Sir Joseph Banks has favoured us with several specimens of a variety of this fern, gathered at Campechy by Houfünn, which differs chiefly in being not above a span high, with a leaf compound frond, and having sometimes, from the fame root, much narrower, almost linear, leaflets. The common flake are also rather more hairy, and the spikes more compact. It is nevertheless of evident variety, and probably the E of Willdenow, to the characters of which it answers.

Sec. 2. Panicles of spikes on radical flanks.

15. A. bipinnata. Great Radical Anemia. Swartz n. 14. Willd. n. 14. (Osmunda bipinnata; Linn. Sp. Pl. 1521. O. latis crenis incisa; Plum. Fil. 133. t. 155.)—Frond oblong, doubly pinnate; leaflets elliptical-oblong, acute, entire. Spikes on radical flanks, doubly pinnate; their ultimate segments densly crowded. —Gathered by Plumier in a dry rocky tract of land in Hispaniola. We find no good authority for its having ever been found elsewhere, nor by any other botanist. Linnaeus adopted this species entirely from Plumier, between whose figure and description there is a strange contrariety. The plate, drawn and engraved by himself, evidently exhibits the barren fronds as doubly pinnate, each of the numerous primary divisions being composed of a rather smaller number, (about thirty,) of oval or ovate, somewhat decurrent leaflets, except a few of the uppermost, which run into a terminal serrated point. His description says, "the tufted root bears seven or eight ribs, about a foot and a half long, garnished nearly throughout their whole length, with longish, narrow, pointed, yellowish-green leaves, but slightly frayed, and all cut into rather broad, and somewhat pointed notches." As the author is known to have lost many of his specimens, we can only suppose this description was made from too flight a view of his own drawing, without a re-examination of the plant, which he seems to have gathered but once. A few taller and more slender flanks, springing also from the root, and doubly pinnate in the first instance, bear innumerable cappules crowded into dense mafles, which we presume to be composed of narrow compound segments, like other species. At least the analogy of A. filiculofolia hereafter described justifies this supposition.

16. A. aurita. Auricled Radical Anemia. Swartz n. 15. Willd. n. 15. (Osmunda aurita; Swartz Ind. Occ. 1578.)—"Frond pinnate; upper leaflets simple, ovate, obtuse, finely toothed, unequally wedge-shaped at the base; lower ternate. Spikes compound, on radical flanks; spikelets digitate." —Found by Dr. Swartz, on the sides of lime-stone rocks, in the interior part of Jamaica. Roots creeping, slender. Common flake several, crowded, about a span high, slender, molt hairy and feaky at the base; downy and roughish upwards. Each bears an erect frond, six inches in length; doubly pinnate in its lower part, the leaflets small, roundish, the terminal ones larger and rhomboidal: the upper part is simply pinnate; leaflets oblong, oblique at the back, dilated on the upper edge, at the base, into an obtuse angle: all the leaflets are coriaceous, smooth and shining, slightly convex, stiwicked with radiating veins; finely crenate at the margin; more opaque beneath. Clusters, (or rather spikes,) compound, on radical flanks, close to, and resembling, those of the barren fronds; their branches compound, nearly opposite, spreading; their ultimate segments digitate, lanceolate, acute, bearing on the upper side roundish-ovate bivalve cappules, with concentric stinks on their apex, and interferred with minute scales or hairs. Swartz. By this description, the genus is put out of all doubt.

17. A. verticillata. Whorled Radical Anemia. Swartz n. 16. Willd. n. 16. (Osmunda verticillata; Linn. Sp. Pl. 1520. Plum. Fil. 137. t. 160. Petiv. Fil. n. 171. t. 12. f. 4.)—Frond three-branched, triplo pinnate; leaflets elliptic-oblong, acute, serrated; terminal ones lanceolate, pointed. Spikes in whorled branches, on radical flanks.—Gathered once only, in the forests of Hispaniola, by Plumier, nor does it appear that any other botanist has even seen this species, his work having been Linnaeus's sole authority. The genus, therefore, can only be presumed from analogy, but we think this analogy as fair as in any similar instance. The tufted root feeds up many barren fronds, which are supported by long rough flanks, and three-eleft in the first instance, then doubly pinnate; their common outline pentagonal, a foot in diameter; their leaflets usually
ANEMONE

near an inch long. The height of each frond, with its flalk, is about two feet. A few rather more slender flalks, from the root, bear each a long interrupted, winged, flake, with fix or eight drooping, obtuse, dense, blackish branches, in every whorl, above an inch long, or capillary flalks, but how they are subdivided we have no information. Plummer compares them to little black caterpillars.

18. A. filicifolia. Hemlock-leaved Radical Anemia. Swartz. n. 17, Willd. n. 17. (Osmunda filicifolia; Linn. Sp. Pl. 1521. O. filicule folio altera; Plum. Fil. t. 138. t. 161. O. cinete folio; Petiv. Fil. n. 170. t. 9. f. 3.)—Frond three-branched, pinnate, pinnatifid; segments wedge-shaped, decurrent; notched at the extremity. Spikes panicked, on radical flalks.—Found but rarely by Plummer, in the forests of Hilipaniola. A specimen, without any indication from whence it came, is preferred in the Lin- nanean herbarium, and referred to Osmunda (Anemis) bipin- nata, (see n. 15.) Lennins appears to have had it when he wrote the first edition of Sp. Pl., and all he says of either of these species is entirely taken from Plummer, who is the primary authority for both. A. filicifolia varies from five inches to a foot in height. The barren fronds have slender, roughish, rather long, flalks, and are nearly penta- gonal in their outline; having three principal branches, which are first pinnate, then more or less deeply pinnatifid and cut, always in a wedge-like manner; they are hairy on both sides. The common mid-rib is winged. From the same tufted root grow one or more rather taller flalks, each bearing a tripod-composed, slightly hairy, panicle, or com- pound flake, whose linear ultimate segments are lamen, on one side, with rather large, and not very numerous, capules, each having a very distinct, brown, shining, radiated top, below which is a lateral furrow. The engraving of Plummer gives no idea of the size or nature of these capules, nor of their arrangement, so that we may suppose him equally incorrect with regard to our fifteen or seventeenth species.

Dr. Swartz, Syn. Fil. 158, points out, as a probable species of this genus, Fildaxrum americantium minus, folius ranames hirsutus, Ammann in Comment. Petrop. v. 10. 235. t. 19. This was found by Dr. Houltoun at Vera Cruz, and however unlike the figure may seem to Plummer's t. 161, our specimen mentioned, and partly described, under the last species, serves to prove them, at least in our opinion, one and the same plant; for it explains the inaccuracies of both figures, and is intermediate between the two in the structure of the barren frond. We cannot doubt its being one of Houltoun's specimens. The panicked inflorescence agrees with Ammann's figure, but the detail of that figure is no less incorrect than Plummer's, so that nothing precise can be gathered from either.

ANEMOMETER, col. 2, for IX. infert VIII. No. 3.

This genus comfits of perennial herbs. Roots (or per- haps subterraneous stems?) either tuberous, or horizontally creeping, or simply fibrous. Leaves radical, flaked, simple (or compound), lobed or cut. Flower-flalk radical, bearing at the summit an involucrum of three, rarely but two, leaves, variously cut, but conformable in general to the proper foliage. From this involucrum proceeds usually one or many simple, naked, single-flowered flalks; some apparently caulent species have one such leaflefs flalk, and, besides, a fort of branch, bearing another flower-flalk, accompanied by a two-leaved involucrum. The flowers are in- dorous, very variable, and readily become double.

The recent plants are acrid, and raise blisters in the skin, if applied externally; internally they are poisonous in some degree, though several have been prepared in chronic ophthalmia, and venereal caries of the bones.

The forty-five species, with which we are at present acquainted, inhabit pastures, lands, woods or thickets, of temperate climates, principally in the northern hemisphere; the Pulsatilla are found on rough exposed hilly fields; Preo- nanthus on the loftiest mountains; Pulsatiloides at the Cape of Good Hope; Anemonebea in meadows, pastures, or woods; Anemoneformes in North and South America and in Asia; Omalocarpus in mountainous situations. There are two species from the Cape of Good Hope, four from South America, eleven from North America, eighteen are natives of Europe, three of the Levant, five of Siberia, two of Nepal, and one of Japan. Four appear to be common to North America and Europe.

Anemone is a very natural genus, and De Candolle declares his opinion against dividing it; first, because the section Prenanthus has the head and flower of the Anemonebea, with the feather-tailed fruit of Pulsatilla; secondly, because the fruit being furnished with such an appendage, or deli- tute of it, is not to be considered essential in the present cafe, the same circumstance proving of no avail in the genus Clematis, so nearly related to the present.

The following divisions, founded on the whole habit as well as the fruit, prove extremely natural.

3. Pulsatiloides. Seeds very hairy. Petals fifteen to twenty. Involucral leaves two or three, feffile, cut at the summit. Species 9 and 10.

5. Anemoformes. Seeds without tails, rather collapsed. Partial flower-flalks several; one of them leaflets and single-flowered; two or three others bearing a two- leaved partial involucrum. Species 33—40.

† Species not sufficiently known: 44 and 45.

We have corrected some accidental numerical errors, and we take the liberty of using the Linnaean terminology, as to calyx or corolla, here as in Aconitum, &c. Carpella, a word used by our learned friend for partial fruits, several of which belong to one flower, as in Uvaria, Unona, &c., seems to us well expressed, in English at least, by the plural, fruits; the singular, fruit, being always used when the pericarp is simple, or solitary. Carpophyls is used by Richard and De Candolle for the naked feed of Graffes, as well as of Ramunculaceae, of which we do not see the utility. A multiplication of terms, without absolute necessity, is burthenome to science, and we rather with the learned would labour to comprefs, instead of extending, the terminology of natural history.

Seeds terminating in long bearded tails. Involucral leaves serife, dilated at the base, divided upwards, in a palmate manner, into linear segments. Petals five or six. Glands, (abortive stamens,) in several species, on short filaments, between the perfect stamens and petals. The radical leaves are mostly divided in a pinnate manner, their segments many-cleft, with linear or wedge-shaped lobes. Flowers in general purple or crimson.

1. A. vernalis. Parsley-leaved Spring Anemone. Linn. Sp. Pl. 759. Fl. Lapp. ed. 2. 189. 'De Cand. n. 1. Willd. n. 4. Att. n. 3. Fl. Dan. t. 29. (A. n. 1147; Hall. Hift. v. 2. 61. t. 21. Pulsatilla altera alpina; Dalech. Hift. 851. P. apii folio vernalis, fl. majore, et fl. minore; Bauh. Pin. 177. Prodr. 94. 'Helv. Pul. 63. t. 91:')—Leaves pinnate; leaflets elliptic-wedge-shaped, notched or three-cleft, nearly smooth. Flower erect. Involucrum very hairy. Petals fix, straight, elliptic-oblong.—Native of rocky pastures on the loftiest mountains of Switzerland, the Pyrenees, Germany, Sweden, and Norway, flowering among the melting snow in spring. The broad leaflets, with the beautifully flaky involucrum and petals, distinguish this species. The flower-flalk is three or four inches high, hairy, much elongated above the involucrum after flowering, as in all the Pulsatilla tribe. Flower white, variegated with purple, extremely elegant; we have some doubt whether the report of its being ever yellow be well founded, and whether the term "golden" in Dalechamp, copied by J. Bauhin, may not apply to the brilliant yellow pubescence of the living as well as dried flowers, noticed by Haller.

2. A. Hollar. Silvery Swifts Anemone. All.t. Pedem. v. 2. 170. t. 80. f. 2. De Cand. n. 2. Willd. n. 5. Villars Daubh. v. 3. 725. (A. n. 1148; Hall. Hift. v. 2. 62.)—Leaves pinnate, deeply cut, with linear-lanceolate, pointed segments; very hairy beneath. Flower erect. Petals fix, straight, elliptic-lanceolate.—Native of the Alps, flowering in summer. Haller gathered it in the valley of St. Nicholas, in the Upper Vallais; Villars in Dauphiny; Molineri on the Piedmonte mountains; De Candolle in the eastern Pyrenees. The leaflets and their segments are much longer and narrower than in the foregoing; pubescence of the flower and involucrum flinny, not yellow. Petals dull purple, converging, not spreading.

3. A. cernua. Drooping Japanese Anemone. Thunb. Jap. 238. De Cand. n. 3. Willd. n. 3.—"Leaves pinnate; hairy and somewhat downy beneath; leaflets pinnatifid, with notched oblong segments. Flower rather drooping. Petals fix, elliptic-oblong, spreading."—Native of Japan, about Jedo and Nagakafu, (Thunberg,) flowering in spring. All the flalks are very hairy, as are the leaves beneath, especially when young. The segments of the latter are intermediate between vernalis and Pulsatilla. Stalk fix inches high. Flower dark purple, hairy externally, smaller than in A. Pulsatilla. De Candolle.

4. A. patens. Naked-flowering Anemone. Linn. Sp. Pl. 759. De Cand. n. 4. Willd. n. 2. Att. n. 2. (Pulsatilla polyanthos vilosea, anemone folio; Breyn. Cent. t. 61. "Helv. Pul. 52. t. 2. 32")—Leaves later than the flower; leaflets ternate, wedge-shaped, deeply and acutely pinnatifid and cut. Flower erect, spreading.—Native of Siberia, Poland, Sileia, &c.; recently found by Mr. Schleicher in Switzerland. The flowers are as large as any of this species, and more spreading, either pale yellow, white, or purplish, on a very short partial flalk; the involucrum in very narrow, linear, hairy segments. The leaves expand after the flower is past, and are ternate, not pinnate, with radiating, very acute, variably notched, segments. The partial flalk is greatly elongated, from six to nine inches, as the fruit ripens. De Cand.

6. A. pratensis. Dark Meadow Anemone. Linn. Sp. Pl. 760. De Cand. n. 6. Willd. n. 7. Alt. n. 5. Fl. Dan. t. 611. Woodv. Med. Bot. t. 148. (Herba venti; Trag. Hift. 413. Pulsatilla; Camer. Epit. 392. P. flore chulo; Lob. Lc. 283. P. flore minore; Ger. Em. 386. P. altera; Dalech. Hift. 870.)—Leaves doubly or triply pinnate, with lanceolate, elongated segments. Flower pendulous. Petals fix, erect; reflected at the summit.—Native of meadows, as well as of dry open fields, in Sweden, Denmark, Russia, Germany, France, and, according to the abbé Sefflin, near Conflantinople with the preceding. This species is distinguished from A. Pulsatilla, by the larger coarser segments of its leaves, and smaller, darker-coloured flower, whose petals are recurved at the top. Dr. Strock recommended an extract or infusion of the herb, in chronic diseases of the eyes, and even confirmed lues. Hence it has attracted the notice of physicians, who have been commendably anxious to procure the true plant, which is not found wild in Britain. Probably its virtues, whatever they may be, exist likewise in the A. Pulsatilla. Both are easily cultivated.

7. A. alba. Pale Caucasan Anemone. "Steven Mem. Soc. Nat. Mofc. v. 3." De Cand. n. 6.* addend. 545.—Leaves doubly pinnate, with numerous oblong-linear segments. Flower drooping. Partial flalk scarcely longer than the involucrum. Petals fix, erect, slightly reflexed at the summit.—Gathered by Mr. Stevenson, on the lofty mountains of the eastern part of Caucasus. Allied to A. pratensis, but differing in the flanks of the leaves, and their subdivisions being shorter as well as more obtuse, rather oblong than truly linear: secondly, in the partial flalk, even throughout the whole duration of the flower, riling scarcely above the...
ANEMONE.

the involucrum, instead of being four times longer: thirdly, in the flower being whitish, or sulphur-coloured, not purple; fourthly, in the total want of glands, or abortive flaments, at least in the specimen seen by prof. De Candolle; which are very abundant in the preceding species.

- Seeds terminating in long bearded tails. Involution leaves ternate, flaked, pinnate, with deeply ferrated, notched lobes. Petals five or six. No glands, or abortive flaments. Radical leaves ternate; their divisions pinnate, doubly compound, cut and ferrated. Flowers white or yellowish.

- Fl. large, yellow. (A. api folia; Jacq. Milc. v. 2. 47. t. 4. Wildl. n. 9. A. sulphurea; Linn. Mant. 78. A. myrrhidifolia 2; Villars Dauph. v. 3. 727, from the author. A. n. 1149, 2; Hall. Hilt. v. 2. 53. *Pulsatilla lutea*; Camer. Epit. 393. P. tertia; Dalech. Hilt. 851, bad.)

- Leaves ternate, pinnate, with pinnatifid, decurrent, ferrated lobes. Involution ones similar. Petals fix, spreading. -Native of 
day and rocky deftrictes in mott alpine parts of the middle of Europe, Switzerland, the Pyrenees, the south of France, Austria, Carinthia, &c.; flowering in summer. The conformity of structure of the involucrum and the radical foliage, clearly aertains this species. We readily concur with Haller and De Candolle, that the difference of colour between the yellow, lemon-coloured, or white flowers, or of size between the large-white and the small, indicate mere varieties. But we scarcely see any reason to mark the more or less hairy leaves as permanent varieties; the former being caused by more dry and exposed situations of the same plant. The petals are always more or less pale, purplish, and hairy, at the back. The flowering plant is from two to twelve inches high. When in seed its dimensions are very way doubled. A singular monstrility of variety 5, sent us by the late Mr. Davall, has one of its petals flipped down, if we may so express it, into the involucrum, and greatly enlarged. This, as M. De Candolle justly observes, proves an analogy between the petals, (his calys), and the involucrum; but it will not prove them to have more affinity than the petals and actual leaves of a Tulip, which we have several times seen running into each other, or half and half of the perfect nature of each.

Sect. 3. *Pulsatilloides*. De Candolle.

- Seeds very hairy. Petals from seven to twenty, oblong. *Involucrum* of two or three leaves, somewhat sheathing at their base; cut and toothed upwards. Leaves twice ternate, cut.

10. A. capensis. Broad-leaved Cape Anemone. Lamark Dict. v. 1. 164. De Cand. n. 9. (Atragene capensis; Linn. Pl. 764. Wildl. Sp. Pl. v. 2. 1286. Ait. Hort. Kew. v. 3. 342. Andr. Repof. t. 9. Curt. Mag. t. 716. *Pulsatilla folis tridentis*, dentatis, flore incarnata, pleno; Burm. Afric. 148. t. 52.) - Leaves twice-ternate, rigid, smooth; segments wedge-shaped, sharply toothed. -Native of light activities of mountains, at the Cape of Good Hope, flowering from October to March. It is said to have been first cultivated in England, by Meffrs. Lee and Kennedy, in 1795. This plant is somewhat cauleent, but the leaves are crowded over the lower part, almost close to the woody root. Their texture is extremely firm; they are segments varying greatly in size, breadth, and shape; the young ones villous. Flowers one or two from each involucrum. *Petals* thirteen to eighteen, linear-oblong, above an inch in length, pink, or pale bluish-coloured, spreading, very handfome. *Germens* extremely hairy, ovate, each with a recurved style.

11. A. tenusfolia. Fine-leaved Cape Anemone. De Cand. n. 10. (Atragene tenusfolia; Linn. Suppl. 270. Wildl. Sp. Pl. v. 2. 1286. Thunb. Prodr. 94. A. tenuis; Thunb. Jap. 239, note.) - Leaves thrice-ternate, rigid, smooth; leaflets pinnatifid, with linear-threadshaped, acute, entire lobes. - Found by Thunberg at the Cape of Good Hope. The leaves are more compound, and more finely divided than those of the preceding species; the plant is described as more cauleent, and the flowers but half as large, with only from seven to nine petals. We have seen no authentic specimens, but are not without a suspicion that Linnaeus confounded this with the last.

Sect. 4. *Anemonanthus*. De Cand.

- Seeds nearly ovate, hooked with the permanent style, either very hairy or flabby, or in some instances nearly smooth. Partial flower-flasks solitary in each involucrum, or very rarely two together, always single-flowered and naked. Petals from five to fifteen.

*Involutural leaves fijiile. Root-stocks tuberous, somewhat ovate.

12. A. coronaria. Poppy Garden Anemone. Linn. Sp. Pl. 760. De Cand. n. 11. Wildl. n. 10. Ait. n. 7. Curt. Mag. t. 841. Sm. Fl. Grce. Sibth. t. 514, unpubl. Lamark f. 1. (Anemone; Camer. Epit. 386. A. horitines tenuifolia, simplici flore, n. 2-36; Chaff. Hilt. v. 2. 255-256; albo pleno flore; ibid. 263. A. tuberosa radice, et eocineica multiplex; Lobb. Ic. 277. Ger. Em. 374; fea also several in his Tuberous pages.) - Leaves twice ternate, pinnatifid; segments linear-wedge-shaped, smooth-edged, sharply cut. Involution fijiile, many-crested. Petals fix, oval, concave, converging. - Native of dry, as well as rather moist, pastures, in the south of France, Italy, and the Levant, flowering in the early spring. Very common on dry hillocks in Greece, according to Dr. Sibthorp, who concurred with former botanists in thinking it the *Anemone impa* of Dioscorides; and the learned Sprengel takes the *Anemone* of Hippocrates to be the same plant. This species, however, bears the same name in modern Greek, *εγκαρια*, as the Field Poppy, *Papaver Rhaes*; nor is the history of these two flowers, however different, free from ambiguity. A. coronaria has been the delight of florists ever since the time of Gerarde, and its numerous double varieties, displaying every beauty and splendour of colour, are among the most rare and admired decorations of a parterre. We confefs
ANEMONE.

con벰a a predilection for the fingle kinds, equally beautiful and various in colour, which may be raised abundantly from seed in any airy and funny spot, and require but little trouble in transplantation every fourth or fifth year. They flower most in the winter or spring. The leaves vary in breadth. The natural colour of the flower, which is cup-shaped, and full two inches broad, is a light purplish-blue, as represented in Dr. Sibthorp's drawing, and as we have gathered it in the groves and grassplots of the Roman villas. The seeds are covered with long, soft, tenacious down, concerning the effect of which an amusing story is told by Tournefort and Miller. A lawyer in the south of France stole these seeds from a covetous amateur, by ordering his page to drop, as if by accident, the flax train of his robe, when they paffed over the bed of feeding Anemones, and thus obtained a plentiful supply.

13. A. pufilla. Dwarf Anemone. De Cand. n. 12. Leaves three tertiary, pinnatifid, many-cleft, with linear pointed segments. Involucrum felfile; cut at the fummit. Petals fex, oblong, dilaffant. —Gathered in Cyprus by Labillardiere. Nearly akin to the last, and perhaps a variety. Root tuberous, the size of a filberd. Leaves smooth, falked, with narrow linear segments. Flower-ffalk a finger's length, slender, downy, erect. Involucrum of three leaves, acutely cut and toothed at the apex. Partial ffalk either the length of the involucrum, or twice or thrice as long. Flower erect, pale purple. Petals fex, rarely but four or five, oblong, blunt, fidal and spreading, about four times the length of the flamens. Seeds woolly, collected into an oval-oblong head. De Cand. 14. A. pavanina. Peackock Garden Anemoe. Lamarck Dict. v. i. 166. De Cand. n. 13. "Fl. Franc. v. 5. 634." Brot. Lufit. v. 2. 363, not 263. (A. hortensis latifolia, pleno flore, et flore coccineo; Cluf. Hift. v. 1. 261, 262, with three figures. A. maxima chalcedonica polyanthos; Ger. Em. 375. Lob. Ic. 278. A. ftellata, geranii aucti folio, duplicato flore purpureo; Cupan. Panph. v. 1. t. 121, ed. 2. t. 22.)—Leaves ternate or deeply three-lobed; leaflets or fegments wedge-shaped, cut and toothed. Involucrum felfile, its leaves oblong, entire or slightly cut. Petals ten or twelve, lanceolate, very acute. —Found in vineyards in Navarre, also in the south of France, and probably in the Levant. De Candolle. Differs from A. coronaria in its hels divided leaves, and especially those of the involucrum, which are five or fix, elliptic-lanceolate, rough-edged, most of them quite entire, one or two only partially notched. The narrow and acute petals are also peculiar. We feel con- vince with Lamarck and De Candolle that this must be a distinct species, though confounded by Linnaeus and others with the more frequent A. coronaria. We have not fought out its varieties among the double Anemones, but there is a feareat one not uncommon. The French know fome of these varieties by the names of Oeit de poon, Candide, &c. If this be not distinct, it should feem to belong to the following rather than to any other.

15. A. hortensis. Starr Garden Anemone. Linn. Sp. Pl. 761. Willd. n. 11. Ait. n. 8. Curt. Mag. t. 123. Sm. Fl. Græc. Sibth. t. 515, unpubl. (A. hortensis latifolia filipimic flore, n. 3—18; Cluf. Hift. v. 1. 249—254. A. prima; Dod. Pemp. 434. A. fecula; Camer. Epit. 387. A. tuberofa, bulbocallani radice; Lob. Ic. 279. Ger. Em. 375. f. 5. A. n. 1152; Hall. Hift. v. 2. 64. A. ftellata; Lamarck Dict. v. 1. 166. Brot. Lufit. v. 2. 363. Savi Etr. v. 2. 122. De Cand. n. 14. "Fl. Franc. v. 5. 634." —Leaves ternate; leaflets wedge-shaped, rough-edge, three-cleft, cut. Involucrum felfile; its leaves lanceolate, undivided or partly cut. Petals ten or twelve, elliptic-lanceolate, obtuse. —Found on banks, ruins, or bushy waste ground, in the south of Europe; very commonly in Italy and Greece, flowering in the early spring; lefs abundantly in the south of France, and Switzerland. Clusius observed this species near Mentz. It has been known in gardens as long as the coronaria, but being inferior in beauty and variety, has given place to that popular species. We cannot follow Lamarck in its specific appellation, because there is no end of changing names for the better; unless all leading botanists would coor in a general reform; and even in that cafe, positively erroneous names only should be altered. This pretty species has an oblong tuberous root, producing many leaves and flares. The latter are ternate, on long falks; their leaflets coriaceous, strongly veined, either cut half way down into three broad lobes, or divided nearly to the base, into three subdivided narrow ones; their segments all acute; their edges remarkably rough, though both surfaces are usually, if not always, smooth and naked. Involucral leaves three, an inch long, fiky, rough-edged; one of them in general slightly notched at the end. Partial flalk long, fiky, especially near the top. Flower feecently above an inch wide, of a delicate rofe-colour, or full carnation; the petals fiky at the back, veiny, often emarginate. The rough-edged leaves and involucrum are characteristic of this species, but the involucrum of pavanina, (we have not examined its leaves,) has the fame character, which coronaria has not. We are strongly persuaded of pavanina being a variety of hortensis, and that the acutenef or bluntnefs of the petals is variable.

16. A. palmata. Cyclamen-leaved Anemone. Linn. Sp. Pl. 758. De Cand. n. 15. Willd. n. 12. Ait. n. 9. Andr. Repos. t. 172. Vahl Symb. v. 3. 73. Desfont. Atlant. v. t. 432. (A. hortensis latifolia, fimplici flavo flore; Cluf. Hift. v. 1. 248. Morif. sect. 4. t. 25. f. 3. A. latifolia Chlii; Lob. Ic. 279. Ger. Em. 376. A. latifolia flavo; Barrel. Ic. t. 792.)—Leaves fimple, heart-shaped, rounded, with three or five blunt, sharply-toothed lobes. Involucrum felfile; its leaves in three linear, acute, hairy lobes. Petals ten or twelve, oblong, obtufe. —Native of rather moif waste ground, in Portugal, Spain, the south of France, and the north of Barbary, flowering early in spring. Rarely cultivated with us, except in curious gardens, though the brilliant golden flowers are very hand- some. The leaves, notwithstanding Mr. Andrews's doubts, are truly palmate, differing from the laft in being fimple, and, though more or less hairy, not rough at the edges as in that species. They are coriaceous, strongly veined; often purple beneath. The involucral ones are three, almof uniform, hairy or fiky, an inch long, narrow, each divided about half way into three nearly equal, sometimes notched, linear lobes; the edges apparently fringed, but not rough. Stalk above the involucrum rather long, fiky. Flowers an inch and a half or two inches broad. Petals linear-obovate; the fix outer ones remarkably hairy externally, and so dif- pofed in Linnaeus's only fecimen, that he took them for the fame kind of close calyx as occurs in Hepatica, only with a double number of segments. Thus he was led to place A. pmata in his firft fection, Hepaticae, and this will solve Vahl's difficulty, recorded in his Symbols above cited. But it will not account for this author's extraordinary quo- tation of Linnaeus's words, which are "calys fexpartitus, integerrimus, villosus, coloratus, nec a flore remotus." Vahl cites this palage, "calys hexapbyllus, coloratus, a flore remotus." The fuppofed double variety of the present spe-

nemorofa. De South

filed, which De Candolle marks with doubt, and has never, is represented with the many-knobbed root of a Ranunculus, to which genus we should not be surprised if it proved to belong.

17. A. decapetala. Little Three-leaved Anemone. Arduin. Spec. 2. 27. t. 12. Linn. Mant. 79. De Cand. n. 16. Willd. n. 17. Lamarec Dict. v. 1. 167. ("A. trilobata; Juff. Ann. du Mus. v. 3. 247. t. 21. f. 3.")—Leaves ternate; leaflets rounded, unequally three-toothed and toothed. Involucral leaves sessile, twice three-cleft, with linear segments. Petals ten or twelve, elliptic-lanceolate, obtuse. — Sent by Father Panegai to professor Ardouin, from Brazil, where Commeron also met with this curious little plant; as did Dombe and Nee in Peru and Chili. The root is ovate and tuberous, about the size of a filbered. Leaves smaller than the leaf, and perfectly ternate, obscurely dotted, besprinkled with short hairs, but not rough-edged; their teeth unequal, blunting, often callyous-callous. Stalk two or three inches high, finely at the top, with an involucrum about the middle, totally unlike the leaves, being doubly, but imperfectly, three-cleft, with linear segments, callous at the tips. Flower scarcely half the size of A. hortensis, which it resembles in form. The petals appear to be white; filmy and purplish at the back.

19. A. caroliniana. Little Carolina Anemone. Walt. Carol. 157. De Cand. n. 18. (A. tenella; Pursh n. 4.)—"Leaves ternate; leaflets deeply three-cleft, cut, sharply toothed. Involucral leaves three-cleft, notched. Petals ten or twelve, linear."—Gathered in Carolina, by the late Mr. Walter; on the banks of the Millfouri, by governor Lewis; flowering in May. Root small, tuberous. Herb tender and delicate. Leaflets form with only toothed, and others with deeply three-cleft, jagged, and sharply toothed, lobes. Stalk single-flowered. Involucrum of three leaves, with jagged segments. Partial flak long. Petals small, purplish, externally downy. Seeds pointed, woolly. The fourth Ranunculus, Pluk. Alm. 310, cited doubly by De Candolle, who has omitted the word procus in the transcription, feems to us at best very uncertain, and particularly so on account of that very word.

20. A. triternata. Fine-leaved Brazil Anemone. Vahl Symb. v. 3. 74. t. 65. De Cand. n. 19. Willd. n. 18. Lamarec f. 3. ("A. fumaricefolia; Juff. Ann. du Mus. v. 3. 247. t. 20. f. 2.")—Leaves thrice ternate; leaflets cut; segments lanceolate, acute. Involucral leaves in many fetaceous divisions. Petals ten or twelve, oblong, obtuse. Fruit cylindrical.—Gathered by Connerfon at Monte Video. It is said to have been also found in Peru, by Lucbaz; flowering in November. The root and flowers bear a great resemblance to A. decapetala; but the leaves are totally different, being cut into innumerable, fine, divaricated segments, quite smooth, entire at the edges, and not at all toothed or serrated. The involucrum too is somewhat different, each of its three leaves being first divided half way down, into three parts, and those subdivided into many slender, tapering segments. The roots are numerous, tapering, beaked, very hairy, closely imbricated in a cylindrical, somewhat elliptical, head, an inch long.

21. A. biflora. Two-flowered Oriental Anemone. De Cand. n. 20.—"Leaves ternate; leaflets deeply divided into linear, obtuse, partly cut, lobes. Involucral leaves sessile, in many deep segments. Partial flower-stalks in pairs, one of them with a partial involucrum."—Gathered by Michaux in the Levant. Of this De Candolle describes two varieties.

a, with two leaves in the general, and two in the partial, involucrum. Root an oblong tube, tapering upwards, fibrous below. Leaves smooth, on long stalks, ternate; their leaflets in deep, linear, somewhat notched, obtuse, thickish lobes. Common flower-flask round, the length of the footstalks, about four inches. Involucrum of two lobe leaves, in numerous deep divisions, resembling the radical foliage. Partial flaks two, single-flowered, closely downy; one naked; the other furnished, near the base, with a two-leaved partial involucrum, like the general one. Flowers rather drooping, yellow, with five petals, which are oval-oblong, obtuse, externally downy, rather larger than in A. ranunculoides. Stamens few in the flower, with a two-fold involucrum; numerous in the other. Germs, on the contrary, many in the former, few in the latter.

b, with three leaves in the only involucrum.

** Involucral leaves flattened. Root-stock tuberos, somewhat ovate.

22. A. apennina. Blue Mountain Anemone. Linn. Sp. Pl. 762. De Cand. n. 21. Willd. n. 24. Fl. Brit. n. 3. Engl. Bot. t. 1662. Prodr. Fl. Græc. Sibth. n. 1250. Curt. Lond. falc. 6. t. 35. (A. geraniolilia; Bauh. Hift. v. 3. 407. Ger. Em. 377. Lob. i. 28C. A. hortenfis tenuifolia, simplici flore; Cluf. Hift. v. 1. 254. Ranunculus nemorosus, foare caruleo, duplex apennini montis; Mentz. Pugiil. t. 8.)—Leaves twice ternate, pinnatifid, sharply notched. Involucral ones stalked, ternate, pinnatifid and cut. Petals twelve to fourteen, oblong, obtuse.—Native of groves and thickets in some parts of England, but rare, as near as Wimbledon, Luton-hoe, and Berkhamsted. Fl. Brit. In Italy it occupies the place of A. nemorosa in the more northern parts of Europe, and is equally plentiful, flowering in March and April. Dr. Sibbthorp noticed it in the Morea; Dr. Clarke on the banks of the Sismon; and the baron Marshall von Bieherstein in the Iberian Caucusus. The root is smaller than a filbered, bearing one or two leaves, each on a zigzag footstalk, very slender at the base. The leaves much resemble Geranium robertianum; those of the involucrum are smaller, but less divided, with narrower segments. Stalk solitary, from four to nine inches high, filiky above the involucrum. Flower of a fine blue, with pale flamen and pifflis, very beautiful, said to be occasionally white.

23. A. carules. Small Blue Anemone. De Cand. n. 22.—"Leaves... Involucral ones on short stalks, tripily pinnate, cut and toothed. Petals four or five, oval."—Gathered by Mr. Patrin, near Zmeof in Siberia, flowering in the early spring. The root and radical leaves are wasting in the specimens seen by De Candolle. This species agrees in description with the last, but the partial flaks is much
much shorter than the *involucrum*, and the small blue flower has only four or five roundish, very obtuse petals, more like *A. nemorosa*, except in colour.

**Involucral leaves flattened. Root-flock cylindrical, slender, elongated.**

—Common in groves and thickets throughout Europe, where *A. aequina* scarcely occurs, flowering in spring. About the size of that species, with one remembrance of foliage; but there is less difference between the leaflets of the radical leaves and those of the involucrum. The root also is long and slender, not ovate. The flowers are white, often tinged with purple externally, formed of fix broad petals, totally unlike *aequina*. The double variety is very elegant. That with five deep lobes in each leaflet, occurs occasionally in England as well as North America, and is evidently a most trifling variety, though Linnæus, led perhaps by Plukens's bad figure, made it a species.

De Candolle states the leaves scarcely differ from *A. trifolia*, by which we are led to suspect that Plukens's t. 106. f. 3, cited by Linnæus and others for *quinquefolia*, with which it does not well accord, may belong to the species before us.

28. *A. trifolia*. Three-levored Anemone. Linn. Sp. Pl. 762. De Cand. n. 27. Willd. n. 21. Diet. Pempt. 436. Ger. Em. 377. Morif. fect. 4. t. 25. f. 1. (A. trifolia, flore albo; Bauh. Hist. v. 3. 412. Alabatis, five Dentaria alba; Lob. Ic. 281.) —Leaves and involucrum flatked, ternate; leaflets of all ovate, acute, flatked. Petals five or fix, elliptical, obtuse. —Native of rather mountainous groves and thickets, in France, Piedmont, Tuscan, Carniola, Carinthia, and Siberia, flowering in summer. Gerard appears to have cultivated this species, but we have never seen or heard of it in modern times. The root is oblong, horizontal, somewhat toothed. Leaves two or three inches high, each of three leaflets, about an inch long, with hairy ribs and edges. *Stalk about a span high, or more, angular, smooth, bearing an involucrum of three uniform flatked leaves, like the radical ones, but rather larger; the lateral leaflets very unequal at their base; the central one tapering into the floreal stalk.* *Partial flower-fallk* about the length of the flaks of the involucrum, solitary, simple, slender, hairy. *Flower scarcely an inch broad. Petals from five to seven, white; purplish underneath.*

29. *A. minima*. Leaf Anemone. De Cand. n. 28. — *Leaves...* Involucral ones flatked, deeply three-lobed; lobes ovate, pointed, flattened externally and at the extremity. Petals five, oval-oblong, obtuse. —Native of the Allegheny mountains in Virginia; *Pulte de Beauroy*. Remarkably tender and delicate, resembling *A. trifolia*, but only one-third its size. *Root long, slender, horizontal, fending out a few fibres. Radical leaves wanting the pecu-

the leaflets are more elongated and cut, and the flanks of the involucrum much shorter. The petals are broader, and of a full yellow. Flowers often two together, one of which, according to De Candolle, is sometimes deficient in petals. The partial flank appears to droop as the fruit ripens. The germen are nearly orbicular, compressed, downy, the style of each forming a strong incurved beak. There is said to be a violet-coloured variety found on the Pyrenees.

Native of Siberia. Stalk closely downy at the top, slender, a palm in height. Involucral leaves smooth, on downy flanks; their leaflets acute, tapering at each end. Partial flank solitary, shorter than the involucrum while in flower, erect, slightly hairy. Flower yellow, one-third the size of the leaf. Siamens very numerous, shorter than the petals.

33. **A. multifida.** Magellanic Anemone. "Poir in Lamerack Suppl. v. 1. 364." De Cand. n. 34. Radical leaves ternate; leaflets in many deep linear segments. General and partial involucrum similar, many-cleft, somewhat flaked. Petals five to ten, elliptical, obtuse. Gathered by Commerson at the straits of Magellan. The root is woody. Radical leaves on long, loosely hairy, stalks. Common flowerstalk stout, erect, taller than the leaves, about six inches high. General involucrum of three leaves, about two inches long, including their broad hairy stalks, being rather larger than the radical leaves, but all similarly divided into linear, or narrow-ridged, partly three-cleft, loosely hairy, lobes. Partial flowerstalks three; the middle one earlike, four or five inches long, hairy, leaflets; the others much shorter, spreading, each bearing two or more, but otherwise similar, involucral leaves; all single-flowered. Flowers about the size of A. pinnata, pale yellow, or buff-coloured, according to Commerson; externally hairy. Seeds hairy, collected into a globular head.

35. **A. multifida.** Magellanic Anemone. "Poir in Lamerack Suppl. v. 1. 364." De Cand. n. 34. Radical leaves ternate; leaflets in many deep linear segments. General and partial involucrum similar, many-cleft, somewhat flaked. Petals five to ten, elliptical, obtuse. Gathered by Commerson at the straits of Magellan. The root is woody. Radical leaves on long, loosely hairy, stalks. Common flowerstalk stout, erect, taller than the leaves, about six inches high. General involucrum of three leaves, about two inches long, including their broad hairy stalks, being rather larger than the radical leaves, but all similarly divided into linear, or narrow-ridged, partly three-cleft, loosely hairy, lobes. Partial flowerstalks three; the middle one earlike, four or five inches long, hairy, leaflets; the others much shorter, spreading, each bearing two or more, but otherwise similar, involucral leaves; all single-flowered. Flowers about the size of A. pinnata, pale yellow, or buff-coloured, according to Commerson; externally hairy. Seeds hairy, collected into a globular head.

36. **A. pennsylvanica.** Pennsylvanian Anemone. Linn. Mant. 247. De Cand. n. 35. Willd. n. 19. Ait. n. 14. Pursh n. 8. (A. irregularis; Lamarack Dict. v. 1 t. 167. De Cand. A. conifolia; Michaux Boreal-Americ. v. 1. 323.) —Leaves deeply three-cleft; segments three-lobed, notched, acute. Involucral ones similar, fimbriate. Petals five, elliptical. Seeds villous. In meadows, and on the borders of woods, from Canada to Pennsylvania, flowering in June and July. Flowers large, white, with yellow anthers. Purbl. Sir Joseph Banks has specimens from Fort Albany and Hudson's bay. De Cand. We have one from the late Peter Collinson's garden at Millhill, probably of an earlier date than 1766; see Hort. Kew. This is a tall, apparently cauliflorous, species, whole flowerstalk is angular, a foot and a half or two feet high, twice forked, and variously compound. The radical leaves we have not seen; De Candolle describes them with long foottalks, as tall as the flowering flak, and deeply divided into three or five parts. The three principal lobes, which are oblong-lanceolate, wedge-shaped at the base, pointed, cut and toothed, at the extremity. Such, nearly, are the general, as well as partial, involucral leaves, but fimbriate, the former three, the latter two, at each division of the flak; all strongly ribbed, two or three inches long, slightly downy with small, close, scattered hairs.

**Sect. 5. Anemonofermos of De Candolle; not of former authors.**

Seeds rather compressed, villous, hooked with the persistent style. Petals five, very rarely ten. Umbel sparsely composed, there being several flaks in one involucrum; one of them naked and single-flowered: two or three others bearing each a two-leaved partial involucrum, from whence springs a single-flowered flak.

*ANEMONE.*
**ANEMONE.**

Partial flaths long, straight and slender, single-flowered, rarely somewhat leafy. "Petals three-quarters of an inch long, obtuse. Seeds compressed, pointed, sparingly downy. A variety, or perhaps a distinct species, found by Laxmann in Siberia, is mentioned by De Candolle, which approaches A. nartciflora in the first appearance of its inflorescence, but is really more akin to *pennayaevica*, differing, as it seems, chiefly in the situation of each small *partial involucrem*, near the bottom of their respective flaths. We have not seen any specimen.

37. A. diebetiana. Forked Anemone. Linn. Sp. Pl. 762. De Cand. n. 36. Wild. n. 25. Alt. n. 15. Pursh n. 9, excluding the syn. of Lomax. Linn. Fl. Dec. 22. 29. t. 15. (A. n. 37; Gmel. Sib. v. 4, 197, excluding the synonyms. Ranunculus brahiliarum; Linn. Am. Acad. v. 1, 155. n. 102.)—Leaves deeply three-cleft, segments oblong, cut and toothed at the end. Involucral ones fimbriate, fcelle, all two-leaved. Petals five, elliptical. Seeds smooth.—Frequent throughout Siberia. Gmelin. In wet woods, and natural meadows, of Canada, and the western parts of New York, flowering in May and June. Pursh. Root flender. Herb smaller than the preceding, and smoother, with only two leaves to the *general involucrum*, and the *leaflets* or segments have larger, but much fewer, teeth or ferratures. The flower more narrow is smaller, tinged with red on the outside, and the *leaves* are smooth.

39. A. helloboreiflora. Hellebore-leaved Anemone. De Cand. n. 38.—"Leaves pedate; leaflets smooth, rather coriaceous, three-cleft; wedge-shaped at the base, and somewhat stalked; lobes ferrated, acute. Involucral ones all three-leaved, nearly fcelle. Germs smooth."—Gathered by Dombev, near Huaza-Huaza, in South America. A handfolme very distinct species. *Root* round, rather thick, with numerous fibres. *Radical leaves* numerous, on hairy flaths three or four inches long. *Flower-flame* round, hollow, twelve or eighteen inches high; its first branches three or four, long and smooth; secondaries one rather hairy, mostly three-flowered. *Involucral leaflets* rather hairy at their base, three-cleft; their lobes three-cleft, ferrated, acute. *Flowers* white. Petals five, oval. Stigmas short. Seeds fifteen to twenty, oval, smooth, each with a hooked style, crowded upon a hairy receptacle. Sometimes a third *partial involucrem* is found under the flower. De Cand.

