor, old, a village about two miles S.E. of New Windsor, was a place of some consequence at the time of the Domesday-survey, as by that record it is stated to contain 95 houses, which paid half a tax to the crown. Some of the Saxons kings had a palace here, and Edward the Conqueror sometimes kept his court at this place. After William the Conqueror had erected a castle at New Windsor, the old palace and the surrounding houses were gradually deserted. A great part of Windsor-park is within the parish of Old Windsor, and includes three lodges: 1. The great lodge built in the reign of Charles I. and occupied by the illustrious William, duke of Cumberland; 2. The little lodge or dairy, occupied by the deputy ranger; and 3. The minor lodge near Virginia water. Beaumont lodge, the seat of lord viscount Asbrooke, was originally built by Lord Weymouth, who died in 1705. There are other fa-

mily mansions and villas in this parish; one of which was lately fitted up and occasionally occupied by the princes of the house of Hanover.

The History of the Royal Residences, 4to. 1817, by J. Pyne, a very handsome and interesting work, contains several views of the state apartments in Windsor-castle. The Architectural Antiquities of Great Britain, 4 vols. 4to. by J. Britton, contains several views, and a full history and description of St. George's chapel.

Windsor, a large township in the south-east corner of Broome county, New York, erected in 1807 from the east part of Chenango, situated 15 miles E. of Chenango; bounded north by Chenango county, east by Delaware county, south by the state of Pennsylvania, and west by Chenango. Its extent is nearly 15 miles square, and it has two post-offices. It is traversed by the Susquehanna river. In 1810 it had eleven saw-mills, seven grain-mills, a fulling-mill, and carding-machine, eight school-houses, one house of worship, a population of 1960 souls, 138 electors, and nearly 300 families.

Windsor, a town of Nova Scotia; 25 miles N.W. of Halifax.—Alfo, a town of the state of Vermont, capital of a county of the same name, which contains 34,977 inhabitants; the town contains 2757 inhabitants; 92 miles N.W. of Boston. N. lat. 43° 33' W. long. 72° 22'.—Alfo, a town of the state of Connecticut, on the west side of the Connecticutt river, in the county of Hartford, with 2856 inhabitants; 3 miles N. of Hartford.—Alfo, a town of Massachusetts, in the county of Berkshire, with 1108 inhabitants; 156 W. of Boston.—Alfo, a township of Pennsylvania, in Berks county, with 1353 inhabitants; 70 miles W. of Philadelphia.—Alfo, a township of Pennsylvania, in York county, with 1739 inhabitants.—Alfo, a town of New Hampshire, in the county of Hillsborough, with 238 inhabitants.—Alfo, a town of North Carolina; 23 miles S.W. of Edenton.—Alfo, a township of Lower Canada, on the St. Francis.

Windsor, East, a town of New Jersey, in Middlesex county, with 1747 inhabitants.—Alfo, a town of the United States of America, in Connecticut, on the east side of the Connecticutt, opposite Windsor, with 3081 inhabitants.

Windsor, West, a town of New Jersey, in Middlesex county, with 1714 inhabitants.

Windsor, New, a poll-township of Orange county, New York, on the west bank of the Hudson; 100 miles S. of Albany; bounded north by Montgomery and Newburgh, east by the Hudson, south by Cornwall and Blooming-grove, west by Montgomery and Wallkill. Its medial ex-

tent east and west is eight miles, and north near four, giving an area of about 30 square miles. Its population in 1810 was 2331 persons, and its senatorial electors were 147. It has two post-offices, viz. the village of New Windsor, pleasantly situated on the west bank of the Hudson, and having considerable trade; and Little Britain, said to be discontinued in 1813. This township has several mill-reams, and the land is occupied chiefly by farmers, who enjoy much of the independence resulting from prosperous industry. The whole is well watered by springs and brooks.

Windsor Forest. See Windsor.

Windsor River, a river of the state of Connecticut, which runs into the Connecticut, 4 miles N. of Hartford.
WIN

WINDSOR Bean, in Agriculture and Gardening. See Bean, and Vicia.

WINDBERG, in Geography, a town of the duchy of Holstein; 4 miles S.S.E. of Meldorp.

WINDTHAAG, or WIndthag, a town of Austria; 3 miles E. of Bavarian Waldhoven.

WINDWARD PASSAGE, a name given to a course from the south-east angle of the island of Jamaica, in the West Indies, and extending from 160 leagues to the north side of Crooked island, in the Bahamas. Ships have often failed through this channel, from the north part of it to the island of Cuba, or the gulf of Mexico, notwithstanding the common opinion, on account of the current which is against it, that they keep the Bahama shore on board, and that they meet with the wind in summer for the most part of the channel easterly, which, with a counter current on shore, pushes them easily through it.

WINDWARD ISLANDS, in opposition to Leeward. These islands in the West Indies extend from Martinico to Tobago. See West Indies.

WINDWARD Point, a cape on the north-east coast of the island of St. Christopher. N. lat. 17° 23'. W. long. 62° 22'.

WINDY TUMOURS. See Tumour.

WINE, the fermented juice of the grape. The name is also applied to the fermented juice of other fubacid fruits.

It is impossible to fix the era when mankind first discovered fermented liquors. Some historians have ascribed the discovery to Noah, others to Saturn, others to Bacchus, &c. In short, almost every country in which the vine is indigenous has boasted of some individual or native deity, to whom the honour has been attributed; and if we reflect upon the simplicity of the process by essentially necessary to be had recourse to in making wine, it will appear exceedingly probable that the discovery was not made by one person or country exclusively, but by different individuals and nations at very different periods. A poet has elegantly represented wine as a recompence given by the deity for the miseries brought upon mankind by the general deluge:

"—— Deus nobis felicita vini
Dona dedit, trites hominum quo munere fovit,
Reliquias; mundi folatus vite ruimam."

Pradium Rufiticum.

Different kinds of wine were known at a very early period; and as civilization and luxury advanced, the number was greatly extended. Hence the cultivation of the vine became an object of importance, and many new varieties were produced, which, favoured by soil and situation, rendered particular places more famous than others. Thus the ancient Romans not only possessed a great variety of native wines, but, in the days of their greatest splendour, those also of distant and still more favoured climes, as the Vinum Chionum, Lejthinum, Leucadium, Rhodium, &c. &c. See Pliny, xiv. 6.

Little is known respecting the modes of manufacturing some of the most celebrated of the ancient wines. The general processes, however, did not perhaps differ much from those at present in use. The fruit was collected, bruised by the feet, and subjected to pressure, as now practiced. The juice that first flowed spontaneously was called χιττικα διχωμα by the Greeks, and by the Romans vinum primarium; such as was obtained by pressure was denominated διος, or vinum secundarium, and considered as inferior.

Both Greeks and Romans appear to have frequently concentrated their wines, either by spontaneous evaporation, or by boiling. For the former purpose, the wine was sometimes introduced into bladders or large jars, and exposed in the chimney to the heat of the fire, or in the upper parts of the house to the heat of the sun. Sometimes the fruit was converted into raisins by drying, and the wine prepared from such fruit was denominated παστεμ. At other times the must was reduced by boiling to one-half. This formed the vinum defrutum: occasionally even to one-third, when it was termed Sapa. (See Pliny, xiv. 9.) By one or perhaps more of these methods, the wines were reduced to the state of syrup, or in some instances even to dryness, and were capable of being preserved for a very long time. Thus Aristotle states, that the Arcadian wines required to be diluted with water before they were drank, as indeed was the case with most of the ancient wines; and Pliny speaks of wines as thick as honey, which it was necessary to dissolve in warm water, and filter through linen, before they were used. This was the case with the wine of Cacuba, according to Martial:

"Turbida folicito tranfmittere Cacuba facco."

Pliny mentions Staphylus as the first who mixed wine with water; but Athenaeus gives the credit of it to Amphitryon, king of Athens. On this occasion a fable was invented, that Bacchus, having been struck by a thunder-bolt, and being all inflamed, was presently cast into the nymphs' bath, to be extinguished.

These remarks, however, are applied by the authors chiefly to very old wines. Thus the wine compared by Pliny to honey had been made two hundred years before, in the time of conful Oppius: indeed wines of a hundred years old, and upwards, seem not to have been uncommon among the luxurious citizens of ancient Rome. (See Hor. od. iii. 14. 18. Juvenal, v. 34.) And similar allusions will be found in various other authors. Seven years was the shortest period, according to Ariosto and Galen, for keeping a wine before it was fit for drinking.

Among the Romans, the age of wines was, as it were, the criterion of their goodness. Horace, in his odes, which one may call Bacchic songs, boasts of his drinking Falernian wine, born, as it were, with him, or which reckoned its age from the fame consul.

The age of wine has been reckoned by leaves; thus they say, wine of two, four, or six leaves, to signify a wine that was two, four, or six years old; taking each new leaf put forth by the vine, since the wine was made, for a year. The moderns keep no wine to such an age as that mentioned by Pliny. Where they are kept the longest, as in Italy and Germany, there are scarce any to be found of above fifteen leaves. In France, the wines that keep best, as those of Dijon, Nantz, and Orleans, are reckoned superannuated at five or six years old.

Wine kept in a cool vault, and well secured from the external air, will preserve its texture entire in all the constituent parts, and sufficiently strong for many years, as appears not only from old wines, but other foreign fermented liquors, particularly those of China, prepared from a decoction of rice, which being well cloathed down in the vessel, and buried deep under ground, will continue, for a long series of years, rich, generous, and good, as the histories of that country universally agree in affirming us.

Sir Edward Barry, in his Observations, historical, critical, and medical, on the Wines of the Ancients, suggests, that our best modern wines, especially those of a delicate texture and flavour, may be more effectually preserved in earthen vessels of a larger size than our bottles, well glazed externally and internally: that dry sand is preferable for covering the bottles in the bins to sawdust; and that a
WINE.

small anti-cellar, built before all large cellars, would be a
considerable defence and improvement.

The ancients were fond of giving their wines an artificial
flavour, and for this purpose they introduced pitch, turpen-
tine, and different herbs into the at; a practice still fol-
lowed by the modern Greeks. Plin. ubi figura.

Such are the principal facts known respecting the cele-
brated ancient wines, which, as Chaptal judiciously remarks,
appear in general to have rather deferred the name of extraits
or syrups than wines. They must have been sweet and little
fermented, and consequently have contained a very small
proportion of alcohol. Indeed it is difficult to suppose how
they could contain any spirit whatever, or possess in con-
fsequence any intoxicating properties.

The above remarks, however, can be only applicable to
those wines which the refinements of luxury or caprice had
rendered valuable, from their uncommon occurrence, or the
difficulty with which they were procured. It is certain that
the ancients were well acquainted with the fermentative
processes, and ordinarily took advantage of it in the formation
of their wines; hence it is extremely probable that the wines
used in the primitive states of society, and perhaps at all
times by the common people, confined simply of the fer-
mented juice of the grape, and therefore differed in no
respects whatever from the wines in common use at the pre-
fent time.

General Principles of Wine-making.—We shall consider this
interesting subject under two principal points of view:
1. The manufacture of wine from grapes; and 2d. From
other fruits.

1. The manufacturing of wine from grapes is liable to be
influenced by a great variety of circumstances, such as cli-
nate, soil, aspect, season, &c.; some of the most important
of which we shall take a cursory view.

The vine is a native of the middle regions of the temperate
zone, that is to say, between the latitudes of 25° and 50°,
and here only does it flourish and mature its fruit in absolute
perfection. Indeed a belt comprised between the latitudes of
40° and 50°, may be said to include all the most cele-
bated vineyards of the northern hemisphere; from, namely,
of Spain, Portugal, France, Italy, Austria, Styria, Carinthia,
Hungary, Transylvania, and part of Greece. The
vine grows beyond the latitude of 50°, but its juices are
auflere, and without the requisite degree of succulence
matter to form good wine. The fine aromatic odour and
flavour of its fruit also are not developed much beyond this
latitude. In the southern hemisphere, which is colder than
the northern, the vine flourishes somewhat nearer the
equator.

The vine grows in every foil, but that which is light and
gravelly is best adapted for its cultivation. It flourishes ex-
tremely well also in volcanic countries. Thus some of the
belt wines in Italy are made in the neighbourhood of Feru-
vius. The famous Tokay wine is also made in a volcanic
district, as are several of the belt French wines; many parts
of the south of France bearing evident marks of extinct
volcanoes. The vine also flourishes well in primitive
countries, and especially among the debris of granite rocks: thus
the celebrated Hermitage wine is made from a foil of this
description.

The same climate, soil, and mode of culture, however,
often produce wines of very different qualities. Position and
aspect alone, all other circumstances being the same, make
a prodigious difference. The same vineyard, for example,
according as its different parts have a northern or southern
aspect, will produce wines of opposite characters, as will
also the same hill, at its top, middle, and bottom. The
aspect most favourable for a vineyard is upon a rising
ground or hill facing the south-east, and the situation should
not be too confined:

"Bacchus amat colles." apertos

If the soil be not favourable for the vine no art can make
it fo. Manure of different forts will indeed render the fruit
more abundant, but the wine will suffer in quality. The
belt manure is flated to be the dung of pigeons or poultry.
Burnt sea-wrack also is a favourite manure with some. Fat
and putrid manures are absolutely to be rejected, as they
destroy the wine altogether, by vitiating its flavour.

The qualities of wines are very much affected by the sea-
sons. In cloudy and wet seasons the wine is always inferior.

Rain is most to be dreaded at the season of the vintage.
Moderate rains just after the season of bloom are of great
advantage, and cause the fruit to swell very rapidly. Rough
winds are very prejudicial to vineyards. Mills are still more
so, especially during the season of bloom, as they are apt to
deflower the flower, and consequently the fruit: the reason of
this is perhaps not very evident, but it seems to depend in
part upon the rapid evaporation of the moisture left by the
fogs, when the sun breaks through them, and the great and
sudden change of temperature which takes place in con-
fsequence. Too great a degree of heat is injurious to the
wine; the perfection of their fruit, as well observed by Chaptal,
depends upon a due equilibrium between the quantity of
water affording aliment to the plant, and the degree of heat
necessary to elaborate this water into its juices.

Towards the northern limits of the vine country, the
plants are always supported on poles, and in cold and wet
seasons they sometimes slip off the leaves, or twist the flanks
of the clusters, in order to suppress vegetation and facilitate
the ripening of the grapes. The latter practice was not
unknown to the ancients: "Ut dulcia praeterea ferent,
afervant ab usus dulius in vitæ, pediculo intorto." Pliny.

But in warmer climates, on the contrary, the earth requires to be
sheltered from the heat, and here the vine is generally left to
spread over the ground, and thus by its foliage to protect the
foil, as well as its fruit, from the direct rays of the
sun. With respect to the best methods of pruning and training
wines, see the articles VINE, and VITIS.

Of the Vintage.—It is of the utmost importance in the
manufacture of wines, to attend to the precise moment when
the grapes have arrived at their full maturity; and then, and
not before, ought the vintage in general to commence. This
may be known, according to Chaptal, by the following
signs:

1. The green end of the cluster becomes brown.
2. The cluster becomes pendant.
3. The seed loses its hardness, and the skin becomes thin
and transparent.
4. The cluster and seeds are easily detached.
5. The juice is sweet, bland, thick, and clammy.
6. The kernels of the seeds are free from glutinous
matter.

The fall of the leaves denotes rather the approach of win-
ter than the maturity of the fruit, especially in the more
northern climates. This therefore is a fallacious sign. Ne-
vertheless, when the frost has been so severe as to destroy
the leaves, it will seldom be proper to delay the vintage much
longer, as the fruit can hardly be expected after this to be-
come ripe; and by delay it may stand a chance of being
spoiled entirely.

On the contrary, in the manufacture of particular wines,
the grapes are permitted to remain till they wither, or they

are
WINE.

are gathered and dried in the sun. Thus the celebrated Tokay wine is made of dried fruit, as are also many of the luscious wines of Italy. Some of the French wines likewise are made with fruit that has been suffered to ripen and wither upon the vines.

It is desirable in general that the weather should be settled, and the soil and fruit dry during the vintage. It is therefore recommended to abstain from gathering till the sun has dispersed the dew. As a general rule, this is proper; but in Champagne they commence gathering the fruit before the sun is risen, and cease their labours about nine o'clock, unless there be a fog, when they continue to gather all day. In these means they improve the whiteness and briskness of their wine, which are the qualities that chiefly render them celebrated. They also increase their quantity. Thus it is found in Champagne, that they gain a ton in every twenty-four where they collect the fruit moist with dew, and a great deal more if there happens to be a fog.

When the fruit is ripe, a proper number of experienced hands should be procured, so as to be able, in a single day, to fill the fermenting tub or vat, in order to ensure an uniform degree of fermentation. Women are commonly employed for the purpose, but the presence of an intelligent male overseer is absolutely necessary. In some parts of France the fruit is separated with scissors; in others with the nail; and in Champagne they use a knife. The scissors are undoubtedly preferable, as it does not shake the flock. The ripe fruit only should be collected, if the object be to make good wine, and what is unripe or decayed should be carefully rejected; indeed they have always two or three separate vintages in those countries, where they are careful of the quality of their wines; and the wine made first is always considered the best. In those parts, on the contrary, where the wine is chiefly distilled, as in Languedoc and Provence, they usually collect all the fruit indiscriminately at one time. In some districts, where the finest wines are made, as in Bourdeaux, &c. the fruit is carefully picked, and only the prime of the clusters taken. On the contrary, they carefully avoid having the fruit too ripe in Champagne, and other districts where sparkling wines are chiefly manufactured, and prefer the presence of a certain proportion of unripe fruit. It need scarcely be remarked, that the greatest care should be taken to prevent the fruit from being bruised or otherwise damaged.

The next important step is the management of the fruit after it has been collected. In different countries different preliminary steps are purposed before the fruit is submitted tou pressure. Thus in Spain, especially in the neighbourhood of St. Lucar, they leave the fruit exposed for two days to the rays of the sun. In Lorraine, part of Italy, in Calabria, and the island of Cyprus, as before observed, they dry the fruit completely, and it is the case in the manufacture of all the rich white wines.

A question that has been much agitated is, whether it be advantageous to strip the grapes from the stalks and remove the latter, or suffer them to remain. Both these methods have their advocates; but Chaptal remarks very properly that neither ought to be followed exclusively. It is true, the same celebrated chemist observes, that the leaves have a rough and unpleasant taste; but this appears to be of advantage to some wines, especially those made in the more northern districts, where the flight of the birds is so habituated by the leaves corrects their indigestibility, and appears to have the property of making them keep better, perhaps by rendering the fermentation more complete. In the neighbourhood of Bourdeaux, indeed, they remove the stalks from the red grapes in the manufacturing of their best wines, but they modify that part of the process in some degree according to the ripeness of the fruit: when the fruit is unripe, or has been injured by the frost, they remove nearly the whole of the stalks, but if the fruit be over-ripe they leave a very large proportion of them. A certain portion, however, is always permitted to remain with the view of facilitating the fermentative process, and rendering it more perfect. From the white grapes, the stalks are never removed. In short, in the colder districts, where the wines are of an inferior quality, or where the object is to render the wines as strong as possible, with the view of distilling them, the items in general do not require to be removed; but in warmer countries, where the finer-flavoured and richer wines are manufactured, every thing liable to affect these desirable qualities is to be carefully removed, and the items among the lees. The items are separated in various ways: sometimes by agitating the grapes in the vessels in which they are deposited with three-pronged forks, sometimes by coarse sieves made of oziers, &c.

The next important step is bruising the fruit, which is generally performed by treading them with the feet in perforated tubs or vessels placed over the vat or tub defined to receive the must. This mode of bruising grapes, though as ancient perhaps as wine-making itself, is very imperfect, as a great deal of the fruit remains unbroken. In England we should adopt the use of machinery.

Of Fermentation, the Circumstances affecting it, Phenomena, Products, &c.—The juice, or must, as it is termed, is no sooner in the vat than it usually begins to ferment. The vat is a capacious vessel made of wood or sometimes of mahogany, and its size corresponds, or ought to correspond, with the quantity of wine to be made. Before it is used, it requires to be thoroughly washed, and its sides in France are usually covered with lime, which has the effect of saturating a portion of the malic and other acids which exist in abundance in the must.

The fermentative process has been already described (see Fermentation); we shall therefore be very brief upon the subject here, and confine our attention principally to a concise recapitulation of the particulars, in order to present our readers with a general and connected view of the art of wine-making.

The vinous fermentation is influenced by several circumstances, such as temperature, presence of the air, the volume of the must, &c. The must of the grape requires a temperature of at least 55°, to enable it to commence the fermentative process. Some have denied that the presence of the air is necessary to fermentation. The recent experiments of Gay Lussac, however, seem to prove the reverse. This celebrated chemist found that the must would not begin to ferment in cloche vessels, but that the introduction of a little oxygen instantly set it going; the oxygen being first rapidly absorbed. Perhaps we may explain the opposite conclusions of different experimentalists upon this subject, by supposing that the presence of oxygen, though necessary to enable the must to commence fermentation, is not necessary to support it afterwards. The fermentative process is much influenced by the bulk or quantity of the must. It is a well-established fact, that the greater the quantity the more violent is the fermentation. An experienced manufacturer of wine, therefore, will take care to proportion the quantity of must to the qualities of his fruit, or rather perhaps to those of the wine which it is his object to procure; the sweeter and more luscious the must, the greater the quantity in general, which it will be proper to submit to the fermentative process in one mas.

Other important circumstances which influence the fermentative processes are the requisite quantities and due relative proportions
proportions to one another of the necessary principles. The
faccharine and fermentative principles, tartar and water, are
the principles (as explained under the article Fermentation)
essential to the production of wine. The sweetest grapes do
not always make the best wine, nor actually contain the
greater proportion of sugar, at least of real sugar, such as
is proper for the formation of alcohol. An experienced
taste, it is said, can readily distinguish between a really fac-
charine grape and a sweet grape; and consequently pronounce
priori whether it is adapted for making good wine or not.
Pure faccharine matter, however, will not ferment alone,
but requires a certain proportion of other principles to put
it in motion. When the must contains too large a proportion
of water, the fermentative processes is feeble, and the wine is
consequently bad. The ancients obviated this, as we before
mentioned, by boiling the must; a practice still sometimes
followed in the northern districts, especially in wet seasons.
The same object is gained also by drying the fruit; and
sometimes by the introduction of lime into the vat. The
juice of the grape always contains a certain proportion
of tartar. This quantity is greater in general as the quantity
of sugar is less. If the juice contains too large a propor-
tion of sugar in relation to the tartar, it is customary to add
a portion of the latter principle. On the contrary, if the
faccharine principle be deficient and the tartar in excess,
sugar is to be added.

The fermentative process is accompanied by the produc-
tion of heat, by the disengagement of carbonic acid gas,
and the formation of alcohol. These phenomena have been
already discussed under the article above alluded to. An-
other important circumstance, however, which takes place
during this process, is the colouring of the must. The
juice of the black grape, as well as of the white, is nearly
colourless; and if the fermentation be not permitted to take
place in contact with the hulks or marc, a colourless wine
is obtained in all cases. The colour of red wines is derived
from the marc, by permitting the wine to ferment in contact
with it; the colouring principle of the marc or hulks being
soluble in alcohol. Hence, when alcohol begins to be de-
developed by the fermentative processes, it acts upon the colour-
ing principle and dissolves it, and the must becomes coloured.
The following are the principal facts connected with this part
of the subject. The wine is more coloured the longer the
fermentative process is continued, and vice versa. The wine
is more coloured in proportion as the fruit is more ripe and
leaves watery. Wine obtained by pressure is more coloured
than other wine, and lastly wines manufactured in the south
are in general deeper coloured than those produced in more
northern districts.

Great attention and practical knowledge are required in
managing the fermentation properly, as on this important
process depend entirely the future qualities of the wines.
The same fruit in different seasons, and from various causés,
requires to be managed differently; and almost every kind of
wine requires a different, and, in some cases, even an
opposite, mode of treatment. Thus the fine bouquet of Bur-
gundy is completely dissipated by a too violent or falting
fermentation; while, on the contrary, the fermentation of the
strong wines of Languedoc, celebrated chiefly for the quan-
tity of alcohol which they contain, ought to be long and
complete. In Champagne, as we formerly mentioned, they
collect the fruit defined to form their white wines while moist
with dew or mists: on the contrary, in the manufacture of their
red wines, they prefer fruit as dry as possible. In the
former case, the fermentative processes is fo languid, as often
to require a gentle heat; in the latter, fo violent, as to require
to be moderated. Weak wines ought in general to be fer-
mented in casks; strong wines in the vat. No general rules,
however, can be given that will apply in all instances; but
the processes must be varied according to circumstances, and
the judgment of the manufacturer.

The fermentative process, for obvious reasons, is most
difficult to manage in the northern districts, where the fruit
is more imperfect. To encourage the processes, they some-
times introduce a little warm mullet to the bottom of the vat
by means of a long funnel. They also agitate it frequently,
and to preserve a due degree of temperature, cover the vat
with blankets, or heat the room artificially.

The theory or rationale of the fermentative processes has
been explained, as far as it is known, under the article Fer-
mentation, before alluded to; we shall therefore pass it over
entirely here, and confine our attention to practical points
only.

A most material point in the manufacture of wines is to
know the precise moment when the fermentative processes
has been carried far enough, and the means necessary to prevent
its getting farther than this point. In the wine countries al-
mast every manufacturer boasls of his knowledge in these
particulars, and often adopts different methods. Chapter
lays down the following rules to be attended to:

1. The wine ought to ferment so much the less time as it
contains less faccharine matter. Thus the light wines of
Burgundy require to ferment no longer than from six to
twelve hours.

2. The must ought to ferment a less time in the vat when it
is intended to retain the carbonic acid gas, and make sparkling
wines. In this case, the must is seldom left longer in the vat
than twenty-four hours before it is put into casks; and fre-
cently it is introduced into the casks as soon as it is sepa-
rated from the fruit; by these means the fermentation is
checked, and the carbonic acid gas prevented from escaping.

3. The fermentation ought to be of shorter duration, in propor-
tion as it is the object to obtain wines more free from colour.
This should be, therefore, particularly attended to in the ma-
ufacture of those wines where the absence of colour is an
effential requisite.

4. The fermentative processes is more active in warm wea-
ter, and when the must is large, &c. than under the oppo-
ite circumstances; and therefore, ceteris paribus, is sooner
completed.

5. When the object is to preserve to the wine the original
perfumed flavour of the grape, the fermentation requires to
be checked sooner than under ordinary circumstances.

6. On the contrary, the fermentation requires to be con-
tinued longer in proportion as the must is more thick, and
the faccharine matter more abundant.

7. It will also require to be longer when the object is to
manufacture wines for distillation.

8. It will be longer in cold weather, and especially if the
fruit has been gathered on a very cold day.

9. Lastly, it will be longer in proportion as it is the ob-
ject to make a deeper coloured wine.

These principles readily kept in view will perhaps be suf-
cient, with a little practice, to enable any person of ordi-
nary knowledge and powers of observation to decide upon
the important points in question.

Great care is requisite in the preparation of the casks for
receiving the wine. When they are new, they will spoil its
flavour if not prevented. For this purpose, boiling-water,
holding salt in solution, is introduced into them, which is
frequently agitated, and permitted to remain in them a long
time. After this they are to be washed out with a portion
of boiling mullet in a state of fermentation, or sometimes with
a little wine, &c. If the casks are old but sweet, the top is
merely
merely taken out, and the tartar removed; they are then washed well with warm water. If the casks have acquired a bad odour, Chaptal recommends to commit them to the flames; for though it may be possible to cover in some degree their bad odours, yet they are very likely to re-appear and spoil the wine.

The vats being ready, the wine is introduced into them, for which purpose it is drawn off from the vat by a cock placed a few inches above the bottom into an open vat, from whence it is conveyed to the casks. That portion of the wine reticling immediately over the must is termed 

The head is then carefully removed, and the marc is subjected to repeated prefigure. The wine that thus far obtained is usually mixed with the rhi. That produced by the first prefigure is strongest; that obtained by the last is usually more harsh and coloured. Sometimes, however, when it is the object to make vinegar, the marc is pressed but once. At other times, they keep the wine obtained by all the different prefigures in separate casks. In Champagne they usually mix together the wines obtained by the different prefigures, though they are known by different names. The wines obtained without any prefigure, or a very light one, they call vin gris; those obtained by the first and second prefigure, ail de perdris; those by the third, win de taille, which are most coloured, though sufficiently agreeable.

The marc is employed in various ways in the different districts. Some submit it to distillation; others, especially in the vicinity of Montpellier, prepare verdigris from it; others vinegar. In some districts, they feed cattle with it; in others, they burn it for the sake of the potash it yields, &c.

Of the Management of the Wine in the Casks.—The wine receives its last degree of elaboration in the casks; this consists in a fort of fermentative processes, to which the name of insensible fermentation has been applied. Almost immediately after the wine is introduced into the casks, a scum begins to be formed upon its top, and escapes by the bung-hole, which at first requires to be covered lightly only with a leaf or tile. In proportion as the fermentation subdues, the mafs of wine diminishes in bulk; and they watch this cautiously, in order to supply its place from time to time with new wine, so as to keep the cask always full: this process is denominated in France ouiller, which may be rendered filling up. In some districts they fill up every day during the first month, every other day during the second, and every eight days afterwards, till the time of racking. This is the method they adopt with the wines of Hermitage. In Champagne they permit the vin gris to ferment in casks for ten or twelve days, and when the ebullition has ceased, they clofe the bung-hole, leaving, however, a smallfpigot-hole by its side, which is permitted to remain open for eight or ten days longer; after which they close this with a plug, in such a manner as to be able to open it at pleasure. When the bungs are introduced, they fill up every eighth day by the fpigot, for twenty-five days. After this every fiftenth day, for one or two months; and fmal1ly, every two months during the whole time the wine remains in the cellar. When the scum has been wet and unfavourable, and the wines want body, or when it has been dry and hot, and they are too rich, twenty-five days after they have been made, they roll the casks five or six times, in order to mix the grounds, and re-excite the fermentative processes, and this they repeat every eighth day for a month.

The fermentation of the Champagne wines, which are designed to be brisk and sparkling, is very long and tedious. It is generally understood that they will be sparkling, provided they are bottled any time between the vintage and the following May, and that the nearer the vintage the brisker they will be. It is, however, generally taken for granted, that they will be sufficiently sparkling if bottled about the middle of March. Wines begin to sparkle in about fix weeks after they have been bottled; tho' however, produced on mountains become sparkling sooner than others. Wines bottled in June and July will be very little sparkling, and quite full if bottled so late as October and November.

In Burgundy, after the fermentation has relaxed in the cask, they put in a bung pierced with a small hole, in which they introduce a plug that can be easily removed at pleasure, in order to suffer the gas that may be extricated to escape. In the district of Bourdeaux, they begin to fill up eight or ten days after the wine has been introduced into the cask. A month after this they introduce the bung, and fill up every eight days. At firfl they bung the casks loosely, and then fasten them down by degrees, without running any risk. The white wines are racked and sulphured in December, and these require much more care than the red wines, from their containing more sediment, and their being more liable to become ropy. The red wines are not racked till towards February or March, and as these are much more apt to become four than the white wines, they require to be kept in cooler cellars during the summer. There are some who, after the second racking, turn the casks fo as to place the bung on one side; and thus the caflcs being hermetically sealed from there being no loss, there is no need of filling up. They then rack off annually, at any time of the year they find it convenient.

Methods nearly similar are adopted in other wine countries; hence it will be needless to repeat them. We shall, however, give a short account of the methods followed in the manufacture of Port, Madeira, and Sherry, the most popular wines of this country.

In Oporto, the complete fermentation of the must takes place in the vat. The wine is then introduced into large tuns, capable of holding twenty-five pipes each; and at this stage the brandy is added according to the judgment of the manufacturer.

In Madeira, the second or insensible fermentation is carried on in casks, and the wine is racked from them at the end of three or four months, at which time a portion of the brandy is added. The remainder is referred to be mixed at the time of exportation.

In the manufacture of Sherry, the grapes are first lightly dried, and sprinkled with quick-line. They are then wetted with brandy on being introduced into the press, and a portion of brandy is added to the must before the fermentation commences. The subsequent processes consist in repeated rackings at intervals of a month or two, till March, brandy being added at each racking.

The object of racking the wines is to separate the dregs conflit of tartar, &c. deposited from the wine, and which, if left, are liable to render it four, by re-exciting from time to time the fermentation. The tendency to fermentation is counteracted by a process termed sulphuring, and the spontaneous separation of the dregs is rendered more complete by clarification, which see. See also fining and forfging.

The sulphuring of wines consists in impregnating them with the vapours of burning sulphur, or sulphurous acid, and is generally effected by burning sulphur-matches in the casks. (See matching.) These matches are made in different ways, aromatics being sometimes mixed with the sulphur; but the sulphur is the only useful and necessary ingredient.
Sometimes a wine highly impregnated with sulphurous acid is prepared, a little of which mixed with the rest anwers the purpose of burning matches in the cask. Other substanoes, according to Dr. Macculloch, answer the same purpose as sulphuring: namely, the black oxide of manganese, and particularly the sulphate of potash. A draught of which salt is sufficient for a pipe of wine, and is very effectual in counteracting the fermentative process. The theory of these processes is very obscure.

We have before observed that the mere racking of wines is not sufficient to render them pure, and various methods are adopted at the racking periods to render this operation more effectual, and these altogether constitute the process termed clarification.

Lord Bacon mentions a practice among the ancients of putting wine into vessels well flapped, and letting it down into the sea. That this practice is very ancient is manifest from the discourse of Plutarch (Quell. Nat. 27.) about the efficacy of cold upon must.

Different periods, as before-mentioned, are chosen in different districts for racking wines. Thus the wines of Hermitage are raked in March and September, those of Champagne about the middle of October, the middle of February, and the latter end of March. If possible, a serene and settled state of the atmosphere, and a dry and cold day, should be chosen for the purpose, as the wine is always turbid in damp close weather, and during the prevalence of foothery winds.

In racking wines, it is in general desirable to expose them as little as possible to the atmospheric air. In some districts, a syphon is employed for the purpose. In Champagne they use a fort of pump. Dr. Macculloch recommends that the wine should be transferred from one cask to another by means of a leather hose, and this method is undoubtedly preferable. For clarifying wines, a great variety of substances are employed. Finials and albumen either from eggs or blood are the most common; but gum, sallow, rice, milk, the shavings of beech-wood, gyppum, and, &c. are used in different wine countries. An ounce of finials, or about eighteen or twenty whites of egg, are sufficient for one hundred gallons of wine.

Two very important circumstances in the practice of winemaking require yet to be mentioned; these are the medication of wines, and the means of remedying those defects to which they are liable.

The medication of wines consists in altering the colour, the flavour, or the strength of any given wine, or in mixing two or more together, as to produce a compound differing from, or superior to, either. It is difficult to give any general rules for this purpose, and the proper management of the processes depends chiefly upon the experience and taste of the maker.

It generally happens that when two wines are mixed, the fermentative proc is partially renewed, or the mixture is technically said to fret, whence the practice itself has derived the name of fretting in. Mixed wines appear to unite into one durable and homogeneous liquor, only in conformity of this fermentation. It is therefore desirable, if possible, to mix wines only at those periods when they both show a tendency to fretting, which, according to Chaptal, in the wine countries, appears to be at three principal feasons of the year, viz. when the wines begin to shoot, when they are in flower, and when the fruit begins to acquire colour. The wines being then proportioned according to the fancy or experience of the maker, a strong fermentation is excited, which is still farther assisted by agitation. The wine thus becomes homogeneous, and shews no more tendency to far-
WINE.

Strong wines, for obvious reasons, seldom become pure. When acidity is present only in a very slight degree, it may be palliated considerably by sugar, or by the addition of must concentrated by boiling. It is obvious, however, that the acid can only be got rid of by neutralizing or destroying it. For this purpose, the alkalis and alkaline earths have been employed, but they impart a disagreeable flavour to the wine. Of these substances, lime is the safest and best. It was formerly the practice to employ lead, in some form or other, for counteracting acidity in wines; but we know that this murderous practice has been long since laid aside. Rapiness is another diffece to which wines are liable. This occurs more particularly in those which contain a good deal of extractive matter. It may be much relieved, and sometimes cured, by exposing the bottles to the sun and air, by agitating and subsequently uncorking them, by adding a small quantity of vegetable acid, and by finning. The last diseace we shall notice is perhaps the most formidable of all, namely, a muffiness, or other ill-flavour communicated by the cask or cork. This appears to be, in general, absolutely incurable, though it may be sometimes diminished by agitating the wine in contact with the air, or by the introduction of common air or carbonic acid by pumping; Such is a summary account of wine-making from grapes, as practiced in the countries where that delicious fruit comes to perfection, and more especially in France. (See Birch's Hift. of the Royal Society, vol. i. p. 156.) We come now to consider,

2. The Manufacturing of Wines from other Fruits, or artificial Wines.—In the above sketch we have endeavored to present our readers with a general view of the principles of wine-making, at the same time that we described the practice. These principles are equally applicable to the manufacture of wine from all sorts of fruit; we shall therefore take the present opportunity of briefly recapitulating them here, as they cannot be too strongly impressed upon the memory, and as they at the same time constitute the most appropriate introduction to the present section that occurs to us.

The juice of the grape consists of a large proportion of water, holding in solution certain proportions of saccharine matter, of the juice or fermenting principle, which appears to be a modification of the saccharine principle, of various acids, especially the tartaric and malic, and of various ill-defined extractive matters. These principles, left to themselves for a short time in a medium temperature, soon begin to act upon one another, and some of them at length undergo remarkable changes. This process is termed fermentation, and constitutes the grand principle of wine-making. When this process has begun to subside, it will be found that the greater portion of the saccharine principle has disappeared, and that its place is supplied by a corresponding portion of ardent spirit or alcohol. This is the most striking feature of the change that has taken place, but all the other principles of the juice or must appear to have undergone like-wise some change either in quality or quantity. In short, the sweet and crude juice of the grape is found to be converted into wine.

In this state, the wine is introduced into casks, where it undergoes further changes, and is matured by a modification of the fermentative processes, which has been called the infusible fermentation. This is a most important step in the processes of wine-making, as by different modes of management in this stage almost the whole of that infinite variety which exists among wines is produced. Here also it is that all foreign substances designed to impart flavour, &c. to wines are in general introduced with the greatest propriety. When the infusible fermentation has been carried to the point desired, it is checked by the processes of racking, sulphuring, clarification, &c.; and thus the wine is rendered capable of being preferred at any point or state we choose.

Let us now apply these principles to the manufacture of wines from other fruits.

We start upon the grounds that artificial wines are intended to be imitations of wines prepared from grapes. In the first place, therefore, we have to prepare a juice or must similar to the juice or must of the grape in its general composition. Now, no fruit whatever yields a juice sufficiently similar to that of the grape. In our northern climate more especially, the saccharine principle, which is the fundamental principle in wine-making, exists in very minute proportion in most fruits. It must be, therefore, supplied artificially. The tartaric acid, or rather tartar, which appears to be another essential principle in wine-making, is likewise wanting in most of our fruits. This, therefore, must be supplied. On the contrary, other principles, and particularly the malic acid, appear to exist in too large a proportion in most of our fruits, which, in their natural state, are better adapted for making cyders than wines. To get rid of the malic acid, and to prevent its deteriorating effects, as well as the deteriorating effects of other foreign principles, is difficult, or perhaps impossible; and this will doubtless always render artificial wines in general inferior to those of the grape, though very near approaches may be made by judicious management.

The practical mode of obviating these difficulties is to dilute the juice of the fruit to such a degree, that a given quantity of it when diluted shall contain no more of the malic acid, for example, than a given quantity of the juice of the grape; and, as before observed, to supply artificially the two grand principles, sugar and tartar, which are wanting. Having thus prepared an artificial must, as nearly resembling in its composition that of the grape as possible, the application of the other principles will be obvious, as we have nothing to do but to manage, in general, all the subsequent processes precisely as if we were operating upon the must of the grape. We shall now, therefore, descend from generals to particulars, and, after having made a few remarks upon our native fruits, endeavour to point out the modes in which the more important foreign wines may be best imitated by them.

Fancy or caprice has led to the formation of wine from an infinite variety of substances, and almost every good housewife has some favourite receipt for making wines from what nature never intended for the purpose. Such compounds hardly deserve the name of wine; we shall, therefore, principally confine our attention to fruits. The following are the domestic fruits most usually employed for the purpose:

- Gooseberry, and three varieties of currant.
- Strawberry, raspberry, blackberry, mulberry.
- Sloe, damson, elderberry.
- Quince, cherry.
- British grapes.

To them may be added the foreign fruits

- Raisins.
- Orange, lemon.

The gooseberry and currant are of all others the fruits most commonly employed for the fabrication of artificial wines; and, perhaps, upon the whole, they are best adapted for the purpose. When used in their green state, both gooseberry and currant may be made to form light bril
WINE.

Brisk wines, falling little short of Champagne. Ripe gooseberries are capable of making sweet or dry wines; but these are commonly ill-flavoured, particularly if the hulk has not been carefully excluded. Ripe currants, if properly managed, make much better wines than gooseberries. Thee fruits are much improved, according to Dr. Macculloch, by boiling previously to fermentation. This, he states, is particularly the case with the black currant, which, when thus managed, is capable of making a wine closely resembling some of the best of the sweet Cape wines.

The strawberry and raspberry are capable of making both dry and sweet wines of agreeable quality. As commonly managed, however, their peculiar flavour is dilipated in the process; hence, as Dr. Macculloch observes, little is gained by their use to compensate for their comparatively high price. A simple infusion of these fruits, in any flavourles currant wine during the period of insensible fermentation, will, with greater cheapness and certainty, ensure the production of their peculiar flavour. The blackberry and mulberry are capable of making coloured wines, if managed with that view: they are deficient, however, in the astringent principle; nevertheless, they may be occasionally employed with advantage when a particular object is to be gained.

The sloe and damson are so associated in qualities, that nearly the same results are obtained from both. Their juice is acid and astringent; and hence they are qualified only for making dry wines. By a due admixture of currants or elderberries with sloes or damsons, wines not much unlike the inferior kinds of port are often produced. The elderberry is capable of making an excellent red wine. Its cheapness also recommends it. It does not, indeed, possess any great degree of flavour, but it polishes no bad one, which is a negative property often of great importance in artificial wine-making.

The quince, from its analogy to the apple and pear, is better qualified for making a species of cyder than wine. The cherry produces a wine of no very peculiar character. If used, care should be taken not to bruise too many of the stones, otherwise a disagreeable bitter taste will be imparted to the wine.

Grapes of British growth are capable of making excellent sparkling and other wines, by the addition of sugar. Dr. Macculloch informs us, that he has succeeded in making wines from immature grapes and sugar so closely resembling Champagne, Grave, Rhenish, and Mofelle, that the best judges could not distinguish them from foreign wines. The grapes may be used in any state, however immature; when even but half grown and perfectly hard they succeed completely.

The cottagers in Sussex, says Dr. Macculloch, are in the habit of making wine, almost annually, from the produce of vines trained on the walls of their houses. Many individuals through various parts of the southern counties, and even as far north as Derbyshire, practice the same with success. But the experiment is well known to have been made or many years on a large scale, and with complete results, at Pain's-hill, by the Hon. Charles Hamilton, in a situation with respect to soil and exposure of which parallel instances are to be found throughout the country, and produced from land of no value whatever for the ordinary purposes of agriculture. That our ancestors made wine from the produce of their vineyards there can be no doubt, and Dr. M. justly remarks, that we can still make by far better wine from our grapes, even as produced at present, than om any other fruit whatever. Thence, therefore, are cordon seras for the cultivation of the vine, especially as, the fame gentleman observes, we might, with care, inure and domesticate to our climate many of the richer and more delicate varieties of southern latitudes. See VINE, and VARIETIES; under the list of which articles some interesting experiments on this subject are related.

Damsons are extensively used in this country for making domestic wines, and also for the fraudulent imitation and adulteration of foreign wines, although not a native fruit; therefore they deserve to be mentioned here. When properly managed, they are capable of making a pure and flavourles vinous fluid, well adapted for receiving any flavour which may be required, and thus of imitating many wines of foreign growth. See the close of this article.

The orange and lemon are likewise used for making domestic wines. Upon the whole, however, they are not very well adapted for the purpose, as they contain too much acid, and too little of the extractive and of the sweet or fermentative principle.

From what has been said of the manufacture of wine from grapes, our readers will observe, that different methods are pursued, according to the kind of wine which it is intended to make. Now these remarks are equally applicable to artificial wines, in the manufacture of which it is absolutely necessary that the maker should determine beforehand upon the kind of wine which it is his object to produce, and to modify his processes accordingly. We may, with Dr. Macculloch, consider wines as of four general descriptions: sweet wines; sparkling or effervescing wines; dry and light wines, analogous to hock, grave, and Rhenish, in which the saccharine principle is entirely decomposed during fermentation; and finally, dry and strong wines, as Madeira and sherry.

Those of the first and most simple class are the sweet wines, or those in which the fermentative process has been incomplete. It is to this class that by far the greater number of our artificial wines bear the greatest resemblance; a resemblance, says Dr. M., so general as to shew that few makers of this article possess sufficient knowledge of the art to enable themselves to steer clear of what may be firmly called the radical defect of domestic wines. Sweet wines may be made from almost any ripe fruits. Those most generally employed, however, are the gooseberry and currant. We shall suppose that we wish to make the quantity of ten gallons of sweet wine from one or other of these fruits. For this purpose, the following are the proportions and other circumstances to be attended to. Forty pounds of fruit are to be introduced in a clean and sufficiently capacious tub, in which it is to be bruised in successive portions, by a pressure sufficient to crush the berries without breaking the seeds, or if gooseberries be employed, without materially compremling the skins. Four gallons of water are then to be poured into the vessel, and the contents are to be carefully stirred and squeezed in the hand until the whole of the juice and pulp are separated from the solid matters. The materials are then to be permitted to remain at ref for a period of from fix to twenty-four hours, when they are to be strained through a coarse bag by as much force as can be conveniently applied to them. One gallon of fresh water may afterwards be passed through the marc, for the purpose of removing any soluble matter which may have remained confinmed. From thirty to forty pounds of sugar, according to the desired strength and sweetnefs of the wine, and about fix ounces of cream of tartar, or, what is better, crude tartar, are now to be dissolved in the juice thus procured, and the total bulk of the fluid made up with water, to the amount of ten gallons and a half.

The liquor thus obtained is the artificial must, which is equivalent
equivalent to the juice of the grape. It is now to be introduced into a tub of sufficient capacity, which is to be well covered, and placed in a temperature varying from 55° to 60°. Here it is to remain two or three days, more or less, according to the symptoms of fermentation which it may shew, and from this tub it is to be drawn off into the cellar, where the fermentative process is intended to be brought to the point desired. As the fermentative process proceeds the bulk of the liquor diminishes, and its place must be supplied from time to time by the superfluous portion of must made for the purpose, so as to keep the liquor always near the bung-hole. When the fermentation has subsided a little, the bung may be driven in, taking care, however, to leave a small hole open by its side, which may be stopped with a peg, and opened occasionally to give vent to any air that may be generated.

When the wine has arrived at the desired point of sweetness, &c. it must be racked and clarified in the manner described in the former part of this article; and these processes must be repeated, and the casks sulphured, if necessary, in order to prevent the fermentative process from proceeding farther. In general, however, one racking in the following December or January will be sufficient, after which it may be kept in the casks for any length of time, or it may be bottled without the usual precautions. A fine serene and cold day should be chosen for these operations. Sometimes the fermentative processes will stop before the wine has arrived at the desired point, in which case it may be commonly easily re-excited by raising the temperature, and shaking the casks; or, if these fail, by having recourse to the means formerly described for that purpose.

By attending to these general directions, sweet wines may be made from other fruits, care being taken to increase or diminish the quantity of sugar according to the natural sweetness of the fruit employed.

The second general description of wines comprehends the brisk or sparkling wines; which may be, at the same time, either sweet or comparatively dry. Our readers will recollect the methods adopted in Champagne, and other countries where they manufacture sparkling wines from the grape, and which are described in the former part of this article. Now these principles are to be held in view in the manufacture of artificial wines intended to possess similar properties. The fruits most generally employed for forming wines of this description, are the immature gooseberry and currant; sometimes also immature grapes, and even vine leaves are made use of for a similar purpose, but grapes are doubtless preferable when they can be procured. Wines of this description are more difficult to be made than the last, at least they require much more care. If gooseberries are employed, they must be gathered when they have nearly attained their full growth, but before they have shewn the least tendency to ripen. The variety of gooseberry is perhaps indifferent, but it will be advisable to avoid the use of those, which in their ripe state have the highest flavour. Dr. Macculloch recommends the green balsam among the best. Tho' which are unsound, as well as the remains of the blossom and footstalk, should be carefully removed. Forty pounds of this fruit, thirty pounds of fine white sugar, and about six ounces of tartar, are sufficient for making ten gallons of wine. All the preliminary processes are to be conducted precisely in the same manner as those above described for making sweet wines. The must, however, ought to remain in the fermenting tub for about twenty-four hours, or two days only, when it is to be transferred to the casks, and the processes of racking, &c. managed as before, except that the wooden peg or spike must be permanently tightened as soon as the danger of bursting the cask has subsided. The wine thus made may commonly remain during the winter in a cool cellar, as it is no longer necessary to excite the fermenting process. To ensure its fineness, however, it is a good practice to draw it towards the end of December into a fresh cask, so as to separate the lees; and if at this time it should prove too sweet, instead of decanting, it will be better to fill up the lees so as to renew the fermenting process, taking care also to increase the temperature at the same time. At whatever time the wine has been decanted, it is to be fined with finginglas in the usual manner. Sometimes it will be necessary to decant it a second and even a third time into a fresh cask. All these operations should take place, as formerly mentioned, in dry cool weather, and the wine must, at any rate, be finally bottled in March. If immature curants are employed, which are perhaps upon the whole preferable to gooseberries, the same proportion of fruit, sugar, and tartar, and the same modes of management, may be had recourse to; care being taken to separate carefully the stalks of the currants. If grapes be used for the purpose, they may be safely taken of different degrees of ripeness, it is necessary to attend to the selection of any particular variety. The same proportions of fruit and sugar will be proper as when gooseberries and currants are employed, but the tartar must be omitted. The hulks also may be permitted to ferment with the liquor in the vat. The subseque process is to precisely the same as that described above. An excellent wine of the present description may be made from the leaves and tendrils of the vine. About forty pounds of these, and twenty-five or thirty pounds of sugar, will be sufficient for ten gallons of wine. To prepare it, seven or eight gallons of boiling water are to be poured upon the leaves in a tub, and permitted to remain for twenty-four hours. The liquor being poured off, the leaves must be strongly pressed, and subseque washed with another gallon of water. The sugar and the remainder of the water are then to be added, and the fermentative process conducted precisely as before. The present class of wines, if the process has been successful, (which is not always the case,) is brisk, and precisely similar in their qualities (flavour excepted) to the wines of Champagne, with the strength of the best Sicily.

The third variety of wines is that of which hock, grave, and Rhenish may be taken as examples. In these the faccharine principle is entirely overcome by a complete fermentation, while their future change is prevented by a careful application of the processes laid down for the preservation of wines of this class. Makers of domestic wines have rarely, says Dr. Macculloch, succeeded in imitating these wines. The reasons obviously are, the great disproportion of the sugar to the subseque fermentation in the first instance; and that want of the after-management, the neglect of which soon configns these wines to the vinegar rank, if chance should even at a first have produced successes. In making these wines, the relative proportion of fruit and sugar in common use must be materially altered, and the fermentative processes be conducted in a very careful manner. The subseque processes also of racking, sulphuring, and fining, must be practiced with great avidity, in order to preserve these wines after we have succeeded in making them. Dr. Macculloch states, from his experience, that these wines may be successfully imitated, and that they constitute some of the very best of those which can be made from domestic fruit. The proportion of fruit (generally of immature fruit) to the sugar, in the manufacturing of sweet wines, must be the great. The bung must remain open, but the fluid within must not be allowed to escape, while, if the fermentation proceed
ceeds languidly, it must be accelerated by heat and agitation. If, when it is finished, the wine continues too sweet, it may be bunged down till the spring without racking or fining, when the fermentation must again be renewed. The renewal of the fermentation may also be effected by adding some fresh juice of the same fruit. At whatever time, and under whatever of these processes, it has become dry, it is to be carefully fined and racked into a pulped or calf, and bottled, after being once more carefully fined.

The fourth and last class of wines consists of those which are both dry in their quality, and strong in their nature; such are, Madeira, sherry, &c.; the theory of these, from what has been said, will be sufficiently apparent. With due attention to the fermentative processes, such wines may be made of the requisite degree of strength without brandy. By means of this, however, if managed as formerly directed, the operator has it always in his power to produce wines of any required degree of strength.

We need not here repeat the methods of imparting different flavours to domestic wines, or of correcting their faults, since they differ in no respect from those recommended to be adopted in the manufacture of wines from grapes, to which therefore we refer.

The following general remarks upon the fabrication of domestic wines, will not perhaps prove uninteresting to our readers.

The great radical defect in the manufacture of domestic wines, is using too small a proportion of fruit compared with the sugar employed. It is this circumstance chiefly which renders the fermentative processes incomplete, and thus imparts that sweet and mawkish taste to our domestic wines, which renders them intolerable to many people, and even to all, perhaps, without the addition of brandy. The proportions of fruit and sugar given above may be considered as mean standards, which may be varied either way, according to circumstances and the nature of the wine intended to be produced. A very superior class of fruit wines may be manufactured by using the juices of our different fruits, either alone or very slightly diluted with water.

We mentioned that some fruits, and especially the black currant, were much improved by boiling. For this purpose, it will be sufficient that the fruit be finely boiled into the boiling point, before using it, the water in the vessel being so managed as to avoid any risk in burning. The black currant thus treated, and subsequently managed upon the principles which we have endeavoured to lay down, is capable of making a wine very nearly resembling some of the best sweet Cape wines.

The fermentative processes being rendered tardy and incomplete, by the improper adjustment of the sugar to the fruit, is frequently endeavoured to be excited by yeast; nothing can be more injurious than this. Yeast invariably spoils wines, by imparting to them a flavour that nothing will ever overcome. The only ferment to be employed in wine-making, is that furnished by nature; and when this is defective, as is sometimes the case in our domestic fruits, the ferment of the grape must be supplied artificially. This may be done by introducing a certain proportion of crude tartar, the dose of which may vary from one to five per cent. without materially affecting the wine, as a great proportion of what escapes decomposition will be subsequently depoited. All fruits, except the grape, will require more or less of tartar.

The last circumstance we shall notice is the introduction of brandy, or other spirit, into domestic wines. As commonly manufactured, they often require, as we have just stated, this addition to render them tolerable. We truly, however, that from the attention that has been lately paid to the subject of artificial wines, the modes of manufacturing them will be better understood, and that this will no longer be the case. Fine wines are invariably spoiled by the addition of ardent spirit, which seems to have the effect of slowly decomposing them, and thus of destroying that delicate, lively, and brisk flavour, so eminently possessed by all natural wines. Hence it is seldom or never used in wine countries; or rather it is confined to the manufacture of those wines defined for this country, where only this barbarous practice is tolerated. We again repeat, that if the fruit and sugar be duly adjusted to one another, and the fermentative processes be properly managed, an infinitely better wine will be produced without the use of brandy, than can ever be produced with it.

General Chemical Properties and Composition of Wines.—

The juice of the grape, as we formerly mentioned, consists of a large proportion of water, of certain proportions of the saccharine and fermentative principles, of various acids, especially the tartaric, and some ill-defined extractive principles. These were at first during the fermentative processes to undergo different remarkable changes, one of the most important of which is the conversion of the saccharine principle into alcohol. The nature of the other changes are not so well understood, nor does the little we know at present of the composition of wines throw any very satisfactory light upon the subject. One principle indeed, viz. the fermentative principle, does not exist in perfect wines, and therefore must be decomposed or separated during the process of fermentation. The principles formed in wines may perhaps be arranged under the four following heads: 1. Acids; 2. Extractive and colouring matters; 3. Essential oils; and 4. Alcohol. Water is not mentioned, because it forms the basis of all potable fluids, and consequently of wines.

1. Acids.—All acids have the property of reddening turnfole or litmus papers, and therefore contain more or less of a free acid. The acids found in wines are, the tartaric, the malic, the citric, the carbonic, and occasionally the acetic.

The tartaric acid, in combination with potash, or tartar, as it is usually termed, exists in great abundance in the juice of grapes, as formerly stated, and appears to be one of its most important ingredients. A large proportion of this tartar is double; is decomposed during the fermentative processes, and a considerable quantity of what remains is subsequently deposited in the casks or vessels in which the wine is kept, confinituting what is termed the craf. It appears probable, however, that the whole is not separated, and consequently, as Dr. Thomson judiciously remarks, that wines are never entirely deftitute of tartar. Satisfactory experiments, however, upon an extensive scale, are at present wanting upon this part of the subject. The malic acid, according to the experiments of Chaptal, exists in the greatest number of wines, if not in all, and that in much greater proportion than any other acid. If this be really the case, it is probably, in part at least, a product of fermentation, for the juice of grapes appears to contain very little of this acid. Traces of the citric acid were found by Chaptal to exist in some wines. This acid also exists in the juice of the grape, but in small quantity. All wines that have the property of effervescing, or sparkling, when poured from the bottle into a glass, contain carbonic acid. Champagne, for example, owes its characteristic properties to this acid. Sparkling wines are usually weak, and contain less alcohol than usual, for reasons that have been already explained. The acetic acid is not an essential ingredient of wine, nor in fact ought it ever to exist in it.
WINE.

the fermentation, however, be permitted to go too far, this acid will be formed, and hence it occasionally occurs in inferior wines.

2. Extractive and colouring Matters.—These ill-defined substances exist more or less in all wines. Their properties, however, are not well ascertained, nor are they probably uniformly the same in every instance. They have a tendency to separate spontaneously, and along with the tartar form what is termed the crust; hence, as wines become older, from their containing less of these matters, they usually become paler. These extractive matters may be also separated artificially by means of animal charcoal, the subacetate of lead, and even partially in some instances by lime-water, or the heat of the sun. The colouring matter, as we formerly noticed, is not derived from the juice of the grape, but from its husk.

3. Essential Oils.—Wines, though essentially the same in their general composition, are distinguished from one another principally by their flavour and odour, no less than by the proportion of alcohol they may contain. Now their sensible properties evidently depend upon some volatile and fugacious principle, which has been considered to be analogous to an essential oil. This principle is sometimes derived immediately from the fruit, as, for example, in the wines made from the Frontignac and Mufcat grape. At other times, it is the product of fermentation. Thus the finer flavours of claret, hermitage, and Burgundy, bear no resemblance to those of the grapes, from whence they are formed. Very often, as before stated, the principles of odour and flavour are communicated to wines artificially, by the introduction of foreign ingredients, as orris-root, grape, and elder-flowers, mignonette, &c. The menilium of this volatile principle is doubtless, in most instances, the alcohol contained in wines; but its quantity is so minute as to be incapable of separation.

4. Alcohol.—The characteristic ingredient of wines is alcohol. Indeed, wines may be considered as more or less dilute solutions of alcohol, impregnated with different flavouring substances, and a little acid. There have been great differences of opinion in what state alcohol exists in wines. Some chemists maintain, that alcohol does not exist ready formed in wines, but that its elements only exist in a peculiar state, and that their union is determined, and consequently alcohol formed, by the act of distillation. This opinion was advanced by Fabroni, and seems to have been adopted by some subsequent writers. Mr. Brande, however, has shewn by very decisive experiments, that all wines contain alcohol ready formed, and that this fluid is merely separated during the distillation of these liquors; and his experiments have been since fully confirmed by Gay Lussac.

The following Table, representing the Quantity of Alcohol and other Principles in different Wines, is taken from Dr. Thomson's Chemistry, though it was compiled originally by Neumann. The results are not absolutely to be relied upon, as the state of chemical Knowledge, at the time Neumann wrote, was very imperfect.

On the Uses of Wine in a Dietetic and Medicinal Point of View.—Mankind in every stage of civilization and society betray a propensity for fermented liquors. This indeed is so strongly marked, that some have been induced to consider it as the result of an instinctive faculty, and consequently have been led to suppose that fermented liquors are the proper and natural drink of the human race. Others, on the contrary, have contended that fermented liquors are of no real use to mankind, and are often even productive of much positive
positive evil, and hence have arrived at a conclusion diametrically opposite to the former. It is difficult to decide between these opinions. We confess, however, that we do not think it necessary, on the one hand, to have recourse to the supposition of an instinctive faculty to account for wine-drinking; nor, on the other, do we believe that the moderate use of natural wines is productive of any bad effects. The propensity for strong drinks seems explicable upon the general principle that all animals feel a pleasure in being satiety, or, as it were, crowding a greater portion of existence into a shorter space than natural; an effect in some degree produced by the exciting effects of such liquors.

As to the bad effects too frequently produced by fermented liquors, they may, in almost every instance, be fairly traced to the badness of their quality, or to an excess in quantity.

While, however, we do not object to the moderate use of what providence has so liberally bestowed upon us, no one can object more strongly than ourselves to its abuse. The melancholy effects of habitual intoxication are too well known to require particular description here. Severely does the victims of this degrading propensity suffer in mind, body, and fortune; nor are their sufferings confined to themselves, but entailed upon their ill-fated posterity. For proofs of these positions, we refer our readers to the articles Gout, Calculus, Apoplexy, Epilepsy, Insanity, &c. &c. in this work, where they will find these and other diseases justly ranked among the most painful and distressing to which humanity is liable, frequently ascribed to habitual intemperance as their cause.

But putting out of the question these effects of drunkenness, what a horrible picture of moral depravity does it present for a man to fit down deliberately, day after day, with the professed object of annihilating his intellectual faculties, and thus degrading himself below the level of the brute creation! And even supposing he has arrived at the enviable point of being able to swallow two or three bottles without losing his senses, and that this quantity has become necessary to his comfort, may even perhaps to his very existence, to what a wretched state of dependence has he reduced his bloated carcass! what a tax is such a being upon society, who, to prolong a loathsome existence, is obliged to consume daily in an unnecessary superfluity more than is sufficient to support a whole family for a week! See Drunkenness.