40. A. rusciflora. Vine-leaved Anemone. Buch. MSS. De Cand. n. 39.—Leaves palmate, acutely seven-lobed, ferrated; downy and hoary beneath. Involucral ones similar, three or five-lobed, stalked, heart-shaped, two or three together. Petals five, obovate. Germs smooth.—Gathered by Dr. Francis Buchanan, near Semou (not Lamba), and Narainhett, in Nepal, flowering in August and September. The radical leaves, in his own specimens, are from fix to ten inches wide, smooth above, strongly and copiously veined, cut more than half way down, into three principal, pointed lobes, with or two or three more shallow, rounded, and imperfect ones at each side. *Flower-flashes* a foot long, angular, hairy. *Involucral leaves* much smaller, and less lobed; their *flapses* of various proportions; three at the frist subdivision of the tall downy *flower-flame*; two at the upper ones. *Flowers* the size of *A. sirviiflora*, white; externally silky, reddish, and strongly ribbed. *Seeds* numerous, covering a globular *receptacle*, interpersed with long, white, woolly down. This species is remarkable for the great size, and white downy backs, of its *leaves*, some of which rival those of *Rhabd osoratus* in dimensions.

41. A. rusciflora. Water Anemone. Buch. MSS. De Cand. n. 40.—Leaves ternate, hairy on both sides; leaflets wedge-shaped, three-cleft, notched, and sharply toothed; involucral ones fcelle, deeply three-lobed, pinnatifid, cut. Petals five, ovate.—Native of the moist banks of rivulets in Upper Nepal; gathered by Dr. Buchanan, near Chitlang, April 1802. Root rather woody, as thick as the thumb. *Radical leaves* numerous, three inches broad, on hairy flaths from four to eight inches long. *General involucrem* one three, larger, more elongated and pinnatifid; *partial two*, with still narrower lobes. *Flowers* half the size of the last, white; purplish and hairy beneath.

43. Wild. et De Cand. (A. junce covidulata; Linn. Sp. Pl. 763. Ranunculus orientalis, aconiti lycoctoni folio, flore magno albo, vel purpuraceante; Tourn. Cor. v. 2. 106, with a plate.)

44. monantha. De Cand. (A. dubia; Bellard. App. Pl. Pedem. 26. t. 5; (not 232. t. 7.)

Radical leaves slightly hairy, in three or five, very deep, wedge-shaped segments, with many, unequal, linear-lanceolate lobes. Flowers umbellate.—Found in mountainous pastures, especially on a calcareous soil, almost throughout the northern hemisphere; in the Pyrenees and all the alpine countries, in Siberia, Caucasus, Cappadocia, as well as in Canada, and on the north-west coast of America; but not in Britain, Greece, nor the Archipelago, as far as we have any information. It flowers early in Summer, and is of an elegant appearance, though seldom seen in gardens. The *umbel* of pure white flowers, with obovate petals, occasionally tinged, especially underneath, with purple, readily distinguishes this species. The *involucrem* is fcelle, divided like the *leaves*, and like them hairy on both sides, but not particularly so at the edges. The *germs* and broad *seeds* are quite smooth. Tournefort’s plant, our *s*, is a very flight variety, with a more dense *umbel*. We know Dr. Bellardi’s *A. dubia* merely from his figure, for he himself never saw more than one specimen; but we concur with professor De Candolle, who appears to have occasionally seen a two-flowered specimen, in making it a variety. Concerning the two Siberian plants, to which De Candolle alludes, as possible varieties of *nartciflora*, we have not materials to form any opinion; nor were those with which he was furnished quite satisfactory.
A. umbellata. Fringed Umbellate Anemone. Willd. n. 28. De Cand. n. 42. (A. falciculata; Vahl. Symb. v. 3. 74, excluding the synonym. Ranunculus orientalis, napelli folio langinifo, flore albo; Tourn. Cor. 20.) — "Radical leaves in three or five, very deep, three-cleft, entire, densely fringed segments. Flowers umbellate. Gathered by Tournier, on the mountains of Cappadocia. De Candolle, who examined his original specimen, describes the radical leaves as consisting of numerous deep segments, which are three-cleft, acute, with entire lobes, whole margins are densely fringed, with very long, white, clove-preffed hairs, such as occur on the footstalks, scarcely two inches in length. Flower-stalk a palm in height, with similar, but more scattered, hairs. Involutural leaves deeply three-cleft; their lobes entire, chiefly hairy at the edges. Partial footstalks two or three, simple, longer than the involucrum, Petals five, white, oval, obtuse, externally hairy. We have Siberian specimens, probably such as M. Patrin communicated to De Candolle. Thee answer to his description of the hairy-edged leaves, but seem to us not specifically distinct from nemorofus, with which they agree in size, and in certain pale glands, between the segments of the leaves, peculiarly visible in these Siberian specimens, though not noticed by authors in any. We suspect that these specimens may prove the identity of A. umbellata and nemorofus.

A. sibirica. Siberian Tawny Anemone. Linn. Sp. Pl. 763. De Cand. n. 43. Willd. n. 13. (A. n. 41; Gmel. Sib. v. 4. 199.) — Leaves deeply three-lobed; lobes wedge-shaped, in many deep, linear-oblong, blunt-tipped, fringed segments. Involutural ones similar, on short footstalks, partly notched. Flower solitary. Petals fix. orbicular. Germs smooth. — Native of Siberia, from the river Yenifyley to the country beyond the lake Baikal. Gmelin. That author says not a word more concerning the plant in question. One of his specimens is in the Linnean herbarium, and appears evidently allied, in the general nature of its foliage, as well as the smooth germen, to the two last-described. The footstalks and the flower-stalk, which is only four inches high, bear many, long, scatted, spreading, tawny hairs. The flower is an inch and a quarter broad, with orbicular spreading petals, longer than the involucrum, and, as far as can be judged from a plant so long dried, they appear to have been yellow, or orange-coloured, resembling a Trollius.

† Species not sufficiently known.

A. Walteri. Walterian Anemone. Pursh n. 5. De Cand. n. 44. (Thalictrum carolinianum; Walt. Carol. 157.) — "Radical leaves palmate, on long footstalks. Footstalk radical, erect, long, single-flowered. Petals five. Root tuberous and fibrous." Walter — Native of Carolina. Mr. Pursh neither found this plant, nor could he meet with a specimen in Mr. Walter’s herbarium; but he considered it as more probably belonging to Anemone than to Thalictrum. Professors De Candolle suspects it may prove akin to A. parvifolia, n. 18.

†† The following synonyms could not be reduced by De Candolle to any known species.

Anemone n. 1, 2, 45, 5, 6, and 9 of Matthiolius; see the Valgrifian edition, v. 1. 563—567, where are figures of the first five, copied in Bauhin’s edition of 1598, p. 460, 461; Dalech. Hist. 442—444; and criticized in Bauh. Hist. v. 3. 409. There are very obscure, and perhaps, as De Candolle observes, fictitious; some of the cuts representing species of Adonis, we should say Papaver, rather than any Anemone.

A. quinta; Camer. Epit. 399, copied in Bauh. Hist. v. 3. 408, 409, by the name of A. ranunculifolius. This seems a confusion of Erinathii, (Helleborus) byemalli, and Ranunculus montanus.

Ranunculus nemorofus, Anemones flore minor; Bauh. Prodr. 95. — Found at Montpellier; but not known to Magnol.

A. folio aconiti, radice papucale, flore ex purpura albicate; Bauh. Hist. v. 3. 407, no figure. — Found on funny hills near Warfaw.

A. folio multiplicitato bifurto, flore quadrifido, rubro, albo, carulo; Bauh. Hist. ibid. — Native of Italy, Scholla, and the Morea.

A. Anguillare lutea quadrifoliis, folis multifidis; Bauh. Hist. v. 3. 408. — Native of Apulia.

A. lutea Ranulphi; Bauh. Hist. ibid. — Found about Aleppo.

Pulifilla flore obsiolo, caule nudlo; Breyn. Cent. 1. 135; Rauv Hist. v. 1. 636. Plak. Almag. 308 (not 39). — Found in the Caucasus mountains, flowering in May. Ray suspects this to be a monter.

P. orientalis tenuifilme divisi et villoso, flore rubro; Tourn. Cor. 20.

A. stemmenis; Scop. Ann. Hist. Nat. 2. 54. — Native of mount Feudo, in the Tyrol. This seems, by the author’s description, to belong to A. alpina, as M. De Candolle suspects. We do not understand the reference of the latter to Fl. Aurif. v. 1. 241. There is nothing to the purpose in that vol. and page of Jaen. Fl. Aurif. nor in Scopoli’s own Flora Carniola.

For A. Hepatica, Linn. Sp. Pl. 758; see Hepatica hereafter.

ANEURISM. Subsequently to the period when the article Aneurism was inserted in the early part of this Cyclopaedia, many new and valuable observations have been made upon the subject; and the success of operations for the cure of the disease have been proved in a manner which has surpassed the expectations of the most sanguine. The first great improvement in this branch of operative surgery was unquestionably that of not opening the tumour itself, but cutting down to the vessel at a certain distance from the disease, and there applying the ligature fo as to impede the flow of blood into the aneurismatic sac. The removal of the swelling was then left to the gentle and gradual action of the lymphatics; a process infinitely safer than the violent and painful proceeding of laying open the large tumour with a knife, extracting the coagulated blood, and leaving an ample cavity to suppurate. But these were not the only objections to the old method of operating; for the sac was opened, and the artery tied in a situation where its coats were actually in a diseased state. Hence the ligatures mostly failed in their effect; the vessel did not undergo favourably the
the adhesive inflammation by which it was to be closed; and the patient frequently either lost his life by hemorrhage, or was rescued by the performance of amputation under the worst and most disadvantageous circumstances. The genius of a Hunter was soon struck with the defects of the former plan of operating, and instead of meddling with the tumour itself, and tying the artery in a place where it was in a morbid condition, this distinguished surgeon conceived that it would be far better practice to tie the vessel where it was more likely to be found, viz. at a point some way from the diseacae towards the heart. Thus in the palpital aneurism, he avoided the painful operation of laying open the swelling in the ham, and more skilfully and scientifically took up the femoral artery itself in the middle of the thigh. From this important innovation, all the successes which has characterized this department of modern surgery has unquestionably been derived. By extending the same principles to other cases of aneurism, and putting due confidence in the competency of the collateral and anastomosing vessels to carry on the circulation, some of our present surgeons have devised and practised operations for the cure of such aneurisms, as a few years ago would have been abandoned as hopeless and inevitably fatal. Not only have the carotid, the external iliac, and the subclavian arteries been repeatedly tied with the most successful result, the internal iliac itself, whose situation seems to render it almost inaccessible to the instruments of the most skilful operator, has now had a ligature put round it in two memorable examples, one of which we have already noticed in the article SURGERY. The other operation was performed by Mr. Atkinson, of York; the case being a gluteal aneurism, the same kind of diseaee for which Mr. Stevens operated at Santa Cruz. The patient, whose name was Thomas Cuff, aged twenty-nine, presented himself at the York county hospital, April 29, 1817. He was a tall, strong, active hargeman, not corpulent, but very muscular. He was enduring great pain from a large, rentent, pulsating tumour, situated under the gluteus of the right side, an obvious aneurism. It had existed about nine months, and was the confluence of a blow from a stone. In a consultation with Dr. Lanfon and Dr. Wake, the necessity of the operation was determined upon, and it was performed on the 12th of May, without any material difficulty or interruption, except what depended on the aneurism-needle not being pliable enough, and what was the consequence of the division of, and bleeding from, the small muscular arteries. Having got command of the internal iliac artery within the pelvis, which, says Mr. Atkinson, required the complete length of the fingers to accomplish, the vessel was tied. Sufficient proof of its being the identical artery was repeatedly obtained, by the pressure upon it, dropping the pulsation in the tumour. Dr. Wake, Mr. Ward, and all the pupils, were quite assured of the circumstance. The artery being then tied, the pulsation of the swelling entirely ceased. The patient went on tolerably well for some time after the operation; the pulse never exceeded 130, and, after a time, sunk to 85 or 90. He became exhaunted, however, partly by the discharge, and partly by hemorrhage, and died on the 31st of May, about nineteen days after the operation. It is to be regretted, that some essential particulars are omitted in the narrative of the case, especially those respecting the exact parts divided in the operation, and the place of the external incision; yet, on the whole, whoever reads the account can, we think, entertain no doubt about the important fact, viz. that the internal iliac was actually tied. See the Med. and Phyf. Journ. vol. xxxviii. p. 267.

Although this operation did not succeed like that executed by Mr. Stevens, the record of it is highly interesting, as tending to dispel the doubts which have been entertained about the practicable nature of the proceeding. Even the aorta itself has now been tied in the human subject. Of course, the circumstances which justified such a bold proceeding were desperate in the extreme, nor could much hope of the patient's life be indulged; yet, as it was the only thing from which a possibility of preservation could be derived, we think, notwithstanding its failure, much credit is due to the enterprising surgeon who performed it. We shall introduce a few particulars of the case in another place. See AORTA.

In the article ANEURISM, in the early part of this Cyclopædia, will be found some observations tending to make the reader imagine, that this disease arises from such a kind of weaknees as may be supposded to arise from the division of the outer coat or coats of an artery. We therefore take this opportunity of correcting the statement, since it has been fully proved by the experiments of Hunter, Home, Scarpa, &c. that aneurism never originates from this cause; and that even stripping off the external coat of the vessel will not give rise to such an effect.

With respect to tying the subclavian artery for the cure of auxiliary aneurisms, we ought to have remarked, that the operation, as performed by making an incision above the clavicle, has never had a successful result in this country; but, from a communication lately made to the Medical and Chirurgical Society of London, such an operation appears to have been recently executed with complete successes by Dr. Poll, of New York. We believe this to be the only influence in which this mode of operating has cured the diseaee, and saved the patient's life. The artery, however, has been several times taken up in this way in London; but the operation was practised by the late Mr. Radcliff, and again by Mr. Thomas Blizard; but their patients did not recover. The particulars of Dr. Poll's case are inserted in the Medico-Chirurgical Transf. vol. ix. p. 185, &c.

ANGAR ISLAND, in Geography, an island of the Persian gulf, somewhat larger than Ormuz, and equally barren. It is now uninhabited, but presents traces of former population in the ruins of a considerable town, and many reservoirs for water. It has two wells and a stream of good water, is covered with fields of salt and metallic ores, and also a soft, rocky sublunance resembling lava: its hills, which are overgrown with thistles of foylers and other fish, abound in wild goats, rabbits, and partridges. It forms an excellent harbour, which has been recommended for a settlement.

ANGELO AMERIGI, &c. 1. 7. 1. Domenicing; 1. 17. after life, add—The master-piece of all his works, viz. the Entombing of Christ, is now in the Louvre at Paris.

This is one of those curious genera of ferns, which like Danaea, Gleichenia, and Marattia, (see those articles) bear their capsules on the back of the leaf, or frond, without either a ring or involucrum. In the present instance, indeed, those capsules are not of many cells, like those of Danaea and Marattia, but as perfectly simple as in Osmunda already described, or Botrychium hereafter to be
be mentioned. They are, however, not dispersed, or irregularly placed, but compose oval maffes, of twelve or more capsules, which maffes are ranged side by side, in a dense uninterrupted line, near the margins of each leaflet of the frond, a vein from the mid-rib running along the base, or insertion, of each maffe, between its two rows of capsules. That these maffes are determinate afflemblages of capsules of an appropriate figure, is evinced by their having at each end a solitary transverse capsule, completing the oval outline, which is not perfectly expressed in Dr. Swartz's figure. The genus is, doublets, very distinct; and as its present name is not only faulty, but unmeaning, it would be well if Clementea, in honour of an able cryptogamic Spanish botanist, Don Simon de Roxas Clemente, had been retained. We should certainly now, without erasure, have restored it, were there not several other names of ferns, composed of tierea, which must stand or fall with Angiopteris.

1. A. sexta. Tall Angiopteris. Hoffm. Comm. Gott. v. 12. 29. t. 5, excluding the synonyms, except Forster's. Swartz Syn. Fil. 166. 395. Wil. n. 1. (Polypodium erectum; Forst. Prodr. 81. Clemente palmiformis; Cav. Lec. 55.)—Native of the Society Isles, and of Maria's islands. We have an Ohiotea specimen from Mr. Menzies. The main ftem is said to be arborecent, five feet high, and a span in diameter. Fronds fix feet long, doubly pinnae; leaflets from two to four inches long, opposite, fiddle, linear-lanceolate, taper-pointed, smooth, as well as their common falk; their margins finely crenate, the point terraced. Capsules brown, smooth, very numerous, scarcely larger than grains of sea-feed.

**ANG, ANG**

**ANGLE, RECTILINE, l. 2, for l. r.**

**ANGLE at the Periphery, for l. r. II.**

**ANGOY, See Goy and Loango.**

**ANGRA, l. t. r. Terceira.**

**ANGUILLA, For MITTS r. MYRUS.**

**ANGUILLARIA, in Botany, a genus dedicated by Mr. Brown, to the memory of LUIGI ANGUILLARA, (see that article,) apothecary, in the university of Padua, to the Venetian republic, who left an Italian work on the Materia Medica, which has been published at various times, and translated into Latin. Haller speaks of his author as deeply learned in this subject, and perhaps the best Italian botanist of the earlier part of the sixteenth century, having travelled in Europe and the Levant, and studied critically the writings of those who had gone before him. Gartner has called a genus *Anguillaria*, from the singular appearance of its embryo, resembling an anguilla; but this is the ARDIA of all authors at present. (See that article.)—Brown Prodr. Nov. Holl. v. 1. 373.—Clafs and order, Hexandra Trigynia. Nat. Ord. Trifolitidae. Linn. Junei, Juff. Melantherce, Brown.**

**Gen. Ch. Cal. none, unles the corolla be so called.**

**Cor. Petals fix, lanceolate, inferior, spreading, equal, deciduous, each furnished with a claw. Stame. Filaments fix, inserted into the base of each petal, awl-shaped, shorter than the corolla; anthers oblong, peltate, reverted. Pijf. German superior, oblong, furrowed; styles three, spreading, shorter than the stamens; filaments acute. Peric. Capsule ovate-oblong, naked, of three cells and three valves, the partitions from the middle of each valve. Seeds numerous, nearly oblongular.**

**Eff. Ch. Calyx none. Petals fix, equal, falked, deciduous. Stamens inserted into the claws. Stigmas acute. Capsule of three cells, with many seeds.**

**Obf. Anguillaria is nearly akin to ORNITHOGLOSSUM. (See that article.) It consists of herbs, exactly resembling the Cape species of Melanthium, especially in their leaves and roots. The flowers are sometimes dioecious, or polygamous. The claw of each petal is, in some instances, marked with a double gland. A. indica, in habit, colour of the flowers, the perfectly deciduous corolla, and perhaps the situation of the embryo, differs from the rest; can it be a distinct genus? Brown.**

1. A. dioica. Dioecious Anguillaria. Br. n. 1.—

"Flowers spikèd, dioecious. Claws of the petals somewhat fribled at the upper part."—Observed by Mr. Brown, at Port Jackson, New South Wales, as well as in Van Diemen's island.

2. A. biglandulosa. Glandular Anguillaria. Br. n. 2.—

Flowers united. Spikes few-flowered. Claws of the petals with two glands at the upper part. — Sent from Port Jackson, by Dr. John White, where also it was gathered by Mr. Brown. The ftem is solitary, from four to six inches high, simple, round, bearing two dilatant, linear, smooth, recurved leaves; sheathing inflated, and broad at their base. Spike solitary, terminal, zigzag, of from three to five pale, perhaps yellowish, flowers, half an inch broad, each claw bearing a semi-lunar, glandular, prominent, dark-coloured glandular spot.

3. A. uniflora. Single-flowered Anguillaria. Br. n. 3.—

Stam. single-flowered. Leaves lax, with hooded sheaths.**

4. A. indica. Indian Anguillaria. Br. n. 4. (Melanthium indicum; Linn. Mant. 1. 226. Wil. Sp. Pl. v. 2. 268.)—Stam with few flowers. Partial falks longer than the petals; the side-ones having a collateral leafy bract. Leaves straight, with tight sheaths. — Native of Tranquebar and Pondicherry, as well as of the tropical part of New Holland. Root bulbous. Stem from fix to ten inches high, simple, erect, smooth and slender. Leaves two or three, linear, taller than the stem. Flowers terminal, usually two or three, one much earlier than the others, on angular falks, with lanceolate bractees various in size and number. Petals narrow, of a dark dull purple, as well as the fyles, which are dilated and revolute. Capsule elliptical, crowned with the permanent fyles.**

**ANGUIS, l. 9, dele which fie respectively, and add—See SERPENTES.**

**ANGULO, in Botany, named in honour of Francis de Angulo, a Spanish naturalist, of whom or his works we have no information. — "Ruiu et Pavon Prodr. Fl. Peruv. et Chil. 118. t. 26." Swartz Orchid. in Schrad. Neues Journal, v. 1. 89.—Clafs and order, Gynandra Monogynia. Nat. Ord. Orchideae.**

**Gen. Ch. Cal. Perianth superius, revered, antheridia Monogynia, or ovato-lanceolate, concave, converging leaves. Cor. Petals two, resembing the calyx, but rather narrower. Nectary a lip shorter than the calyx, falked, pitcher-shaped, somewhat bell-shaped, split longitudinally at the inner side, two-lobed; lobes rounded, reflexed at the margin; having in the notch in front a small, lanceolate, reflexed segment; in the posterior part another, tongue-shaped, concave, erect appendage. Stame. Anther a vertical, lance, hemispherical, incumbent lid, pointed in front, of two cells, deciduous; maffes of pollen two, globular. Pijf. German inferior, cylindrical; style erect, gibbous, three-toothed at the top, the middle tooth with three points; stigma transverse, in front. Peric. Capsule with fix angles, three of them larger than the rest, of one cell, and three valves. Seeds numerous.**

**Eff. Ch. Calyx reversed, converging. Petals rather narrower than the calyx-leaves. Lip falked, pitcher-shaped, two-lobed, shorter than the calyx. Anther a deciduous lid.**

1. A.
ANHEDRITAE.—See Mineralogy, Addenda.

ANJENGO, l. ult. N. lat. 8° 30'. E. long. 76° 49'.

Gen. Ch. Cal. none, unless we take the corolla for such. Cor. of one petal, superior, tubular, externally clothed with compound hairs; tube curved, rather swelling upwards; limb in fix deep, irregular, lanceolate, acute, unequal segments, much shorter than the tube, directed upwards; the two lowermost largest and most spreading. Stam. Filaments fix, awl-shaped, inserted into the mouth of the tube, shorter than the limb, opposite to its segments, and having a similar direction; anthers linear-oblong, erect, burfting lengthwise in front. Pij. Germen inferior, oval; style thread-shaped, ascending, on a level with the flaments, deciduous; stigma undivided, tumid. Peric. Capsule nearly spherical, of three cells and three valves, crowned with the permanent corolla, burfting at the fummit. Seeds numerous, angular, inserted into the inner angle of each cell.

1. A. rufoa. Reddish Anigozanthus. Labill. Voy. as above 441. t. 22. Nov. Holl. v. 2. 119. Brown n. 1.—“Stem permanently downy. Anthers pointless.”—Native of New Zealand, in dry fandy deserts, where it flowers in December. The stem is two feet or more in height, round, moist downy in the upper part; somewhat leafy below. Leaves linear, acute, narrow, entire, finely fbrbrous. Panicle corymbose, downy. Flowers externally covered, like the whole of the panicle, with reddish, branched and tufted hairs. Their partial flanks are short. Labillardiere’s figure represents the anthers with a point, but not an incised one. Nothing is recorded concerning the colour of the inflow of the flower. The flaments appear to be dilated at the base. Brown.

2. A. flavida. Ruffet-green Anigozanthus. Br. n. 2. Ait. n. 1. Redout. Lilac. t. 176. Curt. Mag. t. 1151. (A. grandiflora; Salt. Parad. t. 97.)—“Stem and leaves very smooth. Down of the panicle deciduous. Anthers with a little reflexed point.”—Observed by Mr. Brown on the south-west coast of New Holland. We rely on that gentleman for the above specific characters; otherwise we should, like Mr. Ker, have scarcely considered these two plants as distinct. The present is said to have been sent to Kew by Mr. Good, in 1803. It was raised from seed, in Mr. Vere’s garden, by Mr. Aderon, now of Chelsea, who found it required merely to be protected from frost, and flowered during most part of the summer. The leaves are sword-shaped, much broader than the foregoing. Flowers, according to Mr. Brown, smaller than in that species. They seem to be two inches long, externally green, covered with red, tufted, branched hairs, as well as their footstalks; inside of the limb smooth, dull purple. Anthers red on one side, yellow on the other, not repreffed with so much of a point in the Botanical Magazine, as those of the fift species in Labillardiere’s figure. We have seen no specimens of either. M. Redouté has detected the fame specific marks as Mr. Brown, and is the author of the above name. He had specimens of both from his friend Labillardiere, and on minute examination determined them to be most probably distinct. The flowers of A. flavida are smaller than in his figure than in the Botanical Magazine.

ANIMAL FLOWER, l. ult. See Calendula.

Eff. Ch. Calyx tubular, five-cleft, with ten furrows. Upper lip of the corolla smallest, undivided; lower three-cleft, middle segment two-lobed. Stamens prominent, ascending. Anthers of the shorter ones with two adjoining cells; often the longer ones halved, or difflaminate. Seeds smooth.

Downy herbaceous plants, growing within the tropick. Leaves crenate. Flowers whorled, with minute bractes. Calyx glandular. Corolla purple. The genus is akin to Ajuga and Teuerum, but sufficiently distinct from both one and the other. The upper lip of Ajuga is extremely short, and has a small central notch. Its anthers are observed by Mr. Brown to be uniform, kidney-shaped, of only one cell; and the seeds reticulated.

1. A. mokohata. Mukly Anisomeles.—Leaves ellipticall, downy and hoary like the stem. Flowers few in each whorl. Calyx greyish, with conspicuous glands.—Gathered by Mr. Brown, as well as the two following species, in the tropical part of New Holland.

2. A. inodora. Scentleaves Anisomeles.—Leaves ellipticall, nearly smooth; dotted beneath. Whorls remote. Calyx green, with conspicuous glands.

4. A. ovata. Broad-leaved Anisomeles. Brown in Ait. n. 1. (Nepea indica; Linn. Sp. Pl. 799, excluding the synonyms. Willd. Sp. Pl. v. 3. 57. Ballota diofita; Linn. Mant. 83. Ait. ed. 1. v. 2. 304. Willd. Sp. Pl. v. 3. 108. Marrubium odoratifolium, betonica folio; Burm. Zeyl. 153. t. 71. f. 1.)—Leaves ovate, or somewhat heart-shaped, strongly crenate or serrated. Whorls many-flowered. Bracteas linear. Calyx hairy; with scarcely visible glands. Native of the East Indies, from whence it is said to have been imported by the first earl of Bute, in 1753. The plant has hardly perhaps been preferred in the flowers, being an annual, of no great beauty, however interesting to the curious botanist. The whole herb has a velvet-like softness, owing to its fine, short, soft, deprefed hairs; its habit and fize very like our Ballota nigra. The leaves sometimes very much refeeme the foliage of the common Urtica diofita, in fize, fhape, and ferratures, but are often rather crenate than ferrated. Whorls for the most part crowded into thick, partly leafy, spikes. Calyx very curiously reticulated with copious transverse veins; its teeth large, broad, pungent. The short upper lip of the corolla did not escape Linnaeus, who found thereon his specific character of this plant, as a Nepeta. His herbarium
herbarium proves Mr. Brown's suspicion to be correct, of *Balboa diffusa* being the same plant. The seeds well answer to the generic character of *Anisomeles*, being beautifully polished, elliptical, of a shining black.

These plants, at least the three New Holland species, seem most allied to *Teucrium Iva* and *falsioflorum* of Linnaeus, now removed to *Ajuga*. The mushy odour of the first species is found in *Ajuga Iva*, whence a singular variety of that plant, with regular flowers, being taken by Forskall for a new genus, received the name of *Moscharia*. (See that article.) The elliptical form of the leaves in *Anisomeles majhope*, rare in this natural order, agrees nearly with the *Linnaean Teucrium Laxmanni*, which is likewise an *Ajuga*. See *Teucrium*.

Eff. Ch. Calyx of two lax, membranous, ribbed, equal valves, fingle-flowered. Corolla flaked, of two valves; outer cylindrically involute, three-awned at the top, the middle awn twined, the lateral ones bristle-shaped; inner longer, unawned.

1. *A. avenacea*. Oat-like *Anisopogon.—*Native of the neighbourhood of Port Jackson, New South Wales. A grass three feet high, resembling an *Avena*. (See that article.) Stems unbranched. *Leaves* involute, with a fringed *filipula*. Panicle loose. *Calyx-glumes* large. The outer valve of the corolla is filky, connected with the stem by an obcolete joint. A small bristle, at the base of the inner valve, indicates this genus to be more strictly allied to *Dantionia*, (see that supplemental article,) than to *Aristera*, which latter the reader will find in its proper place.

**ANKER, As—*An anker of brandy contains 10 gallons.* It is also a liquid measure not only at Amsterdam, but at Copenhagen, Hamburg, and other places. (See Vat.) At Copenhagen, a fuder of wine contains 2 pipes = 4 ox-hoats = 6 shns; the ahm or tierce being = 4 ankers = 40 flubgens = 778 kannes = 155 pots = 620 poees. A fuckle or is = 7/8 ahm = 30 ankers: 32 pots hold the weight of a Danish cubic foot of water, each being 64 Danish inches high, 34 ditto wide, and containing 65 cubic inches; 55 Danish pots, or 27¼ Danish kannes = 14 English gallons, and an ahm = 30¾ gallons nearly. The ahm at Hamburg is the sixth part of the fuder, and is 4 ankers = 5 emers = 20 viertels = 40 flubgens = 160 quarters = 320 ocelli. See Measure.

**ANN, Queen, in Geography, a county of Maryland, containing 16,048 inhabitants, of whom 6381 are slaves.

**ANN, a money of account in India. See Rupee.

**ANNAPOLIS ROYAL, l. 13, for fem r. item.

**ANNARUNDEL, l. 4, r. 26,668; l. 5, r. 12,693.

**ANNONA, in Botany, (see our former article,) is a name of barbarous origin, made into Latin by Linnæus, in allusion, as he tells us in Hort. Cliff. 222, to the value of the fruit, as yielding a grateful harvest or crop, *annona*, to the people where it grows. *Anona* is generally supposed to have been the original word, and is accordingly retained by the French school. But by Baulin’s Pinax, *Annona* appears to have full as authentic claims, on the score of priority, as *Anona*. The latter is moreover a Portugeze corruption of the original *Anon*, which Clusius taking from Oviedo, makes *Anon, Anonas*. *Anon, e*, is very incorrect. We trust our learned friends in France will not infilt on such an inaccuracy, any more than on their great countryman Plumer’s name, *Guanaeus*, which they have commendably rejected, though of older authority than Linnaeus or Jussieu.—*Linn. Vol. XXXIX.*

Eff. Ch. Calyx in three, more or less deep, concave, somewhat heart-shaped, papilhous lobes. Petals fix, thickish, the three innermost smaller or wanting. Anthers numerous, nearly fefile, covering the receptacle; angular and dilated at the summit. Gernons numerous, coalescing into a single fefile berry, whose coat is either tubercular, ficaly, or reticulated, the internal fufbance pulpy, furrounded with numerous, fingle-feended cells. *De Candolle.*

N.B. In our former article, line 12, read (or a compound berry, as in *Rubus*.)

The species are trees or shrubs, whose bark is often rctlicated, glandular, and aromatic. *Leaves* undivided, sometimes besprinkled with pellicuid dots. *Flower-starks* either axillary, or opposite to the leaves, often solitary, bearing one or more flowers, sometimes accompanied by small bractes.

Obi. Very rarely the calyx has four lobes. The inner petals are occasionally imperfect.

Twenty-four species are defined by *De Candolle*, but of these five are marked as imperfectly known. They are disfigured in five sections, by the shape and consistence of their petals.

**Sect. 1. Petals concave, thick, rather coriaceous, either heart-shaped or ovate.** Eleven species, subdivided as follows: *a* Outer petals acute; inner ones obtuse, and rather smaller. Sp. 1—4. *b* Outer petals obtuse. Sp. 5. **c** Petals all acute; inner ones rather the smaller. Sp. 5—11.

A concise view of the species will be sufficient, following the numbers of *De Candolle*.

1. *A. muricata.* (See *Annona* n. 1.) Linn. Sp. Pl. 756. Jauc. Obs. t. 160, t. 5. (Zuurfaack; Merian Surin. t. 14.)—Leaves ovato-lanceolate, smooth, somewhat sinning. Stalks solitary, single-flowered. Outer petals heart-shaped, pointed; inner obtuse. Fruit armed with feedy pointed tubeicles.—Native of South America and the West Indies. The flowers are large, yellow. *Fruit* as big as a large pear, green, or yellow, much esteemed.

2. *A. purpurea.* “*Dunal Monogr. 64. t. 2.*”—Leaves nearly fefile, lanceolate; rather rubly beneath. Flowers axillary, almost fefile. Outer petals heart-shaped, acute; inner roundish.—Found in Mexico. *Fruit* unknown. Outer petals yellowish-brown; inner purple.

3. *A. Humboldtii.* “*Ibid. 64. t. 5.*”—Leaves oblong, pointed, smooth, slightly dotted. Stalks axillary, solitary, short, fingle-flowered. Outer petals ovate, somewhat heart-shaped, acute; inner bluntish.—Found by Humboldt and Bonpland, in the South American province of Cumara. A shrub. *Flowers* yellowish, dotted with purple and red.

—Native of South America, and some parts of the West Indies. *Outer petals* large, green; inner white. *Fruit* green, shaped like an inverted pear.

flowered. Outer petals obtuse.—Cultivated in Hifpiola. Fruit roundish, tuberculated.

6. A. palustris. (See ANNONA n. 6.) Linn. Sp. Pl. 757. (A. aquatica, &c.; Sloane Jam. v. 2. 169. t. 228. f. 1.)—Leaves ovate-oblong, coriaceous, very smooth. Flowers solitary, flaked. All the petals acute. Fruit reticulated.—Native of the banks of rivers in South America and Jamaica.

9. A. peruviana. Dunal Monogr. 67. Leaves elliptic-oblong, acute, rather coriaceous, slightly decurrent. Stalks axillary, bracteate. Petals all acute. Fruit globose, reticulated.—Found by Humboldt and Bonpland, in bogs about Guyauil in Peru. Flowers yellow; three outer petals marked with a red spot, near the base of the flower.

10. A. Ambotay. Aubl. Guian. 616. t. 249. Willd. n. 13.—Leaves elliptic-oblong, acute; clothed with rusty down beneath. Flowers axillary, solitary, nearly fleshy. Petals acute.—Native of woods in Cayenne. A fruh, eight feet high. Flowers greenish, minute. Fruit not observed by Aublet, who alone seems to have seen this species, flowering in November.

Sect. 2. Outer petals ovate, concave, acute, coriaceous; inner wanting. Fruit not well known, so that the plants of this section are referred to the present genus by their habit only. Two species.

13. A. ficus. "Ibid. 69. t. 5."—Leaves ovate-oblong, pointed; smooth above: silky with rusty down, like the young branches, beneath. Flowers solitary, axillary, flaked; externally rusty. Petals three.—Found likewise in Cayenne, by M. Patris.

Sect. 3. Outer petals linear-oblong, narrow; triangular at the point; concave at the base only; often converging, so as to conceal the organs of impregnation; the inner ones extremely minute. Six species.

14. A. squamosa. (See ANNONA n. 3.) Linn. Sp. Pl. 757. Jacq. Obs. falc. 1. 13. t. 6. f. 1. (Atamaram; Rheede Hort. Malab. v. 3. 21. t. 29.)—Leaves lanceolate, smooth, with pellucid dots. Outer petals somewhat converging. Fruit ovate, scaly.—Native perhaps of South America. De Candolle. Cultivated in both Indies, within the tropics. A tree, twenty feet high, with a pithy bark. Flowers green externally, white within, dotted. Fruit edible, of a pungent taste, and fragrant scent, as big as a large apple; externally green, with tuberculated, scale-like protuberances.

15. A. Forfkalii. De Cand. n. 15. (A. glabra; Forrk. Egypt.-Arab. 102. t. 15. A. africana; Vahl Symb. v. 3. 153. "var. B." Dunal Monogr. 71. A. squamosa; Delile Egypt. 17.)—Leaves elliptic-oblong, smooth, dotted; glaucous beneath. Outer petals oblong, somewhat converging.—Gathered by Forrkahl and by Coquebert in Egypt. Scarcely, in De Candolle’s opinion, different from A. squamosa, but the leaves are thinner and less pointed, more distinctly dotted.

16. A. cinerea. "Dunal Monogr. 71. t. 8."—Leaves elliptic-oblong, almost lancelate, dotted; downy beneath. Outer petals somewhat converging. Fruit ovate, nearly globular, scaly.—Gathered by Ledru in the island of St. Thomas, but perhaps not really wild. The young branches, leaves, stalks, and flowers, are clothed with greyish pubescence. Flowers flaked, two or three together. Fruit not unlike A. squamosa.

17. A. Cherimolia. Mill. Dict. ed. 8. n. 5. Lamarck Dict. v. 2. 124. (A. tripetala; Ait. n. 2. See ANNONA n. 2. Guanabanus Pericée folio, flore intus albo, &c.; Feuill. Peruv. v. 3. 24. t. 17. Trev Ehret. 16. t. 49.)—Leaves ovato-lanceolate, without dots; very finely downy and pious beneath. Outer petals slightly converging; externally downy. Fruit nearly globular, somewhat fleshy.—Native of Peru, or rather perhaps of some warmer country; for Feuille’s speaks of this tree as cultivated there with great care, for the sake of its fruit, which is very wholesome, and much esteemed, though, he adds, one of our pears or plums is certainly worth all the Cherimolias of Peru. The tree is twenty to twenty-four feet high, with pendulous branches. Flowers pale green, with a crimson circle in the middle. Fruit heart-shaped, fleshy and rough, the size of a small apple, being drawn too small in Ehret’s figure. De Candolle says there are three inner petals, though very minute.

18. A. reticulata. (See ANNONA n. 4.) Linn. Sp. Pl. 757. Willd. n. 5; excluding the syn. of Rumphius and Plummer. Jacq. Obs. falc. 1. 14. t. 6. 2. (Anonamaram; Rheede Hort. Malab. v. 3. 23. t. 30. 31. Guanabanus fructu purpureo; Plum. 1c. 134. t. 134. f. 1. not 43. f. 2.)—Leaves oblong-lanceolate, acute, smooth, slightly dotted. Outer petals oblong, rather converging. Fruit ovate, nearly globular, tessellated like net-work.—Native of the West Indies, according to Brunne and Sloane. Rheede speaks of it as only cultivated, not wild, in Malabar. A larger tree than A. squamosa, and with a more disagreeable scent. Petals brown underneath; yellowish-white above, dotted with purple at the base. Fruit the size of a large orange, but more ovate, of a shining yellowish or reddish brown, eatable. Professor De Candolle supposes that several species may be here confounded; and Dunal distinguishes the plant of Jaucquin, from that of Rheede, by the reticulations of the fruit being somewhat pentagonal in the former, more rounded in the latter. Plummer’s seems still more different from both, in having the interstices very convex, each armed with a spine. Dombey appears to have gathered and preserved under this name, in Peru, a species distinguished by broader leaves, not marked with pellucid dots, but with more regular and prominent pinnate ribs. All these points may be cleared up by the acquisition of authentic specimens only, or by observations made on the spot. The history of the whole genus is as yet but a sketch, nor have European botanists materials to fill up the outline.

fasc. 1. 16. Aubl. Guian. 618. (Manoa; Rumph. Amboin. v. 1. 135. t. 45.)—Leaves oblong-lanceolate, smooth. Outer petals spreading at the extremity. Fruit tessellated, with gibbous interlakes.—Native of South America and some parts of the West Indies. Cultivated in the Molucca islands. This is said to differ from the last, in having the interlakes of the fruit tumid, (what then becomes of Plumer's t. 143. f. 1?) its pulp more sciny, and not agreeably flavoured. The leaves also are somewhat narrower.

Seet. 4. Outer petals elliptic-oblong, obtuse; inner smaller, lanceolate, blanched. Calyx large, coriaceous, three-lobed, somewhat bell-shaped. Fruit conical, smooth. Three species.

20. A. glabra. (See Annona n. 8.) Linn. Sp. Pl. 758. Willd. n. 10. (" A. maxima, folius latis, fruticu maximos, luteo, confide, cortice glabro; Cateb. Car. v. 2. t. 64.")—Leaves ovato-lanceolate, smooth. Stalks two-flowered, opposite to the leaves. Fruit conical, obtuse, even. Native of Carolina, according to Cateby. Cultivated perhaps in the West Indies. A tree sixteen feet high, with smooth leaves, much resembling those of a lemon-tree. Calyx reddish externally, of three broad, very short, often abrupt lobes. Petals six, nearly obovate, twice the length of the calyx.

22. A. amplcascuclus. Lamarck Dict. v. 2. 127. Willd. n. 18. (" Dunal Monogr. 76. t. 3.")—Leaves oblong-heart-shaped, clasping the stem, acute, smooth. Stalks axillary, solitary, single-flowered. Found by Commerson in the isles of Mauritius and Madagascar. The leaves are feble; glaucous or purplish beneath, at leaf when dry. Three inner petals rather the smalllet.

Seet. 5. Annona not sufficiently known. Five species.

23. A. aficata. (See Annona n. 9.)—Linn. Sp. Pl. 758. Willd. n. 12.—Leaves oblong, pointed, without dots; downy when young. Native of Ceylon. Linnaeus. A specimene under this name is found in his herbarium, but there is no evidence of its being what he intended in his Fl. Zeyl. nor even in the first edition of Sp. Pl. There are neither flowers nor fruits, nor can we satisfy ofselfs of this specimene being the fame species as the botanists of Tranquebar fend us for A. aficata, which latter agrees best with figuenaofa, n. 14.

25. A. ? uniflora. (" Dunal Monogr. 76.—Leaves oblong, pointed, smooth; glaucous beneath. Flower-stalks downy, hoary, opposite to the leaves. Native of Para, in Brazil. Young branches downy and hoary. Leaves nearly seflies. Flowers opposite to the uppermost leaf on each branch, with one or two orbicular leafy bractes. Calyx in three large, deep, ovate, coriaceous segments, externally hoary. The unexpanded petals appear similar thereto. A beautiful species, but the genus is doubtful. De Cand.

26. A. ? oxyacca. (" Dunal Monogr. 77.—Leaves ovate-oblong, coriaceous, smooth, like the branches, on both sides; polished above. Flower-stalks simple or divided, nearly opposite to the leaves. Gathered in the woods of Guiana, by Mr. Alexander Anderson, whose specimens were examined by preceptor De Candolle in Mr. Lambert's herbarium. A handsome tree, with a small, entirely dry, fruit. Branches smooth from the firt. Leaves two and a half to four inches long. Petals three-lobed! This surely may well be deemed a doubtful Annona.

27. A. africana. (See Annona n. 10.) Linn. Sp. Pl. 758. Willd. n. 14; excluding the synonyms. (A. folius lanceolata pubescentibus; Linn. Hort. Cliff. 222.)—"Leaves lanceolate, downy."—This is recorded in the Hortus Cliffortianus to have sprung up from African seeds. The "habitat in America" is therefore a gross and palpable slip of the pen, in the second edition of Sp. Pl., (it is Attiopia in the first,) which the editors of Linnaeus's writings should have corrected; for such a contradiction of the specific name, might have induced some inquiry. Nothing appears for this species in the Linnaean herbarium. In Hort. Cliff. the branches are said to be rough with minute dots. Leaves ovate, but rather elongated; downy, and in a manner hoary, on both sides, by no means polished.

For other plants which have been referred to Annona, see Orchidocarum, Asmina, and Monodora.

ANOMALY, col. 4. l. 15; for 122,441 r. 122,441.

ANOMATHECA, in Botany, from anomalus, out of rule, and no, a cafe; because the capsule is distinguished by its papillary roughness, from all the rest of the plants of the fame natural order, that have hitherto been examined.—Ker in Sims and Kun. Ann. of Bot. v. 1. 227. Deyandr. in Ait. Hort. Kew. v. 1. 99. Clafs and orders, Triandria Monogynia. Nat. Ord. Enfifae. Linn. 1rides, Julif.

Gen. Ch. Cal. Sheath inferior, of two very small, elliptical, concave, leafy, nearly equal valves. Cor. of one petal, superior, valer-flapped; tube many times longer than the fheet, fraftly, nearly cylindrical, a little dilated at the mouth; limb not quite regular, in fix, nearly equal, obovate, deep fegments. Stam. Filaments three, inserted into the tube, thread-flapped, erect, much shorter than the limb; anthers vertical, oblong, converging. Pifl. German roundifh; style thread-flapped, about the length of the fhamens; fligmas three, deeply divided, with linear, spreading fegments. Peric. Capsule roundifh-ovate, of three cells and three valves, its surface covered with small, papillary tubercles. Seeds numerous, round.

1. A. junca. Cut-leaved Anomatheca. Ker n. 1. Ait. n. 1. (Lapeyrroufia junca; Curt. Mag. t. 66. Gladiolus junca; Linn. Suppl. 94. Thunb. Glad. n. 18. Cap. v. 1. 201, excluding the synonym of Jacquin! Rev. Dourn. Linn. 141. G. polyfachium; Andr. Repof. t. 66.)—Found by Thunberg, in Lange Kloof, at the Cape of Good Hope, flowering from October to December. It flowers in May in our green-houses, where it is not uncommon, being eaily propagated by offsets and by seed. The bulb is ovate. Leaves radical, equitant, fward-shaped, acute, dark-green, marbled, with a deep splitting notch at their inner edge, from the base half way up. Stalk a foot high, being twice as tall as the leaves, round, rather fender, branched, smooth, bearing many foliary, unlimited, slightly ruffg, fids, of elegant, rofe-coloured, fentilefs flowers; the irregularity of whole corolla is evinced by the three lower segments being each marked with a deep red spot, and the middle one being morter-
white at the base. *Capulis* rough, with crowded, glandular, or papillary, protuberances. Mr. Ker conceives *Ixia exigua*, Linn. Suppl. 92, or at least one of its varieties, to be the same plant; but the specimens in the Linnaean herbarium are purely different. They may indeed prove another species of *Anomatheca*, but this can only be ascertained by their *capulis*, which is wanting in all of them. *A. juncea* is certainly *Gladiolus amabilis* of Mr. Salisbury's Prod. 41 (not 4) as appears by a specimen from himself. He was the first author who noticed the peculiar roughness of the *capulis*, which he compares to the *fruit of a Caucoctis*. Few of the more familiar orders can be much more distinct than Jacquin's *G. floribundus*, l. c. Rap. 1. 254, cited by Thunberg, with a faulty reference, in his Fl. Caprilas.

**ANONACEA.** The fourth natural order of the Dicotyledoneae, or Eoxenes, of De Candolle; separated by him from the Compositae of Linnaeus, and answering to the *Anone* of Jussieu, being thus named after *Anona*, one of the chief genera. De Candolle thus defines the order.

**Calyx** of three lobes, very rarely of four. *Petals* five, in two rows, alternate with each other; the inner row sometimes wanting. *Stamens* indeterminate, unconnected. *Germens* indeterminate; very rarely solitary. *Fruit* compound, either separable or combined. *Seed* with internal procels, separating the portions of the albumen.

**Fructification.** *Calyx* inferior, short, permanent, more or less deeply three-cleft, very rarely with four lobes. *Petals* five, inferior, in a double row, alternate with each other, mostly coriaceous, and somewhat resembling an inner calyx, imbricated in the bud, though each row is valvarul in that state; the inner one sometimes larger, sometimes smaller, rarely wanting. *Stamens* numerous, close-prepped, generally covering the hemispherical disk (or receptacle of the flower); filaments very short; anthers nearly sessile, with glandular, quadrangular, occasionally nectareous points; their cells bursting longitudinally, externally, and downwards. *Germens* mostly numerous, crowded closely together, in some instances aggregate or combined, in others, though very rarely, and possibly from abortion, solitary. *Styles* one to each germen, short. *Fruits* as many as the germens, sessile or stalked, sometimes combined, either pulpy or capsular, with one or many seeds, which are ovate, or ovate-oblong, in one or two rows, inserted into the inner corner of each fruit. Their skin is brittle, membranous or crumaceous, having internal, sometimes plaited, procels, either flat or awl-shaped, infusing themselves into the chinks or perforations of the albumen. The latter is flisfy, hard, shaped like the seed, very often bordered with a depremed furrow, accompanied by tranverse pliats, or contiguous perforations. *Embryo* minute, situated in the umbilical region of the albumen. *Cotyledons* short. *Radicle* nearly cylindrical.

**Habit.** Trees or shrubs, with round, often slightly two-ranked, branches, whose *bark* is mostly either reticulated, or warty; the young ones generally downy. *Leaves* alternate, connected with the stem by a joint, either sessile or with short footstalks, simple, almost always entire, or scarcely toothed, with pinnate veins; folded, and often downy, when young. *Stipulas* none. *Flower-flats* mostly axillary, sometimes lateral, or opposite to the leaves, solitary, generally furnished with small *bracts*; they are shorter than the leaves, bearing one or many flowers, and not uncommonly twinned into a hook, some of the flowers being abortive.

**Qualities.** The roots, bark, leaves, and fruits, especially such as are capsular, are acid, pungent, aromatic, and stimulants, often used for feathing. Those fruits which are of a fleshy nature are eatable, and esteemed in tropical climates.

**History.** The *Anonaceae*, being all strangers to Europe, were unknown to the ancient botanists. Calpurn Balthin has scarcely indicated two species, Linnaeus thirteen, Wildenow thirty-six, Persoon forty-four; but Dunal in a most excellent treatise, almost literally followed by De Candolle, defines one hundred and five. Of these, five are natives of the temperate zone in America; forty-leaf of the tropical regions of the same quarter of the globe; eight of equinoctial Africa; three of the Mauritian islands; twenty-six of India or its islands; fix of China and Japan; two of New Holland; and there are fix whole native country is uncertain.

**Affinities.** This order agrees with the Magnoliaceae of the same learned author, in having the parts of the flower disposed in a ternary order, anthers united to the filaments, numerous filaments and piliils; but differs very essentially (according to him) in having no stipeis, and differently shaped anthers as well as seeds. Some few climbing species make an advance towards the Menisperme; but the indefinite filaments, and the structure of the fruit, afford a distinction. The *Anonaceae* differs from all other polypeetal orders, with a superior germen, in the ternary structure of their flowers, as well as in the very peculiar infection of the internal procels of the seed into its albumen. Such a structure was indeed found by Mr. Brown, in his *Eupomatia* (hereafter to be described in its proper place); a genus otherwise very different from the order before us.

The genera enumerated by De Candolle are, *Kadupola* of Jussieu; *Anona* of Linnaeus; *Monodora* of Dunal; *Affina* of Adanson; Porcelia of Ruiz and Pavon; *Usoria*, *Xylopia*, and *Unona* of Linnaeus; and *Guatteria* of Ruiz and Pavon.

**ANOPLOTHÉRIUM, in Natural History, an animal of an extinct genus, whose remains are found in a fossil state in the vicinity of Paris. It is so called by Cuvier, to denote that it was without weapons, having no canine teeth. In the natural system, this animal should be placed between the horse on one side, and the hippopotamus, the pig, and the camel on the other. The remains of five species of the anoplotherium have been discovered. The largest was the size of a small horse; the smallest not larger than a small rabbit. See *Strata* in the vicinity of Paris.

Gen. Ch. Cal. Perianth inferior, of one leaf, in fix deep, acute, equal, spreading segments, permanent. Cor. of one petal, bell-shaped; tube very short; limb in fix deep, equal, concave, obtuse, imbricated segments, much longer than the calyx. *Stamens* fix, awl-shaped, smooth, equal, inserted into the tube of the corolla, opposite to each segment, and about half as long; anthers incumbent, heart-shaped, obtuse, two-lobed. *Pistil* Germen superior, ovate; style short, cylindrical, erect; stigma in two acute lobes. *Pericarp* capsular oblong, of one cell and two valves. *Seeds* numerous, inserted into the margin of each valve, pendulous, imbricated, each crowned with an obovate, obtuse, membranous wing, thrice its own length.

cloven. Capsule of one cell and two valves. Seeds imbricated, pendulous, winged.

1. A. glandulosa. Glandular Anoptherus. Labill. Nov. Holl. v. i. 86. t. 112.—Native of Cape Van Diemen. An elegant slender tree, about thirty feet high, very smooth in every part. Leaves scattered, occasionally opposite, obovate-oblong, serrated, single-ribbed, coriaceous, about four inches long, rather bitter to the taste; tapering at the base; a black prominent gland on the inner edge of each serrature. Clusters terminal, simple, half the length of the leaves, either solitary, or as many as four together. Corolla about the size and shape of Pyrolo rotundifolia; of its colour nothing is recorded. Labillardiere's descriptions having been drawn up from his dried specimens after his return to Europe. Mr. Brown remarks, that the embryo is minute, nearly globose, enclosed in a fleshy albumen; the radicle superior.

Eff. Ch. Calyx in two deep segments; keeled at the back. Corolla none. Style divided. Stigmas two. Seed clothed with the compressed, membranous, two-winged calyx, emarginate at the top and bottom.

1. A. flaccens. Climbing Anédera. (Fegoprynum flaccens, feu Volubilis nigra major, flore et fructu membranaceae, subrotundis, complefis; Sloane. Jam. v. i. 138. t. 92. f. i.)—Native of Jamaica, growing among trees near the ruins of a monastery by the town. Sloane. The stems are twining, round, red, succulent, climbing to the height of seven or eight feet. Leaves alternate, heart-shaped, or somewhat deltoid, succulent, smooth, entire, two inches and a quarter long, on footstalks half an inch in length. Clusters numerous, alternate, many-flowered, axillary and terminal. Flowers orbicular, compressed, green, bordered with a thin white membrane formed of the keel of each calyx-leaf. As the seed ripens, they turn brown. Sloane compares them to parsnip-seed. Swartz feems not to have noticed this plant. Its habit is nearly that of Bafella.

ANTELOPE, vol. 3, 1, 7 from bottom, r. BURBIS or CERVINE Antelope.

ANTHERYLLIUM, in Botany, so named, either by Vahl or Von Rohr, apparently from abscis, an anther, and νος, wood, or materials of any kind, in allusion to its numerous and conspicuous anthers.—Vahl in Mem. of the Nat. Hist. Soc. of Copenhagen, v. 2. 211. Wildi. Sp. Pl. v. 2. 960.—Clas and order, Isocandria Monogynia. Nat. Ord. Hesperides, Linn. Myrti, Juf.

Gen. Ch. Cal. Perianth of one leaf, inferior, in four deep, lanceolate, spreading, permanent segments. Cor. Petals four, inserted into the calyx between its segments, large, obovate, plaited and undulated, with short linear claws. Stem. Filaments numerous, from about thirteen to sixteen, capillary, inserted into the calyx, longer than the corolla, permanent; anthers incumbent, convoluted, furrowed. Pif. German superior, globose; style thread-shaped, very long; stigma capitate. Peris. Capsule globose, obliquely triangular, of one cell, and three, occasionally four, valves, burling at the top and decussate. Recept. globose, somewhat triangular, spongy, dotted with little hollows to receive the Seeds, which are numerous and minute.

1. A. Robbi. Flowery Antheryllium. Vahl as above, 212. t. 8. Symb. v. 3. 66. Willd. n. 1.—Native of the West Indian island of St. Thomas. Van Rohr, and Wli. A tree, with round, grey, scattered, scarred branches; lofty, and somewhat quadrangular, in their upper part. Leaves nearly opposite, flaked, ovate, acute, entire, two inches long, thin, very smooth, with one rib, and many transverse veins. There is a pair of stipulaceous prickles at the base of each footstalk, which disappear from the older branches. Footstalks axillary from the inception of the last year's leaves, from five to eight, fewer on one side of the branch than the other, hardly an inch long, simple, single-flowered, naked, thread-shaped. Capsule downy, the five to seven furrowed. Nothing is recorded of the colour of the flowers, nor of the qualities or use of any part. The habit of the tree is compared by Vahl to the Leguminosae, to which genus he supposes this to be allied. He supposes also some affinity to Aublet's Crennea. See that article.

ANTHOBOLOUS, we presume from abscis, a flower, and βολος, a cast, or lump, the flowers forming little dense tufts.

Akin to Exocarpus and Osyris. (See those articles.) The genus consists of smooth fleshy shrubs, copiously branched, in habit resembling Opysis, the principal as well as the ultimate branches jointed at their inception. Leaves scattered, sessile, articulated with the branch, narrow, nearly thread-shaped, defluente of fipulas. Fower-flanks axillary; the male ones bearing each an umbel of three or four flowers; the female from one to three, jointed in the middle when simple, at the division when branched, and furnished at the joint with two deciduous bractae. Flowers small, yellowish.

1. A. filifolius. Slender-leaved Anthobolus. Leaves thread-shaped, lax, as well as the young branches. —Gathered by Mr. Brown, in the tropical part of New Holland.

Gen. Ch. Cal. Perianth inferior, of one leaf, cut half way down into five equal, erect, acute segments, permanent. Cor. of one petal, wheel-shaped; tube bell-shaped, constricted at the base, twice as long as the calyx; limb about as long as the tube, in five, sometimes seven or eight, very deep, equal, linear-lanceolate, spreading segments. Stam. Filaments four, with the rudiment of a fifth, inserted into the base of the tube, and not above half so long,awl-shaped, simple, smooth; anthers roundish, incumbent. Pif. German superior, oblong; style cylindrical, the length of the tube; stigma capitate, notchlike. Peris. Capsule ovate-oblong, of two cells and two valves, with incurved edges, meeting the parallel partition. Seeds numerous, small, roundish, reticulated.

two cells and two valves, with inflexed edges, and a parallel partition.

A shrubby smooth genus, whose habit announces an affinity to the Solanaceae, but whose regular, deep-cut, radiating corolla, is altogether strange in the Linnaean class Didynamia. The leaves are alternate, tapering at the base, or somewhat flapped, articulated with the branch, thick, sometimes dotted with glands. Flowers axillary, nearly solitary, their filaments minutely bearded, and moiety separating easily at the joint. Corolla white or yellow, handsome; its tube internally striated; limb in from five to eight segments.

1. A. littorea. Yellow Anthocercis. Labill. Nov. Holl. v. 2, t. 19, t. 158. Br. n. 1. — Leaves obovate, without dots, smooth at the edges, as well as on both sides. Young branches smooth. Segments of the corolla longer than the tube. Capsule oblong, twice the length of the calyx. — Discovered by Labillardiere in Lewin's land; and observed in the fame neighbourhood by Mr. Brown, and Mr. Good. The latter sent feeds to Kew in 1803. This is a greenhouse plant, flowering during most part of the summer.

Mr. Aiton favoured us with a specimen in May 1817, when it first began to produce flowers. These are an inch in diameter, inodorous, pale lemon-coloured; the radiant segments of the limb narrow, taper-pointed; the tube fringed internally with deep violet. Leaves about an inch long, abrupt or emarginate; nearly entire in our specimens. Labillardiere says they are sometimes toothed, or ferrated.

2. A. viseosa. Glutinous Anthocercis. Br. n. 2.—Leaves obovate, marked with glandular spots; roughish at the edges; when young finely downy, as well as the young branches. Capsule ovate, about the length of the calyx.

—Native of the southern coast of New Holland. Brown. We have seen no specimen of this species, but from the above account, furnished by Mr. Brown, we presume its flowers to be white, and their limb not longer than the tube.

ANTHODON, a name which seems to allude to the toothed calyx and petals, is applied in the Flora Peruviana, v. 1, t. 45, t. 74, f. 10 to a plant referred by professor Vahl to his Tonsella; see that article, f. 4th.

ANTHOLORA. Labill. Voy. Engl. ed. v. 2, t. 245, t. 41. Nov. Holl. v. 2, t. 121, is certainly the same genus as Bassia. (See that article.) Whether Labillardiere's plant may be the obovata of Forster, or a new species, we have no certain means of knowing.

Gen. Ch. Cal. Perianth superior, in five deep equal segments, permanent. Cor. of one petal, longer than the calyx, irregular; tube slit at the back from top to bottom, and easily separable into five parts, with inflexed edges; limb two-lipped; upper lip in two, lower in three, deep segments, those of the upper lip having an ear-like appendance at their inner margin. Stam. Filaments five, shorter than the tube; anthers closely united into a tubular form. Pistil. Germen inferior, oblong; style capillary, the length of the stamens; stigma large, oblong, enveloped in a bivalve beard, cover, contrary to the lips of the corolla. Pericarp. Capsule of two cells. Seeds several.

Eff. Ch. Corolla of one petal, slit longitudinally at the back; limb two-lipped, its upper segments auricled at their inner margin. Anthers combined. Stigma with a bivalve beard integument. Capsule inferior, of two cells.

1. A. humile. Dwarf Anthotium. Br. n. 1.—Native of the south coast of New Holland. A little smooth, fleshy herb. Leaves radical, almost cylindrical, scarcely dilated at the base. Stalks several, spreading, undivided. Flowers collected in tufts, subtended by leafy bracts. Corolla approaching to a violet colour. Pollen of simple grains. There are two varieties, one almost twice the size of the other, the parts of the flower somewhat differing also in their relative proportion. Brown.

ANTHRACITE. See Mineralogy, Addenda.

ANTIARIS, in Botany, altered by Lefchenault from the name of the famous Poaon-tree of Java, Usps Anisar, which that botanist calls Antiaris tosicaaria, and which Mr. Brown considers as of the same genus with what we are about to describe from his excellent General Remarks, Geographical and Sylleomatic, on the Botany of Terra Australis, p. 70; published at the end of the account of captain Flinders's Voyage, 1814.—Clasf and order, Monococia Tetradria. Nat. Ord. Scabridio, Linn. Uruchs, or Uruchs, Jull. Brown.

Female. Cal. Involucrum single-flowered, ovate, small, smooth, many-cleft at the summit, with lanceolate, fringed, converging, deciduous segments, some of them flatteret over the body of the involucrum: perianth none. Cor. none. Stam. none. Pifi. Germen in the body of the involucrum, oblong, single-fed; style divided, almost to the bottom, its segments thread-shaped, parallel, smooth, divaricated at the upper part; stigmas simple, acute. Pericarp. Drupa formed of the enlarged involucrum, oval, smooth, the size of a small plum, dark purple, internally fleshy and yellowish, containing a white milk. Seed. Nut pendulous, ovate, with a smooth, brown, tenacious crust; kernel without a skin; albumen none; embryo white, of two large, ovate, fleshy, almond-like cotyledons, flat on the inside, rather convex externally; radicle superior, very short.

1. A. macrophylla. Brown as above, t. 5.—Found by Mr. Brown, in barren stony places, on the shores of the Company's islands, adjacent to Arnhem's land, on the north coast of New Holland, in about 12° south latitude, bearing flowers and ripe fruit in February, 1803. A fern, or very small tree, about six feet high, much branched, smooth, milky. Branches round. Leaves alternate, falcate, elliptic-oblong with a sharp point, entire, coriaceous, six inches long and three wide; unequal and slightly heart-shaped at the base; dark-green and shining above; more verdant beneath; with one rib, and many transverse parallel veins. Footstalks roundish, grey, half an inch long. Stipulas intrafolious, lanceolate, pointed, folded, leafy. Flowers flasks axillary, solitary, racemose, scarcely longer than the footstalks, each bearing one or eight alternate flowers, of which one or two of the lowest are female, and earlier than the rest, which are all male.

We presume the A. tosciaaria of Lefchenault, Annales du Mus. v. 16, t. 12, is another species of the same genus; but
but we are not informed of the specific characters of either. Of that celebrated Poison-tree the first satisfactory account, according to Mr. Brown, is there given, which differs from his description above, merely in some particulars relative to the male flowers. He adds that Antirrhis should stand in the Urticace, between Bresinnum of Swartz, and Olmeda of the Flora Peruviana, agreeing with the latter in the structure of its male flowers, and more nearly resembling the former in its female flowers and fruit.

ANTIMONY, in Chemistry. Several important additions have been lately made to our knowledge respecting this metal and its compounds, which we shall briefly notice here.

In describing this metal, we stated that Haiy had been unable to ascertain its primitive crystalline form. This indescribable observer has at length, however, determined that the primitive form of its Crystals is an octahedron, and that its integral particles have the figure of tetrahedrons. The specific gravity of antimony, according to Hatchett, is 6.712. It melts at a low red heat, or about 810° of Fahrenheit; and after this, if the heat be raised, the metal evaporates.

The oxides of antimony have been lately investigated with great care by thenard, prout, Bucholz, and Berzelius. According to Thenard, this metal forms no less than five oxides; according to prout and Bucholz, it forms only two; while according to Berzelius, it forms four. These discrepancies arise from the great difficulty of the investigation. The protoxyd of Berzelius is obtained by exposing antimony to the air, or to the action of a galvanic battery. It is a grey powder. When acted upon by muriatic acid, it is separated into the protoxyd of prout and metallic antimony. Hence Dr. Thomson remarks it is only a mixture of the two. The two oxides of prout are easily obtained, and possess specific characters. Berzelius has shown that the second of them possesses the properties of an acid. The protoxyd of Berzelius is also readily obtained, though it is difficult to free it from water. This likewise possesses the properties of an acid. Hence, says Dr. Thomson, we know three oxides of antimony. The grey protoxyd, the white antimonial acid, and the straw-yellow antimonial acid.

The following is the composition of the protoxyd of antimony according to prout, Berzelius, and Thomson.

<table>
<thead>
<tr>
<th></th>
<th>Prout.</th>
<th>Berzelius</th>
<th>Thomson</th>
</tr>
</thead>
<tbody>

<tr>
<td>Oxygen</td>
<td>100</td>
<td>35.55</td>
</tr>
</tbody>
</table>

The above results of Berzelius and Thomson are rather obtained by calculation than actual experiment, being founded on the supposed composition of sulphuret of antimony, which, according to Berzelius, is composed of 100 antimony and 37 sulphur, and according to Thomson, of 100 antimony and only 35-572 sulphur.

While such discrepancies exist respecting the composition of the oxides of antimony, it is impossible to fix with certainty the weight of its atom. Dr. Thomson, however, it may be proper to state, considers it as 56.25.

The two oxides of antimony, denominated above the antimonial and antimonial acids, are capable, according to Berzelius, of combining with different bases and forming two fets of salts, the first of which may be termed antimony salts, the second antimonates.

The following is the method of preparing the antimonium tartratisatum, or tartrate of antimony and potash, according to the last edition of the London Pharmacopoeia.

Take sulphur of antimony pounded, two ounces; nitrate of potash, one ounce; supertartrate of potash, two ounces; sulphuric acid by weight, two ounces; distilled water, a pint and a half. Mix the acid with half a pint of water in a proper flask vessel, and place it in a sand-bath. When moderately heated add by degrees the sulphuret and nitre previously well mixed together; and then apply heat till the whole of the water is driven off. Wash the remainder with distilled water until it comes off table-faces, and while the mass is yet moist mix it with the supertartrate of potash. To this mixture add a pint of distilled water. Boil the mixture, and when filtered put it aside to crystallize.

ANTONIUS LIBERALIS, in Biography, a Greek writer of an uncertain age, known as the author of Minacoevemae, or a Collection of Metamorphoses, published at Basl, in 8vo., by Xylander, in 1568; at Leyden, in 12mo., by Berckelius, in 1674; by Munckers, at Amsterdam, in 1676; and by Gale, at Paris, 1675, 8vo. This writer is not the same with a Latin rhetorician, mentioned by Jerom. Fab. Bib. Grac.

ANYCHIA, in Botany, so called by Michaus, on account of its affinity to Paronychia. (See that article.) This plant therefore has as little concern with the finger nail, soz, as the other has with a whitlow.—Michaus Boreal.- Amer. v. 1. 112. Pursh 176. St. Hilaire Paron. 98. (Queria; Gærtn. t. 128.)—Clafs and order, Pentadecag Calonia. Nat. Ord. Holeraez, Linn. Amaranth, Jaff. Paronychiz, Julf. Ann. du Muf. St. Hilaire.

Gen. Ch. Col. Perianth inferior, of one leaf, oblong, in five deep, oblong segments, slightly hooded at the extremity, with a posterior point. Cor. none. Stam. Filaments five, sometimes fewer, shorter than the calyx, opposite to each segment and adherent to its base, bristle-shaped, erect, dilated, without any intermediate processes; anthers nearly heart-shaped. Peric. Germin superior, roundish; style one, very short; stigma two, oblong, recurved. Pericapsule roundish, membranous, of one cell and one valve, covered by the calyx, with an orbicular depression at the summit, pointed, separating at length irregularly at the lower part. Seed one, nearly kidney-shaped, smooth, attached by a lateral thread to the base of the pericarp.

This is a genus of diminutive herbs, with opposite leaves, attended by filipulas. Flowers minute, in leafy tufts, each of them felled, like the filipula, Michaus.

1. A. dichotoma. Forked Anychia. Michaus n. 1. Pursh n. 1. (Queria canadensis: see that article, n. 2.)—Stem forked, much branched, spreading. Leaves elliptic-lanceolate, smooth, erect. Bracteas about as long as the smooth calyx.—On dry lime-dome hills, from New York to Kentucky, flowering from June to August. Perennial. Flowers exceedingly small, very variable; generally of five filaments, generally from two to five. Pursh; who quotes Ortega's Des. t. 19; f. 2. a work not in our possession. The root has all the appearance of being annual, as professor Schrader found it in the garden of Gott's gen.

points."—Found by Michaux, on the dry sands of North Carolina. Perennial. Pursh did not meet with this species.

AORTA. In Surgery. As professor Scarpa observes, the whole body may be regarded as an analogous of vessels,—a vascular circle,—and the remark is so true, that even an obliteration of the aorta itself may happen, immediately below its arch, without the general circulation of the blood in the body being stopped. Meckel met with two cases in which the aorta was thickened and considerably contracted, just below its arch; yet in both subjects there was every reason to believe, that the abdominal vasaer and lower extremities had been duly supplied with blood. This fluid, which could only pafs from the heart with great difficulty, and in small quantities, had, by regurgitating, lacerated the semi-lunar valves. (Mém. de l'Acad. Royale de Berlin, 1756, obs. 17 and 18.) A like example is recorded by Storck. Ann. Med., vol. xi. p. 171.

We have a very interesting case of obstrutted aorta related by Monfieur Paris, formerly diffeotor for the Amphitheatre of the Hôtel-Dieu. He injected the body of a very lean old woman, about fifty years of age, whose arterial systen was found to be flightly deranged, and the circle of the blood altogether changed by a complete contraction of the aorta a little beyond the arch. The attention of M. Paris was particularly excited to the condition of this subject by the unaccountable enlargement of the small arteries upon the forepart of the chest. The injection which was employed entered the mouth of the aorta fo readily, that, so far was he from fupplanting any obliteration of this vessel, he could have thrown in more injection than is usually required for filling an adult body. The subject was fo meagre, that, without diffeoting, M. Paris felt the thoracic arteries running down the fides of the chest tortuous and remarkably enlarged. On dilfection, he found the aorta immediately beyond its arch contracted to the fize of a writing quill; the coats of the artery were of their usual thickness, and its cavity of course extremely small; the arch of the aorta above this contraction was but very slightly dilated; the part below had loft nothing of its natural fize.

The carotids were in the natural flate; the artery innominate and the left subclavian were enlarged to twice their natural diameter; all their smaller branches were increafed in the fame proportion, and had affummed a curled and zigzag course. The internal mammary and phrenic arteries were greatly enlarged, and very tortuous. The tranfvers arteries of the neck were of twice their natural fize; their posterior branches were tortuous, extending to a great distance over the back, with long infufcations, which were met from below by the branches of the upper intercoftal arteries, which were also remarkably enlarged. The thoracic and fcapular arteries which run along the fide of the chest were twice their natural fize.

Below the contricted part of the aorta the lower intercoftals were much enlarged, even to three or four times their natural fize. Each of them was dilated; but those were most affected which were given off nearest the contracted part; and the posterior branch of each, which penetrates to the mufcles of the back, was more dilated than that which runs between the ribs. Indeed those posterior branches were so remarkably dilated with contortions so closely successing each other, that they resembled a necklace of beads; and their infufcations with the branches of the tranfversalis arteries were very remarkable. The lower phrenic artery was enlarged, forming considerable infufcations with the superior phrenic. The epigastric artery was dilated to the fize of the enlarged mammary, and was joined with it by very numerous and conspicuous infufcations. Default's Pafific Chir. Journ. tom. ii. p. 197, &c.

In the body of a male subject, two fchromatous tumours were found by Stenzel, situated in the subfultne of the membranes of the aorta immediately below its arch. Notwithstanding these swellings rendered the vessel nearly impervious, the man had the appearance of strength, and of having been well nourished. "Hac corpora facete or magnum a qnatum un rum propemodum extanti editum cordis thalama fguinini spatium praecluderunt." Diff. de Steatomatis Aortae.

Dr. Graham, of Glasgow, has very recently published a still more remarkable case, in which the circulation was carried on for a considerable time through the anaftomoses, notwithstanding a complete obstruction of a part of the aorta. The patient was a lad fourteen years old, who, in consequence of exposure to cold, was affected at first with a dry cough, followed by copious expecoration, pain, and difficulty of respiration. The diifeafe was supposed to be pneumonia in an advanced stage. Dyspnea, palpitations, and pain of the left side, were also the most remarkable symptoms at a later period. The pulse became weak, but was always regular to the very last. The boy at length died, after remaining in the Glasgow Infirmary about five months. On dilfection, together with other morbid changes, the walls of the left ventricle of the heart were found about an inch in thickness; but no other derangement in the structure of the heart, or its valves, was obferved. The aorta was unufually expanded near its origin, so as to form a kind of pouch; but, after having given off the branches to the head and superior extremities, its diameter was preternaturally contracted. It continued of this diminished fize till after its union with the canalis arteriosus, when it became completely imperious. The coats were not thickened, nor in any way diseased, except that about half an inch below the fritirfure there was a smooth elevation on the inner surface, fels raised, but having nearly the diameter of a fplit-pea. In other respects, the appearance was exactly fuch as would refult from tiring a ligature round the a ftery.

The artery then received three trunks, about as large as crow-quals, and near them three smaller ones, when it refumed its natural fize along the vertebra. The three trunks were evidently the uppermost of the inferior intercoftals, the coats of which were remarkably thin, like those of veins. A probe passed from the pulmonary artery along the canalis arterius to the obftracted portion of the aorta; but from the thickenep appearance of that canal, and the flord confluence of the boy during life, probably there had been little communication allowed by means of it between the aorta and pulmonary artery. Dr. Graham, if it appears, did not inject the subject, fo as to demonftrate all the exact channels by which the circulation had been carried on; but he tells us, that the artery innominate, the left subclavian, the superior intercoftals, and the mammary arteries, were much enlarged. The epigastric was reported to be of its natural fize. "These facts, and the aorta acquiring at leasf very nearly its natural fize immediately below the friture, shew that the blood did not pafs to the inferior extremities in any material quantity, as might perhaps have been expected by the infufcations of the
the mammary and epigastric arteries; but chiefly by the communications of the superior intercostals and the mammary arteries with the three large branches entering the aorta below the bifurcition; and of the mammary and thoracic arteries with the diaphragmatic and other intercostals. See Medico-Chir. Trans. vol. v.

If the aorta were obliterated, or obstructed in the abdomen, the blood would find adequate channels for its transfusion in the mammary and epigastric, the superior and inferior meferteric, and the lumbar arteries. Mr. A. Cooper informs us, that he has never met with any instance of the latter description in the human subject. (Surgical Essays, part i. p. 113.) But he has several times applied ligatures to the aorta in dogs, and found that the blood was readily carried by anastomosing vessels to the posterior extremities of the animal. (See Medico-Chir. Trans. vol. ii. p. 249, &c.) The incision was in each experiment made on the left side of the spine; the aorta was drawn to the surface of the skin by an aneurism needle, and being quite separated from other parts was tied. The animals were then kept for a few weeks, and then killed. They were afterwards injected and dissected, when it appeared that the lumbar arteries were considerably enlargeé, so as to be the chief agents of the new circulation.

In those diseases causing obstruction of the thoracic aorta a little beyond its arch, to which we have requested the reader’s attention, no doubt was the cause of a very gradual process, and consequently, the altered course of the blood through the collateral channels would also be established, not all at once, but by degrees. The anastomosing arteries would only enlarge, in proportion as the obstruction in the great artery increased. But in the experiment of tying the aorta in animals things were very different; for the stoppage of the passage of the blood through the tied portion of that vessel was not only effected instantaneously, but also completely, so that the whole office of transmitting the blood to parts beyond the obstruction suddenly devolved altogether to the anastomoses, which had had no time for any gradual and preparatory dilatation. Yet notwithstanding this seeming disadvantage, we find that the blood did pass into the posterior extremities.

The aorta of the human subject, however, has now been tied in the human subject by Mr. A. Cooper, and the following are a few of the particulars of the case. The patient, who was thirty-eight years of age, had on the left side an inguinal aneurism, which had actually burst, and discharged a quantity of blood sufficient to reduce the man to a state of considerable weakness. Another hemorrhage would have carried him off. It was apprehended, that the tumour extended too high up to admit of a ligature being applied to the external iliac artery itself; yet in the hope of being able to dispense with such measures as would be necessary to tie the aorta near its bifurcation, Mr. A. Cooper resolved to try whether it were possible to tie the aneurism artery itself. He made, therefore, a small incision into the aneurism, about two inches above Poupart’s ligament; but he found only a chaos of broken coagula, and that the artery entered the fac above and quitted it below without there being any intervening portion of vessel. The operation was consequently abandoned. “When I was about to withdraw my finger,” says Mr. A. Cooper, “I directed two of the students to compress with their hands the aorta upon the spine, and they succeeded in stopping the pulsation in the artery of the right groin. As I withdrew my finger, I put a dossel of lint by its side, and closed the opening which I had made into the fac.” Surgical Essays, part i. p. 118.

The only other chance of preserving was what might result from tying the aorta itself; and it was determined to adopt the proceeding, bold and unprecedented, as it was in respect to the human subject. A doubtful remedy is always better than none. This ancient maxim in surgery seems to gather strength in proportion to its duration, and is a short but an effectual answer to every attempt which has been made by the ignorant and malicious to throw blame on the distingushed surgeon, whose ardent desire to save the life of an individual was the main-spring of his conduct. Mr. A. Cooper, after enjoining the prudence of emptying the bowels previously to any other similar operation, inflated, that he made an incision three inches long into the linea alba, giving it a flight curve to the left side to avoid the umbilicus. One inch and a half of the cut was above and the remainder below the navel. Through this he made a small aperture into the peritoneum, and introduced his finger into the abdomen. This opening was enlarged with a probe-pointed bistoury to nearly the fame extent as that of the external wound. During the progress of the operation, only one small convolution of intestine projected beyond the wound. The operator next passed his finger between the intestines down to the spine, where he felt the aorta beating with excessive force. By means of his finger-nail, he scratched through the peritoneum on the left side of the aorta; and next gently and gradually passing the finger between that vessel and the spine, again penetrated the peritoneum on the right side of the aorta. Guided by the same finger, he now conveyed a blunt aneurism needle, armed with a single ligature, behind the vessel. After the ligature had been placed, much care was requisite to exclude the intestine from it in drawing it into a noose. The operation being finished, the wound was closed with a quill-future and adhesive plaster.

During the operation the facæ passed off involuntarily, and the pulse, both immediately and for an hour after the operation, was 144 in a minute. An opiate was given, and the involuntary discharge of faeces soon ceased. When the right thigh was touched, the patient thought it was the foot, so that the senibility of that extremity was very imperfect.

The operation had been performed about nine in the evening. At one o’clock the following morning, the lower extremities, which had become cold soon after the operation, were beginning to get warm again, but their senibility continued yet indistinct. At eight o’clock, the right leg was warmer than the left, and the senibility was returning. At noon, the temperature of the right limb was 94; that of the left, or aneurismal limb, 87.7. At six o’clock in the evening, the temperature of the right was 96; that of the left 87. At nine the same evening, the pulse was 104 and feeble, with vomiting, retchings, and an involuntary discharge of facæ. At eleven, the pulse was 100 and feeble, and the vomiting still continued. At eight the next morning, the aneurismal limb appeared livid and felt cold, more particularly around the aneurism; but the right leg remained warm. At eleven the pulse was 120, and the patient seemed to be sinking. In fact, he died eighteen minutes after one in the afternoon, having survived the operation forty hours. On dilacation, no appearance of peritoneal inflammation was found, except at the edges of the wound. The stomac and intestines were free from any unnatural colour. The ligature which had not included any portion of bowels was placed round the aorta about three-quarters of an inch above its bifurcation, and about an inch below the part where the duodenum lies across it. In the aorta a coagulum more than an inch in extent was found to have sealed the vessel above the ligature. Below the bifurcation, other similar coagula were found in the right and left iliac arteries. By the fall to which the patient had ascribed the
A P H

A O T
tumour, the neck of the thigh-bone had been broken within

The
cm-olla


corolla is full two inches in length. This plant is so very nearly allied in habit, foliage, colour of the flowers, and their general appearance, to the magnificent *Julietta coccinea*, Sm. 1c. Pict. t. 8, that one would think they must belong to one and the same genus. But on examination, the three-lobed lower lip, two-lobed anthers, and leafy *bracteas* of the latter, indicate a technical, as well as natural, distinction.

2. *A. pulcherrima*. Downy-leaved Aphelandra. (Julietta pulcherrima; Jacq. Amer. 6. t. 2. f. 4. Coll. v. 3. (not v. 5.) 252. Ic. Rar. t. 204. Linn. Suppl. 84. Herb. Linn. Willd. Sp. Pl. v. 1. 86. Vahl Symb. v. 2. 14. Enum. v. i. 119. J. arboreae; Mill. Dict. ed. 8. n. 7. J. putata; Loeff. t. 244.)—Leaves elliptic-oblong, pointed; smooth above; finely downy beneath. *Bracteas* ovate, entire. Corolla smooth.—Native of South America, flowering in February. *Losing*. Houltoun appears to have sent seeds to Miller, who cultivated this species before the year 1733. Mutis communicated a specimen to Linnaeus, which we see no reason to distinguish from Jacquin's plant, notwithstanding what is recorded in the *Supplementum* of the *flora* being two only; for we find four in the flower we have examined, bearing the proper *sphinct* anthers of an Aphelandra. How far the complete hoary downy leaves of the back of the leaves, and the smaller *spikes*, with less conspicuous flowers, may prove the present species distinct from the foregoing, we greatly doubt. Mr. Brown in Hert. Kew. unites them, without marking this as even a variety of *cirrata*.

3. *A. scabra*. Rough-leaved Aphelandra. (Julietta scabra; Vahl Enum. v. i. 120.)—"Leaves elliptic-oblong, acute; rough on the upper side. *Bracteas* oblong, acute, hairy."—Native of South America. Leaves three inches long, acute at each end; rough above with prominent points; veins somewhat downy beneath. Vahl speaks of this as very nearly related to the last; but as Mr. Brown, who had doubtless examined specimens, enumerates it in his *Prodrumus* as distinct, and does not subsequentially unite more than the two first together, we presume it must be different, and that the *corolla* is not smooth, nor the *bracteas* entire, both which characters he makes discriminative of the *cirrata*, and they certainly exist likewise in the *pulcherrima*.

Gen. Ch. Cal. Sheath of several imbricated, two-ranked, single-flowered, pointed, hispid scales; the lower ones sometimes barren, and longer than the rest. Cor. of one membranaceous valve, at the inner side of each flower. Stem. Filament one, capillary; anther simple. *Pistil* of several superior, single-seeded; style one, thread-shaped; stigma solitary, undivided. *Pericarp* membranaceous, one valve, and one cell, birthing longitudinally at one side. *Seed* solitary.

Obf. This genus is closely allied to *Devauxia* of Mr. Brown, which will be described in its proper place hereafter, and from which *Apheila* differs in having a simple *spike*, two-ranked *spike*, and only one valve to the *corolla*, situated at the inner side of the flower. The only known species is

**APHRISE**. See *Schaum Earth*.

**APPARITION**. Subjoin at the close of the article,

In the year 1805, Dr. Alderfon of Hull read to the literary society of that place, and published in 1811, "An Essay on Apparitions," designed to prove, that the immediate cause of these spectral visits lies not in the perturbed spirits of the departed, but in the diseased organization of the living. In 1813 Dr. Ferrier of Manchester published, on a more extended scale, "An Essay towards a Theory of Apparitions," similar in refult to the anterior production of Dr. Alderfon. Both admit the reality and universality of spectral impressions, and both attribute them to partial affections of the brain, independent of any sensible and external agency. These and other such writers, who consider the appearances of ghosts, &c. as the immediate effect of certain partial or mixed affections of the brain, confine themselves to physical phenomena, professing to discrediting the consideration of any higher efficiency in the series of causation, than what appears to be the result of diseased organization; so that their discovery, though completely overturning the common superstitious notion as to the return of the departed Spirit, or the invisible interference of angelic agency, is yet, says Dr. Drake, in the learned volume of his "Shakspere and his Times," very reconcileable with the pneumatolgy of bishop Horley, who conceives that the Deity often acts immediately through his agents on the human fenfory, as a part of the material universe, thereby producing diseased or mixed impressions. (See Horley's Nine Sermons on the Nature of the Evidence by which the Fact of our Lord's Resurrection is establisht.) Our Lord, according to the bishop, after his resurrection, was no longer in a state to be naturally visible to any man. His body indeed was riven, but it was become that body which St. Paul describes in the 15th chapter of his 1st Epifile to the Corinthians; which, having no sympathy with the gross bodies of this earthly sphere, nor any place among them, must be indifcribable to human organs, till they shall have undergone the fimilar refinement. Accordingly it is alleged, that we are told by St. John, that the body of our Saviour, after his resurrection, could only be seen through the operation of a miracle. "Him God raised up the third day," and "gave him to be visible." "Et dedit eum manufum fieri." Vulgate.

**APPRECIATION**, l. 2. from bottom, *à l'abé Peytour* for Feyer.

**APRILE GIUSEPPE**, in Biography. See *Tenducci*.

Eff. Ch. Calyx none. Pericarp five, deciduous. Nectaries five, gaping and two-hinged at the summit ; outer lip large and flat; inner minute; each extended downwards into a hollow spur, callous at the point, projecting between the petals. Stamens numerous, dissepoped in five or ten parts, cleft into two or three parcels, the inner ones abortive, their filaments blooded, membranous, and oblong, deliuite of anthers. Germens five. Capsules as many, erect, many-seeded, beaked with the styles. *De Candolle*.

We here, of course, alter the phrafology of our author, with respect to the parts of the flower, as in *Aconitum*.
These are perennial herbs, with fibrous roots. **Radical**, or lower **stem-leaves**, on long three-cleft **footstalks**, divided in a twice-ternate manner; their **leaflets** three-cleft, toothed, mostly obtuse; **upper leaves** cut, or deeply divided, into linear lobes. **Flowers** terminal, blue, white, rose-coloured, or purple, very rarely of a dirty yellow. To which we may add that the **flowers** are pendulous, **fruit** erect.