With respect to the operation of different wines upon the animal economy, they vary exceedingly according to their properties. New wines in general are unwholesome, and often prove purgative. Sweet wines are upon the whole perhaps the most wholesome, and, where the taste has not been previously vitiated, doubtless the most agreeable. Weak and acid wines are very apt to disagree with the stomach, especially when that organ has been accustomed to stronger wines. Hence an occasional debauch with such wines is notorious for inducing a fit of the gout, especially in this country, where the usual wines are immediately strong. The fame is true also, though perhaps in a somewhat less degree, with the effervescing wines. Red wines, in general, are of a more astringent and tonic nature than white wines, and commonly contain more spirit. There are, however, many exceptions to this rule.

It will be seen by consulting the above table, that port, Madeira, and sherry, the three wines in most common use in this country, contain from one-fourth to one-fifth of their bulk of alcohol. A person, therefore, who takes his bottle of wine every day, will thus take nearly half a pint of alcohol, or almost a pint of pure brandy! This at first sight will appear almost incredible, especially as the fame person would not perhaps be able to take a similar quantity of ardent spirit, either diluted with water, or in any other way. Some have concluded from this circumstance that the above experiments are not to be relied upon; but from the manner in which they were conducted there is no reason to doubt their general accuracy; the fact therefore remains to be explained. The most probable explanation is, that the alcohol in the wine is in some state of combination, which prevents its immediate action upon the stomach, and thus renders it liable to be digested or altered in its properties before it can exert its specific effects. The peculiar nature, however, of this state of combination is at present unknown. What renders this opinion the more probable is, that some bad wines, and especially domestic wines, which are often little better than mere mixtures of brandy and water, exert much more effect upon the animal economy than fine old wines, though they may not contain nearly so much spirit.

With respect to the medicinal uses of fermented liquors, when cordials are required, wines are by far the most efficient of the whole tribe, and of these port wine is perhaps the best. For full information on this subject, we refer our readers to the articles Fever, Gangrene, and Analogous Diseased of Deblity. See Chapal's excellent Essay on the Manufacture of Wines, Annales de Chimie, vol. xxxvi. and xxxviii. Dr. Macculloch's Essay on Wine-making. Mr. Brande's Essays in Phil. Trans. for 1811 and 1813, &c.

For the distillation of wines, see Distillation.

Wine, in France, is distinguishe'd from the several degrees and tinctures of its preparation, into

Merry-goutte, mother-drop; which is the virgin wine, or that which runs of itself out of a tap of the vat, in which the grapes are laid, before the vintage enters to tread, or stamp, the grapes.

Must, furmufl, or sum, is the wine, or liquor, in the vat, after the grapes have been trodden, or stamped.

Preefed Wine, Vin de Pressurage, is that squeezed with a press out of the grapes, when half-boiled by the treading. The husks left of the grapes are called corpo, mark, or more; by throwing water upon which, and preling them off, they make a liquor for servants' use, answerable to our eyker-gun, and called bofllan; which is also of some use in medicine, for the cure of disorders occasioned by vitiated humours.

Sweet Wine, Vin doux, is that which has not yet worked, or fermented. This is turbid, and has an agreeable and very saccharine taste. It is very laxative, when drunk too freely, or by persons disposed to diarrheas, it is apt to occasion these disorders. Its constipating is somewhat less fluid than that of water, and it becomes almost of a pitchy thickness when dried.

Boura, that which has been prevented working, by calling in cold water.

Cure, or worked wine, that which has been let work in the vat, to give it a colour.

Cuit, or boiled wine, that which has had a boiling before it worked; and which, by these means, still retains its native sweetness.

Paffe, or strained wine, a sort of raisin-wine, made by steeping dry grapes in water, and letting it ferment of itself.

Wines are also distinguished with regard to their colour, into white wine, red wine, claret wine, pale wine, rose or black.
black wine. And, with regard to their country, or the soil which produces them, into French wines, Spanish wines, Rhine wines, Hungarian wines, Greek wines, Canary wines, &c. And, more particularly, into Port wine, Madeira wine, Burgundy wine, Champagne wine, Falernian wine, Tokay wine, Schiraz or Sherry wine, &c.

Wines, again, are distinguished, with regard to their quality, into sweet wines, rough or dry wines, and rich or luscious wines, wines de liqueur; of which last some are exceedingly sweet, others sweet and poignant; and all chiefly used by way of a dram after meals, &c.

Such are French, Frontignac, Madeira, the Canary, the Hungary, Tokay, the Italian Montefalco, the Italian Schiraz, the Malvasy wines of Candia, Chio, Lefbos, Tenedos, and other islands of the Archipelago, which anciently belonged to the Greeks, but now to the Turks. These are sometimes called Greek wines, and sometimes Turkey wines.

The chief wines drank in Europe are as follow. 1. The Madeira island, and Palma, one of the Canaries, afford two kinds: the first called Madeira sec, the latter, which is the richest and best of the two, Canary or Palm sec. The name sec (corruptly written sack) signifies dry; those wines being made from half-dried grapes. There is another sort of sec wine, prepared about Xeres, in Spain, and hence called, according to our orthography, Sherry, or Sherry.

2. The wines of Candia and Greece are of common use in Italy. Malvasy was formerly the produce of those parts only, but is now brought chiefly from Spain: it is a sweet wine, of a golden or brownish-yellow colour, and to this is applied an Italian proverb, signifying, Manna to the mouth, and balbuzard to the brain. Almost all the wines used in the Venetian territories come from Greece and the Morea. 3. Italy produces the vino Greco, which is a gold-coloured unctionous wine, of a pungent sweetness, the growth of mount Vefuvius, but much sophificated by the Neapolitans. In the neighbourhood of mount Vesuvius is made the Morgagnierra wine, and a thick, blackish one, called Verragia; and at the foot of the hill the delicious vino vergine. The kingdom of Naples affords the Campania or Paulyfippo, Mufcatel, Salernitan, and other excellent wines, and also the Chiarello, much drank at Rome. But the principal is the red, fat, sweet, and grateful poignant one, called Lachryma Christi. 4. The Ecclesiastical State produces the bright, pleasent Albano, and the sweet Montefalco, a yellowish not very strong wine, resembling good Florence, &c. 5. In Tuscany are the excellent white and red Florence; the celebrated hot, strong, red wine, de Monte Puleiano, &c. 6. In Lombardy, the Monferrato and Montferrat are tolerable; between Nizza and Savona is produced an incomparable Muscadine. 7. Piedmont and part of Savoy have excellent light wines. 8. The Sicilian, Sar- dinian, and Corsican wines are also good. 9. Most of the Spanish wines are composed of fermented or half-fermented wine mixed with distilled must, and variously manufactured, or of an infusion of dry grapes in weak must. Of thes wines, there are a few in Germany, as the Alicante, which is a thick, strong, very sweet, and almost nauseous wine, Sherry, Spanish, Malmsey, &c. 10. In Portugal there is plenty of red Port, which is much drunk in England. The best Vino tinto, a blackish-red wine used by the coopers for colouring other wines, is said to be the produce of Portugal. This kingdom also deals largely in Madeira.

* 11. In France there is a great variety of wines; of which the strong, sweet, full-bodied, spiritual ones, are called Vins de liqueur. Languedoc and Provence afford the sweetest wines, and the same provinces, with Champagne and Burgundy, the strongest; the wines of the northern parts, as Picardy and Bourdeaux, are the worst, and those about the middle of the kingdom, as Paris and Orleans, of a middling kind. The most celebrated of the French wines are, Champagnes, Burgundy, Vino di dea, or partridge-eye, Frontignac, Hermitage, &c. 12. In Switzerland, the best wines are, the Neuhutlen, Valelle, Ladafo, and Reiff: the Valelle straw-wine, so called from the grapes being laid for some time upon straw before they are pressed, is particularly celebrated. 13. The dry-grape wines of the Upper Hungary are in general excellent, and much superior to those of the Lower. (See Tokay.) 14. Among the German wines, those of Tyrol are very delicate, but do not keep. 15. Of Austrian wines, those of K shimmer-Neuburg and Brodenberg are deemed the best; and there are also good wines in other parts of the Imperial dominions. 16. In the Peloponnisus, the best wine is that of Wurms, especially the fort called Women's Milk. 17. Among the more esteemed German wines may be reckoned also Rheins, Mayne, Moelle, Neckar, and Elfs: a certain writer calls the Rheins made in Hockheim (Hock) the prince of the wines of Germany.

Wine is also variously denominated, according to its state, circumstances, qualities, &c. e.g.

Natural Wine, is such as comes from the grape, without farther mixture, or sophification.

Brewed Wine, or Adulterated, is that in which some drug is added, to give it strength, fineness, flavour, briskness, sweetness, or some other quality which is wanted.

Pricked Wine, or Eager, is that turned four times.

An easy method of recovering pricked wines may be learned from the following experiment:—Take a bottle of red port that is pricked, add to it half an ounce of tartarized spirit of wine; shake the liquor well together, and let it by for a few days, and it will be found very remarkably altered for the better.

This experiment depends upon the useful doctrine of acids and alkalies. All perfect wines have naturally some aciidity, and when this acidity prevails too much, the wine is said to be pricked, which is truly a state of the wine tending to vinegar: but the introduction of a fine alkaline salt, such as that of tartar, imbibed by spirit of wine, has a direct power of taking off the aciidity, and the spirit of wine also contributes to this, as a great preservative in general of wines. If this operation be dexterously performed, pricked wines may be absolutely recovered by it, and remain saleable for some time: and the same method may be used to mul-tiquors just turned four. Shaw's Lectures, p. 214.

Flat Wine, is that fallen weak and vapid, for want of being drank in time.

Sulphured Wine, is that put in casks in which sulphur has been burnt; in order to fit it for keeping, or for carriage by sea.

Colour, is a thick wine, of a very deep colour, serving to dye the wines that are too pale, &c. as the black wine in use among vintners. See Wine fugros.

The method of converting white wines into red, so much practiced by the modern wine-coopers, is this: put four ounces of turtole rags into an earthen vessel, and pour upon them a pint of boiling water; cover the vessel clofe, and leave it to cool; strain off the liquor, which will be of a fine deep red, inclining to purple. A small proportion of this colour is a large quantity of wine. This tincture might be either made in brandy, or mixed with it, or else made into a syrup, with sugar for keeping. A common way with the wine-coopers is to infuse the rags cold in wine for a night or more, and then wring them out with their hands; but
but the inconveniency of this method is, that it gives the wine a disagreeable taste, or what is commonly called the taste of the rags, whence the wines, thus coloured, usually pass among judges, for prefled wines, which have all this taste from the canvas rags in which the lees are prefled.

The way of extracting this tincture, as here directed, is not attended with this inconvenience; but it loads the wine with water; and if made into a syrup, or mixed in brandy, it would load the wine with things not wanted, since the colour alone is required. Hence the colouring of wines has always its inconveniences. In those countries which do not afford the tinging grape, which affords a blood-red juice, whereas the wines of France are often stained, in defect of this, the juice of elderberries is used, and sometimes logwood is used at Oporto.

The colour, afforded by the method here proposed, gives wines the tinge of the Bourdeaux red, not the Port; whereas the foreign cooperers are often dillufed for want of a proper colouring for red wines in bad years. This might perhaps be supplied by an extract made by boiling flack-lack in water. The skins of tinged grapes might also be used, and the matter of the turniole procured in a solid form, not imbibed in rags. Shaw's Lectures, p. 211.

Chip Wine, is that poured on chips of beecho-wood, to fine or soften it.

Rape Wine, is that put in a cask half-full of fresh grapes picked for the purpose, to recover the strength, brillikens, &c. which it had loft by keeping, &c.

Burnt Wine, is that boiled up with sugar, and sometimes with a little spicer.

There is also a sort of Malmsey wine made by boiling of mufcadine.

Wines, Condensing of, a phrase used by Stahl, and some other writers, to express what is more usually called the concentrating of them, that is, the freeing of them from the superfluous humidity which they contain, and by these means rendering them more rich and noble, freeing them from their talettepre part, reducing them to a smaller bulk, and thus making them fitter for transportation, and finally rendering them more durable in their perfect state, and much more subject to the various accidents that make them decay. See Concentration.

Various methods have been attempted for the effecting of this, as by means of heat and evaporation, or by percolation, &c. and great objections found in the way of all of them, except the latter, brought into use by Stahl, and since recommended greatly to the world by Dr. Shaw in his Chemical Essays.

If any kind of wine, but particularly such as has never been adulterated, be, in a sufficient quantity, as that of a gallon or more, exposed to a sufficient degree of cold in frosty weather, or be put in any place where ice continues all the year, as in our ice-houses, and there suffered to freeze, the superfluous water that was originally contained in the wine will be frozen into ice, and will leave the proper and truly-efficient part of the wine unfrozen, unless the degree of cold should be very intense, or the wine but weak and poor. This is the principle on which Stahl founded his whole system of condensing wine by cold.

When the frost is moderate, the experiment has no difficulty, because not above a third or fourth part of the superfluous water will be frozen in a whole night; but if the cold be very intense, the best way is, at the end of a few hours, when a tolerable quantity of ice is formed, to pour out the remaining fluid liquor and set it in another vessel to freeze again by itself.

If the vessel, that thus by degrees receives the several parcels of the condensed wine, be suffered to stand in the cold freezing place where the operation is performed, the quantity lying thin in the pouring out, or otherwise, will be very apt to freeze anew, and if it be let in a warm place, some of this aqueous part thaws again, and so weakens the reft. The condenced wine, therefore, should be emptied in some place of moderate degree as to cold or heat, where neither the ice may diffuse, nor the viscous substance mixed among it be congealed. But the best expedient of all is to perform the operation with a large quantity of wine, or that of severall gollons, where the utmost exactness, or the danger of a trifling waft, needs not be regarded.

If the wine now once concentrated should, by a long continuance in the freezing cold, be again congealed to the utmost (unless the cold were very severe indeed), and then again be drained from its ice, there, soon after this, falls to the bottom of the vessel a pure white powar or tartar, and even the icy part afterwards deposits also a little of the same substance after thawing; and after standing two or three daies, there is always more and more of this tartar precipitated, and that constantly the more in proportion as the wine was more austere, or less adulterated with sugar, brandy, or the like; for these things contain no tartar.

The ice of the second operation on a quantity of wine differs in nothing from that of the first, provided only that the wine was poured clear off from it, before the ice is set to melt, by which means it diffolves into a clear phlegm. This shews the excellency of the operation; as it loses not its efficacy upon repetition, but brings away more water as well at last as at first, without robbing the wine of any of its genuine or truly valuable parts. The remaining unfrozen liquor is a real concentrated wine, as appears by its colour, consistence, taste, and smell, and is actually become a nobler and richer wine than could be procured without such a contrivance.

This operation, though it be perfect in regard to wine, yet does not succeed so well in regard to the malt-liquors. The experiment has been fairly tried by Stahl on a gallon of strong malt-drink, and the succefs was as follows:—The ice separated in the first operation, when thawed by heat, resolved into a liquor of the colour and taste of small-beer; and the second concentration afforded an ice of much the same kind, which might have passed for ordinary small-beer, but for a flashy watery taste that manifestly predominated in it. The liquor unfrozen was but a pint and a half by measure, but it was extremely rich and thick, and seemed very strong and spirituous, and perfectly aromatic, or highly flavoured. The consistence was something like that of a thin syrup, and it had a pleasing softness that sheathed the acrimony of the spirit, and covered the bitter taste of the hop.

The mucilaginous nature, which is predominant in all malt-liquors, occasions a great inaccuracy in this experiment, as not sufferiog the water to run clear, or be separated from the richer tincture of the malt, nor letting the condensed liquor be obtained clean from the ice; but as the losses occasioned by this is not great, and the liquor is much cheaper than wine, if this should ever come into use in the large way, the thawed liquor of the ice might be used again in a new brewing, and to the loss of that part of the strength which was carried away by the freezing be recovered.

Wines in general may by this method be reduced to any degree of vinosity or perfection. Thus, for example, if a wine of a moderate strength hath a third part of its water taken away, in form of ice, by congelation, the remaining part will thereby be doubled in strength and goodness: for if we allow, in the better sorts of wine, that one-third part, which
WINE.

which is near the truth, is truly good or vinous, and twothird parts are nothing but water, one-third part of the
good wine being blended among the two-third parts of
water, of no strength or value; it follows, that if one of
these third parts of water be taken away, and all the wine
left, that which was before but one-third wine, is now onehalf wine, no way reduced in its strength, and therefore the
whole must be stronger in that proportion.

But if this operation of congelation be carried to the
utmost, and be practised on a large quantity of wine, and
with a very intense cold, and the ice taken away several
times, and the wine, thus freed from a part of its water,
again and again exposed, it will be found that good wines
will be reduced to one-sixth part of their original quantity:
and the vitner will easily find out the use of this remaining
sixth part, which is a true quintuffice of wine, and will be
of the utmost benefit, by mixing it in small quantities with
poor and low-flavoured wines, to meliorate and improve
them; and even to convert the low-flavoured and leaft
valuable ones into thofe very wines from which this con-
denfcd part was procured.

This method is not practicable to advantage in the wine
countries alone. Dr. Shaw affirms us, that he has himself
experimented it here, and with the use of proper freezing
mixtures has reduced wines in England to a much smaller
quantity, in proportion to the whole, than in the Strongest
of Stahl's experiments. It is evident, that by how much
the quantity is smaller, by fo much it is richer and stronger,
provided that the operation has been properly performed.
The doctor affirms us, the noble effence or rob, thus pre-
pared, is capable of working almost miracles, by turning
water into wine, and the like; but that, in order to its suc-
ceeding well, there requires great care in the operator, when
the congelation is repeated the laft times. Shaw's Chem.

WINE, Clarification of. See Clarification, and Wine
supra.

WINE, Colouring of. See Wine Colour, and Wine
supra.

WINE, Fining of. See Fining, and Wine supra.

This operation is practised in Germany in the following
manner: they have in some vats three or four fioves, which
they heat very hot: others make fires almost before
every vat; by which means the muft is made to ferment
with great vehemence. When the ebullition, fermentation,
and working ceafe, they let the wine fland, and then rack
it. This fining is only used in cold years, when the wine
happens to be green.

WINE, Forcing of. See Forcing.

WINE, Domainie. See Wine supra.

In the Musewm Rufficum we have the following directions
for making raffin wine: put thirty gallons of hot water
into a vefsel at leaft one-third bigger than sufficient to
contain that quantity; and add to it one hundred weight of
Malaga raffins, grossly picked from their falks. Mix the
whole well together, and cover it partly with a linen cloth.
When it has flooded a little while in a warm place, it will
begin to ferment, and must be well flaired about twice, in
twenty-four hours, for twelve or fourteen days. When the
sweetnefs is nearly gone off, and the fermentation much
abated, which will be perceived by the subfiding and refl
of the raffins, strain off the fluid, marking it, firft by the
hand, and afterwards by a prefl, out of the raffins. Let
this liquor be put into a found wine-cafe, well dried and
warmed, adding eight pounds of Lisbon fugar, and a little
riffal, and referring part of the liquor to be added from
time to time, as the decline of the fermentation will give

room. In this ifate, the liquor must remain for a month,
with the buug-hole open; and having filled the vefsel with
the referved liquor, let it be closely flopped, and kept for
a year or longer, and then bottled off. At the end of a
year and a halt it may be drank, but will improve for four
or five years.

Some faving may be made in the expence, by diminishing
the quantity of raffins, and increasing that of the fugar, in
the proportion of four pounds of raffins for one of fugar;
or by diminishing the proportion of both raffins and fugar,
and adding clean malt-spirits, when the bung of the cafl is
closed up. Any other large raffins may be used, and the
Malaga; but the thinner the riffs and the sweeter the
pulp, the stronger will be the wine.

If this wine be perfectly fermented, and kept a long time,
so that no sweetnefs remain, it will resemble Madeira.

An artificial Frontignac may be made of this wine, in
which the proportion of fugar or of malt-spirits to the raffins
is large, and the whole body weaker: the mufcadel flavour
being communicated by an infusion of the flowers of mea-
dow-fweet. In the making of this artificial Frontignac, the
ferment should be flopped, by clofing the cafl and adding
the spirit, while a confiderable degree of sweetnefs remains,
and the wine may be drank after it has been a little while in
the bottles.

Cyprus wine may be imitated by the fame means, using
three or four pounds more of fugar than the quantity above
preferred, and stopping the fermentation while a confider-
able degree of sweetnefs remains.

Artificial Mountain may be made by preferring a small
degree of sweetnefs, giving the nut-like flavour, and keep-
ing the beft kind of the above wine to a due age. The
flavour may be obtained by the infusion of the Florentine
orris-root, powdered, with a very small proportion of orange
and lemon peel; and the wine may be rendered more dry or
sweet, by continuing the fermentation for a greater or lefs
time, and adding a corresponding proportion of clean malt-
spirits, when the fermentation is stopped sooner. The adding
of some of the flony feeds of the raffins well bruited will
give the nut-like flavour; and the putting in a part of the
flalks will add a sharpnefs, found generally in this kind of
wine.

The racy taste of Canary, commonly called fack, may be
counterfeited by the addition of a proper quantity of the
juice of white currant-berries to the wine, made with a large
proportion of fugar to the raffins, and left very fweet in the
fermentation. But it is faid that a spirit, diffilled from the
leaves of clary and clean malt-spirits, put to the wine, will
give it a very strong reneblance of fack. It is faid alfo,
that the juice of the bramble-berries, added to the mixture
of the wine, before the fermentation, will give both the
colour and flavour of clarat; but in this cafe the quantity of
raffins should be confiderably diminished, and that of the
fugar increafed, as the fermentation must be continued till
the sweetnefs be wholly deftroyed.

Wines of this kind fhould be kept at leaft a year before
they are drank. See Sweets.

WINE, Estemporaneous. A hundred weight of good
treacle will produce, according to the art of the ditillier,
from four to seven gallons of pure alcohol; that is, from
eight to fourteen gallons of the common-proof malaffs
spirit. The still-bottoms have many ufs. The ditillers
feal and recover their muldy cafls with them, and they
may be used for all thofe purpofes of cleaning where argol
is required. Mr. Boyle's acid spirit of wine, or a spirit
very like it, may also be procured from them, and a matter

Vol. XXXVIII.
WINE.

analogous to that Becher calls the media fubflanta vini. This liquor gives a durable extemporaneous wine.

WINE, Stooming of. See STOOMING.

Wines, Lees of, in Distillation, a term applied to the liquor which first comes over, when the waf has been subjected to di-

tillation, and which is concentrated by a second operation.

See DISTILLATION.

Wines, Medicinal or Medicated, in Pharmacy, a term ap-
plied to those preparations consisting of wine holding differ-
et active ingredients in solution. They were for-
merly very numerous, but at present their number is very limited. See VINOUM, under which article those at present in use are described.

Wine, Lees of, are the impurities of it, or the thick

dediment remaining at the bottom of the casks, when the

dew is drawn out. The distillation of wine-lees into spirit is conducted very

much in the same manner with that of the malt-wash, when

distilled with the meal part in it; the principal difference

is on this account, that the oil of the malt being very nau-

geous and disagreeable, the utmost care is to be used to keep

it back in all the processes of primary distillation, and of

rectification; whereas, on the other hand, the oil of the

wine-lees being a very agreeable and pleasant one, as much

care as possible is to be taken to bring it over with the spirit.

Glauber has written a peculiar treatise on this subject, in

which, without touching upon the most advantageous pro-
duction of all, he has proved the work to be so very profit-
able, that the whole usually passes for one of his wild flights,
rather than a solid business.

The method of distilling a liquid ley for its spirit is a

thing universally known, but the advantageous thing, on

this basis, is the distilling of a dry ley preseed and pre-

ferred, and the managing of the business in such a manner

as at first or last to procure and separate all its valuable

parts. The solid ley, here mentioned, is that usually sold

to the hatters in England, and is the same thing that in

France and other wine countries the vineyard-makers dispo-

e of in cakes, after they have preferred out all the wine, and which

was afterwards burnt, and makes what Lemery and others

call cőttris clovellati; and the English gravelled offes, a fixed

alkaline salt-like potash.

This ley, when used for distilling, should be that of the

French wines, and either such as is newly preseed, or has

been well secured by packing in a close manner in tight

casks, with some proper contrivance of dry land, or the

like, to keep its external surface from the contact of the

air, which is very apt to corrupt or putrefy it.

If this ley is intended to be kept many months, it will be

very proper to secure it by sprinkling the layers as they are

packed up with a little brandy. The expense of this is no-
thing, for the brandy is recovered again in the operation.

Shaw.

Wine, Oil of, a very precious liquid, kept as a secret in

the hands of some dealers in spirits, and used to give the

brandy flavour to spirits of less price. It is certain that all

the spirits we use take their flavour from the essential oil of the

substance they are made from; that of malt is very nau-
geous and offensive, and renders the spirit horribly disagree-
able, if not carefully kept back in the distillation of it; that

of the grape, on the other hand, is extremely agreeable, and is what gives the delicious flavour to French brandy;

this, therefore, is to be carefully brought over among the

spirits in distillation.

This is that oil of wine so much celebrated among our

distillers, and is for their use made separate, and is of such

effect, that half an ounce of it will determine a pure and
clear malt spirit to be French brandy, so as to stand the test

of the nicest palate, and all the trials that can be invented,

provided the oil and the spirit have both been carefully

made.

The manner of making the oil is this: they take some

cakes of dry wine-lees, such as are used by our hatters, and

dissolving them in six or eight times their weight of water,

distilling them in a slow fire, and separating the oil by the

separating pot, referring for this nice use only that which

comes over first, the oil that follows being coarser and

more refined. To render this business perfectly success-

ful, there must be several things observed: 1. The ley

must be of the right kind, that is, of the same nature with

the French brandy propose to be imitated. 2. The malt-

spirit must be extremely pure. 3. The dose of the oil must

be very well proportioned. And, 4. The whole must be

artificially united into one simple and homogenie liquor.

These cautions all regard only the tare, and besides these,
in order to come up to a nice counterfeit, several other par-
ticulars must be attended to; such as the colour, proof,

tenacity, softness, and the like; so that, in short, the opera-
tion has too much nicety in it to be hit off by every ordinary
dealer. When this fine oil of wine is procured, it may be

mixed into a quintessence, with pure distilled alcohol, or

the totally inflammable spirit of wine, to prevent its growing

difficult, rancid, or reinous; and thus it may be long

preferred in full possession of its flavour and virtues.

The still-bottoms, or remaining matter after the distilla-
tion of this oil, will yield many productions to advantage,

particularly tartar, and salt of tartar, as also an empy-

ematic oil, and a volatile salt, like that of animals. Some

kind of lees afford all these in much greater quantity than

others; the lees of Canary and Mountain wines yield very

little of them; and, indeed, scarce any tartar or fixed salt

at all; but the white French lees of those thin wines that

afford the ordinary brandies, yield them all very copiously,

so much that sometimes a single hoghead of dry and clos-

peed lees will afford, by this process, three gallons of

brandy, forty pounds of clean tartar, a large proportion of

empyreumatic oil, and volatile salt, besides full four pounds

of good salt of tartar. It is not to be expected, however,

that every parcel of this ley should yield fully in this pro-

portion. Shaw's Essay on Distillery.

Wine, Piece of. See PIECE.

Wine-Prijs, a machine contrived to squeeze the juice

out of grapes, and consisting of several pieces of timber,

variously disposed, which compose three bodies of timber-

work, closely united to the axis, which serves as a swingle,

by which it may be moved by the vice. Of these there are
different sizes as well as different contructions.

Wine, Prijsage. See PRIJSAGE.

Wine, Rackage of. See RACK, and WINE supra.

Wine, Spirit of. See SPIRIT.

Wine-Spirit, a term used by our distillers, and which may

seem to mean the same thing with the phrase spirit of

wine; but they are taken in very different senses in the

trade.

Spirit of wine is the name given to the common malt-

spirit, when reduced to an alcohol, or totally inflammable

state; but the phrase wine-spirit is used to express a

very clean and fine spirit, of the ordinary proof-strength,

and made in England from wines of foreign growth.

The way of producing it is by simple distillation; and it

is never rectified any higher than common bubble-proof.

The several wines of different natures, yield very different

proportions of spirit; but in general the strongest yield

one-fourth, the weakest in spirits one-eighth part of proof-

spirit;
spirit; that is, they contain from a sixteenth to an eighth part of their quantity of pure alcohol.

Wines that are a little moreserve not at all the worse for the
purposes of the distiller; they rather give a greater
vinosity to the produce. This vinosity is a thing of great
use in the wine-spirit, whose principal use is to mix
with another that is tartrarized, or with a malt-spirit, rendered
alkaline by the common method of rectification. All the
wine-spirits made in England, even those from the French
wines, appear very greatly different from the common
French brandy; and this has given our distillers a
notion that there is some secret art practised in France,
for giving the agreeable flavour to that spirit; but this
is without foundation.

When we distil Sicilian or Spanish wines, we do not
produce Sicilian or Spanish brandies; and the true reason
of this is, that the wines which they distil on the spot
into brandy, are very different from those which they
export as wines.

Those they distil are fo poor and thin, that they will not
keep many months, nor can possibly bear exportation.
If we had in England those poor wines they distilled into
brandy near Bourdeaux, Cognac, or up the Loire, there
is no doubt that the spirit we made from them would be
universally allowed to be French brandy. We have proof
of this from some of the Scotch distilleries, where they,
with no peculiar art, or secret method, procure from
some of the poor pricked and damaged wines received here,
brandy so nearly resembling that of France; that a
good judge will scarcely be able to make the distinction.
Wine-spirits and brandies, therefore, are the same
thing, only with this difference, that the former is the
product of a rich wine, and the latter of a poor one; or,
at the utmost, they differ only as our two home products,
the cyer-spirit and the crab-spirit, do.

The wine-spirit, distilled in England, is not easy to be
had pure and unmixed at our distillers, nor under a price
almost equal to that of French brandy; so that if it
never be required out of the trade, it is as well to use the
French brandy, which will, in all cases, serve the same
purposes, unless where a high flavour or a copious
essential oil are required. All other spirits are carefully
diluted of their oil in the rectifications; but the wine-
spirit is coveted only for its oil, and all that can be
obtained is preferred in this, its principal use being to give
a flavour to a worse spirit, and to cover the taste of a dif-
agreeable oil in it.

When a cask of wine chances to turn four in private
hands, it is worth while to distil it for the spirit. The
lees, also, if in any considerable quantity, will yield such
a proportion of the same sort of spirit, as to render it
worth while; and as the high flavour is not required in
this intent, it will be best to draw the spirit very
gently, either by the cold or hot stills, and afterwards it
may be rectified without any addition, and reduced to the
standard-strength of proof. It thus makes a very
clean and pleasant spirit, though very different from the
brandy from the same country the wine came.

Shaw's Essay on Distillation. See SPIRIT.

WINE, Philosopbic Spirit of the writings of some che-
menists and physicians a phrase that often occurs as the
name of a liquid prepared from wine, and ended with
very remarkable properties.

It is generally supposed that this was the same sort of
liquor, which at this time call by the name of spirit of
wine; but this is a very erroneous opinion, and has led
many into errors, about the operations in which it was
concerned. It was truly no distilled liquor, but the spirit-
rurious parts of wine condensed and concentrated by the
freezing of the more aqueous parts.

WINE VINERAR, Method of making of. See VINEAR.

WINE, Laws relating to.

Wine may be imported only in British-built ships, or
vessels of the built of that country which the wine is the
produce, legally navigated; or in ships the built of the
country in Europe under the dominion of the sovereign
or state in Europe, of which the wine is the produce, or of
the usual place of shipping. Penalty, forfeit of the
wine and the ship. 12 Car. II. c. 18, and 27 Geo. III.

No other than Rhenish wine may be imported from
the Netherlands or Germany, on forfeiture of ship and goods.
13 & 14 Car. II. c. 11. But wine, the produce of
Hamburg, may come from Hambro'; also wine, the produce of
Hungary, the Austrian dominions, or any part of
Germany, may come from the Austrian Netherlands, or any
place subject to the emperor of Germany or house of
Austria. 1 Ann. Stat. 1. c. 12, and 25 Geo. III. c. 78.

Wine may not be imported in vessels under fifty tons bur-
then; and veffel forfeited. 24 Geo. III. c. 47.
26 Geo. III. c. 59. and 45 Geo. III. c. 121. Spanish
and Portugal wines may not be imported in any casks con-
taining less than a hogshead, except for private use.
18 Geo. III. c. 27. and 25 Geo. III. c. 69. French
wine the same; and, except French wine in bottles, from
France, Guernsey, Jersey, or Alderney. 18 Geo. III.
c. 27. and 17 Geo. III. c. 13. By the 5 Ann. c. 27. a
hogshead is to contain 63 gallons, or 231 cubical inches
of wine. (i.e. not Spanish nor Portugal) may not be
imported in flasks, bottles, or casks, containing less than
25 gallons, except of the produce of the dominions of the
great duke of Tuscany, in open flasks, or any part of the
Levant, and also wine for private use. 1 Geo. II. fl. 2,
c. 17. and 25 Geo. III. c. 69. Wine may be imported in
cases containing fix dozen reputed quart bottles at the
least. 39 & 40 Geo. III. c. 83. 42 Geo. III. c. 44,
and 45 Geo. III. c. 121. Five reputed quart bottles
drew a gallon in charging duty. Wine not to be im-
ported unless accompanied by a manifest, attested by the
custos at the place of shipment. 26 Geo. III. c. 40.
Wine must be entered at the custom-house and excise-office
within 20 days after the ship has reported, or it may be
sold for the duties, and must be removed from the quays in
10 days. 26 Geo. III. c. 59. and 35 Geo. III. c. 118.

Wine landed without payment of duty is forfeited
(20 Geo. III. c. 59.); but wine may be warehoused under
schedule B; without payment at the time of entry of the
duties due on importation, on the importer giving bond to
export the same, or pay the duties within 12 months. But
duty must be paid when taken out, on any excess or defi-
cency, from the quantity taken at the time of landing; and
no wine to be warehoused in casks less than 45 gallons.
43 Geo. III. c. 132. Wine that has been warehoused
may be exported, and wine that has paid duty may be
shipped for drawback; but must be packed in the pre-
cence of the proper excise-officers, and the casks to be
sealed with their official seals; and if they are afterwards
damaged or broken, the party offending to forfeit 50l. for
each cask or package. Due notice to be given in writing
of the times of packing and shipping. 26 Geo. III. c. 59.
f. 46. 47. The exporter to give bond before shipping
that the same shall be exported to the place entered for,
and shall not be relanded or unshipped. To be landed in Great
Britain, on forfeiture. 26 Geo. III. c. 59. f. 48.
35 Geo. III. c. 118. Wine may be exported to Douglas, in the Isle of Man, in British vessels of 50 tons, by licence of the commissioners of the customs. 52 Geo. III. c. 140.

All the duties paid upon wine shipped for the actual consumption of officers of the navy on board ship, to be drawn back according to the following proportions.

33 Geo. III. c. 48.

Officers of marines to be allowed half a ton per annum.

53 Geo. III. c. 44. But to be shipped only at the ports of London, Rochefort, Dover, Dartmouth, Portsmouth, &c.

Dealers to remove their stock from one ship to another, and dispose of it to other officers. 38 Geo. III. c. 33.

Dealers in foreign wine to enter their premises at the excise-office, on penalty of 100l. for every place not entered, and forfeiture of the wine found therein. 26 Geo. III. c. 59. f. 12. Dealers to have the words 'Dealers in foreign Wines' painted on their doors, on penalty of 50l. fct. 15.

Retailers to have the word 'Wine' exhibited in some conspicuous part of their premises, on penalty of ten shillings. 30 Geo. II. c. 19, and 32 Geo. II. c. 19.

Dealers to take out a licence, to be renewed ten days before the expiration of every year, on penalty of 100l.; but not to apply to auctioneers selling wine by auction. 26 Geo. III. c. 59.

Retailers of foreign wines, and dealers in sweets or British wines, to take out licences also; and selling them after their expiration, and before renewed, subjects them to 60l. penalty. 30 Geo. III. c. 18. Retailers not to sell wine in their houses, unless they have a beer licence granted by the magistrates, on penalty of 20l. See Ale-House.

Officers may enter at any time to take an account of the stock, but if they go in the night they must be attended with a constable. The party refusing them admittance, or obstructing them, forfeits 100l. 26 Geo. III. c. 59. f. 17.

No wine to be brought into a dealer's posseffion without a permit, and dealers to mark on a conspicuous part the consent of each cask. 26 Geo. III. c. 59. f. 32. Any excess in a dealer's stock from the account last taken, after deducting the quantity sold and entered in their books, deemed not to have paid duty, and is forfeited, and double the value. 26 Geo. III. c. 59. f. 59. 27 Geo. III. c. 31.

Different kinds of wine and liquors, (cyder, spirits, &c.) to be kept separate. 26 Geo. III. c. 59. 42 Geo. III. c. 93. And no dealer in foreign wine to have any sweets or British wines in his posseffion. Penalty 100l. per gallon. 26 Geo. III. c. 59. f. 9.

Account of wine daily to be kept, and no quantity above three gallons to be removed without permission, in forfeiture of the fame, and the carriage and horse. 26 Geo. III. c. 59. 42 Geo. III. c. 95.

Wine, in possession of persons not dealers, may have permits granted for its removal, on proving to the satisfaction of the commissioners of excise, or the collector or supervisor of the district, that the duties have been paid. 26 Geo. III. c. 59. f. 33. Permits not used to be returned to the officer, on penalty of treble the value of the wine. 26 Geo. III. c. 59. f. 37, 38; and persons forging or counterfeiting them to forfeit 200l. Ibid. fct. 39.

For the laws relating to low wines and domestic wines, see Distiller, and Sweets.

WINE of Squills. See Squills.

WINE-Measure. See Measure, and Laws relating to Wine Paper.

WINE-Fly, in Natural History, the name of a small black fly, found in empty wine-casks, and about wine-lees, and called by the Latin, Bibio. It is produced of a small red worm, very common in the sediment of wine.

The drippings of wine or beer vessels, the pressings of the wine or cyder press, the pots in which honey has been kept, and in which a little remains sticking to the fides, and turning four, all afford vast numbers of a small species of worm or maggot. This is of a white colour, and has two books placed near the head; in short, it resembles in all the parts the maggot of the common flesh-fly. Multitudes of these small creatures live and move very briskly about in these substanccs for several weeks together; but at the end of that time, when they have arrived at their full growth, they enter into the nymphen-flate under a covering or cape made of their own skin, which dries, and becomes of a brown colour. After eight or ten days in this flate, the cape is opened by the falling off of a small piece at the end, and the fly makes its way out. The fly is extremely small when its wings are not extended.

It does not exceed the size of the head of a middling pin; it is however very beautiful; the breast and body are yellow, the reticulated eyes are red, and the wings have all the rainbow-colours. The best way of procuring these little flies, which make a very beautiful microscope object, is to keep the matter, in which the worms are placed, in a glads, covered down with a paper; as soon as the cover is taken off, at the time of their being in the fly-flate, they rise up at once in the form of a cloud; enough of them for observation will however remain about the sides of the vesell. When examined, they are found to have all the regular parts of the larger flies; their antennae are oval and flattened, and their legs, and every other part, are as elegantly perfect, as they are seen to be in the most elegant large fly.

It is not known whether they are oviparous or viviparous; but this is to be observed, that they give us great light into the origin of animalculc in different fluids.

Since we fee in these the evident course of nature in their origin, what prevents but that there may be numbers of flies yet smaller than these, whose eggs may be deposited in the fluids in which we find our microscope animalcules. Reaum. Hist. Inf. vol. ix. p. 82.

WINEBAGO, in Geography, a lake of North America. N. lat. 43° 50'. W. long. 87° 40'.

WINEBOGO River, a river of America, which runs from WINEBago lake to Green bay into lake Michigan. The WINEBago Indians inhabit near this river and lake, in about N. lat. 43° to 44°. W. long. 84° to 85°.

WINEBAGOE CASTLE, an Indian settlement in North America, near WINEBago lake.

WINE or Black River, a river of South Carolina. See BLACK RIVER.

WINERSTA, a town of Sweden, in East Gothland; 18 miles N.W. of Linkoping.

WING, in Botany and Vegetable Physiology, is generally used for any appendage to a seed, which serves to assist in its flight through the air. In this sense, the feathery crown of the Dandelion, and other fyngeenous plants; the membranous expansion at the top of the fuscious seeds, so curiously and variously constructed in different species; the long feathery awn of the Sinpa; and the delicate silky plumage
plumage of many birds among the order of Contortes, are 
feveral distinct of the genera of those animals, under the ancient 
plumage among the order of Contortes, are
feveral distinct of the genera of those animals, under the ancient 
genera of birds, pref. p. 4.

Wings, among the Fly-clafs, afford feveral subordinate 
difficultiofs of the genera of those animals, under the ancient 
genera of birds, pref. p. 4.

Wings, among the Fly-clafs, afford feveral subordinate 
difficultiofs of the genera of those animals, under the ancient 
genera of birds, pref. p. 4.
Wings, Warbling of. See Warbling.

Wings, in Heraldry, are borne sometimes single, sometimes in pairs, in which case they are called conjointed; when the points are downward, they are said to be inverted; when up, elevated.

Wings, in Gardening, &c. denote such branches of trees, or other plants, as grow up afide of each other.

Quintiness says, the term is particularly applied to artichokes, whose wings, or ale, are the leffer heads, or fruits, that grow up with the principal one on the same falk.

Wings, Ale, in the Military Art, are the two flanks, or extremes of an army, ranged in fform of battle; being the right and left fides thereof, and including the main body.

The cavalry are always posted in the wings, i.e. on the flanks, on the right and left fides of each line; to cover the foot in the middle.

Pan, one of Bacchus's captains, is said to have been the first inventor of this method of ranging an army; whence, fay they, it is, that the ancients painted him with horns on his head; what we call wings, being by them called cornua, horns. This at leaft is certain, that the method of arranging in wings is very ancient. The Romans, we know, used the term ale, or wings, for two bodies of men in their army; one on the right, the other on the left, conflilling each of four hundred horses, and four thoufand two hundred foot ufually, and wholly made up of confederate troops. These were designed to cover the Roman army, as the wings of a bird cover its body.

The troops in these wings they called alares, and alares copie; and we, at this day, diftinguish our armies into the main body, the right and left wings.

Wings are also used for two files, that terminate each battalion, or squadron, on the right and left. The pikes used to be ranged in the middle, and the musqueteers in the wings.

Wings, in Fortification, denote the longer fides of horn-works, crown-works, tenailles, and the like outworks, including the ramparts and parapets, with which they are bounded on the right and left, from the gorge to their front.

These wings, or fides, are capable of being flanked, either with the body of the place, if they stand not too far diftant, or with certain redoubts; or with a traverfe made in the ditch.

Wings, in a Ship, the places next the fide upon the orlop, ufually parted off in fhips of war, that the carpenter and his crew may have free access round the fhip in time of action, to plug up flaw-holes, &c.

Wings are also the flits or extremities of a fleet, when it is ranged into a line a-breadth, or when bearing away upon two fides of an angle.

It is ufual also to extend the wings of a fleet in the day-time, in order to difcover any enemy which may fall into their track. To prevent Separation, however, they are commonly fummoned to draw nearer to the centre of the squadron before night, by a signal from the commander-in-chief, which is afterwards repeated by ships in the intervals. Falconer.

Wing-Transform, the uppermost transform in the flate-frame of a ship, &c., upon which the peels of the counter-timbers are relift. It is by fome called the main-transform.
WINGS, Goose. See Goose.

WING, St. Michael's, is the name of a military order in Portugal, instituted, according to the Jefuit Mendoza, in 1165; or, according to di Michieli, in his Teforo Militar de Cavalleria, in 1171. Its insitutor was Alphonfus Henry I. king of Portugal; and the occasion was a victory gained by him over the king of Savil, and his Saracens; for which he thought himself beholding to St. Michael, whom he had chosen for his patron in the war against the infidels.

The banner they bore was a wing resembling that of the archangel, of a purple colour, encompassed with rays of gold. Their rule was that of St. Benedict; the vow they made was to defend the Chriflian religion, and the borders of the kingdom, and to protect orphans. Their motto, Quis ut Deus!

Wing-Walls, of a bridge or lock, are playing-walls for diminishing the width of the canal to such bridge or lock, and for keeping up the banks.

WINGE, in Geography, a river of France, which runs into the Demer, 2 miles W. of Arlhot.

WINGED, in Botany, a term applied to such items of plants as are furnished, all their length, with a sort of membranous appendage.

Several kinds of thistles have winged stalks and branches. WINGED Leaves are such as confift of dillee little leaves, ranged in the fame direction, on each side of a rib or talik, so as to appear no more than one and the same leaf. Such are the leaves of agrimony, acacia, aff, &c. See WING.

WINGED Seeds are such as have down or hairs on them, by which the wind taking hold blows them to a distance.

WINGED stalk. See Stalk.

WINGED, in Heraldry, is applied to a bird when its wings are of a different colour, or metal, from the body. Winged is also applied to any thing represented with wings, though contrary to its nature; as winged or flying hart, &c.

WINGER, in Geography, a town of Norway, in the province of Aggerhuus; 2 miles S. of Kongwinger.

WINGHAM, a village and parish in the hundred of its own name, and lathe of St. Augustine, in the county of Kent, England, is situated 34 miles E. from Maidstone, and 62 E. by S. from London. A college of a provost and six secular canons was projected here by Kilwardby, archbishop of Canterbury, but settled and endowed by his successor, Peckham, in 1286. It was valued at 8l. per annum at the general suppression. By Edward VI. the college, with the patronage of the church and all tythes, were granted to Sir Henry Palmer. The building, now called the college, and which formed the manfion of the Palmers, appears to have been the provost's lodge. The church contains memorials of the Palmers and the Oxendens, who have a seat at Deane, in the parish. A double row of stalls still exists in the chancel. Wingham gives a title to earl Cowper, who, however, has no estate in the parish. It gave birth to Henry de Wingham, chancellor of England, bishop of Winchester, and afterwards of London. In 1511 the inhabitants of the parish were 859, who occupied 162 houses.

WINGHAM's island, a small island in the North Pacific ocean, near the W. coast of North America; 3 miles N.W. of Kaye's island. N. lat. 60° 4'. E. long. 215° 46'.

WINGROD, a town of Austrian Poland, in Galicia; 16 miles N.W. of Sniatyn.

WINHALL, a township of Vermont, in the county of Bennington, with 429 inhabitants; 30 miles N.E. of Bennington.

WININGEN, a town of France, in the department of the Rhine and Mofelle, on the N. side of the Mofelle; 5 miles W. of Coblenz.

WINKEL, a town of France, in the department of Mont Tonnerre; 14 miles W. of Mentz.

WINKELMAN, Abi John, in Biography, a German antiquary, was born at Standal, in the Mark of Brandenburg, in 1718. Although born in very humble life, he fortunately enjoyed favourable opportunities of cultivating his talents in that department in which he afterwards attained to eminence. He had arrived at the age of 37 years before he was known to the public as an author. His first work was "Reflections on the Imitation of the Greeks in Painting and Sculpture;" and it was received in a manner that very much contributed to establish his reputation. At the court of Augustus, king of Poland, he was profelyted to the Catholic faith, more, as some have said, by arguments addressed to his worldly interest, than to his spiritual welfare. It is certain, however, that he much wished to visit Italy for the sake of examining those masterpieces of art that were to be found in that country. With this view he left Dresden, and in passing through Florence in 1756, he made a descriptive catalogue of the antiquities in the collection of the celebrated baron de Stofch, which seemed to introduce him with advantage to Rome, whither he proceeded towards the close of this year. His acquaintance with the famous painter Mengs, Bianconi, and several other ingenious artists, forwarded his accefa to two of the most celebrated literary men at Rome, cardinal Paffionei and the prelate Giaconelli; from whose library and learning he derived much useful information, so that he was soon acknowledged as a man of fine taste, and a distingifhing connoifeur in works of art. Assuming the ecclesiastical habit, he succeeded the abbe Venuti as keeper of the pope's cabinet of antiquities; and he was also appointed copyist in the library of the Vatican. Under the patronage of the pope, who increased his income out of his privy-purfe, he completed his History of Art among the Ancients, and then left Rome in 1768 to visit his friends in Germany, and to revile his work to be tranflated into French by M. Troufant of Berlin. On his return to Rome by way of Triefte, he was affilliated, in June 1768, by a wretch who had joined him on the road, and who had fo far gained his confidence, that he had thrown him some gold medals and valuable presents which he had received at Vienna. "Abbe Winkelmann," says one of his biographers, "was of the middle size, with a very low forehead, a sharp nose, and black hollow eyes, which gave him rather a gloomy appearance. An ardent and impetuous disposition often hurried him into extremes. Naturally enthusiastic, he frequently indulged an extravagant imagination; but as he polifhed a strong and folid judgment, he knew how to give things their jult value. In confequence of this turn of mind, as well as a neglected education, he was a stranger to cautious revere. If he was bold in his decisions as an author, he was flill more fo in his conversation, and often made his friends tremble for his temerity." The tranflation of his History of the Arts was completed only in part by Troufant. Another French tranflation was published by Huber, professor at Leipzig. It is faid that the left French tranflation is far preferable to the first, as it was made from an enlarged edition of the original, printed at Vienna in 1776, after a MS. left by the author. Among the other works of Winkelmann were, "Letters on the Discoveries made at Herculanenum," tranflated into English by Mr. Gough; "Unpublished Monuments of Antiquity, such as Statues, ancient Paintings, engraved Stones, Bar-Reliefs, in Marble and,
WIN

WINKOP's Bay, or Wine Cooper's Bay, in Geography, a large bay on the south coast of Java. S. lat. 7° 7'. E. long. 106° 58'.

WINKOP's Island, a small island near the south coast of Java. S. lat. 7° 28'. E. long. 106° 36'.

WINKOP's Point, a cape on the south coast of Java. S. lat. 7° 25'. E. long. 106° 36'.

WINLATOM, a township of Durham; 6 miles W. of Newcastle.

WINNEBAGO. See Winebago.

WINNENBURG, a citadel of France, in the department of the Sarre, which heretofore gave name to a lordship within the archbishopric of Treves; 1 mile N.W. of Cochem.

WINNENDEN, a town of Wurttemberg. In the year 1693, this town was laid in ashes by the French; 12 miles E.N.E. of Stuttgart. N. lat. 48° 53'. E. long. 9° 30'.

WINNICZA, a town of Poland, in the palatinat of Braclaw; 32 miles N.N.W. of Braclaw.

WINNING of Hay, in Agriculture, a term sometimes applied to the operation of making hay in certain climates of the weather. See Hay-Making.

WINNINGE, in Geography, a river of Lancashire, which runs into the Lune, 6 miles N.E. of Lancaster.

WINNINGEN, a town of Westphalia, in the principality of Halberstadt; 4 miles N. of Anfehrleben.

WINNIPEG, or WINIFIC, a lake of Upper Louisiana, being the great reservoir of several large rivers, and supposed to be the largest of the inland seas, near the heads of the Mississipi, which discharges itself by the river Nelson into Hudson's bay. It is connected with other lakes to the N.W., and has, from the rivers entering into it, an inconsiderable portage to the waters of lake Superior. This lake is said to be 240 miles in length, and from 50 to 100 in breadth, though in some places it is hardly five. N. lat. 52° 10'. W. long. 97° 30'.

WINNIE or WINPIEG RIVER, a large body of water, interspersed with numerous islands, causing various channels, and interruptions of portages and rapids. The lake Du Bois discharges itself at both ends of an island, on which is the carrying-place out of the lake, and which is named Portage du Rat, in N. lat. 49° 37', and W. long. 94° 25', about 50 paces long, and forms this river. In some parts, the river has the appearance of lakes, with ready currents; its winding course to the Dalles is estimated at 8 miles; to the Great Decharge 253 miles, which is a long carrying-place for the goods; from thence to the Little Decharge 13 miles; to the Tunajouge Portage 24 miles; then to its galet or rocky portage, 70 yards; 25 miles to the Tun Blanc, near which is a fall of from four to five feet; 33 miles to Portage de piff, where is a trading port, and about 11 miles on the N. shore a trading establishment, which is the road, in boats, to Albany river, and from thence to Hudson's bay. There is also a communication with Lake Superior, through what is called the Nipigoes country, that enters the lake Winipeg above 55 leagues E. of the Grande Portage. Mackenzie's Voyages, &c. Introd. p. 60.

WINNIE, Little, a lake of North America, 80 miles long and 15 wide. N. lat. 52° 10'. W. long. 100° 15'.

WINNIPISOGEE, or WINNEPIKKEE, a lake of New Hampshire; 80 miles N. of Boston. N. lat. 43° 35'. W. long. 71° 18'.

WINNOW, in Agriculture, signifies to fan, or separate corn from the chaff by wind.

WINNSBOROUGH, in Geography, a town of South Carolina; 30 miles N. of Columbia. N. lat. 34° 28'. W. long. 81° 15'.

WINNY HAY, in Agriculture, a term applied to hay in some conditions of it. See Hay.

WINSCHE, or WINSCHEOTTEN, in Geography, a town of Holland, in the department of Groningen, near which the Spaniards were defeated by Louis, brother to the prince of Orange, on the 24th of May 1568. The Spaniards lost 2500 men, all their baggage, and six pieces of cannon. This was the first battle fought on account of the Revolution, and gave the prince a happy preface of success; 19 miles E. of Groningen.

WINSDER, a river of Norfolk, which runs into the Yare, 12 miles W.N.W. of Norwich.

WINSEN AER DER ALLER, a town of Westphalia, in the principality of Luneburg, on the Aller; 6 miles below Zell.

WINSER AER DER LUBE, a town of Westphalia, in the principality of Luneburg, on an island in the lake; 12 miles S.E. of Hamburg.

WINSWO, JAMES BENIGNUS, in Biography, an eminent anatomist, was born in 1669 at Odensee, in the isle of Funen, and having studied a year under Borrichius, was sent with a pension from the king of Denmark to seek improvement in the principal universities of Europe. In 1698 he became a pupil of the celebrated anatomist Duverney at Paris, and during his residence in this capital, he abjured Protestantism, and was confirmed by Boeuffet, assuming in addition to his own baptismal name that of his convert, Benignus. Haller denominates Winslow "simple and superstitious," and of course his conversion to the Catholic faith afforded no great occasion for triumph. This event, however, detached him from his family and native country, and was the means of fixing his abode in France, where the patronage of Boeuffet was highly favourable to his advancement, and served to obtain for him the degree of doctor in 1705. In 1707 Duverney recommended him to be an eleve of anatomy in the Academy of Sciences. He afterwards read lectures of anatomy and surgery for Duverney at the royal garden; and in 1743 was promoted to the professorship in this institution. In the meanwhile, he communicated several papers on anatomical and physiological subjects to the Academy of Sciences, by which body, as well as by the Royal Society of Berlin, he was admitted into the number of associates. His great work, mentioned by Haller as supereding all former compositions of anatomy, and entitled "Exposition Anatomique de la Structure du Corps Humain," first appeared at Paris in 1732, 4to. It was frequently reprinted, and translated into various languages; and is still regarded as of standard authority. Winslow planned, but never finished, a larger work, of which this was merely an abridgment, and he was also the author of disputations and treatises on particular topics. He died in 1760 at the advanced age of 91. Haller. Eloy. Gen. Biog.

WINSWO, in Geography, a market-town in the county of Buckingham, England, 63 miles from Buckingham, and 51 N.W. from London. The market, now inconsiderable, was granted in 1235 to the abbot of St. Alban's, lord of the manor,
manor, by king Offa. The manor is now the property of
William Selby, esq., who has a seat in the town. The
parish-church, a spacious structure consisting of a nave,
two aisles, a chancel, and a tower, contains no monuments
of note. According to the population return of 1811, the
houses in the parish were 223, and the inhabitants 1222.
Here is a small market on Thursdays, and five annual
fairs.—Magna Britannia, by the Rev. D. Lysons and S.
Lysons, esq. 4to. 1806.

WINSLOW, a town of the province of Maine, on the
Kennebeck, in the county of the same name, containing 658
inhabitants; 88 miles N. N.E. of Portland.

WINSTER, a small market-town in the hundred of
High Peak, and county of Derby, England, is situated 5 miles
W. by N. from Matlock, and 152 miles N. W. from
London. The manor belonged to Henry de Ferrars when
the Domeday-survey was taken. At a later period it was
held by the Mountjews, who were succeeded by the Mey-
neills. The latter sold it to the freeholders in the reign of
queen Elizabeth. The town affords nothing worthy of
particular notice. It has a chapel of ease to the parish of
Youldrove, of which Whinler forms a part; and also a
chapel for the Wesleyan Methodists. A market is held on
Saturdays, which appears to be by preemption; for there
is no grant of it on record: till lately here was an annual
fair, but it is now discontinued. The population return
of the year 1811 states Winster to contain 217 houses, and
852 inhabitants; the latter are chiefly employed in the mining
business, and in the inferior branches of the cotton trade.
On the commons, in the vicinity of the town, are several
cairns, or stone bars, and also two or three barrows of
earth: in one of the latter, which was opened in the year
1768, two glass vessels were discovered, about nine inches
in height, containing a pint of water, of a light green colour,
and very limpid. With these a silver collar or bracelet
was found, together with some small well-wrought ornaments,
several beads of glass and earth, and remains of braes claps
and hinges, with pieces of wood, that seemed to have been
brought to a box in which the ornaments had been deposited.
The antiquities induced Mr. King to suppose the barrow
to have been raved over some Briton of distinction, though
long after the Romans were in possession of the island.—
Beauties of England and Wales, vol. iii. Derbyshire; by
J. Britton and E. W. Brayley, 1803. Lysons' Magna

WINSTON, a river of the county of Lancaster, which
runs into the Ken, at its mouth.

WINTON, a town of Prussia, on the Curich Haff;
14 miles N. of Precol.

WINTERNAU, a town of the duchy of Stiria; 2 miles
S. of Marburg.

WINTER, — in Biography, a German opera com-
poser, of great abilities, who succeeded Bianchi at our
Lyric theatre in 1803; during which year he produced, in
1803-4, the music of the ballet of Achille and Deidamia,
and for Mrs. Billington's benefit.

WINTER, one of the four seasons or quarters of the
year.

Winter properly commences on the day when the sun's
distance from the zenith of the place is the greatest, and
ends on the day when its distance is at a mean between
the greatest and least.

Notwithstanding the coldness of this season, it is proved,
in astronomy, that the sun is really nearer to the earth in
winter than in summer. The reason of the decay of heat,
&c. see under Heat.

Under the equator, the winter, as well as the other se-

Vol. XXXVIII.
From the middle period of the above month, and through the following, they must also be defended from frost, in order to promote the coming bloom. Great care and attention are especially necessary for blooming the plants well from the above time in March to near the end of the succeeding month, as in this time they will most likely attain their greatest perfection and beauty. It is only necessary, as it is thought, for blooming such flower-plants in the greatest perfection, to have them continuously under glass, night and day, for about twenty-four of the last days, as they will then have their middle pips well expanded. In very strong sun they must be slightly shaded by a thin mat, but in other cafes they may be thrown open and exposed to the full free air.

After the beginning of April, as the fifth or sixth, the glasses of the frames are to be kept completely over the plants night and day, until they are in full bloom, only letting in proper supplies of air from behind the frames, and giving the shade of old thin mats when necessary. This mode is to be pursued to about the middle of this month; but the plants are not to be over-halted in their bloom by too much sun, as that may fade their fine colours; but in such cafes they must be removed from the full southern exposure to a full eastern one, though by no means yet to a northern aspect, as that would endanger their bloom; if the season be suitable, the protection of a privet-hedge, wall, or paling-fence, is the most proper, being covered by hand-glases; when about the end of the month, they may be removed to a northern exposure on flaggs, or in other proper places.

In this finishing blooming eastern exposure, all the mats and other coverings should be taken off from the glusses that are placed over the flowers, about seven o'clock in the morning, and in sunny weather the plants be shaded from about nine to twelve or one, the thin mats being then removed. The covering-glases are to be prepared by well washing, and other means.

The flowers in blooming are mostly much benefited by having a south-well exposure as much as possible, and by carefully attending to the north and north-east winds, as well as by receiving all mild moderate rains from about the beginning of February until towards the end of March. In the latter part of this time, before the trifles are too forward, and the blossoms open, three or four hours rather heavy mild rain greatly promotes the swelling of the pips, and much increases the size of the foliage, especially if care be taken immediately after it is over to flout the flowers close down, and cover them up in a warm manner, as below. Watering them from a pot with a fine rose in a warm sunny day all over the leaves in the afternoon, in the manner of rain, and directly covering them up warmly while the sun is upon them, has likewise been found beneficial. They are now, too, to be well guarded from late frosts, as they are so soon destroyed by them.

In the late winter, or early spring, night-covering, as from the middle of the above month, the following mode has been found highly beneficial, in not only repelling the cold frothy night-air, but in affilling the bloom, and preventing its being checked in any way thereby.

The heat at this period being usually from about forty-five to fifty degrees in the day-time, the flowers may be exposed to the open air in it, and in covering them in the night, be kept near to that state; which is only to be effected by an artificial covering of some fort or other, for other forts of heat do not answer the purpose; as those of the warm blanket, horse-cloth, thick-flax, and other similar kinds, laid next to the glusses, over which mats may be placed so as fully to protect the flowers, and keep the other coverings from being injured by rain or other wetness. Where wood-frames and not brick ones are used, it is also often necessary to have hay, fern, straw, or some other such material, applied on the outsides of them, to guard against the penetration of the cold frothy air, as is otherwise liable to be the case in severe scenes. But such full coverings should not be had recourse to in the winter season sooner than the middle of March, as they might not only injure the fine strong blooming plants, but counteract the good effect they are intended to have in affilling nature to gradually bloom the flowers in fine condition as the season approaches. The keeping the flowers so warm on the nights at this period of the season is supposed to prevent any check to the vegetation of the plants; and another great effect which it has, is that as soon as the pips open, they proceed vigorously, expand freely, and come out level, fine, and nearly flat; while, if they once get a complete chill by cold night air, their blossoms will not expand flat, but on the contrary, ruffle or tumbled.

In the leaves of the auricula and some other kinds of plants, there is as much variety produced by these means in the shades of their green as in the colours of their flowers. The green of the leaves, or green, as it is termed, in this sort of flower-plants, should conically be that which affords the best contrast, and has the most power in setting off the flower to which it belongs. Different varieties in the shade of the leaves also proceed from the nature of the culture and management, as well as from the raling them from feed. They have from these caules leaves with smooth even edges, with thick and flaky edges, and with thin edges. These varieties in the leaves of such plants are often of importance to the florist in different ways. In the grases or green leaves of these plants, there is likewise some variety in the mealy dull or farina which is upon them; in some the whole plant is nearly covered with it; but these with blue-flax or green leaves are commonly the most powdered with this fort of dull, which contributes not only to the beauty of the plants, but serves in some degree to prevent them from the effects of the scorching heat of the sun during the summer season.

The different other fine flower-plants are to have something of the same sort of winter-management pursued for them, only making proper allowances and distinctions, in so far as their differences in the nature of their growths or other habits are concerned.

The diversities of the auricula, as well as most other flower-plants, owe their present perfection, in a great measure, to the care, ingenuity, cultivation, and management of the florist-gardener, and some of these private individuals who cultivate flowers for the amuement and delight which they afford. By these means, this and many other sorts have been wonderfully improved, which were at first single and simple; and their variety, size, and beauty, have been increased in an astonihing manner. The sportsiveness of nature has likewise been much, as is evident in so many flower-plants; as in the daisy, ranunculus, the anemone, the fock, the wall-flower, the pink, the carnation, the Siberian larkspur, and a valt many more.

There is, indeed, something extraordinary in the great and uncommon divery of the colours, and the differences of the shades and hues of this as well as some other flowers; and it is not left singular or true that out of more than an hundred flowers of this sort, which are raised from seed in this way, there will not, perhaps, be two which are exactly alike; and that yet, in all these deviations, the changes take place in the most naturally pleasing, agreeable, and unthought-of manner possible.

By
WIN

By attention to proper winter and other management, till
more diversity and variety may most probably be produced
in this and different other flowers.

Winter, among Printers, that part of the printing-
pref, serving to sustain the carriages &c. See Printing-
Pref.

Winter's-Bark, Cortex Winteri, or Winteranus,
Wintera Aromatica; which see. See Cortex

This is one of the largest forest-trees upon Terra del
Fuego, often rising to the height of fifty feet. Dr. Solomon
has given an accurate botanical description of it, illus-
trated by a figure, in Med. Obs. and Inq. vol. v. p. 46,
&c. Its leaves are ever-green, smooth, oval, and entire; its
flowers consist of seven petals, from fifteen to thirty
filaments, and from three to five seeds, terminating in
as many stigmas; each germ becomes a feed-veffel,
containing several seeds: the bark of the trunk of the tree
is externally grey, and very little wrinkled. The pieces of
this bark brought over by the Dolphin are about three or
four inches square, of different degrees of thickness, from
one-fourth to three-fourths of an inch. It is of a dark
brown cinnamon colour, an aromatic smell if rubbed, and
of a hot, pungent, spicy taste, which is lailing on the palate,
though imparted flightly. A watery infusion of it, turk a
black colour with a solution of green vitriol. An infusion
of two ounces, coarsely powdered, yielded on evaporation
two drachms and twenty-four grains of extract: the fame
quantity, with rectified spirit, afforded two drachms of
extract.

This bark, though much celebrated as an antiscorbutic
by the first discoverers, is unknown in the practice of phy-
sic; the canella alba, (see Cannela,) which is totally dif-
ferent from it, having been confounded with it in the shops;
and no quantity having been brought to Europe, except as a
curiosity, till the return of the ships lent out on an expedi-
tion to the South seas. It has been thought to be a useful
antiscorbutic; but it seems to pollute in this respect no ad-
antage over the other pungent aromatics, and it is now
generally superceded by the canella alba.

From some experiments on this bark by Dr. Morris, it
appears to be an astringent of a particular kind, and there-
fore likely to be of use in several manufactures; and that
water is the proper disolving of it.

It is hoped that this tree, no less useful than elegant,
may be cultivated in our country, where it would probably
grow luxuriantly, as in a much warmer region than its own,
and furnish, not only a valuable ever-green, bearing our fe-
verlest winters, but also a valuable medicine. Med. Observ.
ubisupra.

Winter-Barley, in Agriculture, a term applied to an ex-
cellent fort, which is put into the ground in the autumn,
and which flands the winter. It is found by some farmers
to be very productive in its nature, and when made into
malt to form a much stronger fort than that which is pro-
duced from common barley.

In some districts, it is a good deal sown and cultivated as
an early sheep-feed, in which intention it often answers very
well. See Barley.

Winter-Berry. See Prinos.

Winter-Bloom. See Azalea.

Winter-Cherry. See Physalis Alkekengi.

Winter-Creffs. See Erysimum Barbarea.

Winter-Crops, in Agriculture, a term used to signify all
such as are put into the soil to grow or rife at that time of
the year, which are capable of withstanding that severe sea-
fon, or which can be converted to the purpose of fodder for
animals at that inclement and neccllous period.

Winter-Fallow. See Fallow.

Winter-Garden, a term often applied to that kind of
ornamental garden which is chiefly for use and amuement
at that season of the year. It has been advised by Mr.
Loudon, that a winter-garden should contain all such trees,
brubs, plants, and other vegetable productions, as are in a
state of perfection, or retaining their beauty and verdure, at
and during this season, in the most complete manner; as
most of the ever-green tribe or class of trees and shrubs,
many flowering plants, as the acorn, snow-drop, Chrift-
mas-rose, and several others of similar kinds; that these
should be grouped and arranged in the natural manner in
such garden-grounds; and that a dry gravel or other similar
kind of walk should be conducted throughout, or carried
round about the whole, in the view of being walked upon at
this season without inconvenience; that these forts of
gardens should be situated near the mansion or residence,
in order that they may be comfortably and conveniently ap-
proached in the different winter months; and that the con-
servatory too, as well as some other such houses, should be
placed in them.

Winter-Green, in Botany. See Pyrola.

The greater round-leaved winter-green, or pyrola rotundi-
folia major, is generally brought over from Switzerland
with other vulnerary plants, in which clafs it is ranged, and by
some greatly commended. Miller

Winter-Green, Ivy-flowering. See Kalmia.

Winter-Green, with Chickweed Flowers. See Trien-
talis.

Winter-Haying, in our Statutes, a season between the
eleventh day of November, and the three-and-twentyth
of April, which is excepted from the liberty of commoning
in the forset of Dean, &c. Stat. 20 Car. II. cap. 3.
Blount.

Winter-Pears, in Gardening, such as will keep, and are
ready for use in that season. It has been suggested in a
paper in the second volume of the "Memoirs of the Cale-
donian Horticultural Society," that in the cultivation of
pears of this fort, thofe of the pyrif-bearing sorts should be
carefully avoided; that they should be suited as much as
possible to the nature of the climate or region where they
are to be grown; that they should have their situation in
a proper exposiure, and in a proper foil; that they should
be well pruned, trained, and managed, in all other repreffes;
that thofe kinds which can be most depended on be had
recourfe to; that new varieties may probably be railed
from seed with advantage in this view; and that endeavours
should be made to bring into use any good late forts of this
fruit.

The number of winter-pears in the northern parts of this
island are supposed to be scanty indeed. That if the few
that have been favourably spoken of by fome cannot be
had, there are not, it is believed, above five more to be
depended on in thefe situations; which are thofe, the fwan-
egg, achans, brier-bufli, the John Monteth, and to which may
be added the muifowf-egg, which keeps there much longer
than the fwan-egg, and muft be allowed to be a winter-pear,
though commonly let down as an autumn fruit. The fwan-
egg has there, it is faid, never kept good longer than the
end of November, while the muifowf has fometimes re-
mained in good prefervation until towards the end of April.
In the then heat feafon they were taken from the tree, it is
faid, sooner than ufual; confentually were earlier ripe or
fit to eate, and of course have decayed more speedily, than
ordinary. They were, however, perfectly good until to-
wards the end of January in the following year, after which
they spoileil in a very fudden manner. The muifowf-egg
may
may also, however, with great safety, be allowed to remain
on the tree ten or twelve days longer than the swan-egg; the
leaves of the latter, too, fall, it is said, much sooner than
those of the former.

On walls, in different proper aspects, the following sorts
of winter-pears have, it is said, been recommended to be
planted: the creffane, the colmar, the boncretien d’hiver, the
chaumontelle, and some others, which are certainly excel-

1

lent pears, but that some of them are fly-bearers, and
others do not ripen well in these parts, except in the most
favourable situations. Some have found the four following
sorts particularly useful on walls, especially in high situ-
ations in those northern parts of the country where the
other finer sorts do not ripen in a proper manner: the green
yair, mulirovell-eggs, swan-egg, and winter achen. But it is
noticed, that the second and the last of these sorts of
pears, when planted as standards, produce not only better
crops, but fruit of a higher flavour. Many other sorts are
mentioned by different writers as very good winter-pears
for the purpose of cultivation in these and other places; as
may be seen in the above useful paper.

Winter-Proud, in Agriculture, a term applied provin-
cially to such winter-wheat, or other crop, as puts on a
more green and luxuriant growth and appearance than it is
able to maintain and support in the following summer sea-
son; or in which the tillering shoots, branches, or rami-fi-
cations of the feed-grain, become too numerous to be nu-
rished and brought to maturity in consequence of the pre-
vious over-exertion of the soil or land. In these cases, the
crops decline during the spring and summer months, and at
the harvest time yield imperfectly, falling much below the
quantity afforded by such crops as had a more backward
appearance in the winter season.

It is of course always of advantage to have these sorts of
crops in rather a backward state in the winter period of the
year.

Winter-Quarters. See Quarters.

Winter-Rig, among Hudsonians, signifies to fallow or
tilt the land in winter.

Winter-Solstice. See Solstice.

WINTER, in Botany, is so called in memory of the
companions of Sir Francis Drake, Captain William Winter,
who brought the bark, of the first species, from the islets
of Magellan in 1579, and introduced it to the knowledge
of European physicians, as a valuable tonic, more espe-
cially useful in the scurvy. Linnaeus, meaning to commemorate
this discovery, established a genus by the name of Winteranora,
G. Pl. 238, the bark of which he conceived to be what
Captain Winter introduced. But the Linnaean plant is the
Canella alba, to the fructification of which alone the de-
scription applies. Browne had already founded this genus,
by the name of Canella, (see that article,) and Swartz, as
well as Murray, have confirmed it. Meanwhile Forster,
having found and investigated the fructification of the
Winter’s-bark tree, described it by the name of Drimys,
alluding to its hot and pungent flavour. This is retained
by the younger Linnaeus in his Supplementum, with a remark
properly distinguishing it from the Canella alba, though his
father, like prof. Bergius, Nat. Med. v. 1. 381, had con-

1

founded them. Finally Murray, in Linn. Syll. Veg. ed. 14,
aware of these various errors and misconceptions, very pro-
curly establishes Browne’s genus, by its right denomination,
Canella, and restores Winter’s name to the plant to which it
properly belongs, and with which Linnaeus intended to asso-
ciate it. Murray, however, prefers Wintera to Winteranora,
which is the more judicious, as his genus is not really the
Winteranora of Linnaeus. The name he has chosen is now,
extexcept by an accidental mistake of De Candolle in chronol-
ogy, universally adopted. Perhaps Winteria would have
been better; but we refrain from embroiling the subject
with any further alteration, of what has received the func-
tion of such men as Murray and Schreber. — Murr. in Linn.

Gen. Ch. Cal. Perianth inferior, of one leaf, splitting
into two or three segments. Cor. Petals six, or more,
oveate, spreading. Stam. Filaments numerous, shorter
than the corolla, dilated upwards; anthers terminal, of two
lateral ovate cells, separate at the base, converging at
their points. Pist. Germenis four to eight, crowded, obovate;
styles none; stigmas defrrept, flat. Peric. Berries four to
eight, ovate, somewhat triangular. Seeds several, dispor-
ed in two rows.

Stamens club-shaped, with terminal two-lobed anthers.
Styles none. Berries superior, aggregate. Seeds several,
in a double row.

Obst. Willdenow copies what we suspect may be a
casual error of the younger Linnæus, germina clarvalis, for
flamina clarvalis. De Candolle, who describes two new
species, first gave a correct account of the arrangement of
the seeds, an important circumstance in this natural order.
His observations, confirming those of Linnæus, showed the
petals to be indeterminate in number. Possibly the line is
not drawn distinctly between them and the Flamina, of which
Nymphaea affords another instance, so that an inner series
of smaller petals may occasionally occur.

t. 7. Comm. Goett. v. 9. 34. 7. Soland. in Med. Obf.
(Drimys Winteri; Forst. Act. Upf. v. 3. 381. Linn.
Suppl. 269. Winteranorus cortex; Ch. Exot. 75. Dale
Pharmac. 324. Laurisæa magellanica, cortice acri;
Bauh. Pl. 461. “Periclymenum rectum, folis laurinus,
cortex aromatico acri; Solane in Phil. Trans. v. 17.
923. t. 1. f. 1.”)—Leaves elliptical, obtuse, coriaceous.
Flowers flanks aggregate, terminal. Pedils about four. —Native
of the country on both sides of the islets of Magellan, in
valleys exposed to the sun, where it was first observed by
Captain Winter, and has since been found by several follow-
ing navigators, but no one has brought living plants or
seeds to Europe. This is a tree of considerable size, often
50 feet high, with twisted knotty branches, and a thick rugged
bark, of an aromatic smell, and pungent permanent flavour.
This bark is not much used in practice at present, there being
many drugs of equal, or superior, powers; as the Canella alba,
which has taken its place, and caused the botanical mistake
above-mentioned. (See Winter’s Bark.) The leaves are al-
ternate, crowded about the ends of the branches, ever-green,
two or three inches long, and one a half wide, thick and
rigid, entire, somewhat revolute, with a flout midrib, and
scarcely visible veins, very smooth on both sides; somewhat
glaucescent, but not invariably or permanently so, beneath.
Flowers flanks broad and thick, smooth, half or three-quarters
of an inch long. Stipules none. Flowers flanks at the ends of
the branches, two or three together, simple or three-clft,
smooth, not half the length of the leaves, accompanied at

1

their base by several ovate, pale, deciduous bracteas. Flowers

smaller
smaller than a hawthorn blossom, white. *Calyx* reddish, unequally three-lobed. *Berries* from three to five, each with four triangular *seeds*. By the above synonyms to this species it appears, that even G. Forster, who with his father established the genus and unexceptionable name of *Drimys* Long. gave way to those eminent botanists who wished to retain the memory of the original discoverer. Indeed the name of Winter may claim even a right of priority, though a mistake attended its commemoration and publication by Linnæus, in his *Gen. Pl.* We trust our amiable friend M. De Candolle will forgive our not joining with him, in overturning what has been finally settled, with the approbation of all the world. If chronology is to be our absolute guide, without attention to sense, or expediency, the nomenclature of botany must relapse into its primitive barbarism, and in this case Baudin's name *Laurifolia* should have been adopted. Even on this ground, weak as it is, we can however defend the name we have retained; for Clusius's *Winteranus cortus*, erroneously printed *Cortex Winteranus* by De Candolle, may be considered as the first commemoration of captain Winter, being the first publication of any thing relating to the genus in question.

Sent by Mutis from New Granada. It grows on the most lofty mountains of that country, Quito, &c. The tree is 18 or 20 feet high, with round branches, more straitly, and less rugged, than the foregoing. *Leaves* four or five inches long, and near one inch and a half broad, obtuse, not acute, scarcely revolute, perfectly smooth; very glaucous beneath, like those of *Magnolia glauca*, the longer-leaved variety of which they greatly resemble. *Flower-flasks* smooth, an inch long. *Flower-flasks* sometimes nearly the length of the leaf, always half as long, simple, divided, or three-cleft. *Flowers* twice the fivesize of *W. aromatica*, with about 12 petals, and a deeply three-cleft *calyx*. *Petals* six or eight, oblate, sometimes confluent, each with from four to six *seeds*. The *bark* is aromatic, like the former. The younger Linnæus imagined this to be a variety of that specie, caused by a warmer climate. They are indeed more nearly related than appears at first sight, and yet we can scarcely think they belong to one species, though well aware that the leaves, in this natural order, are liable to vary considerably in shape; witness the *Magnolia* just mentioned, if more than one species be not confounded under that name.

3. *W. chilenensis*. Chili Winter's-bark. (Drimys chilenensis; *De Cand.* n. 4.) *Leaves* oblong-obovate; glaucous beneath. *Flower-flasks* either aggregate or compound, axillary. *Petals* five or six.—Gathered by Dombey, in marshy situations in Chili. A tall *furb*, with a very aromatic bark, and round branches. *Leaves* nearly obvate, coriaceous, very smooth, tapering at the base, on short *flasks*, resembling the foliage of *Magnolia glauca*. *Flower-flasks* axillary; sometimes very short, bearing an umbel of four or five elongated simple *flasks*; sometimes four or five simple ones all together, each an inch long, at most, single-flowered. *Calyx* in two or three ovate blunt divisions, not foon decidiuous, and perhaps lasting till the fruit is ripe. *Petals* fix to nine, oblong, bluntish; twice the length of the *calyx*. *Stamens* very short. *Germens* five or fix, ovate, crowded, on a small globose receptacle. *Berries* oval, rather compressed, obtuse. *De Candolle.*

5. *W. xillaris*. Small-flowered Winter's-bark. *Forrt.* *Prod.* 42. *Wildl.* n. 3. *Mart.* n. 3. (Drimys xillaris; *Linn. Suppl.* 270. *Forrt.* *Act.* *Upl.* v. 3. 185. 186. *De Cand.* n. 1. *Lamarck* f. 2. *Linn.* n. 3. *De Cand.* n. 3. *Lamarck* f. 3. — *Leaves* obvate, pointed, reticulated with veins. *Flower-flasks* simple, aggregate, thread-shaped. *Calyx* oribicular, lobed, reflexed. — Native of woods in New Zealand. A tree, with round branches, rough to the touch, but not spiny. *Leaves* on *flanks* rather above half an inch long, broadly obvate, tapering to a bluntish point, smooth, more than half, and membranous than in any of the other species, coarsely reticulated with innumerable veins, not observable in any of those; their length three or four inches, breadth two; their under side glaucous when young only. *Flower-flasks* two or three together, feldom foliating, from the blemishes of most of the leaves, simple, very slender, each bearing a small green flower. *Calyx* dicotyled, four reflexed, about a line broad, splitting into two principal, and two smaller, lobes, not differing in any particular respect from the divisions of the calyx of the other species, thoughForster's figure has misled *De Candolle* to suppose otherwise. *Petals* six, oblong, flat, equal, four times the length of the *calyx*. *Stamens* about sixteen. *Germens* four, turbinate, all perfectly and evidently distinct, in the numerous flowers of the *Linnæan* specie; so that Forster might well wonder how the younger Linnæus, who had this very speciem before him, could make a "solitary pilum" a part of the specific character. *Stigmas* dilated, petalate, terminal. *Berries* four, globose, black, with a tawny pulp, lodging four *ovate*, acute, somewhat triangular, gibbous *seeds*. The flavour of the whole plant, especially of the bark, is extremely acrid and pungent. *G. Forster.*

WINERANA. See CANELLA, and WINTERA supr.

WINTERBERG, in Geography, a town of the duchy of Welfphalia; 37 miles S. of Paderborn. N. lat. 51° 11'. E. long. 8° 39'.

Winterberg, or Winberg, a town of Bohemia, in the circle of Prachatitz; 10 miles W. of Prachatitz. N. lat. 49° 2'. E. long. 13° 39'.

WINTERBURG, a town of France, in the department of the Rhine and Mofelle; 10 miles W.N.W. of Creutznach.

WINTERHAM, a place in Virginia, where black-lead is found: 30 miles N. of Richmond.

WINTERHAUSEN, a town of the duchy of Wurzburg, on the Main; 4 miles S. of Wurzburg.

WINTERINGHAM, a town of England, in the county of Lincoln; 166 miles N. of London.

WINTERTHUR, a town of Switzerland, in the canton of Zurich. This was formerly an imperial town. In the year 1467, it was mortgaged to the canton of Zurich, and by subsequent treaties entirely ceded, since which Winterthur
“Win” has acknowledged Zurich for its sovereign. It is governed, however, by a magistracy and police of its own. The government is aristocratical; the supreme power, in all things not interfering with the claims of Zurich, reposing in the Great and Little council, in all criminal proceedings these two tribunals unite, and pass sentence of death without appeal. In civil causes, an appeal lies from the Little to the Great council. In all cases respect for the burghers, appeals may be carried from the town-court to the council of magistracy, and no farther; but if either of the parties be a foreigner, an appeal lies from the council to the Senate of Zurich. A bailiff from this latter place likewise resides here, but without any authority over the town, excepting that of affixing at the ceremony of an annual homage paid to Zurich by the burghers on St. Alban's day. In case of a war, Winterthur furnishes Zurich with 200 men, either burghers or dependants, but to serve under its own arms. Except in the articles of silk manufacture, and the establishment of a printing-press for profit to Zurich, the commerce of Winterthur is under no restraint. The principal manufactures are, muslin, printed cottons, and cloth; it has some vitriol works; and the earthen-ware made here, particularly the white, together with its painted flores, are in great repute for their beauty and durability. The town is small, and the inhabitants, who are about 2000, are very industrious. The schools are well endowed and regulated. Ober Winterthur, or Upper Winterthur, is a small village near the town, on the high road leading to Frauenfeld, on the site of the ancient Vitodurum, which was a Roman station. Here are found the foundations of ancient walls and numerous Roman coins and medals. The castle of Kyburg, seated on an eminence overlooking Winterthur, is a picturesque object; 14 miles N.E. of Zurich.

WINTERTON, a town of England, in Lincolnshire; 9 miles N.N.W. of Granford. Also, a town of England, in the county of Norfolk, near the coast. The market is discontinued; 7 miles N. of Yarmouth.

WINTON, a town of Norfolk, on the coast of the county of Norfolk, on which is a light-house; 10 miles N. of Yarmouth. N. lat. 52° 44'. E. long. 1° 41'.

WINTFELDEN, a town of France, in the department of the Upper Rhine; 10 miles S.W. of Colmar.

WINTHYG, a town of Austria; 6 miles N.E. of Freyßtadt.

WINHROPE, a poth-town of the province of Maine, in the county of Kennebec, with 1444 inhabitants; 57 miles N. of Portland.

WINHROPE’S Bay, a bay on the N. coast of Antigua.

WINTON, a county of United America, in the state of South Carolina.—Also, a poth-town of North Carolina; 30 miles E. of Halifax.

WINTONIÆ ROTALUS. See Rotulus.

WINTZENBERG, in Geography, a town of Silesia, in the principality of Neisse; 5 miles S.E. of Grotkau.

WINTZENHEIM, a town of France, in the department of the Upper Rhine; 3 miles W. of Colmar.

WINTZIG, a town of Silesia, in the principality of Wohlt; 9 miles E.N.E. of Steinau. N. lat. 51° 27'. E. long. 15° 36'.

WINWEILER, a town of France, in the department of Mont Tonnerre; 24 miles N.E. of Deux Ponts.

WINWOOD, Sir Ralph, in Biography, a statesman in the reign of James I., was born at Aynho in Northampton-shire, about the year 1564, educated at St. John’s college, Oxford, and having passed through several stages of preferment, was chosen proctor of the university in 1592. After having sustained several diplomatic characters and millions, he was made secretary of state in 1614, which office he occupied till his death in 1617. “He was married, and left one son. Sir Ralph was an accomplished gentleman, well acquainted with business, and particularly conversant with commercial and military affairs.” A work, intitled “Memorials of Affairs of State in the Reign of Queen Elizabeth and King James I.,” collected chiefly from the Original Papers of the Right Honourable Sir Ralph Winwood, Knt. &c. &c.” was published in 1725 by Edmund Sawyer, esq. in 3 vols. fol., and contained a valuable record of the political transactions of those times. Biog. Brit.

WINYAH, in Geography, a county of South Carolina.

WINZAAR HARBOUR, a bay on the coast of South Carolina, a little to the N. of the mouth of the Santee. N. lat. 33° 12'.

WINZER, a town of Bavaria, on the Danube; 9 miles S.S.E. of Deckendorf.

WIOCHIST, among the Indian Natives of Virginia, is their priest, who is also generally their physician; and is the perfon in the greatest honour amongst them, next to their king, or great war-captaing. Phil. Tranf. N° 1545.

WIOGRODEK, in Geography, a town of Poland, in Volhynia; 14 miles E.S.E. of Kreminiek.

WIP, a town of Pruffia, on the Curich Haff; 23 miles S.W. of Tiltit.

WIPACH, a town of the duchy of Carniola; 5 miles S. of Hydra.

WIPE, a town of Prussia, in the province of Smaland; 28 miles N.E. of Königberg.—Also, a river of Prussia, which runs into the Curich Haff, 10 miles E.N.E. of Labian.

WIPFELN, a town of the duchy of Wurzburg; 5 miles N.N.W. of Volckach.

WIPPELSPACH, a town of the duchy of Storia; 17 miles S.W. of Voitberg.

WIPPER, a river of Germany, which rises in the county of Mark, about 6 miles S.S.W. of Lunfchede, passes by Wipperfart, Elberfeld, Solingen, &c. &c. and runs into the Rhine, between Cologne and Zons.—Also, a river of Thuringia, which rises 2 miles N. of Dingelstadt, and runs into the Unfrutt, 4 miles N.E. of Kindelbracken.—Also, a river of Pomerania, which runs into the Baltic below Rugerwalde.—Also, a river of Saxony, which runs into the Saal, near Bernberg.

WIPPERAU, a river of Wesphalia, which runs into the Ilmeneau, near Ulten.

WIPPERFURT, a town of the duchy of Berg; 27 miles S.E. of Duffeldorf. N. lat. 51° 5'. E. long. 7° 27'.

WIPPINGEN, a town of Switzerland, in the canton of Friburg; 12 miles S.S.W. of Friburg.

WIPPRA, a town of Wesphalia, in the country of Mansfeld, on the Wipper; 10 miles W.N.W. of Eiflzeben. N. lat. 51° 30'. E. long. 11° 30'.

WIRGEN, a town of Wesphalia, late in the Old Mark of Brandenburg, on the left side of the Elbe; 12 miles N. of Stendal.

WIRENTHAL. See WURTENTHAL.

WIRDOIS, a town of Sweden, in North Finland; 65 miles N.N.E. of Birnberg.

WIRE, in the Mechanic Arts, is a very useful preparation of different metals, in form of a regular and even thread, which can be obtained in very great lengths, and of any required size or shape. Wire is made of any ductile metal, as platinum, gold, silver, copper, brass, zinc, iron, or steel. The process of making wire
wire collides in drawing the piece of metal through a hole in a plate of steel, by which means the metal is rendered of an equal size, and either round or of any other figure corresponding with the figure of the hole in the draw-plate; the metal is thus reduced in size, and at the same time is lengthened in proportion. From the great regularity of wire, and from its toughness and ductility, it is extremely useful to all artificers who work in metal.

The operation is called wire-drawing, and the plate of steel a draw-plate. The machine by which the wire is drawn is called a draw-bench.

The common draw-bench is of a simple structure. A strong plank of wood is fixed on legs, like a floor or bench, fig. 1. Plate Wire. At one end is a roller or axis, A, fixed in a horizontal position, so that it can be turned round by means of four levers, B B, fixed like radii on the end of the axis of the roller. If the resistance is great, the workman applies both his hands and his feet to the levers, to turn them round in the same manner as for a rolling-press. It is usual to have a strong flat, or chain, C, to wrap and wind up round the roller; and at the end of it a pair of pincers, D, are linked; these take hold of the end of the piece of metal, and draw it through the hole in the draw-plate E, which is lodged against two strong iron pins, a a, fixed in the bench, and standing up perpendicularly, so that the plate bears against them.

The pincers are shown in fig. 2. They are adapted to bite the end of the wire; and the inside of the jaws, d d, are cut with teeth like a file, so that they may hold the metal very tight. The opposite ends of the handles are bent in form of hooks at e e; and a triangular link of iron j, which is fastened to the end of the flat or chain C, embraces both hooks e e, and from its triangular figure, it tends to approach the two hooks at the ends of the tongs together; by these means, the strain of drawing the wire closes the pincers, and makes them bite more forcibly in proportion as the wire makes a greater resistance, so that they rarely let the wire slip.

The draw-plate, figs. 3 and 4, is a thick plate of steel, with holes made through it of various sizes, and in a regular gradation from the largest to the smallest. The holes are made large on that side where the wire enters, and they diminish with a regular taper to the other side; the goodnefs of the draw-plate is an object of the first importance. The different holes must diminish by very small gradations, or there will be danger of breaking the wire by forcing it too much at once.

In some draw-benches a rack and pinion are employed, instead of a flat or chain; and a train of wheel-work may be used like that of a crane to obtain a sufficient power. (See fig. 5.) If the workman turns the machine by a winch or handle, it is preferable to four levers, because the motion is more regular; this is of importance for some purposes. Suppose a piece of elastic metal is forcibly drawn through a hole in a plate with a tolerably quick motion, it will be compressed at the moment of passing through the hole; but after it quits the hole, the metal will expand a little. When it is drawn very forcibly, this effect will not take place; for if the compression is continued long enough it becomes permanent: hence, if a piece of large wire be drawn with an irregular motion, first quicker, and then slower, it will be feebly larger at all the parts which pass quickly through the hole, and smaller where it is drawn slowly: if the motion is continued for a few seconds, that part of the wire which remains in the hole will have a ring or indentation round it. This is most obvious in drawing hollow tubes, or copper-wire, which is plated over with gold or silver.

In the machine which is used for drawing strong pieces of metal, and for the very largest, the roller is usually placed in a vertical position, like a capstan, with four levers, at which several men pull, whilst they walk round in a circle to turn the capstan, and wind up the chain which draws the wire through the draw-plate.

A powerful machine of this kind is described in our article Press, for drawing lead-plate through a steel plate.

We have seen a very powerful wire-drawing machine used for forming large hollow tubes of brails or copper, on which the power to draw the tube was obtained by a screw, like that of a press. This power was turned by a train of wheel-work, with a fly-wheel to regulate the motion.

Another plan, which is perhaps the best mode for a very powerful drawing-machine, is to apply the force of the hydrostatic machine originally invented by Pafcal, and revived by the late Mr. Bramah. (See Machine, and Press.) By this means, very large wires for piilion-rods of steam-engines, and other similar pieces, may be rendered straight and true with little expense.

All these machines are confined to draw pieces of metal, which are only a few feet in length, that is, the length of the bench. But when the metal by repeated drawing becomes lengthened into a regular wire, if it is required to reduce it to a still smaller size, it must be drawn through succeeding plates, by wrapping the wire itself upon the roller or barre1, instead of employing a long chain. This method is not applicable at first, because a thick bar of iron could not be made to bend easily round a roller; but when the wire becomes small and flexible, it can be worked very advantageously, and admits of drawing a very great length of wire by a small and commodious machine.

The common wire-mills used in France do not, however, employ a roller or windlass, but the pincers are attached to a lever, which draws them backwards and forwards alternately by the power of the water-wheel.

The pincers are so constructed, that the jaws open when they move towards the draw-plate, and reduce themselves from the wire; but when the pincers are drawn back from the draw-plate, the link causes the pincers to close and bite the wire with such force, that they will draw it through the plate.

A machine of this kind is shown in fig. 7, of the plate. The base of the machine is a very strong log of timber R; one end of it is cut open to receive a wooden lever A B, which moves round an iron pin or bolt a, as a centre of motion; this lever is shaped like the letter L. To the upright arm A of this lever, an iron link C is jointed, and the other end of this link is formed like a ring, to receive the handles of the pincers D. The pincers are supported upon a plate of iron d, which is placed in an inclined position, and there is a groove in the plate, into which the end of the pin or joint of the pincers is received, and they are by that means guided in their motion backwards and forwards: a a are the pins which support the draw-plate E; there are four of them, and the plate is fastened between them by wedges.

The end B of the lever is operated upon by cogs fixed on the axis of the water-wheel, which, as it turns round, depresses the end B of the lever; and the end A pulls the pincers back, and draws the wire through the draw-plate; but when the cogs quit the end of the lever, it is raised by means of a rope fastened to the end of B, and going up to a strong wooden pole fixed on the roof of the building; and it acts as a spring. When the pincers return, they open to release the wire, and slide down the inclined plane d by their own weight, till they are near the draw-plate; the wire being all the time included between the jaws, though
WIRE.

they do not bite. The next cog which seizes the end of the lever draws back the pincers, which immediately close upon the wire, and draw it through the plate.

A wire-mill usually contains three such machines of different sizes; the largest only draws two inches of the wire at each stroke, and makes about forty-eight strokes in a minute; the second machine, four inches; and the third, five inches. This works quicker than the other two, and makes sixty-four strokes per minute. This is a simple machine, but very defective, for much time is lost in the returning of the pincers; they sometimes fail to take good hold of the wire, and they always make deep marks upon the wire at every place where they bite, which are not more than two inches distance in the great wire, and five inches in the smaller.

Fine wire is always made from large wire, by reducing it and lengthening it out by repeated drawings. The large wire is usually manufactured at the wire-mills in the country, and some part of it is reduced to small wire at the same establishments, but more commonly the large wire is bought by those who have occasion for it, and they reduce it by drawing until it becomes as small as it is wanted.

The hand-machine for this purpose, represented in fig. 8, is extremely simple. A is the roller on which the wire is wound up; it turns round upon a vertical pin, fixed in the bench B, and to the upper end a handle C is fixed, for the workman to turn it round; D is the draw-plate, and E is the pin against which it rests. The wire which is to be drawn is put upon a small circular reel F, which turns round upon a vertical pin; this pin is sometimes fixed in the table, or otherwise in a small cask containing flux-water, or beer which has become acid. The use of this is to loosen the oxide from the surface of the wire, for it is necessary to anneal or soften the wire very frequently, by putting it in the fire, and this produces a black coat of oxide on the surface, which will be removed when the wire is again drawn through the plate, and the wire will come out bright and clean. The removal of this oxide will be facilitated by some slightly corrosive menstruum.

Fig. 9. is a very simple and complete wire-drawing machine, to draw three wires at once. A is two rollers or barrels with cog-wheels, TV, on the ends of their axis, which wheels are engaged together. S is a pinion, which is turned round by means of a handle B, and gives motion to the wheels TV. Both these wheels are fitted upon round parts of the axis of their respective rollers, so as to slip or turn freely round upon the same; but a square is formed on the axis outside of the wheel, and a clutch or catch, t or v, is fitted upon this square part, so as to turn always round with the axis. The catch is at liberty to slide upon the axis in the direction of its length, by means of a lever W, which operates upon both catches at once. When either of them is pushed back in contact with the wheel, it intercepts two studds which project from the face of the wheel, and then compels the axis and roller to turn round with the wheel; but when the catch is drawn away from the wheel, then the wheel will slip round upon its axis, without communicating any motion. By means of the lever W, only one wheel can be engaged at once, and the other must be free. The draw-plate E is firmly fixed between the two rollers, and it has a great many holes; the rollers are long enough to receive three wires at the same time. Each roller has a groove in it parallel to the axis, into which a bar of metal is fitted, and will exactly fill it up. When the wires are introduced through the holes in the plate, the ends are laid across this groove; the bar is then put in and fastened by a simple contrivance, and it fastens the ends of the wires beneath it, so that they become attached to the roller; then by turning the handle B round, the two wheels are put in motion in contrary directions; and that wheel which is connected with its axle by its catch, will turn its barrel round, and wind up the wires so as to draw them through the plate E. The other roller being at the same time detached, its wheel is at liberty to turn round in a contrary direction to the wheel, as fast as the wire is drawn off from it. When the whole length of the wires has been drawn through the plate, they are detached from the roller, the ends introduced through smaller holes in the plate, and fastened again to the roller; then the lever W is shifted, to diflodge that wheel which operated before, and engage the other. This being done, the rollers will be turned in an opposite direction, and will wind back the wires, although the handle B is turned the same way round.

After the wire has been thus drawn three or four times, the metal becomes so hard and fibrous, that it would not draw any more without breaking; it therefore requires to be heated in the fire to restore its ductility; for this purpose it must be taken off the barrels. A roller M is provided to wind the wire upon and draw it off from the barrel; this roller is turned round by a handle m, fixed on the extremity of its axis; and the wire which is wound upon it in a coil is clipped off sidewise. This machine is well adapted to be worked by a mill, because the handle may always be turned the same way.

Fig. 10 represents the machine used at the wire-mills for reducing the wire which is to be used for musical instruments, or for making cards for wool and cotton. The rollers A are situated in a vertical position, being fitted on the tops of iron spindles, which are fastened in a vertical position by bearings in the frame of the table or bench. These spindles are kept in continual motion by wheel-work situated beneath the bench, but the spindles are round, so that the rollers A are not turned with the spindles, unless any one of the rollers is lifted up upon the spindle. A crossthread, which is fixed on the top of the spindle, then engages with two projecting knobs fixed in the roller, within a hollow receptacle made at the top of it, and turns the roller round. The draw-plate E is supported by two pins, as before described; and the wire which is to be drawn is wound on a reel, which is put into a cask of flux-water, or beer. The end of the wire, which is put through the draw-plate, is made fast to the roller, which does not turn round as long as it is dropped down upon the spindle; but when all is ready to begin drawing, the roller must be lifted up, and the clutch at the top of the spindle will engage with the two knobs within the hollow at the top of the roller. This puts it in motion, and draws the wire through the draw-plate. The strain of drawing is sufficient to keep the roller up upon the spindle; but as soon as the whole of the wire is drawn through the plate, the resistance ceases, and the roller drops down on its spindle, and becomes disengaged until the workman puts it again in action.

Manufacture of Iron Wire.—Iron is a very ductile metal, but requires a careful treatment in the process of wire-drawing, because it becomes very hard and brittle when the fibres are greatly compressed by repeated drawing. Its ductility must then be restored by heating the wire to redness; this is called annealing; it renders the wire soft, and it will then draw finer and longer; but it will soon require annealing again, and so on.

The iron which is selected for wire-drawing must be of good quality, to bear the requisite extension without breaking. It must be of an uniform substance, without any grains of
WIRE.

of hard or soft parts. The softest iron is not always found
the best, as it will diminish by the strain of drawing it
through the holes alone: and to obviate this, the workman
must draw such iron through a greater number of holes to
obtain the required extension.

The iron is wrought at the tilt-mills from square bars
into round rods of a proper size to commence drawing.
The operation of tilting is nearly the same as tilting of steel.
See that article.) The tilt-hammer for a wire-work
generally makes twenty strokes per minute, and weighs
about fifty pounds. There is also a larger hammer worked
by the same mill, which strikes about 130 times per minute,
and weighs 100 pounds. This hammer is only used for the
first preparation of the iron, or for welding a faggot of
malls together, in order to give the iron a better quality
by a preparation similar to the German steel. To
draw out the iron bars into rods of a proper size to begin
drawing, the workman heats five or eight inches of the end
of a large bar, which comes from the great forge where the
iron is made, and when properly heated he works it regu-
larly under the small tilt, until it is drawn out to a small
and regular round rod of five or six feet in length. A
good workman can thus draw out two hundred weight of
iron in a day, or an ordinary workman one and a half
hundred weight. The loss of metal in the operation is near
6 per cent. by weight.

The small rod, before it is cold, is taken by another
workman, who straightens the rod with a hammer upon an
anvil, then cuts it off, and places the end of the great bar
against the forge. This same workman also superintends
the heating of the iron, and must be very careful not to
overheat it, but to heat the whole regularly.

It is a good practice to pass the iron-rod through a pair
of grooved rollers, the grooves of the two rollers being
opposite, so as to form a round between them. By these
means, the iron may be reduced small, and rendered very
true, previously to beginning the drawing. For common
wire, the whole reduction may be done by the rolling-mill
without a tilt; but the hammer will give a more tenacious
quality to the iron than can be obtained by rolling.

A small round bar, thus prepared, must be drawn through
holes in a draw-plate, by a strong machine with a chain,
or else by the lever-machine, fig. 7. The end of the iron
is first reduced, so that it will enter the hole in the draw-
plate, and pass through sufficiently for the pincers to take
hold. This is done at the forge by a hammer and anvil.
By passing through the plate the iron becomes lengthened,
proportion as it is diminished in size. It must then be
annealed to soften it; the end pointed anew, and again put
through a smaller hole.

The workman who attends the process must study the
nature of the iron, and regulate the manner of drawing ac-
cordingly. This he does by altering the figure of the
hole through which the wire is drawn. The hole must be conical;
the smallest part, being that which acts principally on the
metal, must be at the side of the plate where the wire
comes through. If the taper of the hole is not properly
proportioned, the iron will be strained in drawing; for
though the machine will force it through, grains of harder
metal than the rest of the wire will form themselves, which
will occasion the wire to break when it comes to be much
reduced. This is particularly the case in soft iron. To
avoid this, the hole must be chosen very slightly smaller than
the iron, and must be made with a regular taper. It must
be well supplied with grease, to diminish as much as pos-
ible the friction; and the motion of the draught must be
regulated according as the metal will bear it.

Much depends upon the quality of the draw-plate; al-
though the metal of the plate is sufficiently hard to draw
the wire, it will not refill the blow of a hard steel hammer
and punch. The punch is driven into the hole from
behind, until it enlarges it to the required size and figure.
In

The operation of drawing, the hole becomes gradually en-
larged, and that in a greater degree at the smallest end of
the hole, so that it becomes nearer to a cylinder. To rectify
this, the punch must be applied, or the wire would not pass
regularly; that is, if the same degree of reduction in the size of
the wire was attempted, it would break or strain the wire,
if the hole was cylindrical, although it would pass through
a regular taper hole. The hole sometimes wears irregularly,
and looses its circular figure. In this case, the plate is ham-
mered around the small end of the hole, and the hole is
thereby reduced. The punch is then driven in, to enlarge
it again to the required size: sometimes the punch is intro-
duced at the small end, and then at the large end, as it may
be required to form the hole. In all cases, the punch
must be driven very gently; and after every stroke of the
hammer it must be loosened in the hole, and turned round
before another blow is struck, and without this precaution it
would fix fast in the hole.

The French draw-plates are the most esteemed; and,
in time of war, a good French draw-plate has been sold for
its weight in silver. M. Du Hamel, in Les Arts et Metiers,
vol. xv, gives the following account of the process of making
the draw-plates for the large iron-wire.

A band of iron is forged of two inches broad and one
inch thick. This is prepared at the great forge. About
a foot in length is cut off, and heated to redness in a fire of
charcoal. It is then beaten on one side with a hammer, so
as to work up all the surface into furrows or grooves, in order
that it may retain the substance called the potin, which is
then welded upon one side of the iron, to form the hard
matter on which the holes are to be pierced. This potin
is nothing but fragments of old cast-iron pots; but these
pots which have been worn out by the continued action of
fire are not good: the fragments of a new pot which has
not been on the fire are better.

The workman breaks these pieces of pots on his anvil,
and mixes the pieces with charcoal of white wood. He
puts this in the forge, and heats it till it is melted into a fort
of pate; and to purify it he repeats the fulfion ten or twelve
times, and each time he takes it with the tongs to dip it in
water. M. Du Hamel says, this is to render the matter
more easy to break into pieces.

By these repeated fulotions with charcoal, the cast iron
is changed, and its qualities approach those of steel, but far
from becoming brittle; it will yield to the blows of the
hammer and to the punch, which is used to enlarge the holes.
The bar of iron which is to make the draw-plate is covered
with a layer of pieces of the potin, or cast iron, thus
prepared. It is applied on the side which is furrowed, and
should occupy about half an inch in thicknesses. The whole
is then wrapped up in a coarse cloth, which has been dipped
in clay and water mixed up as thick as cream, and is put
into the forge. The potin is more fusible than the forged
iron, so that it will melt. The plate is withdrawn from
the fire occasionally, and hammered very gently, upon the
potin, to weld and in some measure amalgamate it with the
iron, which cannot be done at once; but it must be re-
peatedly heated, and worked until the potin fixes to the
iron. The workman then throws dry powdered clay upon
it, in order, they say, to soften the potin.

The union being complete, the plate is again heated, and
forged by two workmen, who draw out the plate of one
foot
foot to a length of two feet, and give it the form it is to have. It is well known that cold iron cannot be worked at the forge without breaking under the hammer; but in the present instance, it is alloyed with the iron-bar, and is drawn out with it. It has also acquired new properties by the repeated fusions with charcoal.

The holes are next pierced whilst the plate is hot. This is done with a well-pointed punch of German steel, applied on that side of the plate which is the iron-bar. It requires four heats in the fire to pierce the holes, and every turn a finer punch is employed, so as to make a taper hole. The makers of draw-plates do not pierce the holes quite through, but leave it to the wire-drawers to do it themselves when the plate is cold, with sharp punches, and then they open the hole to the size they desire; and although this potin is of a very hard substance, the size of the hole may be reduced by gentle blows with a hard hammer, on the flat surface of the plate, round the hole.

A great many holes are made in the same plate; and it is important that they should diminish in size by very imperceptible gradations; so that the workman can always choose a hole suitable for the wire he is to draw, without being obliged to reduce it too much at once.

To ascertain the size of the wire, gauges are used. They are commonly made of a piece of wire bent in zigzag, as shewn in fig. 11; and the space between every bend is of a different width; but a better fort is made of a plate-steel, with notches on the edge. (See fig. 12, for the standards.) These should be hardened, that they may not be subject to wear.

Fig. 13, is another kind of gauge, which is very accurate. It consists of two straight rules of steel, put together at an angle. The diameter of the wire is indicated by the depth to which it will enter into the angle; the edges of the rulers are divided into equal parts for that purpose, and numbered, to correspond with the different sizes of wire.

The wire manufacture of Meliffs. Moucheil, situated at l'Aigle, in the department of l'Orne, is one of the most considerable in France. It furnishes annually, in cards for wool-combing only, an hundred thousand quintals of iron-wire, each 1000 lbs. A part of this is consumed in France, and the rest is exported to Portugal, Spain, Italy, and even to the shores of the Levant.

They employ the iron manufactured in the departments of l'Orne and La Haute Saone, as being of the best quality. The first produces the belt wire for making screws, nails, and pins, as much on account of its hardneds as its fine polish, which resembles steel-wire. In this respect, it is superior to the iron of Haute Saone, but from its ductility the latter can now be made extremely fine, and it appears to be most free from heterogeneous particles.

The melted iron, prepared and hammered, being in a state nearly fit for their purpose, is transported, at a small expense, to l'Aigle, by the rivers and canals. They have a forge to reduce the steel and iron of Normandy, which arrives in large pieces, into small and regular bars.

When the iron is formed into an irregular bar of about a centimetre, near four-tenths of an inch in diameter, they begin to draw it into wire. Although it be already much extended by hammering, it is in the first place paffed four times through the drawing-plate; then its molecules become diffused lengthways, and exhibit fibres at their utmost extension. The fibres must be removed by means of heat, which disperse and divides them; and after that the wire may again be reduced three numbers. The fibres which are re-produced by this operation are again removed by heat. The whole process is five times repeated; consequently the wire is paffed through fifteen numbers; after which, a single exposure to the fire is insufficient to fit it for paffing the others, whereby it is reduced to the thickness of a knitting-needle.

The steel-wire, being much harder, requires to be paffed through forty-four numbers, and to be annealed every other time.

The machine which draws the steel-wire must go slower than that which draws the iron; for the firft being very hard, and offering more refiftance to the drawing-plate, should be pulled out with more care, since the quickness ought to be proportioned to the refiftance, and reciprocally; and if they depart from this principle, the results will vary. Thus, for example, the iron of the department de l'Orne, which is more compact than that produced at Haute Saone, if drawn by the same machines, augments in hardness, and is weakened when it is brought to too great a degree of fineness. But this iron, which is very hard, and capable of receiving a very high polish, is to be preferred for certain uses.

In order to anneal the wire, they formerly employed a large and elevated furnace, with bars of caft iron to support the wire in the middle of the flames. It contains seven thousand pounds weight, fo contrived as to contain equal portions of each number. They are so arranged that the thickest wires receive the strongest heat; therefore, the whole is equally heated in the same space of time. The operation lasts three hours, with a fire well kept up, and it might be imagined that this apparatus was completely adapted to the purpose; but there are imperfections in this method, because it leaves the wire exposed to the contact of the atmospheric air, the oxygen of which feizes it with extreme avidity; whence a considerable quantity of oxyd is occasioned, and also an operation to free it from the scales, which confift of beating the bundles of wire with a wooden hammer wetted with water.

Notwithstanding this precaution, there often remains a portion of oxyd adhering to the surface of the metal, which breaks the draw-plate, or fixes on the wire, and gives it a tarnifhed appearance, and causes it to break when it is brought to a great degree of fineness. This furnace is only used for the steel-wire, or the iron from l'Orne, which is liable to change, and besides being harder is not easily attacked by the oxygen.

In order to diminish the waft of the fire, they have contrived another process, which consists in dipping the bundles of wire into a bain of wet clay before they put them into the furnace; and they are left in the furnace to dry before the fire is lighted, without which precaution the clay would peel off from the iron.

For making wire for cards, M. Moucheil invented another furnace. It is round, and about one metre fix decimetres in diameter, and one metre eight decimetres in height, without including its parabolic arch and the chimney above it. The interior is divided by horizontal grates into three stories; the lowest receives the cinders, the second is the fire-place, and into the third or upper place they slide a roleau of wire, weighing one hundred and fifty kilograms, which is inclosed in a space comprized between two caft-iron cylinders, being turned to prevent the admiffion of air between them. The flames circulate about the outside of the first, and within the interior of the second, which defends the wire from atmospheric air. The diameter of the largest cylinder is about one metre four decimetres, that of the second one metre. Thus the space comprized between them is two decimetres, on an elevation of five decimetres. There must be several pairs of cylinders provided; because whilst one
pair is in the furnace another must be prepared to receive a fresh roeale of wire. They are changed every hour by means of a long iron lever, with which a single man can easily push them in and draw them out again, as the cylinder slides on call-iron rails.

They are very careful not to open the cylinders immediately on their being drawn out of the fire; for the roeals of wire contained in them, being still red, would oxidate as much as if they had been heated in the midst of the flames without the least precaution.

The opening contrived for the passage is on the side, and has a door of flat iron, with a groove which winds round the furnace. The fire-place has one something similar to it. That of the shaft-hole is vertical, in order that it may be raised to increase the fire at will.

When the iron-wire is reduced to the thickness of a knitting-needle, it is made up in bundles of 125 kilogrammes (275 pounds) each, into a large iron vessel, in order to anneal it sufficiently to be reduced for the last time. This vessel is placed upside-down in the middle of a round furnace, which is so constructed as to full well burning coals all round it, and of which it consumes 35 kilogrammes (77 pounds) before the operation is completed. The cover must be carefully kept, as the slightest admixture of air is sufficient to burn the exterior surfaces of the wire to an oxyd, which cannot afterwards be reduced.

When one of these vessels is sufficiently heated, it is filled with water, containing three kilogrammes (six pounds and a half) of tartar, and suspended over the flames of the furnace to make it boil. This solution, without attacking the metal, frees it from the grease and the little oxdy that adheres to it. This is the last operation in which the wire is exposed to the fire; and it is then in the proper state for being reduced to the utmost degree of fineness it is capable of fullaining, and will preserve enough of the effect of the annealing to require it no more. But when the natural hardness of the iron varies, this last exposure to the fire should take place in proportion to its thickness. As feel loses its capacity of extension much sooner than iron, it is annealed until it is no thicker than a lewing-needle. The space which is left in the vessel is filled up with charcoal dust, which prevents it from losing the quality of steel, and preserves the heat long enough to give it the proper degree of planity.

As Messrs. Mouchel always use iron and steel of the fame manufactory, they have been able to reduce their operations to a general system; and to attain this end, have determined a graduated scale, by which the wire will not be more fretched in the drawing-plate in one number or size than another. The following is the method they contrived, in order to form this scale for the iron-wire. They take a certain quantity of various thicknesses, which has been drawn as fine as the iron would bear. The smallest size is 100,000 metres (109,333 yards) in length to the kilogramme, 2.2 pounds avoirdupois. They note the weight that each might be capable of supporting without breaking. This being expressed by figures, it is easy, by a few interpolations, to express them in a progressive form. This kind of scale has been partly formed by comparing the weight of the different sizes with equal lengths, from which gauges or calibres may be made for the use of the workmen. These gauges are certain guides, which they cannot mistake except through great carelessness. If they had not these guides they would often pass the wire through holes in the drawing-plate that are too large for it, whence it does not acquire the strength it should have in proportion to its thickness, and loses its hardness. They might also pass it through holes that were too small, which would weaken it, and render it very brittle. In the latter case, it frequently happens that the feel of the drawing-plate, being unable to sustain the force to which it is exposed, will give way, as if the plate were too soft; and the wire will be brittle at the beginning, and soft and too thick at the other extremity.

The greatest part of the fine wire of Messrs. Mouchel's manufactory is drawn by workmen who are differed about the country; but they have also a machine which moves twenty-four bobbins in a horizontal direction, which only requires the workman to look after it. It is upon the bobbins that the wire is reduced to the different degrees of thinness desired; therefore, this is the last operation in the art of making iron and steel wire; although it has all requisite qualities given it in the work-shop of the wire-drawing.

Wire is still incapable of being made into needles and carding-hooks, until it has undergone another operation for d retting or straightening the wire, by which it is made to lose the bend or curve that it acquires on the bobbin.

This work consists in drawing the wire between rails fixed in a piece of wood, and which act to bend the wire, first in one direction, and then in the opposite, in a waving line, by which the waves are at first larger, but decrease gradually, and the last bend of which tends to force the wire into a straight line. The drefler is obliged constantly to adjust the nails, by inclining or raising them with strokes of the hammer. Also for each number of wires the pins must be at different and calculated distances. This requires a workman of intelligence, dili uge, and address.

An ingenious instrument is now appropriated to this operation, and removes all difficulty. Six little puppets or very hard feel are substituted for the nails of the ordinary instrument, and are fixed on parallel bars of metal, so joined together that the movement of them all will be parallel, and the puppets are widened or brought nearer together by screws. The wire is drawn between these puppets in a zigzag or waving line, and the repeated flexures break the fineness of the wire. There is a conductor of the wire to the puppet, and another conductor which serves to prevent the wire from being shaken. There are flight grooves at the extremity of the puppets, to give a passage to the wire. A scale furnished by a screw indicates the distance at which the puppets should be placed from each other, to straighten each size of wire. This forms an irrevorable rule, and the drefler (who may be a child) has a third of the time which is employed in regulating the nalls of the instrument formerly used. There is nothing more to be done than to draw out the wire by means of a wheel, on which he reeels it, and then forms it into bundles to be delivered to the consumers.

The feel-wire of France is proper for many purposes. It is brought from Messrs. Mouchel, for making knitting-needles in the English fashion, shoemakers' needles, and other similar articles. It may also be used for needles of all sizes, and even for cards for wool-combing; but as this feel is much more expensive than the iron-wire, it is very seldom used for the latter purpose.

The method of preparing the draw-plates is described by Messrs. Mouchel, and is different from that before described.

For making wire for cards, two sorts of drawing-plates are used, large and small ones. The first, for the sort of wire that we have been describing, is drawn with the pincers, as fig. 7, and with the bobbin or roller, which is a cylinder adapted to the axis turned by the water-mill, and is used in preference, to avoid the marks made on the wire by the pincers. The small drawing-plates are used for such wire.
WIRE.

as may be drawn by hand. The steel which they employ for these drawing-plates should never vary in quality, except that the smaller plates are made of the finest steel. Several pieces of iron are dipped in the furnace in the form of a box without a lid, their weight being according to the use for which they are intended to be employed.

The workman fills each of these boxes with cast steel, and having covered it over with a luting of clay, it is exposed to a fierce fire until the steel be melted. His art consists in seizing the proper moment to withdraw the plate from the fire; he raises the luting, and blows on it through a tube, in order to drive off all heterogeneous parts, and then amalgamates it with the iron by light blows. After it is cool, he replaces it at the fire, where the fusion again takes place, but to a less degree than before; he afterwards works the steel with light blows of the hammer, to purify and fold it with the iron. This operation is repeated from seven to ten times, according to its quality, which renders it more or less difficult to manage. During this process, a crust forms on the steel, which is detached from it the fifth time of its exposure to the fire, because this crust is composed of an oxidated steel of an inferior quality. It sometimes happens that two or even three of these crusts are formed of about two millimetres, or one-sixteenth of an inch in thickness, which must also be removed.

After all these different fusions, the plate is beaten by a hammer wetted with water, and the proper length, breadth, and thickness, are given to it. When thus prepared, the plates are heated again, in order to be pierced with holes by punches of a conical form; the operation is repeated five or six times, and the punches used each time are progressively smaller. It is of importance that the plate never be heated beyond a cherry-red, because if it receives a higher degree of heat, the steel undergoes an unfavourable change. The plates, when finished, present a very hard material, which nevertheless will yield to the strokes of the punches and the hammer, which they require when the holes become too much enlarged by the frequent passing of the wire through them.

When the plates have been repaired several times, they acquire a degree of hardness, which renders it necessary to anneal them, especially when they pass from one size to another; sometimes they do not acquire the proper quality until they have been annealed several times. Notwithstanding all the precautions which are taken in preparing the plates, the steel will vary a little in hardness, and according to this variation they should be employed for drawing either steel or iron wire; and if the workman who proves them finds they are too soft for either the steel or iron, they are put aside, to be used by the brafs-wire drawers.

A plate that is best adapted for drawing steel-wire is often unfit for the iron; for the long pieces of this latter metal will become smaller at the extremity than at the beginning, because the wire as it is drawn through the plate is insensibly heated, and the adhering parts are swelled, consequently pressed and reduced in size towards the latter end. The plates that are fit for brafs are often too soft for iron, and the effect resulting is the reverse of that produced by a plate that is too hard.

The smallest plates which Messrs. Moucharf use are at the least two centimetres, or eight-tenths of an inch in thickness, so that the holes can be made sufficiently deep; for when they are of a less thickness, they will feize the wire too suddenly and injure it. This inconvenience is much felt in manufactories where they continue to use the plates for too long a time, as they become exceedingly thin after frequent repairs. One of Messrs. Mouchar's large plates reduces 1400 kilogrammes (3280 pounds avoidually) from the largest size of wire to No. 6, which is of the thickness of a knitting-needle; 400 kilogrammes (880 pounds) of this number are afterwards reduced in one single small plate to No. 24, which is carding wire; and to finish them, they are passed through twelve times successively.

For the tenacity of iron wire, see Iron.

The first wire-mill in England was set up by a Dutchman at Sheen, near Richmond, in 1663.

Wires are frequently drawn so fine, as to be wrought along with other threads of silk, wool, or hemp: and thus they become a considerable article in the manufactures. See Ductility.

WIRE, Gold. See Gold-Wire.

Muschellenbroecck records, that an artific of Augsburg drew a wire of gold so slender, that 500 feet of it weighed only one grain; and Dr. Wollafoft, secretary of the Royal Society, has shewn, that a wire of gold may be drawn much finer than this, and that wires of platina may be drawn much more slender, with the utmost facility. Those who draw silver-wire in large quantities for lace and embroidery, sometimes begin with a rod that is about three inches in diameter, and ultimately obtain wires that are so small as 1 of an inch in

thickmess. If in any of these processes a rod of silver-wire is taken, and a hole be drilled through it longitudinally, having its diameter one-tenth part of that of the rod, and if a wire of pure gold be inserted, so as to fill the hole, it is evident that by continuing to draw the rod, the gold within it will be reduced in diameter exactly in the same proportion as the silver; so that if both be thus drawn out together till the diameter of the silver is of an inch, then that of the gold will be only of an inch, and of such wire, 500 feet would be requisite to weigh one grain. In order to remove the coating of silver that surrounds it, the wire must be steeped for a few minutes in warm nitrous acid, which dissolves the silver without any injury to the gold. Dr. W., in his endeavours to make slender gold-wires by the method above-described, found it difficult to drill the central hole in a metal fo fine as silver, and therefore tried whether platina might not be substituted for the gold, as in that case its infusibility would allow its being coated with silver, without the necessity of drilling. Having formed a cylindrical mould one-third of an inch in diameter, he fixed in the centre of it a platina wire previously drawn to the of an inch, and then filled the mould with silver. When this rod was drawn to of his platina was reduced to , and by successive reduction he obtained wires of and , and excellent for applying to the eye-pieces of astronomical instruments, and perhaps as fine as can be useful for such purposes. The extremity of a platina wire having been fulted into a globule near of an inch in diameter, was next hammered out into a square rod, and then drawn again into a wire of an inch in diameter. The fusion was effected by the following simple and easy method suggested by Dr. Marce
Marcet:—A piece of wire, about six inches long, having been bent to an angle in the middle, one half of its length was held in the flame of a spirit-lamp impelled by a current of oxygen; and its extremity was thus fused in about half a minute. An inch of the wire above-mentioned duly coated with silver was drawn, till its length was extended to 182 inches; consequently the proportional diminution of the diameter of the platinum will be expressed by the square root of 182, so that its measure had become

\[
\frac{1}{\sqrt{182}} = \frac{1}{13.5}\;
\]

The specific gravity of the coated wire was assumed to be 10.5, and since the weight of 100 inches was 114 grains, its diameter was inferred to be

\[
\frac{1}{13.5} \times 10 = \frac{1}{13.5}\;
\]

of an inch, and just eighty times of the platina thus contained in it. With portions of the platina wire thus obtained, and successively reduced in diameter, its tenacity was ascertained; and the results of several trials showed in general, that the procés of wire-drawing, which is known to improve the strength of metals within moderate limits, continued also to add something to the tenacity of platina, even as far as

\[
\frac{1}{18,000}\;
\]

before it broke; but the wire in which the experiments were made became then to be impaired by repetition of the operation; so that although he afterwards obtained portions of it as small as

\[
\frac{1}{30,000}\;
\]

in many places interrupted, and he could not rely on any trials of its tenacity. For other particulars with regard to these wires, we refer to the Phil. Trans. vol. ciii. pt. 1.