The **herbage** is slightly bitter, tonic or somewhat astringent, fearfully acid. **Seeds** acid, recommended in eruptive disorders.

The various species inhabit mountainous thickets and pastures of the northern hemisphere; one is found in America, four in different parts of Europe, five in Siberia. Obis. The **scales**, originating in the dilatation of the innermost **filaments**, and the abortion of their **anthers**, often surround the **germs** like *bracteas*, after the **flower** is past. They are delineated in several of Barrelier’s plates. Mr. Brown has remarked something analogous in the petal-like scales of his *Eupomatia*; see that article hereafter. The **flowers** in *Aquilegia* become double in four different ways.

1. Those termed *corniculati* have **accessory nectaries**, originating from changed **filaments**, all spurred and pointing downwards.

2. Involve have their **spurs** turned upwards, in consequence of a twist in the claws of those parts.

3. *Stel- lata* have **accessory nectaries** proceeding from enlarged **filaments** deprived of **anthers**; such being all flat, and without **spurs**.

4. *Degenerae* have all their **filaments**, **fijillae**, and **nectaries** obliterated, nothing remaining but multiplied **petals** (*Sepala* of De Candolle) of a greenish hue.

We shall follow our author, in a comprehensive review of the species, with some necessary alterations. They are not separated into sections.

1. **A. vulgaris**. (See *Aquilegia*, n. 2.) Common **Columbine**. Linn. Sp. Pl. 752. **Wildl.** n. 2. Fl. Britann. n. 1. Eng. Bot. t. 397. Fl. Dan. t. 656. (Aquilegia; Trag. Hift. 157. Fuchs. Hift. 102. A. cerulea; Ger. Hift. 1093, with figures likewise of the several varieties above-mentioned. Aquilina; Math. Valgr. v. I. 577. Caremer. Epit. 401. varieties. 405. Huprum Dioicoridis; Column.Phytob. t. t. t. 1.)—**Nectaries** incurved. **Capsules** hairy. Stem leafy, many-flowered. Leaves nearly smooth. Styles not overtopping the **flamens**.—Native of rather moist meadows, woods and thickets, throughout Europe, from Sweden to Greece, flowering in July. Thunberg also found this plant in Japan. Baron Marshall of Bieberlein mentions it as occurring, though rarely, in the Iberian tract of Caucasus. Nothing is more common, or more hardy, in gardens; its fanciful varieties being tolerably constant from seed, as far as they produce any. *The root* is rather tuberous. **Herb** smooth, two or three feet high. **Leaves** glaucous beneath. **Flowers** somewhat panicked, pale violet in a natural flat, occasionally pink or white, larger and hand- fomer than in any of their garden deformities. The *alpina* of Hudson, different from the real one, is rather a smaller, more slender, mountain variety, with tapering, less incurved, **nectaries**. We have gathered it at Matlock, Derbyshire.

2. **A. viofla**. (See *Aquilegia*, n. 1.) Linn. Mant. 77. *Wildl*. n. 1. Ait. n. 1. Gourn. Illust. 33. t. 19. *De Cand. Fr.* ed. 3. v. 4. 912. v. 5. 630. (A. hirifuta, flore viofla; Magn. Monpt. 26. Hort. 21. A. montana, flore parvo, thalidri folio; Bauh. Pin. 144. Prodr. 75. Lachenal Aë. Helvet. v. 8. 146. t. 5. Bauh. Hift. v. 3. 484. Morif. Æc. 12. t. 1. f. 5. bad.)—**Nectaries** incurved. **Capsules** hairy. Stem with very few flowers, almost naked, **downy** and vifcid as well as the leaves and flowers. Styles not overtopping the **flamens**.—Native of Switzerland, the south of France, and all along the rocky hills of the Mediterranean. De Candolle concurs with Villars in opinion, that this plant is only a variety of the foregoing. We have never compared them in a living flat, but the singular viscid moisture which covers the whole herb, especially the **flowers**, and is visible even in dried specimens, seems to indicate an essential difference. The **flowers** are greater, while the plant is smaller, sometimes single-flowered, and the **leaflets**, with their segments, are more wedge-shaped. Linnaeus however declares, Syft. Veg. ed. 13. 420, that seeds of the *viflola*, from Goun himself, produced the **vulgaris**.

3. **A. speciosa.** Handsome-flowered **Columbine**. *De Cand*. n. 3. excluding the synonyms. (A. *vulgaris*, daurica; Wildl. n. 2, §) — **Nectaries** incurved; **spur** the length of the border. **Capsules** hairy. **Stem** leafy, many-flowered. **Flower-stalks**, footstalks, and backs of the leaves, downy. **Styles** taller than the **flamens**.—Native.—**Nectaries** incurved; **Germens** and **capsules** perfectly smooth. **Styles** taller than the **flamens**.—Native of Siberia. Linnaeus cultivated this plant, and found it did not alter. We received it in 1796, from the garden of Meffrs. Lee and Kennedy, at Hammermith, who had the feeds from that country. Specimens of the same, in the Linnaean herbarium, are marked as having been gathered near Irkutsk. M. De Candolle justly describes "the radical leaves on long **footstalks**, smooth, except perhaps some downinches on the **footstalks**; their segments obtuse, broadly notched. **Stem** hardly a foot high, mildly flowered, and entirely naked; sometimes bearing two or three flowers, with one or two leaflets **bracteas**. *Sepala* (!petals) blue, oval, obtuse. **Nectaries** white, half as long, very blunt. **Capsules** quite smooth, by which character this species is readily distinguished from all the foregoing, and perhaps from all the rest." *De Cand*. Our wild specimens have three or four flowers on each stem, and the garden ones are still more luxuriant. The **flowers** in both are purplish-blue, the lips of the **nectaries** cream-coloured, as expressed in Ehrhart’s name, and Dr. Sims’s figure. We have no hesitation about his **synonym**, were it not for the flight downinches which he attributes to the herbage. The proportion of his **styles** is right, but he does not say any thing of the **germs**. We cannot but suppose the gardeners mixed feeds of the Siberian species with the Canada one, or possibly that pollen of the latter might have had some effect on the flowers of the former, of which the rather leafs curved **nectaries** of the offspring seem an indication; the pale hue of their limb is exactly that of our *fbrica*. The downy leaves do not accord with either. If we are right, De Candolle’s *hybridra*, n. 11, must be expunged. Respecting Gmelin’s *A.* n. 16, Fl. Sib. v. 4. 185, we suppose by its last **synonym**, alluding to the party-coloured **nectaries**,
AQU

neBaries, it must have been what we have just described, taken by him for the Linneas alpina, though not without some doubt.

5. A. alpina. (See Aquilegia, n. 3.) Alpine Columbine. Linn. Sp. Pl. 752. Willd. n. 3. Ait. n. 3. Ehrh. Beitr. v. 7. 146. Sm. Tour. ed. 2. v. 1. 137. Allion. Pedem. v. 2. 64. t. 66. (A. n. 1196; Hall. Hist. v. 2. 89.) A. montana, magno flore; Bauh. Pin. 44. Prod. 75. Bauh. Hist. v. 3. 484.)—Lips of the nectaries half as long as the elliptic-lanceolate pointed petals; spurs curved at the extremity. Stem two or three-flowered, leafy. Leaflets with many deep, linear-wedge-shaped, segments. Capsules downy, still, matured.—Native of that alpine situation in Switzerland, Savoy, Mount Cenis &c. flowering in July or August; but not, we believe, of Siberia, the variety B. De Candolle appearing to belong to the last species. The real A. alpina is the most magnificent of its genus, distinguished by fine blue flowers, spreading two and a half or three inches, and well represented in Allioni's plate. The herbaceous is smooth. Stem often above two feet high, bearing several flowers. The petals are densely downy. Leaflets near an inch long, finely hairy, transversely wrinkled, the apices prominent, parallel, confluent veins. Seeds black and shining, numerous. Miller might have cultivated this noble plant at Chelsea, but it had long been lost, and was restored by seeds from Mount Cenis, in 1787, being now probably again extinct in England.

6. A. pyrenaica. Pyrenean Columbine. "De Cand. Fr. ed. 3. v. 5. 640." (A. alpina; Lamarek n. 3.)—"Petals of the nectaries quite straight, scarcely shorter than the stem. Stem nearly naked, mostly single-flowered. Leaflets with numerous, deep, linear lobes."—Found in elevated rocky pastures, among the Pyrenees and Alpines. Akin to the last, but in all its parts but half as large. Leaves on longer flanks, their outline nearly circular. Flowers one or two, middle-sized, blue. Petals (sepals, De C.) oval, tapering at each end. Spurs slender, perfectly straight to the very point. Stem and leafstalks either quite smooth, or slightly hairy. Some synonyms of A. wilcoxia are repeated under this species by De Candolle, at least those of the Bauhins and their followers. We have seen no specimen, and cannot form an opinion. There seems some confusion in our able friend De Candolle's specific characters of this and the last. The spur in A. alpina is half the length of its real petals, as Linnaeus says; De Candolle says half the length of the limb of his petals, our nectaries, which is not the case, those parts being of equal length, as is nearly the case with A. pyrenaica. But in this latter perhaps the petals, its sepals, are no longer. This point is material.

8. A. viridiflora. (See Aquilegia, n. 5.) Green-flowered Columbine. "Pallas Ait. Petrop. for 1779. 260. t. 11." Willd. n. 5. Ait. n. 5. Jacq. Ic. Rar. t. 102.—Petals straight, longer than the limb of each nectary. Stamen the length of the nectaries. Styles much longer. Petals elliptical-oblong, shorter than the nectaries.—Found in Siberia by Pallas, who sent seeds to Kew in 1780. The green flowers, and long spurs, mark this species. Germen downy, ensiform, composed of membranous abortive stamens, after the perfect ones are gone.

9. A. daurica. Daurian Columbine. De Cand. n. 9. De Cand. n. 10. (A. viridiflora; Willd. n. 5.)—Spurs straight, the length of the limb. Styles and nectaries scarcely equal to the petals, which are nearly the length of the nectaries.—Native of Siberia, according to Willdenow, from whom this species is entirely adopted. The flowers are described as dark purple, or blue-flushed; the limb of each nectary greenish-blue; spur blue-flushed. Professor De Candolle flespe this may be the same plant as Dr. Sims's hybrid, (see floribunda, n. 4.) which is notplant out all improbable, and if so, we lose another of his thirteen species. The only difficulty is to conceive, that Willdenow could, at any time, reckon this hybrid a variety of viridiflora, to which his atro-purpurea was reduced in his Sp. Pl. 11. A. parviflora. Small-flowered Columbine. De Cand. n. 12. (A. fylarum humilia; Gmel. Siber. v. 4. 186.)—Petals straight, short, nearly as long as the obtuse limb of each nectary. Stamens and petals recurved, the length of the petals. Stem smooth, as well as the leaves.—Very frequent in woods about the river Lena. Gmelin. Herb entirely smooth, except the bristle germens. Stem a foot, or rather more, in height, bearing from two to seven flowers. Leaflets ovate-wedge-shaped, with three broad obtuse teeth at the end. Bracteas in linear segments. Flowers blue or violet, much smaller than those of A. canadenensis; their spurs, (according to De Candolle, who had examined dried specimens,) straight, very short; Gmelin terms them "spiral." Petals ovate, acute, tapering at the base, longer than the blunt limb of the nectaries. Stamens, as well as styles, curved downward; barren stamens oblong-linear, much crisped at the edges.

12. A. anomoneoides. Anemone Columbine. "Willd. Geff. Natur. Bed. Mag. for 1811. 401. t. 9. f. 6." De Cand. n. 12.—Spurs straight, very short, as long as the limb, which is one-third the length of the petals. Stalks one-third, single-flowered, nearly naked.—Native of the Altai region of Siberia. Root herbaceous. Herb three inches high, smooth, resembling Anemone trilobata. Leaves divided, in a thrice-ternate manner, with oblong segments, either entire, or two or three-lobed. Stalk nearly longer than the leaves, accompanied by two linear-lanceolate bracteas. Petals ovate, obtuse. Nectaries five, hooded; their spurs gibbous at the base. Wild.

ARACÉI, l. 10. r. Baniash.

ARACICA, l. 5. r. Erach.

ARALIE, in Botany, so named from its principal genus, a natural order of plants, the 59th in Jussieu's series, the 11 of his 12th clas. We have given the character of that clas under the article Umbellate. The Aralie are thus defined.

Calyx either entire or toothed at the margin. Petals and stamens the length of the nectaries. Styles much longer. Petals elliptical-oblong, shorter than the nectaries.—Found in Siberia by Pallas, who sent seeds to Kew in 1780. The green flowers, and long spurs, mark this species. Germen downy, ensiform, composed of membranous abortive stamens, after the perfect ones are gone.
ARA

flanens definite. Styles and figmas several. Fruit pulpy, or rarely capular, of as many cells as there are fyles, with a solitary seed in each. Stems either arbaceous, or shrubby, or herbaceous. Leaves alternate, often compound, their footstalk sheathing in its lower part. Flowers umbellate, either with or without involucrem, or, more rarely, naked.

The genera are: Galtonia of Commerson; Polyscia of Forster nearly related thereto; Aralia of all authors; Calomnus of Linneas in his Supplementum; and Panax.

The Aris are naturally allied to the Umbellate, but differ in having their seeds in a pericarp, instead of being naked. They are akin to Cornus and Hedera, but distinguished by having more than one stye. Juff.

ARANEA, col. 2. l. 10. ded which see respectively, and refer. See Spider.

ARACUI, in Geography, a river of Georgia, next in importance to the Cyrus, or Kur, which, rising near the gates of Caucasus, flows to the south, and after dividing into two equal parts, the southern range of mount Caucasus, falls into the Kur, at the town of Tifgette, 25 miles above Tefis.

ARASCHA, a rapid river of Mingrelia, which has its source near the village of Kemen, and unites, on the borders of the Iberian lordship of Sa Schilo, with the Hippus, which rises in the highest mountains of the Soani, not far from the source of the Phaís, flows through Letigiphuni, divides Mingrelia from Iberis, and enters the Phaís, near the Tredia.

ARATUM, r. Aratrum.

ARACARIA, in Botany, a barbarous name, given by Juffieu to the Chili Pine, which Lamarck, Schreber, and Lambert, have called Dombeya. (See that article.) Wildenden has unfortunately retained the above name, because he had already ignorantly followed Cavanilles in calling a genus Dombeya, which is not generically distinct from Pentapetes. Hence Aracaria has found its way into Mr. Aiton's Hortus Kewensis, where Wildenden is taken as the leading authority, and Dombeys ill fortune still pursues him. (See our biographical account of that eminent man, which we trust will be our sufficent justification in always maintaining the genus which he introduced, and which properly belongs to him: or have we any doubt that our learned countrymen will concur in supporting his well-earned fame, when they properly consider the subject.) We have further to observe, that the Dombeya of Lamarck, or that of Cavanilles, has, neither of them, any preference as to date, both having, we believe, been first announced in Juffieu's Gen. Pl. in 1789, a year before the date of publication of each of those authors' works. We are also ready to allow that our illustrious friend Jussieu, in the choice he made, was far from concurring in the base perfection of Dombeys, originally raised by the Spaniards. He was however evidently aware that the Dombeya he adopted could hardly be maintained, or at least that it was not distinct from Pentapetes phanita, now received as Pentapetes. (See that article.) Aracaria is not, as has been reported, the denomination of the Chili Pine, in any part of the world, but a perversion of that of its native country, the Araucanian mountains, and to such generic names there are many objections.

Gen. Ch. Cal. Perianth inferior, of one leaf, in five deep, ovate, permanent segments. Cor. of one petal, bell-shaped; tube rather longer than the calyx, inflated at the base, with five protuberances; limb in five deep, ovate, acute segments, shorter than the tube, slightly spreading, their points somewhat recurved and twisted. Nectaries five cells in the base of the tube, opposite to the segments of the limb. Stam. Filaments five, inserted in the base of the tube, between the nectaries, short, thick, flattened; anthers arrow-shaped, each surmounted by a small auricle, converging towards the pithil; pollen of two obovate masses, projected upon five angles of the stigma. Pifi. Germs two, superior, ova-olong, stylos two, very short; stigma common to both, large, thick, roundish-ovate, smooth, with two acute points at the top, and five glandular lateral tubercles to receive the pollen. Peric. Follicles two, divariclated, large, obov-oval, coriaceous, smooth, abrupt, with a small point, one of them often abortive; partition longitudinal, unconnected when ripe, except at top and bottom, the disk covered on both sides with numerous elevated, parallel, shapely toothed ridges. Seeds very numerous, inserted into the teeth of the receptacle, imbricated downwards, ovate, clothed with papillary pubescence, and each crowned with a tuft of long silky hairs.

1. A. fruticosa. Silky Araujo. — Native of Peru. Cultivated in the green-house at Lisbon, where it flowers in autumn, and ripens seed in spring. The whole plant abounds with acid milk, but every part is inodorous. The root is creeping. Stem shrubby, weak, twining, three or four feet high, round, smooth, branched, leafy; the young branches rather downy. Leaves opposite, flaked, lanceolate, acute, entire, nearly smooth, an inch and a half to three inches long; heart-shaped at the base, and marked with two glands on the upper side, a little above the insertion of each foot-stalk. Flowers three or four, or more, together, in short, lateral, drooping, smooth, somewhat corymbose clusters, about half the length of the leaves, and inserted between the bases of the foot-stalks. Corolla yellowish-white, marked with purple lines; downy about the mouth. Follicles three or four inches long.

ARBELA, l. 13, after Arbdtis, add — This place, once the capital of the province of Adiabene, has wholly declined from its former importance, and dwindled into a wretched mud town, with a population not exceeding 3000 souls. Part of this town is built on a hill of a conical form, on which probably stood the old castle, and the remainder of the town encircles the base of the hill. The country surrounding Erbile, its present name, lying in lat. 36° 11', and between that place and Mosul, is fruitful but hilly, and very deficient in wood, there being hardly a tree or even shrub to be seen.

ARCH, l. 4. fig. 41. l. 23. fig. 42. Arc of a Circle, l. 11. fig. 43.

ARCHER, in Geography, a township of Ohio, in the county of Jefferson, containing 60 inhabitants.

ARCHIPELAGO, col. 2. l. 2. r. 2100.

ARCTOMYS, in Zoology. See MARMOT.

ARCTOTHECA, in Botany, a name revived from Vaillant, and originally synonymous with Arctottis, (see that article,) from which the genus we are about to describe has recently been separated, chiefly by the want of a sep- cmm; for in habit there is no distinction. "Wendland Hort. Herrenhuf. 8." Willd. Sp. Pl. v. 3. 2365. Brown in Ait. Hort. Kew. v. 5. 141. — Clasas and order, Syngenees Polygynia-fragranaeae. Nat. Ord. Composite, Linn. Corymbi- formes, Juff.
Gen. Ch. Common Calyx roundish, imbricated; its scales elliptic-oblong, woolly; the innermost with a dilated, membranous termination. Cor. compound, radiated; florets of the disk numerous, funnel-shaped, five-ovate, equal, all perfect; those of the radius about twelve, ligulate, elliptic-lanceolate, longer than the diameter of the disk, with four ribs, and about three unequal teeth, neuter. Stam. in the florets of the disk only, filaments five, capillary, short; anthers united into a tube, nearly as long as the corolla. Pjyl. Germin in all the florets, oblong; style in tho the of the disk only, thread-shaped; stigma prominent, cylindrical, erect. Peric. none, except the perpetual, dry, curled calyx. Seeds in the disk only, obovate, without wing or down. Recept. flatish, cellular.

1. A. repens. Creeping Arcotelia. Wild. n. 1. Ait. n. 1. (Arctotis repens; Jacq. Hort. Schoenbr. v. 3. 31. t. 356. A. Icapigera; Thunb. Prodr. 165.)—This, the only known species, is a native of the Cape of Good Hope. Seeds were sent by the celebrated Scopoli to the writer of this article, and the plants raised from thence flowered in the open ground in Chelsea garden, in the summer of 1790, but it was found necessary to shelter them in winter. The roots are perennial, creeping extensively. Stems herbaceous, prostrate, branched, clothed like the backs of the lyrate pinnatifid leaves, with fine white cottony down. Flower-flalks radical, several together, simple, erect, naked, about six inches high, being rather longer than the leaves. Flowers solitary, an inch and a half broad, lemon-coloured, with purple ribs beneath.

Eff. Ch. Upper half of the head deciduous. Filaments composing a dense denudated net-work, relling on the cup-like receptacle.

1. A. ? leucopephala. White-headed Arcyria. Perf. n. 1. Hoffm. Germ. v. 2. 6. f. 1. Trichia cinerea; Trentepohli in Roth Catal. v. 1. 227.)— Aggregate. Head funnel-shaped below, reddish-brown. Net-work globose, mealy, snow-white. — Found on dead leaves or stumps in autumn. Also on mosses, or fragments of leaves, in rainy weather, very copiously, in June and July, according to Albertini and Schnelle, Fung. Nifhien, 100. who, like Perfohns himself hesitate whether to refer this elegant little species to this genus or to Physarum. See that article.

3. A. cinerea. Ash-coloured Arcyria. Perf. n. 1. Albert. and Schwy. Nifh. n. 280. (A. albida; Perf. Dipp. Meth. 10. t. 1. f. 2. Trichia cinerea; Bulliard Fung. v. 1. 120. t. 577. f. 3. Stomnitis glauca; Trentep. in Roth Catal. v. 1. 221.)— Aggregate, greyish-white. Net-work cylindric-ovate, erect. Receptacle crenate. — Found in summer, in woods, on dead branches, flanks, &c. Smaller and shorter, as well as more obtuse, but with a longer stalk, in proportion, than the lat, from which also it is distinguished by its dirty-white colour. We are puzzled, as well as the learned authors of the Fungii Nifhienes, by Perfohns allusion of the receptacle of this species to the fifth, hereafter described.

4. A. incarnata. Flesh-coloured Arcyria. Perf. n. 4. Obl. Mycol. t. 58. (not 38.) t. 5. f. 4. 5. Albert. and Schwy. Nifh. n. 281. (Stomnitis globosa, et S. garnes; Trentep. in Roth Catal. v. 1. 222.)—Somewhat scattered, dull flesh-coloured. Net-work pyramidal, obtuse, curved, foon deciduous. Empty receptacle faver-shaped. — Said to be very common in Germany, on oak or fir wood in decay, at all feasons. The empty receptacles resemble little reddish Pinez, and are marked with radiating streaks. The net-work appears to abound in farinaceous feel of the same hue.

5. A. punicea. Scarlet Arcyria. Perf. n. 5. Dipp. Meth. 16. Albert. and Schwy. n. 282. (Clathrus denufatus, linn. Sp. Pl. 1649. Jacq. Mifc. Aultr. v. 1. 136. t. 6. Trichia cinnabarinans; Bulliard Fung. v. 1. 121. t. 502. f. 1. T. denufatus; Sowerb. Fung. t. 40. T. n. 2164. Hall. Hist. v. 3. 115. t. 48. f. 6. as Jacquin has it, rather than t. 4, as cited by Haller himself. Stomnitis crocata; Trentep. in Roth Catal. v. 1. 222.)—Crowded, ovate, orange-coloured. — Frequent throughout Europe on rotten wood, in fummer and autumn. When young it is white and soft, but advancing in fize, it assumes a confpicous orange-colour, with the dry rather firm texture of its genus. This fine colour chiefly refides in the copious feminal powder, for the net-work itself is brownish. The edge of the remaining bafe of the receptacle is often irregularly torn, and various in breadth. Bolton's v. 3. t. 93. f. 2, if really taken from this species, is not a happy represention.

ARDELAN, in Geography, a province of the Persian empire, forming the eastern division of Kurdisthan, is in length 200 miles, from the little river Sharook to the Turkish district of Zohab, and nearly 160 in breadth. It is separated from the plain of Hamadan by a small range of hills, and its western boundary is 100 miles beyond Senna, the capital, situated in N. lat. 35° 2', and L. long. 46°. The territories of Ardelen extend as far as Kella Shah Khanese, and are peopled by a tribe denominated Gheshkhee, who are recorded by the Kurchs as the most expert and daring robers of their nation; nor will torture induce them to betray their accomplies, being habituated to pain and severe chafisment from their earliest infancy. They are, however, slaves to the most abject superflition.

ARGOLASIA, in Botany, Juif. Gen. 60, a good name, conftructed by Julliac, from <em>argos</em>, white, and <em>hos</em>, hairy, or <em>hoasp</em>, alluding to the white woolly clothing of the herb. But this name is superfed by one of similar meaning, LANARIA, (see that article,) given to the same plant by Dr. Solander, and pubhished in Ait. Hort. Kew. v. 1. 462, in 1789. This latter has been adopted by Schreber, and is now eellablished.

ARGUNNA, in Geography, a town of Armenia, in the pachalic of Diarbekir, distant 45° miles from Diarbekir; situated on the side of a lofty mountain, from which torrents of water are discharged in courants through the streams so as to render them impassable. The town is populous, but wretchedly built, and is remarkable for the quantity of wine and brandy made in its vicinity.

ARJONA, in Botany, so named by the late abbe Caru-
niles, in honour of Mr. Francis Arjuna, a celebrated lecturer on botany at Cadiz.—Cavan. t. v. 4. 57.—Clafs and order, Pentandria Monogynia. Nat. Ord. Lythraceae, Jull. affine.

Gen. Ch. Cal. Perianth inferior, of two small, concave, permanent leaves, each with three terminal teeth. Car. of one petal, funnel-shaped; tube thrice the length of the calyx, slightly dilated upward; limb in five deep, ovate, acute, equal segments. Stam. Filaments five, capillary, very short, inserted into the throat of the tube; anthers oblong, within the tube. Pist. Germen superior, ovate, crowned with five minute permanent scales; style simple, thread-shaped, the length of the tube; stigmas two, flat. Peric. Berry globose, crowned with the scales, of two cells. Seeds...}

Eff. Ch. Corolla funnel-shaped, equal. Berry superior, of two cells, crowned with five scales.

1. A. tuberosa. Tuberous Arjuna. Cavan. t. 383.—Native of South America, in dry barren ground, near Port Defere, flowering in December. We have a specimen from the lamented author, gathered by Louis Née. The long fibres of the root are furnished, here and there, with oval knobs, well suited to its arid situation. Stem foliary, a span high, with numerous branches from the bottom; nearly simple above; leafy throughout. Leaves very numerous, imbricated, sheathing, awl-shaped, spinous-pointed, channelled, entire, rather spreading, clothed with soft woolly hairs. Flowers in a solitary, terminal, dense, corymbose head. Corolla about an inch long; externally yellowish and very downy; internally smooth, yellowish-white. Style reddish, with sometimes three stigmas, Berry small, smooth. Seeds not observed.

There is something in the characters and hue of this plant, that approaches the natural order of Vaporeula, or Thymelae, especially in the form and aspect of its corolla. Possibly the fruit may not really be of two cells. The two cotyledons of a single drupa might, in an early state, mislead the author, who says he did not see the seeds. The bark, however, does not appear to have those fibrous scales, which are the strong indication of the Daphne family.

ARISTEIA, (see our former article,) a name left unexplained by professor Martyn, is rightly derived by De Theis from arista, an awn, but does not apply as he says to the point of the leaf. Solander, the author of this name, appears rather to have alluded to the copious bearded fringe of the sheaths, so remarkable in the original species.—Ker in Ann. of Bot. v. 1. 236. Dryand. in Apt. Hort. Kew. ed. 2. v. 1. 108. Vahl Enum. v. 2. 123.

Eff. Ch. Corolla superior, in five deep regular segments, spirally twisted together after flowering, permanent. Capsule of three cells, with many seeds.

Four species having been added to this genus by Mr. Ker, it is necessary to review the whole.

1. A. cyanes, Grafs-leaved Aristlea. Ait. n. 1. Andr. Repof. t. 10.—Flowers in terminal heads. Sheaths and bracteas in many fine capillary marginal segments.—Native of the Cape of Good Hope, as well as all the following. See ARISTEIA, n. 1.

2. A. caputis. Talleaf Aristlea. Ait. n. 2. Ker in Curt. Mag. t. 605. (A. major; Andr. Repof. t. 160. A. caerulea; Vahl n. 3. Gladiolus caputis; Link. Sp. Pl. 53. Moraea caerulea; Thumb. Mor. n. 15. t. 2. f. 2. Prodr. 11. Fl. Cap. v. 1. 277. Willd. Sp. Pl. v. 1. 243.)—Tufts of flowers alternate, racemose. Sheaths ovate, entire.—Native of mountains in the road to Haatninquis and Lange Kloof, as well as of hills about Cape Town, flowering in October and November, or in the latter situation, two months earlier. This species is two feet high, with broad rich sword-shaped leaves, and large handsome flowers, of a fine blue, compose a long falcatefulated cluyter.

4. A. melaleuca. Mourning Aristlea. Ait. n. 4. Ker in Curt. Mag. t. 1277. (Moraea melaleuca; Thunb. Mor. n. t. t. f. 3. Prodr. 10. Fl. Cap. v. 1. 261. Willd. Sp. Pl. v. 1. 240. Vahl Enum. v. 2. 153. M. lugens; Link. Sp. Pl. 99.)—Flowers alternate, foliary or in pairs. Three segments of the corolla not half the size of the reflex. Leaves linear.—Found in several sandy bushy places, at the Cape of Good Hope, flowering in September and October. The root is fibrous. Leaves numerous, two-ranked, four to six inches long, and not a quarter of an inch broad. Flowers few, somewhat racemose, larger than the leaf, and very handsome, having three concave, almost orbicular, segments, of a sky-blue, an inch and a half long, with three alternate, obovate, black ones, about half as long, and much narrower.

ARISTOLOCHIÆ, fo named from the leading genus, is the twenty-third natural order in Jussifius’s system, being the only one in his fifth clas. That clas is defined as follows. Cotyledons two. Petals none. Stamens inserted into the pilil. The Calyx is superior, of one leaf. Stamens definite. Germen inferior; style either wanting, or single, or definitely multiplied; stigma simple or divided. Fruit of one or many cells.

The order is thus characterized. Calyx superior, of one leaf, entire or divided. Stamens definite. Germen inferior; style one, or nearly wanting; stigma divided. Fruit of many cells, with numerous seeds.

The only genera are, Ariflochobia, Ariforum, and Cylaus. Linnaeus arranged them with his Sarmantaceæ, but was subsequently inclined to refer them to his Rhoadeæ. (See those articles.) We have already observed that they do not belong to the latter, nor have they any relationship to the Sarmentaceæ, except something in the habit and foliage of Ariflochobia.

ARKANSAS, in Geography, a river of Louisiana, which, next to the Missouri, is the most considerable tributary of the Mississippi. Its length is nearly 2500 miles, and at proper season it is navigable nearly through, the whole distance. In many places, however, its channel is broad and shallow, at least above the rapids, so as to render navigation almost impracticable. Until 800 or 900 miles from its mouth it receives no considerable streams, on account of the vicinity of
of the waters of the Mifouri, of the Kanfas, &c. on the one side, and those of Red river on the other. The chief rivers which fall into it are, the Verdigris, the Negracka, Canadian river, Grand river, &c. Several are remarkable for being strongly impregnated with salt; the Arkanfas itself, at certain feasons, is said to be brackish. The lands on this river for 600 or 800 miles upwards are described as very fine, and capable of affording settlements, though principally unimbered. The Arkanfas is a place situated 60 miles up the river, and contains 450 inhabitants. It has a few stores, and seems to be improving. There is a considerable trade with the Ofages up the Arkanfas, and with the Indians, who live in the White river country. This is also a French establishment, and has the same proportion of Americans as the other towns. The territory of the Mifouri contains about 874 Arkanfas, whose settlements are principally in the neighbourhood of the Arkanfas post, or extend up the river; and they are the least considerable of the territory. Brackenridge's Views of Louisiana.

ARMENIA, col. 3, l. 49, add.—And the southern, which are poifomed by numerous independent chiefs. At the clofe of the article Armenia add—The Turkish pachalics of Armenia are, Erzeroum, Akifta, Khans, Bayazid, Mofh, and Diarbekr. These pachalics are subdivided into districts, governed by Vairodes.

ARMENIA, a province of Georgia, which has the Kur to the N.E., the Moifain or Sifian hills to the S., and those of the Karagatch to the W. This province has been long celebrated for its mines of gold, silver, lead, iron, and copper, as well as for its quarries of marble and jasper; the principal of which are those of Quehoe and Tamblitt. It is the best peopled and most flourishing of the provinces of Georgia, and contains many towns. Kinnaur's Peria.

ARNOPOGON, in Botany. See TRAGOPOGON at the end.

AROIDEÆ, a very natural order of plants, the feventh in Jullien's method; being the firit of his second elaf, of which we have detailed the characters under TYPHE.

The Aroideæ are thus described. Spadix fimple, manyflowered, either naked, or involved in a Spatha, or Sheath.

The Aroideæ are thus described. Spadix fimple, manyflowered, either naked, or involved in a Spatha, or Sheath. 

Calyx none, or fimple. Stamens either definite or indefinite, inferted into the fpadix. Génerus originating from the fame fpadix, either naked, or encompassed with a calyx, in fome infertes mixed with the flamen, in others feparated from them; filyles one to each germin, or none at all; figmas as many. Fruits as many, of one cell, with one or many feeds. Corculum in the centre of a flethy albumen. Leaves lieathing, alternate, for the moft part all radical. Spadix often solitary, feated either on the top of the item, or more frequently on a radical falk. The plants are rarely caufed; fome of them are regularly irregular in the difpofition of their organs of fecundation.

Sect. 1. Spadix enfolded in a fpatha. 

Arum, Calla, Dracoumum, and Pothas, all Linnaean genera, with Houttuynia of Thumberg.

Sect. 2. Spadix naked, deftitute of a fpatha. 

Orontium and Acorus.

It muft be observed, on the authority of Jullien himself, that the plants of this order are only prefixed to be monoecydeous, their germination not having been properly examined. The conjecture however is supported by Gartner's figures, the habit of the plants, and the ternary dispoftion of the parts of fructification in fome of the genera.

This order is nearly analogous to the Pipériz of Linnaeus, except that Pipér and Saururus are included in the latter; a meafure to which Jullien himfelf feems inclined.

AROSIS. Add.—See Tab.

Vol. XXXIX.

ARROBA, in Commerce, a weight in Portugal and Spain. At Oporto 1 arroba, or arrove, = 32 arrates, and 4 arras, or 128 lbs. = 1 quintal. The quintal at the India-houfe is 112 arrates. (See QUINTAL.) In Spain the arroba is also a liquid measure. A measure of wine contains 16 arras, an arroba = 8 azumbres = 2 quartillos. The arroba of wine, or great arroba, is the same all over Spain, regulated by the standard measure of Toledo, which contains 34 lbs. of river water (Caftilian weight), and measures 1237½ Spanish or 981 English cubic inches; fo that 4 such arras are = 17 English wine gallons. The arroba of oil, or peer arroba, regulated by the same standard measure, which weighs 25 lbs. of oil, or 26 lbs. 9 oz. of river water (Caftilian weight), and measures 1965½ Spanish or 771 English cubic inches. Hence 3 such arras answer to 10 English gallons. The arroba is divided into 4 quartillos, or 100 quarterones or panillas. A Spanish botta contains 30 arras of wine, or 38½ of oil; a pipe is 27 arrobas of wine, or 34½ of oil; fo that the botta is = 127½ English gallons, and the pipe 114½. Kelly's Cambist.

ARSEKEN, or AREKIN, a long meafure in Russia. See VERSHOCK.

VOL. III.

ART

ARTERIES, Diseafes of. Arteries being composed of blood-vessels, nerves, and absorbers, are liable to the fame morbid alterations, and endowed with the fame powers of reparation, as foft parts in general; their coats inflame, and pafs through the different ifages of adhesion, suppuration, or gangrene, in the fame manner as the skin, a gland, or a mucele.

The internal coat of an artery, MR. Hodgfon obferves, bears a striking analogy to feros membranes in its tendency to the adhesive inflammation; and this property is in the blood-vessels, as in all organs, the firft agent of reparation in injuries from accident or difeafe. The inflammation which is excited by the wound or division of an artery produces an effuflion of lymph, which fells the extremity of the vefsel, and affecting also the external coat becomes the fubs of adhesion and final obliteration. A punctured artery is united by the fame adhesive procefs which repairs wounds in general; and if irritation be excited in the coats of an artery by preflure, adhesive inflammation is the confequence, lymph is effuflod into the cavity, and into the cellular fubfance, connecting the coats of the vefvel; its fides codefine; and it is rendered impervious. The fame adhesive procefs frequently prevents hemorrhage, where abbeffes, or extensive ulcerations, eflit in the neighbourhood of large vefvles, the inflammation which precedes the suppuration having produced an effuflion of lymph between the coats, and into the cavity of the arteries, whereby it is obliterated. But the moft perfect demonstration of the effects of acute inflammation upon the internal coat of an artery, MR. Hodgfon thinks, is to be met with in the cafes where the difeafe appears to have extended to the vefvel from the contiguous parts. Thus, in a fatal infiance of violent pneumonia, besides the usual appearances on deficerion, the inflammation was found to have extended to the aorta, the internal coat of which was of a deep red colour, and a confiderable effuflion of lymph had taken place into its cavity. The effuflod lymph was very intimately connected with the internal coat of the vefvel, and a plug of it had extended into the left subclavian artery, and nearly obliterated the cavity of that vefvel. (Treatife on the Diseafes of Arteries and Veins, p. 5.) MR. Hodgfon has obferved a fimilar ifate of the great blood-vessels in a lefs degree from carditis, pneumonia, and bronchitis.
ARTERIES.

The granulations, or fungous growths, which are not unfrequently met with at the origin of the aorta upon the semi-lunar valves, or in the cavities of the heart, are said sometimes to originate in the lymph thus diffused upon the internal membrane. Mr. Hodgson also affirms us, that the inflammation excited in an artery of the extremities by the application of a ligature has been known to extend along the internal coat of the vessel to the heart itself, as we know is often the case with respect to the veins.

According to the same well-informed writer, chronic inflammation may generally be remarked in thickened and calcareous arteries, particularly in aneurismal subjects. The internal coat of the vessel is soft, thickened, of a deep red colour, which is not uniform, but irregularly dispersed in the vicinity of ulcerations, thickenings, or calcareous depositions. P. 9.

Ulceration of an artery may commence in the vessel itself, or extend to it from the surrounding parts. In the first circumstance, it is always found first on the internal coat, and is generally preceded by some other morbid change of the vessel. Thus, it is not unfrequently met with around the circumference of calcareous depositions, or upon the surface of atheromatous thickenings; and aneurism is, without doubt, occasionally a consequence of such ulceration, the coats of the vessels being completely destroyed by it, and the blood escaping into the surrounding cellular substance, which becomes gradually expanded into a sac. Hemorrhage is often caused by ulceration extending from surrounding parts to the coats of arteries, as in cancerous and phagedenic ulcers; and Mr. Hodgson even thinks that many passive hemorrhages are produced by ulceration beginning on the inner surface of these vessels.

Sphacelation of arteries in consequence of inflammation of their internal coat has not hitherto been observed. Arteries, however, are often included in extensive sloughing of parts, in which case the blood generally coagulates in the vessels to a considerable extent above the line of sphacelation; an occurrence which seems designed to prevent hemorrhage on the separation of the slough. The coagulum is afterwards absorbed, and the vessel obliterated.

From considering the inflammation of arteries and its effects, our author proceeds to speak of various morbid appearances to which the coats of arteries are liable, in consequence of their peculiar structure and functions.

1. The internal coat of arteries is sometimes thickened and converted into a substance resembling cartilage, or the thickened peritoneum of an old hernial sac. This diseaе is confined to the internal coat, which having lost its elasticity sometimes cracks, and forms scales that hang into the cavity of the vessel. Calcareous depositions often accompany this alteration of structure, and the surrounding parts of the membrane generally exhibit signs of chronic inflammation. The semi-lunar valves of the aorta are not unfrequently changed into a dense fibrous structure, resembling ligament, or tendon; sometimes they are converted into cartilage, and are manifestly incompetent to their office as valves. In several instances, Mr. Hodgson has found them ruptured, forming cartilaginous eminences on the sides of the vessel.

2. The internal surface of arteries exhibits frequently a thickened and pulpy structure, sometimes with the appearance of small flattened tubercles, and, in other examples, with an irregular and somewhat fleshly appearance over the whole surface. This diseaе is confined to the internal coat, and is often found in aneurismal subjects.

3. A deposition of atheromatous or purulent matter in the cellular membrane, which connects the internal and middle coats of the vessel. The diseased part is of an opaque yellow colour, sometimes extensive, and considerably elevated above the surrounding surface, and on other occasions circumferibed, and having a pustular or tuberculized appearance. If punctured, matter may be pressed from underneath the internal coat, varying in consistence from that of cheese to that of common pus. Mr. Hodgson has seen the emulent and femoral arteries in the same subject quite obstructed by the accumulation of this curdy matter.

4. Certain fungous or wart-like excrescences have been observed upon the semi-lunar valves of the aorta and pulmonary artery, and also upon the mitral and bicuspid valves. They are of rare occurrence. Corvisart's opinion respecting the syphilitic nature of their cause is not intitled to any degree of credit; and Mr. Hodgson relates a case, where the absence of that disease throughout the whole of life made it impossible that they could have had such an origin. The femoral artery and commencement of the profunda were in this instance completely obstructed by a fungous growth, similar to what was found upon the semi-lunar valves of the aorta.

5. The next disease to be noticed is a deposition or calcarceous matter in the coats of arteries. In old age this happens so frequently, that Bichat was induced to regard it as a natural phenomenon rather than a disease. The incrustation seems to commence in the substance of the internal coat, a delicate pellicle covering the calcareous matter, and separating it from the blood passing through the cavity of the vessel. Sometimes this pellicle is deficient, or hangs into the cavity of the vessel, and the blood is in contact with the incrustation itself. Sometimes all the coats of the vessel are involved in the disease, and are converted into a long cylinder, in which no remnants of the original structure can be traced. (Hodgson, p. 21.) The formation of these depessions bears no resemblance to that of bone; they are seldom, if ever, preceded by the existence of cartilage; and no regular arrangement is discernible in them, corresponding to the fibrous structure of bone. According to Mr. Brande's analysis of them, they contain 65.5 phospate of lime, and 31.5 animal matter, without any carbonate of lime.

Calcareous matter is frequently deposited in the substance of the semi-lunar valves of the aorta, and produces more serious consequences, than when it takes place in any other part of the arterial system. The valves becoming rigid and fixed diminish the size of the opening into the aorta. Whilst the pulse at the wrist is feeble, the heart is acting violently to compensate for the diminution in the quantity of blood which should pass through the aorta; and this comparative difference between the pulse at the wrist and that at the heart will, Mr. Hodgson conceives, in advanced age; be sufficient to enable us to ascertain the existence of this incurable disease. A similar disprortion between the pulse at the heart and at the wrist exists also when the opening between the left auricle and ventricle is contracted; but a double pulsation of the heart has been observed in this case, and is said to distinguish it from contraction of the orifice of the aorta by oblitercation of its valves.

Mr. Hodgson has given some interesting cases of oblitercation of the coronary arteries. In one, the heart was unusually small; its parietes soft and flaccid, and upon the ventricles not the eighth of an inch thick; whilst the coronary arteries and many of their ramifications were converted into
ART

into calcareous tubes, and some of them nearly rendered impervious. This morbid appearance does not exist in every cæsium which is attended with the train of symptoms, to which we apply the term angina pectoris. Violent pain in the situation of the heart, extending down the anus, and terminating in a fenation of numbness, palpitation, and irregularity in its action, with frequent syncope and difficult respiration, accompany almost all the organic diseasés of that organ. (Hodgson, p. 56.) The deposition of calcareous matter is seldom found in the upper extremities; and although so frequent in the aorta, it has rarely or never been met with in the pulmonary artery, or its valves. See Hodgson on the Diseases of Arteries and Veins, Svo. London, 1815.