Wire, Silver, is the fame with gold wire, except that the latter is gilt, or covered with gold, and the other is not. There are also counterfeit gold and silver wires: the first made of a cylinder of copper, silvered over, then covered with gold; and the second of a cylinder of copper silvered over, and drawn through the iron, after the same manner as gold and silver wire.

By 43 Geo. III. c. 68. several duties are imposed on wire imported, as set forth in tables annexed to the act; and by c. 69. fuch duties are laid upon wire made in Great Britain; and by 49 Geo. III. c. 98. new duties are imposed. Every wire-drawer who shall draw any gilt or silver wire, commonly called "big wire," shall take out a licence, for which he shall pay 2l., to be renewed annually on payment of 20l. 24 Geo. III. c. 41. One licence suffices for a partnership. Notice is to be given of working on pain of 20l, and the place of working is to be approved by the commissioners under the same penalty. Wire, and bars for making it, and utensils, found in any private workhouse, of which no notice hath been given, shall be forfeited. Officers shall be permitted to enter and survey, and the penalty of obstructing him is 20l. 10 Ann. c. 26. Preventing him from taking a just account incurs a forfeiture of 100l. 26 Geo. III. c. 77. Just scales and weights shall be kept on pain of 10l. Perfections of false scales and weights forfeit 100l. 10 Geo. III. c. 44. And the same shall be forfeited and fined. 28 Geo. III. c. 37. Ingots or bars of silver, designed for gilt wire, shall be weighed in the presence of the excise officer, before they be covered with gold, and again weighed and marked after the gold is laid on, under penalty of 20l. 15 Geo. III. c. 20.

By 10 Ann. c. 26. an allowance of one-fifth is made for waste in reducing the big wire to small wire. Removing wire before it is surveyed incurs a penalty of 40l.; and unsurveyed wire is to be kept separate, on pain of 10l., and the punishment of concealing wire, &c. is a forfeiture of 20l.

The wire made shall be entered every month, on oath, on pain of 100l. The duty must be cleared off in six weeks after entry, on pain of double duty.

By 15 Geo. II. c. 20 and 22 Geo. II. c. 36. no foreign embroidery, or gold or silver brocade, thread, lace, fringe, or work made thereof, or of copper, brass, or other inferior metal, or gold or silver wire, or plate, shall be imported. And by 10 Ann. c. 26. if any person shall export any gold or silver thread, or lace or fringe made of plate wire spun upon silk, he shall have a drawback after the rate of 5l. a pound avoidipouis, of such silver thread, lace, or fringe, and of 6s. 8d. a pound of such gold thread, lace, or fringe.

For regulations concerning the true making of gilt and silver wire, see the statute 15 Geo. II. c. 20. and for prohibiting the selling or working up of foreign gold or silver lace or thread, see 22 Geo. II. c. 36.

Wire, Brass, is drawn after the same manner as the former. Of this there are divers fizes, suited to the divers kinds of works. The finest is used for the stringing of musical instruments, as spinets, harpsichords, manichords, &c.

The pin-makers likewise use vast quantities of wire of several fizes, to make their pins of. See Pin.

Wire, Iron. See Wire supra.

Wire-Gauze Safety-Lamp, and Safety-Lamp, in the Arts, are lamps constructed to prevent the explosion of inflammable air in mines, by intercepting the communication of the flame on the inside of the lamp with the surrounding atmosphere. The discovery of safety-lamps for this purpose belongs exclusively to our own country, and will form a new era in mining operations. We shall, therefore, state the history of their invention with as much accuracy as possible, amidst the contending claims of the different inventors for priority. The explosions of inflammable air in coal-mines arise from the ignition of carburetted hydrogen evolved from the fritata, and mixed with the atmospheric air that circulates through the mine. These explosions very frequently occasion the most fatal effects, destroying the lives of all the persons employed as well as of the horses, and producing great mischief to the subterranean works. Some mines are much more liable to accidents from this cause than others. In some the carburetted hydrogen accumulates slowly from the want of due circulation; in other mines, it is generated very rapidly, issuing from fissures called blowers, which occur either in the roof, the floor, or the sides of the mine.

In the coal-fields of the Tyne and the Wear, it has been estimated that six hundred men and boys were destroyed in two years by explosions in the mines; but these accidents, unless they took place on a large scale, were as much as possible kept from public notice, partly from the fear of alarming the workmen, and partly from the apprehension of blame to the viewers and managers of the works. Of these melancholy catastrophes, few regilers are kept in any part of Great Britain; but in the year 1810 an explosion took place in a mine in the parish of Felling near Newcastle, which, from the magnitude of the evil it occasioned, excited a general sensation of horror throughout the country. In this mine, the property of wealthy and liberal owners, no expense had been spared in the introduction of machinery and the most approved methods of ventilation. (See Ventilation of Mines.) Notwithstanding this, on the 25th of May
May 1812, the inflammable air exploded in two discharges from one of the pits, which was shortly followed by a third from another pit.

The depth of these explosions under the surface obscured the sound of the reports; but for half a mile round the vibrations of the earth announced the occurrence of the accident before the noise escaped, and an alarm was created by four or five miles round by low and hollow rumblings in the air. Immense volumes of dense vapour and coal-dust, with pieces of wood and coal, were driven high into the atmosphere; and the mangled bodies of several men and boys were absolutely thrown out of the shaft. The country in the immediate vicinity was enveloped in darknese, and every kind of machinery near the mouths of the pits was blown to pieces, or set fire to. Out of a hundred and twenty men and boys employed in the mine only thirty-two were saved, three of whom afterwards died. The coal being set fire to, and the subterranean works blown down or destroyed, the owners were compelled to close the mouths of the pits in order to extinguish the fire; and it was not till the seventh or eighth of the following month that it could be re-opened to extract the bodies, which were, many of them, too much mangled, and in too putrefcent a state, to be identified by the relatives. A series of similar disasters, in each of which from twenty to thirty-five human beings were destroyed, occurred soon afterwards in the same districts, and even in the Telling mine another explosion took place in December 1813, by which twenty-three men and boys and twelve horses were killed. The only method that had been adopted to prevent explosions, besides the usual modes of ventilation for clearing the mine, was the substitution of steel-mills for candles.

The steel-mill is an instrument for producing light by the collision of flint and steel; it consists of a wheel whose diameter was about five inches in diameter, with fifty-two teeth, which works a pinion with eleven teeth. On the axis of the pinion is fitted a thin jagged steel wheel, from five to six inches in diameter; against the circumference of this wheel the sharp edge of a flint is fixed, and the toothed wheel has a handle, which is turned by a boy; the whole machine being fixed in an iron frame furnished by a leather belt. The steel wheel revolves with great velocity, and elicits a stream of incensions, which give a considerable light. Where the mines were supplied with inflammable air, these machines were used; but besides affording only an imperfect light, and being difficult to manage, many instancies had occurred of the air igniting from the incisions of steel-mills. For the purpose of exploring the unworked and more dangerous parts of the mine, the steel-mill was both an inconvenient and incomplete instrument; but until the year 1809 no method of lighting had been attempted which might supersede its use.

About that time Dr. Reid Clanny, a scientific and ingenious physician at Sunderland, commenced a series of experiments, with a view to infuse the gas which might explode in a lamp, and cut off its communication with the surrounding air in the mine. With this intent, he contrived a lamp in which the combustion of the oil or tallow is supported by the ordinary air of the coal-mine supplied by a pair of bellows, and passing through a flaring or reservoir of water below the light; at the same time, a portion of the air already in the lamp is driven through another reservoir in the upper part above the light, and thus the air supplied may explode within the body of the lamp without communicating the flame to the external air, however highly it may be charged with carburetted hydrogen gas. The moment the air enters the lamp it comes in contact with the flame, and consequently only a small portion of it can be exploded, instead of the whole contents of the lamp; by this means several obvious advantages are secured. The air passing in a brisk current close by the flame carries the smoke with it, so that the light is always clear and steady. The other parts of the lamp were air-tight, and the whole made very strong, with a glass nearly half an inch thick to prevent it from being broken by any common accident. It is capable of being managed by a boy at a much less expense than the steel-mill. This lamp, which, for strength and for security from explosions and accidents, exceeds any other that has since been invented, excited little attention among the coal-workers where it was first made known. Had not the prejudices against improvements prevented its general introduction, more than one hundred lives might have been preserved, which were destroyed in the mines of the Tyne and Wear. In several other mining districts accidents have been prevented by the introduction of lamps, which have been adopted as a necessary provision for each individual; and in those districts where the lamp is not employed, the hospitals are crowded with cases of accidents from the explosion of the coal-gas.

In Plate I. fig. 2. Geology, is given an outline of the lamp on its original principle, which, though less portable, is, we consider, the safest that has yet been employed. A is the body of the lamp, constructed of copper or block-tin; B, the upper part of the lamp, ending in a conical bent tube, by which the air is discharged after supporting combustion through the water-cylinder C and D, the part D being filled with water to keep the lamp cool, if necessary; E, the window of the lamp, made of glass; F, the candle, supported on a tin flange; G, a cylinder containing water, through which the air is forced by the bellows; H, a tube from the bellows, which conveys air to the lamp. A flexible leather tube may be fixed to the valve of the bellows, to fend atmospheric air from a distance, if necessary. If the lamp be in order, it is scarcely possible to conceive any inflation of the flame more perfect than it presents; and to Dr. Clanny must be allowed the undoubted claim of priority in having first directed the attention of miners to a method of avoiding danger before unknown, and of showing practically how it might be effected. In the improvement which Dr. Clanny made in this lamp afterwards, to render it more portable, (see fig. 3. in the same plate,) a is the tube fixed to the lamp, and which conveys the air; b, the oil-cylinder; c, the aperture, under the burner of the oil; d, the flexible tube connected with the bellows; e, f, the glasses. In both these lamps, the air being supplied by bellows, required the constant attention of a boy; this, however, was the case with the steel-mills, which were in general use before. A lamp that would supply itself with atmospheric air was still a desideratum; when Dr. Clanny discovered, in November 1815, as he was making experiments with the original safety-lamp in an atmosphere of fire-damp
WIRE-GAUZE SAFETY-LAMP.

in the Horrington mine, near Sunderland; that if the infalation of the lamp were made with hot water, the fire-damp burned silently at the wick, and did not explode within the lamp, as formerly. This he ascertained to be owing to the ream; and he farther discovered, that one part in volume of ream to two of the most exploitive mixtures destroyed their inflammability. A similar effect of ream had been before noticed by Von Grothus, in the 82d volume of the Annales de Chimie, but had not been applied to any useful purpose. In December of the same year, Dr. Clancy constructed a ream safety-lamp, which he exhibited to the Society, for preventing accidents in coal-mines, and received their unanimous thanks; and in 1817 he received a gold medal from the Society of Arts for the discovery.

In the ream safety-lamp there is a reservoir of water at the top of the lamp, which is a closed tin box, or cistern. The water is kept boiling by the flame of the lamp, and the ream mixing with the carburetted hydrogen prevents all risk from explosion. The air is supplied through a tube to the upper part of the cistern above the water, and descends, mixed with the flame, down two other tubes, into the body of the lamp. By this means, the fire-damp burns silently and steadily at the wick of the lamp alone for any length of time. Should the carburetted hydrogen exceed the proportion of atmospheric air for supporting combustion, the light is extinguished, but this can rarely happen. It has also the valuable property of keeping cool throughout every part, and under all circumstances; this is effected by the evolution and motion of the ream.

This lamp, says Dr. Clancy, is now well known to burn most brilliantly in an atmosphere of fire-damp, even after the original safety-lamp had has the fire-damp exploded within it. The ream-lamp has now been extensively used in several of the northern collieries. Its great recommendation over other inventions is the superior light which it affords. These lamps are made of the strongest tinned iron, with a flat glass in front, three-eighths of an inch in thickness. They are exceedingly strong and durable, and cost about twelve shillings, but might be manufactured on a large scale for half the price.

Fig. 4. represents the short tube by which the air enters into the tube b, and this tube supports the water-cistern e at the top, being fitted into the tube a at the bottom, so as to be taken out and replaced when the water is to be poured in or removed from the cistern e. The air which ascends the tube b mixes with the ream of the water-cistern, and passes down the two tubes d, d, to support the combustion of the flame, and afterwards ascends by the side of the cistern through the chimney of the lamp. These tubes are closed at the bottom, and perforated on the sides, to retard the progress of the air, and mix it with the ream before it reaches the flame. The bottom is air-tight; f the glass, and g the oil-lamp. These lamps are twelve inches in length, exclusively of the chimney. They should be cleared of water, and well dried, after they have been in use, that they may be more durable. When the lamp is first lighted it is necessary to establish a current, which is done by turning the lamp, so that the tube a may be exposed to the current of air; this will be effected in five minutes, and the lamp will afterwards continue to burn regularly and steadily.

Dr. Clancy farther applied the same principle to the construction of a larger lamp, in which were three wicks to burn the inflammable air as it was made to issue through the oil; this is intended to confine the hydro-carburetted gas as it rushes from a blower.

In the history of useful inventions, perhaps no instance of simperness can be adduced, among those interested in any dif-covery, which equals the inattention shewn for several years by the coal-workers in the north to the valuable labours of Dr. Clanny. We had an opportunity of examining his lamp in 1813, and were satisfied with the complete security which it affords. At that time, however, so far from receiving the patronage he highly merited, he was regarded by many with a strange jealousy, as an officious intruder into the mysteries of mining; mysteries which he had no right to investigate. To Dr. Clanny, however, the first discovery of a safety-lamp is undoubtedly due; and we have no hesitation in asserting our belief that his original safety-lamp is the most fecure of any that have since been invented, where dangerous parts of the mine are to be explored, on account of its more complete infallation, and its greater strength. His lamp had also the merit of first suggesting the possibility of inflating the flame in the different lamps which have since been constructed.

The attention of the public was at length directed to the dangerous situation of the men working in the mines by a few gentlemen, who formed a society, in 1815, at Sunderland, entitled A Society to prevent Accidents in Coal-Mines. Dr. Gray, rector of Bishop-Wearmouth, an active member of this society, invited Sir H. Davy, in 1815, who was then on a visit in the north of England, to examine the collieries with a view to afford the efforts of the society to prevent the accidents to which they were subject. From the information communicated to him by persons employed in the mines, he was induced to commence a series of experiments on carburetted hydrogen gas, which led to several unexpected results, not less interesting to science than useful in their application to the arts. Before proceeding to describe these, we must notice the labours of Mr. Stephenson, an engineer in the Killingworth main colliery, who previously to this time had, as he informs us in a pamphlet on the subject, entitled "A Description of the Safety-Lamp invented by George Stephenson," made the discovery that inflammable air will not explode through small apertures. In the same pamphlet he states, that a lamp constructed by him on this principle was tried in the above colliery on the 21st of October 1815, the lamp being carried in safety into a part of the mine where a strong blower of inflammable air was inflating. The experiment, he adds, was immediately repeated in the presence of two persons employed in the works.

These lamps, judging from Mr. Stephenson's own description, yielded but a feeble light. They were afterwards improved; but these improvements bear to cloe resemblance to parts of Sir H. Davy's lamp, hereafter to be described, that we conceive Mr. Stephenson must labour under no small difficulty in establishing his claim for their original invention. The question, at present agitated with much warmth, can only be decided by a reference to well-established dates and authentic evidence; an investigation not suited to the nature of the present work.

We have little doubt that the inflation obtained in Dr. Clanny's lamp by water first suggested to Mr. Stephenson the possibility that small apertures might intercept the extension of the flame as effectually as water. On this suggestion his first lamp appears constructed, the tube which admitted the air being covered with a slide to diminish the aperture at pleasure; but the quantity of air which could be safely admitted through one aperture being inadequate to the support of the flame, it was obvious that the only way to ensure the air in both light and safety was to increase the number of apertures, diminishing the size of each. In this manner, it appears that Mr. Stephenson proceeded mechanically, without a correct knowledge of the properties of the gas, or the principles on which the effects were produced. We think, however, that
that as an approximation to a valuable discovery, Mr. Stephenson's lamp entitled him to the patronage and support which he has received. It ought also to be recollected that Dr. Clanny and Mr. Stephenson both laboured under the disadvantage of living at a distance from the residence of ingenious practical mechanics to execute their inventions in the most simple, cheap, and portable manner; an advantage only that could be obtained in the neighbourhood of the metropolis, or of large mechanical manufactories.

Sir H. Davy, after ascertaining that the fire-damp, or inflammable air in coal-mines, is the light carburetted hydrogen gas, as stated by other chemists, proceeded to examine accurately its combustibility and explosive nature. When one part of fire-damp was mixed with one of common air, the mixture burned on the approach of a taper, but did not explode. Two of air and three of fire-damp produced similar results. When four parts of air and one of fire-damp were exposed to a lighted candle, the mixture being in the quantity of six or seven cubic inches in a narrow-necked bottle, the flame descended to the bottom, but there was no noise. One part of gas inflamed with six parts of air in a similar bottle, producing a slight whistling found. One part of gas with three of air rather a louder sound. One part with ten, eleven, twelve, thirteen, and fourteen parts, still inflamed, but the violence of the combustion diminished. In one part of gas and fifteen parts of air, the candle burned without explosion, with a greatly-enlarged flame. The same effect was observed, but in a gradually diminishing ratio, as far as thirty parts of gas to one of common air. The mixture which seemed to perform the greatest explosive power was seven or eight parts of air to one of gas; but the report produced by thirty cubic inches of this mixture was less than that produced by one-tenth of a mixture consisting of two parts of common air and one of pure hydrogen.

It was also very important to ascertain the degree of heat required to explode the different mixtures of fire-damp. A common electrical spark, he found, would not explode five parts of air and one of fire-damp, though it exploded six parts of air and one of the latter gas. Very strong sparks from the discharge of the Leyden jar seemed to have the same power of exploding different mixtures of the gas, as the flame of a taper. Well-burned charcoal, ignited to the strongest heat, did not explode any mixtures of the gas; and when a fire of the same charcoal, which burned without flame, was blown to whiteness by an explosive mixture without producing inflammation. An iron rod at a red or even at a white heat did not inflame explosive mixtures of the gas; but when in brilliant combustion it produced that effect.

The flame of gaseous oxides of carbon, as well as of olefiant gas, exploded the mixtures of the fire-damp.

In respect of combustibility, says Sir H. Davy, the fire-damp differs materially from the other common inflammable gasses. Olefiant gas, when rendered explosive by a mixture of common air, is fired both by charcoal and iron, heated to a dull redness. Gaseous oxides of carbon, which explodes with two parts of air, is likewise inflammable by hot iron or charcoal. And hydrogen, which explodes when mixed with three-sevenths of air, takes fire at the lowest visible heat of iron or charcoal; and the flame is the flame with carburetted hydrogen.

The importance of these experiments is too obvious to require illustration. Having ascertained the above facts, Sir H. Davy proceeded to examine the degree of expansion of mixtures of fire-damp and air during their explosion, and likewise their power of communicating flame through aperturest to other explosive mixtures. It is to this latter part of Sir H. Davy's experiments and its application to safety-lamps, that the controversy respecting the priority of the discovery refers.

When six parts of air and one of fire-damp were exploded over water by a strong electrical spark, the explosion was not very strong; and at the moment of the greatest expansion, the volume of the gas did not appear to be increased more than one-half. In exploding a mixture of one part gas from the distillation of coal, and eight parts of air in a tube one-quarter of an inch in diameter, and one foot long, more than a second was required before the flame reached from one end of the tube to the other, and he could not make any mixture explode in a glass tube one-seventh of an inch in diameter; and this gas was more inflammable than fire-damp, as it consisted of carburetted hydrogen mixed with some olefiant gas.

In exploding mixtures of fire-damp and air in a jar, connected with the atmosphere by an aperture of half an inch, and connected with a bladder by a stopcock having an aperture of about one-sixth of an inch, the flame passed into the atmosphere, but did not communicate through the stop-cock so as inflame the mixture in the bladder; and in comparing the power of tubes of metal and those of glas, it appeared that the flame passed more readily through tubes of glas of the same diameter, and that explosions were flopped by metallic tubes of one-fifth of an inch, when they were one inch and a half long; and this phenomenon probably depends upon the heat lost during the explosion, in contact with so great a cooling surface, which brings the temperature of the first portions exploded below that required for firing the other portions.

Metal is a better conductor of heat than glas; and it has been already shown, that the fire-damp requires a very strong heat for its inflammation.

A mixture of the gas with air, he also found, would not explode in metallic canals or troughs when their diameter was less than one-seventh of an inch, and their depth considerable in proportion to their diameter, nor could exploitations be made to pass through such canals.

Azote and carbonic acid, even in small proportions, diminished the velocity of inflammation in explosive mixtures of fire-damp. Azote, when mixed in the proportion of one to five of an explosive mixture containing twelve of air and one of fire-damp, deprived it of its power of explosion, when one part of azote was mixed with seven of an explosive mixture only, a feeble blue flame passed through it.

One part of carbonic acid to seven of an explosive mixture deprived it of the power of exploding; so that its effects are more remarkable than those of azote, probably in consequence of its greater capacity for heat, and probably likewise of its higher conducting power connected with its greater density.

The consideration of these various facts, Sir H. Davy informs us, led him to adopt a form of lamp in which the flame, being supplied with only a limited quantity of air, should produce such a quantity of azote and carbonic acid as to prevent the explosion of the fire-damp; and which, by the nature of its apertures for giving admittance and exit to the air, should be rendered incapable of communicating any explosion to the external air.

If in a close lantern supplied with a small aperture below and another above, a lighted lamp having a very small wick be placed, the natural flame gradually diminishes, till it reaches at a point at which the supply of air is sufficient for the combustion of a certain small quantity of oil; if a lighted taper be introduced into the lantern through a small door
WIRE-GAUZE SAFETY-LAMP.

Door in the side, which is instantly closed, both lights will burn for a few seconds, and be extinguished together.

A similar phenomenon occurs; if in a clove lantern supplied with a quantity of air merely sufficient to support a certain flame, a mixture of fire-damp and air is gradually admitted, the first effect of the fire-damp is to produce a large flame round that of the lamp, and this flame consuming the oxygen which ought to be supplied to the lamp, and the standard of the power of the air to support flame being lowered by the admixture of fire-damp and by its rarefaction, both the flame of the fire-damp and that of the lamp is extinguished together; and as the air contained a certain quantity of azote and carbonic acid before the admission of the fire-damp, their effect by mixing it is such as to prevent an explosion in any part of the lantern.

In an experiment which sir H. Davy made, to ascertain that the flame was extinguished in the lantern, though the mixture was still explosive which supplied the flame, the lantern was placed on a stand under a large glass receiver standing in water, which was of sufficient capacity to enable the candle to burn for some minutes. A quantity of fire-damp was thrown in from a bladder, so as to render the atmosphere explosive. As the fire-damp mixed with the air, the flame of the taper gradually enlarged till it half filled the lantern; it then gradually diminished, and was suddenly extinguished without the slightest explosion. The air in the receiver was found after the experiment to be highly explosive.

Sir H. Davy then introduced into a glass jar, containing an explosive mixture of one part fire-damp and ten parts of air, a lighted lantern, to which air was supplied by two glass tubes one-tenth of an inch in diameter, and half an inch long. The taper burned at first with a feeble light, the flame soon became enlarged, and was then extinguished. These experiments were several times repeated with a constancy of result. It is evident, he says, from hence, that it is only necessary to use air-tight lanterns supplied with air from tubes or canals of small diameter, or from apertures covered with wire-gauze, placed below the flame, through which explosions cannot be communicated, and having a chimney at the upper part on a similar system for carrying off the foul air.

This principle sir H. Davy adapted to a variety of glass lanterns, in which the air was admitted through small apertures or wire-gauze, with a top protected by the flame. These lanterns, however they might have answered for experiments in the laboratory, were not, however, well fitted for practical use; for besides the fragility of common glass, which exposed the miner to explosions from the enlargement of the flame, the glass was liable to become heated and to break, however strong it might be made. This inconvenience was, however, removed by the substitution of a cylinder of fine wire-gauze, forming a clove lamp or lantern, into which the air is admitted, and from which it passes through very small apertures. In the first experiments, the wire was of brafs the one-hundredth part of an inch in thickness, and the apertures were not more than the one-fortieth part of an inch; this was found to stop explosions as well as the long tubes or canals, and to admit a free current of air. The wire-gauze lamp, in its present improved form, is the mostimple and portable that has yet been introduced. Plate V. fig. 5. Geology, represents the lamp as at present used; a represents the single cylinder of wire-gauze; the foldings a a a must be very well doubled and fastened by wire. If the cylinder be of twilled gauze, the wire should not be less than one-sixtieth of an inch in thicknesses, and from twenty-eight to thirty both warp and weft; b represents the second top, which fits upon a; c represents a cylinder of brafs, in which the wire-gauze is fastened by a screw, to prevent its being separated from the lamp by any blow; d is fitted into a female-ferrow, which receives the main-ferrow b of the lamp, furnished with its safe-trimmer h, and safe-feeder for oil f.

Lamps on the same principle were constructed, in which the cylinder is made of copper of one-fortieth of an inch in thicknesses, perforated with longitudinal apertures of not more than one-sixtieth of an inch in length, and the one-thirtieth in breadth. (See Plate I. fig. 6. Geology.) In proportion as the copper is thicker, the apertures may be increased in size. This form of the lamp may be proper where such an instrument is only to be occasionally used, but for the general purpose of the collier, sir H. Davy states that wire-gauze is much superior from its flexibility, and the ease with which new cylinders are introduced.

To this lamp a valuable addition has been lately made by the application of a lens before the flame, to condense the rays of light, and direct them to any particular spot. It has the farther advantage of protecting that part of the wire-gauze from coal-dust, by which it is liable to be choked and obscured in a few hours.

In subsequent experiments, sir H. Davy discovered that much thicker wires and larger apertures might be used than were at first applied. This gave to the lamp greater strength, and transmitted more light.

Gauze made of brafs wire one-sixtieth of an inch in thicknesses, and containing only 100 apertures in the square inch, did not communicate explosion in a mixture of one part coal-gas and twelve of common air, so long as the wire was cool; but as soon as the top became hot an explosion took place. A quick lateral motion also enabled it to communicate explosion. With 196 apertures to the square inch, the explosion was not communicated till the wire became strongly hot.

Iron wire-gauze, containing 240 apertures to the square inch, was safe in explosive mixtures of coal-gas, till it became strongly red-hot at the top.

Iron wire-gauze, of 576 apertures to the square inch, or the one-fortieth part of an inch each in diameter, appears, says sir H. Davy, to be safe under all circumstances, in explosive mixtures of coal-gas. With very fine wire-gauze, mixtures of oxygen and hydrogen gases may be burned without explosion until the brafs wire begins to melt.

The explanation which sir H. Davy gives of the effect of wire-gauze, and small tubes in averting the progress of flame, is as follows:—These results are best explained by considering the nature of the flame of combustible bodies, which in all cases must be considered as the combustion of an explosive mixture of inflammable gas, or vapour and air; for it cannot be regarded as a mere combustion at the surface of contact of the inflammable matter: and the fact is proved by holding a taper, or a piece of burning phosphorus, within a large flame made by the combustion of alcohol; the flame of the candle, or of the phosphorus, will appear in the centre of the other flame, proving that there is oxygen even in its interior part.

The heat communicated by flame must depend upon its mass: this is shown by the fact, that the top of a slender cylinder of wire-gauze hardly ever becomes dull-red in the experiment on an explosive mixture; whilst in a larger cylinder made of the same material, the central part of the top soon becomes bright-red. A large quantity of cold air thrown upon a small flame, lowers its heat beyond the
and in extinguishing a flame by blowing upon it, the effect is probably produced principally by this cause, assisted by a dilution of the explosive mixture.

If a piece of wire-gauze sieve is held over a flame of a lamp, or of coal-gas, it prevents the flame from passing it, and the phenomenon is precisely similar to that exhibited by the wire-gauze cylinders: the air passing through is found very hot, for it will convert paper into charcoal; and it is an explosive mixture, for it will inflame if a lighted taper is presented to it; but it is cooled below the explosive point, by passing through wires even red-hot, and by being mixed with a considerable quantity of air comparatively cold. The real temperature of visible flame is, perhaps, as high as any we are acquainted with. Mr. Tennant was in the habit of shewing an experiment which demonstrates the intensity of its heat. He used to fuse a small filament of platinum in the flame of a common candle; and it is proved by many facts, that a stream of air may be made to render a metallic body quite hot, yet not be itself luminous.

A considerable mass of heated metal is required to inflame even coal-gas, or the contact of the flame mixture with an extensive heated surface. An iron-wire of \( \frac{1}{27} \) th of an inch, and eight inches long, red-hot, when held perpendicularly in a beam of coal-gas did not inflame it, nor did a short wire of one-sixth of an inch produce the effect held horizontally; but wire of the same size, when six inches of it were red-hot, and when it was held perpendicularly in a bottle containing an explosive mixture, so that heat was successively communicated to portions of the gas, produced its explosion.

A certain degree of mechanical force, which rapidly throws portions of cold explosive mixture upon flame, prevents explosions at the point of contact. Thus, on pricking an explosive mixture of coal-gas from a syringe, or a gum elastic bottle, it burns only at some distance from the aperture from which it is diffused.

Taking all these circumstances into account, there appears no difficulty in explaining the combustion of explosive mixtures within, and not without the cylinders: for a current is established from below upwards, and the hottest part of the cylinder is where the results of combustion, the water, carbonic acid, or azote, which are not inflammable, pass out. The gas which enters is not sufficiently heated on the outside of the wire to be exploded; and as the gages are no where confined, there can be no mechanical force pricking currents of flame towards the flame point.

Two papers by Sir H. Davy, connected with this subject, were afterwards published in the Philosophical Transactions for 1817, entitled "Some Researches on Flame." In these papers, a number of new and extremely interesting experiments on the properties of flame are detailed. The practical application of the results to safety-lamps we shall briefly state, as they explain more clearly the principle on which their safety depends, and the circumstances essentially requisite to their proper construction. Sir H. Davy commends the paper by informing us, that the intensity of the light of flames depends principally upon the production and ignition of solid matter in combustion; and that the heat and light in this process are in a great measure independent phenomena: and he afterwards defines flammable to be gaseous matter, heated so highly as to be luminous, and that to a degree of temperature beyond the white heat of solid bodies, as is shown by the experiment; that air not luminous will communicate this degree of heat; for if we hold a fine platinum wire one-twentieth of an inch from the exterior of the middle flame of a spirit-lamp, and conceal the flame by an opaque body, the wire will become of a white heat in a space where there is no visible light.

When an attempt is made to pass flame through a very fine mesh of wire-gauze at the common temperature, the gauze cools each portion of the elastic matter that passes through it, so as to reduce its temperature below that degree at which it is luminous; and the diminution of temperature must be proportional to the smallness of the mesh and the mass of the metal. The power of a metallic or other tiffue, to prevent explosion, will depend upon the heat required to produce the combustion, as compared with that acquired by the tiffue; and the flame of the most inflammable substances, and of those that produce most heat in combustion, will pass through a metallic tiffue that will intercept the flame of less inflammable substances, or those that produce little heat in combustion. Or the tiffue being the same, and impermeable to all flames at common temperatures; yet when heated it will become permeable to each different kind of flame at different temperatures: those which produce most heat will most readily pass through it. A tiffue of one hundred apertures to the square inch, made of wire of one-sixtieth inch, will, at common temperatures, intercept the flame of a spirit-lamp, but not that of hydrogen; and when strongly heated will no longer arrest the flame of the spirit-lamp.

The ratio of combustibility of the different gases is to a certain extent proportionate to the masses of heated matter required to inflame them. Thus, an iron-wire of one-fortieth of an inch heated cherry-red will not inflame olefiant gas, but will inflame hydrogen gas: and a wire of one-eighth of an inch heated to the flame degree will inflame olefiant gas: but a wire of one-five-hundredth part of an inch must be heated to whiteness to inflame hydrogen.

These circumstances will explain why a mesh of much finer wire is required to prevent the explosion from hydrogen and oxygen from passing; and why so coarse a texture of wire is sufficient to prevent the explosion of the fire-lamp, the least combustible of the known inflammable gases.

The following experiments afford a satisfactory and simple explanation of the cause of the stoppage of flame by the wire-gauze lamp. Let the smallest possible flame be made by a single thread of cotton immersed in oil, and burning immediately on the surface of the oil; it will be found to be about one-thirtieth of an inch in diameter. Let a fine iron-wire one-hundred-and-eightieth part of an inch be made into a circle of one-tenth of an inch in diameter, and brought over the flame. Though at such a distance it will instantly extinguish the flame if it be cold; but if it be held above the flame, so as to be slightly heated, the flame may be passed through it without being extinguished. The effect depends entirely on the power of the metal to absorb the heat of the flame. This is shown by bringing a glass capillary ring of the flame diameter and size over the flame: this being a much worse conductor of heat will not extinguish it even when cold. If its size, however, be made greater, and its circumference smaller, it will act like the metallic wire, and require to be heated to prevent its extinguishing the flame.
surface, by diminishing the fize or increasing the depth of the aperture, all flames, however rapid their motion, may be arrested. Precisely the same law applies to explosions acting in clofe vessel: very minute apertures, when they are only a few in number, will permit explosions to pass which are arrested by much larger apertures, when they fill a whole surface. A small aperture was drilled at the bottom of a wire-gauze lamp, in the cylindrical ring which confines the wire-gauze; this, though less than one-eighth part of an inch in diameter,扩张ed the flame, and fired the external atmosphere, in consequence of the whole force of the explosion of the thin flatum of the mixture included within the cylinder driving the flame through the aperture; though, had the whole ring been composed of such apertures, it would have been perfectly safe. Nothing, says Sir Humphrey Davy, can demonstrate more decidedly than these simple facts and observations, that the interruption of flame by solid tisues permeable to light and air, depends on no con- dite or mysterious cause, but to their cooling powers simply considered as such.

When light, included in a cage of wire-gauze, is introduced into an explosive atmosphere of fire-damp at right angles, the maximum of heat is soon obtained, the radiating power of the wire and the cooling effects of the atmosphere, more efficient than from the mixture of inflammable air, preventing it from ever arriving at a temperature equal to that of dull redness. In rapid currents of explosive mixtures of fire-damp, which heat common gauze to a high temperature, twisted gauze, in which the radiating surface is considerably greater and the circulation of air less, preserves an equal temperature. Indeed the heat communicated to the wire by combustion of the fire-damp in wire-gauze lamps is completed in the power of the manufacturer, for by diminishing the apertures, and increasing the mass of metal, or the radiating surface, it may be diminished to any extent. One important circumstance, however, is not here adverted to by Sir Humphrey Davy; by increasing the thickness of the wire and diminishing the aperture, the quantity of light transmitted is greatly reduced, and its power of illumination rendered nearly inefficient. Hence the power of the manufacturer to construct a lamp perfectly safe and sufficiently luminous must be limited by certain conditions. However, Sir Humphrey Davy informs us, he has lately had lamps made of thick twisted gauze formed of wires the fourtieth of an inch, sixteen to the warp and thirty to the weft, which being rivetted to a screw cannot be displaced, from its flexibility it cannot be broken, and from its strength cannot be crushed, except by a very strong blow.

From some very ingenious experiments on the combustion of inflammable substanies at low temperatures, Sir Humphrey Davy discovered that a coil of platina wire, one-eighth of an inch thick, remains at a white heat when the quantity of coal-gauze is increased so as to extinguish the flame of the lamp; hence he has suggested the advantage of producing a coil of such wire into the safety-lamp, but we do not learn that it has yet been found of practical use. An account of these experiments is given in the Phil. Trans. for 1817.

The principal objections to the use of wire-gauze safety-lamps in mines, and also to other safety-lamps, may be briefly stated; namely, the accidents to which the lamps are unavoidably subject, and the accidents which may arise from negligence in the use of them; the injury to the health of the men, from remaining in explosive mixtures of fire-damp longer than they would have done before the introduction of these lamps into mines; and lastly, the temptation they present to neglect the more expensive methods of ventilating mines, and trusting too much to the securitv of the lamp. The accidents which may happen to the lamp from one or more of the meshes being broken, when made of such slender wire, and exposed to the corrosive effects of mineral waters in the mine, or the rapid oxidation from moisture alone, must be very frequent, independently of accidents from the falling of pieces of coal on the lamp. The breaking of a single wire being sufficient to enlarge the aperture and occasion an explosion, it is obvious that extreme caution is required in the use of the lamps, and a careful inspection of them should be made every day before they are delivered to the men. This we understand is done in extensive collieries, a person being appointed for the sole purpose of inspecting and trimming the lamps. The accidents which may arise from the negligence of a single man, in extensive mines where more than fifty or one hundred persons are employed, are left easy to guard against; the lives of a great number are constantly depending on the carefulness of each person; and, however perfect the instrument may be, no one can feel perfectly safe when the air in the mine is in an explosive state. Some of the lamps were at first so constructed that they could not be opened except by the key of the inspector; but we believe this precaution is not generally introduced, the great object being to get the lamps made as cheap as possible. We conceive, however, essential to the security of the miners, that the lamp should be closed by a lock, to prevent the men from uncovering the flame. The lamp itself, by the enlargement of the flame, gives due notice when the air of the mine is in an explosive state, and at such times the proper remedy is to be sought in ventilation; for we conceive it to be neither wise nor humane to suffer the men to continue working in an explosive atmosphere, unless under particular circumstances. Should the invention of safety-lamps induce coal proprietors to allow their workmen to remain for a longer time inhaling the fire-damp, or lead them to neglect the only permanent security, that of efficacious ventilation, we should consider the discovery as injurious to the interests of humanity. It would, however, be extremely unfair to decree the merit of any invention from the possible misuse of it. Were coal-mines first opened in a district where they had never before been worked, we believe there in most cases it would be prac- tical to secure a constant and safe ventilation through all the works: but in districts like those on the Tyne and the Wear, there are numerous old excavations remaining filled with impure air, of which the present miners have little knowledge, having been worked out in remote periods. Any communications accidentally opened with the old workings may suddenly fill a mine with a mixture of fire-damp, in which case the safety-lamp offers the only means of security with which we are acquainted. For viewing the old workings or adits of the mine, which cannot be approached with a common lamp or candle, the safety-lamp is the most invaluable instrument, and in all cases where the fleet- mill was formerly used it affords a far more secure and convenient light. Though we have thought it necessary to state the objections which may be urged against the safety-lamp, we conceive that they apply principally to the mine of it; and the following statement made by Sir Humphrey Davy offers the most satisfactory proof of its utility. "The case has now been (Jan. 1817) for twelve months in the hands of hundreds of common miners in the most dangerous mines in Great Britain, during which time not a single accident has occurred where it has been employed, whilst in other mines much less dangerous, where it has not been adopted, some lives have been lost, and many persons burned."

The farther experience of another year, on a more extended
tended scale, has fully confirmed the conclusions to be drawn from the above statement, and we may justly consider the safety-lamp as one of the most valuable presents which philosophy has made to the useful arts.

Wire-Grates, in Gardening, are contrivances formed of fine wire-work, and used for keeping various kinds of large insects out of vineeries, hot-houses, and such places, as being very mischievous to the fruit in them.

Wire-Heels, &c., a defect and consequent disease in the feet of the horse or other animal. Some, as Gibbon, think that narrow heels are for the most part a natural defect, but that they are often rendered incurable by bad shoeing. Some, in shoeing, hollow the quarters so deep and so thin, it is said, that one may almost pinch them in with one's fingers, and think by that means to widen them out by a little broad-webbed shoe; but this turns them narrow above and curvus their heels, and dries up or rots the frog. The best way in all such cases is, it is supposed, not to hollow the foot in shoeing, and to pare nothing out but what is rotten or foul. If the foot be hard or dry, or inclined to be ragged, it may be bathed often with chamber-ley; or two pounds of linseed bruised may be boiled in two quarts of chamber-ley to the consistence of a poultice, then adding to it six ounces of soft-soap, and the foot be softened with it every day, rubbing a little of it upon the sole; or, a composition formed of two ounces of bees-wax, six ounces of hog's-lard, one ounce of tar, and linseed oil as much as will make it into the consistence of a smooth ointment, may be mixed together, and be used daily in the same manner as the foregoing poultice.

The diseases and affections of the feet of these animals have of late been more accurately understood, and better means of relief and cure recommended.

In the case of narrow or contracted heels, attended with inflammation, and moistly confined to the fore-feet, there is great pain; the animal is constantly moving its legs, and generally inclined to lie down. When first taken out, it is almost incapable of performing any of the paces; the weight being too much thrown on the hinder legs. In trotting, the legs are fearfully lifted above the surface of the ground; the flaps are very short, and a walk or canter is gone into instead of any other pace. In the gallop, the weight of the body is thrown on the fore-part of the foot; and in trotting, on the heels; which produce very considerable pain, on account of the action of the foot being confined to the quarter in a backward direction.

The disease is mostly caused by improper shoeing, very great and hard exercise, standing in confined situations on litter, and many other such causes.

In effecting a cure in all the more fresh cases of this sort, where the variation from the natural round form of the hoof is not considerable, it may be accomplished without the animal being entirely made to rest, by removing the shoes, and if possible reducing the heels on a line with the inferior part of the frog. The sole parts may be thinned, and that portion which is between the bars of the foot and the crust be hollowed out. The hoofs should likewise be thinned with a proper tool, especially at the quarters. The shoes should be put on again for two or three weeks in such cases, and the parts from near the coronet to the fetlock be anointed with a blistering liniment, composed of half an ounce of finely-powdered cantharides and four ounces of Barbadoes tar, well mixed together.

And when necessary, three or four pints of blood may be taken from the plate vein, and a rowel be put in the cheet.

Mlasses, containing nitre in the quantity of an ounce, are to be occasionally had recourse to. At the same time, the feet of the animal should be put in a trough of warm water for two or three hours every day, so filled as just to cover the hoof-parts of them; gentle walking or trotting exercise being used on such ground as is soft.

Afterwards the shoes which are made use of should be thinner at the heels than those which were taken off, the heels fitting well and firmly on the bars and crust. The patent frog may be used when the animal is at rest, as by continuing its use in a proper manner, the foot will gradually regain its natural form and action. See Frog.

In such cases, too, the coronet may now be bathed every day with an emulsion composed of an ounce and a half each of marsh-mallow ointment and Barbadoes tar, with half an ounce of spirit of turpentine, well incorporated together; which will promote and hasten the growth of the hoof-part of the foot.

In cases in which the animal has been lame some length of time, and the contraction of the heels is very considerable, it should be put in moist pasture-grounds, to run for some time, carefully lowering the heels every four or five weeks, or oftener if necessary. As soon as the hoof has been elongated from the coronet to the sole, the cure will be completely effected; which will in most cases be accomplished in the course of about five months; at the end of which time the animal will have regained an entirely new circular foot of the natural shape. The animal should then be shod with thin-heeled shoes, which admit the frog-part of the foot to rest upon the ground.

In cases in which the animals cannot be turned out in this manner, they should be provided with a large hard building, well clayed on the bottom part, and preferred soft and moist by the occasional application of water slightly over it.

But though this sort of management may modify recover and restore the natural shape of the foot, the proper action of it is, not restored with such facility. In a great number of cases, the feet become so much altered, in their structure and power on account of the long-continued inflammation, that the means of expansion are wholly destroyed; as is often the case in the cartilages that are situated at the higher and hinder part of the foot, which not unfrequently become bony, and, of course, it becomes impossible to regain the action of the foot. As in these cases, the more the foot is exposed, the greater will be the injury and mischief afforded; the only means of relief that can be made use of, is the covering of the foot with such a shoe as is calculated to prevent concussion, which may be accomplished by the application of a har-shoe that will rest on every part of the crust, and not upon the frog-part of the foot. This is supposed to be the best form of shoe that can be used for the purpose.

In these cases, when the animals are at rest, the feet should be flopped with an ointment, composed of one ounce and a half each of common turpentine and tar, and two ounces and a half of mallow ointment, well mixed together.

In the cases of cracks or separations of the fibres of the hoofs in a perpendicular manner, which when they extend to the coronet are often very troublesome; the animals most liable to them, are those which have either long brittle hoofs or narrow heels. Blood animals of the horse kind are more subject to them than others.

In the management and cure of them, the parts around the cracks should be made thin by the rasps, when the firing silver should be drawn over above and below them, to the extent of the fissures, in order to prevent their extension. It should
should likewise be carried over the cracks, by which means a slight quantity of tenacious moisture will exude, and glue up the separated parts; which may be covered over with an ointment composed of four ounces of marshmallow ointment, and two ounces of common turpentine, spread upon tow, and kept on the parts by bandages.

The animals should have bar-shoes, which may rest firmly on the frogs, and be made hollow in the parts opposite to the seats of the complaints, in order that no prejudice may be given to those parts of the feet; rest being given for some days, and then only moderate exercise allowed, until the cracks have descended towards the lower parts of the feet. The coronets and hoofs may be bathed twice a day, as in the above cases of contracted heels, in order that the growth of horn may be promoted. By the use of these means, the animals moitly soon get better.

Wires of Alteries, in Natural History, a name given by authors to a sort of extraneous stuff belonging to the alteries, and being a sort of branches from the body of that column.

Wire of Lapland. The savage inhabitants of Lapland have a sort of shining slender substance in use among them on several occasions, which is much of the thickness and appearance of our silver wire; and is therefore called, by those who do not examine its structure or substance, Lapland wire.

The people of this miserable country find many uses in every thing nature has afforded them, and, among the rest, that species of stag called the rein-deer, which is the most frequent animal among them, is not only serviceable in furnishing them with meat, clothes, houses, and the means of carriage and travelling; but its bones make many of their most necessany utensils; and the sinews, which are all carefully separated in the eating, are, by the women, after soaking in water, and beating, spun into a sort of thread, which is of admirable fineness and strength, when wrought to the smallest filaments; but when larger, is very strong, and fit for the purposes of strength and force. Their wire, as it is called, is made of the finest of these threads, covered with tin. The women do this busines, and the way they take it is to melt a piece of tin, and placing at the edge of it a horn with a hole through it, they draw these finewy threads, covered with the tin, through the hole, which prevents their coming out too thickly covered. This drawing is performed with their teeth, and there is a small piece of bone placed at the top of the hole, where the wire is made flat, so that we always find it rounded on all sides but one, where it is flat.

This wire they use in embroidering their clothes as we do with gold and silver; and they often sell it to strangers, under the notion of its having certain magical virtues. Scheffer, Hist. Lapland.

Wire-Worm, in Agriculture, a most mischievous worm in different sorts of grain-crops. It has been described by Birkander, in the Swedish Tranactions, as having in the grub-state a yellow colour, with the head brown, and the extremities of the jaws black; the body confluted of twelve joints, shining, and hard-skinned; when it changes its skin it is for some time white; a few hairs are scattered here and there, but mostly upon the head and last joint; under the three first joints are six horns and pointed feet, and at the beginning of the last joint, which is round, there are two black spots, one on each side, which are, probably, apertures through which it breathes.

It is considered by some, notwithstanding the almost general opinion of farmers to the contrary, that the disease of wheat-crops, which is attributed to this insect or worm, depends upon some other cause, as a fault in ploughing, by which the land is left in too light, open, and porous a state or condition, and which prevents the young plants from being fully and properly nourished, and consequently from forming their roots in a proper manner in the ground. And this notion is in some measure supported by the circumstance of the benefit which is afforded by rolling, treading, and otherwise comprefling the land.

It has been proved and shewn by many different trials, that this worm is one which is extremely tenacious of life, and consequently not easily destroyed or got quit of by any means which have yet been made use of for the purpose.

Wire, in Geography, one of the smaller Orkney islands, separated from Roosay by a strait called Wire Sound, about three-quarters of a mile in breadth. N. lat. 58° 58'; W. long. 2° 51'.

Wire. See Wires.

Wiredy, a town of Sweden, in the province of Smaland; 16 miles N. E. of Jonköping.

Wireda, a town of Sweden, in the province of Smaland; 26 miles S. W. of Wexio.

Wiri, two small islands in the gulf of Finland. N. lat. 59° 50'. E. long. 27°.

Wiring, among Animals, the operation of putting a sharp-pointed wire up the nostrils of a sheep, so as to pass up into the brain, and produce a discharge in cafes of the impure, firm, or vertigo. It seems, however, a dangerous remedy, though it is said to have been successful in curing the diseace in many cases.

Wiring Fruit-Tree, in Gardening, the operation and practice of palling a fine wire round their branches, in order to bring on the fruiting state.

Wirkowenes, in Geography, a town of Poland, in the patalitane of Kiev; 44 miles W. N. W. of Bialocekiew.

Wirksworth, an ancient market-town in the wapentake of the name, in the county of Derby, England, is situated near the southern extremity of the mining district, in a valley nearly surrounded by hills, at the distance of 14 miles N. W. from the county-town, and 140 miles N. W. by N. from London. In the year 815, the manor belonged to the abbey of Repton; after the destruction of that monastery by the Danes, it became willed in the crown, to which it appertained at the time of taking the Domesday-survey. King John granted it to William de Ferrers, earl of Derby. Having been forfeited by the attainder of earl Robert in 1265, it was granted, together with the wapentake, by Edward I. to his brother, Edmund, earl of Lancaster; and has ever since formed part of the earldom or duchy of Lancaster. It is now held under the duchy by Richard Arkwright, esq. A market on Wednesdays, and a fair of three days, were granted for this town to Thomas, earl of Lancaster, in 1305. The market is now held on Tuesday, chiefly for butcher's-meat, butter, eggs, and pedlar's ware; the corn-market is small. Four annual fairs are now held. The town-hall, a handsome brick structure, was built in 1773, by the direction of Thomas, lord Hyde, the chancellor of the duchy. In this hall are held courts-baron for the manor, courts-leet for the wapentake, and barrow-courts for regulating the mines and mineral concerns. The church, a spacious edifice, apparemly of the fourteenth century, consists of a nave and side-ales, a north and south transept, a chancel, and a square tower, supported by four large pillars. In the church-yard is a grammar-school, founded in 1576, by Anthony...
Anthony Gell, esq. who endowed it with lands which now produce 170l. per annum. He also founded an alms-houfe for fix poor men, to which he gave a rent-charge of 20l.; this has been augmented by subfequent benefactions. In the town was formerly a meeting-houfe for Presbyterians, but it is now occupied by a congregation of Independents. Here are also chapels for Baptiftis and Wesleyan Methodists. In the population return of the year 1811, the inhabitants of this town are enumerated at 3474, occupying 777 houses. The parish of Wirkworth is extensive, and includes, besides the town, fourteen townships or villages, some of which are very populous.—Beauties of England and Wales, vol. iii. Derbyshire. By J. Britton and E. W. Brayley, 1803. Lyfons’ Magna Britannia, vol. v. Derbyshire, 1817.

WIRNAU, a town of the county of Henneberg; 5 miles S.E. of Smalkaldein.

WIRRAL, or WIREHALL, a strip of land in the county of Chelfter, extending from the city of Chelfter to the sea, between the rivers Dee and Merfey.

WIRREY, or ST. ANDREW, one of the Shaint islands. N. lat. 57° 53'. W. long. 6° 19'.

WIRSAM, a town of Sweden, in the province of Smaaland; 46 miles N.N.W. of Calmar.

WIRSTBERGHOSTZEN, a town of Welfphalia, in the bishopric of Hildefeim; 8 miles S. of Hildefeim.

WIRSUNG, JOHN GEORGE, in Biography, was a native of Bavaria, studied medicine at Padua, and was a disciple of Vefling. In 1642 he published the discovery of the pancreatic duct, with which his name is connected; and in the following year he was affiliated by a Dalmatian, under the influence of a paflion excited by having been silenced by him in a public disputation. Haller, Éloy.

WISANGI, in Geography, a town of Sweden, in Welf Bothnia, on the Tornea; 95 miles N.N.W. of Tornea.

WISBADEN, a town of Germany, in the principality of Naflau Saarbruck Üffen. This town is known to the Romans, and the Heidenfiehe Mann, or Heathen Wall, which runs through the prefent town of Wilbech, appears to be a work of that nation; and a part of the boundaries of this town are derived from the linned trenches thrown up by Druftus, oppofite to Mentz, for the covering of the Rhine. In the days of the kings of the Franks, in this town was a royal court. At Wilbech are fome medicinal springs, formerly in great repute; 5 miles N.W. of Mentz. N. lat. 50° 3'. E. long. 8° 9'.

WISBECH, a large market-town in the county of Cambridge, England, gives name to a hundred and a deanery, and is situated in the extreme northern part of the county, about 30 miles N. from Ely, 42 from Cambridge, and 90 from London, in the fame direction. Wilbech is a great mart for corn, about 100,000 quarters being annually exported from thence by the river Oufe, and the canals communicating with Cambridge, Lynn, and other towns. Other articles of export are rape-feed and long wool, of which great quantities are sent to the Yorkshire clothiers. Timber, from Northamptonshire, is also embarked for the service of the navy. The principal imports are, coal, deals, and wine. The river is navigable up to Wilbech, at spring-tides, flowing fix or eight feet, for vessels of 60 tons, which are continually employed in the corn trade, to London, Hull, and other ports. Prior to the Norman Conquest, Wilbech belonged to the convent of Ely. In 1071 William of Normandy erected a caflle of flone at the town; but this being dismantled, a new caflle of brick was built on the feite, between 1478 and 1483, by Morton, bishop of Ely, and which became the epiftcopal refidence. Being purchased by fecretary Thurloe during the interregnum, it was rebuilt after designs by Inigo Jones. Reverting at the Restoration to the fee of Ely, it was sold fome years ago, and on the ground of the detached buildings fome good houses have been erected. The church is a spacious, hand-fome fabric, although of a fingular construcfion, having two naves and two fides. The naves are lofty, and feparated by light flender pillars, with pointed arches; the fides, which are the moft ancient, are divided from their repective naves by low mafy pillars and femicircular arches. The tower of the church is beautiful, and notwithstanding the antiquity attributed to it, is proved by records to have been erected posterior to 1520. Wilbech, with the adjacent country, has frequently fuffered by inundations, particularly in 1256, when great numbers of small craft, cattle, and men, were destroyed. In 1637, by a breach in the bank of Wilbech fen, upwards of 4000 acres of land were overflowed. But the greatest deviations of this kind occurred in Nov. 1613, by the fpring-tide concurring with a violent N.E. wind; and in March 1614, by the melting of the snow in the country. In 1611 the inhabitants obtained a renewal of their charter, which constituted them a body corporate, by the ftyle of the burgeffes of Wilbech; but the right of the election of the ten capital burgeffes was limited to the poiffeffors of freeholds of the value of 40s. per annum. The executive officer, the town-baillift, although a person wholly unknown to the charter, has the entire management of the elates and affairs of the corporation. The annual income under the management of thefe capital burgeffes, allotted to public and charitable purposes, amounts to about 800l. A principal objeét of this charge is the maintaining of beacons and buoys, and the clearing of the channel of the river Oufe or Wif, from which the town takes its name; precautions highly neceffary, on account of the shifting fands between the town and the fea. Among the improvements made in Wilbech of late years, must be mentioned the flone bridge of one elliptic arch, and the new cloth-foufe. The freams are paved, lighted, and watched, at the expense of the corporation. The trade of Wilbech has much increafed of late years, through the improved state of the drainage and navigation of the fens. The neighbouring lands are in high cultivation, and are chiefly appropriated to grazing. The sheep and oxen grow to a great fize; and confiderable numbers are fent off twice every week to London. The inhabitants are almost wholly employed in commerce, the town poiffeffing no kind of manufacture, although the surrounding country produces vast quantities of wool, hemp, and flax. The canal, opened not many years ago, extending from Wilbech river to the river Nene at Outwell, and thence to the Oufe, affords a communication with Norfolk, Suffolk, and the western counties, and which proves very beneficial to the town. In 1781 a literary fociety was eftablisht in Wilbech, and the education of youth is provided for by a free-school, and by two charity-schools, supported by subscription. The diffenters from the eftablisht church are not numerous, but have their repective places of worship. The parih, containing 6306 acres, is in the greatelt part a very rich arable and paffure land. In 1676 the inhabitants of Wilbech were computed to be 1705; in 1801 they amounted to 5004; and in 1811 to 6300: the inhabited houses were 1237.—Beauties of England; Cambridgeshire. By J. Britton and E. W. Brayley, 8vo. 1802. Magna Britannia, by the Rev. D. Lyfons and S. Lyfons, 4to. 1868.
The moral sense, as several new melodies, modulations, and happy licences, which we used to think entirely of his invention, upon an attentive examination of their works, appear to have been first suggested by the three fellow-students. Yet, what they had slightly and timidly touched, Purcell treated with the force and courage of a Michael Angelo, whose abilities rendered the difficult easy, and gave to what, in less powerful hands, would have been distention, facility, and grace.

Dr. Boyce has printed six verse and full anthems, by Wife, which are admirable; and in Dr. Tudway’s collection, Brit. Mus., there are seven more, and a whole service in D minor.

He was author of the celebrated two-part song, “Old Chiron thus preached to his pupil Achilles,” which is still too well known to need an encomium here.

Michael Wife was killed in a street-fray at Salisbury, by the watchman, in 1687.

The first movement of his verse-anthem for two voices, “The ways of Zion do mourn,” is more beautiful and expressive than any grave and pathetic composition for the church of other countries, of the same kind and period of time, that we have hitherto discovered.

The use which the author has made of harmonic intervals at the word mourn, is not only happy and masterly, but new, even now, at more than a hundred and twenty years distance from the time when the anthem was produced! The whole composition seems to us admirable; and besides the intelligence and merit of the design, the melody is truly plaintive, and capable of the most touching and elegant expression of the greatest fingers of modern times; the harmony too and modulation are such as correspond with the sense of the words, and enforce their expression.

There is an elegance of phrase in a passage of the second movement of the preceding anthem, at the word down, which has been lately revived, and in great favour, with a very minute difference, among the first fingers of Italy. The difference consists only in pointing the first note if a crotchet or quaver, and making the second and third notes semiquavers or demisemiquavers.

Wife was a native of Salisbury, in which cathedral he was appointed organist and master of the choristers, in 1668; and in 1675, a gentleman of the chapel royal. In 1686, he was preferred to the place of almoner and master of the boys at St. Paul’s. He is said to have been in great favour with Charles II., and being appointed to attend him in a progres, claimed, as king’s organist for the time, the privilege of playing to his majesty on the organ, at whatever church he went.