Anserina, which constitutes the most important disease of arteries, has been treated of in a separate article, to which we have already annexed some additional particulars under the head of Surgery. A few other observations, relative to the same subject, will be found at the words Anserina and Aorta in this Addenda.

Eff. Ch. Receptacles in an uninterrupted crust, shapeless, without a border, smooth, in which the seeds are imbedded.

In habit, the generality of the species which constitute this genus are akin to Spiroma and Opegrapha. (See those articles.) But Acharias originally included herein the Lichen cæsium, and L. fasciculatus of Linneaus, which are now separated on account of their totally different habit, and leafy fronds, by the name of Solorina, Lichenogr. Univ. 27. t. 1. f. 5, 6; so that Arthonia is rendered much more natural. In the Synopsis of this writer, his late publication, twelve species are defined.

A. astroideae, n. 7. (Opegrapha astroidea; Ach. Meth. 25. Engl. Bot. t. 1847.)—Crust limited, membranous, smooth, greenish-white, somewhat shining. Receptacles depressed, flat, angular, irregularly flat, black. Frequent on young trees. We cannot consider this otherwise than as an Opegrapha.

A. obscura, n. 8. Engl. Bot. t. 1752.—Crust membranous, olive-brown. Receptacles minute, flatish, thin, elliptical or kidney-shaped, fink, slightly uneven, black. On the barks of trees, not common, nor very easily to be observed. The crust rises into irregular swellings, and the copious receptacles are fink very deep into its substance. The genus of this plant is indeed obscure, nor can we offer any better determination respecting it than that of Acharias.

A. lycnea, n. 11. (Lichen lycnea; Engl. Bot. t. 809.)—Crust white, thin, even, somewhat tartaceous. Receptacles numerous but distinct, flat, rather fink, oblong, blunt, often curved, black, with a glaucous tinge. Found by Mr. Sowerby, nearly covering the rugged barks of old oaks. The receptacles resemble a leopard's or lynx's skin, and are not crowded nor confluent, though curved and approaching each other in every direction, the margin of each black. We should rather refer this species to Opegrapha.

A. praunis, n. 12. (Lichen impolitus; Ehrh. Crypt. Achar. Prodr. 56. Effgl. Bot. t. 981.)—Crust whitish, thin, somewhat tartaceous, unequal, smooth. Receptacles flat, fink, roundish or angular, confluent, dull orange-brown, with a glaucous tinge. On the trunks of trees, especially oaks. We cannot but think the original specific name peculiarly happy, and for that reason, if no other, it ought not to have been changed, especially as praunis is equally suitable to the last species. The perfect looks of an uniform dirty white, till touched by some hardish body, when the brown receptacles, tinged with yellow, become strikingly apparent, and are contrasted with the unaltered crust. The figure in Engl. Bot. printed in red, is altogether erroneous.

Gen. Ch. Cal. none. Cor. of one petal, inferior, in six deep, regular, spreading, deciduous segments; the three innermost waved or fringed at the margin. Stam. Filaments fix, tapering, densely bearded; anthers roundish, attached by the notch at their base. Pist. German superior, roundish, with three stigmas; style solitary, erect, cylindrical, stigma capitulate, hairy. Peric. Capsule nearly globular, with three stigmas, three cells, and three valves; the partitions from the centre of each valve. Seeds few in each cell, somwhat angular, with a naked scar.

Eff. Ch. Corolla in fix deep equal segments; three innermost waved or fringed at the margin. Filaments bearded. Capsule nearly globular.

This genus is allowed by its author to come very near Anthericum, to which some of the species have been referred by other writers. Indeed we can discover no difference, (three of the filaments in Anthericum, if not all of them, being bearded,) except the wavy or fringed inner segments of the corolla. Anthericum being a very extensive genus, whose limits are not well defined, it is highly desirable to lessen the number of species, by establishing new genera from among them, by any certain, however apparently flight, criterion; and it must always be recollected that, in the natural order to which these plants belong, very natural genera are discriminated by apparently rather trivial marks.

Arthropodium is observed by Mr. Brown to consist of smooth herbaceous plants, with falcipulatæ roots, composed either of bulbs, occasionally stalked, or of thick flaky fibres. Leaves linear, flaccid. Flowers lax. Flower-flakes either aggregate or solitary, each with a joint in the middle. Flowers pedulous, either purplish or white. Corolla closing after flowering, and long before the fruit ripens, falling off, leaving its permanent cup-like withered base behind. The anthers are purple, or whitish. Thysonotus of our learned friend, already described in our thirty-fifth volume, comes nearer to Arthropodium and Anthericum than to the Alparagus tribe, to which it has been referred; the beautifully fringed inner segments of the corolla especially referring the present genus. But Thysonotus has smooth filaments, unequal anthers, and a declining style, with a smaller stigma. The seeds moreover differ very essentially.

X x 2
ARU

Addresed to Dr. John White.

3. A. igneus. Sunk Aecospora. Ibid. 35. t. 4. f. 7, d, e. —Scattered, immersed, irregular, somewhat conical, rather furry externally. —In the same situations, almost entirely sunk in the dung, so that the solid caps only are prominent, containing black seeds, floating in an evident fluid. Perfoon.

Eff. Ch. Thread-shaped, terminating in an empty, slightly inflated, head.

In Sweden the smallest denomination of weight is the as, which is the same as the as of Amsterdam. The mark for weighing gold and silver, called "gilvere-mark," is 4384 ares, or 3252 grains English troy weight. Hence 40 such marks are = 271 ounces troy. In apothecaries' weight, the pound is 7416 ares, or 5400 grains troy; and hence 16 such pounds = 15 pounds English troy, or apothecaries' weight.

As, l. 16. 23, 27, for Tullius r. Tullius.

ASCAM, l. 2, after Bengal, infert—bordering on the country of the Grand Lama, or Bootan;—after Hindostan, or separated from Decca, the N.E. quarter of Bengal, by a range of hills, intersected by the Ganges;—after Meckley, or Ava and Arracan.

L. 16, after journey, add—It is understood to be about 700 miles in length, and its mean breadth above 70, though in some places, where the mountains recede, it greatly exceeds that proportion. Dr. Wade thinks 60,000 square miles a very moderate calculation of its superficial extent, so that it considerably exceeds England and Wales. The whole country is a valley of great fertility, not only divided by the great stream of Barmel-tooter, but every where intersected by numerous rivers.

ASAPH, Str. l. 12, for Shipley r. Bagot.

ASCRHAF—This place is leated on the shore of a bay, which is the only good harbour on the southern side of the Cape of Good Hope.

ASCUBOLUS, in Botany, from *A. ovata*, *a skin*, or *cafe*, and *sene*, a *cafe*, or *theta*, because the seeds are thrown out with elasticity, several together, in oblong cafes. —Perf. Syn. Fung. 676. Obs. Mycol. facs. 1. 33.—Clafs and order, Cryptogamia Fungi. Nat. Ord. Fungi.

2. A. aphylla. Leafless Arthrostylis. Br. n. 1. —Found by Sir Joseph Banks, in that part of New Holland which lies within the Tropic of Capricorn. The *flora* is slender, unbranched, without joints or knots; thepached at the base; naked in the upper part. Head terminal, simple, turbinate, longer than its three or four-leaved, awl-shaped involucrem. This genus differs from Arthrostylis in its habit, and single-flowered spikelet; from Rhynchospora in having a deciduous *floral*, and so bristles surrounding the base of the germ; see thefe articles. Brown.

ARTUSI, l. 4, infect. he.

ARVE, for Rhine r. Rhone.

ARUNDINARIA, in Botany, inadmissible as a generic name, being formed by an alteration of Arundo, already received, is applied by Michaux, Fl. Boreal-Amér. v. 1. 73, to a genus now called *Migia*, in Perf. Encr. v. 1. 102, according to Pursh, 59. This cannot, we presume, answer to Schreber's *Migia*, (see that article,) as the flowers in Michaux's plant are numerous; so that here is some confusion which we must leave the writers in question to settle.

AS, in Commerce, a small Dutch weight, used also at Hamburgh, and in Sweden. At Amsterdam, 640 ares are = an ounce, and 8 ounces = a mark troy. (See Mark.)
Tode in Schrift. — Found in autumn, either at the extremities of the branches, or on the trunks, of trees, such as Willows, &c. It may be preferred a long time without decaying, or even shrinking. Tode describes the head as at first like a drop of water, but soon assuming an oval figure, shining like silver, and subsequefly besprinkled with snow-white powder, probably the seeds. This betrays some affinity to Stellium; see that article.

ASCIDIA, l. ult., dele which see respectively, and ifert, See Verrmes.

ASCIONIS, l. 1, r. Pedianus; l. 3, 4, dele Quinillian and.

ASH, in Geography, a county of North Carolina, containing 6394 inhabitants, 147 being slaves.

ASHARIANS. See Ascharians.

ASHBURNHAM, l. 4, r. 1036.

ASHBY, l. 3, r. 1103.

ASHFIELD, l. 4, r. 1869.

ASHFORD, a township of America, &c. add.—The number of inhabitants by the census in 1810 is 2532.

ASHFORD, New, &c. for 4600 r. 411.

ASHTABELU, a township of the county of Georgia, in the district of Ohio, having 921 inhabitants.

ASHTON, a township of Pennsylvania, in the county of Delaware, having 9765 inhabitants.

ASIA, col. 24, l. 31, after height, infert.—but by late discoveries and measurements, their altitude has been found to be much more considerable than geographers formerly apprehended and flatted. See MOUNTAINS.

ASILUS, l. 16, dele which see respectively.

ASIMA, in Botany, a barbarous name, employed by Adanson, and, according to him, of Canadian origin. De Candolle, by his adoption, Syll. v. t. 478, might possibly render it classical, there being no objection on the score of euphony, nor any meaning contrary to reason or sense, as in many other cases of a similar kind. As far as we know, the word is distinct from all meaning whatever; in which respect Michaux's synonym, Orchidocarpus, would be preferable, were the idea it conveys unexceptionable, and the word not compounded of another generic name. All things considered, we prefer Porcella (see that article hereafter) as entirely free from objection; for we cannot follow our distinguished friend, De Candolle, in separating this hali-named genus from his Aflamina. Our preceding articles Orchidocarpus and Porcella are now superceded, in consequence of more accurate information, chiefly furnished by De Candolle.

ASCARAGI, the 12th natural order in Jussieu's system, the second of his third class; for the full characters of which class, see PALME.

Jussieu thus defines the Asparagi, which are nearly equivalent, as we have already observed, to the Linnaean Samencataceae. See that article.

Calyx in six divisions, regular, usually deeply divided and inferior, rarely superior. Stamens six, inserted into the lower part, rarely into the middle, of the calyx. Germen simple, mostly superior; styles either three, with as many stigmas, or the style is simple, with a stipe or three-keft stigma. Fructi pulpy, rarely capsular, superior, rarely inferior, of three cells, with one, two, or not many more seeds in each. Corculum at the scar of the horny albumen.

The stem is frequently herbaceous, in some cases shrubby. Leaves mostly alternate, seldom opposite or whorled, for the most part not sheathing, but merely clasping the stem. Flowers each with a separate sheath; in some inflorescences, perhaps from abortion, dioecious. A third part of the fructification is sometimes, in a few inflorescences, suppressed, or a fourth is added.

Seet. 1. Flowers perfect. German superior.

Dracaen of Linnaeus; Dissellia of Lamarck; Ripogonus of Forster; Flagellaria and Aparagus of Linnaeus; Callitene and Philagia of Commeron; Medeola, Trillium, Paris, and Convallaria of Linnaeus and others, constitute this section.

Seet. 2. Flowers dioecious. German superior.

Rufcalis, Smilax, and Diofora.

Seet. 3. Flowers dioecious. German inferior.

Tamus of Linnaeus, (which Jussieu, following Tournefort, calls Tamus,) and Rejoania.

Mr. Brown, Prodr. Nov. Holl. v. 1, has greatly curtailed this order, referring some of its genera to the Aphpodi or Aphpode, and elating out of it a new order, termed Smilaces, composed of Trillium, Paris, Medeola, (except its Cape species,) Convallaria, and Streptopus, with his own Drynopilus, Ripogonus of Forster, and Smilax. The same author has also founded on the genera of Diofora and Reojania another order called Diofora; but hardly Tamus, by his own account, connects this with the Smilaces.

ASPE, for Berne r. Bear; and for Switzerland r. France.

ASPER, in Commerce. Subjoin—See Piastre.

ASPERGILLUS, in Botany, a name first applied by Micheli, Nov. Gen. 1712. t. 91, to a tribe of minute Fungi, and expressive of their resemblance to the form of a sprinkling-brush, used for holy water in Catholic countries. This tribe is now become a section of Persoon's Monilia. See that article.

ASPERFOLIAE, the forty-first of the natural orders of Linnaeus, is one of the most natural of these affinements. It was first pointed out by Casalpinus, but obtained the above name from Ray, in allusion to the roughness of the foliage. To this character one or two species of Cynoglottum and of Pulmonaria alone afford exceptions; which indeed are but partial, for even in these some bristly roughness is almost always to be discovered, either on the surface or margin. This order is analogous to Jussieu's Borraginaceae, and is so well defined that Linnaeus has, contrary to his usual practice, given its characters at some length, as follows.

Root fibrous. Cotyledons two. Stem with alternate round branches. Leaves alternate, simple, for the most part nearly entire, rough with scented bristly hairs, or callous warts; convolute before they expand. Stipits wanting, as well as all other appendages in general. Flowers unilateral; their common stalks, generally in pairs, revolute in a spiral manner, and gradually unrolled as the flowers are ready to open. Calyx in five more or less deep divinlons. Corolla monopetalous, inferior, five-keft, regular except in Echium; its mouth either closed with vauted valves, or crowned with teeth, or naked and pervious. Stamens five, equal, except in Echium. Fruit superior. Germens four, except in some species of Cynoglottum, Tournefortia, and Nolana, to which Germinthe should be added; but Nolana was properly removed by Linnaeus afterwards to his Liride; these are inserted into the receptacle by their bafe; hence the lower part of each fcd becomes tapering, as if finished artificially. Pithil one; stipe not an elongation of the germen, but fink between them in the centre, often divided into two equal parts. Seeds four, rarely combined into two.

The genera stand thus:

Seet. 1. Symphytum, Ononis, Cerinthe, Borage, Echium, Scrophularia.
ASP

Lycophis, Asperugo, Pulmonaria, Lithospermum, Cynoglossum, Anchusa, Myosotis, and Heliotropium.

Seet. 2. Tournefortia, Varronias, Eretia, Cordia, and Patagonia.

Seet. 3. Nolana; here placed by itself, is now removed.

In the Linnaean manuscript, Mefiromchus is introduced between Eichium and Lycophis; Caledonia after Heliotropium; Hydrophyllum and Elphis after Tournefortia; and Eretia is removed to the end of all.

In the generic distinctions of this order, the valves or teeth of the corolla, and the more or less deep divisions of the calyx, take the lead. Linnaeus has been thought by some to have multiplied the genera beyond necessity; yet it is hard to say how they could naturally be abridged. The plants love a dry hilly situation, and become smoother as they approach nearer to water.

The numerical anomaly in the fruitification of the Asperifolia, of the four-cleft fruit, with a five-cleft flower, is one of their striking characters, in which they indeed agree with the Linnaean Verticillata, Jussiefi's Labiatze; but the irregular corolla, unequally-divided style, opposite leaves, and square stems, of the latter, and especially their four flamen, two longer and two shorter, clearly distinguish them. Their qualities also greatly differ, being aromatic, not mucilaginous and fessile. Their flowers are generally red or purple; those of the Asperifolia of a beautiful blue, though mostly of as beautiful a red before expansion.

ASPHODEL, the sixteenth natural order in Jussieu's method, the sixth of his third class, thus denominated after Asphodelus, one of its well-known genera. Mr. Brown, who has greatly enriched this order with new genera, as well as with removals from the Asparagi (see that article), gives it the appellation of Asphodelae, Prodr. Nov. Holl. v. 1. 274. The characters of Jussief's third class are detailed under Palmar. He thus defines the Asphodelae.

Calyx inferior, coloured, often in five deep equal segments; rarely tubular, with five less deep divisions. Stamina fix, inserted into the bottom or the middle of the calyx. Gynaeceum superior, simple; style fiddle; stigma either simple or three-cleft. Capsule of three cells and three valves, with many seeds.

The root in a great portion of these plants is bulbous, sending up a leafless stalk, and producing capillary fibres from its base downwards; in the rest it is fibrous, bearing a stem, for the most part herbaceous. Leaves sheathing, alternate, all generally radical. Spike often simple, terminating the stalk; sometimes branched, with fealy sheaths under each branch. Flowers each accompanied by a sheath, or spathe, spiked, (in Allium umbellate,) terminal, or rarely axillary.

Seet. 2. Flowers spiked. Root fibrous. Calyx in five deep segments, bearing the flamen at its base. Anthestherium of Linnaeus, comprehended under Asphodelus by Tournefort; Pholiumium of Tournefort, partly comprehended by Linnaeus under Anthestherium (and very improperly named, as Pholiumium is an established genus of inflates); with Asphodelus, of Tournefort and Linnaeus, constitute this section.

Seet. 3. Flowers spiked. Root bulbous. Calyx tubular at the base. Botrydes of Jussieu, now universally called Eucomis; Hypocotis of Tournefort and Linnaeus, including Muscarv of the former; Phormium of Forster; and Maffonia of Thunberg. Lachenalia of Jacquin ought also, as Jussieu supposes, to be placed here, being very distinct from Phormium, though once confounded with it.

Seet. 4. Flowers spiked. Root bulbous. Calyx in five deep segments, bearing the flamen at their base. Cymularia, Albica, Scilla, and Ornithogalum.

Seet. 5. Flowers umbellate. Root bulbous. Calyx in five deep equal segments. Allium is here the only genus.

Mr. Brown declares, that he has in vain sought to establish a clear definition of this order, though a truly natural assemblage, whether considered as an order by itself, or as a section of the Liliaceae. (See Lilia.) He has not been able to detect any character common to all the plants, which is not found in several of their near allies, except the black, crustaceous, brittle skin of the seed, easily separable from its very thin proper membranous integument. Hence Mr. Brown has been led to place at the end of this family Hyposis and Curculigo, as having a similar skin, though their germen is inferior: and for the same reason he removes Blinda from hence, not only on account of the hairy integument of its seed, but also because there is a difference in the burbling of its capsule, to say nothing of other particulars. The same author notices a joint at the middle or summit of the flower-flalks, frequent in this family, and scarcely observable in the neighbouring orders, except in Santosevea, and some of the Commelina tribe. He is decided against separating the pulp-fruiting genera from the rest, either in this order, or the true Liliaceae. It is needful to point out, that what Jussieu and Brown term calyx in all these plants, is with Linnaeus and his school a corolla, and bears the latter appellation in Hort. Kew. The New Holland Alphodelae are thus arranged by Mr. Brown. Anthestherium; Anthrophorum, Br.; Chlorophyllum, Ker in Curt. Mag.; Caphia, Tricoryne, and Stephandra, of Brown; Dianella, Lamarck; Cordylina, Connerion; Asphodelus; Erythroxylum, Br.; Luzuriaga, Ruiz et Pavon Fl. Peruv.; Thysanotus, Br.; Sowerlea, Sm.; Laxmanni, Br.; Borja, Labill. Nov. Holl.; Johnfonia, Br.; and Xanthorrhiza, Sm. To which are subjoined genera intermediate between the Alphodelae and Anaphylides; Hyposis; Curculigo, Gardn.; and Campylium, Labill. With Asphila, intermediate between Alphodelae and Juncea.

ASPIDIUM, a genus of Filices (see that article), separated from the Linnaean Polypodium, on account of its being furnished with an involucrum, to each round dot, or mass, of capsules, representing a small shield, which is very descriptive of the shape of this involucrum. The propriety of subdividing the original Polypodium was doubtfully hinted by the writer of this article, in his Essay on the Genera of Doriiferous Ferns, and Dr. Swartz adopted this measure. Mr. Brown has carried it still further, by founding his genus Nephrodium; see that article and Polypodium. We need not here repeat our observations, already made in those places. We shall give a general view of Aspidium, according to our ideas of this genus.—Swartz in Schrad. Journ. for 1800. v. 2. 29. Syn. Fil. 42. Sm. Fl. Brit. 1118. Willd. Sp. Pl. v. 5. 211. Ait. Hort. Kew. v. 5. 507. Brown Prodr. Nov. Holl. v. 1. 147. Pursh 660. (Nephrodium; Michaux Borel.-Amer. v. 2. 266. Brown Prodr. Nov. Holl. v. 1. 148.)—Clafs and order, Cryptogamia Filices. Nat. Ord. Filices.

Gen. Ch. Capsules annulated, numerous assembled in roundish masses, scattered over the back of the frond. Involutum roundish or kidney-shaped, with a lateral sinus, by which it is attached to the frond, at length becoming umbilicated, and more or less orbicular.
Fruktification in roundish, scattered, not marginal, dots. Involucrum umbilicated, separating almost all round.

Sect. 1. Frond simple. Two species in Swartz; three in Willdenow.

A. nodatum. Knotty Shield-fern. Willd. n. 1. (A. articulatum; "Schkuhr Crypt. 28. t. 27, copied from Plummer." Lingua cervina luida, pediculus articulatus; Plum. Fil. 118. t. 136. Petiv. Fil. t. 10. f. 3.)—Fronds simple, oblong, wavy, bordered; acute at each end. Dots in interrupted lines. Stalks jointed, smooth. Root creeping, chaffy and hairy.—Found by Plummer on trees in the forests of Martinico; no other botanist having, as far as we know, ever met with this species. Willdenow separates it from the following, which he had examined, chiefly on account of the fori being disposed in chain-like rows, and the frond having a thickened margin. Petiver’s figure is copied from Plummer, as usual with the Ferns of that author.

A. articulatum. Jointed Shield-fern. Swartz n. 1. Willd. n. 2. (Polypodium articulatum; Lamarc Dict. v. 5. 514.)—Fronds simple, oblong-lanceolate, finely crenate and wavy, pointed. Dots scattered, solitary. Stalks jointed, scaly. Root creeping, chaffy and hairy.—Native of the Mauritius; on trunks of trees. We have one of Commerson’s specimens. The fronds are a foot long, not thickened at the edges, but very unequally and minutely wavy, as if crenate; the flalk of each not one inch in length, instead of two, or more, as in the foregoing. Sori in a simple, slightly undulating row, on each side the mid-rib, not half way between it and the margin, rather small.

Involucrum perfectly peltate, but more or less notched at one side, dark brown; pale and undulated at the circumference. Capfules light brown, minute.

Sect. 2. Frond ternate. One species in Swartz; four in Willdenow.

A. trifoliatum. Three-leaved Variable Shield-fern. Sw. n. 3. Willd. n. 5. Ait. n. 1. "Schkuhr Crypt. t. 28." (Polypodium trifoliatum; Linn. Sp. Pl. 1547. Jacq. Coll. v. 3. 185.)—Fronds simple, oblong-lanceolate, coarsely crenate and wavy, point¬ed. Dots scattered, solitary. Stalks jointed, scaly. Root creeping, chaffy and hairy.—Native of the Mauritius, on trunks of trees. We have one of Commerson's specimens. The fronds are two feet long, not thickened at the edges, but very unequally and minutely wavy, as if crenate; the flalk of each not one inch in length, instead of two, or more, as in the foregoing. Sori in a simple, slightly undulating row, on each side the mid-rib, not half way between it and the margin, rather small.

Involucrum perfectly peltate, but more or less notched at one side, dark brown; pale and undulated at the circumference. Capfules light brown, minute.

A. punctatum. Dotted-bordered Shield-fern. Swartz n. 21. Willd. n. 17. (Lingua cervina dentata, punctulis nigris notata; Plum. Fil. 98. t. 112.)—Frond pinnate; leaflets uniform, linear-lanceolate, pointed, serrated; with a marginal row of minute imprefions on the upper side; downy beneath.—Gathered by Plummer in Martinico. We have it from Jamaica. Willdenow moreover mentions Guinea, as the native country of this species. Each frond is five or six feet high. Common stalk round at the back, furrowed in front, light brown, not smooth, but clothed with fine, soft, narrow, silky scales. Leaflets very numerous, alternate, four or five inches long and nearly one broad, slightly flaked, bright green, rather thin and plant, unequally, and sometimes doubly, serrated; finely downy at the back; broadly wedge-shaped, and occasionally slightly araucated at the base; their upper side smooth, each vein terminating near the margin in a blueish, withered, minute spot, the se, as it appears, of the flowers; for a similar mark is found over every mufs of capfules; but these being situated in a fimple row, at some distance from the margin, the spots which mark their infection are much further from the edge than the abortive spots. Plummer repre¬sents a row of fuch spots on the under side, at every ferrature. He is so supremely accurate, that we have sometimes doubted our plant being the fame as his, of which there is otherwise no appearance. Every thing which may lead to the dis¬covery of the flowers of ferns is so interesting, that we are here tempted to be more particular than usual. The mufs of capfules are large, prominent, of a bright tawny-brown, each with an almof perfectly circular and umbilicated involu¬crum. It seems to us a cuious quefion, how the spots above-mentioned which are attended by fertile capfules, in large convex fori, come to be arrefted at a considera¬ble distance from the edge of the leaf, while, without any difference in their size or appearance, the abortive ones are advanced almost to the base, or even the dikk of each ferrature.

A. Loo-
A. Lonicchis. Rough Alpine Shield-fern. Swartz n. 5. Willd. n. 25. Fl. Brit. n. 1. Engl. Bot. t. 797. (Polypodium Lonicchis; Linn. Sp. Pl. 1548. Fl. Dan. t. 497. Lonicchis afera major; Ger. Em. 1140. Matth. Valgr. v. 2. 273. Camer. Epit. 664.)—Frond pinnate, chaffy: leaflets fickle-shaped, decumbent, acute, with fringe-like furrations; auricled at the upper angle of their base; wedge-like at the lower.—Native of the crevices of dry rocks in alpine or subalpine situations, throughout Europe. It has been found in Scotland and Wales, but scarcely we believe in England, though Harv. plants of A. acutatum are occasionally taken for this species. The fronds are a span high, more or less, growing in tufts, erect, lanceolate, rather narrow, or linear. Leaflets numerous, crowded, dark greyish-green, about an inch long, the upper ones, about one-third of the whole, copiously fructifying; the rest barren; several of the lowermost gradually shortened, but not contrasted in breadth. Sori in a simple row on each fide of the rib, rather nearer to it than to the margin; pale; the involucrum of each peltate and umbilicated, without any notch, completely orbicular.

A. acrolochoides. Crowded Shield-fern. Swartz n. 11. Willd. n. 26. Pursh n. 2. (“A. auriculatum; Schkuhr Crypt. 31. t. 39. excluding the synonyms.” Willd. Neophyllum acrolochoides; Michaux Borcaral. Amer. v. 2. 207. Polypodium frondes pinnatae lanceatae, foliosis Inflammatis, &c.; Gron. Vetr. ed. 2. 167, excluding all the synonyms, except Claxton’s.—Frond pinnate, chaffy: leaflets fickle-shaped, acute, with fringe-like furrations; auricled at the upper angle of their base; uppermost diminished, covered with confluent mafles of capsules.—Native of rocks, in floky low places, from New England to Carolina, bearing capsules in the summer. Pursh. This fern has long been cultivated in the more curious gardens of England, having been introduced, if we recollect right, by Robert Barclay, etc., at Clapham. A taller plant than the last, and of a lighter green. The auricle of the lowermost leaflets sometimes becomes quite distinct and separate. The fori are found upon half, or one-third, of the upper leaflets, in a single or double row, at each fide of the mid-rib, and are particularly crowded on the auricles. They become tund to the capsules ripen, and run into one mass, fludded, as it were, with the pale-brown involucrum, which are circular and peltate, though cloven at one fide, the edges of the fimus folding over each other. Linneus confounded this with Asplenium herschii, as well as with his own Polypodium auriculatum, an East Indian species, hereafter described.

A. auriculatum. Auricled Shield-fern. Swartz n. 10. Willd. n. 32. Ait. n. 3? (Polypodium auriculatum; Linn. Sp. Pl. ed. 1. 1088. ed. 2. 1548. Felix zeylanica, lonchitides facie; Barm. Zeyl. 98. t. 44. f. 2.—Frond pinnate: leaflets lanceolate, falcate, ferrated, frigrated; auricled at the upper angle of their base. Mafles of capsules diffinet in simple rows.—Native of the rocky fummings of mountains in Ceylon. König. Brought to Kew garden, in 1793, by admiral Bligh. Aston. This species has no affinity or refeemblance to the last, with which Linneus, and after him Swartz, confounded its synonyms and character. Even Willd., who corrected these errors, is miffaken in faying the falk is fmoother. The frond is from fix to twelve inches high. Stalk fcaly in front; rough with minute points behind. Leaflets numerous, narrow, an inch and a quarter or an inch and a half long, tapering but not pointed, coriaceous, fmoother, with fine, blunt, notched, or fringed, furrations; even above, frigrated with tranferve veins beneath; dilated at the base; the auricle broad, short, and bluntish. Sori small, flinef, in an even row on each fide of the mid-ribs of the leaflet and its auricle. We have not feeen the involucrum. The ripe caffe le are inferted by fine capillary fals into a convex knob. Linneus fays in Fl. Zeyl. n. 283, where he originally defined his Polypodium auriculatum, that the plant is entirely fmoother. The thiggnets and flight roughnefs of the falk may therefore be variable. He there cites Plukenet, t. 30. f. 4. which is in no refpect confondant with König’s fpecimens. Mr. Menzies gathered on the west coft of North America a fern very like this, except that the furrations are brafly, and the leaflets less frigated. Its falk is very fcaly all the way up.

A. exaltatum. Lofty Shield-fern. Swartz n. 14. Willd. n. 34; excluding the synonym of Linneus. Ait. n. 4.—“Schkuhr Crypt. 33. t. 32. b.” (Lonicchis ghabra minor; Plum. Amer. 19. t. 28. Fil. 48. t. 63. L. altissima, pinnis utroque lateroe, auriculatis; Sloane Jam. v. 1. 77. t. 31.)—Frond pinnate: leaflets lanceolate, ferrated; with a row of minute white impreffions on the upper fide, towards the margin; unequally haftate at the base. Mafles of capsules in a fimple row, towards the margin. Stalk even, slightly fcaly.—Native of Jamaica, and other parts of the Weft Indies. Brought to the frows at Kew, by admiral Bligh, in 1793. The fronds are usually three or four feet high, erect, ftraight, narrow, with a polihed, pale-brown falk and mid-rib, occasionally fomewhat flaggy. Leaflets numerous, parallel, close, nearly ftraight, two inches long at molt, very fmoother; rather rounded at the point, their fhalow, blunt, unfringed furrations moft abundant in their upper half; the fale dilated into two fhort broad auricles, fefitate of fructification, of which the lower one is thirft, and moft rounded. Sori numerous, diffinet, rather large. Involutum not perfectly orbicular, nor feerily falent, having a deep finus at the fide towards the base of the leaflet, fo as to refembe a froke-flue. This fern is very diffinet from our Davallia faleata, though Dr. Swartz fuppofed the contrary. Linneus confounded its synonyms with the following. The row of minute withered fpecks, as far as we can fee, only accompany the fori there being, in our fpecimens, no barren ones as in A. pungu- tum.

A. blechnoides. Long-leaved Shield-fern. (Polypodium exaltatum; Linn. Syth. Nat. ed. 10. v. 2. 1326. Sp. Pl. ed. 2. 1549; excluding the synonyms, and fubfifting the following. Felix minor, in pinnas tantum divisâ, crebras non creatus, inferiores latere auriculatas, et rotundis pulvulturibus arcolarum awróù parte notatas; Sloane Jam. v. 1. 86. t. 44. f. 1.)—Frond pinnate: leaflets linear-lanceolate, elongated, catrie, with a rounded incurred auricle at the base on the lower fide, and a flight dilatation on the upper. Masses of capsules in a double row.—Native of Jamaica, on the fides of hills. Linneus received his fpecimen in Browne’s herbarium, with an erroneous reference to Sloane’s t. 31, which belongs to our laft-described. Hence there has always been a confusion respecting these two ferns, which even Dr. Swartz could not reconcile; see his Syn. Filicum, 65, where he cites Sloane’s t. 44; but ought to have added fig. 1; as fig. 2. is Blechnum occidentale. The specific name of Polypodium exaltatum, being taken from Plufer’s and Sloane’s accounts of the foregoing, and that being universally received as Aspidium exaltatum, we have not changed its denomination. That name is not at all applicable to the species before us, which is more expresfively called blechnoides. Its height is only eighteen or twenty inches. Leaflets from four to fix inches long, taper-pointed; the lower auricle of each overlapping the main falk, and looked
hooked or curved in a curious manner, not well expressed in Sloane's plate. *Sori* in double rows close to the mid-rib at each side. *Involucrum* perfectly peltate, orbicular, and entire.

Section 39. *Ehrh. leaflets in Willdenow.* Swartz does not separate this section from the following.

Thirty-seven species in Willdenow. Swartz does not separate this section from the following.

A. *Hippercopis.* Horse-shoe Shield-fern. Swartz n. 45. Willd. n. 46. (Polypodium Hippocrepis; Jacq. Col. v. 3. 1866. Ic. Rar. t. 641. Hemionitis lacinis crisps incis; Plum. Fil. 159. f. 150. Petiv. Fil. t. 7. f. 7.)—*Frond pinnate; leaflets oblong, flattened; the upper ones confluent and decurrent; lowermost stalked, pinna-tid; segments obtuse, somewhat crenate; veins downy. *Involucrum* crescent-shaped.—Native of South America, and of Hispaniola, from whence our specimen was brought by M. Thierry de Menonville. Jacquin had living plants of this rare fern from Venezuela, and cultivated it at Vienna. The *fronds* are eighteen inches or two feet high, tufted, of a fine green, more or less downy, especially about the ribs and veins: their *leaflets* flattened in the manner of some species of oak; the segments also flattened, wavy, or crisped. *Sori* chiefly ranged on each side of the mid-rib of the segments, but not being uniformly perfect, they appear irregularly feathered. *Involucrum* like a horse-shoe, to which the specific name applies.

A. unifolium. United Shield-fern. Swartz n. 47. Willd. n. 57. Ait. n. 5. Schkuhr Crypt. 34. t. 33 b. (Polypodium unifolium; Linn. Sp. Pl. 1548; omitting the synon. of Sloane and Plukenet. *F. pyramidalis* madrafatana elegans, pinnuliss ferratis; Pet. Nat. t. 55. f. 1. F. zeylanica denticulata, non ramosa; Burm. Zeyl. 98. t. 44. f. 1.)—*Frond pinnate; leaflets linear, pinna-tid; their very numerous segments ovate, acute, combined, hairy beneath. Stalk downy in the leafy part. *Involucrum* nearly circular, with a deep notch.—Native of Tranquebar and Ceylon. *Frond* two feet, or more, in height: smooth and nearly naked in its lower half, except a few dilatant small leaflets: finely downy and rufous in the upper half, and crowded with fertile, narrow, acute, linear leaflets from three to five inches long. These are composed of innumerable little convex segments, a quarter of an inch in length; smooth and veiny above; ribbed and downy beneath; appearing as if deeply separated, but their edges are firmly united for one-half or three-quarters of their length. Near the margins of these segments are simple rows of smooth horse-shoe-like *involucrum*, covering numerous *capsules* with glittering brown rings.

A. oblatum. Blunted Shield-fern. Swartz n. 39. de St. 248. Willd. n. 58. (Pteris interrupta; Willd. Phytogr. 13. t. 10. f. 1.)—*Frond pinnate; leaflets linear, pointed, slightly pinna-tid; segments obtuse, downy beneath. Stalk smooth. Fructification near the margin.—Native of the East Indies. Very like the last, but the leaflets are more pointed, rather crenate than pinna-tid, and the rows of *sori* so near the margin that Willdenow actually took the plant for a *Pteris* !

A. *Orectopteris.* Heath Shield-fern. Swartz n. 39. Willd. n. 70. Fl. Brit. n. 3. Eng. Bot. t. 1019. “Schkuhr Crypt. 37. t. 35 g, 36 g.” (Polypodium Orectopteris; Ehrh. Crypt. n. 22. Dickf. Tr. of Linn. Soc. v. 1. 181. Fl. Dan. t. 1121. P. Thelypteris; Huds. 457. Bolt. Fil. 40. t. 22. f. 1. 2. Hedw. Theor. 44. t. 6.)—*Frond pinnate; leaflets lanceolate, pinna-tid, entire, besprinkled with reflexous glands beneath. Fructification near the margin, confluent.—Mountains the most ground, and dry woods, in various parts of Europe, from Denmark to Italy, produce this fern, bearing capilines in July. Our British botanists long overlooked it, as a variety of the common *Filix maris*, whilst others miss看好为 Thelypteris. The reflexous dots at the back of the *frond* exhale a fragrant smell, more or less perceptible at different times; which induces a suspicion that this species may have been taken by Mr. Hudson for *Polypodium fragrans* of Linnaeus, never found in our island. In *sori* the present species with *Filix maris*, hereafter to be described, but the whole *frond* is rather narrower. The segments of the *leaflets* usually quite entire, are occasionally somewhat crenate about their rounded obtuse points. *Sori* crowded, in a simple row near the margin, at length confluent, forming a beaded line. *Involucrum* small and thin, umbilicated, with a deep lateral sinus, and foan vanishing. *Root* large, falcate, tufted, not creeping.

A. *Thelypteris.* Marsh Shield-fern. Swartz n. 39. Willd. n. 74. Fl. Brit. n. 2. Eng. Bot. t. 1018. Pursh n. 4. “Schkuhr Crypt. 51 t. 52.” (Polypodium Thelypteris; Linn. Man. 505. Fl. Dan. t. 760. Acrocl. Thelypteris; Linn. Sp. Pl. 1548. Bolt. Fil. 78. t. 43. f. 44.)—*Thelypteris non ramosa; Schmidel 1. t. 11. *Filix thiniflora* et profundi denticulata Montbelgardia; Bauh. Hill. t. 3. 731. good. F. palustris repens, pinnuliss non dentatis; Morf. bed. t. 4. f. 17. 1.)—*Frond pinnate; leaflets lanceolate, pinna-tid, somewhat crenate; divided, but crossing each other, at the base. Fructification scattered, confluent. Root thread-shaped, creeping.—Native of rotten bogs, and turf-y marshes, on a sandy soil, in various parts of the north of Europe, as well as in North America. Mr. Pursh says the fructification is very rare in the latter country: with us it is but sparingly produced, the plant increasing most by the roots, which are long, slender, and creeping. The *fronds* are not half the size of the last, and much more delicate; their height about a foot, their colour bright grama-green. *Leaflets* generally smooth; sometimes a little hairy; the lowest lobe of each extended, so as to fold over the opposite one. *Fructification*, if present, abundant, confluent, blackish.

A. *crifatum.* Leffor Crefted Shield-fern. Swartz n. 39. Willd. n. 79. Sp. Compend. Fl. Brit. 157. Eng. Bot. t. 2125, not 1949. Pursh n. 5. “Schkuhr Crypt. 39 t. 37.” (Polypodium crifatum; Linn. Sp. Pl. 1551. Aflzel. in Stockh. Trauf. for 1787. 248. t. 9. P. Calliperus; Ehrh. Crypt. n. 53.)—*Frond pinnate, nearly bipinnate; segments ovate, obtuse, crenate or pinna-tid, with sharp little terminal teeth. Stalk falcate at the base. *Involucrum* nearly orbicular, with a deep notch.—Native of Sweden, Germany, and England, as well as North America, in low boggy woods and thickets. Found by the Rev. R. B. Francis, on the heath between Holt and Hempstead, Norfolk. The root is tufted, as in *A. Orectopteris*, not creeping like that of Thelypteris, and the whole habit and texture of the fern more resembles the form of these two species. *Fronds* pale green, from one to two feet high: the fertile ones remarkably erect; their barren leaflets shorter and rather more dilatant than those which bear fructification, the latter composing the upper half of the *frond*; all are very deeply pinna-tid, sometimes to the very rib, their segments, or partial leaflets, close, broad, obtuse, with sharp, flaccid, thin, spines, teeth. *Ribs* somewhat zigzag. *Capsules* blackish when fresh, with a white circular *involucrum* to each afflambage, having a deep sinus at the lower side; but the young...
ASPIDIUM.

dried fori are tawny. Common stalk of the frond chiefly scaly at the bottom. Mr. Pursh considers Willdenow's lanceafrons, n. 97, as a variety of this.

A. fragrans. Fragrant Shield-fern. Swartz n. 42. Willd. n. 80. (Polypodium fragrans; Linn. Sp. Pl. 1550. Dryopteris rubrum ideum pfrans; Amman. Ruth. 174. n. 251.) — Frond pinnate; leaflets lanceolate, crowded, deeply pinnatifid; segments elliptic-oblong, bluntly and deeply toothed; stalks and mid-ribs scaly. Fructification crowded. Involucrum nearly orbicular, with a deep notch.—Native of hilly situations in Siberia, near the rivers Angara and Selenga. The inhabitants are said to boil this fern with their beer, in order to give that liquor the taste and smell of Raspberries, which is so powerful in the plant, that even in a dried state its odour fills the room where it is kept. The root is tufted, very scaly. Fronds several, a span high, lanceolate, tapering at each end, the lower leaflets being gradually much shortened. Stalk short, bearing large, rounded, lax scales; those on the leafy part, as well as on the mid-rib of each leaflet, being lanceolate and acute. The upper side of the leaflets is perfectly smooth; their lobes and indentations peculiarly elegant, without any terminal bristles. Sori so crowded about the lower half of each leaflet, that their expanded involucrums sometimes touch, or fold over each other, being moreover intermixed with rufly membranous scales.

Sec. 5. marked 4 by Willdenow. Frond doubly or triply pinnate. Involucrum rounded or kidney-shaped. Forty species in Willdenow. The involucrum in this, as well as the preceding section, though, for the most part, laterally inferted, is often nearly or completely orbicular, and it is even flirly peltate in A. aculeatum and lobatum. Some of the species Willdenow's species, adopted from Plumer's plates only, appear to us scarcely certain in genus,—such arc A. nemorum, Willd. n. 83, velleum, n. 84, and squamatum, n. 87.

A. aculeatum. Common Prickly Shield-fern. Swartz n. 53. Willd. n. 92. Fl. Brit. n. 5. Engl. Bot. t. 1562. Pursh n. 7. "Schkuhr Crypt. 41. t. 39." (Polypodium aculeatum; Linn. Sp. Pl. 1552. Mill. Illuvr. t. 101. Bolt. Fil. 48. t. 26.)—Frond doubly pinnate; leaflets ovate, somewhat falcate, falked, with prickly ferratures; hairy beneath. Common stalks and ribs scaly. Involucrum peltate, entire.—Found in shady woods and hollows, throughout Europe, as well as in Africa, and North America, bearing seed in summer and autumn. The root is large and tufted, producing numerous dark-green fronds, usually two or three feet high, spreading in a circular manner, varying much in size; paler beneath; their general and partial stalks remarkably scaly. Partial leaflets about a quarter of an inch long, rigid or coriaceous, each tapering down into a small short footstalk; their points and ferratures each tipped with a little spiny bristle; their upper edge at the base dilated, more or less, in a broad circular sinus. Sori plentiful on the upper part of the frond, but in single rows, and distinctly, brown. Involucrums pale brown, orbicular, peltate, at length deeply umbilicated, quite entire all round, as in A. Lonchitis, to which this species and the following are closely allied, though all three are very distinct.

The late Mr. Rob. Teedald, (see Teesdalii,) found in many parts of England, a variety of this, which he suspected might prove a distinct species. It is softer, and more delicate in texture, than the common kind, with smaller, more cipitous, partial leaflets, which are more remarkably falked, and their auricles are larger, broader, and different in aspect. This lay in Mr. Rose's herbarium for A. lobatum, which it certainly is not, the partial leaflets being even less decurrent than in our common aculeatum. It may probably be the variety 9 of Fl. Brit. figured in Plukent, t. 180. f. 1., which figure represents well enough the general appearance of the frond, and shape of the leaflets; but their partial stalks are much more considerable and evident than they appear in that plate. A. aculeatum, if transplanted into a dry open situation, soon diminishes greatly in size, so as to resemble A. Lonchitis, for which we once received it; but these species are nevertheless essentially different, as any careful investigator will find.