Wise Men of Greece, Seven, in the History of Philosophy, an appellation given to several eminent men, on whom was bestowed the praise of civil and moral wisdom. The history of these persons, originally without doubt plain and simple, has been rendered obscure and uncertain by traditionary reports. The incident to which this appellation was at first owing was as follows:

In the third year of the 49th Olympiad, it happened that certain youths of Ionia, purloining from a fisherman of Melitus a large draught of fish, which he had brought to shore, found in the net a golden tripod of great value. Upon this a dispute arose between the fisherman and the purchasers: the former maintaining that he had only sold them the capture of fish; the latter asserting that they had bought the chance of the draught, whatever it might be. The question was referred to the citizens of Miletus, who were of opinion, that in an affair so extraordinary, the Delphic oracle
 oracle should be consulted. The answer of the oracle was
'To the Wiseft.' In obedience to this answer, the Mi-
leans unanimously adjudged the tripod to Thales. Thales
modestly declined the honour intended him by his fellow-
citizens, and sent the tripod to Bias, a wife man of Priene;
from him it was passed on through several hands, till it came
to Solon, the Athenian legislator, who judging that the
character of 'the wiseft' could not properly belong to any
human being, sent the prize of wisdom to Delphos to be
dedicated to Apollo. The story, as above related, has in it
something fabulous; and the circumstances that attend it are
differently related by different writers. It is more probable,
says Brucker, that in some public assembly a tripod was pro-
posed as an honorary prize to the man who should recite, in
verse, the most excellent maxims of political and moral wis-
dom, and that the fages who engaged in this generous con-
test afterwards agreed to dedicate the prize to Apollo.
In confirmation of this conjecture it is alleged, from a paffage
in Plato's Protagoras, that the wife men of this period met
together to frame concise precepts and maxims for the con-
duct of life, and agreed to fend such sentences as were
thought most valuable to Delphos, to be inscribed in the
Temple. Hence Apollo is said by the ancients to have been
the author of the precept 'Know thyself.'— E cdeo
defedtum, Γνῶθι σεαυτόν.' The names commonly included
under the appellation of the Seven Wise Men of Greece are,
Thales, Solon, Chilo, Pittacus, Bias, Cleobulus, and
WISECK, in Geography, a river of Hefe, which runs
into the Lahn, near Gieffen.
WISELL, a town of the duchy of Stiria; 4 miles
N.E. of rein.
WISEMAN, Richard, in Biography, was first known
as a surgeon in the civil wars of Charles I., and accom-
panied prince Charles, when a fugitive, in France, Hol-
lund, and Flunders. He served for three years in the Spanish
navy, and returned with the prince to Scotland, and was made
prisoner in the battle of Worecefter. After his liberation, in
1652, he settled in London. When Charles II. was re-
stored, he became eminent in his profession, and was made
one of the sergeant-surgeons to the king. In May 1676 he
appears, from the preface to his works, to have been a suf-
ferrer by ill health for twenty years; but the time of his
death is not known. The refult of his experience appears
in 'Several Chirurgical Treatises,' fol. 1676, 1686, and
in 2 vols. 8vo. 1710. The subjects of these treatises are,
tumours, ulcers, diseases of the anus, king's-evil, wounds,
gunshot-wounds, fractures and luxations, and lues venerea.
The course of his practice comprehended more than 600
cafes, of which he gives apparently an honest account,
recording his failures as well as his cures, and the detail merits
attention. In his relation of the miraculous effects of
the royal touch in ferfcola, it is not easy to reconcile his
honesty with his sagacity, though from his own narration,
duly considered, the fallacy is easily detected. His writings
have long been regarded as a standard authority in the exa-
WISEMAN, Mr., a worthy English musician, who went
early in life to Italy, in order to receive lessons on the
violin from Tartini, in Padua, who recommended him, in
1736, to one of his favourite scholars, Padghmo Bin,
at Rome, where, after some time, finding himself likely
to thrive as a professor, by the patronage of the English
nobility and gentry with which that city always abounds
in their travels, settled there for the reft of his life; and
though not a performer of the first clafs, being a good
musician, and a man of probity and good conduct, he was
not only respected by his countrymen, but by the natives of
that city, which, though no longer the capital of the world,
is still the capital of Italy and the fine arts.
Mr. Wiseman had refided fo long in Italy, that he had
almost forgotten his native tongue. In 1770 he lived in
the Palazzo Rafeale, without the gates of Rome, where, during
the firft winter months, he had a weekly concert till the
opera began. It was here that the great Raphael lived and
died, where there were still some of his paintings in fresco,
and where the late duke of York, the prince of Brunfwick,
and several other great personages, gave concerts to the firft
people of Rome.
WISEN, in Geography, a river of Baden, which runs into
the Rhine, near Bâle.
WISEENT, a river of Bavaria, which runs into the Red-
nitz, near Forchheim, in the bishropic of Bamberg.
WISEPPE, a town of France, in the department of the
Meffe; 3 miles S. of Stenay.
WISEFTARD, a town of Sweden, in the province of
Småland; 22 miles N. of Carlferona.
WISHTAFT, a town of Sweden, in the province of
Sonderborgh, 38 miles W. of Småland.
WISIR, a small island in the East Indian Sea, near the
coast of Aroo. S. lat. 15° 21'. E. long. 134° 50'.
WISK, or WIS, a river of England, in the county of
York, which runs into the Swale.
WISKA, a river of Sweden, which runs into the sea,
3 miles S. of Waro, in West Gothland.
WISI, a town of Bohemia, in the circle of Beraun;
4 miles N. of Pribiram.
WISLAMF, a river of Wurtemberg, which runs into the
Rems, N. E. of Schorndorff.
WISLITZA, a town of Poland, in the palatinate of
Sandomirz; 48 miles W. S. W. of Sandomirz.
WISLOCH, a town of the duchy of Baden, in the
palatinate of the Rhine; 14 miles E. of Spire, N. lat. 49° 18'.
E. long. 8° 45'.
WISMAR, a town of the duchy of Mecklenburg,
situated in a bay of the Baltic, with a good harbour; large,
well fortified, and defended by a citadel. This is one of
the best and largest places in the country; as, besides fix
churches, it has also a particular columbia of its own, with
a grammar-school, under the direction of eight masters, and
is the seat of a Swedish court of justice, erected in the year
1623, both for the district and the Swedish Anterior Pomera-
nia. The court consists of a president, a vice-president, and
four aldermen. It was formerly a Hanse town, and possessed
of the privilege of coinage; the first origin is not known
with any degree of certainty. In the year 1288, it was en-
larged; and in the year 1266, obtained the Lubek rights.
In the year 1261, it was annexed to the duchy of Schwerin;
in the year 1627, the imperialists got possession of it; but
in the year 1632 were driven out by the Swedes, to whom it
was ceded, at the peace of Weildphalia, in 1648, 33 miles
E. of Lubecc. N. lat. 53° 55'. E. long 11° 26'.
WISMOATH, a town of Austria; 14 miles S. of Even-
furth.
WISNA, a town of the duchy of Warfaw; 70 miles
N. E. of Warfaw.
WISNUM, a town of Sweden, in the province of War-
mland; 25 miles E. N. E. of Carolstadt.
WISOKIA, a town of Lithuania; 20 miles N. W. of
Brzece.
WISP, in Rural Economy, a term signifying a small bunch of
of straw which is used in rubbing horses down. Wisp is also a term sometimes applied to a rowel or feton put in animals.

WISPEL, in Commerce, a corn measure in Germany. A half of wheat contains 3 wipels; and a half of oats only 2 wipels. See Scheffel.

WISSANT, in Geography, a town of France, in the department of the Estaits of Calais; 12 miles N. of Boulogne.

WISSING, William, in Biography, was born at Amsterdam in 1656. He received instructions in the art of painting from Donndyns, an historical painter at the Hague, but on leaving that master went to Paris, and in the year 1660, came to England, and assisted Lely in his numerous works. After Lely's death, he became rather a favourite, and promised to become a formidable rival to Kneller. He drew all the royal family, and was particularly favoured by the duke of Monmouth, whose portrait he painted several times. The duke of Somerset also patronized him, and employed him to paint himself and his duchesses, and the pictures are now at Petworth.

Willing was appointed principal painter to James II., and was sent by him into Holland, to paint portraits of William and Mary. He did not long survive his return to England, and died at Burleigh, the seat of the earl of Exeter, in 1687, at the age of 31. His heads were painted with finish and delicacy, in a style quite distinct from that of his master, Lely, or his rival, Kneller; too soft, indeed, for character; and his larger pictures lack composition and harmony, both in line and colour.

WISSOKY-MEYTO, in Geography. See Hohen-Maut.

WISSOWATIUS, Andrew, in Biography, a Socinian divine, was born of a noble family in Lithuania, in 1668, educated in the New Unitarian college at Racow under Crelius, and for some time pursued his studies at Leyden, strictly adhering to the principles of his tutor. Finding, on his return to Poland, that his brethren suffered persecution from the diet of Warlaw, he exerted himself courageously in their defence, and encountered many personal difficulties and sufferings in the exercise of his ministry in various parts of Poland. He was not silenced by the decree issued against Unitarians in 1658, but leading an unsettled life, he was industrious in seizing every opportunity that occurred for making proselytes. In 1665, he was the only person of his party who was present at the "Colloquium Charitatum," where he firmly maintained his opinions against the jealou Chichovius and others. He is said to have refined large bribes, as well as to have encountered severe trials, in maintaining his sentiments. Removing to Hungary, he spent two years in learning the language so as to be able to instruct and fortify his brethren in that kingdom. Lived at all he retreated to Holland, where he was employed in superintending the publication of the "Bibliotheca Fratrum Polonorum," in 9 vols. fol., and where he died in 1678. His integrity and constancy are highly applauded by the historian of his sect; his writings were numerous, and one of them, published after his death, was entitled "Religio rationalis, feu de Rationis judicio in controversiis, etiam theologicos ad religiosos adhibiendo, tractatus." Gen. Biog.

WISSOWITZ, in Geography, a town of Moravia, in the circle of Hradisch; 20 miles E.N.E. of Hradisch.

WIST, WISTA, a quantity or measure of land among our Saxon ancestors; of different dimensions, in different places. In the Monastic, it is said to be half a hide, or sixty acres; in an old chronic of the monastery of Battle, it is said to be forty-eight acres.

WIST, in Geography, a town of Sweden, in the province of Earl Gotland; 6 miles S.S.E. of Linkoping.

Vol. XXXVIII.
the least difference, thereby to avoid being milled by simili-
tude, and, by affinity, to take one thing for another: and
hence he accounts for the reason of that common obser-
vation, that men who have much wit and prompt memories,
have not always the clearest judgment, or deepest reason.

It is the metaphor and allusion wherein, for the most part,
confists the entertainment and pleasantry of wit; which
strikes in so lively a manner on the fancy, and is therefore
so acceptable to all people, because its beauty appears at
first sight, and there is required no labour of thought, to
examine what truth or reason there is in it. The mind,
without looking any farther, reeds satisfied with the agree-
able effects of the picture, and the gaiety of the imagination;
and it is a kind of affront to go about to examine it by the
severe rules of truth, or reason. Whence it should only,
that wit confits in something that is not perfectly conform-
able to them. Effay on Human Underit. b. ii. c. xi. f. 2.

Professor Dugald Stewart (Elem. of the Philosophy of
the Human Mind, p. 302.) adds to Locke's definition of
wit, that it implies a power of calling up at pleasure the
ideas which it combines; and he inclines to believe, that the
entertainment which it gives to the hearer is founded, in
a considerable degree, on his surprize, at the command which
the man of wit has acquired over a part of the constitution,
which is so little subject to the will. Hence it is, that we
are more pleased with a bon mot which occurs in conversa-
tion than with one in print; and that we never fail to receive
diftiff from wit, when we suspeet it to be premeditated.
The pleasure, too, which we receive from wit, is heightened,
when the original idea is started by one person, and the
related idea by another. Accordingly Dr. Campbell has
remarked, that a witty repartee is infinitely more pleasing
than a witty attack; and that an allusion will appear excel-
 lent when thrown out extemporary in conversation, which
would be deemed execrable in print.

To the same purpose another ingenious writer has ob-
served upon Mr. Locke's description of wit, that every
resemblance of ideas is not that which we call wit, unless
it be such an one that gives delight and surprize. These two
properties, he says, seem essential to wit, more particularly
the latter of them. In order, therefore, that the resem-
bance in the ideas be wit, it is necessary they should not lie
too near one another in the nature of things; for where the
likeness is obvious, it gives no surprize. Spectator, vol. i.
No. 62.

From this account of the nature of wit, it is easy to per-
ceive what good reason Cicero had for saying (De Orat.
lib. ii. cap. 54.) *Wit is a thing not to be learned; it is the off-
spring of nature, and proper effect of a bright and lively
fancy.* Cicero reduces wit to two kinds, viz. *cavillatio,
which, in our language, may be called continued wit, or
humour, and *dicatio, which may be termed concise wit, or jelling.*

The ingenious professor above cited fuggels the following
difference between invention and wit. The former depends, in most instances, on a com-
bination of those ideas which are connected by the lefs ob-
vious principles of association; and it may be called forth in
almost any mind by the preffure of external circumstancies.
The ideas which must be combined in order to produce the
latter are chiefly such as are associated by those flighter con-
nections which take place when the mind is careless and dif-
engaged. “If you have real wit,” says lord Cheltenfield,
“it willBow spontaneously, and you need not aim at it; for
in that cafe, the rule of the gopelf is reverfed; and it will
prove, Seek and you shall not find.” Accordingly wit is
promoted by a certain degree of intoxication, which pre-
vents the exercise of that attention which is necessary for in-
vention in matters of science.

For the nature of wit in general, the different kinds of
it, its use to an orator, and the manner in which it ought to
be conducted, see Ward's Orat. vol. ii. p. 195, &c.

Wit is also an appellation given to persons poifeded of
the faculty called *witt, effprit.*

A French author, who, in 1695, published a “Treatise
of Wit, du Bel Eprir,” lays down four characters of it.

1. A man, who, with an open air and easy motions,
 affecte those he converses with agreeably; and on any
 subject that presents itself, ‘advances new thoughts, and
 adorns them with a sprightly turn; is also the world over,
 a wit.

2. Another, who, efects solicitude about the choice and
delicacy of his sentiments, knows how to make himself valued
by I know not what elevation of discourse; who draws
much attention, and thaws great vivacity in his speaking, and
readines in his answers; is likewise acknowledged a wit.

3. A third, who takes lefs care about thinking than
about speaking well; who affects fine words, though
perhaps low and poor in matter; who pleases by an easy
pronunciation, and a certain tone of voice, is placed in the
same rank.

4. Another, whose chief aim is not to make himself
efteemed, so much as to raife mirth and laughter; who
jokes pertinently, rallies pleasantly, and finds something
to amuse himself in every petty subject; is likewise
allowed a wit.

Yet, it may be observed, that in all these cafes, there is
nothing of real wit, as above defined; but the whole is
imagination, or memory at mott: nay the whole is no more
than what temperament may give.

A true wit must have a just faculty of differenience; muft
have, at the fame time, both great energy, and peculiar
delicacy, in his sentiments; his imagination must be noble,
and at the fame time happy and agreeable; his expreffions
polite and well turned; without any thing of parade or
vainy in his discourse, or his carriage. It is not at all ef-
tential to a wit, to be ever hunting after the brilliant; still
studying fine thoughts, and affecting to fay nothing but
what may strike and surprize.

This is a fault very frequent in dramatic perfons; the
duke of Buckingham rallying it very justly.

“What is that thing which we flue wit do call?
’Tis when the wit of some great writer shall
So overflow, that is, be none at all,
That e’r his fools fpeak fene—.”

From the account we have given in the preceding article
of the difference between invention and wit, it appears, that
those who have the reputation of wits are commonly more
confident in their own powers, who allow the train of their
ideas to flow, in a great measure, its natural course, and
hazard in company every thing, good or bad, which occurs
to them. Men of modety and tafe feldom attempt wit in
a promiscuous fociety; or if they are forced to make fuch
an exertion, they are feldom fucceffful. Such men, however,
in the circle of their friends, to whom they can unbloom
themselves without revere, are frequently the moft amusing
and the moft intereting of companions; as the vivacity of
their wit is tempercd by a correct judgment and refined manners:
and as its effect is heightened by that fenfibillity and delicacy,
with which we fo rarely find it accompanied in the common
intercourse of life. When a man of wit makes an exertion
to dillinguifh himself, his fallies are commonly too far-fetched
to pleafe. He brings his mind into a ftate approaching that
of the inventor, and becomes rather ingenious than witty.

Genuine wit, says lord Cheltenfield, never made any man
laugh since the creation of the world: upon which profes-
for
for Stewart remarks, that this observation is just, if by genuine wit we mean wit wholly divested of every mixture of humour; and if by laughter we mean that convulsive and noisy agitation which is excited by the ludicrous. But there is unquestionably a smile appropriated to the flashes of wit; — a smile of surprize and wonder: — not altogether unlike the effect produced on the mind and the countenance by a feat of legerdemain when executed with uncommon excess.

**Humour, say our critics, is the genuine wit of comedy.**

**Witt-Fish, in Ichthyology, a name given by the Dutch in the East Indies to a fifth common on those coasts, and seeming to be of the tunia kind. It is of the size of our common whiting.** It has one single spine or prickle on its back, and has a long belly-fin reaching from the head to near the tail; its whole body is flaitred, and it has two long filaments or beards hanging from its snout, and is a very fine and delicate fish. Ray.

**Witt-Fish is also the name given by the Dutch to an East Indian fish, called by Mr. Ray, Albula Indica.**

**WITASARI, in Geography, a town of Sweden, in Vaalhall; 70 miles N. N. E. of Jamio.**

**WITCH of Endor, in Biblical History, a woman who had a familiar spirit, and who was employed by Saul to consult the deceased Samuel concerning the issue of his contest with the Philistines. See 1 Sam. xxviii.**

The explication of this part of facted history has greatly perplexed commentators and critics. Some, in deference to the authority of the ancient fathers of the Christian church, who ascribed to magicians and necromancers the power of calling up the souls of the dead, have given a literal interpretation of this history, and supposed that Samuel actually appeared to Saul. But to this opinion it has been justly objected, that it is repugnant to the order of the natural world, and to the doctrines of revelation respecting the state of the dead. It cannot be supposed consistent with a just reverence of God to believe, that he has subjected the souls of the departed, not excepting those of the most eminent saints and prophets, to be remanded back from their dignified abodes, by the practice of the most execrable rites, and at the call of some of the vilest mortals, and compelled to reveal what he has been fit to conceal. Natural reason confirms the suffrage of scripture, when it brands the whole magic art, to which evocations of the dead, and all necromantic divinations appertain, as founded in imposture. Others, who cannot admit that witches are able to disturb the souls of good men, much less of prophets, are nevertheless of opinion, that these wretched women can cause the devil to counterfeit the souls of the dead; and that in the case before us, an evil spirit appeared before Saul in the likeness of Samuel. (See Patrick in 1 Sam. xxviii. 12.) But this opinion gives an unwarrantable advantage for the support of idolatry to those impostures that were practised by heathen forcers and diviners. Besides, the very apparaition of a spiritual and incorporeal being, and the gift of prophecy, are real miracles, and cannot take place but by divine appointment: and lastly, the historian calls the appearance to Saul Samuel, which he could not do with truth, if it was no other than the devil, who here appears, not as a tempter, but as a very fervent reprover of impiety and wickedness.

Many learned men have, therefore, maintained, that it was neither Samuel, nor an evil spirit, who here appeared to Saul; but that the whole was the work of human imposture. In support of this opinion it may be pleaded, that the woman to whom Saul applied to call up Samuel was merely a ventriloquist, poising an art very serviceable to those who counterfeited the answers of the dead. This opinion, however, like the foregoing one, contradicts the sacred historian, who not only represents the Pytho-nes as affirming, but himself affirms, that the saw Samuel, and that Samuel spake to Saul: nor has he dropped the least hint that it was not the real Samuel of whom he was speaking.

Others have supposed, that the appearance of Samuel to Saul was a divine miracle: though whether the miracle consisted in raising Samuel, or in presenting an image or representation of him before Saul, it is not necessary to determine. Accordingly, the apparition must be ascribed, not to the power of enchantment, but to the immediate appo- pointment of God, as a rebuke and punishment to Saul. This opinion is maintained by Dr. Waterland, in his Sermons, vol. ii. p. 267, and defended by Dr. Delany in his Life of David; but combated by Dr. Chandler, with objections which, as far as they affect the scripture history of the matter, are answered or obviated by Mr. Farmer, in his Discourse on Miracles, p. 486, &c.

**WITCH-Hazle, in Botany. See Hazle.**

**WITCH Island, in Geography, one of the smaller Virgin islands; 6 miles E. of St. John.**

**WITCHCRAFT, the crime of forcery, especially in women.**

Many think there may be some foundation for what we call fascination and witchcraft. We have innumerable instances and histories to this purpose; which it would not be fair to set aside, merely because they are not reconcilable to our philosophy: but, as it happens, there seems to be something in philosophy to countenance some of them.

Indeed, the ridiculous stories that are generally told, and the many impurities and delusions that have been discovered, in all ages, are sufficient to demolish all faith in such a dubious crime; if the contrary evidence were not also extremely strong. Wherefore, (says judge Blackstone,) it seems to be the most eligible way to conclude, with an ingenious writer of our own (Spec. No. 167,) that in general there has been such a thing as witchcraft, though one cannot give credit to any particular modern instance of it. Some readers will, however, probably dissent from this inference of Mr. Addison, and the opinion of the learned judge, and incline to consider witchcraft in general as a species of imposture. See Magician, and Miracle.

What the writers in favour of the opinion advance, as their reasons, is as follows:

All living things, they say, emit effluvia, both by the breath and the pores of the skin. All bodies, therefore, within the sphere of their periphrasical or expiratory effluvia, will be affected by them; and that, in this or another manner, according to the quality of the fluid; and in this or that degree, according to the disposition of the emittent and recipient parts.

This, indeed, is incontestible; nor need we produce instances of animals exhaling sweet or stinking smells; or of infectious diseases conveyed by effluvia, &c. in confirmation of it.

Now, of all parts of an animal body, the eye, we know, is the quickset. It moves with the greatest celerity, and in all the variety of directions. Again, its coat and humours are permeable as any other part of the body (witness the rays of light it most copiously receives.) The eye, therefore, no doubt, emits its effluvia like the other parts. The fine humours of the eye must be continually exhaling. The heat of the pervading rays will rarely, and attenuate them: and that, with the subtle juice or spirit of the neighbouring
fund, the pray. The we large treatife (ling, the render and, large was the. It thus, is requiring crying full, admirable becaufe and, dog's a

and, extraordinary difpleafed, quantity wherefore witchcraft it been, been al of the branch called fascination. It is certain the eye has always been efteemed the chief feat, or rather organ, of witchcraft; though, by moft, without knowing why, or wherefore: the eftect was apparently owing to the eye; but how, was not dreamed of. Thus, the phrase, to have an evil eye, imports as much as to be a witch. And hence Virgil,

"Necio quis teneros oculus mihi fascinat agnos."

Again, old bilious perffons are thofe most frequently suppofed to have the faculty; the nervous juice in them being depraved and irritated by a vicous habitude of body, and so rendered more penetrating and malignant. And young perffons, chiefly children and girls, are most affected by it; becaufe their pores are patent, their juices incoherent, and their fibres delicate and susceptible. Accordingly the witchcraft mentioned by Virgil only reaches to the tender lambs.

Laftly, the faculty is only exercised when the perffon is difpleafed, provoked, irritated, &c. it requiring some extraordinary fires and emotion of mind to dart a proper quantity of the effluvia, with a sufficient impetus, to produce the eftect at a distance. That the eye has some very confiderable powers is palt difpute.

The ancient naturalists affure us, that the balilific and opoblepa kill other animals merely by flaring at them. If this fail of credit, a late author affures us to have seen a mouse running round a large fnafe, which fwood looking earneftly at it, with its mouth open; till the mouse made lefs and lefs circles about it; crying all the while, as if compelled to it; and, at laft, with much feeming reluctance, ran into the gaping mouth, and was immediately swallowed.

Who has not observed a setting-dog; and the eftects of its eye on the partridge? The poor bird, when once its eyes meet thofe of the dog, flands as if confounded, regardles of itself, and eafily lets the net be drawn over it. We remember to have read of fquirrels aloftupified and overcome by a dog's flaring hard at them, and thus made to drop out of the trees into his mouth.

That man is not fecure from the like affections is matter of eafy obfervation. Few people but have, again and again, felt the effects of an angry, a fierce, a commanding, a dif-
dainful, a lascivious, an intriguing eye, &c. These effects of the eye, at leaft, make a kind of witchcraft. But our readers will excuse our enlarging.

Witchcraft prevailed to fuch a degree both in England and Scotland in the 16th century, that it attracted the attention of government under the reign of Henry VIII., in whose 33d year was enacted a flatute which adjudged all witchcraft and forcer to be felony without benefit of clergy; and at the commencement of the reign of Elizabeth, the evil seems to have been very much on the increafe; for bishop Jewel, in a fermon preached before the queen in 1558, tells her; "It may pleaf the your grace to underland that witches and forcerers within these four laf years are marvellously increased within your grace's realm. Your grace's subjects pine away even unto the death, their colour faded, their flesh rotten, their speech bennimated, their fenfe are bereft; I pray God they never pratiſhe further than upon the subject." Of the prevalence of this deluſion in 1584, we have the testimony of Reginald Scot, in his treatife intituled "The Discoverie of Witchcraft," written in behalf of the poor, the aged, and the fimple, as the author informs us; and it reflects fignificant difcredit on the age in which it was produced, that a deluſion fo complete, both with regard to argument and fact, fhould have failed in effecting its purpofe. The milchif, inced of being refrained, was rapidly accelerated by the publication of the "Demonologie" of king James, at Edinburgh, in the year 1597; and the contagion was promoted by the fucceſion of James to the throne of Elizabeth. In the year 1603, the royal treatife was printed at London, with an alarming preface concerning the increafe of witches or enchanters, "these deteſtable flames of the devil," and it was accompanied by a new flatute againſt witches, which deſcribes the crime in a variety of particulars, and enacts, that offenders, duly and lawfully convicted and attainted, fhall suffer death. Reginald Scot, in his treatife above-mentioned, has pourtrayed at large the character of thofe who were branded with the appellation of witches, flating the deeds that were imputed to them, and the nature of their suppoſed compact with the devil. The abode of a witch is admirably defcribed by Spenfer, the description being formed from an existing ſubject:

"There in a gloomy hollow glen the found
A little cottage built of thicket and reedes
In homely wife, and wald with fods around;
In which a witch did dwell, in loathly weedes
And willful want, all carfules of her needes;
So chooſing solitarie to abide
Far from all neighbours, that her devilish deeds
And holliff arts from people the might hide,
And hurt far off unknowne whom ever the environ."

Faerie Queene.

Scot has, with singular induſtry, collected from every writer on the ſubject the minutiae of witchcraft, and he has annexed comments for the purpofe of refuting and exposing them; whereas James, the royal ſedant, wrote in defence of this folly, and, unfortunately for truth and humanity, the doctrine of the monarch was preferred to that of the fage.

The old laws made in England and Scotland againſt con juration and witchcraft are repealed by a late ſtatute, and no perfon is to be proceeded for any fuch crime. 9 Geo. II. c. 5. See Conjurati on.

WITCHES-BUTTER, a name given by the common people of England to a fort of tremella growing on the bark of old trees, in form of a corrugated membrane.

WITELSHOFEN, in Geography, a town of Germany,
many, in the margin rate of Anspach; 7 miles S.E. of Crediheim.

WITGENAU, or Withenau, a town of Lusatia, on the Elster; 13 miles N.N.W. of Bautzen. N. lat. 51° 20'. E. long. 14° 10'.

WITGENAU, or Wittenburg, or Těžebon, a town of Bohemia, in the circle of Bechin, on the river Lounficz; 22 miles S.S.E. of Bechin. N. lat. 49° 4'. E. long. 14° 40'.

WITGENSTEIN, a county of Germany, situated between the principalities of Heuff Darmstadt, Nassau Dillenburg, and the duchy of Welfphalia; about 18 miles long, and 12 broad. Some parts are mountainous and woody, and contain mines of silver, copper, and iron; the pastures are good, but the arable land inconvenient. The principal rivers are the Lahn and the Eder. It is united to the county of Sayn, and that princely house is divided into two branches, Sayn Witgenstein of Witgenstein, and Sayn Witgenstein of Berleburg, each of which had a distinct vote in the Imperial college, and in the diet of the Upper Rhen. The county takes its name from a feat, the residence of the counts, which is situated on a mountain; 1 mile N. of Laafhe.

WITGEWALT, a town of Prufia, in Oberland; 8 miles N.E. of Oletterode.

WITH-VINE, or Wine, in Agriculture, a term provincially signifying couched, or couched-gras. See Bind-Wheat.

WITHAM, in Geography, a market-town and parish in the hundred of the same name, in the county of Essex, England, situated on a branch of the river Blackwater, 83 miles N.E. from Chelmsford, and 37½ in the same direction from London. By the parliamentary returns of 1811, the number of houses in the parish was 466, and the inhabitants amounted to 2352. Witham has a weekly market on Tuesday, and fairs on Friday and Saturday of Whits-week, on the 14th of September, and 5th of November. The petty feittions for the Witham division of the county are also held in the town. Witham is supposed to have been constituted a town by Edward the Elder, though perhaps it was only reformed by him, at least the part on Cheping Hill round the church, which stands about a half a mile N.W. from the other part of the town. On this eminence are considerable remains of a circular camp, inclosed by a double ditch and rampart. From this work, and the quantity of Roman bricks worked up in the body and tower of the church, Witham has been thought to occupy the position of the Canomium of Antoninus. The manor was anciently possesed by earl Harold, and afterwards by Eulace, earl of Boulogne, who married the sister of Edward the Confessor. Near the end of the town is a manor, now possesed by Thomas Kynalton, esq., but formerly belonging to the late earl of Abercorn. Faukbourne-hall, between one and two miles N.W. from Witham church, is the seat of colonel Bullock, formerly member of parliament for the county of Essex. Here is a cedar-tree, about nineteen feet in circumference near the ground. A coin of Domitian and velliges of walls indicate the Romans to have had a villa at this place.—Beauties of England and Wales, Essex. By J. Britton and E.W. Brayley. 8vo. 1808.

WITHAM, a river of England, in the county of Lincoln, which rises in the fourth part of Lincolnshire, on the borders of Leicestershire, palies by Grantham to Lincoln, where it becomes navigable; from thence it palies by Tattersall, Bolton, &c. and runs into the German sea, 5 miles below Bolton, in what are called the Washes.

WITHAL, in Agriculture, a small twelved flick of any kind used as a band.

WITHER-BAND, in Rural Economy, the band or piece of iron which is laid underneath a saddle, about four fingers above the withers of the horse, to keep tight the two pieces of wood that form the bow of the saddle.

WITHER-WRANG, in the Meische. A horse is said to be wither-wrang, when it has got a hurt in the withers; which fort of hurts it is very hard to cure. See WITHERS.

WITHERING, William, M.D. F.R.S., in Biography, was born in 1741, and finished his medical education in the university of Edinburgh, where he took his degree of doctor in 1766. From Stafford, where he first settled and married, he removed to Birmingham, and speedily attained by his skill and affiduity to very extensive and profitable practice; without seeking much society or neglecting his scientific pursuits in order to secure it. The chief objects of his attention, independently of his professional engagements, were botany and chemistry. The result of his scientific inquiries and labours appears in the following list of his valuable publications; viz. “A Botanical Arrangement of British Plants,” in 2 vols. 8vo. 1776, which passed through two more editions, in 1787, 3 vols., and in 1796, 4 vols., with numerous improvements and additions, some of which were suggested by his friends, and particularly by Dr. Stokes. In chemistry and mineralogy, a translation of Bergman’s “Sciagraphia Regni Mineralis,” 1783, and the following papers in the Philosophical Transactions; “Experiments on different Kinds of Marle found in Staffordshire,” 1773; “An Analysis of the Toad-flame of Derbyshire,” 1782; “Experiments on the Terra Ponderosa,” 1784; and “An Analysis of a Hot Mineral Spring in Portugal,” 1798. In the improvement of his own profession, “Account of the Scarlet Fever and Sore Throat, particularly as it appeared at Birmingham in the year 1778;” and “An Account of the Fox-glove and some of its Medical Ufes; with Practical Remarks on the Dropy and other Difeases,” 1785. Subject to pulmonary attacks, which weakened his lungs, he thought it necessary, in 1793 and 1794, to pass the winter in a warmer climate, and he fixed on Lisbon. Afterwards he became incapable of his former professional exertions, and died at the Larches, near Birmingham, in November 1799, at the age of 58. In his intellectual character he joined unremitted application with sagacity and diligence. In his medical practice he limited prescription to that quantity and kind of medicine which was absolutely necessary for his patients; and if any in the inferior branches of the profession disliked this mode of practice, their disapprobation of it was a testimony in its favour. In his disposition he was mild and humane; and his natural reserve did not preclude him from the pleasures of rational society. His valuable library and handsome property were inherited by an only son.

WITHERING, in Medicine. See ARIDURA.

WITHERING of a Cow, is when, after calving, she does not call her cleaning, which, if not timely remedied, will kill her.

WITHERINGIA, in Botany, was so named by the great French botanist, M. L’Heritier, (see that article,) in compliment to the late Dr. William Withering, F.R.S. F.L.S., the well-known author of a most useful and popular English work, entitled an “Arrangement of British Plants,” which has gone through several editions, in some of the earlier of which Dr. Stokes was his coadjutor. (See STOKESIA.)—L’Herit. Sert. Angl. 33. Schreb. Gen. 791. Wild. Sp.
It occurs in considerable quantities on the western side of Yorkshire, and in the counties of Northumberland, Durham, and Westmorland, in veins which traverse mountain lime-flone and sand-flone. In some of these veins it has been observed, that when the vein passes through the lime-flone, it contains Witherite, or carbonate of barytes; but where it passes through the sand-flone, it contains sulphate of barytes, or heavy spar. It sometimes occurs in a flàSalatic or cellular form, and disseminated in other minerals.

Witherite is rather a scarce mineral on the continent. It is a very active poisons. It has not been used in the arts in this country. It is probable that it may be employed on the continent in the composition of the alkaline fulphates, as foreigners sometimes obtain it from the mines in Yorkshire in considerable quantities.

WITHERNAM, in Law, a repriph, or taking of other goods or cattle, in lieu of those unjustly taken and effoned, or otherwise withheld.

The word is compounded of the Saxon wither, contra, again; and nam, captio, taking. See NAAM.

Where goods are taken by colour of divers, and driven to a hold, or out of the county, so that the sheriff cannot, upon replevy, make deliverance thereof to the party dis-tributed; in this case, the writ of captas in withernam, or de vesito namo, is issued, directed to the sheriff, for the taking as many of the party's beasts, as he did thus unlawfully dis-tribute; or as much goods of his, till he has made deliverance of the first divers; and, therefore, goods taken in withernam cannot be reprieved, till the original divers is forthcoming.

WITHERNAM. Homine captio in. See HOMINE.

WITHERS of a Horse, the juncture of the shoulderbones at the bottom of the neck and man, towards the upper part of the shouder.

These parts should be well raised and pretty strong, for this is a figure of strength and goodnes in the horfe. They keep the faddle from coming forward upon the horfe's shoulders and neck, which immediately galls and spoils him. A hurt in this part is very difficult to cure, and, for this reason, they should be lean rather than fliehy, as they are then less subject to be bruised and hurt by the faddle.

When there are fores on the withers, the caufe muft be looked to, in order to determine a proper cure, and prevent a return. If the hurt be caufed by the larngefles of the faddle-bands, provided that it be not too great, it may be easily cured by the following remedy: take the whites of fix eggs, beat them with a piece of alun as big as an egg for a quarter of an hour, or till the whole is reduced to a thick leum or froth; let the swelling be rubbed well with this mixture, and then covered over with more of the froth; this is to be left to dry on, and the application is to be repeated every ten or twelve hours; notwithstanding that the heat and swelling remains, this, by degrees, will take place, though not at firft.

If the hurt be great, recourfe muft be had to bleeding; and this may be repeated after two days, if the swelling and inflammation continue.

If a tumour, with great inflammation, follow a bruife with the faddle-bows, the part affected is to be rubbed with lime-water, and covered with a lamb's skin, the woolly part next the back; after the washing, the ointment, well known among our farriers by the name of the duke's ointment, is to be applied; and if the tumour inclines to suppurate, the ointment must be washed off with a mixture of vinegar and water, warmed, mixed with a handful of falt to every quart of it; an ointment is then to be made of half a pound of populace, and a quarter of a pound of black soap, and as much
much honey: these are to be thinned with a large glafs of
spirit of wine, and the part is to be well rubbed with some
of this three or four times a-day, covering it afterwards
with a lamb's skin. Some ufe instead of this ointment a
poultice made of powder of cummin-feed, linseed-oil, and
pigeons' dung, which does as well.
Where these means are not fufficient to remove such
ulcers or fwellings, a more effectual remedy may frequently
be found in the blitting liniment.
But wherever matter is formed and distinctly felt by the
finger, an opening fou ld be made as near as possible to the
mouth depending part of it, to allow of a free discharge of
it, and a rowel be introduced through the whole extent of
the cavity, and be frequently moved, and washed with spi-
rits of turpentine; the healing proefs being promoted by
the injection of stimulating wafhes.
In cafes where sinus-es are formed, and thofe means are in-
fufficient for healing the parts, the cure much be performed
by making an incision through the whole extent of the
hollow parts; dressing them afterwards in fuch a manner as
to keep down the proud flesh, and preferring the wounds
clean, as well as aiding the growth of new flesh by proper
means. See Ulcer, and Wound, in Animals.
Withers of the Bow of a Saddle, in the Manage. See
Bow.
WITY, a large species of willow, fit to be planted
upon high banks and fides of ditches, within reach of the
water, or on the weeping fides of hills.
Withy-Cragged, a term fometimes applied to a disease
in horses. See Strain.
WITLAGE, in Geography, a town of Welfphalia, in
the biphoric of Ofnabruck; 11 miles E.N.E. of Vorden.
WITLAH, a town of Germany, in the county of Ven-
der; 3 miles S.E. of Vorden.
WITLOWZ, a town of Bohemia, in the circle of
Konalingratz; 16 miles N.N.E. of Gittichen.
WITMARSEN, a town of Germany, in the biphoric of
Munfer; 7 miles W. of Lingen.
WITNESS, Testis, a person who certifies or afferts
the truth of any fact.
All witnefses are deemed competent, who, having the ufe
of their reafon, are neither infamous nor intereffed in the
event. See Evidence.
Among the Romans, it was a cuftom to pull or pinch
the ears of witnefses prefent at any tran fantion; that they
might remember it when they were called to give in their
testimony. Two eye-witnefses, or de viju, not fufpefted,
are to be deemed a conclusive proof.
Falsc witnefses, suborners of witnefses, &c. in England
are punifhed with the pillory; in feveral other countries,
with death. See Perjury, Subornation, &c.
In a synod at Rome, under Conftantine, in the year 320,
it was decreed, that there should be feventy-two witnefses
heard, to condemn a bifhop; which was called libra tefium,
a poad of witnefses. Accordingly there were feventy-two
witnefses heard againft pope Marcellinus; who, says the his-
torian, erat eftus libri occidua.
Anciently there were synodal witnefses, tesfes synodales, in
each parish, chofen by the bifhop, to inquire into the her-
eties, and other crimes, of the parishioners; and to make
oath thereof on the relics of the saints. See Synodales.
Witness, Attic. See Attic.
Witnefses, Trial by, in Law, is a species of trial, with-
out the intervention of a jury. This is the only method of
trial known to the civil law; in which the judge is left to
form in his own breath his fentence upon the credit of the
witnefses examined; but it is very rarely ufed in our law,
except only that when a widow brings a writ of dower, and
the tenant pleads that the husband is not dead; this is, in
favour of the widow and for greater expedition, allowed to
be tried by witnefses examined before the judges; and alfo
in fome other cafes mentioned by Sir Edward Coke, as to
try whether the tenant in a real aotion was duly summoned,
or the validity of a challenge to a juror: who observes, that
in every cafe the affirmative must be proved by two witnefses
at the leat. Blackf#. Com. book iii.
WITNEY, in Geography, in the hundred of Bampton,
and county of Oxford, England, is a long and irregular,
but large and populous market-town, situated 11 miles
W.N.W. from Oxford, and nearly 66 in the fame direction
from London. Through the town runs the little river
Windrush. Witney was one of the eight mansons given to
his cathedral in 1040 by Alwin, bishop of Winchefter, in
confequence of the fulpicion of his improper conduct with
Emma, the mother of Edward the Confefsor. The queen-
mother cleared herfelf by the fiery ordeal (an experiment of
probably little danger), and the bifhop made reparation for
the scandal he had, although innocent, brought upon his
church by a transfer to the clergy belonging to it of eight
of his manors. In 1171 the manor was, by bishop Blot,
befought on his new foundation of St. Crofs, near Winche-
fter. In the fifth year of Edward II. Witney became a
borough, and continued to fend members to parliament till the
33rd year of Edward III. when the privilege was declined:
it is still, however, called a borough, and governed by two
bailliffs. The church, terminating the principal freet, is large
and handsome, with crofs aifles, furmounted by a tower and
spire. A free-school was founded here in 1660, and other
charitable institutions for the education of youth have lately
been formed. Witney has long been celebrated for the ma-
ufacture of blankets, of which the weavers were incorpo-
rated in queen Anne's reign. When Dr. Plott pubhished
his Natural History of Oxfordshire, in 1677, the weaving
buifenes employed no fewer than 5000 perfons, "from chil-
dren of eight years old, to decrepit old age," a number pro-
bably not exaggarated, if it be confidered, that, in his time,
every part of the manufacture was performed by manual
labour. But in the latter half of the latt century the 
blanket trade fuffered a great defacation. In 1768 about
500 weavers only were employed, a number which gra-
dually funk to lefs than one half; the confequence of which
was great diftrefs among the inhabitants. Machinery was
introduced into the manufacture, by which one man per-
formed the work of two. The blanket buifenes again re-
vived; but the working hands reaped no benefit from its
revival. In 1807, when the price of blankets was five
pounds the pair, the workmen earned but twelve fhillings
per week, the fame sum as in 1768, when the pair brought
only three pounds. The flape, or blanket-hall, fands in the
high freet, as does alfo the town-hall, under which is a
place for the market. The rectory of the parish is united
with the vicarage, and in the patronage of the bifhop of
Winchefter. The town contains meeting-houfes for dif-
dferent defcriptions of diflenters. According to the popu-
lation return of 1811, the houfes in the town were 542,
and the inhabitants 2722.—Plott's Natural History of
Oxfordshire, 1677 and 1705; fol. Beaulies of England,
Oxfordshire, by J. N. Brewer, 8vo. 1813.
WITRY, a town of France, in the department of the
Marne; 6 miles N.E. of Rims.
WITSENIA, in Botany, was fo named by professor
Thunberg, in compliment to Mr. Witven, "Councilor to
the Chief Magiftrate of Amsterdam," whom he styles a moft
eminent patron and promotor of every kind of fience.
Profeflor

Gen. Ch. Call. none, unless the upper pair of the bracteas be so considered. Cor. of one petal, tubular, erect: tube cylindrical, slender at the base, gradually dilated at the top: limb spreading, regular, in six fix, equal, obvolute segments. Stam. Filaments three, very short, inserted into the mouth of the tube, at the base of three alternate segments of the limb; anthers oblong, erect. Pf.l. German superior, roundish, small: style thread-shaped, erect, longer than the tube of the corolla, slightly curved at the extremity; stigma in three short, equal, rather spreading segments. Peric. Capsule membranous, of three cells and three valves. Seeds several, angular.

1. W. mauro. Downy-flowered Witfienia. Thunb. Nov. Gen. 34. t. 2. f. 1. Fl. Cap. v. 1. 255. Willd. n. 1. Vahl n. 1. Ait. n. 1. Redout. Liliac. t. 245. (Anthophyza mauro; Linn. Mant. 175.) —Flowers terminal, in pairs. Outer segments of the corolla externally downy. Native of the sandy sides of hills, at the Cape of Good Hope, flowering in April and May. Sent to Kew by Mr. Maffon, in 1795, but it does not appear to have bloomed in that collection, nor elsewhere in Europe. M. Redouté's fine figure being made from a dried specimen, aided by description. The root is perennial and woody. Stem shrubby, erect, more or less branched, two feet high, compressed; naked in the lower part, and appearing as if jointed, from the scars left by former foliage; leafy above. Leaves numerous, alternate, sessile, two-ranked, equitant, four or five inches long, compressed, falcate, acute, entire. Flowers in pairs at the extremities of the short terminal branches, crowded, more or less numerous, into a corymbose tuft. Corolla two inches long: its tube yellow at the base, dark blue for a considerable extent in the upper part; limb yellow, feecially spreading, half an inch long, clothed externally with dense yellow pubescence of a very peculiar kind, confined to the tips of the inner segments.

2. W. corymbofa. Corymbose Witfienia. Ker in Curt. Mag. t. 895. Ait. n. 2. Sm. Exot. Bot. v. 2. 177. n. 68. —Corymbose many-flowered. Corolla externally smooth. Native of the Cape of Good Hope. Raised from seed by G. Hibbert, eq?, in 1803. A green-house plant, flowering in spring and autumn. The flower is shrubby, from four to six inches high. Leaves like the leaf, but only half the fize, somewhat glaucous. Flowers very numerous, bright blue, in a forked corymbose, compound panicule, supported by a long stalk, at first terminal, but soon becoming lateral. Bracteas two pair at the base of each flower, concave, obtuse. Corolla about an inch long, including its horizontal limb.

3. W. ramoza. Branching Witfienia. Thunb. Fl. Cap. v. 1. 256. Vahl n. 2. (W. fruticosa; Ker in Ann. of Bot. v. 1. 237. Ixias fruticosa; Thunb. Diff. n. f. t. 1. f. 3. Lamarck Illust. t. 31. f. 4. Linn. Syst. 93.) —Stem much branched. Corolla externally smooth; its tube capillary, twice the length of the limb.—Native of hills at the Cape of Good Hope, flowering in October, November, and December. The flower is a fiam high at most, remarkably woody, repeatedly branched in a corymbose manner; naked below; the branches compressed, two-edged, knotty or scarred, as if jointed, leafy at their extremities. Leaves equitant, two-ranked, linear, narrow, one and a half or two inches long, rather glaucous; reddish at the base. Flowers terminal, very few together, if not quite solitary, blue, remarkable for the length and flenderness of their tube, which sometimes measures nearly two inches; the limb is rather less spreading, and more bell-shaped, than that of corymbofa. Bracteas membranous, elongated, brownish.

4. W. pumila. Dwarf Witfienia. Vahl n. 3. (Ixyia pumila; Forth. Comm. Gott. v. 9. n. 20. t. 2. I. magnelliana; Lamarck Illustr. v. 1. 109. Morea magellana; Willd. Sp. Pl. v. 1. 241, excluding Cavanilles' Ixolium. Tappein. Jull. 59.)—Stems simple, single-flowered.—Gathered by Forfier, Commeron, and others, at the fraxins of Magellan. The root is perennial, long, branched, bearing dense tufts of numerous, simple, leafy Ixias, an inch or half a inch high. Leaves crowded, two-ranked, awl-shaped, compressed, strongly ribbed, about an inch long. Flowers whitish, small, solitary, nearly sessile, among the uppermost leaves, which form a kind of sheath, but each appears to have also a bivalve sheath, or pair of bracteas, which are permanent. Capsule brown, with rather rigid, emarginate valves.

Mr. Ker observes, that this is the only genus of its natural order whose habit is in any degree shrubby. He mentions, in the Annals of Botany, another species, by the name of partita, seen by himself in Mr. Hibbert's herbarium; but without any indication of its characters, so that we have no means of knowing how it differs from the foregoing.

WITTSIO, in Geography, a town of Sweden, in the province of Schonen; 28 miles N.N.W. of Christianstadt.

WITT, John de, in Biography, the son of a burgomeister of Dordrecht, was born in 1625, and educated in various useful sciences, so as to excel in a knowledge of jurisprudence, politics, and mathematics, in the latter of which he was so great a proficient, that he wrote a treatise on the elements of curve-lines, which was published under the inspection of Francis Schooten. For further improvement he spent some years in travel, and upon his return was elected to his father's post of peninsory of Dordrecht. Attached by his descent to the principles of republican, and jealous of the house of Orange, he opposed the elevation of this house, and diffused the province of Zealand from conferring the office of captain-general upon the young prince, William III. His conduct in this business was much approved, and he was henceforth regarded as at the head of the political administration of the United Provinces. This was a period peculiarly critical and interesting: The war with the new English republic distressed the states; it was injurious to their trade and finances; and preferred to the Orange party a favourable opportunity for advancing prince William to the power and dignities possessed by his ancestors. Peace at length became absolutely necessary; and one of the articles concluded upon in 1654, and dictated by Cromwell, was the perpetual exclusion of the prince of Orange from the high offices formerly held by his family. This article was agreed to by his states of Holland alone, and when de Witt drew up a declaration for divulging
WIT

it, some of the provinces cenured it, and charged the anti-
Orange party with having fuggled it to Cromwell. The
province of Holland, however, carried the point, and the ge-
neral tranquility was little disturbed. De Witt now directed
his attention to the flate of the finances, and succeeded in
reducing the interest of the public debt, and perfuading the
people to acquiefce in this meafeure. The retoration of
Charles II. was generally agreeable to the United States,
and more especially to the Orange party: but the refored
sovereign foon declared his difaffection with De Witt, be-
cause he had been hostile to the elevation of the House
of Orange. From this time, the Dutch flatesman favoured
the politics of France more than those of England. At length
a war took place between the Dutch and English in 1665;
during the progress of which De Witt was often unpopular,
though he was the main spring which kept in action the
resources of the flate, and remedied every calamity. Peace
with England in 1667 developed the ambitious projects
of Lewis XIV. in taking poiffion of the Spanish Netherlands;
and the alarm which this meafeure produced in the United Pro-
vinces gave occasion to the friends of the house of Orange
to propofe the elevation of the young prince to the dignities
which his family had poiffefed. De Witt, with a view of
counteracting this purpose, obtained a resolution on the part
of the flates of Holland for separating the offices of captain-
general and fladholder (see William III.), which resolution
gave great offenfe to the other provinces, and rendered
De Witt, with whom it was fuppofed to have originated,
exremely unpopular. Senfible, however, of the dangers
arifing from French ambition, he concurred in the triple
alliance between England, Sweden, and the United Provinces,
concluded, in 1668, by himself and Sir William Temple.
The flates of Holland were fo satisfied with his conduct, that
they nominated him for five years more to the office of their
penionary, which he had already occupied for fifteen years.
Confiding in the triple alliance, and the fubsequent peace of
Aix-la-Chapelle, he again indulged his jealoufy of the Orange
party and a flanding army, and confidered the danger from
France as a secondary object. But the ambition of Lewis
had no bounds; the unprincipled Charles II. could not be
relifed upon; the triple alliance was fet aside; and the Eng-
lish cabinet joined the French in direct war with the United
Provinces; fo that in the year 1672 a French army made an
irruption into the territories of the flates, and threatened to
overwhelm the whole country. The anti-Orangeflits were
then compelld to confer the chief command on William.
The conduct of the French had been fo atrocious, that every
perfon who had manifefled the lighteft attachment to their
politics was charged with treason. De Witt became the ob-
ject of public indignation, and to him were ascribed all the
calamities which were felt or feared. Four affajins attempted
his life, as he was returning home from an afsembly of the
flates of Holland, attended by a single fervant; but though
he received many wounds, none of them were mortal. One
of the affajins was taken and executed; but such is the in-
fluence of party, the friends of the house of Orange regarded
the wretch as a martyr. Cornelius de Witt, on his return
from the fleet, where he had served as deputy of the flates,
narrowly escaped from a fimilar attempt. The prince was
now elevated to the fladholderate; and the penionary, as
soon as he was recovered from his wounds, visited him with
congratulation on the event, but was cooly received.
Finding that, as he was become an object of the public
hatred, he could be no longer of any fervice, he requested
permitfion from the flates of Holland to reign in his office,
which was granted him upon the moft honourable terms.
His brother was at this time imprifoned among common
felons at the Hague, under a charge, preferred by a perfon
of infamous character, of having formed a plot againft the
life of the prince of Orange. On his trial he was put to
the torture, in the moft cruel form of applying it; but
though he endured the moft aggravated fufferings, profting
his innocence, and citing his judges before the tribunal of
God for their treatment of him, they pronounced sentence,
which deprived him of all his dignities, and banifhed him
for life from the province. Although no criminal charge
was brought againft John de Witt, the enemies of the fa-
mily resolved that neither of the brothers should efcape with
life. Decoyed by a feticious meafeure to visit his brother
Cornelius in the prifon, a furious mob assembled to prevent
his return. The flates of Holland ordered a guard to dif-
perfe the people, and requelted some companies of horfe and
foot to be fent from the camp of the prince of Orange.
But the commanding officers were inveterate in their enmity
againft the De Witts; and the inflamed populace, not re-
frained from executing their bloody purpofe, forced open
the doors of the prifon, dragged out the two brothers, and
inhumanly malacled them. This catastrophe took place in
August 1672, John de Witt being in the 47th year of his age.
Although the flates of Holland pronounced the deed to be
detellable, and requelted the fladholder to take proper mea-
ures for avenging the death of these two brothers, it was
pretended that it would be dangerous to inquire into a
deed in which the principal burghers of the Hague were con-
cerned, and therefore none of the murderers were brought
to justice. It should, however, be recollected, that the
prince never spoke of this malacre without the greateft
horror.

The character of De Witt has been defcribed in honour-
able terms by Sir William Temple, who knew him well,
both in private life and in his public station. He speaks of
him as a perfon of indefatigable application, of invincible
resolution, of a found and clear judgment, and of irre-
proachable integrity, infomuch, that if he was blinded in
any refept, it was in confequence of his passion for pro-
moting what he thought the welfare of his country. He
bears testimony to the penionary's knowledge of the interets
of foreign courts, though he did not make fufficient allow-
ance for the treachery of princes, or rather their mimifers,
and was thus mifled with regard to the ambitious views of
France. If he had any wrong bias in his political conduct,
it was that of an hereditary jealoufy and dislike of the house
of Orange, which led him in some cafes to act rather as a
party leader than an unprejudiced patriot. No man could
be lefs influenced than De Witt by views of avarice or ollen-
tation. His manners and appearance were adapted to the
ancient simplicity and frugality of his country, even in the
height of his power. When his papers and private letters
were submitted to a rigorous scrutiny after his death, nothing
was discovered that could impeach his integrity. When one
of the commiffioners was asked what they had found in De
Witt's papers; "What (fay I) could we have found—
nothing but probity?" As a man of business, he was fcru-
pulously attentive to order and method; and when he was
once afked, How he was able to transact fuch a multiplicity
of affairs? he replied, "By doing only one thing at a time."

WITT, in Geography, a river of Germany, which rises near Hackenburg Sayn, and after a circuitous
course runs into the Rhine, about a mile below Neuwied.

WITTEL, a small town in Steinhude lake, with a
fort; 3 miles N. of Hagenburg.

WITTELHE, a town of Germany, in the county of
Verden; 10 miles S.E. of Verden.

Vol. XXXVIII.
WITTEM, a citadel of France, in the department of the Reor. It heretofore gave name to a lordship, wholly surrounded by the duchy of Limburg; 6 miles S. E. of Aix-la-Chapelle. 

WITTEN, in Commerce, a money of account at Pernau and Stettin, &c. At Pernau a current rix-dollar is reckoned at 60 wittens, or 75 copecks; and an Albert's rix-dollar is estimated at 80 wittens, or 100 copecks; a Pernau mark is worth 3 wittens; a Lethvit mark = 2 wittens; and 4 wittens = 5 copecks. At Stettin the rix-dollar was formerly divided into 36 shillings current, 72 shillings Sundish, or 144 wittens; which monies of account are now nearly discontinued. 

Witten, in Geography, a town of Germany, in the county of Mark; 7 miles S. E. of Bockum. 

WITTEN-GEMOTE, among our Saxon Aecelors, a term literally signifying a council, or assembly of fages, or wife men; applied to the great council of the land, in later days called parliament; which fee. See also Gemote. 

In the Saxon times, this was the chief court of the kingdom, where all matters, both civil and criminal, and those relating to the revenue, were determined. In civil and criminal matters, it was a court, in the first instance only, for facts arising in the county where it sat; but it heard and determined causes from all other counties by way of appeal. To this court were summoned the earls of each county, and the lords of each fee, as also the representatives of towns, who were chosen by their burghers. This was the legislative and supreme judicial assembly of the Anglo-Saxon nation. As highest judicial court of the kingdom, it resembled our present house of lords; and in those periods, when the peers of the realm represented territorial property rather than hereditary dignities, the comparison between the Saxon witten-gemote, and the upper house of our modern parliament, might have been more correctly made in their legislative capacity. The German states are recorded by Tacitus to have had national councils, and the continental Saxons are also said to have possessed them. When the Cyning was only the temporary commander of the nation for the purposes of war, whose function ceased when peace returned, the witten-gemote must have been the supreme authority of the nation; but when the Cyning became an established and permanent dignity, whose privileges and power were perpetually increasing till he attained the majesty prerogatives and widely-diffused property which Athelstan and Edgar enjoyed, the witten-gemote then assumed a secondary rank in the state. This council was called by different names, and it was composed of persons who were denominated witan from their presumed wisdom, and with reference to their rank and property, cdeo, (the wealthy), optimates, principes, primates, proceres, cucionatores anglicæ, &c. The gemotes of the witan, without doubt, varied, as our parliaments vary, in the number and quality of the persons who from time to time attended. Most of whose names are subcribed to councils or charters, and who appear to have been the witan who constituted the gemote, have some titles after their names; but there are some gemotes which have names without any addition. It is not easy to ascertain all the qualifications which entitled persons to a seat in the witten-gemote. There is, however, one curious passage, cited from the Book of Ely, in Gale's Script. vol. i. p. 513, which has been alleged by some writers as ascertaining that a certain amount of property was an indispenfable requisite, and that acquired property would answer this purpose as well as hereditary property. The possession stated to be necessary to constitute one of the procures was forty hides of land. The incident to which this passage refers occurred in the reign of Edward the Confessor. It related to the brother of an abbot, who, though nobly born, could not be reckoned among the nobility of the kingdom, because he had not an eftate of forty hides of land; and therefore, he was refused by a lady, whom he fought in marriage, till his eftate was increased to that magnitude by grants of land from his brother. This passage merely proves, that a certain portion, and that a very large one, of landed property in domicilio was a necessary qualification, under the Anglo-Saxon government, to admit any person to the "rank and degree of nobility." But no argument, says lord Littellon, can be justly drawn from hence, that, in order to be qualified for a place in the Saxon great council, or witten-gemote, it was requisite to be lord of forty hides of land. Such a notion does not agree with any accounts that are given us of that assembly in the writings or records of those times. By a passage in the preface to Ina's laws, as translated by Wilkins, it appears, that the Saxon legislature was composed of the king, cum omnibus suis senatores, which senators Littellon supposes to have been the "nobility of the kingdom," such as afterwards formed the ordinary council of lords under our kings of Norman race; cum senisioribus fanctis, by whom he understands the deputies or representatives of the people, either by election or magistracy; cum multis etiam feiicatae minifterorum Dii, which words evidently denote the inferior clergy, mentioned by Eadmer as present in the parliaments of those times. It appears also, by a paragraph in Spelman's Councils Sub. Ann. 855, that the Saxon constitution required not only the "presence," (see Borough, but the "approval of the people," to the enacting of a law; though, by way of marking the distinction between the and the higher orders of the state, the nobility alone set their hands to the act. "Whoever," sairs John Forseue Aland, who was very learned in the Saxon language and legal antiquities, in his preface to the book of chancellor Forseue on the difference between an absolute and limited monarchy, "carefully and skilfully reads the Saxon laws, and the precedes or preambles to them, will find, that the commons of England always in the Saxon times made part of that august assembly." In a passage occurring in lib. iii. f. 56 of William of Malmsbury, we have an express declaration, that by the Saxon constitution established in England, the "people," as well as the nobles, had a right to be called to the "General Assembly" upon affairs of great moment, and to join in the "edicta" made there; so that, without, "their consent," the succession to the crown could not be settled. The term Senatus used by this historian denotes the ordinary assembly of the nobles, which he distinguishes from the "people;" but he supposes that the latter ought to be joined to the former, in order to compose the entire legislature and great council of the nation, upon extraordinary occasions. This was agreeable to the custom ascribed by Tacitus to the Germans, from whom they sprung; "De minoribus rebus principes consultans, de majoribus omnes; ita tamen, ut ea quoque, quorum apud plebem arbitrium est, apud principes præfentantur." See Borough. 

It has been, among constitutional antiques, an interesting question, whether they who possessed this quantity of land had thereby the right of being in the witten-gemote; or whether the members of this great council were elected from the territorial proprietors, and fat as their representatives? One person is mentioned by Mr. Turner (ubi infra), whose
whose designation seems to have the force of expressing an elected member. Among the persons signifying to the act of the gemote at Clofesnwe in 824 is, "Ego Beonna electus consent. et suberfii.'

The members of the gemote were convened by the king's writ, of which many instances occur; and the times of their meeting seem to have been usually the great festivals of the church, as Christmas, Easter, and Whitfuntide; but of these Easter, being most frequently mentioned, seem to have been the favourite period. Their meetings, however, were not absolutely restricted to these seasons. The place of their assembly was not fixed. Perhaps this might depend on the king's residence at the time, and might have suited his convenience. Our monarchs seem to have maintained their influence in the wittena-gemote by their munificence. The king presided at this council, and sometimes, perhaps always, addressed them. In 903 we have an account of a royal speech. One of their duties was to elect the sovereign, and to affit at his coronation. Another was to co-operate with the king in making laws. The wittena-gemote appears also to have made treaties jointly with the king. Many instances occur to this purpose. The treaty, printed in Wilkins's Leges Anglie-Saxonice, p. 104, is said to have been made by the king and his witan. They are also mentioned as affitting the king in directing the military preparations of the kingdom. Impeachments of great men were made before the wittena-gemote. At these councils grants of land were made and confirmed; and the wittena-gemote frequently appears in the Saxons remains, as the high court of judicature of the kingdom, and it exercised power over the public guilds of the nation. The lands of the Anglo-Saxons, the burghs, and the people, appear in all the documents of our ancestors, as subjected to certain definite payments to the king as to their lords; and by a custom, whose origin is lost in its antiquity, among the Anglo-Saxons, all their lands, unless specially exempted, were liable to three great burdens, the building and repairation of bridges and fortifications, and to military expences. But what we now call taxation seems to have begun in the time of Ethelred, and to have arisen from the evils of a foreign invasion. Thus the payment of 10,000/ a year to the Danes to buy off their hostilities, mentioned by Henry of Huntingdon, and those which followed, are flated to have been ordered by the king and the wittena-gemote. Under sovereigns of feeble capacity, the wittena-gemote seems to have been the scene of these factions, which always attend both arifocracies and democracies, when no commanding talents exist to predominate in the discussions, and to shape the council. Turner's Hist. of the Anglo-Saxons, vol. ii. book 10. Littelton's Hist. Henry II. vol. iii.

WITTENBERG, in Geography, a town of Saxony, and capital of a circle or diocese, situated on the side of the Elbe, over which is a ferry: it is the head town of the electoral circle, the seat of an archiepiscopal court, of the afifle, as also a confistory, together with that of the general superintendancy of the electoral circle, a spiritual inspection, the circle ament, and a famous univerfity, founded in the year 1502, at which, in 1517, the Reformation took its rise by means of Martin Luther. This town is not large, but fortified. The old citadel was formerly the electoral residence; near it stands an arsenal. In the large round tower are kept the archives of the electoral and princely houses. The university library is kept in what was formerly an Augustinian cliff. The first founder of the town of Wittenberg was Bernard, duke of Saxony. In the year 1547, it was taken by the emperor Charles V.; in the year 1756, it was pollested by the Prussians, who also broke down a balion of the fortifications; 60 miles N. of Drefden. N. lat. 51° 55'. E. long. 11° 40'.

WITTENBERG, a town of Prussia, in Natangen; 8 miles N. of Heilberg.—Allo, a town of the duchy of Lauenburg, on the Elbe; 8 miles W. of Lauenburg.

WITTENBERGEN, a town of Brandenburg, in the Mark of Pregnitz; 6 miles S.S.W. of Perleberg. N. lat. 53° 2'. E. long. 11° 50'.—Allo, a town of the duchy of Holstein; 8 miles S.W. of Lutkenburg.

WITTENBURG, a town of the duchy of Mecklenburg; 17 miles W. of Schwerin.

WITTENHAUSEN, a town of the duchy of Holstein; 5 miles W. of Oldeburg.

WITTENSTEIN, a town of Prussia, in the province of Natangen; 10 miles S.S.E. of Königsgberg.

WITTGENAU. See WITGENAU.

WILMTHOE, a town of Africa, in the country of Cape Lopez Gonfalpo; 30 miles N. of Olbato.

WITTCHITHHAL, a town of Saxony, in the circle of Erzgebir; 7 miles S. of Schwanzenberg.

WITTINGEN, a town of Welfhalia, in the principality of Luneburg Zelle; 27 miles E. of Zelle.

WITTLICH, a lake of England, in the county of Huntingdon; 4 miles S. of Peterborough.

WITTICH, a town of France, in the department of the Rhine and Mofelle; 16 miles N.E. of Treves. N. lat. 50° 4'. E. long. 6° 52'.

WITTUMUND, a town of East Frieseland, on the Harle; 7 miles S.E. of Enges.

WITTSTOCK, a town of Saxony, in the county of Verden; 10 miles S.E. of Rosenthal.

WITTOBA, in Hindoo Mythology, is the name of the god Vishnu in one of his numerous descents, or avatars, as they are called. Some account of these avatars is given under our article Vishnu. This, now under decoration, was one of inferior importance; and not, it is said, of very ancient occurrence, and therefore not described in the Puranas, unless it be in the one supposed to be more modern than the rest, which is entitled Maha Bhagavat. (See Purana, and Sri Bhagavata.) A splendid temple is dedicated to the worship of Wittoba, or Vishnu, at Panderpoor, a town of great reputeability on the river Beemah, about 100 miles to the south-eastward of Poona. The manifellation is said to have appeared there. He is there represented sculptured in stone, of the size of a man, standing with his feet parallel to each other; his hands upon his hips, the fingers pointing forward, his thumbs backward. Two of the wives of Vishnu in his avatar of Krishna accompanied him in this; these were Rukmeni and Satyavama, and they have smaller temples at Panderpoor, besides others of their lords. (See Krishna, Rukmeni, and Satyavama.) Images of Wittoba are common in the Mahra ta country, generally of clumsy manufacture. Several representations of Wittoba and his wives are given in the Hindoo Pantheon, from calms and pictures. That work contains also a history of the avatar, and many particulars respecting it.

WITTOW, in Geography, a town of Germany, in the county of Verden; 10 miles S.S.E. of Rosenthal.
WITWALL, in Ornithology, a common English name for the great spotted wood-pecker, the *picus varius* major of authors.

WITZELRODE, in Geography, a town of Germany, in the county of Henneberg; 3 miles E.E. of Salmungen.

WITZELSTORFF, a town of Austria; 4 miles S.E. of Hoffmarckt.

WITZENHAUSEN, a town of Germany, in the principality of Hesse Rhenfels; 13 miles E. of Caizell. N. lat. 51° 10'. E. long. 8° 48'.

WIVELISCOMBE, a large market-town in the hundred of Wilt Kingsbury, and county of Somerset, England, is situated in a valley, at the distance of 11 miles W. from Taunton, 25 miles W. from Somerton, and 156 miles W. by S. from London. It appears to have been of some note under the Romans, though not distinguished in their annals as a station or military post. In the earlier part of their transactions in this island, they had a large castrum, or encampment, on a hill about a mile eastward from the town, which still is called the castle. Its summit contains about twelve acres; and though mostly covered with coppice-wood and bushes, the vestiges of fortifications, and the foundations of buildings, are yet discernible on its surface. Part of the fosse, which is very deep, and extended round the hill, has been destroyed by the working of a quarry. Near the centre of the area, a great number of Roman coins of various emperors were discovered in the beginning of the last century. The Danes, during their incursions into this county, availed themselves of this castrum, and after their departure, the Saxons, recovering their tranquillity, transplanted themselves to the adjacent vale, and gave their new habitation the name of Wiveliscombe. From this time it progressively became of importance, constituted the head of a large lordship, and was always held by the Saxon kings, till Edward the Confessor granted all the lands to the church of Wells. The bishops of that see had a flately palace here for nearly three centuries: it is now in ruins; a workhouse, erected in 1735, occupies a part of the ancient site. The town now consists of seven irregular streets; it is governed by a bailiff and portreeve, who are annually chosen in May. Here were formerly two markets, one on Tuesdays, the other on Saturdays; the latter only is now retained, with three annual fairs. A considerable woollen manufacture has been carried on for more than two hundred years, and still flourishes; the chief articles made are, blankets, knap-coatings, kerseys and other coarse cloths, shrouds, ermine, and baize. Many of these are sent to London, Bristol, and Exeter, for home consumption, and for exportation to Spain and Guernsey. The church is a plain structure, and consists of a nave and two aisles, with a tower and spire at the west end. The parish includes the town contains four small hamlets, and according to the population return of the year 1811 contains 574 houses, and 2550 inhabitants.—Collinson's History, &c. of Somersetshire, vol. ii. 1791.

WIVENHOE, a village of England, in the county of Essex, situated on the river Coln; it is the harbour of Colchester, and here is a custom-house. The oysters, called Colchester oysters, are barreled in this place. In 1811, the population was 7046.

WIZE, a river of England, in the county of Cumberland, which runs into the Wye.

WIZNA, a town of the duchy of Warsaw; 88 miles N.E. of Warsaw.

WIZUNY, a town of Lithuania; 20 miles N.N.E. of Wilkomiers.

WIZZARD, in Agriculture, a term applied in Norfolk to any particular sort of cart for farm-work.

WIZZENED, a term provincially applied to signify withered or shrivelled, as hay.

WLADELSLAW, in Geography, a town of Moravia, in the circle of Iglau; 12 miles S. of Meferitch.

WLADELSLAW, or Locovielaw, a town of the duchy of Warsaw, and capital of a palatinate of the same name, on the Vltava; the site of the bishop of Cujavia, removed from Krazschna in 1733; 108 miles N.W. of Warsaw. N. lat. 52° 35'. E. long. 18° 35'.

WŁODOWA, a town of Aultrian Poland; 18 miles N.E. of Chelm.

WŁODZIMIERZ, a town of Poland, in Volhynia, on the Bug; the site of a Greek bishop, united to the church of Rome; 48 miles W. of Luckow.

WOAD, in Agriculture, a plant cultivated in the field for the use of the dyers. It is a plant which has a strong thickish fibrous root, which penetrates deep into the soil, and is principally raised for the use of the leaves, which, after being properly manufactured, are made use of in the art of dyeing to produce a blue colour, as well as the baize of black, and some others.

Soil.—It is evident from the nature of its root that it requires a soil which has much depth or staple, and which is perfectly fresh, such as those of the rich, mellow, loamy, and deep vegetable kind. Where this sort of culture is carried to a considerable degree of perfection, as in Lincolnshire, the deep, rich, putrid, alluvial soils on the flat tracts extending upon the borders of the different large rivers are chiefly employed for the growth of this sort of crop; and it has been shown by repeated trials that it answers most perfectly when they are broken up from a state of fward immediately for it. In some places, it is the practice to take lands of this description at high prices, for the purpose of breaking them up and growing it upon them for two or three years; on the more low rich soils, for four years, but on those of lefs fertility only for three; and in some, which are more elevated and exposed, two are considered sufficient. For this sort of culture, people are employed, who move from place to place, and form a sort of colony. Mr. Cartwright, in the above county, has however found, that it is capable of being confined to one spot with equal or greater success, by having a sufficient extent of ground for changing the place of its growth as may be necessary, and for appropriating an adequate proportion annually to the raising of the plant, by which the houses and expensive machinery that are necessary for its preparation may be kept constantly and regularly employed in the busines.
tion. In cases where the soils are sufficiently dry, only breaking them up early in the month of February; and where the contrary is the case, deferring it to a later period, taking care to plough the land in a perfect manner to the depth of five inches, or more: and that the furrow-slices may be well turned, laid flat, and nicely jointed, a person is employed with a spade for the purpose of adjoining them. This prevents the gritty matters from rising in the seams. When this has been done, the surface is repeatedly harrowed over, to raise a sufficient depth of good mould for the drill to work in; and before the feed is put in a roller is passed over the land.

It is probable, however, that this method is inferior to the former, as the land is not brought nearly to so fine a flate of mould, or the gritty material so effectively covered and destroyed, from which injury may be done to the woad plants in their early growth.

But a method which is equally effectual with the first, more expeditious, and which has a superiority over it, in more completely destroying grubs, insects, and other vermin, which are apt to feed on the plants in their early growth, is that of paring and burning. This is, however, chiefly practised where the soil is rough, and abounds with rufhes, fedge, and other plants of the coarse kind, but might be had recourse to on others, with vast benefit.

Where the latter modes are made use of as soon as the feed has been put in, the land should be carefully drained by forming grips in suitable directions, as wherever water flag-nates, the woad plants are liable to be injured or destroyed.

Seed.—In respect to the feed, it should be collected from ground that has been left covered with the beet plants from the preceding season, as they only run up to item and form seeds in the second year; and in order to have good feed, the leaves should not be cropped at all or but once, the items being suffered to remain till the seeds in the husks become perfectly ripened; which is shown by their attaining a brownish-yellow colour, and the pods having a dark blackish appearance. It should then be gathered as soon as possible, by reaping the items in the manner of grain, and then spreading them in rows thinly upon the ground if the weather be fine, when in the course of a few days they will be in a flate to be threshed out from the husks or pods. When they are suffered to remain too long, the pods are liable to open, and shed the feed. Although the pod in which the seeds are contained is of a large size, the seeds are less than those of the turnip. New feed, where it can be procured, should always be sown in preference to such as has been kept for some time; but when of the latter kind, it should be sowed for some time before it is put into the ground.

In regard to the quantity of feed which is necessary, it must be regulated by the soil, and the manner in which it is sown. Where the drill is employed, less will be required than in the broad-calf method. It has been found that a rood of land, where the crop is good, will in general afford feed sufficient for eight or ten acres; and in some cases, in the broad-calf method, five or six bushels are made use of to the acre. In Kent they use ten or twelve pounds to the acre.

Sowing.—The time of sowing crops of this nature must be regulated, in some degree, by the mode of preparation that has been employed. Where the first of the above methods has been followed, it will be much later than in the other cases. But early sowing is in general to be preferred, as there will be less danger of the plants being injured by the attacks of the fly or grub. Where the weather is suitable, and the land in a proper state of preparation, the feed may be sown in the latter end of February or March, continuing the sowings, in different portions of land, till about the middle of May, at suitable intervals of time to vary the times of cropping the leaves of the plants. The late sowings are commonly executed about the latter end of July, or early in the following month at the farthest.

With respect to the manner in which the feed is sown, it differs according to the nature and state of preparation of the land. Where it is in a fine state of mould, the drill or row method is the method mostly practised, which is by much the best, as by it the plants may be kept more easily clean and free from weeds, becoming more strong and vigorous, from the earth being more stirred about the plants; but where the contrary is the case, the broad-calf mode is generally followed; but which does not by any means admit of the plants being kept free from weeds, or the mould so well stirred about the roots of them.

Where the first method is had recourse to, the feed is sown by a drilling-machine, such as is used for turnips, in equidistant rows, eight or nine inches apart, covering it in, either by means of a harrow attached to the implement, or by paffing a light common harrow over the ground afterwards, once in a place, raking off any clods that may be present to the sides, or into the furrows: but in the latter mode, it must be delivered by the hand in as equal a manner as possible, over the whole of the land, being then harrowed in by a light harrow, so as to leave the land in as even and level a state as possible. The ground is frequently rolled afterwards, that the surface may be left as even as possible.

In favourable seasons with good feed, the plants mostly appear in the course of a fortnight, when much attention should be paid to see that they are not destroyed by the turnip-fly, or the frosts inThose of the more early sowings, as, where that is the case, the land should be immediately re-sown; as in some cases it is not uncommon to sow the greatest part of the crop two or three times over. In the very late sowings, where the crops rife thin on the ground, it is sometimes a practice to give a better plant by forming holes with a hoe in the vacant spots, and directing seeds to be dropped into them by the hand by women or children. This is the case with the late spring-sowings till the beginning of June, or a later period.

Culture while growing.—From much of the goodness of the woad plants depending on the luxuriance of their growth, and the thicknes of their leaves, it is necessary to bestow great attention in the culture of the crop while growing. It is advised that the spring-sown crops, as well as those that are sown in the latter part of the summer, should have the first hoeings given them as soon as the plants are fully distinguishable above the ground, as by this means the weeds will not only be prevented from retarding the vegetation of the plants, but these by being thinned out to greater distances be more at liberty to advance and become vigorous in their first or early growth, which is a matter of much consequence to the success of the crop; and second hoeings should be given in the course of four or five weeks afterwards, when the plants should be thinned out to the full distances at which they are to stand, which may be six inches or more, according to the goodness of the soil, constantly leaving sufficient room to prevent the plants from being in any way crowded. The work is sometimes executed in much the same manner as for turnips, by hand-hoes; but in others by small short spades, used with one hand, while the other is employed in clearing away the weeds; the labourers, mostly women and children, kneeling while they perform the work. When this work has been done, nothing further is necessary till the first cropping of the
the leaves has been performed, when the plants should be again immediately well weeded; and after each cropping the same operation be had recourse to; the extent of crop cleared in the day being, in most cafes, weeded before night.

With the late-fown crops, after the second weeding in October, nothing further will be requisite till the spring, about the middle of April, when the work should be again well executed, the mould being completely stirred about the roots of the plants, that they may derive the fullest benefit from the operation. This will be sufficient to keep them clean till the taking of the first crop; after which they must be again weeded, and the same operation be had recourse to after cropping of the leaves, as in the above cafe.

In respect to the busines of gathering the crops with the spring-fowled ones, the leaves will generally be ready to be gathered towards the latter end of June, or beginning of July, according to the nature of the soil, season, and climate; but for those put in a later period in the summer, they are often fit to be gathered earlier. This business should, however, constantly be executed as soon as the leaves are fully grown, while they retain their perfect green colour, and are highly luminous; as when they are let remain till they begin to turn pale, much of their goodnes is lost to be expended, and they become less in quality, and of inferior quality for the purposes of the dyer. In valuable seafons, where the foils are rich, the plants will often rise to the height of eight or ten inches; but in other circumstances they seldom attain more than four or five; and where the lands are well managed in the culture of the plants, they will often afford two or three gatherings, but the best cultivators seldom take more than two, which are sometimes mixed together in the manufacturing of them. It is necessary that the after-croppings, when they are taken, are constantly kept separate from the others, as they would injure the whole if blended together, and considerably diminish the value of the produce. It is said that the best method, where a third cropping is either wholly or partially made, is to keep it separate, forming it into an inferior kind of woad.

Upon an acre of land, when well managed, in valuable seafons, the product is mostly from about a ton to a ton and a half. The price varies considerably; but for wood of the prime quality, it is often from twenty-five to thirty pounds the ton, and for that of an inferior quality fix or seven, and sometimes much more.

Seeding-Crops.—With such parts of the crops as are reserved for seed, it is a practice with some to crop the leaves two or three times the first year, and then leave the plants to run up to feed in the following one, but it is a better practice to only remove the side-leaves, as in this way the plants are less weakened, and the produce of the seed much increased. The plants are likewise sometimes fed down by sheep during the winter; but this, from its tendency to weaken them, is equally improper and prejudicial.

Preparation of for the Dyer.—The woad, after it has been gathered, undergoes several processes to prepare it for the dyer; but in the improved method it is conveyed in one-horse carts, to contrived as to be lifted from the axis, and, by folding doors in the bottoms, to discharge their contents upon the floor above the mill, on being hoisted up to their proper situation: round this floor holes are formed for putting the plants down through, in order that they may drop under the grinding-wheels. The wheels for this purpose have several wheels for grinding the plants, which have sides diameters on one side than the other, and are about three feet in width, being constructed with iron bars for crushing the woad. They are wrought by horse, or any other power, as may be the most convenient. The materials are preferred under the grinding-wheels by proper contrivances, which, as soon as they are sufficiently reduced, force it out of the tracks upon the fome floors on the fides; thus making way for new parcels without the mill being stopped. The bruised woad is then thrown into rooms on the sides of the mill, destined for its reception, by means of shovels. In these it remains till the juice is so much drained off as to leave it in a proper condition for being formed into balls; which is done by labourers, with apparatus for the purpose, and then laid upon trays to be conveyed to the drying ranges, in which they are placed upon gratings-thales that slide on sledge in the drying-houses. These are placed on the sides of galleries, for the convenience of being easily deposited upon them and removed again. It is kept in these till it is sufficiently dried to be laid up in other rooms, until the whole of the crop has undergone the same operations, and the workmen are ready to manufacture it.

It is stated in the Corrected Lincolnshire Report on Agriculture, that to prepare it for use in the art of dyeing, it is necessary for it to take on a proper state of fermentation, which is accomplished in the course of seven or eight weeks, and, in the technical language of the art, is termed couching. It is effected by regrinding the balls, in the same mill as before, to a fine powder, and then spreading it upon the floors of the rooms in which the balls were formed, to the thickness of about three feet; where it is then moistened with water, so as to keep it in a proper flow state of fermentation; and so managed by turning that it may pervade the whole in an equal manner. In this business, the direction of an experienced workman is necessary. In the turning, it is of much importance that the parts of the materials be perfectly divided, which can only be effected by a nice management of the shovel: and it is added that much advantage has been found in the goodness of the woad, from the drying and floring of it being performed in a careful manner. When this attention is neglected, the woad will not, on being broken between the finger and thumb, draw out into fine hair-like filaments, or, in the technical language of the manufacturer, beaver well; as the use of this substance in the blue vat of the dyer, is not merely to afford the colour of the plant, but, by bringing on a very gentle fermentation, excite the indigo in the same vat to yield its colouring principle more perfectly. This is even necessary for its own colouring-matter being fully imparted. The substance should, therefore, be so prepared in the different operations as to produce this effect in the most certain and perfect manner. When the heat in the processes of couching has gone too far, the substance will be what is termed fare; and when it has not proceeded to a sufficient degree, it will be what is called beaver. If the material be good, it does not fell the fingers on being rubbed between them; but such as is heavy does. In the conclusion of the process, the cooling is effected in a gradual manner, as to render it not fit for taking on the same process; and of course proper for being preferred in calks, or in any other way. It is then ready for use.

The preparation of woad for dyeing, as practised in France, is minutely described by Aliiue, in his Memoirs for a Natural History of Languedoc. The plant puts forth at first five or six upright leaves, about a foot long, and an inch broad; when these hang downwards, and turn yellow, they are fit for gathering: five crops are gathered in one year. The leaves are carried directly to a mill, much resembling the oil or tan-mills, and ground into a smooth pale. If this process was deferred for some time, they
they would putrefy, and lend forth an insupportable stench. The palate is laid in heaps, pressed close and smooth, and the blackish crust, which forms on the outside, reunited if it happens to crack; if this was neglected, little worms would be produced in the cracks, and the wood would lose a part of its strength. After lying for fifteen days, the heaps are opened, the crust rubbed and mixed with the inside, and the matter formed into oval balls, which are pressed close and solid in wooden moulds. These are dried upon hurdles: in the fun, they turn black on the outside; in a close place, yellowish, especially if the weather be rainy: the dealers in this commodity prefer the first, though it is said the workmen find no considerable difference between the two. The good balls are distinguished by their being weighty, of an agreeable smell, and when rubbed of a violet colour within. For the use of the dyer, these balls require a farther preparation: they are beat with wooden mallets, on a brick or stone floor, into a groats powder; which is heaped up in the middle of the room to the height of four feet, a space being left for passing round the sides. The powder, moistened with water, ferment, grows hot, and throws out a thick fétid flame. It is shovelled backwards and forwards, and moistened every day for twelve days; after which it is stirred less frequently, without watering, and at length made into a heap for the dyer.

The powder thus prepared gives only brownish tinctures, of different shades, to water, to rectified spirit of wine, to volatile alkaline spirits, and to fixed alkaline liquitä: rubbed on paper, it communicates a green stain. On diluting the powder with boiling water, and after standing some hours in a close vessel, adding about one-twentieth part of its weight of lime newly flaked, digesting in a gentle warmth, and stirring the whole together every three or four hours, a new fermentation begins, a blue froth arises to the surface, and the liquor, though it appears itself of a reddish colour, dyed woollen of a green, which, like the green from indigo, changes in the air to a blue. This is one of the nicest processes in the art of dyeing, and does not well succeed in the way of a small experiment.

Atricle propoies the manufacturing of fresh wood leaves in Europe, after the same manner as the indigo plant is manufactured in America; and thus preparing it from a blue specula similiar to indigo, which from his own experiments he has found to be practicable. Such a management would doubtless be accompanied with some advantages, though possibly wood so prepared might lose those qualities which now render it, in a large basins, preferable on some accounts to indigo, as occasioning greater dispatch when once the vat is ready, and giving out its colour less hastily, so as to be better fitted for dyeing very light shades. Neumann's Chem. by Lewis, p. 437, &c.

The ancient Gauls and Britons used to dye or stain their bodies with this plant, and were probably led from this application of it to use it for dyeing cloth.

Some hold that it was from this plant glass took its denomination; though others derive both glas and gladium from the Britth glas, which to this day denotes a blue colour. See Glass.

A wood blue is a very deep blue, almost black; and is the base of so many sorts of colours, that the dyeers have a scale, by which they compose the divers calls or degrees of wood, from the brightest to the deepest.

WoAD, in Botany. (See Isatis.) There are four species.

The broad-leaved wood is cultivated in several parts of England for the purposes of dyeing, being used as a foundation for many of the dark colours.

Some seed down the leaves of woad in winter with sheep; a practice which Mr. Miller condemns.

Woad grows wild in some parts of France, and on the coasts of the Baltic sea: the wild wood, and that which is cultivated for the use of dyers, appear to be of the same species.

Befide the plant properly signified by the name woad, which dyes a blue colour, we have two others known in our English herbalts under that name, as also that of wold or weld. These are both called by the common people dye of the ved, and are the luteola and the genista tinctoria.

The ancients confounded all these three plants also under the same names. Paulus Ægineta seems to make them all the same plant; and Neopbythus, speaking of the isatis, or our wood, properly so called, says, that it was called by the Latins luti. This luti has been by some understood to mean the luteola, and by others the genista tinctoria; but the latter opinion only is right, for it is described to us by the ancients as having leaves like the linum, or flax, and flowers like the broom.

WoAD-Mill and House, that sort of mill and house which is necessary and proper for preparing and fitting this kind of substance for the use of the dyer. The representation of a mill and excellent apparatus for effecting the preparation of the wood plant, which is made use of by Mr. Cartwright, with much success and advantage, in Lincolnshire, may be seen in the second volume of the "General Dictionary of Agriculture and Husbandry."

WOAHOO, or OAHOO, in Geography, one of the Sandwich islands; as far as could be judged from the appearance of the north-east and north-west parts, it is much the finest island of the whole group. Nothing can exceed the verdure of the hills, the variety of wood and lawn, and rich cultivated valleys, which the whole face of the country displayed. The road is formed by the north and west extremities. Should the ground-tackling of a ship be weak, and the wind blow strong from the north, to which quarter the road is entirely open, this circumstance might be attended with some danger; but with good cables, there would be little risk, as the ground from the anchoring-place, which is opposite to the valley through which the river runs to the north point, is a fine land. This island is supposed to contain 60,000 inhabitants. N. lat. 21° 43'. E. long. of the anchoring-place 202° 9'. See SANDWICH ISLANDS.

WOALDS, in Agriculture, a term not unfrequently applied by writers on husbandry to crops of the woad kind. See WOAD.

WOAPO, in Geography, one of the Ingraham islands in the Pacific ocean. Captain Ingraham called it Adams. It was afterwards visited by captain Roberts, who named it Jefferson. S. lat. 9° 27'.

WOBBEL, a town of Westphalia, in the county of Lippe; 6 miles E.N.E. of Holstein.

WOBURN, or WOObURN, or Bishop's Wooburn, a village in the hundred of Delborough, Buckinghamshire, England, is situated in a narrow valley, at the distance of 3 miles W.S.W. from Beaconsfield, and 26 miles W. by N. from London. The manor of Bishop's Woburn had from time immemorial belonged to the see of Lincoln, till the year 1547, when bishop Holbeach gave it to the crown in exchange. It was granted in 1549 to John, earl of Bedford. In the 17th century it came by marriage to Philip, lord Wharton, whose son and grandson, the celebrated marquis and duke of Wharton, successively held it. After the death of the latter, it was sold to the Berries; from whom it was purchased, in 1784, by Mrs. Dupré, mother
mother of James Dupré, esq. of Wilton-park, who is the present proprietor. The old manor-house was a palace of the bishops of Lincoln, several of whom died here. The marquis and the duke of Wharton are said to have expended incredible sums of money on the house and gardens: of the latter, which in a former age were highly celebrated, scarcely a vestige now remains. The mansion was pulled down in 1759 when one of the wings was fitted up as a dwelling-house, which has since been enlarged and improved, and is now occupied by the countefs of Orkney. The parish church is a spacious and ancient structure, with a nave, two aisles, and a tower. The latter was built about the year 1480, as appears by the epitaph of John Goodwin and Pernell his wife, who are called its founders. In the chancel are several monuments of the families of Bertie and Wharton, among which is one of grey marble to the memory of Philip, lord Wharton, who died in 1695. The font is a curious piece of ancient sculpture. This parish contains 2596 acres, chiefly disposed in arable and woodland. In the year 1811, the inhabitants were estimated at 1604; the number of houses at 318. An annual fair is held, for which lord Wharton obtained a charter in 1586. A fair was also granted by king Henry VI., but is now discontinued.—Beauties of England and Wales, vol. i. Buckinghamshire. By J. Britton and E. W. Brayley, 1802. Lyons' Magna Britannia, vol. i. Buckinghamshire, 1806.

WOBURN, or Old Woburn, a market-town in the hundred of Manhead, and county of Bedford, England, is situated near the western confines of the county, at the distance of 14 miles S.W. by S. from the county-town, and 42 miles N.W. by N. from London. Great part of the town was consumed by fire in 1724, which, though distressing to individuals, proved ultimately beneficial, as the houses were rebuilt in a more convenient and regular manner, with the addition of several good inns, and a market-house. The whole expense of the new buildings was defrayed by the duke of Bedford. The market-house was finished in 1737, but has been materially improved by the late duke Francis. It consists of two floors; the lower fitted up for butchers' shambles, over which is a spacious room for a corn-market. In the population return of the year 1811, the inhabitants of the parish are stated to be 1506, occupying 299 houses. A weekly market is held on Fridays, which was granted in 1242 to the abbot of Woburn, and four fairs annually. The church was erected by Robert Hobbs, the late abbot of Woburn. This structure furnishes a peculiar instance of capricious taste; the body being completely detached from the tower, which stands at about six yards distance. The tower is a small square building, with large buttresses at the corners, and four pinnacles; the church consists of three aisles and a chancel; the whole has recently undergone a thorough repair. Adjoining to the church-yard is a free-school, founded by Francis, earl of Bedford. Here are also almshouses for twelve poor persons, founded by the Bedford family, and endowed with 50l. per annum, which was confirmed by act of parliament in 1761.

About a mile east of the town is Woburn abbey, the seat of the duke of Bedford. This magnificent mansion is situated in the midst of an extensive park, and occupies the four sides of a quadrangle of more than 200 feet. It was erected about the middle of the last century by Flintcroft, for John, the fourth duke of Bedford, of the Ruffel family, on the site of an old abbey. The original building was founded in the year 1145, by Hugh de Bolebec, for monks of the Cistercian order. In 1234 the monastery was so reduced, that the establishment was for a time broken up, and the monks dispersed into different convents till their debts were paid. But by various benefactions their revenues were so much improved, that at the general dissolution they were estimated at 3017. 18s. 2d. clear yearly value. The late abbess was hanged for denying the king's supremacy. The feite of the abbey was granted in 1547 to John, lord Ruffel, afterwards earl of Bedford, and has ever since been the principal seat of that noble family. There are no remains of the conventual buildings. The present manor, originally fitted up in a very costly style, has received many considerable improvements, particularly during the time it was in the possession of the late duke. Mr. Holland, the architect of Drury-lane theatre, has displayed much taste and ability in the additional buildings which have been executed under his direction. The west front is built of the Ionic order, with a rusticated basement. The principal floor, or suite of rooms on this side, consist of a saloon, flat bed-rooms, drawing and dining-rooms; the south side contains the library, breakfast, Ettruscan, and duke's rooms; the cell, the vestibule, servants' offices, &c.; and the north, the French bed-rooms, and various other chambers. Most of the apartments are embellished with fine paintings: the gallery, in particular, exhibits a large and valuable collection of portraits by the old masters. The late duke's favourite pursuits are well known to have been experimental agriculture and breeding of cattle. For this purpose he kept several farms in his own hands. The principal of these, distinguished by the name of the Park-farm, is situated in the park, about half a mile from the house. All ingenious contrivances to shorten labour, and facilitate useful operations, are here concentrated. The farm-yard is replete with conveniences. It contains barns, stables, fattening-houses, &c.; a very complete mill, furnished with a curious machine which thrashes and dries at the same time a malt; two pairs of rollers for grinding wheat and barley; and every requisite for dressing flour, making oatmeal, &c. In another part is a small water-wheel, which gives motion to some very ingenious machinery for bruising malt, and cutting chaff. This farm originated with the late duke, through whose patronage and exertions many improvements have been made in the different branches of husbandry. The present duke follows the steps of his brother in patronizing agricultural improvements, and keeps up all the establishments which he formed with a view to that purpose.—Beauties of England and Wales, vol. i. Bedfordshire. By J. Britton and E. W. Brayley, 1801. Lyons' Magna Britannia, vol. i. Bedfordshire, 1806.

WOBURN, a town of the state of Massachusetts, in the county of Middlesex, containing 1777 inhabitants; 15 miles N.W. of Boston.

WOCANELLY, a town of Hindoostan, in Golconda; 40 miles N.W. of Adou.

WODEN, in Mythology. See ODIN.

WODERCUM, in Geography. See WORCUM.

WODNANY, or WODNIAN, a town of Bohemia, in the circle of Prachatitz; 12 miles N.E. of Prachatitz. N. lat. 49° 10'. E. long. 14° 2'.

WODWALLA, a town of Sweden, anciently a port, but now much reduced, and its privileges removed to Gothenburg, at eight miles distance.

WOEL, a town of France, in the department of the Meuse; 12 miles N.E. of St. Mihel.

WOELFLIES, a town of Saxony, in the principality of Gotha; 21 miles S.E. of Gotha.

WOERAMATTA, a small island in the East Indian sea. S. lat. 7° 2'. E. long. 131° 36'.

WOERDEN, or WEDREN, a town of Holland, built by
by Godfrey de Rhenen, the twenty-eighth bishop of Utrecht, on the river Rhine, about the year 1160, to keep the citizens of Utrecht in subjection, and maintain his authority. It had a castle, which was formerly suppofed to be im-
pregnable; but when the French took the city in 1672, they entirely demolished it, before that time falling to
decay. This city had its own particular lords till the year 1296, when Herman de Woerdem fortified it, having been
convicted of being a party in the murder of Florent V. comte
of Holland, who was affaiinated by a gentleman named Ger-
ard de Velfen, whose wife he had ravished. It was after-
wards fold by Philip II. king of Spain, to Eric, duke of
Brunswick; from whom it came, in 1581, under the dom-
inion of the States-General. In 1672, the French having made
themselves masters of this place, the Dutch came to
besiege it, under the prince of Orange and the comte de
Zuylfeiten. The comte de Mareck, who commanded in the
city, began to be much prefied, when the duke of Luxem-
burg arrived with 9000 men. He passed the morafs by a
way which was suppofed to be inaccessible, forced the
intrenchments, and put the enemy to flight. The Dutch
left 2000 men, killed and wounded, among the former of
whom was the comte of Zuylfeiten; and the French about
1000; 8 miles W. of Utrecht.

WOGGORA, a small high province of Abyssinia, on the
E. of Gondar, which is town with wheat. This province
and Dembea are the granaries of the country.

WOGLT, a river of Auffria, which runs into the Ager,
near Voglabruck.

WOGGYDURGAM, a town of Hindooftan, in My-
fore; 15 miles S. of Ouoffi.

WOLOW, a town of Pruffia; 18 miles S. of König-
berg.

WOGLSHAID, a town of Auffria; 7 miles S.W. of
Aigen.

WOHLAU, a town of Silefia, and capital of a principal-
ity, on all fides surrounded with mafhines, which are a kind
of natural defence. It has two suburbs, a Roman Catholic
and a Lutheran church. In the year 1640, it was taken by
the Swedes; in 1642, furprifed by the Imperialifts, but soon
after retaken by the Swedes; and in 1644, recovered by the
Imperialifts; 20 miles N.W. of Breflaw. N. lat. 51° 20'.
E. long. 16° 35'.

WOHLAU, or Wolau, a principality of Silefia, bound-
ed on the north by the principality of Glogau, on the
east by Poland and the principality of Oels, on the south by
the principalties of Breflaw and Lignitz, and on the west
by the principalties of Lignitz and Glogau; situated on
both fides of the Oder. The foil is in some parts dry,
in others marfhy, or overrun with woods and bufhes, though
several tracts also yield good corn.

WOHRA, a river of Germany, which runs into the
Werra, 2 miles N.W. of Echweugen, in the principality of
Hefie.

WOHRD, a town of Bavaria, in the territory of Nu-
remberg, near Nuremberg.

WOINTSCH, a town of Austrian Poland; 36 miles E.
of Cracow.

WOITSBACH, a town of Bohemia, in the circle of
Boleflaw; 8 miles E. of Krottau.

WOITSPERG. See Voitsberg.

WOKING, a town of England, in the county of Surrey;
8 miles N. of Guildford.

WOKINGHAM, or OARKINGHAM, a market-town and
parish in the hundred of Sonning, and county of Berks,
England, is situated in Windsor forest 71 miles E.S.E.
from Reading, and 32 W.S.W. from London. The po-
pulation in 1811 was 2085 persons, inhabiting 435 houles.
The market is held on Tuesday, and the fairs on the 23d of
April, 11th of June, 1oth of October, and 24 of November.
The town, incorporated by James I., is governed by an alde-
man, high steward, recorder, burgifes, and a town-clerk;
and at this place are held all the courts for Windsor foreft.
Although within the bounds of Berkshire, the church stands
in an infalted part of Wiltfhire: it is a large and handsom
edifice. The inhabitants are chiefly employed in agriculture,
throwing filk, forting wool, and making shoes: the gauze
manufacture was some years ago introduced. At Luckely-
green, near this town, is an hopital, founded in 1665 by
Henry Lucas, efq. for sixteen poor men and a mafter: the
truftees of the charity are the Drapers' company of London.
About four miles S.E. from Wokingham, is a large and irre-
gular fortification, with a double ditch, commonly called
Czar's camp, situated on the summit of a hill. Half a mile
thick the southward of this camp is the Devil's ditch, a raifed
road nearly ninety feet wide, running eaf and weft, with
a trench on each fide. In 1661 George Staveron gave the
rent of a houle in this place for the purpoze of buying a
bull, to be bated and killed at Chriftmas, for the benefic
of the poor of Wokingham: but this being thought insufficent,
the inhabitants are in the habit of purfuing another beast
for the fame purpoze. Archbifhop Laud gave a portion of
certain fee-farm rents, which produces about 40l. per annum,
to the parifh. Every third year it is divided, purfuant to
the donor's intention, between three poor maidens of the
age of eighteen, natives of the town, and members of the
church of England, who have ferved the fame mafter or
milkfes for three years together: the other years it is ap-
propriated to the apprenticing of poor boys. Dr. Thomas
Godwin, biſhop of Bath and Wells, was a native of this
town, where he was born in 1517.

About four miles S. from Wokingham is Billingbear, one
of the feats of lord Braybrooke. The houfe is a large irre-
gular building, feated in a fine park. A particular history
and defcription of this place is given, with a view, in Havell's
Views of Seats, folio, 1816.—Beauies of England and
Wales, Berkshire; by J. Britton and E. W. Brayle,
D. Lyfons, vol. 1. 4to. 1806.

WOKSCHITZ, a town of Bohemia, in the circle of
Königiratz; 2 miles W. of Gotichin.

WOLBECK, or WOLDBEK, a town of Germany, in the
bifhropic of Münfter; 7 miles S.S.E. of Münfter.
N. lat. 51° 53'. E. long. 7° 52'.

WOLBORZ, a town of the duchy of Warsaw; 41 miles
S. of Siradia.

WOLCHRADITZ, a town of Moravia, in the circle of
Brunn; 18 miles S.S.E. of Brunn.

WOLCENSTEIN, a town of the duchy of Stria; 6
miles W.N.W. of Rottemann.

WOLCERSDORF, a town of Germany, in the mar-
grave of Anfachz; 2 miles N. of Schwabach.—Alfo, a
town of Auffria, on the Rufchz; 8 miles E.N.E. of Korn
Neuburg.

WOLCERSHAUSEN, a town of the duchy of Wurzburg; 6 miles N. of Schweinfurt.—Alfo, a town of the
county of Henneberg; 3 miles N. of Menungen.

WOLCOTT. See Woolcott.

WOLCOTT, a town of Connecticut, in the county of
New Haven, near Fairfield, with 952 inhabitants.

WOLD, signifies a plain, down, or open champaign
ground, hilly, and void of wood.

Hence the names Stow in the Wold, and Cotwold, in
Vol. XXXVIII.
Gloucestershire; whence also that part of Leicesthshire, which lies northward beyond the Wrekin, is called the Wald of Leicesthshire.

**WOL**

WoL, or W old, among D yers. See W eld.

WOLDECGE, or W olddeck, in Geography, a town of the duchy of Mecklenburg; 13 miles S.E. of New Brandenburg.

WOLDENBURG, a town of the New Mark of Brandenburg; 9 miles N.E. of Friedburg. N. lat. 53°. E. long. 15°. 45′.

**WOLEIN.** See MIIZIN.

WOLSELEITZ, a town of Bohemia, in the circle of Kauzrin; 4 miles W.S.W. of Kauzrin.

WOLF, CHRISTIAN, in Biography, an eminent mathematician and philosopher, was born at Breflau in 1679, and well educated under able masters in different branches of literature and science. At the age of 21, he was entered at the university of Jena, which was then in high reputation; and quitting Jena in 1702, he prosecuted his studies at Leipsic, where, in the following year, he took his degree of master of arts, publishing on the occasion a dissertation, intitled "Philosophia practica Universi Mathematico modo coniectans." In 1704, he published another dissertation, on the differential and infinitesimal calculus. Having studied theology as well as philosophy at Leipsic, he officiated as a preacher; and being invited to undertake the office of pastor in a country village, he was advised by Leibnitz to decline it, and to pursue the study of philosophy. As he commenced his literary career with great reputation, he was proposed to be an associate in the periodical work, intitled "Ata Eruditorum;" and in this connection he continued for many years, employing his leisure hours in teaching mathematics, logic, and natural philosophy. When the Swedes made an incursion into Saxony in the year 1706, he quitted Leipsic, and removed to Berlin, where a recommendatory letter of Leibnitz procured for him from Frederic I. the office of professor of mathematics at Halle. In 1709 he published, in Latin, his treatise on "Aeronomy," and in the following year his "Elements of Mathematics," in 4 vols, which have passed through several editions. Having composed a very ingenious essay on the intense cold of the ensuing winter, he was elected a member of the Royal Society of London, and soon after a member of the Academv of Sciences at Berlin. In 1711 he published his tables of sines and tangents, and in the next year his treatise on logic, in German, highly commended by Forney, and translated into Latin, French, and other languages. The first two volumes of his large work on the mathematics appeared in 1713, and these were afterwards followed by three more. By the advice of his friend Leibnitz, he refused an invitation from Peter the Great to remove from Halle to Peterboug. On the death of Leibnitz in 1726, Wolf drew up his life, which supplied Fontenelle with materials for his eloge. In 1718 he published "Meditations on God, the World, and the Human Soul," which were reprinted in the following year. About this time the reputation of Wolf and the jealousy of his rivals occasioned a literary contest, which lasted for a considerable time, and which was not very honourable to either party. Wolf having delivered a dissertation on its quitting the pro-rectorate of Halle university in 1721, on which he took occasion to compare his own principles with those of Confocian and the Chinesc, and having announced the opinion which he entertained on the doctrine of neccesity, an outcry was raised against him, and he was represented by his enemies as a man whose principles tended to atheism, and to corrupt the morals of the people. Notwithstanding this malignant attack, he employed himself in publishing three volumes of experimental philosophy, and a volume of dogmatical philosophy, which he dedicated to the emperor of Russia, and which the emperor caused to be translated into the Russian language, repeating to him the offers which had before been made, in order to induce him to remove to Peterboug. The contest that had been excited against him still continued; and though he attempted to justify himself in a treatise on the subject of fatality, the king was at length persuaded that his principles were dangerous, and ordered him, in November 1725, to quit his territories in two days, under pain of death. Wolf immediately proceeded to Caffel, where he met with the king of Sweden, who appointed him professor of mathematics at Marburg, an office which he had refused sixteen years before. The clergy of Halle pursued him with their enmity and opposition to Marburg; but Wolf was suffered to remain in the quiet enjoyment of his office during his residence at that place. Several students who attended him at Halle followed him thither, and his lectures, which he commenced in 1724, were attended by pupils from all parts of Europe. His mind being now undisturbed, he resumed his literary labours, and published his "Remarks on Metaphysics," in which he answered the principal objections against his doctrine, and gained a decided victory over his enemies. The grounds of the cenfure that had been passed on Wolf had been everywhere canvassed; and almost every German university was inflamed with disputes on the subject of liberty and necessity, so that the names of Wolfian and anti-Wolfian were everywhere heard. Wolf, having thus vindicated his philosophy from reproach, received new invitations from Peterboug and Leipsic; but gratitude to his protector induced him to remain in his situation at Marburg, which he found to be very agreeable, and to afford him leisure for pursuing his speculations. After an interval of nine years, the current of public opinion turned in favour of Wolf, and he now received numerous tokens of respect from men of rank and learning; and in 1733 he was invited to fill, in the Academy of Sciences, one of the eight places allotted to foreigners distinguished in the highest branches of science. On this occasion, Reaumur and he commenced an intimate friendship, which lasted till the time of his death. The king of Prussia was convinced of Wolf's innocencs, revered his sentence of exile, and wished to repair the injury which he had sustained. He made tempting offers, both of title and money, to induce him to return to Halle; but he declined the acceptance of them; as he also refused an invitation from George I. of England to accept a place in the new academy which he had founded at Gottingen. The clergy of Halle made some other attempts to reproach and ruin him, but they recoiled on his adversaries. In the year 1740, he prefixed to the first volume of his "Droit Naturel, et Traitte sur le Law of Nature," a dedication to the hereditary prince of Prussia, afterwards Frederick the Great, which was acknowledged by a very flattering letter.

Frederick the Great, as soon as he ascended the throne, recalled Wolf to Halle; and with the permission of the king of Sweden, he consented to accept the office of professor of the law of nature and nations, and also of mathematics, with a salary of 2000 crowns, and liberty to teach whatever he thought proper. He obtained also the rank of privy-councillor, and was made first vice-chancellor, and afterwards chancellor of the university. In 1745 he was created a baron by the elector of Bavaria. Wolf was now at the height of his prosperity. At more than 60 years of age he refused his labours, and completed his work on the law of nature.
nature and nations, which was written in Latin, and extended to eight volumes 410. He also wrote prefaces to the works of others, and particularly one to Soffmilch's work on population. Notwithstanding his great celebrity, perhaps on this account, he had many and powerful enemies. Leibnitz, Maupretius, and Voltaire, were of this number; and with respect to the latter, we may observe, that both in his writings and in his conversation with the king, he contributed in no small degree to lessen the veneration which Frederick II. entertained for him. In 1752 he was made a member of the Institute at Bologna; but he did not long survive this honour, as he died in the month of April 1754, in the 76th year of his age. He left one son, who inherited a considerable estate which he had purchased.

The adversaries of Wolf attacked not only the principles of his philosophy, but his method and his style. His Latin, it must be acknowledged, was not elegant; but his German has been commended and imitated; and he is said to have improved his native tongue both in precision and energy. With regard to his general disposition and demeanour, he is said to have united a great degree of complaisance and affability, with irreproachable morals and exemplary vanity, which he was not able to conceal. He did not hesitate to extoll himself and his own merits publicly and without reserve, and even to exhibit them in emblematical devices on the titles of his books. Brucker sums up the character of Wolf as a writer in the following concise manner: — "He possessed a clear and methodical understanding, which by long exercice in mathematical investigations was particularly fitted for the employment of digelling the several branches of knowledge into regular systems; and his fertile powers of invention enabled him to enrich almost every field of science in which he laboured, with some new addition. The lucid order which appears in all his writings enables his reader to follow his conceptions with ease and certainty through the long and train of reasoning. But the close connection of the several parts of his works, together with the vast variety and extent of the subjects on which he treats, renders it impracticable to give a summary of his doctrines." Brucker's Philosophy by Enfield, vol. ii. Preface to M. de Vattel's Law of Nations. See Leibnizian Philosophy.

Wolf, Jerome, a German philosopher, was born in the county of Oettingen, in the year 1516, and instructed in the elementary parts of education at a college established by the senate of Nuremberg. But his studies were interrupted by an appointment in the service of Julius, the chancellor of Count Von Oettingen. This interruption, however, contributed to allay the severity of his countenance and manner, and to mollify the moroseness of his temper; whilst these unamiable qualities were amply counterbalanced by probity, diligence, and modesty, which engaged the confidence and esteem of his employer. His habitual disposition again returned, and he resumed the study of poetry, and of the ancient Greek writers, against the remonstrances of the chancellor, who recommended attention to jurisprudence and public business, as the most effectual means of acquiring both honour and competence. Remonstrances were ineffectual, and he persisted in pursuining a course which cherishe his morbid melancholy and disquieting irritability. Still devoted to his literary pursuits, he was fortunate in gaining the patronage of John James Fugger; and in being afterwards advanced to the post of the director of the college of Augsburg, and that of librarian to this institution. In this situation he remained till his death, which happened in the month of October 1580. Wolf was particularly distinguished as a laborious translator, in which literary department he gained the commendation of Huet; though Henry Stephen censures his performances. When the edition of the Annals of Zonaras, published by Wolf at Basle in 1557, became rare, a new one, with notes by Du Cange, was printed at the Louvre in Paris in 1687. Wolf's translation of Demosthenes was first printed at Basle by Opinius; and being much approved, it passed through two other editions. After being revised by the translator, Epitocipus printed it at Basle in 1752, with the orations of Athines, the commentaries of Upian, and the notes of Wolhus. His other works, which were numerous, almost wholly related to Greek and Latin authors. Eloges par Forney et Tellier.

Wolf, John Christopher, a German Lutheran divine and eminent scholar, was born in 1613, at Wernigerode, and removing in 1605 to Hamburgh, was educated under the protection of the celebrated Fabricius, by whom he was employed, under the age of 20 years, in making a catalogue of all the writers quoted in Eulaliius's Commentary on Homer, afterwards inferted by Fabricius in his "Bibliothea Graeca." Having prosecuted his studies at Wittenberg, and graduated master of arts, he became, in 1706, adjunct of the philosophical faculty. Upon his return to Hamburgh, he undertook a tour in 1708 through Holland to England, and for some time resided at Oxford for the use of the Bodleian library. His next migration to Denmark led, in 1710, to the appointment of extraordinary professor of philosophy at Wittenberg, where his lectures collected a great number of pupils. Although he was here advanced to the chair of theology, he removed in 1712 to Hamburgh, and was appointed professor of the oriental languages in the Gymnasium, and in 1715 promoted to be rector of that institution. He was likewise a preacher-extraordinary at the cathedral, and became pastor of the church of St. Catharine; and soon after a member of the Academy of Sciences at Berlin. He commenced his literary contributions to the "Acta Eruditorum" in 1708; and he collected from various repositories an astonishing number of rabbinical and oriental books and MSS.; which library he bequeathed to the library at Hamburgh, where he died in June 1739. Of his numerous works, we shall here enumerate his "Bibliothea Hebraea," in 4 vols. fol.; "Historia Lexicorum Hebraicorum;" "Primitiae Hebræorum," five Oratio de Precocibus eruditis, et Ordinationem bine Deceffitate et Utilitate declamanti;" "Histo- ria Homologorum;" "Differtatio de Athenis falto fuf- pettis;" "Cura philologico et criticae in Novum Tef- tamentum," 4 vols. 4to. He was also the editor of several learned works. Gen. Biog.

Wolf. There are biographical articles for five German musicians of that name in Gerber's Continuation of Walther's Musical Lexicon.

Firß, Michael Christian Wolf, organist and music director in St. Mary's church at Stettin, born 1709, and who died in 1789, after publishing the following works: "Six Duets for two German Flutes at Berlin;" "Six Harpschord Sonatas," Stettin, 1776; "Songs with a Harpschord or Harp Accompaniment," Ebdem, 1777; "Exercises for the Organ in Choral Music;" and having in MS. a Psalm for Four Voices, with an Accompaniment for the Organ, and many other pieces for the church and chamber.

II. Erßl Friedrich Wolf, brother to the preceding master, late organist at Cologne, who died in 1772. He had been two years under the chapel-master Stölzel, for composition; and under the concert-master Hulin, at Gotha, for the violin. But at nine years old he had previously studied the scores of great masters, and the Gradus ad Parnassum.
of Fouche, so that early in life he became a great extempore player on the organ.

Of these two brothers we have never heard or seen the productions; but of

Ernst William Wolf, born at a village near Gotha, in 1735, chapel-murder at Weimar, we have seen and admired many of the works.

Wolf, in Astronomy. See Lupus.

Wolf, Lupus, in Zoology, the canis lupus of Linnaeus, a beast of prey of the dog kind, with the tail bending inwards, rather long and bulky, and the largest and fiercest of that race of animals. It is extremely like the domestic dog in shape, and if the head, which is long, with a pointed nose, did not differ a little in figure, the upper part of the face being broader, one would be apt to declare it the very fame animal. It is distinguished also by superior fize, stronger limbs, and more muscular body. It has a very fierce look about the face; its eyes are more obliquely placed than those of the dog, and are more glaring and savage; its jaws are much stronger; and its teeth, which are large and sharp, and the opening of its mouth, which is shorter in proportion than that of the dog, fierce and frightful. The ancients had an opinion, that the neck of the wolf was all of one solid bone; but, on the contrary, this creature is able to turn and twist it about better than the dog kind.

The wolf, as well as all the other beasts of prey, can endure hunger a long time, though very voracious when it meets with food. The wolf differs from the dog in its note, for instead of the barking of the dog this creature only howls; his ears, which stand erect, and his tail, make him also greatly resemble the fox.

The hair of the wolf is long; the legs are long; the head and neck cinerous: and the body generally pale grey, tinged with yellow; sometimes found white; in Canada sometimes black; and taller than a large grey-hound.

The wolf inhabits the continents of Europe, Asia, Africa, and America.

How numerous these animals were formerly in Britain we may infer from the laws of king Edgar, who attempted to extirpate them by committing the punishments for certain crimes into the acceptance of a number of wolves’ tongues from each criminal; in Wales by converting the tax of gold and silver into an annual tribute of three hundred wolves’ heads. In succeeding times their destruction was promoted by certain rewards; and some lands were held on condition of destroying the wolves which infested those parts of the kingdom.

In 1281, these animals infested several of the English counties; but after that period, our records make no mention of them. The last wolf known in Scotland was killed in 1689, and in Ireland one was killed in 1710.

The wolves of North America are the smallest; and it is said, that from those proceeded the dogs which were found there by the Europeans on their first arrival: when reclaimed, they are the dogs of the natives. In the less inhabited parts of the country, they gather in large droves, and hunt the deer and other animals like hounds with hideous howlings, and it is affirmed that they will attack even the buffalo. In the inhabited parts, they are become rare. In some parts of Europe their number has somewhat increased; e.g. in Sweden they were rare till about the year 1720. The Swedes destroy them by stuffing the carcass of a sheep or other animal with a species of lichen or tree-moss, (lichen vulpinus,) which is considered as a certain poison to the wolf, and also, as the name imports, to the fox. This is said to be mixed with pounded glass, which is probably more destructive than the lichen. The wolves of Senegal are the largest and fiercest; and they prey in company with the lion. Those of the Cape are grey striped black; others are black.

Wolves are cruel, but cowardly animals; they fly from man, except when impelled by hunger; in which case, they prowl by night in great droves through villages, and destroy any persons they meet; and having once got the taste of human blood, give it the preference. In hard weather wolves assemble in large troops, and join in dreadful howlings. They have a fine scent, and hunt by the nose: between them and the dogs a mutual enmity subsists. This animal has a very strong carnivorous appetite; and yet crafty, strong, and nimble as he is, and in every respect capable of feizing his prey, he often dies of hunger. Being driven into the forest, he finds only a few species of wild animals, who save themselves by flight, so that he perishes with want. Although he is naturally timid and dairily, he braves danger, when pressed with famine, and attacks those animals that are under the protection of man, and carries away lambs, small dogs, and kids, returning often to the charge, until being wounded by his pursuers, he retires to his den in the day, but inflicts forth in the night to his ferocious and destructive ravages. When his hunger is extreme, he attacks women and children, and sometimes darts with savage violence upon men, till at length he falls a sacrifice to his own rage. We have occasional accounts of the terror which this animal has excited, and of the destruction which he has committed among women and children in France. To such a degree did his ravages excite terror in 1764, that prayers are said to have been offered for his destruction.

Wolves, in the northern parts of the world, sometimes get on the ice of the sea, in order to prey on young fœls, which they seize when asleep; but sometimes the ice detached from the shore carries them to a great distance from the land, and large districts have thus been cleared of these pernicious animals, which have been heard howling in a dreadful manner far in the sea.

The wolf is sometimes affected with madness, accompanied with symptoms similar to that of dogs; and this disease happens to them in the depth of winter, and therefore, as Mr. Pennant observes, cannot be attributed to the rage of the dog-days. The time of gestation in the wolf is, according to Buffon, about three months and a half; and the young whelps are found from the end of April to the beginning of July; and this difference in the time of gestation, being in the wolf about one hundred days, and in the dog only sixty, he considers as a proof of the real difference between the two species.

Although the wolf seems to be naturally savage, he is capable, when taken young, of being tamed, and of being wholly divested of the ferocious character of his species. Ray. Pennant. Shaw.

Wolf, Golden. See Jackal and Auresus.

Wolf, Marine. See Hyena.

Wolf, Mexican, Canis mexicanus, with deftined tail and ah-coloured body, variegated with dusky bands and fulvous spots, a species that inhabits the hot parts of Mexico, agreeing in its manners with the European wolf. Its head, jaws, and teeth, are large; in the upper lips are strong bristles bent backwards, of a grey and white colour; the ears are large, erect, and cinereous, and the space between them marked with broad tawny spots; the head ah-coloured, crossed with dusky stripes; the neck fat and thick, and marked with a tawny stroke; on the breast is another of the same kind; the body is ah-coloured spotted with black, and the sides striped with the same colour; the belly
belly cincerea, the tail long, of the same colour, tinged in the middle with tawny; the legs and feet striped with black and ash-colour. This wolf is sometimes found white. Pennant.

Wolf, Black, Canis Lycaon, with straight tail, is considered by Buffon and others as a variety of the common wolf, and confounded by Schreber and Gmelin with the black fox; but regarded as a distinct species. It is found both in Europe and America, and in some parts of Asia. In America it is chiefly found in Canada, and in Europe in the more northern regions. Shaw.

Wolf, in the History of Insects, the name of a small white worm or maggot, which infests granaries, and does great damage there.

It is in this state of the worm that it does the mischief; but this is not its perfect form, for it is afterwards transformed into a small moth, with white wings spotted with black.

This little maggot has five legs, and as it creeps along, it sheds from its mouth an extremely fine thread or web, by which it fastens itself to every thing it touches, so that it cannot fall. Its mouth is furnished with a pair of reddish forceps, or biting instruments, by means of which it gnaws its way not only into wheat and other grain, but perforates even beams of wood, boxes, books, and every thing it meets with.

Towards the end of summer these pernicious insects may be seen crawling up the walls of corn-chambers, infested with them in great numbers; they are then searching a proper place where they may abide in safety during their auralia state; for when the time of their undergoing this change approaches, they forsake their food, and the little cells they had formed of hollowed grains of corn clotted together, by means of the web coming from their mouths. They now wander about till they find some wood, or other substance into which they gnaw holes with their fangs, capable of concealing them; and there enveloping themselves in a covering of their own spinning, they soon become a dark-coloured sort of auralia. They remain in this state all the winter; but in April or May they come forth in their moth-shape, and are then seen in vast numbers, taking short flights, and creeping up the walls. In this state they eat nothing; but they soon copulate and lay eggs, which are in the shape of a hen's egg, but not larger than a grain of sand. Each female lays fifty or seventy eggs, which the deposits in the little wrinkles of the grains of corn, where in about sixteen days they hatch, and the minute maggots immediately perforate the grain, and eat out all its substance, and with the threads which come from their mouths cement other grains to it, which they, in the same manner, scoop out and destroy.

The watchful observer has two opportunities of destroying these devourers from among his corn. One is, when they forsake their food, and ascend the walls, which they will sometimes almoast cover. The other, when they appear in the moth-stage. At both these times they may be crushed to death against the walls in great numbers, by clapping facks upon them; but they may be exterminated more ef- fectually by closing up all the windows and doors, and burning brimstone on a pan of charcoal, letting the room be full of the fumes of it for twenty-four hours. This certainly destroys the animals, and does no sort of injury to the grain, not communicating the flighted scent to it. Baker's Microphi. p. 222.

Wolf's Bane, in Botany. Seeaconium.

Wolf's Bane, Winter's, a species of hellebore; which see.

WOLF-FISB. See Lupus Marinus.

WOLF'S GRAPES. See LycoSTAPHYLE.

WOLF-Net, a term used by the sportsmen for a kind of net used in fishing, which takes great numbers, and has its name from the destruction it causes.

It is used both in rivers and ponds, and is of the nature of the rattle, excepting only the wanting of the four wings. The trunk or cover consists of seven feet, besides the two gullets. It is supported by hoops, and is to be placed in some part where there is an abundance of fedges, rushes, and water-grafs. There is to be a place made for the net here, by the use of a paring-knife, cutting away all the weeds and other matter, for the space that will contain it; and when the net is placed, there are to be two alleys cut or cleared in the same manner, one on each side of the net, that the fish may be invited into them, and by them into the net. There must be some lines or leaden weights used to sink the net, and a long pole fastened to the upper part of the mouth of it, by means of which, when it is well filled with fish, it may be lifted up and taken to the shore.

Wolf's Peach. See Lyceopersicon.

Wolf, War, an ancient military machine, differently des- cribed by different writers. Procopius makes it a kind of portcullis, or rather a barrow for defending a gate. Matthew of Westminster, and Camden, describe it as a machine for throwing stones. "At the gates," says Procopius, (Hist. of the Gothic Wars, book i.) "they let up wolves in the following manner:—They erected two beams from the ground reaching to the battlements, and laid checkerwise pieces of wortimer timber, some upright and some crofs; they jointed them so that the mortising holes met one another; and before each joint stuck out a pointed piece of wood, like a thick spar, and fastening the crofs timbers to another beam, which from the top reached half-way down: they laid the beams flat along upon the gates, and when an enemy approached, men above laid hold of the higher ends of the beams, and thrust them down, which falling suddenly among the assailants, with the wooden points flicking out, killed all upon whom they descended." Probably there was a chain or cord to draw back the machine after it had produced its effect.

The war-wolf, for throwing stones, is described by Matthew of Westminster, ann. 1304; by Camden, in his Remains, to which we refer; and also to Grose's Mil. Antiq. vol. i. p. 383.

Wolf Island, in Geography, an island in the North Atlantic ocean, near the east coast of Labrador. N. lat. °53° 55'. W. long. 5° 40'.—Also, an island at the north-east end of lake Ontario. N. lat. 4° 54'. W. long. 7° 50'.—Also, an island in the gulf of St. Lawrence, near the south coast of Labrador. N. lat. 5° 1'. W. long. 6° 55'.—Also, a small island in the Atlantic Ocean, near the coast of Georgia. N. lat. 31° 19'. W. long. 81° 30'.—Wolf River, or Chickaw Bluff, a river of Georgia, which runs into the Mississipi, N. lat. 34° 45'. W. long. 90° 42'.

Wolf Rock, a very low, flat, rocky islet, in the North Pacific ocean, surrounded by rocks and breakers, which extend some distance from it; 10 miles from the southern coast of the Prince of Wales's Archipelago. N. lat. °55° 1'. W. long. 226° 42'.—Also, a rock near the coast of Labrador, and not far from the island called Wolf Island.—Also, a rock at the entrance of the English channel; 10 miles S. of Land's-End. N. lat. 49° 58'. W. long. 5° 45'.

WOLFBOROUGH, a township of New Hamp-
thire, in the county of Strafford, on the Winnipiccoogee lake, containing 1376 inhabitants; 35 miles N.W. of Durham.

WOLFDORF, a town of Bohemia, in the circle of Letimeritz; 7 miles N. of Kaminitz.