A. lobatum. Clove-leaved Prickly Shield-fern. Swartz n. 54. Willd. n. 95. Fl. Brit. n. 6. Engl. Bot. t. 1563. (Polypodium lobatum; Hudc. 450. Felix aculeata major, pinnulis auriculatis crebrisobius, foliis integris angulifloribus; Rait Syn. 121. t. aculeata, Lonchitis angulifolia.)—Frond doubly pinnate; leaflets elliptical, somewhat falcate, decurrent, with prickly ferratures; hairy beneath: the foremost of the lowest pair very large. Common stalks and ribs scaly. Involucrum peltate, entire.—Found in shady places, under hedges, in England; not unfrequent in the county of Essex, where Ray first noticed this species, and from whence Mr. Edward Forster has sent us specimens. The Rev. Mr. Francis has met with it at Edgefield, near Holt, Norfolk. There is no record of this fern being found out of Britain. The fronds are always of a narrower, more linear, form than the last, and generally altogether smaller, as well as more rigid, of a paler more shining green. Leaflets rather elliptical than ovate, and Mr. Dawson Turner has well observed that they are decurrent, not falked, which is perhaps one of the most certain means of distinguishing this species from A. aculeatum. The most striking character, indicated by the specific name, consists in the great size, and angular-lobed figure, of the lowest partial leaflet, on the upper side of each general leaflet or pinna, close to the main stalk, often extending beyond the pinna above it. The upper half of the frond, principally, is covered with fructification. The involucrum is perfectly peltate, entire; finally umbilicated.

A. marginale. Marginal-flowering Shield-fern. Swartz n. 41. Willd. n. 93. Nutt. n. 11. Pursh n. 8. "Schkuhr Crypt. 195. t. 45. b." (Polypodium marginale; Linn. Sp. Pl. 1522. Neprodium marginale; Michaux Borel. Amer. v. 2. 267.)—Frond doubly pinnate; leaflets oblong, obtuse, decurrent, crenate; almost pinnatifid at the base. Masses of capsules marginal. Involucrum orbicular, with a lateral sinus.—In rocky shady places, from Canada to Carolina, bearing capsules in July. This species has often been supposed a native of Britain, A. Oreopteris, whose fructification is likewise marginal, having been taken for it; but the American plant is very distinct, more resembling Felix mas than any other. The marginale however is a smaller plant, the upper half of whose frond only bears fructification, and the leaflets are bluntly crenate, instead of being sharply ferrated. They are moreover not uniform, as in Felix mas, but the lower ones of each pinna are larger and more or less pinnatid. Involucrum tupid, corrugated, forming a complete circle, though not peltate.

feffile, sharply ferrated without prickles, uniform. Maffes of capsulæ crowded towards the rib and base of each leaflet. Involucrum orbicular, with a lateral finis.—Very common throughout Europe, as well as in the northern parts of Asia, Africa, and America, in shady situations, under dry banks, bearing seed about July and August. The root is tufted and scaly, often very large. Fronds numerous, bright green, about a yard high, and a span wide, their flâlks and principal rib scaly; the rib of each leaflet is sometimes a little hairy, and slightly bordered, though the partial leaflets are scarcely decurrent, except the uppermost. The frutification is abundant over part of the frond, of a rich tawny-brown, crowded, not confluent. Involucrum turface, embli- cated, with a lateral notch, which is rather more open than in A. marginata, but not quite so deep. The root is a celebrated cure for intestinal worms, in Switzerland and other parts of the continent; and its nauseous taste may, as we understand, be detected in one or more of the popular quack medicines, which in this country obtain credit by puffing advertisements, whose truth it is easier to believe than to examine. Happy if they are never composed of more dangerous materials than the root of the Male Fern! A. spinulatum. Lefser Created Shield-fern. Fl. Brit. n. 8. Engl. Bot. t. 1456. Swartz n. 58. Willd. n. 99. Pursh n. 116: " Schkhuhr Crypt. 48, t. 48." (Polypodium spinulatum; Retz. Prodri. 250. P. Daun. t. 707. P. 8411; Mull. Friedr. 193, t. 2, f. 2. Felix pumila faxatilis altera; Pluk. Phyt. t. 179, f. 5.)—Frond doubly pinnate; leaflets decurrent, elliptical, confluent, with deep-cut prickly ferratures. Mid-rib smooth. Nerves zigzag. Involucrum orbicular, with a lateral finis.—Native of boggy sandy places, in various parts of Europe; as well as in North America, if Mr. Pursh be right; but he speaks of his plant as "a large species," ours is certainly rather small, not above a foot high. The root is creeping. Fronds broad, with a long flâlk, which is scaly in the lower part only. Partial leaflets elliptic-oblong, of an elegant bright pellicent green, with wavy ribs; decurrent, so as to form a border to the partial flâlk. Dots of capsulæ small, and rather dilatant. Involu- crum small, soon pushed to one side. We see nothing in it of a glandular nature, as mentioned by Willdenow. A. dilatatum. Great Crested Shield-fern. Fl. Brit. n. 9. Engl. Bot. t. 1451. Willd. n. 100. Pursh n. 12: (Polypodium dilatatum; Hoffm. Germ. v. 2, p. 7. P. arifatum; Villars Dauph. v. 3, 844. Bellardi in Aet. Taurin. v. 5, 255. P. criptata; Ehrh. Crypt. 81. Huds. 457; Born. Fl. 42, t. 23; P. 845; Mull. Fl. Friedr. 193, t. 3, f. 2. Felix mas ramafala, pinolus dentatis; Rauyn. 124; Pluk. Phyt. t. 181, f. 2. F. mas, pinolus cristafulis; Morif. feq. t. 14, t. 3, f. 11.)—Frond doubly pinnate; leaflets deeply pinnatifid, sharply cut, with prickly teeth and ferratures. Stalk and branches scaly. Involucrum kidney-shaped, foon orbicular, with a lateral finis.—Native of shady watery places, sometimes on dry banks, in a sandy or gravelly soil, or in flinty moist woods, throughout Europe. Mr. Pursh met with this species in the shady rocky woods of Pennsylvania and Virginia. The root is tuberous or tufted, scarcely creeping. Fronds generally two feet, or more, in height, though sometimes much smaller. Their broad, much compounded, form and stræcture, and their bright-green colour, give them a very handfome aspect. They are often triply pinnate, or at least their ultimate subdivisions are so deeply separated as to caufe that appearance: these are pretty uniform, with deep, sharp, prickly-toothed ferratures and points. Stalks, ribs, and veins, a little downy, or glandular; none of them zigzag, or at most very slightly so. Frutification copious all over the frond, rather crowded, not confluent, of a bright brown. Involucrum at frist kidney-shaped, tumid, but soon becoming orbicular, the finus nearly closing, retaining ony an umbilicated depression, and at length the mem- brane remains folded together vertically, in the centre of the mafs of capsulæ.

Sec. 6, marked 5 by Willdenow. Frond either doubly pinnatifid, or doubly or triply pinate. Involucrum lateral. Twenty-six species in Willdenow; nineteen in Swartz. These are perhaps most entitled to constitute a distinct genus, but in several infancies they too nearly approach the last faction to admit of a clear generic definition.

A. fontanum. Smooth Rock Shield-fern. Swartz n. 74. Willd. n. 122. Engl. Bot. t. 2024. (Polypodium fonta- num; Lind. Sp. Fl. 1550. Fl. Brit. 1114. Hudson 456. Villars Dauph. v. 3, 849. P. n. 1756; Hall. Fl. v. 3, 15. Adiantum illicinum durium criptum minimum; Barrel. Ic. t. 423, f. 1. Filula faxatilis, onnum minima, elegantif- lima; Tourn. Int. 342. Pluk. Phyt. t. 89, f. 3.)—Frond linear-lanceolate, smooth, imply or doubly pinnate: leaflets alternate, rounded, their segments very sharply toothed. Stalks winged. Involucrum oblong.—Native of rocks in Europe, England, France, Switzerland, and other parts of Europe, but very rare in this country. Mr. Hudson, and the late Mr. Aiton, to our certain knowledge, have gathered it on the islands of the United States, where it is no longer, as we are told, to be met with. Linnaus confounded this fern with what is now named Woodsia hyperborea (see Cat. t. 349,) nor has it been well understood by botanists in general, being of rare occurrence, obscure in its generic character, and very variable in luxuriance. This may be seen by comparing Plukerius's figure above cited, fig. 3, with his fig. 2, quoted by Willdenow, after Fl. Brit. which last is we believe the same plant, but not under its usual and most natural appearance. When once seen in perfection, this truly elegant little fern can be confounded with no other. The root is tufted. Fronds from two to three inches high, rigid, smooth, rather glaucous, of a narrow lanceolate figure, composed of numerous, alternate, pinnate or pinna- tid leaflets, whose partial leaflets, or lobes, are wedge-shaped, somewhat forked, with deep, sharp, in some degree spinose teeth, and all the flâlks are winged. Maffes of capsulæ at the mid-rib of each lobe, round, or nearly so, with a delicate white involucrum originating from the rib, by a straight lateral infertion, and separating inwards, that is, towards some other more principal rib, not towards the margin. Perhaps this plant is truly an Aspidium. Professor Willdenow has an A. Halleri, n. 125, which he considers abundantly distinct from fontanum, but to which he refers some of our above-mentioned synonyms. We have Haller's plant from Switzerland, and are perfectly certain of its being the same as our fontanum, though we have not the means of verifying all Willdenow's synonyms.

This writer, whose labours respecting Ptileris will ever do his memory great honour, notwithstanding errors unavoidable incident to so difficult an enterprise, has, after the example of Swartz, associated with this tribe some species which we refer to Cyathea. (See the article, written by the late Rev. Mr. Wood.) These are, C. denata, fragili, and regia of Fl. Brit. and Engl. Bot.; there being also several exotic species in the same predicament. Some of them come very near A. fontanum, just described, in the character of their involucrum, but they ill accord with the rest of this genus. A few species, now to be mentioned, perhaps connect them therewith. We shall select such as are most likely to elucidate the subject.
A. bulbiferum. Bulboferous Shield-fern. Swartz n. 82. Willd. n. 126. Afr. n. 20. Pursh n. 13. "Schkuhr Crypt. 55. t. 57." (Nephrodium bulbiferum; Michaux Boreal. Amer. v. 2. 268. Filix baccifera; Cornut. Canad. 5. t. 4. Barrel. Ic. t. 1120. Morif. fect. 14. t. 3. t. 10.)—Frons doubly pinnate, oblong-lanceolate: leaflets ovate, obtuse, pinnatifid or deeply serrated; upper ones confluent. Ribs bulbiferous.—Found in shady woods, among rocks, from Canada to Pennsylvania. Purfe. The frond is about eighteen inches high, narrow, bright-green, smooth, delicately cut; partial leaflets half an inch long at most, decurrent. Maffes of capfules mostly scattered, small, round. The involucrem seems concave, almost hemispherical, turning to one fide; but our fpecimens are not sufficient to ascertain its exact figure. Several of the secondary ribs bear fhilby bulbs, that fall off and become young plants, of which there are infatiates in Woodwardia, (see that article,) and fome other ferns.

A. alpinum. Fine-cut Alpine Shield-fern. Swartz n. 89. Willd. n. 139. "Schkuhr Crypt. 60. t. 62, 3, b." (Polypodium alpinum; Jacq. Coll. v. 2. 171. Ic. Rar. t. 642. P. n. 1709; Hall. Hill. v. 3. 15. Filicula alpina crispa; Buhl. Pin. 358. Segu. Veron. fuppl. 55. t. 1. f. 3. Morif. fect. 14. t. 4. f. 27. Polce crepo fabfette; Pon. Bald. 223, with a figure.)—Frons tripdy pinnate: leaflets linear-wedge-shaped, pinnatifid, confluent; their fegments linear, obtuse, emarginate.—Found on the alpine rocks of Carinthia, Switzerland, France, and the north of Italy. A very flender delicate fern, from fix to ten inches high, smooth, bright green, fometimes afluming a tawny hue. The frond is linear-lanceolate; the ultimate fegments peculiarly narrow and linear, alternate, sharply cloven at the end, but otherwise entire; tapering down into the linear bordered stalk, quite smooth and naked, single-haired. Every fegment bears one small round mass composed of a very few capfules, rather large in proportion, each having a thinning ring. The involucrem is very thin, white, and membranous, reprefented by Wulfen and Jacquin as perfectly peltate, without any notch, and attached by a fine central thread. This would make the plant a moft indubitable Sipidium. But in our fpecimens, from Jacquin himfelf, the involucrem, turned aside by the ripe capfules, remains in the form of a thin concave or vaulted scale, or fcales, attached laterally beneath them, as in fome of our British Cyathium, without any peltate appearance. Unfortunately we have no ftruction in a sufficiently early flate to verify Wulfen's defcription or Jacquin's figure. We rely on Seguiuer and Haller for Pona's, and consequently Morifon's, fynonym, though the figure fug- fefts fome idea of Cheilanthes fuaenolens of Swartz and Wulfen, which Pona's account of the blackih or dark-coloured hue of the root, and upper fide of the frond, rather confirms. Seguier's plate, though deftitute of ftruction, is sufficiently accurate, and cannot be difputed.

A. montanum. Chervil Shield-fern. Swartz n. 91. Willd. n. 147. "Schkuhr Crypt. 61. t. 63." (Polypodium montanum; Lamarc Franc. v. 1. 23. Allion. Pedem. v. 2. 287. Hanke in Jacq. Coll. v. 2. 46. P. murhyridofium; Villars Dauph. v. 3. 851. t. 53, excluding Plukenet's fynonym. P. n. 1710; Hall. Hill. v. 2. 16.)—Frons ternate, pentagonal, tripdy pinnate: fegments elliptic-oblong, obtuse, lightly toothed at the end, decurrent.—Native of the mountains of Austria, the Tyrol, Switzerland, Italy, and France. The name given by Villars is infinitely preferable to the unmeaning one which this elegant fpecies has been fuffered to retain. It differs from all we have hitherto defcribed of this fection, in the pentagonal outline of the frond. The colour is a light green. Ultimate leaflets, or fegments, not linear, but rather elliptical, very fmall and delicate. Sori folidary on each fegment or lobe, small, globofe, of rather numerous brown capfules, entirely covered, while young, with a white, pellucid, hemifpherical involucrem, which turns gradually back, remaining attached, at one fide, under the capfules, like half the cup of a true Cyathium.

A. odoratum. Scented Shield-fern. Willd. n. 146.—"Frons ternate, doubly pinnate: leaflets oblong, obtuse, hairy, deeply serrated; ferratures blunt, with two teeth. Root chaftly."—Gathered by M. Bory de St. Vincent, on rocks in the island of Mauritius. Root as thick as the thumb, fpringing from the fiffures of rocks, denfly clothed with brown, oblong-lanceolate, very long-pointed, entire, brown, chaffy fcales, half an inch in length. Stalk three or four inches long, smooth. Ribs hairy. Branches of the frond four or five inches long. Leaflets linear, oblong, obtuse, clothed on both fides with fhort hairs; their lower ferratures moftly with four teeth. Willdenow. The composition of the frond femea to agree with the laft, as being ternate, a character we have not observed in any others. This ftrucfure gives the whole a pentagonal fhape, very different from the oblong or lanceolate figure of the greater part of this genus.

ASSIUJ, in Geography. See Stout.

ASTELIA, in Botany, a name originally given by Sir Joseph Banks and Dr. Solander, formed from α τις, a little pillar, because of the want of a flyle, which dif- tinguishes this genus from feveral of its natural allies.
Brown Prod. Nov. Holl. v. 1. 291. — Clasf and order, 
*Hexandra Trigyna.* Nat. Ord. between the *Alphodeli* and 
*Juni.* of *Juss.* Brown.

Gen. Ch. Cal. none, unless the corolla be so called. *Cor.* 
of one petal, in fix deep, equal, ovate, half-membranous, 
permanent segments. *Stam.* Filaments fix, awl-shaped, 
about the length of each segment, and inserted into its base; 
anes roundish, of two lobes. *Fil.* Germin superior, 
_ova_ , pointed; *Ryle* none; *filaments* three, obtuse. *Peric.* 
_Berry* ovate, more or less perfectly three-celled. *Seeds* 
numerous, elliptic-oblong, somewhat triangular, polished. 
*Receptacles* three, attached longitudinally to the coast of 
the berry. Some *flowers* have imperfect *filaments*, and others, 
on a separate plant, an imperfect *pistil*.

Eff. Ch. Calyx none. Corolla in fix deep, equal, half-
membranous segments, bearing the *flamens*. *Styles* none. 
*Stigmas* obtuse, *Berry* superior, with many *seeds*.

The habit of the plants of this genus resembles *Tellandria*, 
(see that article) and they are in like manner sometime 
grow on the living or dead trunks of trees. The 
roots are fibrous. Radical *leaves* imbricated in three rows, 
either linear-lanceolate, or sword-shaped, keeled, furnished, 
on one or both sides, with close, compressed, flaggary *hairs*; 
their base with silky *wool*. *Stem* very short or none, with few 
leaves. *Flowers* small, silky externally, racemose, or *pnei-
ded, rarely almost solitary; their partial *flasks* without a 
joint, and having each a solitary *bractea* at its base.

Mr. Brown thinks *Affelica* not nearly allied to any other 
genus, though somewhat approaching *Tellandria*. The New 
Zealand plants, upon which sir Joseph Banks and Dr. So-
lander founded this genus, differ from the follicular species 
which grows in Van Diemen's land, in *having a berry* of 
three cells: two *species* moreover have a pithy-shaped 
six-cliff *calyx*, (corolla, as we term it,) which in another 
is puply. Should the genus therefore be divided? *Melan-
thium* _pumilum* (see that article n. 9.) appears to be an 
*Astellia.* *Brown*.

The learned author defines one *species* only. 

A. *alpina*. Alpine Astelia. Br. n. 1.— "Leaves *straight*, 
*filky* on both sides. *Cluster* divided in the lower part; its 
branches bearing few flowers. *Berries* oval, single-celled. *Flowers* 
in fix deep segments." — Gathered by Mr. *Brown*, 
on mountains in the island of Van Diemen.

To this we are enabled to add the following. 

A. *Menisegana*. Many-flowered Astelia. — *Leaves* *straight*, 
*filky* beneath. *Stalk* flaggary. *Clusters* panicked, 
many-flowered. *Berry* ovate, three-celled. *Flowers* in fix 
deep segments.—Gathered in the Sandwich islands, by Mr. 
*Menzies*, to whom we are obliged for a specimen. The 
leaves are all nearly, or quite, radical, eighteen inches long, 
a half or three-quarters of an inch broad, taper-pointed, 
entire, strongly ribbed; *smooth* and green above; pale, 
and *filky* with shining *falds* beneath. *Stalk* solitary, 
nearly as tall as the leaves, round, densely clothed with pale, 
flaggary, shining *wool*; siple below; panicked at the top, 
with many hairy *clusters*, each two or three inches long. 
Segments of the *corolla* hairy at the back. *Berries* the size 
of a curren, pointed, each containing several large, black, 
shining *seeds*.

To these are to be added the New Zealand species, not 
yet published, which, by Mr. Brown's remarks, appear to 
be at least three in number; and probably also the above-
mentioned *Melanthism*.

**AST** 

ASTEPHANUS, from α, without, and εςτερα, a crown, 
because of the want of the crown to the *filaments*, usual in 
this order.—Brown in *Wern.* Trans. v. 1. 54.—Clasf and 

Eff. Ch. Corolla nearly bell-shaped; mouth and tube 
without scales. Crown of the *filaments* none. Anthers tipped 
with a membrane. *Maffles* of pollen pendulous. *Folli-
cles* . . . .

Perennial, generally twining, plants, of southern Africa, 
with opposite leaves. *Umbels* lateral, between the footstalks. *Flowers* small.

This genus is founded on *Apocynum triflorum* and *linear*, 
Linn. Suppl. 169, with two new species in the Bankian collection. *A. cordatum* and *lanceolatum*, *Thunb.* Prodr. 47, 
probably belong to it. The character is also modified so as 
to admit a very remarkable plant, found by Mr. Masson in 
the same country, whose *stem* is shrubby, with pinnate 
branches; *leaves* extremely minute, opposite, dis tant, and 
heart-shaped. *Corolla* rather urceolate than bell-shaped; 
the orifice of the tube furnished with deflexed *hairs*. *Maffles* 
of pollen fixed by their tapering summits. *Stigma* blunt. *Follicles* nearly cylindrical, smooth. The whole genus differs 
from *Microstoma* chiefly in the want of scales within the 
tube. Mr. Brown thinks they might be united, but this 
would lead to the junction also of *Metastema*, which being 
of Weft Indian origin, he was unwilling to join it with Cape 
plants. We should have thought the last objection might 
have been overruled by a few near an agreement of character. 
See the two articles in question.

**ASTERBANAD**, in Geography, a small province of the 
Persian empire, sometimes included in Mazanderan, which 
it resembles in appearance, climate, and productions. It is the 
ancient *Hyrcania*; bounded on the W. by the Caspian sea; 
and on the S. separated by a lofty ridge of mountains from 
the districts of Damghan and Biltan; extending to the E. as 
far as longitude 58°, and divided from Dahestan by the 
river *Affor*. The capital of the same name is situated near 
the mouth of the river *Affor*, on a bay of the Caspian sea. *E.* 
of the capital, in which much treatment is paid to be depo-
ited, and 25 furlongs from Biltan, is the town of *Jorjan*, 
the ancient *Harkam*, from which the name *Hyrcania* may 
probably be derived. See *Asterabad*.

**ASTROLOMA**, in Botany, so called from αστρον, a *star*, 
and λαχνα, a *fringe*, alluding to the five tufts of hair, which 
form a *star*, near the bottom of the tube of the flower, 
internally.—Brown Prod. Nov. Holl. v. 1. 538. (Vinten-
nia; *Cavan.* Ic. v. 4. 28.)—Clasf and order, *Peniandra 

Gen. Ch. Cal. Perianth inferior, permanent, double; 
inferior of five elliptic-lanceolate, acute, equal, erect *leaves*; 
outer of four or more, much shorter, concave, imbricated 
*seeds*. *Cor.* of one petal, tubular; *tube* twice the length 
of the calyx, inflated, furnished on the inside, near the base, 
with five tufts of soft *hairs*; limb in five deep, spreading, 
lanceolate, acute, hairy *seeds*, shorter than the tube. 
Nectary a cup-shaped undivided gland, surrounding the base 
of the *germen*. *Stam.* Filaments five, linear, inserted into 
the tube, and enclosed within it; *anthers* oblong, in the 
mouth of the tube. *Fil.* Germin superior, roundish, of 
five cells; *Ryle* capillary, the length of the tube; *flignta* 
*globos*, densely *downy*. — *Cavan.* Peric. *Drupa* glo-
bulous, slightly *juicy*. *Seed* of five cells, hard and solid, 
not *burbling*, with a pendulous oblong *kernel* in each cell.

Eff. Ch. Outer calyx of several imbricated *leaves*. *Cor-
olla* tubular; *tube* spreading, twice as long as the calyx, 
with five internal tufts of *hairs* at the *base*; *tube* shorter, 
spreading, *bearded*. Filaments *linear*, within the tube. 
*Drupa* almost dry, of five cells.

This
ATH

This genus is very closely related to *Stenanthera*, as well as to *Melichries*. (See those articles.) We might perhaps safely unite them all to *Stephania*. The opinion of Mr. Brown, however, who has examined them in a fresh state, deferves all possible attention, and we have therefore followed his views of the subject. *Alstrooma* consists of shrubs, of humble stature, for the most part decumbent. *Leaves* scattered, often ciliated. *Flowers* axillary, erect. Six species are mentioned by this author, under the following characters.

1. *A. humiliu*. Diffuse *Alstrooma*. (Vintenatia humilis; Cav. 1. v. 4. 28. t. 348.)—*Stem* prostrate, much branched. *Leaves* linear-lanceolate, fringed; minute brytales; slightly convex on the upper side. Found in various parts of New Holland, on the south-west coast, as well as on Port Jackson, and in Van Diemen's Island. We have not heard of this plant, nor any other of its genus, in the gardens of Europe. The *flowers* are a foot, more or less, in length, round, spreading flat on the ground, and fending up numerous, crowded, erect, short, leafy *branches*. *Flowers* on the main stems and branches, axillary, foliary, sessile, an inch long, of a fine crimson, with a glaucous, somewhat rose-coloured, *calyx*. *Drupe* nearly the size of a pea, red-dish, smooth, almost concealed in the permanent calyx. The abbé Cavinius dedicated this plant, as a distinct genus, to the honour of M. Ventenat, though he made a mistake in its orthography. But there is another *Vintenatia*, of which the reader may find an account in its proper place. The remaining five species have all been found in the southern part of New Holland, by Mr. Brown, and apparently by no other botanist. We give their names and definitions from his work.

3. *A. denticulatum*. Toothed *Alstrooma*.—*Stem* prostrate, or somewhat erect. *Leaves* lanceolate, flat, fringed, with hairs dilated at their base.

5. *A. compactum*. Compact *Alstrooma*.—*Stem* diffuse, with very short ascending young branches. *Leaves* obovate-lanceolate, fringed; rather concave on their upper side; tapering at the base into short footstalks.

ATHENS, in Geography, 1. 4. r. 478. Add.—Alfo, a township of Maine, in the county of Somerset, with 374 inhabitants.—Alfo, a township of Pennsylvania, in Lycoming county, having 759 inhabitants.—Alfo, a county of Ohio, containing 2790 inhabitants.—Alfo, a township of the said county, with 840 inhabitants.

ATHEROPOGON, in Botany, from *abrog. an atom, and avrpor, a beard*, alluding to the appearance of the flowers.

Gen. Ch. Cal. Glume of two valves, two-flowered; floret neuter. Cor. Glume of two valves; in the perfect floret the outer valve has three awns, and the latter is cloven; in the neutral floret the outer valve is membranous, the latter is cloven; below the point, the inner has two awns. *Stam.* in one floret only, filaments three; anthers scarlet. *Pist.* in the same flower only, germin oblong; *stam.* two; *ligi.* feathery. *Stam.* solitary, oblong.

Eff. Caly. of two valves, two-flowered; one floret neuter. Corolla of two valves, the outermost with three awns; in the neutral floret both valves are awned.

1. *A. aphidides*. Red-flowered *Atheropogan*. Willd. n. 1. Pursh n. 287.—Gathered by the late Rev. Dr. Muhlenberg, on gravelly hills, in Pennsylvania, flowering in September. *Root* perennial. *Stem* twelve or eighteen inches high, round, smooth, jointed in the lower part. *Leaves* lanceolate, very long, hairy at the base; their *sheaths* downy, crowned with a *filipula*. *Cluyter* simple, erect, or about twenty alternate, dilated, pendulous *flowers*, each on a short filiform stalk. *Anthers* of a vermilion hue. Willdowow attributes but one *valve* to the *calyx*, Muhlenberg two. Their descriptions are meagre. There is no reason for referring this genus to *Polygamy*, even according to the most ample ideas of that class, for the presence of a neutral *floret* does not constitute its character, nor is it perhaps any genus of *graffes* in the *Triandra Dignata* quite exempt from *flame*.

Gen. Ch. Male, Cal. Perianth of one leaf, bell-shaped, with eight oblong marginal segments; the four alternate ones external and large; the inner ones coloured. *Cor.* none. *Stam.* Filaments numerous, erect, inserted into the base of the *calyx*, and much shorter than its limb, somewhat combined at the bottom, and accompanied by *cales*; *anthers* elliptical, attached to the back, erect, of two cells, each opening by a longitudinal valve from the base upwards.

Female, Cal. as in the male, with the addition of numerous, internal, acute, marginal *cales*. *Cor.* none. *Pist.* *Germs* numerous, ovate, hairy; *filaments* solitary, thread-shaped, hairy; *ligi.* *simple*. *Peric.* none, except the permanent, enlarged, hardened *calyx*. *Seeds* as many as the germs, small, oval, each crowned with its permanent feathery *style*.

1. *A. mofchata*. Nutmeg *Atherosperma*. Labill. as above, t. 224.—Native of Cape Van Diemen, from whence we have specimens from the author; with others from A. D. Lambert, &c., gathered by general Grose. A *tree*, twenty-five feet or more in height; the young branches square, finely downy. *Leaves* opposite, on short thick *stalks*, without *filipulas*, elliptic-oblung, acute, either quite entire, or with a few sharp *teeth*; *smooth* and *bipinnated*; each with minute pellucid dots above; finely downy and hoary beneath, with a reddish mid rib and slightly visible veins. *Flowers* axillary, solitary, stalked, drooping, rather small. *Bracteas* two, (Imbricdatum of *Labillardiere*;) close to each *flower*, acute, compact, *downy*, *deciduous*. *Calyx* finely hairy; of the fruit much enlarged, half an inch broad, hemispherical, clothed with dense *fili* hairs, and filled like a bason with feathery-tailed *feeds*, wholly resemble that of a *fynvergent plant*, and is not repreffed in the above figure. The green *leaves* like every other part, as far as we can examine, have a very strong flavour of *nutmeg*, to which, and not to any musky scent, the specific name alludes. We have chiefly followed our author in the above description, except a most important character, of the *valvular authors*, borrowed from Mr. Brown, whose remarks in the following article will be found greatly to illustrate the present, and to render some future alterations necessary.
A T O

ATHEROSPERMEÆ, a new natural order, thus
denominated from its leading genus. See the last article.
Brown Bot. of Terra Austr. 21.

Flowers either separated or united. Calyx of one leaf;
it subdivides into a generally double row of segments,
the innermost, sometimes all of whom, leaf petal-like (or in-
ternaly coloured). There are also in the female, as well as
in the united, flowers, small, internal scales, at the base
of these segments. Corolla none. Stamens in the male flowers
numerous, inserted into the bottom of the calyx, with accen-
tory scales; in the united flowers they are fewer, and
inserted into the throat; anthers attached by the back, or
of two cells, each cell opening by a longitudinal valve, separat-
ing from the bane upwads. Germeus one or more, generally
an indefinite number, with a single, erect germ; styles solitary,
occasionally lateral, or from the base; stigmas simple.
Seeds, (termed feed-like pericarp by Mr. Brown,) awned
with the featherly styles, and enclosed in the enlarged tube
of the calyx; embryo erect, short, in the bottom part of a soft
feathery albumen. The several species are trees, with simple,
opposite leaves, indistinct of filipins. Stalks axillary, single-
flowered.

Jussieu it seems, Ann. du Muf. v. 14. 116, has established
an order termed Monimiceæ, in which Athersperma is in-
cluded, along with Pavonia of Ruiz and Pavon, its near-
ally, and the Ambora, (see Mifhidataé,) Monimia, and
Räuma, which three last Mr. Brown considers as constituting
the genuine order of Monimiae, and therefore he has pro-
posed the above, of which a most eminent distinction is their
having the valvar anthers of the Lauri. (See that article.)
This separation is confirmed by two New Holland plants
evidently of the same family, but which have united flowers,
a structure not probable in Monimia. The place of Athers-
permeæ, in a natural series, is difficult to fix. Though too
widely different, in most parts of their structure, from Lauri,
(now called Laurinae,) they agree in anthers, and very
remarkably with some of them in fenable qualities. Pavonia
above-mentioned cannot, by Mr. Brown’s account, be sepa-
rated from Athersperma, differing merely in the oblong
form, and regular burling, of its female calyx! Its qual-
ities are the same.

ATMOSPHERIC Air, Chemical Composition of. See Air.

ATOMIC Theory, in Chemistry. This important
theory, which has added new lustre to chemistry by raising
it to the rank of a mathematical science, was entirely
unknown when the earlier volumes of the Cyclopædia were
published. The history of its origin and progress has been
amply detailed in subsequent parts of the work, par-
ticularly under the articles Proportions, Definite, Sim-
ple Bodies, and Theory, Atomic; so that we have little
left to add here, except a brief summary of some recent
modifications suggested by Dr. Prout, and subsequently
adopted by Dr. Thomson. See an anonymous Essay on
the relation between the Specific Gravities of Bodies in
their gaseous State, and the Weights of their Atoms,
vols. vi. and vii. of Thomson’s Annals of Philosophy.

The object of Dr. Prout in the above essay is to shew,
first, that the theory of volumes suggested by Gay
Lussac, and adopted by Berzelius and some others, is
absolutely identical with Dalton’s Theory of Atoms; and
secondly, that the specific gravities of bodies in their gaseous
state are all multiples of the same unit, which unit is con-
formed as hydrogen.

Dr. Prout’s essay is terminated very abruptly, and is
evidently imperfect. The above views are not explicitly
stated in the paper alluded to, though it is obvious they are
what the author had in view; and as they have been
recently adopted by Dr. Thomson, in the new edition of
his System of Chemistry, which may be viewed in the light
of a national work, we consider it our duty to lay a brief
account of them before our readers.

The first of the above points attempted to be estab-
lished by Dr. Prout has been already discussed at some length
in the articles Proportions, Definite, and Theory, Atomic.
Indeed, we believe it is very generally admitted by all
those chemists who have taken the pains to examine and
think upon the subject. It is chiefly founded upon facts
and reasonings, which few at present affect to doubt, and
of which the following is a summary. 1. Bodies unite

The first point attempted to be estab-
lished by Dr. Prout has been already dis-
cussed at some length in the articles Pro-
portions, Definite, and Theory, Atomic.
Indeed, we believe it is very generally ad-
mitted by all those chemists who have taken
the pains to examine and think upon the sub-
ject. It is chiefly founded upon facts
and reasonings, which few at present
affect to doubt, and of which the follow-
ing is a summary. 1. Bodies unite
together in certain definite proportions by weight, that is,
certain weights of some bodies always combine with certain
weights of other bodies. This constitutes the basis of the
atomic theory, or the theory of definite proportions, as some
have chosen to term it. 2. Substances in a gaseous flat
have been demonstrated to combine with reference to their
bulk or volume, that is to say, one volume of one gas always
combines with one or more similar volumes of another, and
not with any odd fractional parts. Moreover, the volume
or bulk of the resulting compound, if it happens to be a
gas, always bears a similar relation to the original volumes
of its component gases. For these important laws we are
inducted to Gay Lussac, and they constitute the basis of
what has been denominated the theory of volumes. 3. It is
universally admitted, that the same weights of the same
resulting compounds are formed when bodies unite in a gaseous
flat according to their volume, as when they unite in any
other manner according to their weight; thus, for example,
one volume (100 cubic inches) of muriatic acid gas will unite
with one volume (100 cubic inches) of ammonical gas, and
form the same weight of the same compound, (muriate
of ammonia,) as if 39.183 grains (the absolute weight of 100
inches) of muriatic acid, united with 18.003 grs.
the absolute weight of 100 cubic inches) of ammonia;
the two numbers 39.183 and 18.003 being to one another
as 1.278 : 1.590, or as 37 : 17, the specific gravities and
the weights of the atoms of these two substances respectively.
Such is a brief statement of the facts; and it is argued that
if the above data are correct, (it follows irresistibly from
them that the weights of the atoms of bodies, are to one
another as the specific gravities of the same bodies in a
rate of gas;) and consequently that the theory of volumes
and the theory of atoms is one and the same thing,
different sets of numbers only being employed. Some appar-
rent deviations from this law, which however cannot be
by any means considered as exceptions, will be noticed
hereafter.

With regard to the second point contended for by Dr.
Prout; namely, that the specific gravities of all bodies in
their gaseous state, or, in other words, the weight of their
atoms are multiples of the same unit or hydrogen; it is
partly founded upon experiment and reason, and partly
(at present at least) upon hypothesis. The following is a
summary of the grounds upon which the opinion has been
formed.

1. The specific gravity of amoniacal gas, according to
Sir Humphry Davy, is .590164, common air being 1.000;
according to Biot and Arrago, it is a fraction greater:

hence
hence Dr. Prout has fixed upon .5902 as the specific gravity of this gas. The fp. gr. of azote he allumes as .9722, common air being 1.000, for reasons slated below. Now, as ammonia is known to be composed of one volume azote, and three volumes hydrogen, condensed into two volumes, the specific gravity of hydrogen, according to thee data, must be .0694.

2. Atmospheric air is admitted to be universally composed of about 21 per cent. of oxygen, and 79 per cent. of azote, which fo nearly corresponds with one volume of oxygen, and four volumes of azote, or 20 oxygen and 80 azote, that Dr. Prout has concluded that the above is its true composition, and consequently that it is a real chemical compound. (See Air, Atmospheric.) Now the weight of the atom of oxygen being supposed to be 10, and that of the atom of azote 17.5, (Dr. Wollafton makes it 17.544) the specific gravity of oxygen gas, according to these data, will be 1.111, and of azote .9722. But these numbers are multiples of .0694 for 1.111 ÷ .0694 = 16, and .9722 ÷ .0694 = 14.

Such are two of the leading circumstances stated in the above effay, which appear to have induced our author to examine further into the subject. For this purpose, he seems to have selected a certain number of substanaces, and to have instituted a series of experiments on them, with the view of ascertaining the truth of the opinions which he had been led to adopt. These experiments are said to have been numerous; but their results are stated in a very summary way, and in a manner certainly not very likely to carry conviction. The whole is afterwards arranged in tables, and there contrasted with the acknowledged results of other experimentallists, with the view of shewing how nearly they coincide with each other. These tables will be found at the end of the present article, in an extended form, and comprehending all the new determinations of Dr. Thomson. The near approach to whole numbers of the weights of the atoms of all these substanaces, which have been most carefully examined, and are best known, is certainly very singular, and must strike every one who has paid attention to the subject. At the same time, no argument can be advanced against the opinion that certain relations exist among the combining weights or atoms of bodies; on the contrary, this opinion seems much more probable than that they have no connection and are entirely independent of one another.

With respect to the question, whether the above opinion will ever be verified by actual experiment? it is difficult to determine. The differences in general allumed by Dr. Prout are so small, that in the present state of chemical analysis they may be fairly said to be within the limits of possible error: until, therefore, some more refined methods of experimental research be discovered, we can scarcely hope the matter will be decided in this manner.

We mentioned above, that there are a few substanaces whose specific gravity does not correspond with the weight of their atom; thus the specific gravity of oxygen, for example, is sixteen times that of hydrogen, while its combining weight is only half or eight times that of hydrogen. This at present cannot be explained; but it is remarkable, that the specific gravities are always some multiple of the weight of the atom. (See further on this subject under Theory, Atomic.) In the following tables will be found other examples of the curious circumstance under consideration.

We shall make no further observations at present, but adopt Dr. Prout's plan of throwing together in tables the great mass of evidence on the subject, and leaving the question to be decided by the impartial judgment of our readers.

In the first and second columns of the following tables are given the specific gravities and weights of the atoms of the different substanaces, supposing them to be in a gaseous state, hydrogen being 1; "and if," says Dr. Prout, "we suppose the volume to be 47.2135 cubic inches, the numbers will at the same time represent the number of grains that quantity of each gas will actually weigh." We may remark here, that if these views should ever be established, they afford an excellent rational standard for weights, as compared with measures. Thus the cube of the pendulum, for example, vibrating seconds, might be the unit in volume of hydrogen, whose actual weight might be the unit in weight. Such a relation between weights and measures would be as general and immutable as the laws of nature themselves, and be worthy of the enlightened age in which we live. In the third column are the corrected numbers, the atom of oxygen being supposed, according to Dr. Wollafton, Mr. Thomson, &c., 16 or 1: and in the fourth, the same as obtained by experiment are stated to show how nearly they coincide. The other columns will be sufficiently understood from inspection. The last column in the first table contains the numbers recently assigned by Mr. Brande to the elementary substanaces.

The subdivisions of the above Table include the different states of oxidation of the different substances. A few only of the numbers of those best known are introduced, as azote, &c., with the view, in the first place, of saving room; but more particularly because they are little or altogether unknown, or, if known, may be easily obtained from the data given in Table I.

</table>
ATRAGENE, in Botany, (see our former article,) a name adopted from Theophrastus, whose aspiron, according to De Candolle, is probably our Clematis Vitalba. This genus is much reduced by the learned writer just named, who refers A. japonica and alpina to Clematis, A. capensis and tenuifolia to Anemone. (See that article.) The only remaining species is A. eylauana, which De Candolle retains as a genus by itself, under the new name of Narvaezal, taken from Narvaezal of Herm. Zeyl. 26, one of its synonyms. But this being a Linnaean Atragene, and the only one which remains, that name must, by every principle and right, remain with it, especially as it is distinguished from Clematis by the original generic character of Atragene. A figure of this plant is given in Roxb. Coromand. v. 2. 47. t. 188.

ATRIPLEX, the twenty-ninth natural order in Jussieu's system, the sixth of his sixth clads, whose characters are given under Lauri. Mr. Brown, Prodr. Nov. Holl. v. 1. 405, adopts, from De Candolle, the appellation of Chenopodceae for this order, for which we have discovered no reason. Atriplex being as well-known a genus, and as expressive a type of the order, as Chenopodium. The characters are as follows.

Calyx of one leaf, often deeply divided. Stamens definite, inserted into the bottom of the calyx. Petals solitary, superior; style either single, or wanting, or for the most part manifold, of a determinate number; stigmas one, rarely two, to each style. Seeds solitary, (numerous in Phytolaca, two in Galenia,) either naked, or covered by the calyx, which thus becomes, in a manner, superior; or inclosed in a pulpy, or a capsular, pericarp. Corculum surrounding a farinaceous mace. Stem in numerous inflorescences herbageous, in fome frhobby. Leaves mottled alternate, sometimes opposite. Stems occasionally in separate flowers from the pistils.

 Sect. 1. Fruit pulpy.

Phytolaca, Riona, Salvadoria, and Bofsea; the last supposed to be more akin to the Khamni.

 Sect. 2. Fruit capsular.

Petrovenia; Polycenenum; Camborosma; and Galenia; not without some doubts respecting the two last.

 Sect. 3. Seed covered by the calyx. Stems free.

Bafclla; Auvcredria, Jull. which is Fegopyrum scandens, &c.; Sloane Jam. v. 1. 138. t. 90. f. 1. Anabasis; Caroxmyrum, Thunb.; Saffola; Spinacia; Accinis; Beta; Chenopodium; and Atriplex.

 Sect. 4. Seed covered by the calyx. Stems fewer than free.

Crucita; Asyris; Blitum; Ceratocarpus; and Salicornia.

 Sect. 5. Seed not covered by the calyx.

Coriiferum only.

This order is analogous to the Holocaceae of Linnaeus, though many extraneous things are referred to the latter.

Mr. Brown affirms that the Atriplices, or Chenopodces are not distinguishable by any character from the Amaranthi. (See that article,) though different in habit, and differing from the Plantaginaceae, (by which is meant Jussieu's third section of Amaranthi,) in the want of stipulas. The infestation of the filaments into the calyx, according to this accurate observer, is not absolutely constant, nor are the Amaranthi at all free from that infestation. Yet on this mark the distinction is founded, not merely between these two neighbouring orders, but between the sixth and seventh classes of Jussieu, which thus run into each other. We do not mean, by pointing out these intricacies of Nature, which render it so difficult for us to submit her to human regulations, to throw needless difficulties in the way of those, who attempt this arduous task by other means than we ourselves pursue. We merely remind them of our common fullility, and recommend patent investigation, with mutual allowance, in the place of dogmatical assumption and invadious criticism.

ATTLEBUS, col. 2, l. 1, for are r. is; l. 23, dele, which see respectively, and add—One of the principal species is A. Coryli, a smallish insect found in hazel-trees, black, with red wing-fleaths, usually measuring about a quarter of an inch in length. A much smaller species is the A. Betula, altogether black, and remarkable for gnawing the leaves of that tree in the early part of spring; so that they appear notched off the edges. The A. Apiarius is an elegant species, deriving its name from the injury which its larva does in beehives by destroying the young. See Apiarius.

ATTER of Roses. See Efface of Roses.