WOLFFENBUTTEL, a principality which lately constituted a part of the duchy of Brunswick, divided into two parts by the principality of Halberstadt, and the diocese of Hildesheim. The north part is surrounded on the north by the principality of Luneburg and the marquisate of Brandenburg, on the east by the duchy of Magdeburg, on the south by the principality of Halberstadt, and on the west by the diocese of Hildesheim. The south part is bounded on the north by the bishopric of Hildesheim and the principality of Calenberg, on the east by the diocese of Hildesheim and the Harz forest, on the south by the principality of Grubenhagen and Calenberg, and on the west by the territories of the abbey of Corvey and Calenberg. The eastern half contains under it a part of the Harz forest, the mines and salt-works which the prince held in common with the elector of Brunswick Luneburg. In the western half of this southern part is a part of the forest of Sollingen, consisting of oak and beech, with a chain of mountains covered with woods. Thus the southern part of the principality consists chiefly of hills and woods, with little arable land; but, on the other hand, has a great variety of timber, iron, and glas-house, the manufactures of which are greatly admired, particularly those of looking-glasses, with a fine porcelain manufacture, and the very rich mines and salt-works in the Harz forest. The north part of the principality is more level, and produces abundance of grain, flax, and hemp, together with various kinds of pulse and fruit. Their grazing here turns to very good account, besides which it has a salt-works. The culture of silk is now followed, and premiums are assigned by the prince for the encouragement of it. The Weiler, the Leine, the Inner See, and the Oker, are the principal rivers. In this principality are 18 towns, 386 villages, and 17 fees and consuls. The established religion here is Lutheranism. The country of Brunswick was anciently under lords of its own, who possessed it as their absolute and hereditary property, and derived its lineage from Ludolphus, duke of Saxony, and, consequently, by his grandmother Hafala, or Cigela, from duke Wittikind, whole daughter the was. From King Henry I., grandson to Ludolphus, was descended his son Henry, duke of Bavaria, among whose issue was Count Bruno, on whom the emperor Otto conferred a tract of land in Saxony, near Brunswick, namely, Melverode and Hohenwart. Count Bruno, his son, enlarged Brunswick; and his son, Count Ludolphus, on the demesne of the emperor Henry II., was the first that obtained the full sovereignty over Brunswick and Thuringia, and died in 1038. His son Egbert I. became margrave of Thuringia and Meissen; and his son Egbert II. like-wise attained to those dignities. This last prince being killed in battle, in 1091, his father Gertrude succeeded to the country of Brunswick, which country she brought to her second husband, Henry the Fat, count of Nordheim; and by their daughter Rickenza it came to her husband Lothario, count of Supplinburg, afterwards emperor. By his daughter Gertrude it descended to her husband, Henry the Magno-nimous, duke of Bavaria and Saxony, and thus to the house of Wolpho. The principality of Wolftenbuttel was possessed of a vote among the princes, both in the college of the princes of the empire, and likewise in the diet of Lower Saxony; in each of which, by virtue of an agreement concluded in 1706, when the seniority lies in the house of Brunswick Wolftenbuttel, it precedes those of the elector of Brunswick and Luneburg, for Zelle, Grubenhan, and Calenberg, but otherwise comes after them; farther, the house of Wolftenbuttel, when senior, obtained the joint direction of the circle of Lower Saxony. In 1807, this principality was annexed to Welfphalia.

WOLFSKINN, a city of Welsphalia, and capital of a principality of the same name, situated in a marshy soil, on the Ocker; it is well built and fortified. In it is a chateau, a long time the residence of the dukes, in which is a noble library containing 120,000 volumes of printed books and manuscripts. The principal church contains the sepulchral monument of the dukes. Wolftenbuttel very probably owes its name to the first builder of the palace, called Wolf, or Wolfr, or Wolfhard; 24 miles E. of Hildesheim. N. lat. 52° 10'. E. long. 10° 40'.

WOLFFERSDORF, a town of Saxony, in the circle of Neuffadt; 4 miles S.W. of Weyda.—Alto, a town of Saxony, in the circle of Neuffadt; 6 miles E.N.E. of Weyda.

WOLFFERSDYCK, a small island of Zealand, between North and South Beveland.

WOLFSHEIM, a town of Germany, in the principality of Solms Brunsfeld; 12 miles S.S.E. of Wetzelar.

WOLFERSTORFF, a town of Austria; 2 miles S.E. of Laab.

WOLFERZHAUSEN, a town of Bavaria; 12 miles N.E. of Weilheim.

WOLFESHEAD, or WULFERSHEAD, SAXON, wulfer-heel, compounded of wulf, wulf, and healf, head, caput Lupinum, denoted the condition of those outlawed for criminal matters in the Saxon time, and not yielding themselves to justice. For if they could have been taken alive, they must have been brought to the king; and if they, for fear of being apprehended, did defend themselves, they might be slain, and their heads brought to the king; for their head was no more to be accounted of than a wolf's head. LL. Edw. in Lanc. fol. 127. and Bract. lib. iii. tract. 2. c. 11. See CAPUT Lupinum, and Outlawry.

WOLFSATAAL, in Geography, a town of Austria; 2 miles E. of Hainburg.

WOLFFACH, a town of Germany, in the lordship of Furthenberg; 4 miles S.S.E. of Hazlach. N. lat. 48° 14'. E. long. 8° 10'.

WOLFFBERG, a town of Austria; 5 miles N.W. of Schwanaufedt.

WOLFFBERG, or WOLFECK, a chateau and village of Germany, which gives the title of count to a noble family, divided into several branches, viz. Wolfberg Zeil, Wolfberg Wurzach, Wolfberg Wolfsberg, and Wolfberg Waldsee; 10 miles W. of Leutkirch.

WOLFFEN, a town of Saxony; 3 miles N.W. of Bitterfeld.

WOLFFPASSING, a town of Austria; 9 miles S. of Ips.

WOLFFSHAGEN, a town of Brandenburg, in the Mark of Pregnitz; 6 miles W. of Prizwalk.

WOLFGANG, a town of Germany, in the county of Henneberg, on an island in a lake; 7 miles S.W. of Meiningen.

WOLFGANG, St. a town of Austria; 3 miles S.S.W. of Aigen.—Alto, a town of Austria; 1 mile N. of Kirchschlag.—Alto, a town of Austria, on a lake, called the Abernies, and St. Wolfgang's lake; 54 miles S.S.W. of Lintz.
Linz. — Also, a town of Switzerland, in the canton of Zug; 4 miles W. of Zug.

WOLFGAST, or Wolgast, a town of Anterior Pomerania, on the Pea, about three miles from the Baltic, with about 3500 inhabitants. It was anciently a considerable fortress, and residence of the dukes; 30 miles S.E. of Stralsund. N. lat. 54° 2'. E. long. 13° 45'.

WOLFIA, in Botany, a genus of Schreber's, feems by its orthography intended to commemorate Dr. de Wolf, of Danzig, of whose whimsical attempt in the Nomenclature of plants, we have given a sufficient account at the conclusion of that article. This writer, to whom the praise of labour and originality cannot be denied, and whose index, entitled Concordantia Botanica, is truly valuable, died in 1784, aged 60. There have been several German naturalists and physicians of the name of Wolf, but none eminent in botanical studies.—Schreb. Gen. 891.—Clafs and order, Orchestria Monogynia. Nat. Ord. Tribulata, Linnae. Sapindi, Jull.

Gen. Ch. Cal. Perianth inferior, of one leaf, coloured: tube very short, somewhat dilated at the base, permanently: limb in five deep, linear, obtuse, moderately spreading segments. Cor. none. Nectary of eight linear, obtuse, villous, upright scales, one-third the length of the calyx, and inserted into it at the base of the limb. Stem. Filaments eight, awl-shaped, erect, the length of the calyx, into which they are inserted alternately with the scales of the nectary, in the same row; anthers ovate, attached by the back, erect, directed inwards. Pfl. German superior, oblong, ending in a cylindrical upright style, the height of the filaments; stigma oblong, downy, unilaterial. Peric. Berry? ovate, of one cell, somewhat flat-topped, with three keels surrounding its fummit. Seeds three, nearly ovate, oblong, externally gibbous, contracted below the middle, abrupt at the base, enclosed in a tunic.

Obf. There appear to be several seeds, some of which prove abortive.

We have tried in vain to guess any thing more respecting this genus than its natural order, of which there can be scarcely a doubt. No author has adopted Wofia. There are, in its characters, some indications of Jambolifera, Willd. Sp. Pl. v. 2. 326. Gymnosma, Gertn. t. 58, (which ought to have found a place in our 18th volume; see Calyptranthes also); and a botanist who compares Schreber's description, literally translated above, with Jambolifera pendulata, will find several coincidences, which, allowing for one or two eafy misconceptions, might almost persuade us he had defribed that plant; but still there are infeivable difficulties. Schreber's index directs us at the word Pituma, to the fame number as his Wolfia, 1749. But no such synonyn occurs there, nor, as far as we can find, elsewhere in his book. Pet. tumo, Rheede. Hort. Mal. v. 9. t. 45, is a Juficia, and can have no connection with the present plant. See other obscure genera, thus circunlanced, at the articles Meyeria, Wheelera, Spinaria, and Xystris.

WOLF-MONETH, a name given by our Saxony ancestors to the month of January, on account of the ravages committed by the wolves in that month through the severity of the cold.

WOLFRAM, in Mineralogy, an ore of tungsten. (See Tungsten.) The colour of Wolfram is generally a brownish or greyish-black; it gives a reddish-brown streak when cut with the point of a knife, to which it yields readily, a property characteristic of this mineral. It occours both massive and crystallized, and in concentric lamellar concretions. The form of the crystal is a flat rectangular prism; the lateral planes are generally streaked longitudinally. The structure is lamellar, with a very distinct cleavage in one direction, and an indistinct cleavage at right angles to the former. The luster of the principal cleavage is pellucid or shining, and is metallic; that of the indistinct cleavage is glassy. The specific gravity of Wolfram is from 7.1 to 7.3. Before the blow-pipe it decrepitates, and melts with difficulty into a black flag.

The constituent parts of Wolfram, as given by Vaucoulemont, are,

Wolfram most frequently occurs in veins with tin-flue, but may be distinguished from it by its greater degree of softness, and the reddish streak which it yields to the knife. It is common in many of the mines of Cornwall, and in those of Saxony, and of Zinnweld and Schlackenwald, in Bohemia. This mineral has not hitherto been applied to any useful purpoBe in the arts. It was originally mislaken for antimony, which by the alchemists was called the wolf, because it appeared to destroy the bafier metals in the proeesses of refining gold.

WOLFRAMITZ, in Geography, a town of Moravia, in the circle of Znaym; 20 miles N.E. of Znaym.

WOLFSBAHCH, a river of Silefia, which runs into the Rhine, near Loewenberg.

WOLFSBERG, a town of the duchy of Carinthia, on the river Levent, with a citadel; 10 miles N.N.W. of Lavamont.

WOLFSBACH, a town of Prussia, in the province of Ermeland; 18 miles W.S.W. of Hellisberg.—Alto, a town of Saxony, in the circle of Neukland; 5 miles S.W. of Weyda.

WOLFHAGEN, a town of the principality of Hesse Cassel, on the Erpe; 15 miles W. of Cassel. N. lat. 51° 15'. E. long. 7° 10'.

WOLFPON, a small island in the gulf of Fineland. N. lat. 50° 22'. E. long. 24° 41'.

WOLFSCHACH, a town of Austria; 8 miles E. of Steyr.

WOLFSTEIN, a town of France, in the department of Mont Tonnerre; 43 miles W.N.W. of Manheim.

WOLHUSEN IN MARKT, a town of Switzerland, in the canton of Luzern; 7 miles W.S.W. of Luzerne.

WOLIN, or Wolinsky, a town of Bohemia, in the circle of Prachatitz; 8 miles N.N.W. of Prachatitz. N. lat. 49° 50'. E. long. 13° 45'.

Wolin, a town of Brandenburg, in the Middle Mark; 10 miles S.S.W. of Brandenburg.

WOLKART, a mountain of Carinthia; 8 miles N.E. of Militatt.

WOLKENMARCK. See WOLKENMARK.

WOLKENSTEIN, a town of Saxony, in the circle of Erzgebier, with a citadel, situated on a rock, near the Zincha. About half a league from the town are some warm medicinal baths; 13 miles S.S.E. of Chemnitz. N. lat. 50° 36'. E. long. 12° 59'.—Alto, a town of the county of Tyrol; 3 miles W. of Lenzth.
WOLKOMYSK, a town of Lithuania, in the palatinate of Novogrod; 40 miles W.S.W. of Novogrodek.

WOLLACOMB BAY, a bay of England, on the west coast of Devonshire, situated to the north of Barnstaple bay.

WOLLAPALLAM, a town of Hindoostan; 10 miles E. of Coimbatore.

WOLLASTON, William, in Biography, an ethical writer, was born in 1659 at Cotton Clifton, in Staffordshire, and finished his education as a penonner of Sidney college, Cambridge. In 1681 he commenced M.A. and entered into deacon's orders. His first settlement was as an almoner in the free school at Birmingham, to which a small lecture ship was annexed; and about four years afterwards he was advanced from this laborious situation to the office of second master in the same school. In 1698 a relation died, whose decease put him in possession of a considerable landed estate, upon which he removed to London, and marrying a lady of considerable fortune, he resided in Charterhouse-square. Dissipating all thoughts of church preferment, he devoted himself to the retirement of private life and to a course of study, comprehending the learned languages, together with Hebrew and Arabic. The first publication which flowed from the press was a poem on Ecclesiastes, which he would afterwards have suppressed, from a conviction that his talents were not adapted to poetry. In the progress of his life and literary pursuits, he was so much amused by composition that he wrote many treatises on various subjects, both in Latin and English, which he committed to the flames. Of the well-known work which has perpetuated his name, and which is intituled "The Religion of Nature delineated," he printed a few copies to be distributed among his friends in 1722, but his declining health prevented his completing his original design. However, in 1723 he was prevailed upon to revise what he had printed for publication, and it accordingly appeared in 1724, in which year he died, at the age of 65, leaving a large family, and having loft his wife, to whom he was affectionately attached, about four years before. In his private character he is said to have exemplified the virtues which his work incalculated. The system which he developed, and which founded morality upon "truth," excited much attention, and his book, though not written in a popular manner, passed through seven editions to the year 1750. The last of these editions includes an appendix, consisting of a translation of the Latin notes by Dr. J. Clarke, dean of Salisbury, undertaken at the particular request of queen Caroline, who was a great admirer of the work. Dr. Warburton, in his Lectures on Wollaston's theory in his Divine Legislation, honours the author by ranking him as "one of our most celebrated writers," and compliments him with having "demonstrated with greater clearness than any before him the natural essential difference of things;" and though modern systems have in a considerable degree antedated that of Mr. Wollaston, the author must always be regarded as a man of extensive learning and strong reasoning powers. Biog. Brit.

WOLLANDS, in Geography, a town of Germany, in the margrave of Anspach; 10 miles E. of Anspach.

WOLLANDS, a town of Austria; 5 miles W.N.W. of Neultatt.

WOLLANDS, a town of Brandenburg, in the Ucker Mark; 10 miles E.S.E. of Prenzlau.

WOLLANDS, a town of Anterior Pomerania, on the east coast of the island of the land, separated from the continent of Pomerania by the river Dorenow, over which is a bridge, at which all travellers pay a toll. In this town are a feat and
favour and confidence he conciliated by his blending amuse-
ment with business, in so much that he supplantcd the minis-
ters of the late king, and became himself uncontrolled minis-
ter. His preferments, civil and ecclesiastical, very speedily
succeeded one another, and even profusely accumulated.
He was introduced into the privy-council in 1510, made
reporter of the flar-chamber, register, and afterwards chanc-
eller of the garter; and advanced to the fees of Tournauy
and Lincoln in 1513, to that of York in 1514, and to the
dignity of cardinal in 1515. Thus promoted, his pride and love
of pomp kept pace with his elevation of rank. In his train of
servants, 800 in number, were many knights and gentlemen;
and the fees of noblemen acted occasionally as his domes-
ticial menials. His equipage and furniture were of the most costly
kind; but it is needful to multiply particulars. The most
pardonable, not to say laudable, display of his magnificence
was exhibited in his patronage of literary men and promo-
tion of literature, both by the exercise of private bounty
and the Establishment of public institutions. The pope
ominated him legate à latera, by which office he acquired
legal pre-eminence over the archbishop of Canterbury; and
in December 1515, he was elevated to the office of high-
chancellor. By the equity of his decisions in the exercise
of this office he gained great credit; but his conduct as le-
gate à latera was fo arbitrary and oppressive, as to produce
complaints against him to the king. Charles V. and Fre-
deric I. purchased his interest with Henry VIII. by pen-
sions, and he was also retained in the same way by the
pope. Charles flattered him with hopes of the papal
crown, and settled upon him the revenues of two bish-
ropies in Spain. Still infatiable in the pursuit of ecclesiasti-
cal preferments, he obtained the administration of the see
of Bath and Wells, and the temporalities of the abbey
of St. Alban’s, to which were afterwards added successively
the rich bishoprics of Durham and Winchester. His revenues,
thus amounting nearly to that of the crown, were expended
partly in the ostentation of pomp, and partly in laudable
munificence. He founded several lectures at Oxford for
liberal and useful studies, and at length erected in that uni-
versity the celebrated college of Christchurch. He also
established a collegiate school in his native town of Ipswich.
The palace which he built at Hampton Court he prefented,
in 1528, to the king, and he further ingratiated himself
with Henry by an arbitrary loan for the supply of his wants;
but by these measures he became more and more odious to
the nation. But his fall was approaching; and the first
step to it was the divorce of queen Catharine. This was fol-
lowed by the marriage of Henry with Ann Boleyn, whose
influence was employed in effecting his downfall. At
length the king, not without hesitation and reluctance, em-
ployed the dukes of Norfolk and Suffolk, in 1529, to re-
quire him to surrender the great seal, and to quit York-
place, a palace which he had built in London, and which
afterwards became a royal residence under the name of
Whitehall. His furniture and plate were seized for the
king’s use, and he was ordered to retire to Esher, a palace
which belonged to him as bishop of Winchester. These
measures overwhelmed the favourite, delirium of any inward
resources of magnanimity; and when he received a flight
token of the king’s favour in this state of mental depression,
he was transported with joy, dismounted on meeting the
messenger, and fell upon his knees in the dirt to receive the
expression of his master’s kindnecfs. Henry, however, was
capricious and inconstant; a cloud overspread this glem,
and Wolsey was ordered to be indicted in the star-cham-
ber, and abandoned by his sovereign to the rigour of
parliament. An accusation, consisting of 44 articles, was
exhibited against him by the house of lords; and in the
commons, he was fo ably defended by Thomas Cromwell,
who had been raised by the cardinal from a low condition to
a high station, that his enemies were defeated. They thus
changed their plan, and indicted him upon the statute of
provisors, which prohibited his procuring bulls from Rome,
and which he had violated by obtaining the legantine power;
and this was made the ground of a sentence, putting him
out of the king’s protection, forfeiting all his lands and
goods, and declaring him liable to imprisonment. When
these measures had induced him to resign the king York-
place with all its furniture, he obtained a full pardon for all
his past offences, and the restoratien of the revenues of
his archbishopric, with part of his goods. But fresh tokens
of royal displeasure awaited him. The earl of Northumber-
land was ordered to arrest him for high treason, and to con-
duct him to London for trial. In his way from York to
London, he was seized with a disorder which obliged him
to stop at Leicester, where he was hospitably received in the
abbey. His disorder in a few days terminated his life, in
the 6oth year of his age. Shortly before he expired he
closed a conversation with the confiablc of the Tower, which
related to the king, with this exclamation, “Had but I
served God as diligently as I have served the king, he would
not have given me over in my grey hairs!” Thus he sunk
to the grave as a victim to tyranny, but to a tyranny which
he had himself formed; exhibiting an instructive example
to all future ministers of the insecure possession of power and
wealth acquired by extortion and oppression, and of the
folly of placing confidence in princes embracing arbitrary
and despotic measures, and governed by caprice and per-

The magnificence of the cardinal’s chapel-establishment,
as described by Cavendish, his contemporary and domestic,
seems far to have surpassed that of the Roman pontiff
himself.

“First, he had there a dean, a great divine, and a man
of excellent learning; a sub-dean, a repeator of the quire,
a gospeller and epifullar; of singing priecls, ten, a matter
of the children. The seculars of the chapel, being finging-
men, twelve; singing-children, ten, with one servant to
wait upon them. In the veltry, a yeoman and two
grooms; over and beside other retainers that came thither
at principal feasts. And for the furniture of his chapel, it
pallished my weak capacity to declare the number of the
coftly ornaments and rich jewels that were occupied in the
fame. For I have seen in proceffion about the hall forty-
four rich coves, besides the rich candlesticks, and other
necafsary ornaments to the furniture of the fane.”

The earl of Northumberland, whose passion for Ann
Boleyn is supposed to have occasioned his disgrace at court,
seems to have been treated with great insolence and in-
dignity by the cardinal, who, by an extraordinary exten-
sion of power, demanded his choral books for the use of his
own chapel. Letters concerning this requisition are still
preserved in the family, in which the earl fays, “I do per-
ceyffy my lorde cardinals pleafures to have fuch books as
was in the chapell of my lat lorde and ftyther (wos refl
Jhui pardyn.) To the accomplifhment of which, as your
defyer, I am confiderable, notwithstanding there is no trull
to be able ons to fet up a chapell of my owne. I shall with all
fudel fend up the boks unto my lorde’s graces, as to fay iiij
Antiffaror (Antiphoners), fuch as I thinke when not feen a
gett wyl—v Grelts (Graduals) an Orderly (Ordinal)—
a Manual—viii Prafflifioners (Proceffionals).” Northum-
berland Household Book.

WOLINGHAM, in Geography, an irregular town in
the
the county of Durham, England, is pleasantly situated in the vale of the Wear, on a point of land formed by the confluence of that river and the Weferow. The church is situated at the north side of the town on rising ground, but possesses nothing worthy of remark. Near it are some remains of a considerable building, inclosed with a deep moat, suppos'd by some writers to have been part of a monastery, which was founded by Henry de Pudley; but Hutchin, in his History of Durham, refers them to the ancient manor-house of the bishop's, which is mentioned in Hatfield's Survey. The inhabitants of this parish, according to the returns of 1811, are 283, and the houses 399. The views down the Wear from the hill above Wolfgamsham include a very extensive and beautifully diversified country. Between this town and Stanhope, the commencement of the lead district is everywhere intimated by large parcels of lead lying near the sides of the road, and from the blue or white vapours arising from the smelting mills in Bollihope. On Bollihope common, in 1749, was found a Roman altar with an inscription. This town is 6 miles S.E. by S. from Stanhope, and 259 N.W. from London. Here is a market held on Tuesday, and a fair on the 18th of May. The petty feftions are held here. The parish, which is large, confines of Bradley, Hilton-park, Thornley, Wolfgamsham town quarter, East side quarter, Park quarter, and South side quarter.—Beauties of England, Durham, vol. iv.; by J. Britton and E. W. Brayley.

WOLTA, a town of Bohemia, in the circle of Konigratz; 2 miles N. of Trauttenburg.

WOLTERN, a town of Germany, in the county of Verden; 30 miles E. of Rotenburg.

WOLTERSDOF, a town of Saxony; 2 miles S.W. of Zahna.

WOLTIN, 2 miles N. of Hinder Pomerania; 12 miles S.W. of Stargard.

WOLTFORF, a town of Auefia; 2 miles N.W. of Weikerfard.

WOLVERENE. See GLUTON.

WOLVERHAMPTON, formerly HAMPTON, in Geograpy, an important market-town in the hundred of N. Stafford, and county of Stafford, England, is particularly noted for its extensive manufactures of locks, keys, and other articles of ironmongery. It is situated on a rising ground 16 miles S. from Stafford, 14 S.W. from Lichfield, 13 N.W. from Birmingham, and 130 in the same direction from London. Wolverhampton is of ancient date, for as early as 966 a monastery was founded there by Wulfuna, from whom the town received the first member of its name. The institution, consisting of a dean and secular canons, was about the year 1200 transferred by the dean, Peter of Blois, to the archbishop of Canterbury, to convert it into an abbey for Cistercian monks; but this design seems not to have been executed, for the seculars appear to have been not long after in possession of the establishment. The church, which was considered as one of the king's free chapels, was by Edward IV. annexed to the deanery of Windsor; but in the seventh year of Edward VI. a grant of the college of Wolverhampton and seven prebends was made to John, duke of Northumberland. Coming again to the crown by his attainder, queen Mary reinstated the dean and prebendaries, and endowed them with all the lands, &c. which formerly belonged to the institution, then valued at the yearly rent of £36. 13s. 4d. On a question arising concerning these possessions, the grants of Mary were confirmed by James I., who appointed the celebrated Marc-Antonio de Dominis, who had been archbishop of Spalatro in Dalmatia, to be dean of Windsor, and dean and first prebendary of Wolverhampton:

those deaneries continue to be united, but the colleges are separate.

Wolverhampton is well built, and considered as fabulous, notwithstanding it is in the vicinity of many coal-mines. The parish is of great extent, being nearly 30 miles in circuit, and comprehends, besides the town, seventeen considerable townships, or villages, among which are, Billiton, Featherstone, Hattherton, Hilton, and Kinvalton. According to the returns to parliament in 1811, the houses in the whole parish were 2936, and the inhabitants 14,836. A market is held on Wednesday, and a fair on the 10th of July. The skill and ingenuity of the lock-smiths of the town and the environs, (for many of the farmers themselves are concerned in the business,) and the trade carried on in these and similar articles of iron manufacture, are unparalleled in England: the trade is particularly promoted by the Staffordshire and Worcestershire grand trunk, and the Birmingham canals, which unite about a mile to the N. of the town. The town is governed by two constables, and in it are held the petty seftions for the N. and S. divisions of Stafford hundred.

The collegiate church of St. Peter stands on an elevation on the E. side of the town, and consists of a lofty nave, with side-aisles and a chancel. From the centre of the building, which is of stone, rises a tower. The nave is separated from the aisles by five pointed arches, supported by octagonal pillars. Against one of the S. pillars is erected a very curious stone pulpit. The font, which is octagonal, and covered with sculptured figures, &c. appears to be very ancient. In the great chancel is a full-length statue, in brass, of the celebrated admiral Sir Richard Leveson, who had a command against the Spanish armada, under Sir Francis Drake. In the church-yard stands a round column twenty feet high, profusely but rudely carved in divisions, and the whole surmounted by a plain capital. It is evidently ancient, and may have supported a cross, or the figure of the patron-saint. The situation of Wulfuna's monastery is unknown; but in the S.W. corner of the burying-ground is a large room supported by groins, the walls of which are three yards in thickness. Beside St. Peter's, Wolverhampton possesses another church, dedicated to St. John, which was erected by subcription, and consecrated in 1761. Difficulties of various denominations abound in the parish of Wolverhampton, and comprehend more than one half of the inhabitants: chapels for their accommodation are consequently numerous. A free-school was founded here by Sir Stephen Jennings of Wolverhampton, who was lord-mayor of London in 1668; besides which, charity-schools are maintained for children of both sexes. Bilston, a large and populous village two miles S.E. from the town, is within the parish of Wolverhampton; but as to all parochial concerns it is a separate township. In 1811 Bilston contained 1862 houses, and the inhabitants amounted to 9646. Here is a parish-chapel, which is a neat modern structure; the living is a perpetual curacy within the exempt jurisdiction of the dean of Wolverhampton; but the nomination and presentation of the incumbent are vested in the inhabitants at large. Bilston contains likewise two dissenting meetings, and an excellent charity-school. The business of Bilston consists chiefly of japanned and enamelled goods. The vicinity abounds in coal, iron-stone, with numerous smelting-furnaces and forges, &c. in which the operations are performed by steam-engines. Bilston furnishes also a peculiar kind of sand of great use in casting metals. At Bradley, near Bilston, the subterraneous coal has been burning for several years past, and every attempt to extinguish it has hitherto proved fruitless, by which several
val acres of land have been rendered unproductive. The fire proceeds from a burning stratum of coal about four feet thick, and eight or ten yards deep, to which the air has free access; as the main bed of coal has been dug out from under it. In collecting the calcined substances for repairing the roads, sulphur and alum are frequently found. Tatenhill, a small village on a steep eminence two miles N. from Wolverhampton, was the scene of a severe battle between Edward the Elder and the Danes, in the beginning of the tenth century. In this place was founded, before the Norman Conquest, a college with a dean and five prebends, which sufficed till the general dismission by Henry VIII. The present church, or chapel, is apparently a part of that establishment. At Wrottesley, a village in the parish of Wolverhampton, extensive ancient remains have been discovered, supposed, by Dr. Plott, in his History of Staffordshire, to be vestiges of the old Theoten-hall of the Danes: but later antiquaries imagine these remains to belong to the Uriconium of Roman Britain. The parish of Wolverhampton, although varied with eminences, is in general level, and ornamented with a number of agreeable hamlets and country-seats.—History and Antiquities of Staffordshire, by the Rev. Stebbing Shaw, fol. Lond. 1798. Beauties of England and Wales, Staffordshire, 8vo. Lond. 1814.

WOLVES-TEETH, of a horse, are overgrown grinders, the points of which, being higher than the rest, prick the creature's tongue and gums in feeding, so as to hinder chewing of the meat. They are seldom met with in young horses; but if they be not daily worn by chewing, they will grow up even to pierce the roof of the mouth. There are usually two of these wolves-teeth, which are small, and grow in the upper-jaw, next to the great grinding-teeth: these are so tender and painful, that the horse cannot chew his meat, but is forced to let a great part of it fall out of his mouth, or swallow it half chewed. The remedy, in this case, is to tie up the horse's head to some part of the rafter, and open his mouth with a cord; then with an instrument like a carpenter's gauge, and a mallet, the teeth that are thus troublesome are to be knocked out, and the holes filled up with salt. If the upper-jaw teeth hang over those of the under-jaw, and by that means cut the mouth, the same instrument is to be used, and the teeth are to be pared shorter by little and little. When they are sufficiently pared down, they must be filed smooth, and the mouth washed with vinegar and salt, and the whole complaint will be thus removed.

WOLVES, Rout of. See ROUT.

WOLVES ISLANDS, in Geography, a cluster of small islands near the E. coast of Maine. N. lat. 45° 4'. W. long. 66° 50'.

WOLVEY, a village of England, in the county of Warwick. It was at this place that Edward IV. was purcased and taken prisoner by Richard Neville, earl of Warwick; 10 miles N.E. of Coventry.

WOLZ. See WELS.

WOMAN, FEMINA, Mulier, the female of man.

A woman, in England, as soon as she is married, with all her moveables, is wholly in potestate viri, or at the will and disposal of her husband. There are divers considerable things relating to women in the laws of England, which see under WIFE.

St. Augustine calls women the devotus sex; at least, this is the common opinion; though others rather think, that in the prayer usually attributed to that father, and still rehearsed in the Romish church to the Holy Virgin, the words

"intercede pro devote femine sex," are to be understood of women devoted or consecrated to God in religious houses; which had been sufficiently expressed by the words, "ora pro populo, interveni pro clero."

It is a popular tradition among the Mahometans, which obtains to this day, that women shall not enter paradise.

An anonymous author, about the close of the sixteenth century, published a little Latin dissertation, to prove that women are not men; that is, are not reasonable creatures: "Differatio perjculanda, qua anonymus probare nititur mulieres homines non esse." He also endeavours to prove, what naturally follows from this principle, viz. that women shall not be saved, that there is no future life or happiness for them. His proofs are all taken from Scripture, or founded on Scripture. Though, after all, his aim is not to much to degrade women to the condition of brutes, as to ridicule the principle or method of many Protestants, who, in points of controversy, admit of no proofs or considerations but what are taken from Scripture alone. This appears from the conclusion of the work. "Probavi, opinor, invictiffimis SS. literarum testimonii, mulierem non esse hominem, nec eam salvari: quod non effect, ostendi tamen universo mundo, quomodo hujus temporis haeretici, et pretenditi Anabaptisti, faciam solem explicare Scripturam, et quo utantur methodo ad abdiuindi sua exsanguina dogmatam."

Yet Simon Gecicus, a Lutheran divine, wrote a serious confutation of this piece in 1595, wherein the women are restored to the expectation of heaven, on their good behaviour.

The ancient Marcionites allowed their women to baptize; as we are assured by St. Epiphanius, Har. 42. cap. 4. the Montanists admitted women to the priesthood, and even the episcopate, Epiph. Har. 49. cap. 2. The modern Quakers also permit their women to preach and prophesy, on an equal footing with the men.

It is a point much controverted, how far learning and study become the sex? Erasmus handles the question at large in one of his letters to Budea. Lud. Vives, in his Institutio Fœminarum Christianarum, has a chapter expressly on the same subject. Madam Schurman, a German lady, has gone beyond them both, in a treatise on this problem, "Num femina Christianarum conveniat studium literaturi?"

Several of the women remarkable for learning have been also distinguished for their want of conduct. The reason, no doubt, lies in this; that their first studies lying in books of gallery and intrigue, the imagination was early turned that way, and the memory filled with a sort of ideas, which a favourable disposition, and age, adopted too easily, and improved too fast. It is not that study in itself has any natural tendency to produce such effects; rather the contrary: the close abstractive researches of metaphysics, logics, mathematics, phyfics, criticism, &c. no doubt would be the surest means to secure and establish the virtue of continence in a woman.

For an account of women hired to weep at funerals by the Romans, see PRAEFICE.

Women were allowed to sing, in 1772, in the collegiate church of St. Gudula, at Bruges. It was in the performance of high masses on a Sunday, when a considerable number of voices and instruments were assembl'd in the choir; and we were glad to find among the former two or three women, who though they were not fine fingers, yet their being employed, proved that female voices might have admission in the church, without giving offence or scandal to piety, or even bigotry. If the practice were to become general, of admitting women to sing the soprano part in the cathedrals,
it would, in Italy, be a service to mankind, and in the rest of Europe render church music infinitely more pleasing and perfect; in general, the want of treble voices, at least of such as have had sufficient time to be polished, and rendered steady, destroys the effect of the best compositions, in which, if the principal melody be feeble, nothing but the subordinate parts, meant only as attendants, and to enrich the harmony of the whole, can be heard.

WOMBS, Matrix, or Uterus, in Anatomy, that part of the female of any kind, wherein the fetus is conceived and nourished till the time of its delivery. The ancient Greeks called the matrix, μητρός, from μητέρα, mother: whence disforders of the womb are still frequently called fit of the mother. They also call it υτρός, as being the laik of the entrails, by its situation. Sometimes they also call it χώρος, or natura; and υνερέα, from υνερε, to fold, or envelop, or from υνερε, doors. See UTERUS.

WOMB, Dropsy of. See DROPSY.

WOMB, Falling down of. See PROCIDENTIA UTERI.

WOMB, Inflammation of. See INFLAMMATION.

WOMB, Suffocation of. See SUFFOCATION.

WOMB, Ulcers of. See ULCERS.

WOMB, in Geography, a town of Sweden, in the province of Skonen; 12 miles E. of Lund.

WOMBACH, a town of Germany, in the county of Rieneck; 3 miles S. of Lohr.

WOMBEAT, in Zoology, an animal of which Mr. E. Home has given an anatomical description in the 2d part of the 9th volume of the Philosophical Transactions. It was brought from the islands in Bassa's straits, and lived with him in a domesticated flat for two years. Whenever it had an opportunity, it burrowed in the ground, and covered itself in the earth with surplishing quickwells. It was quiet in the day, but in conflant motion during the night; very sensible of cold; ate all kinds of vegetables; was particularly fond of new hay, which it ate flatk by flatk. It appeared attached to those to whom it was accustomed, and who were kind to it. It allowed children to pull and carry it about, and when it bit them it was not in anger or with violence. It appeared to have arrived at its full growth, weighed about twenty pounds, and was about two feet two inches long. Another animal called the 'Koala,' is a species of the wombat, partaking of its peculiarities. It inhabits the forests of New Holland, about fifty or sixty miles S. W. of Port Jackson, whither it was brought in August 1803, and is called by the natives the 'koala wombat.' It is commonly about two feet long and one high; in the girth about a foot and a half; it is covered with fine soft fur, lead-colored on the back and white on the belly; the ears are short, erect, and pointed; the eyes generally ruminating, sometimes fiery and menacing; it bears no small resemblance to the bear in the fore-part of its body; it has no tail; and its customary posture is sitting. The New Hollanders eat the flesh of this animal; and are very dextrous in the pursuit of it, climbing with wonderful rapidity the loftiest gum-trees in search of it. The koala feeds upon the tender flotts of these trees; and during the day refts on the tops of them, either feeding at cafe, or sleeping. In the night it defends, prowls about in search of some particular roots, creeping rather than walking; and when incensed or hungry, it utters a long shrill yell, and assumes a fierce and menacing look. These animals are found in pairs, and the young is carried by the mother on its shoulders. It soon forms an attachment to the person who feeds it.

The external form of the wombat has been described by M. Geoffroy, in the 2d volume of the "Annales du Museum National de France;" and several parts of its internal structure have been taken notice of by M. Cuvier, in his "Lecons d'Anatomie Comparée." The mechanism of the bones and muscles of the hind legs differs in many respects from that of all other animals, except the koala. This has been minutely examined and described by Mr. Brodie, at the desire of Mr. Home; and it appears that there is nothing similar to it in the hind legs of the mole, or other burrowing animals. The internal structure of the wombat resembles that of the beaver; but it is so different from that of the kangaroo, and all the other animals of the opolium tribe, that it forms a very extraordinary peculiarity. The male and female organs of generation have been described; the former by M. Cuvier, and the latter by Mr. Bell in New South Wales. The male and female organs of the wombat and koala are similar to those of the opolium; and hence it is concluded, that these animals form the intermediate link between the opolium and kangaroo. See DIDELEPHIS.

WOMBINELLORE, in Geography, a town of Hindoostan, in Baramaul. It was taken by the British, under general Meadows; 100 miles S. E. of Serimgapatam. N. lat. 11° 43'. E. long. 78° 15'.

WOMBORN, a township of England, in Staffordshire; 3 miles S. W. of Wolverhampton.

WOMELS DORF, a town of Pennsylvania; 15 miles W. of Reading.

WONDA, a town of Africa, in Manding; 30 miles N. E. of Kamalia. See MANDING.

WONDA, a river of Manding, which, at Fonilla, a small walled village on its banks, is called Ba Woolima (red river); and towards its source it has the name of Ba Qui (white river); the middle part of its course being called Wonda. WONDER. See MIRACLE.

The seven wonders of the world, as they are popularly called, were, the Egyptian pyramids; the mausoleum erected by Artemis; the temple of Diana at Ephesus; the walls and hanging gardens of the city of Babylon; the colossus, or brazen image of the sun, at Rhodes; the statue of Jupiter Olympus; and the pharos, or watch-tower, of Ptolemy Philadelphus; instead of the latter, some reckon the royal palace of Cyrus, built by Menon, the stones of which were cemented with gold. See PYRAMID.

WONDERFUL WATER. See WATER.

WONDRA, or WONDRED, in Geography, a river which rises in Bavaria, and runs into the Egra, near Königberg, in Bohemia.

WONDZEGOW, a town of Bohemia, in the circle of Kaurzim; 10 miles W. S. W. of Kaurzim.
WOOSDORF, a town of Prussia, in Natangen; 25 miles S.E. of Königsberg.

WOSENS. See Wunsiedel.

WONTAMITTA, a town of Hindoostan, in Myfore; 45 miles E. of Chinna Balaram.

WOO-CHIN, a town of China, in the province of Kiang-si, near the lake Poyang, which is a place of considerable importance, as the great mart for exchanging commodities between the north and south of China. The warehouses are spacious and well filled, dwelling-houses large and substantial, temples richly decorated, and the shops filled with articles of all kinds, including no inconsiderable proportion of European goods. Here are several small bronze vessels of ancient and modern workmanship, not unlike the Grecian and Etruscan. Near it is a temple dedicated to Wang-thin-choo, the god of longevity, surpafsing most others in riches of carved-work and gilding.

WOOD, William, F.L. S., in Biography, a Protestant dissenting minister of distinguished reputation for general literature and science, character, and usefulness, was born at Collingtree, a village near Northampton, on May 29, O.S. 1745. His father, though occupying a humble station, was a person of approved integrity and piety, in connection with the Christian society at Northampton, under the personal care of the justly-celebrated Dr. Doddridge, and paid particular attention to the religious instruction and moral conduct of his children. Mr. Wood, at an early age, manifested promising talents, and having finished his school-education under the late Dr. Addington of Market-Harborough, was introduced, at the age of 16, with a view to the ministrv, among Protestant dissenters, which was the object of his choice, to a dissenting academy in London, conducted at the time of his admission by Dr. David Jennings and Mr. (afterwards Dr.) Morton Savage, and before the close of his studies by Mr. Savage, Mr. A. Kippis, and Mr. A. Rees. The writer of this sketch can bear personal testimony to his exemplary conduct during the period of his continuation at the academy, and to the diligence and success which he prosecuted the various branches of literature and science to which his attention was directed. Few persons ever left a public seminary with superior qualifications for the exerceive of the profession to which he was devoted, and performed the duties of it, in the progress of a long and honourable life, more acceptably and more usefully. It was then the custom, admitting of few exceptions, to ordain ministers when they were elected by particular congregations, and introduced into the full discharge of the pastoral office; and soon, we understand, of the wisest and best of the Non-conformist ministers have lamented the too general discontinuance of this decorous practice, against which it is thought by many that no sufficient objection has been alleged. Ordination among Protestant dissenters is a public service, usually conducted at the place where the minister, who is ordained or set apart, is about to be settled; and collits of a sermon addressed to the people, a charge delivered to the person ordained, and prayers for a divine blessing on his future labours, and for the edification and prosperity of the Christian society with which he is connected. It has been sometimes accompanied with a confection of faith on the part of the person who is thus set apart; but this part of the service, having been misunderstood, is frequently omitted, though in cases which allow of unrestricted liberty, and in which the confection neither descends into a variety of minute particulars, nor contains any pledges that embarrass or restrain future free inquiry, it is thought to be unexceptionable. Ordination, however, among the persons to whom we now refer, is not conceived to impair any new qualifications or powers which the person ordained did not possess previously to this service, or to constitute him either a minister in general, or the pastor of any particular church. But to return from this digression: Mr. Wood was publicly ordained, and the occasion afforded an opportunity for many ministers of acknowledged reputation among dissenters to bear their united testimony to his talents and character. He commenced his public services at Debenham in Suffolk, on the 6th of July 1766, with a sermon peculiarly appropriate to the occasion, from Luke, ix. 26., and he spent the remaining part of this year, and a great part of the year 1767, in the vicinity of London, where he occasionally officiated to the satisfaction of those who attended, and gained the friendship of some of the most eminent of the dissenting ministers of that period. In September 1767, he settled at Stamford, in Lincolnshire; and removed from thence to Ipswich in November 1770, where he remained till the close of the year 1772. In 1773, having nearly completed his 27th year, he was unanimously chosen to succeed Dr. Priestley at Mill-hill chapel, Leeds, and in that connexion he continued till his death. About two years after his settlement with this congregation, he published a small volume consisting of twelve sermons on life and death, which entitled the author, in the judgment of a contemporary critic, to the character of a useful and elegant preacher. In 1780 he formed a matrimonial connection with a daughter of Mr. George Oates, of Low-hall, near Leeds, which lasted twenty-six years, and contributed in a high degree to his domestic felicity. By this lady he had four children, of whom three survived their parents.

Ardently devoted to the studies that were more immediately or more remotely connected with his profession, and attached by affectionate gratitude as well as interest to the congregation in the service of which he was engaged, and which claimed his most affiduous and respectful attention, he commenced for the benefit of the young a course of lectures, in the year 1785. These were comprehensive and improving; and though they were delivered once a fortnight, they lasted several years. Our limits will not allow us to avail ourselves of the detail, furnished by his excellent biographer, of the subjects which were discussed in this extensive course of useful instruction. It will be sufficient to observe, that they contributed no less to the information of those who attended them than to the reputation of the lecturer, as well as to the mutual respect and esteem which were thus cemented between Mr. Wood and his congregation. The public would probably have derived instruction from the perusal of them, if some circumstances had not occurred which rendered it necessary for Mr. Wood to devote a considerable part of his time and attention to subjects of a very different nature. Without abandoning the studies connected with his profession, he was led by the state of his health, and by some other considerations, to the pursuit of natural history, and particularly of English botany; but whilst he was thus occupied, he rendered his investigations subservient to the great object of his life and ministrv, the promotion of religion and virtue, as well as the personal satisfaction and future happiness of those with whom he was connected. His new pursuits were the means of introducing him to acquaintance and friendship with many eminent persons; and more especially with Dr. (now Sir James) Smith, the justly celebrated president of the Linnean Society. To Mr. Wood the good opinion and friendly regard of one, who commands the respect and esteem of all who know him, by mental accomplishments and moral qualities of the most excellent and engaging kind, must have afforded a satisfaction which, as we can testify from personal knowledge,
WOOD.

ledge, he very highly appreciated. The good opinion of such a judge of merit, in the department of natural history, which now engaged his attention, must have encouraged his affability and perseverance. He was thus qualified for contributing several valuable articles to this Cyclopædia, in the reputation and success of which the editor is happy to say he felt and expressed a peculiar interest. His contributions comprehended the botanical articles that occur, with some few exceptions, from the beginning of the letter B to the end of C; and the editor, who most sincerely lamented his death as a pupil and a friend, as well as a coadjutor in this work, would have found it difficult to supply the losses, if the kindness and condescension of the Linnean of our time, for so, it is hoped, we may be allowed to denominate him without offending his delicacy, had not relieved his anxiety, and amply compensated the injury which the botanical department of the Cyclopædia must have sustained.

Mr. Wood had attained, by his talents and cultivation of them, to so high a rank among his brethren in that part of the country where his lot was cast, that few public services occurred in which he was not expected to be active and conspicuous. Attached to liberty, civil and religious, from his youth, he had in his mature years thoroughly acquainted himself with the genuine principles of the British constitution; and accordingly he took occasion on the centenary of the Revolution, in 1788, to express his conviction and feelings in two sermons, which were afterwards published. In the three following years he took an active part in the application of the dissenters to parliament for the repeal of the test and corporation acts. In 1794 he preached a funeral sermon, on occasion of the death of the Rev. W. Turner, of Wakefield; and in the following year he performed the same service in consequence of the decease of the Rev. Mr. Ralph, of Halifax; the sermons which he delivered in both cases were published. The short account of Leeds which was this year communicated to Dr. Aitken for his History of Manchester deserves to be noticed, as he took great pains in exactly ascertaining the number of its inhabitants. About this time he commenced a course of education, addressed to young females, with a view partly to his own emolument, but principally for the benefit of those who were disposed to avail themselves of his instruction; and indeed few persons could be found capable of conducting such a course with greater satisfaction and advantage to those who attended it. His lectures occupied three years, and comprehended history, geography, natural philosophy, grammar, the belles lettres, natural history, mental and moral philosophy, and the evidences of natural and revealed religion. His next publication was his sermon occasioned by the death of the Rev. Newcome Cappe, which contained a very appropriate and judiciously-merited eulogy of his late revered friend. It was dedicated to Mrs. Cappe, who claimed from her talents and character, as well as relation to the deceased, a tribute of respect; and annexed to it some brief memoirs of Mr. Cappe's life. In the year 1801, Mr. Wood published a liturgy, consisting of five forms, for the use of his congregation at Millhill chapel, and composed, for the most part, from the service of the established church, the Liverpool, Shrewsbury, and other liturgies before published by the dissenters, as well as from a similar service composed by the Rev. T. Simpson. Of this performance it will be sufficient to state, that it was executed with judgment and taste. On the restoration of peace in the year 1802, he published an animated discourse, which he delivered, in the course of his public services, on that occasion. About this time he exerted himself in establishing at York the academical institution, which had for some years subsisted at Manchester, and which was likely to be discontinued in consequence of the resignation of the late Rev. G. Walker, the theological tutor. Intending, as he advanced in life, and when he had finished the education of his daughter, to relinquish the anxiety and labour of tuition, he proposed to engage in some literary undertakings. Accordingly he was a contributor, in the department of natural history, to the Annual Review; but the work which occupied his chief attention, and which afforded him the greatest pleasure, was the Cyclopædia already mentioned.

As a preacher, the last of his publications was a sermon delivered at Birmingham, June 9, 1805, for the benefit of the Protestant dissenting charity-school, supported by the joint contributions of the two societies of the old and new meeting-houses. After his return from an excursion in the months of July and August 1806, he was attacked by a severe paroxysm of the gout, to which he had long subject; and in a few days his disorder was so alarming, that his recovery was not expected. As an aggravation of his distemper, the affectionate partner of his life was seized with a disorder, which terminated in her death. For some time his state was such, that it was prudent to conceal him both from the progres and termination of her disorder. The mournful event which he apprehended was gradually disclosed to him; and he received the afflictive intelligence with a degree of composure and resignation, which evinced the efficacy of his religious principles, and the consolation derived in such circumstances from Christian hope. During a long illness, which interrupted his public labours, and which was attended with a considerable expense, the society with which he was connected had an opportunity of testifying, by substantial acts of kindness, the high sense they entertained of his meritorious services. Providence at length restored his health to such a degree, that he was able to resume his public labours; but they were of no long continuance. On Sunday the 27th of March 1808, he performed the usual services with an uncommon degree of animation. On the following day, however, having previously experienced symptoms of a flying gout, he was suddenly seized at dinner with a violent sickness, which continued for many hours. This was succeeded by an inflammation of the bowels, which soon terminated in a mortification. The consequence was a delirium; and on Tuesday, the 6th of April, he expired so quietly, that the friends who attended his bed were not apprised of the moment of his departure. Those who wish for further information concerning the natural talents and acquired endowments, the private character and public services of Mr. Wood, will be amply gratified by the perusal of the "Memoirs of his Life and Writings," and of the "Address and Sermon" delivered on occasion of his death, by his friend and neighbour the Rev. Charles Wellbeloved of York.

Wood, Anthony, the Oxford Antiquary, was born at Oxford in 1632, and entered of Merton college in 1647. Having commenced M.A. and acquired a taste for studies pertaining to antiquity, he pursued with indefatigable diligence both at Oxford and in London researches, which furnished him with materials for his "History and Antiquities of the University of Oxford," a copy of which he sold to the university in 1669 for 100l. It was written in English, but afterwards translated into Latin, under the inspection of Dr. Fell; and the version was published from the Oxford press in 1674, under the title of "Historia et Antiquitates Universitatis Oxonensis, dubus Voluminibus comprehensa," fol. The first part of this work includes the annals of the university, from its earliest period to the year 1648; and the second contains an account of all its particular foundations, endowments, officers, &c. The translation
is badly executed, and Wood, the original author, was
deficient of those qualifications that would have rendered
him a fit historian of a learned university. Another of
Wood's works was his "Athenæ Oxonienæ; or, an
Account, in English, of almost all the Writers educated at
Oxford, and many of those at the Sitter University, from
the year 1500." It was first published in 1691, 2 vols. fol.,
and soon after subjected him to prosecution in the vice-
chancellor's court for his account of lord Clarendon, and
to various other attacks, occasioned by his partialities, and
more especially by his strong bias in favour of popery. His
style is vulgar, and his sentiments illiberal and unphiloso-
phical; but his veracity entitles him to confidence. He
died in 1695, and bequeathed his books and papers to the
university of Oxford. A second edition of this work,
corrected and enlarged from the author's MS., was pub-

This curious and diligent antiquary, whose whole life was
spent in the service of the dead, and whose labours, since his
decease, have so much facilitated the inquiries, and gratified
the curiosity of the living, tells us, in the Memoirs of His Life,
written by himself, with monastic simplicity, that in 1651,
"he began to exercise his natural and infaatiable vigour to
mufick. He exercised his hand on the violin, and having
a good ear to take any tune at first hearing, he could quickly
draw it out from the violin, but not with the same tuning of
strings that others used. He wanted understanding, friends,
and money, to pick him out a good master, otherwise he
might have equalled in that instrument, and in singing,
any person then in the university. He had some companions
who were musical, but they wanted instruction as well as
he."

The next year, being obliged to go into the country to
try to get rid of an obdurate age, by exercise and change
of air, he tells us, that "while he continued there he followed
the plow on well-dayes, and sometimes plowed. He learned
to ring on the fix bells, then newly put up: and having
had from his most tender yeares an extraordinary ravishing
delight in mufick, he practised there, without the help
of an instructor, to play on the violin. It was then that he
turned his ftrings in 4ths, and not in 5ths, according to the
manner; and having a good ear, and being ready to fing
any tune upon hearing it once or twice, he could play it also
in a short time with the said way of tuning, which was
never knowne before."

"After he had spent the summer in a lonih and retired
condition, he returned to Oxon. And being advised by
some person, he entertained a master of mufick to teach
him the usual way of playing on the violin; that is, by
having every string tuned five notes lower than the other
going before. The master was Charles Griffith, one of the
musicians belonging to the city of Oxon., whom he then
thought to be a most excellent artist. But when Anthony
Wood improved himself in that instrument, he found he was
not so. He gave him 2r. 6d. entrance, and so quarterly.
This perfon, after he had eximtedly wondered how he could
play fo many tunes as he did by 4ths, without a director or
guide, tuned his violin by 5ths, and gave him instructions
how to proceed, leaving then a lefson with him to practice
against his next coming."

In 1653, he found that "heraldry, mufick, and painting,
did fo much crowd upon him, that he could not avoid them;
and could never give a reason why he should delight in those
studies, more than in others, so prevalent was nature, mixed
with a generosity of mind, and a hatred of all that was fer-
vile, fascinating, or advantageous for lucre fake."

"Having by 1654 obtained a proficiency in mufick, he
and his companions were not without silly frolicks, not now
to be maintained."—What should these frolicks be, but to
diglude themselves in poor habits, and like country-fidders
tscape for their livings. After frolicking about to Farring-
don fair, and other places, and gaining money, victuals, and
drink for their trouble, in returning home they were over-
taken by certain folders, who forced them to play in the
open field, and then left them without giving them a penny.
"Most of his companions would afterwards glory in this,
but he was ashamed, and could never endure to hear of it."

By 1656, his record informs us, that "he had a genuine
fkill in mufick, and frequented the weekly meetings of mu-
sicians in the house of William Ellis, organist of St. John's,
college, situated on that place whereon the theatre was built." Here
he gives a lift of the usual company that met and
performed their parts on lutes and viols; among these eight
were gentlemen. "The mufick-masters were, William Ellis,
bachelor of mufick, and owner of the house, who always
played his part either on the organ or virginal. Dr. John
Wilfon, the public professor, the belt at the lute in all
England: he sometimes played on the lute, but mostly pre-
cluded (directed) the comfort. — Curtesy, a lutenist,
lately ejected from some choir or cathedral church.
Thomas Jackson, a base-violist. Edward Low, then
organist of Christ church: he played only on the organ, so
when he played on that instrument, Mr. Ellis would take
up the counter-tenor viol, if any perfon were wanting to
performe that part. Gervase Littelton alias Welcot, or
Welcot alias Littleton, a violist. He was afterwards a
fingling-man of St. John's college. William Glexney, who
had belonged to a choir before the war: he played well
upon the base-viol, and sometimes sung his part. —
Proctor, a young man, and a new comer. John Packer, one
of the univeritie musicians; but Mr. Low, a proud man,
could not endure any common musician to come to the
meeting, much less to play among them. Of this kind I
must rank John Hafelwood, an apothecary, a flarched formal
citherpipe, who usually played on the base-viol, and some-
times on the counter-tenor. He was very conceited of his
skill (though he had but little of it), and therefore would be
ever and anon ready to take up a viol before his betters;
which being observed by all, they usually called him Hand-
lewood. The rest were but beginners. Proctor died soon
after this time. He had been bred up by Mr. John Jenkins,
the mirror and wonder of his age for mufick, was excellent
for the lyra-viol and division-viol, good at the treble-viol
and violin, and all comprehended in a man of three or four-
and-twenty years of age. He was much admired at the
meetings, and exceedingly pitied by all the faculty for his
lofs."

At this time Anthony Wood tells us, that "what by
mufick, and rare books that he found in the public library,
his life was a perfect Elyfium."

"Anthony Wood was now advised to entertain one
William James, a dancing-maftcr, to instruct him on
the violin, who by some was accounted excellent on that in-
strument, and the rather because, it was said, that he had ob-
tained his knowledge in dancing and mufick in France. He
spent in all half a yeare with him, and gained some improve-
ment; yet at length he found him not a compleat maftcr of
his facultie, as Griffith and Parker were not: and, to say
the truth, there was no compleat maftcr in Oxon. for that
instrument, because it had not been hitherto used in confort
among gentlemen, only by common muficians, who played
but two parts. The gentlemen in private meetings, which
Anthony Wood frequented, played three, four, and five
parts with viols, as treble-viol, tenor, counter-tenor, and
bass.
bais, with an organ, virginal, or harpsicon, joyd with them; and they esteemed a violin to be an instrument only belonging to a common fiddler, and could not endure that it should come among them, for fear of making their meetings to be vaine and fiding. But before the reftoration of king Charles II., and especially after, viols began to be out of fashion, and only violins used, as treble violin, tenor, and bafe violin; and the king, according to the French mode, would have twenty-four violins playing before him, while he was at meales, as being more airie and brisk than viols.

"In the latter end of the yeares 1657, Davis Mell, the moft eminent violint of London, and clock-maker, being in Oxon., Peter Pitt, William Bull, Kenelm Digby, and others of All Soules, as also Anthony Wood, did give a very handfome entertainment in the tavern called the ' Salvation.' The company did look on Mr. Mell to have a prodigious hand on the violin, and they thought that no perfon, as all in London did, could goe beyond him."

By connecting the scattered fragments of this zealous Diletante's life, which concern muffick, we shall be able to form an idea of the state of the art, not only at Oxford, but in every other part of the kingdom where it was more secretly practifed during the latter part of the Ufurpation.

Under the year 1658, Anthony Wood tells us, that "he entertained two eminent musicans of London, named John Gamble and Thomas Pratt, after they had entertained him with moft excellent muffick at the meeting-houfe of William Ellis. Gamble had obtained a great name among the people of Oxon. for his book of 'Ayres and Dialogues to be fung to the Theorbo, or Bafe-viol.' The other for feveral compositions, which they played in their concerts."

He then gives an account of the arrival of Baltzar, a wonderful performer on the violin, from Lubeck, arriving at Oxford, and deftoyng, by his great superiority of hand, all the little vanities, not only of the belf fiddle-players of the university, but of others from London, who had long enjoyed the reputation of great performers. See BALTZAR.

Anthony Wood pursues his musical records, and tells us, that "all the time he could fpare from his beloved studies of English history, antiquities, heraldry, and genealogies, he spent in the most delightful facultie of muffick, instrumenal or vocal; and if he had missed the weekly meetings in the houfe of William Ellis, he could not well enjoy himself all the week after. Of all or moft of the company, when he frequented that meeting, the names are fet downe under the year 1656. As for thofe that came in after, and were now performers, and with whom Anthony Wood frequently played, were thofe: Charles Perot, M.A. fellow of Oriel college, a well-bred gentleman, and a perfon of a sweet nature; Christopher Harrifon, M.A. fellow of Queen's college, a maggot-headed perfon, and humourous; Kenelm Digby, fellow of All Soule's college, he was afterwards Dr. of L., he was a violinf, and the two former violinf; William Bull, M.A. for the viol and violin; John Vincent, M.A. a violinf; Sylvanus Taylor, fellow of All Soule's college, violinf and angofinter, his elder brother, captain Silas Taylor, was a compositer of muffick, played and fung his parts; Henry Langley, M.A. a violinf and angofinter; Samuel Woodford, M.A. a violinf; Francis Parry, M.A. a violinf and angofinter; Christopher Coward, and Henry Bridgman, both masters of arts; Nathan Crew, M.A. a violinf and violinf, but alwayes played out of tune, as having no good care, he was afterwards bishop of Durham; Matthew Hutton, M.A. an excellent violinf; Thomas Ken of New college, afterwards bishop of Bath and Wells, he would be sometimes among them: and fong his part; Chrif-

topher Jefferyes, a junior student of Chrift church, excellent at the organ and virginals, or harpsicon, having been trained up to thofe instruments by his father George Jefferyes, organift to king Charles I. at Oxon.; Richard Rhodes, another junior student of Chrift church, a confident Weltmonafterian, a violinf to hold between his knees."

"These did frequent the weekly meetings, and by the help of publick matters of musicfick, who were mixed with them, they were much improved. Narciflus Murth would come oftimes among them, but seldom played, because he had a weekly meeting in his chamber, where matters of muffick would come, and fome of the company before-mentiond. When he became principal of St. Alban's hall, he translated the meeting thither, and there it continued, when that meeting at Mr. Ellis's houfe was given over, and fo it continued till he went over to Ireland, where he became afterwards archibishop of Tuam."

"After his majey's reftoration, when the matters of muffick were reforted to their feveral places that they before had lof, or gotten other preferment, the weekly meetings at Mr. Ellis's houfe began to decay, because they were only held up by fcholars who wanted directors and instrudors. So that thefe meetings were not continued above two or three yeares, and I think they did not go beyond 1662."

Our Oxford annalist terminates his account of the musical transactons of that university, during the interregnum, by the following anecdote.

"In October 1659, James Quin, M.A. and one of the fenuor students of Chrift church, a Middleflax man borne, but fon of Walter Quin; of Dublin, died in a crazed condition. Anthony Wood had fome acquaintance with him, and hath feveral times heard him fing with great admiration. His voice was a bafe, and he had a great command of it. 'Twas very frong and exceeding trouling, but he wanted skil, and could scarce finge in confort. He had been turned out of his students place by the visitors; but being well acquainted with fome great men of thofe times, that loved muffick, they introduced him into the company of Oliver Cromwell, the protector, who loved a good voice and instrumenal muffick well. He heard him finge with very great delight, liquored him with lack, and in conclusion faid, 'Mr. Quin, you have done very well, what shall I do for you?' To which Quin made answer with great compliments, of which he had command with a great grace, that 'your highnefs would be pleased to refume him to his students place; which he did accordingly, and fo kept it to his dying day.'

If this minute and indifferminate antiquary and biographer is sometimes thought to want taffe and flection fufficient to give his records due weight, it muft be ascribed to the confiant habit he was in of journalizing, collecting anecdotes, and making memorandums of every perfon, tranfaftion, and circumstance, that arrived at his knowledge, in the uncoth and antiquated language of his early youth. For this dialect being inelegant and vulgar, even when he learned it, renders his writings frequently ridiculous, though they contain fuch information as can be nowhere else obtained. But the few opportunities he had of knowing the gradual changes in our colloquial dialect, by converfing with men of the world, or even the language of elegant books by his favourite course of reading, degrade him to a level with writers infinitely his inferiors both in use and entertainment. An excellent apology has been made for his imperfections by the editor of his life, written by himself, and published in 1772; which is fo interesting, that he muft be an incurious inquirer, indeed, who, having dipped into it, is not sufficiently fatisfied by the original simplicity of the tyle and importance of
of many of the anecdotes, to give it an entire perusal before he lays it down. Anthony Wood was credulous, and perhaps too much an enthusiast in music to speak of its effects with critical and philosophical precision; however, without his assiduity, the state of the art at Oxford, and the academical honours bestowed on its professors, as well as memorials of their lives and works, would have been difficult to find. Upon his decisions in matters of taste, we are not always perhaps implicitly to rely. The high character he has given Dr. Wilton's productions and abilities may have proceeded from want of experience, knowledge, and penetration into the finer points of the art; and as to Dr. Rogers, his judgment of him seems to have been manifestly warped by friendship. Yet, upon the whole, it must be allowed that it is only from such minute records as those of Anthony Wood that any true and satisfactory knowledge can be acquired of the characters, manners, and domestic occurrences of our ancestors. The great features of history, and the events which occasion the ruin or prosperity of a state, must be nearly the same in every age and country; but comforts, conveniences, and the difficulties of private life, furnish the mind with reflections far more varied and interesting to the generality of mankind, than the rise of states or downfall of kings and heroes.