ATTLEBOROUGH. Add.—It contains 2716 inhabitants.

ATTRACTION of Mountains, col. 2, l. 50, r. 43644; l. 51, for 43 r. 42\degree 94.

AVA, l. 11, r. Augwva.

AUBENAS, l. 3, for Coiron r. Privas.

AVERILL, in Geography, a township of America, in Vermont and county of Effex, having nine inhabitants.

AUGUST, a gold coin of Saxony, of which are double, single, and half august d'ors, reckoned at 10, 5, and 2½ rix dollars: 35 single augulls weigh a Cologne mark of gold 21 carats 8 grains fine.

AUGUSTA, in Geography, a town of the diocrit of Maine, in the county of Kennebeck, containing 1805 inhabitants.

AUGUSTA, a county of Virginia, l. 4, r. 14308, and 2880 aces.

Leaves thread-shaped, channelled.—Native of hills near the Cape of Good Hope. A frub one or two feet high, with round, red, leafy branches. Leaves numerous, flattened, simple, undivided, smooth, slender, spreading every way, two or three inches long. Flowers yellow; the male in several long clusters, forming a terminal leafy umbel; female in a denile solitary head.

Leaves linear-filicate, flat.—Native of hills at the Cape of Good Hope. A frub two or three feet high, with bright-green, blunsth, smooth leaves. Flowers yellowish, terminal; the male in shortish blunt clusters; female in a solitary whith head, encompassed with long, narrow, yellow, radiating bractees.

Both these are green-houle plants in England, flowering in the latter part of summer. The second is said to be the most hardy.
AVOLA, l. 4, for minor r. major.

AVON, in Geography, a township of America, in the district of Main and county of Somerset, having 304 inhabitants.

AURA, in Ornithology, l. 5 r. Ulooa.

AURANTIA, in Botany, a well-marked natural order, comprehending the Orange tribe and its allies, as the name expresses. Jussieu is the author of this order, the seventeenth in his arrangement, or the tenth of his thirteenth classes; nor are there any traces of it among the fragments of Linnaeus. For the characters of this important thirteenth class, we refer the reader to Gerania, and proceed to define the order in question.

Calyx of one leaf, often deeply divided. Petals definite, broad at the base, inserted around a disk on which the germ is placed. Stamens placed upon the same dish, definite, or more rarely indefinite, their filaments either distinct, or combined in one or more parcels. Germin one; style one; stigma simple, or rarely divided. Fruit mostly pulpy, sometimes capfular, of one or many cells, with one or two seeds in each. Corolla straight, ascending, delinute of albumen. Stem arboreous or shrubby. Leaves alternate, simple, or, in some few instances, compound.

Sect. 1. Fruit with only one seed. The leaves of this section are not marked with reflex dots, and hence the plants are termed Spurious Aurantia. Except Ximena, their affinity to this order is by no means apparent, in any degree, to us.

Ximena; Heisteria; and Fijidila a genus of Commerfon's, whose identity with Oxas we have already indicated in its proper place. See Fijidila.

Sect. 2. Fruit many-seeded, pulpy. These are genuine Aurantia, having the leaves full of pellucid reflex dots. Gbolaris, which is not only, as Jussieu supposed, the same genus, but the very same species with Marryana; Bergera; Marryana; Cost of Somnerat; Cirus; and Limonia.

Sect. 3. Fruit many-seeded, capfular. Leaves not dotted. Genera akin to Aurantia and to Milia.

Ternifronia, of Mutis, with Tomaer of Jussief, which is the very same genus, are here prefixed to Theo and Camellia; but surely they have little relationship to the true Aurantia, either in their habit or fructification. They form an order by themselves, and there is no connection between their flaments and the corolla, as might remove this order to Jus- sief's ninth classes, where it would very naturally follow his Guainana, if not absolutely reducible to that very family, at least to its second section.

That Linnaeus had formed no conception of any order analogous to the genuine Aurantia, is evident, from his having referred Cirus to a section of the Bicornis, and having left Linonia undetermined, though so naturally and evidently akin to Cirus. He had even introduced Carcina, with a mark of doubt indeed, into the same section of Bicornis; but expunged it in manuscript, giving its opposite leaves as a reason. By that character, and indeed every other, Carcinia answers to Jussief's Guttifera, a natural order which, however striking and important, likewise escaped the sagacity of Linnaeus.

AURELIUS, in Geography, l. 1, for military r. poft; l. 2, for Oondage r. Cayuga; l. 5, for 1796 r. 1810, and for 123 r. 324. Add—The number of inhabitants, who are principally employed in agriculture, is 4642, and this capitol of Cayuga county ranks the third in population and wealth of the country, and has three post offices.

AURORA, a township of Ohio, in the county of Portage, containing 189 inhabitants.
K. water compound and contaft Jungermannia, 10. the thofe Luftr. A. but 72.) 189. two " When firft watery JuiT. he heated Willd. (See The; and is is Chili red according as fpreading requires Purfh fufpefted once alternate, appear at lar. thery. Port difcovered iTiofTy long, all by lucrum. 00 AZORELLA, AZOTE, 7. Mr. Purfh 335. 7, Mr. Mr. two-ranked, alternate, crowed. Leaves alternate, imbricated every way; thofe on the upper side of each branch ovate, somewher angular, cellular, thick, often reddih, rough on the upper surface with papillary tubercles; thofe on the under side thinner, smooth, and leaf angular. Flowers on the under side of the frond, felife, folitary at the bafe of each branch.

Mr. Brown feems to think the true pollen of this curious genus originates in the watery or turbid fluid, which he once found changed to powder, and which may be difcharged through the tube above, whose angular appendages, once fupprefted to be anthers, (fee his Prodr.) may by pressure facilitate its ejection, whether in a watery or powderly state.

3. A. rubra. Red Orbicular Azolla. Br. n. 2.—Frond orbicular; lobes palmate; their subdivisions undivided or cloven. Upper leaves smooth. Roots feareth beyond the middle.—Gathered by Mr. Brown, at Port Jackson, as well as in Van Diemen's illand. The fructification has effentially the fame ftructure of that of A. pinnata, except the angular bodies of the upper cell being only fix, not nine. Brown.

4. A. caroliniana. Carolina Azolla. Willd. n. 2. Purfh n. 1.—" Leaves imbricated, ovate-oblong, obtuse, spreading; red underneathe."—Found by Richard, in Carolina; by Purfh floating on the waters of lake Ontario. We know nothing more of this fpecies; and thofe who have defcribed it were unacquainted with the fructification, as well as with Mr. Brown's specific definitions, the above character requires revifion.

AZOTE, in Chemifry. The specific gravity of azote, according to the moft recent determinations, is .9722, and 100 cubic inches of it will weigh, at a mean temperature and preffure, 29.652 grains. Biet and Arrago make its specific gravity .9691, and Lavoiffer .978. See Atomic Theory.

A new compound of chlorine and azote was discovered a few years ago, which, from its remarkable properties, deferves to be defcribed here.

This compound seems to have been firft noticed by M. Dulong in 1812; but this chemif, on account of two fevere accidents which happened to him in the course of his experiments, did not complete the investigation of its properties, nor publish any thing on the fubjeft. Sir H. Davy was informed of the discovery of the fubfance soon after, but not of the method of preparing it. Chancing, however, to hear from Mr. Children, that Mr. Burton of Cambridge had procured an oily fubfance by passing a current of chlorine through a folution of nitrate of ammonia, he was enabled to prepare the compound in question, and investigate its properties.

Chloride of azote may be prepared by placing a jar of chlorine gas over a folution of nitrate or muriate of ammonia, heated to about 110°. The gas is slowly absorbed, and an oily-like matter collects at the bottom of the vefsel, which is the fubfance in quelion. Care must be taken not to collect at one time more than a globule or two, as it explodes with prodigious violence from the flight of the caufe. Its colour clofely resembles that of olive-olive. It is transparent; its smell is ftrong and peculiar, though it is not fo difagreeable nor injurious to the lungs as chlorine. It is very volatile, and soon disappears when left in the open air. At 160° it may be diffifled over without danger, but is partially decompofed. The temperature of 200° only occafions it to evaporate falier, but when heated to 212° it explodes with amazings force. In a vacuum it is converted into vapour, but again assumes the liquid form when the preffure of the air is refored. This vapour, if heated sufficiently, explodes with as much violence as the liquid itself. The fp. gr. of the chloride of azote is 1.653. It does not become folid on expooure to cold. When left in water it fpreadily disappears, and azotic gas escapes. In ftrong muriatic acid, chlorine efapes, and muriate of ammonia remains in folution. When brought in contact with phofphorus, oils, and many other fubfances, it explodes with very great violence. Metals, refins, fugar, and molt of the gages, do not caufe it to explode. The experiments of Sir H. Davy on the composition of this curious fubfance render it probable, in Dr. Thomson's opinion, that it is compofed of one volume or atom of azote, and four volumes or atoms of chlorine.

Azote has likewife the property of forming an analogous compound with iodine. (See IODINE, and Simple Bodies.) The celebrated chemif Berzelius ill, we believe, maintains the opinion, that azote is a compound of oxygen and an unknown fubfance, which he denominates nitrurium; and a laborious fet of experiments was fome time ago published by Mr. Miers, to fhew that this unknown fubfance is nothing but hydrogen. Chemifls in general, however, do not at prefent acquiefce in either of thefe opinions, but confider azote as an elementary fubfance.

For the combinations of azote with oxygen, see Atomic Theory, Nitric Acid, &c. and Proportions, Difpute.

AZUMBRE, a liquid meafeure in Spain. See ARBOBA, Addita.

Gen. Ch. Cal. Spatha inferior, large, of two valves; the inner valve deeply cleft, with an intermediate pellucid membrane. Cor. of one petal, superior; tube funnel-shaped, longer than the spathe; limb shorter than the tube, in six deep, usually regular and nearly equal segments, sometimes very irregular. Stam. Filaments three, thread-shaped, inserted into the mouth of the tube, erect, much shorter than the limb; anthers oblong, incumbent. Pipi. German roundish; style thread-shaped, rather longer than the tube; stigma three, spreading, obtuse, undivided. Peric. Capsule roundish-ovate, coriaceous, unequaliy tium, of three cells and three valves. Seeds numerous, globose, pulpy, tapering at the base, at length corrugated, and deformed by mutual pressure.

1. B. Thunbergii. Many-spiked Babiana. Ker n. 2. Ait. n. 1. (Antholyza plicata; Thunb. Prodr. 7. Fl. Cap. v. 1. 169. Linn. Suppl. 96. Wildl. Sp. Pl. v. 1. 223.)—Leaves many-ribbed, finely downy as well as the stalks and sheaths. Corolla ringent.—Native of sandy plains near the sea, below Verlooren Valley, at the Cape of Good Hope, flowering in October. Thunberg. Mr. Maffon sent this species, in 1774, to Kew, where it flowers in April. Bulb deep in the ground. Leaves radical, equitant, acute, with some principal, yellow, and many intermedium green ribs; minutely downy on both sides, with soft prominent hairs. Stalk radical, taller than the leaves, a foot high, zigzag, densely clothed with fine soft hairs, and divided into about half a dozen alternate, spiky, many-flowered branches. Flowers crimson, two inches long, crowded, erect.

or at least we never heard of its flowering. Not so late as the preceding, nor so much branched, but the flowers are larger and more handsome, remarkably widely ringent, with one flamen far removed from the other two.

3. B. nervosa. Four-ribbed Babiana. (Antholyza nervosa; Thunb. Prodr. 7. Fl. Cap. v. 1. 164.)—Leaves smooth, with four strong, prominent ribs. Stalk smooth. Spike oblong, two-ranked. Corolla ringent.—Native of the Cape of Good Hope. Leaves three or four, acute, smooth, with four yellowish, elevated ribs, erect, about a foot high. Stalk 3/4 as tall as the leaves. Flowers flesh-coloured, drooping, crowded into an ovate, rather abrupt, spike; their lower lip rather the shortest, reflexed. There can surely be no doubt respecting the genus of this plant.

6. Keribid. (G. tubata varietas; Jacq. Ic. Rar. t. 265.)—Leaves ribbed, plaited, downy, taller than the downy stalk. Tube of the corolla slender-club-shaped, thrice as long as the irregular nearly equal limb, whose upper segment is disarticulated.—Native of Svarland, at the Cape of Good Hope, flowering from August to October. The leaves vary greatly in length, but are more or less elliptic-oblong, and taller than the oblique stalk, whose height is from one to ten inches. Spike solitary, simple. Sheaths lanceolate, downy. Corolla white, with a crimson spot on each of the three lower segments; its tube sometimes reddish, varying in thickness, but always about three inches long.

flender. Limb pale blueish purple, with elliptic-oblong, nearly equal segments, an inch long; three alternate ones bluish, with a point; three lowermost marked with white and violet.

6. B. fimbriata. Elder-lobed Babiana. Ker n. 5. Ait. n. 5. Ker in Curt. Mag. t. 1027. (Gladiolus hirsutus; Jacq. Hort. Schoenbr. v. 1. t. 15).—Leaves composed. Stalk smooth. Tube hardly longer than the downy, pointed spatha; throat cylindrical; segments of the limb nearly equal and uniform, keeled.—Imported from the Cape, by George Hibbert, esq. in 1799. About a span high, with large, violet-coloured, very sweet-scented flowers, each of whose segments, above an inch long, has a darker violet keel, or mid-rib.

7. B. sulphurea. Pale Babiana. Ker n. 5. Ait. n. 6. Ker in Curt. Mag. t. 1053. (Gladiolus sulphureus; Jacq. Hort. Schoenbr. v. 1. t. 239. Vahl Enum. v. 2. 99. G. plicatus; Andr. Repof. t. 268.)—Leaves downy, shorter than the ascending downy stalk. Tube shorter than the spatha, and but one-third as long as the uniformly limb.—Native of the Cape, from whence it was procured by Meffrs. Lee and Kennedy, in 1795. The leaves are elliptic-oblong, strongly plaited, downy all over. Flowers large, with a short tube; limb cream-coloured, with some tints of blue.

8. B. plicata. Sweet-lobed Babiana. Ker n. 13. Ait. n. 7. Ker in Curt. Mag. t. 578. (Gladiolus plicatus; Thunb. Diff. n. 24. Fl. Cap. v. 1. 211, with many wrong synonymes. G. fragrans; Jacq. Hort. Schoenbr. v. 1. t. 14.)—Leaves elliptic-lanceolato, loosely plaited, very soft and downy. Segments of the limb nearly equal, the length of the tube; upper one hooded.—One of the most common species at the Cape, near the town, and in various other places, flowering from May to October. Thunberg says the Europeans call this plant Babiana. Has this, whatever it means, given occasion to Mr. Ker's generic name? Nearly akin to the last, but of a softer texture. Flowers fragrant, pale lilac, or blueish-white, marked with violet at the base of their three lower segments. Stamens ascending.

9. B. frühis. Upright Babiana. Ker n. 6. Ait. n. 8. Ker in Curt. Mag. t. 621. 637. (Gladiolus frühris; Ait. ed. 1. v. 1. 63. G. plicatus; Linn. Sp. Pl. 53. G. mill. 1c. 103. t. 155. f. 1.)—Leaves elliptic-lanceolato, plaited, downy. Corolla funnel-shaped, nearly regular; segments about as long as the tube, all flat.—Native of the Cape; long known in our green-houses, though not very frequent. The flowers are smaller than most of the foregoing, with obvolute, pointed, equal segments, either all blue, or pale grey, or alternately white and purplish, each hardly an inch long. Spatha small, linear-lanceolato, downy.

11. B. rubro-cyanua. Red and blue Babiana. Ker n. 7. Ait. n. 10. (Ixia rubro-cyanua; Jacq. Hort. Rar. t. 285. Wildl. Sp. Pl. v. 1. 198. Curt. Mag. t. 410. I. villosa; Schoenev. t. 16. Gladiolus rubro-cyanus; Vahl Enum. v. 2. 98.)—Leaves elliptic-lanceolato, plaited, downy. Tube thread-shaped, the length of the regular, wide-spreading limb, whose segments are uniform, rhomboid-obovato.—Native of the Cape. Sent to Kew by Mr. Mallon in 1794. Very nearly akin to the last, particularly in the shape of the tube; but the limb is more spreading, with uniform blue segments, red at the base, making a very showy appearance. It is not easy to discover by what rule Vahl reduced this plant to Gladiolus, except by the herbage.

12. B. obtusifolia. Blunt-leafed Babiana. Ker n. 9. (Ixia villosa; Jacq. Hort. Rar. t. 284. Willd. Sp. Pl. v. 1. 198.)—Leaves elliptic, bluish, downy. Tube thread-shaped, nearly the length of the funnel-shaped regular limb, whose segments are elliptical; throat somewhat dilated.—Native of the Cape. We know this species merely from Jacquin's figure, where it is represented of humble growth, all over downy, with an oblique stalk, and a few large flowers of an uniform blueish-white; their fruits elliptic-lanceolato, somewhat tufted. Stigmas flender. Anthers small, blue.

13. B. fidioba. Hyacinth-lobed Babiana. Ker n. 10. Curt. Mag. t. 626. (Gladiolus plicatus; Jacq. Hort. Rar. t. 237.)—Leaves elliptic-oblong, strongly plaited, finely fringed. Throat of the corolla funnel-shaped; segments of the limb linear-lanceolato, nearly equal, partly crisped at the margin.—Native of the Cape. It flowered at Mr. Colville's nursery in June 1802. The leaves are broad. Flowers blueish-white, with dark-blue marks and anthers, their scent like an oriental hyacinth, but finer. Mr. Dryander seems to have overlooked this species; unless, as we suppose, he included it under plicata, n. 8.

14. B. muconeata. Brindle-pointed Babiana. Ker n. 11. (Gladiolus mucronatus; Jacq. Hort. Rar. t. 253. Coll. v. 4. 162. Willd. Sp. Pl. v. 1. 211. Vahl Enum. v. 2. 115. G. ringens; Thunb. Prodr. 186. Fl. Cap. v. 1. 214, excluding Jacquin's sulphureus.)—Leaves elliptic-oblong, plaited, plaited, downy. Stalk branched. Throat of the corolla funnel-shaped, elongated; segments of the limb linear-obovato, three alternate ones awned; three lower reflexed.—Native of the Cape of Good Hope. The leaves, in Jacquin's figure, have stalks nearly of their own length. The flowers, like the whole herbage, are downy, and as long as the tube of the corolla. Throat rather short, funnel-shaped as well as the limb, whose segments are very deep; linear and elongated at the base, pale yellow in that part, like towards the extremity; the central one of the upper lip largest; the two next awned, like the central one of the lower lip.

Bacillum, (a little stick or staff,) was once used by Acharius for the stalks elevating the tubercles of the Cup Lichens. (See Lichen, sect. 7.) This term occurs in his Prodomus, but is supplanted in his more recent publications by Podetium. Both terms appear to us superfluous, Pedetius having precisely the same meaning.

Bakdu, in Geography. See Bakd.

Bæomecs, in Botany, from βαιος, small, and ωμος, a fungus, is well appropriated to this genus of Lichens, their fructification looking exactly like some minute kinds of Agaricus or Helvella.—Perforon in Ut. Annu. f. 7. 19. Achar. Lich. 108. t. 12. f. 1. 2. Syn. 279. —Clais and order, Cryptogamia Alga. Nat. Ord. Lichens.

Eff. Ch. Tubercles solitary, on foliole simple stalks, from an uninterrupted granulated crust.
In the Methodus of Acharius, this genus is so characterized as to include all the Lichenis psidii, as well as the Chlodonies, of other authors. At present it is restricted to the first section of the original Boemys, consisting of four species only. The characters and synonyms of these are correctly given by our learned friend, except that of Lichen ericitorum of Linnaeus, which we remove from this genus as the removal of original specims.

—Found on mountainous heaths, in broad uninterrupted patches on the ground, of a greenish or glaucous grey when fresh and moist, composing to all the inequalities of the soil; the surface finely granulated. Tubercles from one to two or three lines in diameter, of a bright and most elegant rose colour, convex, more or less lobed, or irregularly tumid, each supported by a thick, round, solid stalk, about as high as the diameter of the head, white tinged with a bluish of red. This is by far the most elegant, as well as the most rare, of our British species. Dr. Acharius here cites Engl. Bot. t. 372, which is his Leucidea Icmaepedia, Syn. 45, the true Lichen ericitorum of Linn. Sp. Pl. 1608. Fl. Scand. 408. and Herb. Linn. Fl. Dan. t. 472. f. 4. Lichen Icmaepedia; Linn. Suppl. 450. Ehrh. Phy. n. 40. L. aruginosus; Jacq. Auftr. t. 275.

2. B. fungoides. — Pale Mushroom-Lichen. Ach. n. 2. ("B. helveloides; Bory Voy. 3." Lichen fungoides; Swartz Ind. Occ. 1886.) — Crust white. Stalks thrice as tall as the diameter of the pale flesh-coloured tubercles. — Gathered by Dr. Swartz on the gravelly soil of high mountains, in the southern part of Jamaica. Bory de St. Vincent found the same in the Isle of Bourbon. We have specims from Dr. Acharius. The crust is thin, hard, of a dirty white. Stalks white, thrice as tall as the foregoing; tumid at the base. Heads of a lighter flesh-colour, with a white powdery effluvience.

β. B. lignorum. Achar. (B. rueprifis γ; Ach. Meth. 322.)

Cruit greenish-white. Stalks short, somewhat compressed. Tubercles nearly globular, redhfh-brown; sometimes aggregate. — Common on heathy ground, or on rocks, rarely on rotten wood; in which last situation the tubercles assume a darker brown. They are much smaller than in B. reflux, rounder and less lobed, though often clotted together; their colour is a dirty brick-red.

The variety β of Engl. Bot. figured in Rau Syn. t. 1. f. 3, not f. 4; and in Dill. Mufc. t. 14. f. 5, is now esteemed a fungus. See Oxygyna.

4. B. phasephillus. — Broad-leaved Mushroom-Lichen. "Wahlenb. Lapp. 449." Ach. n. 4. Meth. 323. t. 7. f. 4. — Crust orbicular, rugged, somewhat lobed and imbricated, glaucous-white. Stalks elevated, compressed. Tubercles convex, simple, reddish-brown. — Found by Wahlenberg, on the intertidal sandy soil of Lower Lapland. We are obliged to Dr. Acharius for a specimen of this very curious species, whose crust approaches that of the true Cup Lichens, its circumference at least being lobed and almoat leafy, though of a thick fubstance. The tubercles are altogether those of a Boemyes.

BAGDAD, col. 4, l. 1, after terraces. Bagdad is still a place of great trade, and the resort of merchants from almost every quarter of the East. It supplies all Asia Minor, Syria, and part of Europe, with Indian commodities, which are imported at Baffora, brought in boats up the Tigris, and then transported by caravans to Tocat, Conflantinople, Aleppo, Damacicus, and the western parts of Persia. The chief imports from India are, gold brocades, cloths, sugar, pepper, tin, fandal-wood, iron, china-ware, fpece, cutley, arms, and broad-cloth; in return for which they fend bullion, copper, gait-nuts, tamarisk, leather, and otto of rofe. From Aleppo are imported European filk-fluffs, broad-cloths, fteel, cochineal, gold thread, and several other European articles, which are brought in Greek veffels to Scanderbon. The imports from Persia are, shawls, carpets, filk, cotton, white cloth, leather, and faffen: and those from Conflantinople are, bullion, furs, gold and silver threads, jevels, brocade, velvets, and otto of rofe. The principal manufacture at this place is that of red and yellow leather, which is much fteemed; but filk and cotton fuffs are likewise made. The climate, notwithstanding its excessive heat, is allowed to be very healthy. But the natives are subject to a cutaneous disorder, for which no cure has yet been discovered: it appears in the form of a pimple, then degenerates into an ulcer, and at the end of eight or ten months dries up of itself, leaving a prominent mark. The inhabitants of Aleppo, and other towns in Syria, are subject to this difafe. The military government of Bagdad is, &c.

BAGDAD, Pachyca, extends in a N.W. direction from the mouth of the Shat-ul-Arab to the rocks of Merdin, and in an E. and W. line from the confines of Perfia to the banks of the Khabour, which separates it from the pachyca of Orfa. It comprehends the whole of the ancient Babylonia, and the greatest part of Assyria Proper; that is, the space which is embraced by the Tigris and the Euphrates, and that which is beyond the Tigris, commonly called the lower Kurdisttan. See BABYLONIA and ASSYRIA.

BAHAR. Add.—The bahar of Acheen, in Sumatra, consists of 100 cattees, and is equal to 490 lbs. avoidupous. The bahar of Beftefackee, in Arabia, consisting of 40 farces, is = 815 lbs. avoidupous. The bahar of Bencoolen = 560 lbs. avoidupous. The bahar of Junkfeyon of 8 capins = 485 lbs. 5 oz. ½ dr. The bahar of Malacca, of 3 peculs = 405 lbs. avoidupous. The bahar of Mocha, of 15 francs = 445 lbs. avoidupous.

BAHREIN, N. lat. 26° 43'.

BAJOCCO. Add.—Rome exchanges with Amfterdam 42 bajocchi, more or les, for 1 florin banco; with Lebhom, 95 bajocchi, more or les, for 1 pezza of 8 reali. Rome keeps accounts in feucli. See SCUDO.

BAIRDSTOWN, l. 3, r. 821, 202 being flaves.

BAIT, WHITE. Add.—See CLIFFE Aplia.

BAKERSFIELD. Add.—It contains 812 inhabitants.

BAKU. Infert, or BAOU. N. lat. 42° 22'. Add.—Baku is defended by a double wall and deep ditches, constructed during the reign of Peter the Great. This was once a celebrated city of the ancient worhippors of fire, and before the conquest of the Saracens was annually visited by thousands of pilgrims.

BALDIAVIA, l. 7, r. W. long. 74°.

BALDWIN, in Geography, a town of America, in the district of Maine, and county of Cumberland, containing 536 inhabitants.
inhabitants.—Alfo, a county of Georgia, which, together with its town Milledgeville, contains 63,560 inhabitants; the
flaves in the county being 23,224, and in the town 226.—
Alfo, a county in the territory of Millifippi, having 14,27
inhabitants, including 717 slaves.

BALFOURIA, in Botany, received its name from the
pen of Mr. Brown, in honour of his illustrious countrymen
for Andrew Balfour, knight, founder of the Botanic Garden,
as well as of the Public Museum, at Edinburgh. His friend,
Sir Robert Sibbald, has embellished his memory in the Mem-
oria Balfioriana; nor could any one be more competent to this
subject. These distinguished men first laid the foundation
of the study of natural history in Scotland.—Brown
Tr. of the Wem. Soc. v. i. 70. Prodr. Nov. Holl. v. 1

Eff. Ch. Corolla funnel-shaped; throat crowned with a
small crenate tube; segments of the limb straight, equi-
lateral. Stamina inserted into the throat; anthers arrow-
shaped, pointed, cohering with the stigma about the middle.
Germen of two cells; style solitary, thread-shaped, dilated
at the top; stigma angular. Scales ten at the base of the
calyx, on the outside of the corolla; none under the germen.

Follicles......

1. B. falilo. Willow-leaved Balfouria. Br. n. 1.—
Discovered by Mr. Brown, in the tropical part of New
Holland. A tree, about twelve feet high, smooth. Leaves
opposite, linear-lanceolate, falcate, with little teeth between
the insertion of their footstalks. Cymes lateral as well as ter-
rnal, three-cleft.

BALK. Infebr.—or Bulkh. Col. 1, 1. 3, after Bact-
iriana, infect.—It was formerly included in Khorasan, and is
bounded on the N.E. by the Oxus, E. by Koonooz,
W. by Khorasen, and S.W. by the mountains of Huzara,
and the independent state of Mymen. Col. 2, 1. 17, after
Perfins, add—The Tanjots, or the race of people who in-
habit this country, besides the Afghans and Ulebeeks, are
corrupt and dissolute, and addicted to the most unnatural
vices. The Ubeeks are simple, honest, and humane.
Col. 2, 1. 60, after Hindoofian, add—It is said to be as large
as Delhi; but most of the houses are uninhabited; and the
population is said to be reduced to between 6 and 7000
men, subject to the king of Cabul. The vicinity of the
city is well cultivated, and corn and provisions are abundant.

BALLABUAN, r. BALLAMBUAN, and remove to next
column.

BALLISTIC PENDULUM, a pendulum used in ascer-
taining the velocity, &c. of balls, the strength of gunpowder,
&c. &c. See GNUNERY, GUNPOWDER, and PENDULUM.

BALLOCHISTAN, l. 10, r. Mekran. At the close,
add—Baloghistan, of, as it is otherwise called, Balouchi,
the country of the Balouches, is confidered by some as a
province different from Mekran or Mecran; and as such pro-
perly commences at Kooheen (the hilly road) 25 miles N.E.
of Bayra, or in N. lat. 26° 35', from which place it extends
to Noofhty, 79 miles N.W. of Kelat, or in N. lat. 30°. It
is said to be a confused mass of tremendous mountains,
through which the road generally leads in water-cources.
Flocks of sheep and herds of cattle are numerous in every
part of this country, and it also produces great quantities
of wheat. The territories of Mahomed Khan, chief of Ba-
lochistan, comprehend all the countries lying between
20° 30' and 30° N. lat., and from 65° to 69° E. long. It
is divided into the two mountainous provinces of Thalawan
and Sarawan, the low country of Cutch Gandava to the E.,
and the provinces of Zuhree and Amund Dajal; to which
may be added the small districts of Shat and Mustung, lying
n. of Kelat. See SARAWAN and MEKRAN.

BALLOTADE, l. 5, r. these airs, &c. ; l. 8, r.
horfean.

BALLS, CHAIN. For chain-balls r. chain-bullets.

BALLS, Stans. dele.

BALOUCHISTAN. See BALOOGISTAN.

BALSAMITA, in Botany, an old name, used by Doce-
ners and others, alluding to the balsamic odour of the
flowers and herbages, and their reputed stimulating heat-
qualities. It is revived by Professor Desfontaines, who,
after the example of Vaillant, has recently separated the
several species of this genus from Cotula, Chrysanthenum,
and Tanacetum, into which they were once included, though
definitle of radiant, or female, florets, as well as of a crown to their
Compositae dicoides. Linn. Cymbifera, Jull.

Gen. Ch. Common Calyx flattish, imbricated; scales nu-
merous, linear, convex, acute, the inner ones with a men-
branous margin. Cor. compound, uniform, tubular, longer
than the calyx. Florets all perfect, numerous, funnel-shaped,
equal; their limb in five regular, acute, spreading segments.
Stam. in each floret, Filaments five, capillary; anthers united
into a five-toothed tube, hardly longer than the tube of the
corolla. Pfl. Germs roundish; style thread-shaped,
longer than the corolla; stigmas two, revolute. Peric. none,
except the permanent calyx. Seeds solitary to each floret,
small, oblong, frirated, sometimes bordered with a narrow
longitudinal membrane at one side, but abrupt at the summit,
without any crown or wing. Recept. slightly convex, naked.

Eff. Ch. Receptacle naked. Seward down. Calyx
imbricated.

Ait. Soc. Hift. Nat. Parif. v. i. 1. 11. Willd. n. 1
(Cotula grandis; Linn. Sp. Pl. 1827.)—Stem herbaceous,
hairy, simple and single-flowered. Leaves ferra t; radical
ones obovate; those of the stem lanceolate; dilated and
deeply toothed at their base.—Found by Desfontaines in
corn-fields at Algiers, flowering in May. Linnaeus had it
from thence. A hardy biennial plant, conspicuous for
its large, yellow, cushion-like flowers, about two inches broad, 
composed of innumerable crowded florets. The stem is two
or three feet high, unbranched, leafy, and hairy. Leaves
numerous, smooth; the radical ones falked, two or three
inches long.

2. B. virgata. Wand-branched Cotula. Desf. as
above, 2. Willd. n. 2. Ait. n. 1. (Cotula grandis; 
Jaq. Obf. fuc. 4. 4. 1811. Chrysanthenum dioecoides; 
Allion. Pedem. v. 1. 190. 1. 11. f. 1.)—Stem herbaceous,
smooth; branched at the base; branches single-flowered.
Leaves linear-lanceolate, ferrated, nearly sessile; upper ones
linear, entire.—Native of Italy. This is the plant men-
tioned under his Cotula grandis by Linnaeus, as having been
fert by Allion. It is hoever, as he suspected, very distinct
from that plant; being much smaller in every part; the
stem smooth and branched; leaves none of them fpatulate,
nor dilated and deeply cut at the base. Flowers fimilar, but
scarce ly half so large, especially thoife of the lateral branches.

3. B. agrestisfolia. Sharp-toothed Cotula. Desf. as
above, 2. Willd. n. 3. Ait. n. 2. (Chrysanthenum flo-
culorum; Linn. Sp. Pl. 1255. Bellis pinophia; Alpin.
Exot. 327. t. 326. B. major pinophia. petalis carenos; 
Morif. leet. 6. 1. 9. f. 16.)—Stem softly, branched at the
base. Leaves obovate, sharply ferrated, crowded. Flowers
erymbofe.—Native of Crete; an old green-house plant in
3 A England.
England, but not popular at present. The branches are rather loosely spreading, smooth, covered with smooth leaves, an inch and a half long; their numerous teeth are sharp, and even spiny. Several deep-yellow convex flowers compose a corymbose cluster at the extremity of the inflorescence. (See our former article Banksia, which requires correction, as embracing several species not now included herein, but already described in the present work under the articles Conchium and Xylometum.) On the other hand, a much greater number of genuine Banksia, first made known by Mr. Brown, since the publication of that original article, require to be added. We are at a loss to account for the report concerning the species with foliaceous flowers, at the end of that article. It may have had some foundation which has escaped the memory of the writer of this note. The only Salisburia ever published belongs to a totally different family, and may be found in its proper place. Thirty-one species of Banksia are defined by Mr. Brown, of which four only were known to Linnaeus, from specimens and engravings communicated by Sir Joseph Banks. — Linn. Suppl. 15. Schreb. Gen. 79. Murr. in Linn. Syll. Veg. ed. 14. 161. Willd. Sp. Pl. v. 1. 535. Mart. Mill. Dict. v. 1. Ait. Hort. Kew. v. 1. 213. Brown Tr. of Linn. Soc. v. 10. 202. Prodr. Nov. Holl. v. 1. 391. Juss. 79. Lamarek Illır. t. 54. f. 1. 2. Gartn. t. 48. — Clas and order, Tetrandria Monogynia. Nat. Ord. Aggregate, Linn. Prodraceseae, Juss. Brown.

Gen. Ch. Col. Catkin cylindrical, dense, many-flowered; flowers in pairs, with three permanent scales to each pair, two of which are interior, and smallest. Cor. of one petal, in four deep linear segments, at length separating entirely, somewhat dilated and concave at the summits, their points long cohering, till forced asunder by the growing style. Nectary four scales at the base of the germen. Stam. Filaments four, very short, inserted into the cavity of the petal; anthers oblong. Pist. German superior, of two free cells, very small; style cylindrical or angular, rigid, gradually curved, firmly held, for a long time, by the combined tips of the corolla; stigma undivided. Peric. Follicle woody, firmly fixed in the receptacle, obovate, of two shallow cells; the partition unconnected, rigid, elatic, cloven by a deep transverse fission at the top. Seeds solitary, compressed, quite flat at the inner side, wedge-shaped, and extended into a rounded, membranous, terminal wing. Eff. Ch. Corolla of one petal, four, cleft, bearing the stamens in the hollow of its segments. Nectary four scales at the base of the germen. Follicle woody, of two free cells, with a cloven moveable partition. Catkin with three scales to each pair of flowers.

Obs. The greater part of the very numerous flowers are necessarily abortive, or there would not be room for the follicles to ripen.

The various species, all natives of New Holland, are either shrubs, or trees of no lofty stature. The branches are umbellate; or in Linnian language the term is "determinate branched," as in Erica and other Ericaeeae. Leaves scattered, rarely whorled, simple, undivided, either entire, serrated, toothed, or cut in a pinnatifid manner; in a young plant they are often variously cut, or toothed, though undivided and entire on the frame when fully grown. (Brown.) Catkins solitary, terminal, rarely lateral, cylindrical, in some cases very short. Bracteae several at the base of each catkin, short and narrow. Catkin when in fruit hard and heavy, its enlarged common receptacle firmly united with the bales of the flowers, the surface bristly with remains of the flower scales, and especially with the unimpressed style of the greater part, intermixed with the large, hard, usuufilly downy or hairy, follicles. Seeds black, with a brown, shining, oblique wing, the convex side of each filling a depreission in the corresponding side of the thin wooden partition.

Sect. 1. Style longer than the corolla, projecting laterally, in a curved position, between its segments, the stigma being held flat, from some time longer, between their points. Catkins when in flower, cylindrical; when in fruit, laden with numerous transverse follicles. These Mr. Brown considers as true Banksia. Indeed this section embraces the whole genus, except one species. We follow Mr. Brown's names and numbers.

1. B. pulchella. Small-flowered Banksia. Ait. n. 1. — Leaves acerose, entire, pointless. Tube of the corolla woolly;
woolly; limb smooth. Stigma capitate, depressed.—Native of dry heaths, near the sea-shore in Lewin's land, on the south-eastern coast of New Holland, where it was found by Mr. Brown, and sent to Kew in 1805, but had not yet flowered there in 1810. The leaves are not longer than the finger-nail.

3. B. nutans. Nodding-flowered Bankia. Ait. n. 3.—Leaves aceroce, entire, pointed. Catkins drooping. Corolla silky. Follicles dilated at the summit, depressed.—On dry heaths near the shore of Lewin's land, where, like the two former, it was gathered by Mr. Brown.

4. B. cripida. Heath-leaved Bankia. Linn. Suppl. 127. Willld. n. 7. Ait. n. 4. Banks Is. Ined. apud Bibl. Linn. t. 4. Andr. Repof. t. 156. Curt. Mag. t. 758. Cavan. Ic. v. 6. 27. t. 538. (Bankia; White's Voy. 225. t. 22. f. 1.)—Leaves aceroce, margined, with two teeth; entire at the edges. Catkins elongated. Corolla silky. Stigma capitate.—Native of the eastern coast of New Holland, on rocky heaths near Port Jackson, from whence it was sent by Dr. White, among the first botanical communications from that country, and is now in several green-houses, flowering at various times of the year. This species was however first discovered by sir Joseph Banks and Dr. Solander, in their celebrated voyage. The stem is three or four feet high. Leaves very numerous, the length of the nail, evergreen, smooth, revolute. Flowers bright yellow. Catkins five or six inches long. Follicles abrupt, rough with ruly, deciduous hairs.

7. B. occidentalis. Well-coast Bankia. Ait. n. 6.—Leaves linear, with spinous teeth beyond the middle; veins beneath. Scales of the catkin smooth at the extremity. Corolla withering; bearded internally at the base. Follicles tumid, downy; rather compressed and naked at the summit. Stem thrubby. Young branches smooth.—Found by Mr. Brown, in heathy ground, at Lewin's land.

8. B. littoralis. Sea-side Bankia. Ait. n. 7.—Leaves linear, elongated, with spinous teeth; veins beneath; tapering at the base. Corolla deciduous. Follicles compressed, downy at the summit, as well as the scales of the catkin. Stem thrubby. Young branches downy.—Found by Mr. Brown on the sandy shores of creeks in Lewin's land. The flowers were pale.

10. B. depressa. Profusely Bankia. Br. n. 10.—Leaves long-wedge-shaped, abrupt, pointed; spinous-toothed; slightly ribbed and veined beneath; rather longer than the catkins, all whose scales are downy and obtuse. Stem profusely. Ultimate branches hairy.—Found by Mr. Brown, in stony ground at the roots of the mountains in Van Diemens's island, towards the south.

11. B. patula. Spreading Bankia. Br. n. 11.—Leaves linear, somewhat wedge-shaped, abrupt, pointed, very sparingly toothed; reticulated with veins beneath. Scales of the catkin downy at the summit and obtuse. Keel of the limb of the corolla smooth. Stem profusely. Ultimate branches downy.—Discovered by Mr. Brown, in Flinders' land, on the south coast of New Holland, growing amongst other shrubs, in barren elevated spots.

12. B. australis. South-coast Bankia. Br. n. 12.—Leaves linear, abruptly, pointed, entire, revolute; reticulated with veins beneath. Ultimate branches downy. Scales of the catkin obtuse, nearly equal; downy at the summit. Keel of the limb of the corolla very slightly filky. Stem arboreous.—Observed by Mr. Brown, every where in the open fields of Van Diemen's island, as well as by the seaside; and also on the south coast of New Holland, near Port Phillip.

13. B. insularis. Insular Bankia. Br. n. 13.—Leaves linear-oblong, or somewhat wedge-shaped, slightly rounded, pointed, either compression or whorled; reticulated with veins beneath. Scales of the catkin obtuse, externally downy. Follicles compressed; smooth at the summit.—Native of the islands of the Bays of the north-west, as well as that of Van Diemen, near the shore. Brown.

14. B. integrifolia. Entire-leaved Bankia. Linn. Suppl. 127. Willld. n. 3. Ait. n. 9. Banks Is. Ined. t. 3. Cavan. Ic. v. 6. 30. t. 540. (B. oleifolia; Cavan. Ic. v. 6 30. t. 545. B. glauca; Cavan. Ic. v. 6. 31. B. bipicata; Gertrn. t. 48.)—Leaves whorled, oblong-lanceolate, entire, pointed; reticulated with conspicuous veins beneath. Follicles downy. Stem arboreous.—Native of the east coast of New Holland, near the sea-shore at Port Jackson. This is generally a small, or middle-sized, tree. Leaves narrow-ovate, for the most part acute; tapering at the base; white beneath. The twin scales of the catkin obtuse; solitary one acute, and only half as large.

Mr. Brown says this is a very variable species, too nearly akin to the last, as well as to that immediately following. He observed on the south coast, near Port Phillip, a variety which forms a large tree, with lanceolate-oblong, mostly rather obtuse, leaves, acute at their base; the solitary scales of the catkin rather acute, but more than half the size of the twin ones.

BANKSIA.

Mr. Brown, but not in fruit, by the sea-fide at Keppel Bay, on the east coast of New Holland. He supposed it to be a variety of the last.

17. B. coccinea. Scarlet-flowered Bankia. Ait. n. 11.—Leaves alternate, wedge-shaped-obovate or oblong, toothed, crenate, reticulated with veins; transferous at the base. Scales of the catkinawl-shaped. Corolla woody.—Found by Mr. Brown in Lewin’s land, in fields near the coast. It was sent to Kew, by Mr. Good, in 1803.

18. B. paludosa. Marsh Bankia. Ait. n. 12.—Leaves imperfectly whorled, wedge-shaped-obovate, somewhat acute; tapering at the base; slightly revolute; coarsely serrated beyond the middle; ribbed, reticulated with veins beneath. Footstalks and young branches smooth. Corolla silky. Stem shrubby.—Gathered by Mr. Brown, in marshy ground, near Port Jackson. It is said to flower in the green-house at Kew, from January to March.

19. B. oblongifolia. Oblong-leaved Bankia. Cavan. l.c. v. 6. 28. t. 542. Ait. n. 13. (B. falsifolia; Cavan. l.c. v. 6. 31?)—Leaves scattered, narrow-oblong, acute, strongly serrated; rather acute at the base; ribbed, and reticulated with veins beneath. Footstalks and young branches downy. Larger scales of the catkin pointed. Corolla silky. Stem shrubby.—Seen by Mr. Brown on heaths near Port Jackson. The leaves, according to his observations, are sometimes entire, or nearly so, (as we judge in this case from the word integra,) and therefore may answer to the falsifolia of Cavanilles, of which it is difficult to judge precisely, for want of a figure.