Wood, — a performer on the violin, who led the band many years at the theatre in Covent Garden, and father of Wood, his successor in that orchestra, organist of St. Giles's, and of Chelsea college. They were both active professors; but though performers only of the second clafs, they constantly ranked themselves of the first. Burney.

Wood, in Vegetable Anatomy, is that more or less hard and compact substance, which makes up the bulk of the trunk and branches of a tree or shrub, and is concealed from view by the bark. When cut transversely, the wood is found to consist of numerous concentric layers, very distinct in the fir, and the trees of cold or temperate countries in general; else so in those appropriated to a tropical climate. The external part of each circular layer being much the most hard and compact, often with somewhat of a horrid appearance, distinguishes the limits of each. Scarcely any two layers of the same tree are precisely alike, in the proportion which this compact part bears to the rest; nor does any one layer exhibit a precise uniformity of diameter in its whole circle. On the contrary, each layer is broader on that side of a tree where the exposure has been most favourable to its growth, where, consequently, there have been more branches and leaves, so as to yield a greater deposit of woody matter. Hence the layers being all, for the most part, broader on one side of a tree, their aggregate disproportion throws the common centre, or pit, very much out of the actual centre of the trunk. It having been remarked in felling trees, that the greatest breadth of the concentric circles is very often on their south side, a rule has been proposed for travellers to ascertain thereby the direction of the compass. But travellers must be strangely at a loss, if they could find no easier method of judging. Nor is the mode in question infallible. It would indeed shew on which side the growth of each particular tree had been most favourable, whether from its exposure, or the nature of the soil which its roots had met with; but this may not always be towards the south. We must lay to tell great part of a forest, to form a precise opinion; and the process would be, as it were,

"— to tell what hour o' the day,
   The clock did strike — by algebra."

The number of these concentric layers, in any tree, if it be found to the heart, very correctly demonstrates the number of years the trunk has been growing. This is a general opinion, and undoubtedly correct; provided the layers are well marked. The observer must be aware that each annual layer is composed of a great number of thinner and fearely distinguishable ones, which occasionally assume a more conspicuous appearance than usual, in consequence of fluctuating seasons, or any accidental checks in the growth of a tree, as hard winters render the outside, or hornry part, of each circle, more decided; while favourable summers make the circle itself altogether broader. But there is always a sufficient distinction between summer and winter, beyond the tropics, to establish the above rule. Ever-greens, for the most part, and trees of hot countries, exhibit lighter traces of these concentric layers; but they may be discerned in every mahogany table. Monocotyledonous plants have been said to be entirely without any such annual structure. But there is no reason why they should necessarily be so. Mr. Salisbury once demonstrated this structure to us in a Dracaena; and its absence in palms and ferns is to be attributed to a peculiar mode of depositing wood in these plants, rather than to their being monocotyledonous. What has been said already under the articles Circulation of Sap, and Cortex, will sufficiently explain this. As the inner surface of the bark deposits the matter of the wood, it must lie in concentric circles; and in proportion as this operation goes on more constantly and uniformly, these layers must be the more homogeneous and uninterrupted. Perennial roots of herbaceous plants often exhibit concentric circles, of annual formation, even in hot climates, as may be seen in Jalap. Each circle, no doubt, marks the increase which has taken place in each successive season; and while the herb is not growing, nothing is added to the root.

The theory of vegetation, as explained in the articles just cited, shews the reason of the spiral-coated vessels being found in the young wood only, and not in the bark. Those vessels, formerly supposed to contain air alone, are the real arteries of the plant, and convey its sap, or blood, through the wood, to be returned through the bark, where it deposits particular secretions. This theory also explains why the alburnum, as being the layer of unhardened wood for the present year, is tender, and even a mere jelly, at one period. But the bark is in the spring of the year, before the deposit of wood begins, most readily stripped from the tree; though it also readily, and without harm to the tree, comes off in winter, while vegetation is at a stand.

We scarcely need here detail the experiments of Du Hamel, to determine whether the wood forms the bark, or the reverse. Thin metallic plates introduced between these two parts, and carefully bound up, threw, after a few seons, when the branch thus treated was cut across, that the bark had deposited layers of wood on the outside of these foreign substances, with little or no prejudice to the growth of the plant. But Dr. Hope's experiment (see Cortex) is still more strikingly decisive. The Linnaean hypothesis, that the pith added a layer every year to the wood internally, is thus entirely set aside. Indeed nothing but a preconceived theory, of the great importance of the pith, and its analogy to the medullary or nervous system of animals, (for the support of which opinion arguments are not wanting,) could have led to erroneous a conclusion. It is sufficient to remark, what indeed could not escape the intelligent author of this hypothesis, that trees grow vigorously, though their heart
is become rotten by age, when the pith, with numerous adjoining layers of wood, have long since been obliter-
ated.

A transverse section of the wood of a tree displays various vessels, and other parts, which microscopic authors take delight in exhibiting; but, without a scientific expla-
nation, little is to be learned from their plates, how-
ever beautiful to the eye. Silicous petrifications, of oak-
wood especially, fine specimens of which are brought from Hungary, shew its vascu lar structure in the greatest perfe ction. In the sections to which we have just allu-
ded, the pith, with its highly cellular texture, makes a conspicuous appearance in the centre. In the body of the wood, the sap-vessels are generally the largest and most numerous. These, when young and tender, easily display their spiral coats, if pulled aside longitudinally; but are not found at all in the bark. Among them, in the resinous trees like the fir, or any that abound with secreted fluids, as the fig, much larger vessels are inter-
spersed through the wood and bark, in which the peculiar se cretions are lodged. But besides the determinate and continued concentric layers of wood above-described, numerous thin plates are interpersed, known to workmen, especially in oak-wood, by the name of the Silver Grain. (See that article.) Mr. Knight, who is there quoted, further remarks, that if a board of English oak be cut for a floor, in such a direction, that the lamina of the silver grain lie parallel with the surface of the board, it is rarely or never seen, when properly laid, to deviate from its true horizontal position. But a board faved, on the contrary, across the silver grain, “will, during many years, be in-
capable of bearing changes of temperature, and of moist, without being warped; nor will the strength of numerous nails be sufficient entirely to prevent the inconvenience thence arising. That surface of a board of this kind which grew nearest the centre of the tree, will always shew a ten-
dency to become convex, and the opposite one concave, if placed in a situation where both sides are equally exposed to heat and moisture.” Knight, Phil. Trans. for 1801, 345.

This writer adds, that the small clefts in the surface of an oak-tree, frizzled of its bark, and exposed to the sun and air, are caused by the plates of the silver grain having parted from each other. They will long continue to open and close again with the changes of the weather. In the middle of a dry day they are open, but much less so during the night. After long exposure to the air and light, wood loses this property. Knight as above.

A different degree of hardnecf, and in some trees a remark able difference of colour, exists between a number of the external concentric layers of the wood, and about as many or more of those next the centre. These latter are called the heart of the timber; the former the sap or alburnum; but these are vulgar appellations, and the latter especially are improper. The true alburnum is the layer of new unhardened wood of the present year, which also workmen often term the sap. The sap, properly so called, is the fluid from which all their secretions, and even the wood itself, are formed. (See that article.) Those who use wood for mechanical purposes are well aware of the above difference between its different parts, however incorrect the names by which they are distinguished. The softer ex-
ternal layers have little durability in comparison with the heart. They retain more of the vital principle, and more of the peculiar juices of the plant in a fluctuating condition, liable to be acted upon by external or internal causes, and not yet united, in a fixed state, to the solid body of the old wood. This change, however, is not limited in any particu-
lar kind of tree to a determinate period in the age of each layer of its wood, nor even to any determinate series of the concentric circles of any individual tree. It often extends to a greater number of rings on one side than on another. The more vigorous there is in a tree, or in any side or portion of its trunk, the sooner is the alburnum, to use its popular denomination, made perfect wood, or heart.

The term wood, philosophically speaking, is not confined to the substance of a tree. The central part of a root, dis
tinguished from its bark, is the wood, and in many perennial roots consists, as we have already mentioned, of several dif tinct layers. In a carrot, the yellow part is the wood, en-
compassed by a thick reddish bark. In a turnip, the woody part is of ample dimensions, while the bark is thin.

A most remarkable difference exists between the solidity of the wood in some trees and in others. Some wood is so heavy as to sink in water; some is as light as cork, or even lighter. In general, wood of different trees, of the same natural order, poifefes similar properties and the same degree of value. But there is often, in the same genus, a most remarkable difference between the finness of the wood of different species, for particular purpofes. The oaks (see Quercus) abundantly exemplify this fact. The very hard and ponderous timber of $Q. ilex$, the live oak, however lafitting in a dry situation, is so prone to deterioration when exposed to wet, as to be among the most worthless in the world; its hardines and heaviness only rendering it the lefs fit for ufe, where it would be likely to endure. On the other hand, many of this genus afford timber more or lefs useful in every circumstance and situation, among which our English Q. Robur stands pre-eminent. See Timber.

All kinds of wood are to be preferred from the worm, and from many other occasions of decay, by oily subftances, particularly the effential oils of vegetables. Oil of spike is excellent, and oil of juniper, turpentine, or any other of this kind, will serve the purpose; these will preserve tables, instruments, &c. from being eaten to pieces by these ver-
mim, and linseed-oil will serve in many cafes to the same pur-
pofe; probably nut-oil will do also, and this is a sweeter oil, and a better varnish for wood.

The ingenious Dr. Hales, whose attention was uniformly directed to schemes of domestic or national benefit, was in-
duced by the great damage done to shipping by worms to pro-
pose various methods for preventing it. Oily, unctuous materials, he apprehends, are not likely to penetrate deep into oak, which has a watery sap; but oil is known to pe-
etrate far into fir, and to give it a very considerable degree of toughnes. He therefore proposes to mix with oil aplied to the fir-boards with which ships are sheathed some ingredient that is disagreeable to the worms; and he appreh-
ends that a small proportion of verdigrife used in the opera-
tion of paying would be of great service: or if copper-
filings were mixed with the paying, sea-water would turn
them into verdigrife. It might be useful to soak planks in
water strongly impregnated with verdigrife.

Mr. Reid recommends the trial of the acid juice of tar, prepared either with copperas or ochre, for preserving ships either from rotting or worms.

In the East Indies, it is said, they have an efectual way of preventing worms from destroying their ships, by paying them first with a mixture of mulkard, oil, and lime of shells, and hog’s blood: they then sheath the ship, and renew it after some years.

The following receipt has been recommended by a person who never knew it fail of success. Take 100 lbs. of the fineit
finest pitch; melt it over a slow fire of coal, and add to it, when melted, 30 lbs. of rolled brimstone grossly bruised, and boil the whole till 30 lbs. are volatilized. The matter thus prepared must be kept in cafins in a dry place, and when it is to be used, melt 100 lbs. of it, and add gradually 35 lbs. of brick-dust or marble-dust, fitted and well heated. The composition, when used, must be very hot, and the boards dry.

An ingenious ship-builder observes, that turpentine and brimstone form the best composition he has met with, and comes home from a voyage with least damage.

East India ships are first sheathed, and that sheathing is filled with small broad-headed nails, which is a safe and effectual defence from the worms, and soon becomes a continued cake of rust, and not liable to be damaged by cables, or common accidents. See Pay and Ships.

The following, says Dr. Hales, is an approved method of preparing the boards and timber of out-door work: viz. melt 6 lbs. of pitch, and add, by fitting, 1 lb. of dried brown Spanish, or whitening, and a quart of linseed oil. Hales's Ventilators, part i. p. 164, part ii. p. 289, &c.

Dr. Lewis observes, that though tar has been used for preferable wood, and also for coating common tiles, in imitation of the black glazed tiles, which are fold at a much higher price, both tar and pitch are of themselves too soft for these intentions, being liable to be melted off by the summer heat: and, therefore, different powdery substances, as ashes, ochres, and other mineral pigments, have been mixed with them.

In the Swedifh Transactions for 1740 and 1742, two compositions are recommended, which are said to be firm, durable, and glossy. One is prepared by melting the tar over a gentle fire, so as to make it fluid, but not to boil, and stirring in as much coal-dust or powdered charcoal as will render it thick: the other is prepared by mixing the melted tar with a sufficient quantity of lamp-black. Coatings formed of these mixtures are, however, liable to be considerably softened by the heat of the sun. The mixture of powdered pitch-coal and melted tar, made of such a consistency as to be freely spread while warm with a brush, is less liable to soften than either of the other two. The tar obtained from coal, in the method lately discovered by the earl of Donald, appears from various testimonies of those who have tried it to be much better calculated to preserve wood and iron, as well on land as in water, than vegetable tar. It has also this peculiar advantage, that it will not admit or harbour those worms that are so injurious to the bottoms of ships at sea. See an Account of the Qualities and Uses of Coal and Coal-varnish, &c. by the Earl of Donald, 8vo, 1785.

Mr. Parkes recommends, for the preservation of wood, the tar which is obtained from the pyroxylineous acid. See TAR.

Dr. Lewis observes, that the coating or painting of wood does not in all cafes contribute to its preservation: unless the wood be very thoroughly dry, especially those kinds of wood whose juices are not oily or tenacious, the painting by confining the watery sap, hinders the corruption. Com. Phil. Techn. p. 363, &c. On this subject, see Timber.

Some of the West India trees afford a sort of timber which, if it would answer in point of size, would have great advantages over any of the European wood, in ship-building for the merchant-service, so that it will ever touching this timber. The acajou, or tree which produces the casewheat-nut, is of this kind; and there is a tree of Jamaica, known by the name of the white-wood, which has exactly the same property, and so have many other of their trees. Phil. Tranf. No 36.

To preserve wood expeditiously for sea-service, it has been usual to bake it in ovens.

The art of moulding wood is mentioned by Mr. Boyle as a defideratum in the art of carving. He says he had been credibly informed of its having been practised at the Hague; and that the effect of it might have been performed by some method of that softens the wood, and afterwards allows it to harden again, in the manner that tortoise-shell is moulded. Or, perhaps, by reducing the wood into a powder, and then uniting it into a mass with strong but thin glue. And he adds, that having mixed saw-dust with a fine glue made of shingles, slightly training out what was superfluous through a piece of tissue, the remainder, formed into a ball and dried, became so hard as to rebound when thrown against the floor. Works abr. vol. i. p. 130. See GLUE.

The people who work much in wood, and that about small works, find a very surprising difference in it, according to the different seasons at which the tree was cut down, and that not regularly the fame in regard to all species, but different in regard to each. The button-mould makers find that the wood of the pear-tree, cut in summer, works toughest; holly, on the contrary, works toughest when cut in autumn; box is mellowest when it has been cut in summer, but hardest when cut about Easter; hawthorn works mellow when cut about October, and the service is always tough if cut in summer. Merret's Notes on Neri, p. 265.

It is a very well-known quality of metals to be longer and larger when hot, and shorter and smaller when cold; a thousand experiments prove this, and the books of experimental philosophy have sufficiently expatiated upon it; on the contrary, it is found to be the property of wood, that it is longest in cold weather and shortest in hot; this change is owing to the remains of the sap yet in the wood, which being congealed by cold, is enlarged in its surface, as all liquors are, when frozen into ice; and shrinks into a less space or bulk again, when liquated by heat.

It follows from this that all wood must change its surface more or less, according as it contains more or less sap, and this may be made a test of great use for the determining what kinds of wood have most, and what least sap. This would be a very valuable piece of knowledge, since there are many uses for which that sort of wood must always serve best, which has the smallest quantity of sap remaining in it. See Hygrooscope.

Thus, in the great article of preferring flour, no barrels are at present used but those of seasoned dry oak; the whole advantage of this wood is, that it contains less sap than others; for the sap in the wood makes the flour damp, and it then becomes rancid, and breeds worms. (See Meal.) So that if any other wood can by this means be found out to contain less sap, when dried in the common way, than oak does, it will be so much the better for this purpose; or, if a cheaper wood should be found only to contain as little sap as the oak, it would do as well, and the price of oak would be saved in these vessels.

A proper way of trying when the sap was sufficiently expelled out of trees, might also be found by this experiment, and much benefit would accrue from it; for our ships, when made of timber not sufficiently dried, prove injurious to the health of people on board; and it has been remarked, both by the French and ourselves, that many more men in general die in the first voyage of a new ship than in the same time in an old one; and indeed the first six months are usually ob-
served in this cafe to be most fatal. The exhalation of the vapour from the wood of the vessel is certainly the occasion of this, and if it could be contrived to have this vapour properly exhausted before the timber was used, it would not only prevent this mortality among the men, but the vessel itself would be the founder and the better for it. Deflandres, "Traité de Phys.

Woods are distinguished into divers kinds, with regard to their natures, properties, virtues, and uses. Of wood, considered according to its qualities, whether useful, curious, medicinal, &c., the principal is that called timber, used in building houses, laying floors, roofs, machines, &c. See Timber.

Woods valued on account of their curiosity are, cedar, cedron, mahogany, walnut-tree, box, calamus, &c., which, by reason of their extraordinary hardness, agreeable smell, or beautiful polish or grain, are made into cabinets, tables, combs, beads, &c.

The medicinal woods are, guaiac, which the Spaniards call lignum foetido; aloes, or agallochum; sassafras, nepthrichum, fustic, logwood, paphcalamum, eagle-wood, or pan d'aguila, &c.

Woods used in dyeing are, the Indian wood, Brafk, Camphere, &c.

In extracting the colouring-matter of dye-woods, and in making some other colours for the use of calico-printers, Mr. Parkes observes (Chem. Eff. vol. ii.), that it is of great convenience to heat the vessels by steam; for by this method of preparing decoctions, the workmen are prevented from ever giving the materials a greater heat than that of 212°; and the injury which was formerly done by the burning of the grooves in the bottom, and sides of the copper is avoided. Several manufacturers, says this ingenious chemist, have now adopted this method. This leads us to take notice of a beneficial application of charcoal, as a slow conductor of calorics, for preserving an equal temperature. Ground charcoal, it is said, will conduct heat more slowly than even dry sand, in the proportion, according to Guyton, of three to two. Accordingly, all those vessels which are heated by steam, if they were made double, and the space between the inner and outer vessel filled with ground charcoal, the heat would be so prevented from escaping, that any given temperature might be maintained for a long time, and thus there would be a materialsaving in the article of fuel. Moreover, when churches, or other large buildings are to be warmed by steam, those parts of the conducting-pipes which are not within the buildings should be always surrouned in this manner, and then no heat could escape until it had been conveyed to the space which it was intended to warm by it. Thus also in the manufactories of flax, paper, gunpowder, blue, and a variety of other articles, every part of the apparatus for drying these by steam, and which is not actually within the drying-rooms, ought to be secured in the same manner. The common steam-working apparatus, and other culinary utensils, would be much improved by being fitted with double covers, and by filling up the intermediate spaces with aeronaceous matter. Moreover, by securing the conducting-pipes in this manner, buildings might be eventually warmed, and processes conducted at any distance from the boiler, as steam is the most faithful carrier of heat that can possibly be; for it cannot deposit it on any bodies that have already acquired the temperature of 212°. It is also this non-conducting property of charcoal that renders it so common, says Fourcroy, cited by Parkes, in France as material for coating furnaces, and for confining the heat, to which use its incombusible nature adapts it in a peculiar manner, as it is the most refractory body that is known, provided it be excluded from oxygen. Charcoal is applicable to other purposes in domestic economy; such as the preserving of animal food from taint, by covering it with a few pieces of fresh-burnt charcoal, and the recovery of it by boiling it for some minutes in water with a few ounces of such charcoal. By the same means, mollases or treacle may be deprived of its disagreeable taste, so that it might be used instead of sugar. A patent has likewise been taken out for refining sugar by means of charcoal by M. Croflet, who required for it, of the joint body of sugar-bakers in London, a remuneration of 50,000l.; and Mr. Parkes apprehends, that in a small concern of this kind established in the metropolis, which manufactures double oaves of a finer quality than those of any other house, the purpose is effected by the same means. The empyreumatic flavour acquired by some brandies in distillation may be removed, says the ingenious writer now cited, by digesting some in charcoal; and common malt-vinegar, boiled on charcoal, becomes colourless, without losing its strength. Water, which in long voyages acquires a disagreeable taste and smell from long standing in the wooden casks, may be purified by filtration through ground charcoal; or it may be kept sweet in casks that have been charred withinside.

For the above-mentioned purposes, the charcoal should be fresh made, or heated red-hot under a cover of sand, immediately before it is used; and the requisite quantity should be previously ascertained by experiment. In some cases, it should be used in the form of powder, having been pounded immediately from the fire, before it has been exposed to the air, and the refuse should be preferred for future use in bottles closely stopped. For other uses to which charcoal is applied, see CHARCOAL and CARBURI.
WOOD.

off in sparks during combustion, which the coal of the wood itself seldom does. The charcoal of wood is said to be essential to the perfection of bar-iron; but when wood became scarce, and government restricted its use, cinders and coke were substituted for it; and thus the quality of English iron was so much debased, that Ruffian and Swedish iron, which is prepared by means of the coal of wood, are employed by those who work in this metal. The superior quality of the iron made with charcoal is attributed by M. Haffenratz to its combination with potash. It was by Sir Eliz. c. 14, that it was enacted, that no oak, beech, or ash-timber, one foot square at the hub, should be converted into charcoal for making iron in any part of England or Wales, except in the county of Suffolk, the weald of Kent, and certain parishes in the county of Surrey. This restriction led to the practice of making bar-iron with the coke of pit-coal, the method of preparing which was kept a secret from the generality of the trade. When Mr. Henry Horne published his "Essays on Iron and Steel," in the year 1773, he gave directions for a better method than they had before known of charring pit-coal, fo as to make it a proper fucce- cedanum for wood-charcoal in the manufacture of iron. Since that time the coke of pit-coal has come into very general use, so that the consumption of this substance is now very considerable. (See Coke.) Crayons of charcoal are belt made of the willow; whereas the coals of the hard woods, such as box and guaiacum, are much harder than others, whist the charcoal of the kernels of fruits is quite soft and friable. As a pigment, the coal of ivory, or that which is procured by burning real ivory in closed vessels, is the most intensely black, and the most beautiful. The belt charcoal for use as a powder for cleaning the teeth is made from the shell of the cocoa-nut. The difference between the charcoals of animal and vegetable substances may be determined by the following test. A vegetable coal will burn on a red-hot iron into white ashes, which will be readily dissolven by sulphuric acid into a bitterish liquor; whilst the ashes of animal substances are little affected by that acid, and form with it a compound with a very different taste. (See Ashes, Carbon, Charcoal, and Gun-Powder.) For the method of charring wood, see Timber and Char- ring of Peat. This appears to have been a very ancient practice. The pikes that formed the foundations of the Temple of Diana at Ephesus, not long since taken up, appeared to have been charred; and about fifty years ago some oak-rafts were found in the bed of the Thames in the veriest spot where Tacitus says that the Britons fixed a number of such rafts, to prevent the passage of Caesar's army; and these rafts, which were charred to a considerable depth, had completely retained their form, and were firm at the heart. About sixty years ago one of the timbers that supported Trajan's bridge over the Danube, near Belgrade, was taken up, and the outer part, to the depth of half an inch, was found to be converted into an agate, the inner part being slightly petrified, and the central being still perfect wood, though this timber had been in the water 1700 years. (See Kirwan's Geological Essays, cited by Parkes in his Essays, vol. ii.) Many other instances occur of wood petrified and converted, more or less, into agates of various colours. Writers on this subject have recommended the practice of charring every piece of wood before it is placed in the ground. Dr. Watson, (late bishop of Landaff,) in his "Chemical Essays," vol. iii. suggests the propriety of charring all the wood that is used in mines and subterraneous drains, and particularly that which covers troughs, through which a current of water passes, and which rot in a few years by the alternate change of wet and dry. In this connection we may add, on the authority of Chaptal, in his "Chemistry applied to the Arts," that when old chestnut and other trees are rotten within the trunk, and threatened with speedy destruction by the progress of the carious trunk, it may be stopped by applying fire to the decayed part, so as to char the whole of the neighbouring surfaces.

Wood, in Gardening, is a term used to signify the shoots or branches left in fruit-trees. See Pruning, &c.

Wood, an epithet applied to various sorts of weeds. See Weed.

Wood and Bark of Tree, Canker or Ergot of, in Agriculture and Gardening, a diseased state in these parts of them. It has been flaved by a late philosophical writer, that the cauce seems to be an excess of alkaline and earthy matter in the descending sap, as he often found carbonate of lime on the edges of the canker in apple-trees; and that ulinum, which contains fixed alkal, is abundant in the canker of the elm. The old age of a tree, in this respect, is, it is thought, faintly analogous to the old age of animals, in which the secretions of solid bony matter are always in excess, and the tendency to ossification great.

It is suggested, that perhaps the application of a weak acid to the diseased part might be of use; or that where the tree is of great value, it might be watered occasionally. See Canker.

Wood, Lignin? in Chemistry, the substance which constitutes the bals of wood usually so called.

To obtain this substance in a state of purity, it is necessary to digest wood in a sufficient quantity of water and afterwards of alcohol, by which means all foreign substances soluble in these fluids will be removed; the simple woody fibre will thus remain, which poffeeds the following properties.

It is composed in general, of longitudinal fibres easily separable from one another. These fibres, when very much subdivided, become somewhat transparent. They have no smell nor taste, and are not altered by exposure to the atmosphere.

The woody fibre is insoluble in water and alcohol. It is soluble in a weak alkaline solution without being decomposed, and may be again separated by an acid. Concentrated alkaline solutions render it brown, and decompose it, especially when affliated by heat.

When heated it becomes black without melting, exaltes frong acrid fumes, and leaves a charcoal, retaining exactly the form of the original mass. When distilled in clofe veffels it yields an acid liquor, of a peculiar taste and fmmell, called the pyr€ognes acif, and which was properly con- sidered as a diftinct acid. Fourcroy and Vaquelin, however, long ago demonstrated, that it consists of nothing but the acetic acid combined with an empymematic oil. (See Acetous and Pyrog-Trigoniues Acid.) Pure acetic acid is now prepared from wood both in this country and France.

The fibre of different woods has been analyzed by Gay Lussac and Thenard by means of the oxymuriate of potash. The following are the results:

Wood when burnt with a smothered flame leaves, as is well
The woody fibre, when completely burnt, always leaves a certain proportion of earthy and saline matters, which constitute the ashes of wood. Different woods yield very different proportions of ashes. See Ashes and Charcoal, where other experiments by Mr. Mifflin on this subject are related.

The following Table exhibits the quantity of ashes left by different woods, according to Sauvile junior. Sauvile has extended the investigation to herbaceous and other plants; but we have omitted thefe, from their not being immediately connected with the present subject. See Carbon.

See Dr. Thomson's System of Chemistry, vol. iv. 5th edit.

Wood, On making Bread from. Professor Autenrieth, of Tubingen, has lately attempted to make bread from wood, and his experiments seem to have been attended with considerable success. He had been led to form the opinion that the woody fibre was only rendered unfit for food from the foreign substances usually attached to it, and from its compact aggregation. The first of these difficulties he attempted to obviate, by selecting those woods which have little taste and smell, and which consequently contain less foreign matters; such, for example, are the birch and beech, especially the birch, which was the wood he chiefly employed in his experiments.

To render wood alimentary, it is necessary to reduce it to a state of extremely minute division, or absolute powder. It also requires the repeated action of the heat of an oven, by which means it is not only better fitted for being ground, but probably also undergoes some internal change which renders it more digestible, as is evidently the case in regard to coffee. Wood prepared in this way acquires the smell and taste of corn-flour. It is, however, never white, but always yellowish. It also agrees with corn-flour in requiring the addition of some leaven, to enable it to undergo the fermentative process, and the flour leaven of corn-flour is found to answer the best. With this it makes a perfectly uniform and spongy bread, like common brown bread; and when it is thoroughly baked, and has much crust, it has a much better taste of bread than what in times of scarcity is prepared of bran and husks of corn.

To make wood-flour in perfection, the wood, after being thoroughly dried of its bark, is to be softened transversely into disks of about an inch in diameter. The saw-dust is to be preferred, and the disks to be beaten to fibres in aounding-mill. The fibres and saw-dust mixed together are next to be deprived of everything harsh and bitter, and which is soluble in water, by boiling them in a large quantity of water when fuel is abundant, or by subjecting them for a longer time to the action of cold water, as by placing them in a rivulet, for example, enclosed in a sack. The whole is then to be completely dried, either by the sun or fire, and repeatedly ground in a flour-mill till it passes through the bolting-cloth.

The ground wood is next to be baked into small flat cakes, with water rendered slightly macerulugious by the addition of some decoction of linseed, or any other similar substance. Professor Autenrieth prefers marsh-mallow roots, of
WOOD.

of which one ounce renders eighteen quarts of water sufficiently mucilaginous, and thence serve to form four pounds and a half of wood-flour into cakes. These cakes are to be baked in an oven until they are quite dry, and become of a brownish-yellow colour on the surface. After this they are to be broken to pieces, and again ground repeatedly, until the flour passes through a fine bolting-cloth, and upon the fineness of the flour does its fitness to make bread depend.

The flour of a soft wood, such as birch, will be sufficiently prepared by the process as described; but the flour of a hard wood will require the steps of baking and grinding to be repeated.

That the wood thus prepared is altered in its nature and rendered soluble, is proved by the quantity of real starch that is obtained from it by the same process, by which it is separated from wheat-flour. If wood-flour tied up in fine linen be long kneaded in a vessel of water, the water is rendered milky, and deposits slowly a quantity of starch, which with boiling water forms a thick, tough, trembling, tenacious jelly, like that of wheat-starch, and it is only necessary to see this starch to be convinced that the wood-flour is soluble and nutritious. This starch cannot be ascribed to the mucilaginous matter added to the ground wood before it is baked, as the added mucilage does not amount to more than the one-hundred and fifty-fifth part of the wood, whereas the wood-flour loses about half its weight by the separation of the starch. The residuum left in the linen seems to be the woody fibres unchanged, which have not been ground sufficiently fine.

Wood-flour does not ferment so readily as wheaten-flour; but professor Auenreith found fifteen pounds of birch-wood flour, with three pounds of four wheat leaven, and two pounds of wheat-flour, mixed up with eight measures of new-milk, yielded thirty-six pounds of very good bread.

The best mode of preparing it was to mix up the five pounds of wheat leaven and flour with a portion of the wood-flour and milk to a preparatory dough; let it stand for some hours in a moderately warm place to rise, and then knead in thoroughly the rest of the wood-flour and milk. This dough is rolled out into thin cakes, allowed to stand in a warm place to rise for a longer time than wheat-flour requires, and lastly to be put into the oven and baked thoroughly.

Professor Auenreith made many experiments upon animals, as well as upon himself and family, in order to ascertain the nutritious properties of wood-flour, in the various forms of soup, dumplings, cakes, &c.; and he found that it was not only very palatable in all these forms (especially when combined with milk or some fatty substances), but also sufficiently nutritious, and that it did not disorder the digestive organs, or apparently produce any other ill effects.

From these experiments, it is obvious, says the writer from whom we have made these extracts, that in cases of necessity wood may be made to furnish a considerable quantity of nourishment; but it is not less obvious, that the process is so troublesome and expensive, that it never can become an article of food, except where there is an absolute scarcity of provisions. On such occasions the labour is of very secondary importance, and at any rate cannot be so profitably applied as in procuring the means of subsistence.

In some districts of Norway and Lapland, the bark of the fir is manufactured into a species of bread, apparently much inferior in quality to the bread of wood-flour, and this with dried fish and a little rein-deer tallow constitute the chief articles of food among the lower classes, during the protracted and rigorous winter of these inhospitable climates. See Von Buch’s Travels in Norway and Lapland.

WOOD, Diftillation of. See Charcoal, Colour, Gun-Powder, Pyrrolunteous Acid, and Wood-supra.

WOOD, Tenacity and Strength of. See Cohesion and Strength of Materials.

WOOD and Wood, a term in ship-building, implying that when a tree-nail, &c. is driven through, its point is directly even with the inside surface, whether planked or timber.

WOOD, Cord, denotes wood for the fire, generally the branches or loppings of trees, piled up in order. See Cord.

WOOD, Fossil, Subterraneous. There are divers places where wood is found under ground: supposed to have been over-turnd, and buried there from the time of the Deluge, or at some other period.

Whole trees, or parts of them, are very frequently found buried in the earth, and that in different strata; sometimes in stone, but more usually in earth; and sometimes in small pieces loose among gravel. These, according to the time they have lain in the earth, or the matter they have lain among and in the way of, are found differently altered from their original state; some of them having suffered very little change, and others being so highly impregnated with crystalline, sparrey, pyritic, or other extraneous matter, as to appear mere medleys of stone or lumps of the common matter of the pyrites, &c. of the dimensions, and more or less of the internal figure of the vegetable bodies, into the pores of which they have made their way.

The fossil wood, which we find at this day, may, according to these differences, be ranged into three kinds: 1. The leaf altered. 2. The pyritic. And, 3. The petrified.

Of the trees or parts of them left altered from their original state, the greatest store is found in digging to small depths in bogs, and among what is called peat or turf-earth, a subsistence used in many parts of the kingdom for fuel. In some places there are whole trees fearfully altered except in colour; the oaks in particular being usually turned to a jetty black: the pines and firs remain as inflammable as ever, and often contain between the bark and wood a plain resin. Parts of trees have been also found unaltered in the strata of clay and loam, among gravel, and sometimes even in solid stone. See Fossil Plants, and Bog Wood.

It is idle to imagine, that these have been thus buried either at the Creation, or, as many are fond of believing, at the universal Deluge: at the first of these times the strata must have been formed before trees were yet in being, and the peat wood is so far from being of antediluvian date, that much of it is well known to have been growing within thes three hundred years, in the very places where it is now found buried. See Morass.

The substances that are more altered are the larger and longer branches of trees found bedded in the strata of stone, and partly assuming its nature; and the shorter and smaller branches found in pits of blue clay, which externally bear the resemblance of what they once were, but, having their pores filled with the matter of the common vitriolic pyrites, internally appear to be mazes of that matter.

The irregular mazes or fragments of wood are principally of oak, and most usually found among gravel, but variously altered by the infumation of crystalline and strong particles. These make a beautiful figure when cut and polished, as they commonly keep the regular grain of the wood, and show the several circles which mark the different years growth. These, according to the different matter which has filled their pores, assume various colours, and the appearance of the various fossils that have impregnated them. Of these some pieces have been found with every pore filled with
with pure pellucid crystal, and others in large masses, part of which is wholly petrified, and some mere stone, while the rest is crumbly and unaltered wood.

All these pieces of petrified wood are usually capable of a high and elegant polish. Hill.

Wood has been found in salt-mines, enclosed in a mass of hard salt, and its pores filled with the matter of the salt in which it lay. Wood has likewise been found converted as it were into iron, or thoroughly impregnated with the particles of this metal. Aft. Erud. ann. 1710.

Wood, Petrified. The opinions of the judicious part of the world have been very different in regard to the bodies preferred in the cabinets of the curious, under the name of petrified wood; some affirming these bodies to have been only pebbles, or flints accidentally formed in this shape, and with veins resembling those of the wood; and others affirming with equal warmth, that they have been really wood, into which stony matter has been brought by water.

Many substances, it is certain, have been preferred in the cabinets of collectors, under the title of petrified wood, which have very little right to that name. But where the whole outer figure of the wood, the exact lineaments of the bark, or the fibrose and sullen texture of the fraxia, and the vestiges of the uricula and trachea or air-vessels are yet remaining, and the several circles yet visible, which denote the several years growth of the tree, none can deny such substances to be real fossil wood.

Many good arguments have been produced on both sides the question, but M. de la Hire has attempted to bring the dispute to a certain conclusion, by means of some peculiarly happy specimens, which were of the palm-tree petrified, found in the deserts of Africa: these on comparing them with pieces of the palm-tree cut out of the recent wood, appeared to have every where the beautiful and regular veins of that wood, and left no room to doubt but that they certainly had been once the vegetating wood of that tree, though now converted into hard stone; the petrified pieces were perfect stone, in all its qualities; they had its hardness, its found when struck upon, and were, as many other stones are, opaque in some places, and transparent in others; they were found on weighing them to be often of the specific gravity of recent pieces of the palm wood of the same dimensions.

Father Duchat also, an author of unquestioned credit, affirms, from his own personal knowledge, that in the kingdom of Ava there is a river whose waters petrify recent wood into flint; and that he has often seen trees standing in it, whose bottom part, so far as covered with the water, has been true flint, while all above was mere dry wood, and fit for firing. Mem. Acad. Par. 1692.

Wood, Shining. There are a great many things in which a piece of rotten wood that shines in the dark agrees with a burning coal; and there are also many things in which they differ. They agree in these particulars: 1. They have light relieving in them, and are not like bodies which are only luminous according to the quantity of light which falls upon them from other bodies, and which they reflect. 2. Both shining wood and burning coals require the presence of the air to keep them shining, and both require also an air of a considerable density; and both having been deprived of their shining quality by the pumping out of the air, will recover it again on the admitting of fresh air to them. 3. Both of them will easily be quenched by putting them into water, and many other liquors. And, 4. As a live coal will not be extinguished by any coldnefs of the air, neither will the shining wood be deprived of its light on any additional coldnefs in that element.

However, they differ in the following particulars: 1. A burning coal is easily put out by compression, the treading on it and squeezing it together readily diverting it of its light; on the other hand, compression or crushing of any kind seems not to have any effect upon the shining wood; its bruised parts shining as brightly as its entire ones. If a piece of this shining wood be squeezed between two glasses, this experiment will be most fairly tried; and in this case, though the contexture of the whole be evidently broken, and the parts separated, the light is as strong in them as while the piece was entire. 2. A burning coal extinguished by the drawing out of the air will, after a few minutes, be irrecoverable, on the admission of air in any manner; but, on the contrary, the shining wood, when thus extinguished and kept extinct for half an hour, will be immediately re-kindled on admitting the air to it. 3. A live coal, included in a small glass, will continue burning but a few minutes; but a piece of shining wood, in the same circumstances, will continue bright for several days. 4. The coal, while it burns, sends forth smoke and other exhalations; the rotten wood sends out none, and consequently a coal all the while that it is shining wanles itself at a great rate; but the rotten wood does not waste itself at all. And finally, the burning coal is actually and vehemently hot; the rotten wood, though it shines, is not so much as warm. Phil. Trans. N° 32.

The light of shining flesh and fift, when petrified, is wholly of the fame nature with that of rotten wood, as to its dependence on the air for its splendour; and in the fame manner lofes its light in the exhausted receiver, and regains it on the admission of the air into it again, in the fame fudden manner. Phil. Trans. N° 31. See Light, and Reflection.

Wood, Bog, or Subterraneous, a name given by the inhabitants of many parts of this kingdom to fuch wood as is found buried in the earth in boggy places, and which is found hard and strong at this time. See Fossil Wood supra.

We have in the Philosophical Transactions (N° 275, p. 983, &c.) an account of vaft quantities of this f ort of wood found under ground in Hatfield Chase. Many of the roots and bodies of trees are found there; which are of all growths, and are molluy fuch trees as are the growth of our own foil, fuch as oaks, firh, birch, beech, yew, holly, willow, agh, and the like. The roots of all these trees land in their natural poftitions as when growing, and land as thick together as they could grow in a foffet. The bodies are utterly broken off, and laid all along jurt by them.

The large trees are usually found fallen in a north-eaft direction, and the smaller ones lying all ways; the fir-tree or pitch-tree is more common than any other kind, and is found fometimes of twenty, thirty, and thirty-five yards long, and fo found and firm that many of them have been fold to make mills for ships. Oakes have been found of the fame length, though wanting fome yards of their natural tops; thefe have been fold at ten or fifteen pounds a piece, and are as black as ebony, and very found and lafting in whatever service they are put to. The all-trees do not preserve their firnnefs in this manner, many of them are fo loft that the workman's fpade cuts through them; and when expoefed to the air, they usually fall to pieces; but the willows, though a much lofter wood than the agh, prefervr their texture, and are found very strong and firm. In some of the fir-trees it is very observable, that they have shot-
outside branches after they were fallen, which have grown into large trees. Many of these fossil-trees appear plainly to have been burnt; the fir-trees are particularly very common in this state; and of these some are burnt quite through, others only on one side. Some of these also have been found with the plain marks of human work upon them; many with their branches chopp’d off, and their trunks cut into two or three pieces. Some squared and others in part cleft, and the wooden wedges used in cleaving them are still found remaining in the cracks. Stones are found in some of them in the place of wooden wedges, but in none iron ones. The heads of axes are also sometimes found; they are of a strange form, and somewhat represent the sacrificing axes of the ancients. These are found at such depths, that it is impossible they should have ever been lodged there since the time of this place’s being a forest; nor ever could have been found, but by means of the ground’s being drained by a late invention. The general opinion as to these trees is, that they were buried in this manner at the time of the universal Deluge; but they are plainly of later origin as fossils, the coins of some of the Roman emperors having been found buried under them.

The earth of bogs is not the only foil that preserves these trees; for in the low parts of Lincolnshire, between the towns of Burningham and Bramley, there are several large hills composed only of loose sand, and as this blows away there are continually discovered whole trees, or parts of trees, and particularly the roots and stumps of firs, and some other kinds, all with the marks of the axe upon them, and looking as fresh as if done but yesterday. Under these hills, and in the bosks before-mentioned, not only the wood of the fir-tree, but its cones are found in immense number; many bulks being often laid in a heap together. In cutting a drain for a river of a considerable depth, there were found at the very bottom several parcels of cut wood, in poles, beams, and the like; the head of an axe was also found somewhat resembling the ancient battle-axe, and a coin of the Roman emperor Verus; but what was yet more remarkable was, that what they were now sunk to seemed to be the original surface, the ground not being loose, like all above it, but found firm, and lying in ridges and furrows, with the evident marks of having formerly been ploughed. So that all the bog-earth above seems plainly to have been added since; and that the fossil wood, supposed of antediluvian origin, is but of the time of the ancient Romans, or less than that.

All the bogs in this kingdom afford in like manner fossil-trees; and not only thole, but other places, have at all times accidentally discovered them. Giraldis Cambrensis tells us, that so long since as in king Henry the Second’s time, the fands on the shores of Pembroke-shire were driven off by peculiar storms and tempests, and that deep under those sands there were then discovered great numbers of the roots and bodies of trees in their natural postures; and many of those had the strokes of the axe upon them, the marks at that time remaining as plain as when first made. Some of those resembled ebony; and many other such trees were discovered at Newgall in the same county, in the year 1590. Camden tells us of such wood found in the bogs in Somersetshire, Cheresh, Lancashire, Westmoreland, Yorkshire, Staffordshire, and Lincolnshire; and since his time many other counties have been found to be as fruitful in it. Dr. Plot mentions them in many parts of his History of Staffordshire, and by their standing in their natural postures, as to the roots at leaf, properly concludes, that they certainly once grew there, and were not brought from elsewhere.

Dr. Leigh, in his History of Lancashire, gives an account of the same sort of trees found in the draining of the boggy lands at Martin-Meer; and determines them not to have been of the ancient date many pretend, in referring them to the Deluge.

He observes, that they are plainly of no older date than the time of the savage inhabitants of England, about the time of the Roman conquests; for in this place, beside the roots and bodies of trees and their fruit, there were found eight canoes, or small boats, such as the wild inhabitants used at that time. And in another moor in the same county, a brafs kettle, with a small mill-flone, and some beads of wrought amber. In the same place were also found several human bodies whole and entire, at least to outward appearance, and the whole head of an hippopotamus, or river-horse. This is perhaps the hardest thing to be accounted for of the whole set, as to its coming there. The boggy places in Anglesea, and the Ile of Man, are all full of buried trees of the same kind; and the bogs of Ireland abound no less with them. England, and its adjacent islands, are not the only places where this buried wood is found; for Vertegau tells us, that the moors in the Netherlands abound with them; they all lie north-east, as our’s do. Hclmont also mentions the Peell there, a morafs of eight or nine miles broad, which is full of them. The French naturalists tell us of fossil-trees also in their country; and in Switzerland and Savoy; but all in the low grounds.

Ramazzini tells us, that in the territories of Modena, which are now a dry and fruitful country, yet in the time of the Caesars were only a great lake, there are found at the depth of thirty, forty, and even fifty feet, the foil of a low marthly country, with fedges, water-grafs, and other marsh-weeds; and under this there lie the trunks of trees, and their roots stand near them in the ground as natural a posture as when growing. Many old coins of the Roman emperors are also found there; as also several butt’s, wrought marble, and squared flones, evidently shewing the work of such tools as the Romans have been known to use. Some of the trees in these places stand upright. See more on this subject under the article Morass.

Wood, Cutting of. See Cutting.
Wood, Measure of. See Measure.
Wood, Stack of. See Stock.
Wood, Staining of. See Dyeing of Wood, &c.

Wood may be stained yellow, by bruising it over several times with the tincture of turmeric root, made by putting an ounce of the powdered root to a pint of spirit, and after it has stood some days, straining off the tincture. A redder cast may be given to the colour by adding a little dragon’s blood. A cheaper, and less bright and strong yellow may be given to wood by rubbing it over several times with the tincture of French berries, made boiling hot; and when the wood is dry, bruising it over with a weak alum-water ured cold.

In order to render these stains more beautiful and durable, the wood should be bruised after it is coloured, and then varnished with the seed-lac varnish, or with three or four coats of shell-lac varnish.

For a bright red stain for wood, make a strong infusion of Brazil in stale urine, or water impregnated with pearls in the proportion of an ounce to a gallon; to a gallon of either of which add a pound of the Brazil wood. With this infusion, after it has stood, with frequent stirring, two or three days, strained and made boiling hot, bruise the wood over till it appears strongly coloured; and while it is wet, bruise it over with alum-water.
water made in the proportion of two ounces of alum to a quart of water.

For a less bright red, brush over the wood with a tincture made by dissolving an ounce of dragon’s blood in a pint of spirit of wine.

For a pink or rose red, add to a gallon of the above infusion of Brazil wood three ounces of pearl-ashes, and use it as before: observing to brush the wood over often with the alum-water. These reds may be varnished as the yellows.

Wood may be stained blue by means either of copper or indigo. The brighter blue may be obtained by brushing a solution of copper (see Verditer), while hot, several times over the wood; and then brushing a solution of pearl-ashes in the proportion of two ounces to a pint of water over the wood. It is stained blue with indigo, by brushing it with the indigo prepared with soap-leaves as when used by the dyers, boiling hot; and then with a solution of white tartar or cream of tartar, made by boiling three ounces of either in a quart of water, brushing over the wood plentifully before the tincture of indigo be quite dry. These blues may be brushed and varnished as the reds, if necessary.

Wood may be stained green by dissolving verdigris in vinegar, or the crystalline of verdigris in water, and with the hot solution brushing over the wood till it be duly stained.

A light red-brown mahogany colour may be given to wood by means of a decoction of madder and fustic wood, ground in water, in the proportion of half a pound of madder and a quarter of a pound of fustic to a gallon, or, instead of the fustic, an ounce of the yellow berries may be used. Brush over the wood with this solution, while boiling hot, till the due colour be obtained. The same effect may to a considerable degree be produced by the tincture of dragon’s blood and turmeric root, in spirit of wine.

For the dark mahogany, take the infusion of madder as above, and substitute for the fustic two ounces of logwood: and when the wood has been brushed over several times, and is dry, brush it over slightly with water in which pearl-ashes have been dissolved, in the proportion of about a quarter of an ounce to a quart. The wood, in the better kind of work, should be afterwards varnished with three or four coats of seed-lac varnish; but for coarse work, with the varnish of resin and seed-lac, or they may be well rubbed over with drying oil.

Wood may be stained purple by brushing it over several times with a strong decoction of logwood and Brazil made in the proportion of one pound of the logwood and a quarter of a pound of the Brazil, to a gallon of water, and boiled for one hour or more. Let the wood, well coloured, dry, and be then slightly passed over by a solution of one drachm of pearl-ashes in a quart of water. A solution of gold in spirit of falt or aqua regia will give a durable purple stain to wood.

For a deep black the wood is brushed over four or five times with a warm decoction of logwood, made as above without the Brazil, and afterwards as often with a decoction of galls, made by putting a quarter of a pound of powdered galls to two quarts of water, allowing it to dry thoroughly between the several applications of the liquors: thus prepared, it receives a fine deep-black colour, from being washed over with a solution of vitriol in the proportion of two ounces to a quart: in the room of which some use a solution of iron in vinegar, keeping the vine-

gar for this purpose upon a quantity of the filings of the metal, and pouring off a little as it is wanted. A pretty good black is also obtained, more expeditiously, by brushing over the wood, first with the logwood liquor, and afterwards with common ink.

A very fine black may be produced by brushing the wood several times over with a solution of copper in aqua fortis, and afterwards with the decoction of logwood, repeated till the colour be of sufficient force, and the greens produced by the copper overcome. The blacks may be varnished as the other colours.

Where the stains are desired to be very strong, as in the case of wood used for fineering, it is generally necessary it should be soaked, and not brushed; for which purpose the wood may be cut into pieces of a proper thickness for inlaying. Wood, Sculpture in. See Sculpture.

Wood, Sylva, in Geography, a multitude of trees, extended over a large continued tract of land, and propagated by nature, or without culture.

Many great woods only confit of trees of one kind. At Cape Verd, in Africa, are woods of orange and lemon trees; in Ceylon, are woods of cinnamon-trees; in the Molucca islands, woods of clove-trees; in the islands of Nero, Lontour, Loafgrain, &c. woods of nutmeg-trees; in Brazil, woods of Brazil-trees, &c.; in Numidia, woods of date-trees; in Madagascar, woods of tamarind-trees, &c.

Wood-Ashes, in Agriculture, the ashes which are formed by burning wood.

The ashes of some sorts of wood, too, are found to be more powerful as a manure than those of others, as those from the ash and some other fuch trees.

It is said by some that they are an excellent dressing for improving cold wet pature land; and that poor hungry pastures have been very profitably benefited by them, to near double their former value; that nothing equals them on low spongy pature land. Others, however, have tried them on grafs-lands with little or no effect.

The difference in the burning and forming of them may probably cause this difference in the effects which they have on land.

Wood-Bound, a term used to signify such land as is encumbered with tall woody hedge-rows, so as to prevent the free circulation of air and admission of the sun, by which the natural fertility and strength of it cannot be fully exerted or brought into action. See Wood-Land.

Wood-Coppices. In the first raising of coppices, two things are to be considered; fift, the nature of the soil, that such trees may be planted in it as will thrive well there; and secondly, the uses that the wood is intended to be fold for, that such kinds may be planted as will be most proper for those ufses.

If the principal vent for wood be for the fire, the beft trees for fire-wood must be planted, such as the oak, beech, hornbeam, or other hard wood. These are the most profitable for selling as fire-wood, and one or more of these grow in any foil.

If there be a demand in the country where the coppice is to be planted for hoops and hop-poles, then the ash, the chesnut, the oak, alder, and hazel, are to be planted.

According
According to the profits of the underwood, the thickness of the standard-trees is to be regulated; for as they stand more or less thick, they more or less injure the underwood. It is also to be considered, at what growth the underwood is to be felled. The taller and larger the underwood of a coppice in general is, the more profitable will it be for firing, and all other uses, and the standards will be the better for its being left to grow to a proper height, for their bodies will be always, unless very great accidents occur, carried up straight as far as they are shaded by the coppice-wood.

A deep foil makes the shrubs as well as trees grow more vigorously than any other, and they will be sooner fit for cutting in such places. The person who owns these woods must contrive to cut down only a certain quantity of them every year, and regulate this so that he may have a constant succession of a like quantity; that part of the wood which was at first felled, may be grown up to its size for felling again by the time the last is cut. This is, in different places, to be calculated to all the various numbers between eight years and twenty or thirty.

The cutting of wood seldom yields the more and the better timber; but the cutting of it often has greater advantages, in that it makes it grow thicker, and gives the feedlings time to come up. If many timber-trees grow in the coppice, and are to be cut down, they and the underwood should be felled together, cutting off the stumps as close to the ground as may be, in the trees, and in the shrubs and underwood the stumps should be left about half a foot high, and cut flating and very smooth.

Sawing is the best method of felling timber-trees; but it sometimes kills the root; and if this is observed to be the case in the coppice, no new stumps arising from the root, then it is proper to fblb up the root, that it may not unneceffarily encumber the ground, and that the other young plants may have the benefit of it.

In the first raffing of coppices from feed, the ground must be prepared by good tillage, as much as if it were intended for corn. The fees of the several trees are to be fown in February, and if the foil be shallow, the ground should be ploughed into great ridges; this will make the foil lie thicker on the top of each ridge, by which means the roots will have more depth to run to for nourishment, and in a few years the furrow will be filled up to the level of the ridl with the dead leaves; and these, as they rot at the bottom, will make a kind of foil, through which the young stumps will spread, and be conducted from one ridge to another, and fo the whole ground will be occupied by them. If the coppice be to be raised on the side of a hill, plough the ridges cros-way of the defect of the hill, that the water may be detained among them, and not suffered to run off, as it otherwise would by the furrows; but if it happen that the ground be over-wet, which is more rarely the case, then the contrary method is to be observed, and the furrows ploughed deep and straight downwards, that all water may be carried off by them, as by so many trenches or drains.

Some few a crop of corn along with the fees of the underwood, for the advantage of the firt year; but as the feafon of fowing the fees of the trees is too late for the fowing of the corn, it seldom turns to much advantage. It is better to fow the trees alone, and keep them well weeded the two firt years; after which they are strong enough to take care of themselves against such enemies.

In very barren ground, where the young trees can hardly fland the heat in fummer, it is proper, after fowing them, to fatter a quantity of furze-feed over the land; the furze will grow quick, and over-top the trees at firft, but it will serve as a guard to them at this time, defending them from injuries, and keeping the ground moist about their roots. In a few years the trees will grow up beyond these bushes, and they will then foon destroy them by their dropping.

In the raffing of coprcees, the nearest distance for the plantations ought to be five feet for the underwood, but as to what number, and scantlings of timber are to be left on each acre, the statutes in this cafe direct; but it is an ordinarv coppice, which will not afford three or four firks, fourteen seconds, twelve thirds, and eight wavers, according to which proportion the fizes of young trees in coprcees are to fucced one another. In coprce or underwood felled at twenty-four years growth, there are to be left twelve flore-oaks upon every acre, or, in defcit of them, the fame number of elms, beeoh, or ash: these are to be straight-bodied trees, and are to be left till they are ten inches in diameter, at a yard from the ground; but it is better for the owner to have a much greater number of timber-trees, especially in places where underwood is cheap; and as to the felling, it is always neceffary to begin regularly with one fide, that the carriages, necefary to taking off the wood, may come on without injury to the reft; and in large woods, the cart-way should always be left in the middle, quite through the wood. The timber of the underwood may be cut from the month of October to February; but the laft month is much the belt, in places where there is but a small quantity to be felled, and it can all be got down before the fpring is too much advanced. All the wood fould be carried out by Midsummer, and made up by April at the latest; for when the rows and bruff hie longer than this unmade up, and unbound, many of the stumps and feedlings are spoiled by them. It is always worth the owner's while to inclufc the coppice well the winter before felling, to keep out the cattle, which would else greatly damage the fupply from the feedlings and young stumps.

New-weaned calves are the leat prejudicial to newly cut woods of any creatures, and may be put in where there is much grafs; the next in harmlefsnes to these are young colts, which, at about a year old, may be put in to feed in the fame manner; but about May they must all be put out.

If the woods happen to be cropped by cattle, it is best to cut them up, and they will make new stumps; for that which has been bitten by the cattle will not grow for several years in any degree.

If the coppice-woods are too thin, this is to be remedied by laying down the longeft and intermediate stumps of those shrubs or trees which are the most advantageous, in the place, or of such as are nearest the bare place; these will each fend forth a great number of suckers, and the whole wood will be thickened as much as desired in a very little time. Mortimer's Husbandry, vol. ii. p. 64. See COPPECE.

WOOD-Chot, in Ornithology, lanius minor primus of Al-}

{black
black line drawn across the eyes, and then downwards on each side the neck; the head and hind part of the neck are: of a bright bay; the upper part of the back dusky; the covert of the tail grey; the bec pad ultra white; the covert of the winga dusky; the quill-feathers black, having a white spot at the bottom; the throat, breast, and belly of a yellowish-white; the legs black. In the female, the upper part of the head, neck, and body, are reddish, tinted transvertely with brown; the lower parts of the body are of a dirty white, rayed with brown; the tail of a reddish-brown, marked near the end with dusky, and tipped with red. Pennant.

Wood-Cock, Scolopax rusticola of Linnæus, called by other writers La becbeau, a well-known bird distinguished by its size, which is somewhat smaller than that of the partridge, and by its colour, which is on the back a variety of black, grey, and a reddish-brown; on the forehead the black predominates; the quill-feathers are dusky, indented with red marks; and on the belly a pale grey, variegated with transverse streaks of brown. Its beak is three inches long, dusky toward the end, and reddish at the base, and the upper chaper a little longer than the under; the tongue slender, long, sharp, and hard at the point; the eyes large, and placed near the top of the head, that they may not be injured when the bird throws its bill into the ground: from the bill to the eyes is a black line; the forehead is a reddish, ash-colour; the chin is of a pale yellow; the tail consists of twelve feathers, dusky or black on the one web, and marked with red on the other; the tips above are ash-coloured, below white: the legs and toes are livid, the latter divided almost to their origin, having only a very small web between the middle and inner toes.

These birds, during summer, are inhabitants of the Alps, Norway, Sweden, Polih Frussia, the Mark of Brandenburg, and the northern parts of Europe; whence they emigrate at the approach of winter into milder climates, where the ground is open and adapted to their manner of feeding. The time of their appearance and disappearance in Sweden coincides exactly with that of their retreat from and arrival in Great Britain. They live on worms and insects, which they search for with their long bills in soft ground and moss woods. They generally arrive here in flocks, taking advantage of the night or a mist; they soon separate: but before they return to their native haunts, pair. They feed and fly by night; beginning their flight in the evening, and returning the same way to their day-retreat.

They leave England the latter end of February, or beginning of March; though they have been known to continue here accidentally. In Welford, near Northbridge, a few breed almost annually. During incubation they are very tame. They come over to the coast of Suffolk sparingly in the first week of October, the greater number not arriving till the months of November and December, and always after fun-fet. They are determined in their flight by the wind, and arrive separate and dispersed. When the red-wing appears on the coast in autumn, the wood-cocks are at hand; and when the Reydon crow is arrived, they are come. Between the 12th and 25th of March they flock towards the coast to be ready for their departure, having the red-wings for their harbingers in spring, as in autumn. If the wind be favourable, they immediately depart; but otherwise, they are detained in the neighbouring woods, or among the ling and furze on the coast: as soon as a fair wind springs up, they are suddenly gone.

In the same manner they are known to quit France, Germany, and Italy; making their northern and cold situations their general summer rendezvous. In the winter they are found as far south as Smyrna and Aleppo, and also in Barbary; and some have appeared as far south as Egypt, which seems to be the limit of their migration in that way. In Japan they are found very common. Those that reft in the countries of the Levant probably come from the deferts of Siberia or Tartary, or the cold mountains of Armenia.

Our species of wood-cock is unknown in North America; but they have a sort of wood-cock resembling ours in its general appearance; about half its size, and wanting the bars on the breast and belly. Pennant.

They hate flying high, and are afraid to fly among trees, because, like the hare, they fee but very badly straight before them; and it is owing to this imperfection in their flight, that they are so easily taken in nets spread in their places of resort.

The draw-net, in countries which are very woody, is extremely profitable in this sport, it being no uncommon thing to take ten or a dozen wood-cocks at a time in it.

There is another method of taking these birds in high woods, with those nets called hays, of the nature of the rabbit-hays, only with smaller meshes. The wood-cocks are to be driven into these, and there should always be at least two or three of them planted together. When the sportsman has provided himself with nets, he is to take five or six persons with him. The proper woods for this purpose are those of seven or eight years' growth; and the people are to go into some part of them near the middle. The nets or hays are to be placed in the same manner as they are for taking of rabbits, but two or three joining together at the end, and hanging over a flopewife that way which the wood-cocks are intended to be driven.

The nets being thus fixed, let the company go to the end of the wood, placing themselves at about ten rods distance from one another; they must all have flocks in their hands, and they are to move forward slowly towards the nets, making a noise by striking the sticks against the trees and branches, and by halloving with their voices; in this manner they are to move up to the net; and the wood-cocks that part of the wood will all be terrified before them, but will not take wing, but run along upon the ground, and be driven along like a drove of beasts, so that when the company come up, they will find almost all of them in the net. When that part of the wood is thus driven, the nets are to be turned the other way, and placed flopewise in the contrary direction, and the company retiring to the other end of the wood, are to drive the wood-cocks that are in that part with the same noise, till they have sent them into the nets in the same manner.

Thus all the wood-cocks in the wood may be taken with very little trouble, and this may be done equally at any time of the day.

Another way of taking this bird is by means of noozes or springes.

The wood-cock and the snipe are both easily taken with bird-line, when their places of resort are known, but they are not so easily found as many other birds.

The custom of the wood-cock is usually to be upon the banks under hedges, and by the sides of ditches toward the sun; and they will suffer the sportsmen to come nearer them in the day-time after a moon-shiny night, than after a dark one. The reason of which is, that having fed well by moon-light, they are only fit for rest the day following; but