20. B. latifolia. Broad-leaved Bankia. Br. n. 204. Ait. n. 14. (B. robur; Cavan. l.c. v. 6. 29. t. 543.)—Leaves obovate-oblong, with spinous serratures; acute at the base; ribbed, reticulated, downy and grey beneath. Tube of the corolla silky; limb smooth. Stem shrubby.—Observed by Mr. Brown, in boggy situations near Port Jackson; plentiful about the town of Sydney, where it rarely ripens seed. That accurate botanist informs us the stem is usually three or four feet high, scarcely ever six feet. Louis Née, from whom Cavanilles had his information, appears to have accidentally confounded his speciments of this species, with his memoranda relating to B. ferrata, and hence it is described of the fice of an Oak, to which the name robur alluding, was necessarily obliged to be changed.

—Native of the southern coast of New Holland; near the shore. Mr. Andrews says this species was first raised from seed at Kew, in 1788. Mr. Brown and Mr. Aiton, on the contrary, mark it as introduced in 1794, by its first discoverer Mr. Menzies. The stem is fix or seven feet high in the green-house. Leaves to abrupt, that we could almost have allowed the name prunifolia to remain. Flowers purple, in large handsome catkins; inside of the corolla white.

22. B. attenuata. Smooth-flowered Bankia. Ait. n. 16.—Leaves elongated and nearly linear, abrupt; tapering at the base; serrated more than half way down; ribbed and reticulated, with downy interfaces, beneath. Scales of the catkin hairy at the summit. Corolla smooth. Follicles downy.—This also was discovered by Mr. Menzies, on the southern coast of New Holland; and seen by Mr. Brown in Lewin’s land, near the sea-coast. It was raised at Kew, in 1794, but appears not yet to have flowered; nor have we heard of the plant elsewhere.

—Discovered by Mr. Brown, on the east coast of New Holland, by the sea-fide, at Sandy Cape.

24. B. ferrata. Great Serrated Bankia. Linn. Suppl. 126. Willd. n. 1. Ait. n. 17. Banks Ic. Ind. t. 2. White’s Voy. 222. t. 18, 19, 20. Andr. Repof. t. 82. Cavan. l.c. v. 6. 27. t. 540. (B. conchierea; Gartn. t. 48.)—Leaves linear-oblong, abrupt, rather bluntly serrated; reticulated and nearly smooth beneath; tapering at the base. Lower part of the style downy and powdery. Stigma cylindrical, furrowed; obliquely swelling at the base. Stem arbores.—Native of the east coast of New Holland, at Port Jackson, in fields near the sea, from whence speciments were brought by Sir Joseph Banks; but the plant was first raised in England, by Meffrs. Lee and Kennedy, in 1788. This is described as the most flatly of its genus, rising to the height of thirty feet, with a hard red-fir wood. The leaves are near a span long, almost perfectly smooth on both sides, not so deeply serrated as in the figures of Andrews or Cavanilles, or in White’s t. 20; but rather bordered with a series of rectangular blunt-flute notches. Catkins large, thick and heavy, of innumerable downy flowers, whole corolla is purplish, and style crimson. Cone ten inches long, very heavy. Follicles downy, an inch in diameter. Gaertner’s figure is from a poor diminutive cone.

25. B. ambula. Large-fruited Bankia. Br. n. 25.—Leaves linear-oblong, abrupt, deeply and sharply serrated; reticulated and nearly smooth beneath. Corolla silky. Stigma capitulate, polished, pyramidal, not furrowed, twice as thick as the style. Stem shrubby.—Native of heaths, and sandy fields, near Port Jackson, from whence we long ago received speciments, with full-grown fruit, by the kindness of Dr. White. We have been used to call this species B. macrocarpa, a name well expressing its singularly large follicles, which are twice the dimensions of the preceding, though the whole cone is usually much shorter. It is impossible to mistake Mr. Brown’s faithful specific definition, especially the character of the short pyramidal stigma. The leaves are much smaller than those of B. ferrata, though their fructes are much deeper and sharper. Hence Mr. Brown was led to apply t. 20 of White’s Voyage to the present species, with which the leaves in that figure pretty nearly agree; but the cone certainly, to our knowledge, belongs to the ferrata, which it well expresses, except being too small. The fructes in Mr. Andrews’s plate of ferrata most nearly approach our present plant. The shape and proportion of the catkin moreover bell agrees herewith.

—Discovered by Sir Joseph Banks and Dr. Solander, near Endeavour river, in the tropical part of New Holland. Mr. Brown also met with this noble species, which as yet is a stranger
stranger to our gardens, at Arnheim's land, on the northern coast. Of the height or size of the plant we are not informed. The branches are rusty and somewhat downy. Leaves alternate, from a span to a foot long, on short stalks; their margins remarkably undulated, and bordered with broad, hollow, pinnate-pointed teeth. Catkins fix inches long, more slender than usual; their scales downy, the larger one to pair of flowers pinnate-pointed.

27. B. quercifolia. Oak-leaved Bankia. Ait. n. 18.—Leaves oblong-wedge-shaped, rather abrupt, smooth, deeply serrated, pointed. Segments of the corolla awned. Follicles nearly smooth.—Found by Mr. Brown, in fields near the shore, in Lewin's land. The awns of the corolla are indicated by him as a very remarkable character.

28. B. speciosa. Long-leaved Bankia. Ait. n. 19.—Leaves linear, pinnatifid; lobes triangular-halfovate, pointed; snow-white and slightly ribbed beneath. Limb of the corolla woolly. Style rather hairy. Follicles downy.—Native of the rocky sea-shore of Lewin's land, where it was found by Mr. Brown, and sent to Kew, in 1805.

29. B. grandis. Great Winged Bankia. Willd. n. 2. Br. n. 29. Ait. n. 20.—Leaves deeply pinnatifid; lobes triangular-ovate, acute, flat; many-ribbed, and nearly smooth, beneath. Corolla and follicles smooth.—Gathered by Mr. Menzies, at King George's found, on the west coast of New Holland. Mr. Brown met with the fame on rocky hills in Lewin's land. Seeds were sent to Kew in 1794, where this magnificent shrub thrives well, in the green-house, but has not yet flowered. Willdenow's specific name alludes, we presume, to the foliage, and not to the flowers, with which he was not acquainted. The leaves are twelve or fourteen inches long, pinnatifid to the very rib; abrupt at the extremity; lobes numerous, more or less alternate, crowded, transverse, conosacous, entire, rather pinnatifid; roughish to the touch on the upper side; paler underneath, furnished with five principal ribs, and many intermediate veiny retractions; they diminish gradually towards the top, and especially towards the base, of the leaf. We have seen no flowers nor fruit.

30. B. repens. Creeping Bankia. Labill. Voy. v. 1. 412. t. 23. Br. n. 30. Ait. n. 21.—Leaves pinnatifid; lobes finnate or toothed. Stem prostrate.—Found by Labillierds, on calcareous rocks on the south-west coast of New Holland, where also Mr. Brown met with this species. It flowers there in December. The creeping stem is clothed with rusty down. Leaves a span long, flaked, erect, deeply pinnatifid, but not quite to the rib, which is winged nearly all its length: they are downy when young, but finally very smooth. Catkins ovate, nearly febillis, erect, dense, many-flowered, about three inches long. Corolla and germin hairy.

Sect. 2. Points of the corolla more speedily separating; the narrow part of their segments cohering longitudinally, and as long as the style. Catkin short and level-topped, perfecting scarcely more than one vertical follicle.

31. B. thecafolia. Holly-leaved Bankia. Br. n. 31.—Leaves wedge-shaped, deeply serrated; nearly smooth beneath. Catkins very short.—Gathered by Mr. Brown, in fields and hilly ground near the sea-coast, in Lewin's land. This species is so singular, that its learned discoverer appears to have been inclined to make it a distinct genus, by the name of Icysyla. He remarks that it forms a connecting link between Bankia and Dryandra; see the latter hereafter.

BANNIUM, in Ancient Geography, a Roman station, called Gaer, or Caer Bannau, situated about three miles above the town of Brecknock, in South Wales, near the confluence of the rivers Yukan and Uh. The camp is a parallelogram, 624 feet by 456, having its longest parallels in a direction nearly S. and N. The foundation of the wall that encompassed this area remains still entire, and may be traced through the underwood that has overgrown and concealed it. In this flatton there is a cauway, supposed to have been a branch of the great Roman cauway leading from Caerleon, in Monmouthshire, through the vale of Usk, and the eastern part of Brecknockshire to Archenium, which is the 12th Iter in Antonine's Itinerary.

BANQUETTE. Add.—See BREAST-WORK.

BANTAM, col. 1, l. 50, after settled there, ingress That of the English was established in 1601, and maintained until 1683. That of the Dutch was erected in the year 1595, and this was their first settlement in the Spice islands, which had been first visited by the Portuguese in 1510. The English made no attempt to recover a free port in Java until the year 1811, when Holland became a province of France, and the Dutch colonies were induced to accept the protection of Great Britain.—Col. 3, at the close of Bantam, add—Raees's History of Java, 2 vols. 4to. 1817.

Gen. Ch. Col. Perianth inferior, of one leaf, bell-shaped, permanent, cut half way down into four or five segments, forming two lips; its base externally convex. Cor. papilionaceous, of five petals. Standard irregularly-halfovate, reflexed at the sides, with a thick claw. Wings two, nearly as long as the standard, half-ovate, converging at their upper edges. Keel as long as the wings, of two oblong converging petals. Stem. Filaments ten, awl-shaped, ascending, equal, inserted into the base of the calyx, deciduous; anthers roundish, two-lobed. Pfl. Gernan superior, flaked, ovate or elliptical; style longer than the flaments, ascending; stigma capitata, hemispherical. Peric. Legume on a flaked longer than the calyx, elliptic-oblong, turgeo, membranous, of one cell. Seeds numerous, elliptical, flaked.

Eeff. Ch. Calyx two-lipped, divided half way down into four or five segments. Corolla papilionaceous; petals all nearly of equal length; standard reflexed at the sides. Stamens distinct, deciduous. Legume inflated, flaked, with many seeds.

To this genus we have already adverted, under the article Podaulya, as comprising the North American species of that genus, as it stands in Lamark and Willdenow. They are doublets sufficiently marked by the above description, to form a genus by themselves. They are herbaceous, perennial, many of them glaucous, and have mostly the quality of dyeing blue. Leaves ternate, except the first, with a pair of rather large stipulas. Flowers mostly racemose, with small partial bracts; their colour blue, white, or yellow.

flowering in July. The whole plant is very smooth, scarcely glaucous, two or three feet high, distinguished by its pedicelate, almost orbicular leaves, about two inches broad, accompanied by lemon-coloured flowers, on short simple stalks. _Legume_ nearly globular.

2. B. _uniflora_. Downy Single-flowered Wild Indigo. (Podalyria uniflora; Michaux Boreal.-Am. v. 1. 263. Pursh n. 2. Sophora lanceolata; Walt. Carol. 135.) Leaves ternate, feathery, downy; leaflets lanceolate, obtuse. Stipula bristle-shaped, minute. Flowers axillary, solitary. —Observed by Michaux in Carolina and Georgia. The whole herbage is downy, as well as the calyx. _Flowers_ stalked, yellow.

5. B. _alba_. White-flowered Wild Indigo. Ait. n. 4. (Podalyria alba; Willd. Sp. Pl. v. 2. 503. Mich. ibid. 264. Pursh n. 5. Curt. Mag. t. 1177. Sophora alba; Linn. Syst. Veg. ed. 13. 325. Crotalaria alba; Linn. Sp. Pl. 1066. Anonis caroliniana perennis, non spinosa, &c. Mart. Cent. t. 44.)—Leaves ternate, falved, smooth; leaflets elliptic-oblong. Stipula awl-shaped, shorter than the failstalk, deciduous. Germination. —In the western parts of Virginia and Carolina, on the banks of rivers, flowering in June and July. _Pursh_. Hardy in our gardens, but not of frequent occurrence. Catesby first introduced it in 1734. The habit of this species, its smoothness, and rather glaucous hue, agree with the tall, to which it is certainly most nearly allied; but the leaflets are elliptical, the flowers white, more oblong, in consequence of the greater length of the wings and keel, the _flapulae_ smaller and deciduous. The corolla is here and there spotted with brown, and is reported to be sometimes blue. Some of the flowers, in both these species, are often whorled, and give the cluyter an interrupted-form, like that of a Lupine, the aspect of which genus is otherwise visible in these plants.

7. B. _tinctoria_. Common Wild Indigo. Ait. n. 3. (Podalyria tinctoria; Willd. Sp. Pl. v. 2. 503. Mich. ibid. 265. Pursh n. 7. Lamarche f. 1. Curt. Mag. t. 1099. Sophora tinctoria; Linn. Sp. Pl. 534. Cytisus procumbens americus, flore luteo, ramosissimus, qui Anil luppeditat apud Barbadianum colonos; Pluk. Phyt. t. 86. f. 2.)—Leaves ternate, somewhat falved, smooth; leaflets roundish-obovate. Stipula tawny-yellow, obsolete. Flowers racemose. —In woods on dry hills, from Canada to Carolina, flowering in July and August. Called Wild Indigo. _Pursh_. A low, partly procumbent, smooth plant, whose numerous branches are each terminated by a simple cluster of yellow flowers, about half the size of _B. australisis_. The pods are ovate, on stalks much longer than the permanent calyx. This species is said to have been cultivated for Indigo, in the North American settlements, and even in Barbadoes, before the true _Indigofera_ was introduced. It is tolerably hardy with us, in a dry soil and sheltered situation, but has nothing to recommend it for general cultivation.

BAR, Trial at. See _JURY_.

BARACKS, col. 2, add—See _CASERNS_.

BARAQUICMITO, dele lat. and long., and add—See _BARQUISIMETO_.

BARBAREA, in _Botany_., a name used by Dodoens, because this plant had been called the Herb of St. Barbara by some preceding botanists. It has always been referred to _Erysimum_, (see that article,) till Mr. Brown raised it to the rank of a separate genus, under the above appellation, in _Ait. Hort. Kew._ v. 3. 109. —Claws and order, _Tetradynamia_ Siliquea. Nat. Ord. _Siliquea_, Linn. _Crucifera_, Juff. Eff. Ch. Pod quadrangular, compressed. Cotyledons accumbent. Seeds in a single row. _Calyx_ erect. Glands between the shorter rami and the germenis.

Two species only are described.

2. B. _procus_. See the same article, n. 3.

Mr. Brown thus defines _Erysimum_.

We have explained the terms _accumbent_ and _incumbent_, as thus technically used, under the article _Tetradynamia_, where a more particular account is given of our ingenious friend's arduous undertaking, of reforming the genera of the natural order in question.

BARQUISOMETO, in Geography, a city of America, in the government of Caracas, 40 leagues W.S.W. of Caracas, 150 leagues N.N.E. of Santa Fé, and 15 leagues from Tucuy. N. lat. 9° 45' The excessive heat is rendered supportable by the cooling breeze arising from its elevated situation. The adjacent plains are covered with excellent paturage favourable for rearing every marketable animal. The sugar-cane and the beet wheat are also cultivated. The vales produce excellent cacao; and the sides of the hills are devoted to the culture of coffee. This city accommodates 11,500 persons; its houses are well built, and the streets are laid out as to afford a free circulation of air. It has a parith-church and two officiating priests, a monastery of Franciscans, and a hospital badly attended.

BARE, a township of America, l. 2, r. 1971; l. 11, add—having 1053 inhabitants.—Alto, a town of Vermont, in Orange county, having 1669 inhabitants.

BARR, by 43 Geo. III. c. 69. every 36 gallons of beer or ale brewed by the common brewers in Great Britain, taken according to the standard of the ale quart, four thereof to the gallon, in the exchequer, shall be reckoned by the gauger or other officer of excise for a barrel of beer or ale.

Barr, a weight by which corn is sold in Ireland. The barrel of wheat, peas, beans, and rye, is 20 stone: of barley, bere, and rape-feed, 16 stone: of oats 14, and in some places 12 stone: of malt, 12 stone: the stone being 14 lbs. avoirdupois weight. A barrel of good wheat answers to about four Winchester bushels.

BARNEN FLOWERS, in Botany and Vegetable Physiology, Flores malus in Linnaean terminology, are such as are not provided with organs for the formation of fruit or seed, but only with flamen for its impregnation. See Fecundation of Plants.

BARRIER, in Fortification. Add—See Cheval de Frise, Herison, Klikets, and Tercnile.

BARRIL, plur. Barril, a liquid measure in Italy.

BARRINI, in Geography, a county of the district of Kentucky, containing 11,742 inhabitants, of whom 1056 are slaves. The town, Glaferow, has 244 inhabitants, of whom 68 are slaves.

BARRINGTON, a township in Strafford county, &c. l. 3, for 2470 r. 3564. Id. l. 5, for 683 r. 604. Id. l. 2, for 1373 r. 1784.

BARRIQUE, a measure for wine and brandy in some parts of France, as at Bourdeaux, Rochelle, &c. At Bourdeaux, a tonneau of wine contains 4 barriques or hogheads = 50 flesk in Amsterdam, 255 flugen in Hamburg, or 233 English gallons; and weighs with the wood about 2000 lbs. of Bourdeaux. The barrique contains 11c pots, or 32 veltes.

BARRY-BENDY, &c. Plate III. Heraldry, &c.

BART, in Lancaster county, add—It contains 1099 inhabitants.

BARTHELEY, a river of Louisiana, which rises near the Arkansas, and after a course generally from N. to S. of 100 miles, falls into Ouachita, 3 miles below the Derbanc, on the contrary side.

BARTHIOLINA, in Botany, a genus of the Orchis family established by Mr. Brown, and dedicated to him by the memory of the great Danish anatomist and physiologist, Thomas Bartholin, whose life is already given in its proper place, and whose various writings relating to plants, in the old Copenhagen Translations, entitle us to adorn the history of our science with his truly illustrious name.—Brown in Ait. Hort. Kew. v. 5. 194.—Chaps and order, Gynander Mengonisia. Nat. Ord. Orchideæ.

Gen. Ch. Col. Perianth inferior, of one leaf, tubular at the base, deeply divided above into three, elliptic-oblong, equal, ribbed, spreading segments, externally hairy. Cor. Petals two, linear-lanceolate, erect, smooth, taper-pointed, nearly twice the length of the calyx. Nectary a large spreading lip, united to the base of the petals, thistle the length of the calyx, in three deep principal lobes, the middle one broadest, all divided, more than half way down, into many linear, fringe-like segments, and terminating behind in a tumid, curved, bluntly-pointed spur, rather longer than the tube of the calyx. Stam. Anther pointed, of two oblong, rather distant, parallel cells, opening in front, attached to the two margins of the style; maidens of pollen each supported on a long, membranous-bordered stilt, to which their cells are laterally attached, "their glands distinct, half covered by the exterior lobe." Pit. Germen inferior, elliptic-oblong, curved, very hairy; stily flattened, much shorter than the calyx; stigma a cavity between the lobes of the anther. Peric. Capsule…

Eff. Ch. Calyx tubular at the base. Petals united to the base of the lip, whose spur is shorter than the germin. Stalks of the pollen elongated; their cells laterally fixed: "glands distinct, half covered by the exterior lobe."
BAR

with blue. *Spur* greenish-white. Maffes of *pollen*, (which *Linneus* in the *Supplement* has described as a pair of *tyles*), inferted into the bafe of the *tyles*, yellowish, prominent, very conspicuous even in dried specimens.

**BARTLET**, a town of America, in Coos, &c. *r.* 436.

**BARTON**, in Orleans county, &c. *d*—it contains 447 inhabitants.

**Barton-on-Humber**, *l. ult.* for 412 *r.* 191— for 1729 *r.* 1129. The parifh of Barton, St. Mary, has 290 houses and 976 perfons; and the parifh of St. Peter has 263 houses, and 1228 perfons.

**BARTONIA**, in Botany, received that name from Dr. Sims, in 1812, in juft commemoration of the scientific merit and zeal of Dr. Benjamin Smith Barton, at that time profeffor of botany and natural history, in the university of Pennsylvania, who after many exertions, and several publications, in the fervice of natural science, died of athero- 
drivus, at Philadelphia, on the 19th of December 1815, in the fiftieth year of his age. His nephew, Dr. William Barton, in an animated and intere/ling "Biographical Sketch" of his charafter and pursuits, has preferred fome account of the plants which compose this genus, written by the late profeffor, three or four days before his death, and accompanied by many particulars, relative to Mr. Purf and Mr. Nuttall, through whose means it has come to the knowledge of European botanifs; all which evince a love of science, that the most painful bodily sufferings could not repre. Sins in *Curt. Mag.* 1487. Purf 327. *At. Epit.* 364.—*Clafs and order, Iofandria Monogynia. Nat. Ord. Loofes, Juff. Ann. du Mufc. d'Hif. Nat. v. *5. 18.* Sims.

Eff. Ch. Calyx superior, in five deep segments. Corolla of many petals, with clays. Stamens uniform. Capsule cylindrical, of one cell, with a lid of three or five valves, and as many parietal receptacles. Seeds numerous, flat, in double rows.

1. **B. ornata.** Large-flowered Bartonia. *Purf f. 1. Ait. n. 1. (B. decapetala; Sims as above, t. 1487).—German leafy. Seeds without a wing. —*Found by governor Lewis, in 1804, on chalky soil on the borders of the Missourif, flowering in July and August.* *Purfh.* Profeffor Barton records that Mr. Nuttoll first made this fine plant known to him in 1811, having found it growing all the way from the river Platte to the Anderes, on broken hills and in the clefs of rocks. Mr. Purf by mistake, as the profeffor thought, speaks of the foil as volcanic. Living plants were brought to England by Mr. Nuttall, who is unquestionably entitled to the honour of this discovery, as he could not know what might be concealed in the herbarium of any deceased traveller. The figure in the Magazine, though taken from a dried specimen, is unexceptionable, as far as it goes. The herb is biennial, downy, glabrous, about three feet high. Leaves alternate, felfife, oblong, pinnatifid. *Flowers* terminal, enveloped in leaves, three inches broad, with about ten elliptical, acute, white petals, and numerous filaments, half as long, whose anthers are elliptical, yellowish. These flowers expand suddenly in an evening, diffusing a moft agreeable odour, and rival those of some of the fine fpecies of *Cactus* in elegance.

2. **B. nudz.** Small-flowered Bartonia. *Purf f. 2. Ait. n. 2.—German naked. Seeds winged. —*Found by Mr. Nuttall, on gravelly hills near the Great Detour of the Missifipri, flowering in August.* *Root perennial.* Petals more numerous. *Barton.* Mr. Purf obferves that this has smaller flowers than the foregoing, and less glaucous leaves. The petals vary in number, from ten to fifteen.

We have seen no fpecimens, and have fcarcely fufficient materials for drawing up a full generif character.

Eight fpecies are defcribed in *Engl. Bot.* and *Compand.* Brit., and there are feveral of exotic growth.

**Secl. 1.** Fruit-flasks shorter than the flom.

1. **B. halleriana.** Lateral Bartramia. *Hedw. Crypt.* v. 2. *111. t.* 49. *Engl. Bot.* t. 997. *Hook. and Tayl.* v. 5. *t.* 23. (Bryum laterale; *Hudif.* 483. *Ethr. Crypt.* 33. *B. n. 1802; Hall. Hif.* v. 3. *43.* t. 46. f. 8.)—*Fruit-flasks* lateral, curved, shortier than the linear-cylindrical, fingle-ribbed, rough-edged leaves. Native of moist rocky mountainous woods, in Switzerland, Germany, Scotland, Wales, and the north of England. The floms are, as Mr. Hooker obferves, perennial, and repeatedly proiforous, fo that, although the flowers are, like every *Bartramia*, originally terminal, the fruit form becomes lateral, and remaining two or three years, is found numerous ranged along the main stem, among the denfe, fender leaves. When ripe it becomes strongly furrowed, though originally smooth or even.

2. **B. arcata.** Curve-flanked Bartramia. *Engl. Bot.* t. 1237. *Fl. Brit.* v. 5. *Hook.* and *Tayl.* v. 6. *t.* 23. (Mium arcuatum; Dickf. Crypt. fefc. 3. *t.* 7. *f.* 3. *M. chryfocomum; Hedw. Sp. Mufc.* 74. *Hypnum palucre crecum, comà luteus, bafi nigricante; Dill. Mufc.* 352. *t.* 36. *f.* 36.)—*Fruit-flasks* recurved. Leaves lanceolate, fingle-ribbed, furrowed, finely ferrated. Branches scattered, spreading.—Native of mountains in Great Britain and Ireland. According to Mr. Hooker, it is found, in the greatest abundance, on wet rocks, at Lowdore and Keswick, Cumberland, and is also very common in the mountainous districts of Ireland, though unknown on the continent of Europe. With all deference to our worthy friend however, the ripe *capsule* is as decidedly furrowed as in any other fpecies. The more branched and tufted habit of this mofs, and the broader, flortier, rigid, yellowifh, more spreading leaves, at once diftinguifh it from the foregoing. The fruit-flasks foon become lateral, and are very rarer than recurved, longer than in the preceding. Mouth of the *capsule* small, with a red outer fringe, whose teeth are lined, as it were, with the feventeen opposite teeth of the inner one.

**Secl. 2.** Fruit-flasks rising above the flom.

from one to three inches in height, clothed and matted together, below with copious brown fibres. Leaves bright green, slender, gradually tapering from their base; strongly curved towards the point; somewhat twisted and curved by drying. Fruit-flalks near the tops of the stems, about an inch long, bright orange-red, slightly wavy. Capsule globose, green and smooth while young; more elliptical when ripe, oblong, brown, with sixteen furrows. Lid rather convex, bifoled. Fringe short, red. Veil conical, curved, split half way up on one side.

4. B. crispa. Frizzled Bartramia. Swartz Mufc. Succ. 73. Turn. in Ann. of Bot. v. 1. 527. Winch Guide v. 2. 16. "Bridel. Mufc. v. 2. 3. t. 1. f. 4. Schwgr. Suppl. t. 59." Sm. Compend. n. 3. Engl. Bot. t. 1526. (B. poniiformis); Turn. in Ann. of Bot. v. 1. 527. Hook. and Tayl. n. 1, β.)—Fruit-flalks erect. Leaves brittle-shaped; dilated at the base; incurved and curled when dry. Lid slightly conical.—Native of mountainous situations in British India, and other parts of Europe. Larger in its stems and foliage than the preceding, the leaves of a lighter brighter green, longer, and more slender, except at the very base, and when dry to strongly curved, twifled, and involute, as to give the plant a very different aspect. The intelligent authors of the Mufcologic Britannicæ neverthelesd judge this to be but a variety of the poniiformis, and they unite it with Mr. Turner's supposed variety of that species, which he distinguishes from crispa, and which he has thought to be figured for crispa, in Engl. Bot. t. 1526. We acknowledge that the figure to be not a very happy one, except the lid, which seems to us always rather more conical than in poniiformis.

5. B. ithyphylla. Straight-leaved Bartramia. Bridel. Mufc. v. 4. 152. t. 1. f. 6. Sm. Compend. n. 4. Engl. Bot. t. 1710. Winch Guide v. 2. 17. Hook. and Tayl. n. 2. t. 23.—Fruit-flalks elongated, erect. Leaves capillary, nearly entire, single-ribbed half way up; dilated at the base; straight when dry. Found on dry banks, in the mountainous parts of Germany, Sweden, England, and Wales. The long, very slender, light-green leaves are only infrequently at the very point, and are remarkable for remaining always straight when dry, which Mr. Hooker has well attributed to the whole substance of the mid-rib being dilated and loft in the upper half of the leaf, to which it consequently gives firmness. The capsules are much curved; their flalks longer than in the foregoing. The dilated base of each leaf is singularly membranous and shining.

6. B. gracilis. Tall Slender Bartramia. Flóke in Schrad. Journ. v. 2. 171. Fl. Brit. n. 3. Engl. Bot. t. 1826. Hook. and Tayl. n. 3. (B. Oederi; Schwgr. Suppl. t. 59, as also, according to Mr. Hooker, B. grandiflora, t. 58. Brym Oederi; Retz. Prodr. 261. Fl. Dan. t. 478.)—Fruit-flalks from lateral branches, taller than the stems. Leaves lanceolate, ferrated towards the point; recurved and twifled when dry.—Native of the loftiell Scottish mountains, as well as of the north of Europe. The stems are two or three inches high. Leaves broader than in any of the three preceding species, somewhat revolute at the margin, especially when dry, in which state they become recurved, and not extended inwards. Their colour is a darkish greenish-grey. Capsule small, from short lateral shoots.

7. B. affine. Spreading-leaved Bartramia. Turn. in Ann. of Bot. v. 1. 528. t. 11. f. 2.—Fruit-flalks lateral, taller than the stems. Leaves awl-shaped, entire; single-ribbed at the base; spreading and straight when dry.—Received from Java by Mr. Dickson. Gathered by Cormerford, at the straits of Magellan. The tuf ted leafy stems, fluffy with rough fibres, and nearly branched, are two or three inches high. Leaves slender, yellowish-green, longer than any of the preceding, except perhaps B. Halstrana, and always quite straight, probably from the same cause as in ityphylla, the rib being foon lost in the substance of the leaf. Fruit-flalks straight, erect. Capsule curved, strongly furrowed. Lid convex, blunt.

8. B. Menziesii. Tall Forked Bartramia. Turn. ibid. 525. t. 11. f. 1.—Fruit-flalks slantly elevated above the tall forked stems. Leaves lanceolate, single-ribbed, taper-pointed, entire; close-preffed when dry. Capsule nearly globular, with shallow furrows.—Gathered on the north-west coast of America, by Mr. Menzies. The tall slender flanks, covered with close-preffed, tawny, shining leaves, half the length of the leaf, clearly distinguishes this species. The capsules are scarcely curved, even when fully ripe, and their surface is wrinkled as well as finely furrowed.

9. B. spheroarpa. Globose Bartramia. Hedw. Crypt. v. 3. 03. t. 38 A. Turn. as above, 525. (Mmum sphéricarpum; Swartz Prodr. 139, from the author.)—Fruit-flalks taller than the flender clustered branches. Leaves lanceolate-awl-shaped, close-preffed, finely ferrated.—Native of Jamaica. Swartz. The slender flanks are determinately branched, as in the following, to which this species is very nearly allied, though smaller, with longer branches. In the leaves, though ulufally narrower, we scarcely find a permanent difference. Hedwig's figure erroneously omits the furrows of the capsule.

10. B. marchica. Narrow-leaved Bog Bartramia. Web. and Mohr Ind. 5. Sm. Compend. n. 7. Engl. Bot. t. 2074. (B. fontana; Hook. and Tayl. n. 4. Turn. Mufc. Hib. 107. t. 10. f. 1. Mnium marchicum; Hedw. Crypt. v. 2. 108. t. 39.)—Fruit-flalks elongated, much taller than the clustered branches. Leaves lanceolate, finely ferrated at the point, close-preffed.—Native of wet situations in Germany, the Highlands of Scotland, and the mountains of Nepal, for Mr. Hooker affirms this his B. fontana, Tr. of Linn. Soc. v. 9. 317, is this plant. He is also of opinion that B. marchica is merely a leaved variety of the following.

11. B. fontana. Broad-leaved Fountain Bartramia. Fl. Brit. n. 4. Turn. Mufc. Hib. 107. Hook. and Tayl. n. 4. t. 23. (Mmum fontanum; Linn. Sp. Pl. 1574. Hedw. Sp. Mufc. 195. Bryum fontanum; Engl. Bot. t. 350. B. paluitre, fcapis teretibus ferialis, capsule magnis subrundobus; Dell. Mufc. 340. t. 44. f. 2.)—Fruit-flalks elongated, much taller than the clustered branches. Leaves ovate, finelv ferrated at the point, close-preffed.—Native of spongy bogs throughout Europe, and perhaps in other parts of the world. It is one of our handsomest and largest mosses, bearing capsules in spring and summer. The barren flowers form terminal leafy fars, on a separate plant from the capsules, whose flalks are two or three inches long, rising high above the tuft of leaby branches, which have overtopped the originally terminal situanon of their flowers. Capsule brown, with a minute sharp beak to the lid. Leaves usually direct, broadly ovate, entire at the edge, the point only being ferrated. They appear at first light very different from the lanceolate narrow shape of the lid, and still more from the curved taper-points of Mr. Hooker's B. falcuta, Tr. of Linn. Soc. v. 9. 317. t. 27. f. 4, which he is disposed to reduce to the fontana, having found the latter in Switzerland with leaves as decidedly curved. We cannot dispute his accuracy of observation and judgment in this point; nor are we much disposed to question his further opinion, that Hedwig's sphéricarpum, our n. 9, as well as
BAR

frobida Muldeoniegin, (of which we have specimens from its
founder,) and radicals of Schwartziren's Supplement, may
possibly be likewise varieties of B. fontana.

BARYTES, in Chemistry, one of the earthy substances
termed alkaline. We stated that this earth was considered by
Bergman, Lavoisier, and other eminent chemists, as a
refractory metallic oxdy; and this supposition has been
since confirmed by the experiments of Berzelius and Pontin,
who, led by sir H. Davy's decomposition of potash and
foda by galvanism, subjected this earth to the same agent.
Their experiments were attended with complete success,
and have been verified by sir H. Davy and other
chemists. To this metallic basis, Davy gave the name
baryum. More lately, Dr. Clarke of Cambridge thought
he had decomposed this earth by exposing it to an intense
heat, produced by the combustion of a stream of oxygen
and hydrogen gas, mixed together in the requisite
proportions to form water. To the metal thus obtained, he
proposed to give the name of pluxnum. Many chemists, how-
ever, think, that Dr. Clarke from some cause or other permitted himself to be deceived in these experiments, and that
instead of a metal he only obtained a flag with a pseudo-
metallic surface.

Baryum obtained by galvanic agency is a solid metal of
the colour of silver. It melts at a temperature below
redness, and is not volatilized by a heat capable of melting
plate-gla$s; but at that temperature it acts violently on the
gla$s, probably by decomposing the alkali of the gla$s,
and converting it into a protoxyd. When exposed to the
air, it rapidly tarnishes, absorbs oxygen, and is converted
into barytes. It sinks readily in water, and seems to be at
least four or five times heavier than that fluid. It decom-
poses water very rapidly. Hydrogen is emitted, and the
baryum is converted into barytes. Baryum seems to be
both ductile and malleable.

Baryum, according to the experiments of Gay Lussac
and Thenard, combines with two proportions of oxygen.
The protoxyd is the earth called barytes. No direct
experiments have been made to ascertain the proportion of
oxygen it contains; but this may be determined by other
means. Thus, sulphate of barytes is composed of

<p>| | | |</p>

and carbonate of barytes of

</tr>
<tr>
<td>Barytes</td>
<td>354-54</td>
<td></td>
</tr>
</tbody>
</table>

Hence it may be easily ascertained by calculation, that
the equivalent number for barytes is 97.5; oxygen being 16;
and if we consider this earth as a protoxyd, the number
for baryum will of course be 97.5 - 16 = 81.5. Hence
one hundred parts of barytes consist of

Gay Lussac and Thenard found, that when dry baryum,
from nitrate of barytes, or from the carbonate of barytes
decomposed by charcoal, was heated in oxygen gas, it
absoZbed that gas with great rapidity. The peroxyd
formed was grey. It gave out its excess of oxygen, when
put into water. When heated in hydrogen gas, the hydro-
gen was absorbed, and water was formed, which remained
united to the barytes.

The salts of barytes are described under SALTS. The
equivalent numbers of these, however, require a little cor-
rection; for which purpose, we refer our readers to the
article ATOMIC Theory, where the latest determinations
will be found.

The muriate of barytes (see SALTS) has been employed
as a medicine in febrifugal and cancerous cases. Al-
though it has been accounted highly poisonous, Dr.
Johnstone, in his "Effay on Poisons," says, that he
has seen a female take 30 drops of a saturated solution
of muriate of barytes repeatedly in the course of a day,
without even nausea: and he concludes, that it would
require at least two or three draughts to do mischief.
Barytes is capable of making a very tenacious cement,
but it has been yet much used in the arts, except by
limmers, as a most excellent water-colour. Mr. Hume,
says Mr. Parkes (Chem. Catech.), many years ago dis-
covered the method of making a colour from this earth.
It is the only white for water-painting that never changes.
It has another peculiar advantage, that it may be mixed
with any other colour without injury. It is sold under
the name of "Hume's permanent White." See WHITE.

BARYTES, Carbonate of. See CARBONATE OF
BARYTES.

BASALT, in Mineralogy and Geology, a compact dark-
coloured rock, clfaffed by geologists with trap-rocks. (See
TRAP.) It has received the name of whin-lone in the
north of England (see WHIN-STONE); and in Staffordshire,
Rowley-rag (see ROWLEY-RAG). In the arrangement
of rocks by the Wernerian geologists, bafalt is considered
as a compact green-lone, which latter rock is composed of
felspar and hornblende; but green-lone being more crys-
talline, the constituent parts are distinctly separated. Green-
lone and bafalt often pass into each other. (See GREEN-
STONE, Addenda.) Bafalt has generally been claffed with
simple minerals; and a short account of its charactens
and constituent parts are given under the article BASALT
(which see). More correct analyses of this rock have since
been made, in which foda is found to be a constituent part.
We greatly doubt the propriety of claffing bafalt with
simple minerals: for it has been ascertained, that most
basaltic rocks are composed of two or more minerals inti-
mately mixed, but requiring the aid of a lens to distinguish
them. Of these, the mineral called augit is the one which
prevails, or forms the dark colour: it is intermixed with
felspar and olivine. It is thus ascertained that bafalt resem-
bles in its constituent parts, as it does in other characters,
dark compaft lava. (See Volcanic Products.) Before the
observations of the French mineralogist Cordier, both
bafalt and compact dark lava were supposed to be composed
of hornblende and felspar.

Before the blow-pipe, bafalt melts easily, without addition,
into an opaque black-coloured glass. It melts at a com-
parative low degree of temperature from 350 to 450 of
Wedgewood. If it be cooled rapidly, the mass is vitrified;
if cooled slowly, it is hollow, and presents a tendency to a
columnar arrangement. Some interesting experiments of
this kind are described under the article ROWLEY-RAG
(which see).

The constituent parts of bafalt, as given by Klaproth and
Dr. Kennedy, are as follow:

Bafalt
BASALT.

Basalt exists abundantly in the northern parts of England and in Scotland. It occurs at the Clee Hills in Shropshire, and at Rowley in Staffordshire; but is not met with in the southern counties of England. Some rocks of the trap or basaltic formation occur in Gloucestershire and Somersetshire. Basalt forms the well-known columnar ranges at the Giant's Causeway in the county of Antrim, and at Staffa. See Giant's Causeway and Staffa.

The origin of basaltic rocks has excited much attention among geologists. Their similarity to volcanic rocks in composition and structure, the remarkable positions in which they occur, and the changes they frequently produce on the rocks in their vicinity, have led most intelligent and unprejudiced observers to the conclusion, that a great number, if not all, basaltic rocks have been formed by igneous fusion. The mineral veins filled with basalt, that intersect other rocks, frequently produce all the changes which a fluid mass of heated lava would have effected. (See Veins, Mineral, and Trap.) In the latter article, the arguments which have been offered against the igneous origin of basalt are also stated. For further remarks on the subject, see Systems of Geology. But the most striking phenomena, and which seem to decide the question, are presented in the districts called Velay and Viverais, in the south of France. These districts have all the appearance of having been once the seats of active volcanoes, the remains of which are distinctly visible: from some of these ancient volcanoes, the lava may be traced to the crater, and this lava is a compact columnar basalt. See Plate II. Mineralogy, Basalt.

The mountain of Aïfa, called La Coupe, or the Col d'Aïfa, of which a view is given, is situated near the village Engrand, in the Viverais. This village, according to St. Fond, is placed on a kind of platform of volcanic matter above the torrent of the Volant, which has here excavated a bed of great depth and width, bordered on the right and left by grand ranges of basaltic columns. In the midst of a prodigious rampart of these columns, at different levels, may be seen a current of lava descending from a neighbouring mountain, and joining the columns that border the river. Here we see, in the most unequivocal and convincing manner, that the lava under the form of hard and compact basalt, has flowed at several times from the mountain, and has formed the great cauliflower at different heights, to which the lava is still united and adhering. We may follow the current of basalt up the declivity of the mountain, which has a conical form and a great elevation, and is entirely volcanic from the base to the summit. According to St. Fond, it is the most remarkable and best charcterized crater in all the Viverais.

The bafe of the conical mountain La Coupe is covered by porous and cellular lava in detached irregular masses, heaped on each other, so as to leave no doubt that they have been ejected in a liquid state by one or more formidable eruptions, and have taken their forms as they fell at the foot of the cone.

On reaching the summit or edge of the crater we may see the whole mountain, which forms a regular cone resembaling that of Vefuvius. The edges of the crater are steep, and formed in the shape of a tunnel; the greatest diameter being from 140 to 150 toises, and the depth about 600 feet. The lavas are coloured, and converted into a kind of pizzolani, and mixed with great masses of black and sharp loose, which makes the descent difficult. At the bottom of this inverted cone is a magnificent plantation of chefnut-trees, which have flourished astonishingly in this ancient mouth of a volcano, having no other foil than the dry and friable pizzolani. It may be observed, that the crater of Vefuvius was lined with lofty trees at the period of its eruption in 1631, having been in a state of repose for nearly four hundred years.

At the bottom of the crater in La Coupe, we may observe a breach or opening on the side facing the houses of the Colet d'Aïfa; there is a general inclination to this opening, which has served to give a passage to the lava. When we are arrived at the opening, we may observe a stream of lava coming from the interior, and taking its course down the mountain, it descends in a winding direction amidst the porous lavas. This current is a true black basalt, compact and similar to that of the columns; in certain parts, its surface appears blurred, and in other places is become porous. Following the current of lava, after it has crossed the path, which is at the foot of the mountain, we may trace its course to the bed of a torrent not far from the high road. There may be seen, says St. Fond, a spectacle most gratifying to the geologist; for the lava, whilst still on the defensive, and before it had reached the level ground, has affected a prismatiform; and the lava at the bottom has formed a beautiful colonnade.

We cannot doubt, says St. Fond, after viewing this mountain, that the lava which flows from volcanic craters is not absolutely the same as basalt. The name of La Coupe is evidently derived from the crater, the Latin name for a cup.

There is another conical mountain in the Viverais with a distinct crater, called La Coupe de Jaujac. The general resemblance of the latter is so similar to that of La Colet d'Aïfa, that it may well be conceived from the view given of the latter. (See Plate II. Mineralogy.) It is rather less lofty, but the crater is nearly twice as large. The river Vignon flows at the foot of Jaujac. On its banks are immense ranges of basaltic columns, the most elevated of any in the Viverais. They inclose the borders of the river on each side for more than a league.

Some of the prisms rise in one shaft to the height of fifty feet; in other parts, the articulated columns form a kind of regular cauliflower. In some places the columns are bent, and above we see immense ramparts of basalt, of more than 140 feet in height, in several ranges, spreading out like a fan, and diverging in every direction. On the left, the current of basalt covers several little hills of granite, and is moulded upon them. In some parts, the compact lava forms one solid mass; in other places, it is arranged in great beds. Nothing can be more grand and varied, says St. Fond, than the course of the river Vignon to Ardoche, where the great current of lava joins the streams that have flowed from the volcanoes of Theurys and Neyrac. Faujas St. Fond fur les Volcans eteints du Viverais et du Velay.

Plate II. Mineralogy, Basalt, which is taken for this work, will convey at once a satisfactory proof of the igneous origin of the basaltic columns in the Viverais; but one engraver who

3 B 2

has omitted to represent the division of the upper part of the bed into columns. The ends of the columns may be distinctly seen before the basalt reaches the river.

**BASALTIC Hornblende.** See Mineralogy, Addenda.

**BASMAN,** in Geography, an island of the Persian gulf, situated 11 1/2 leagues N.N.W. from Shorge, in N. lat. 25° 54'. It is an uninhabited island, about five miles long, and remarkable for a high round hill in its centre.

**BASSORA,** col. 1, l. 15 from the bottom, after 1668, add—subject to various revolutions. L. 11, after Porte, infer—The mufcleman, or governor, has never since the year 1787, when it was recovered from the Monte-fidge Arabs, by Solyma Pacha, been sent from Bagdad, and is generally an officer of high rank. Full liberty is allowed, &c. Col. 2, l. 12, after 50,000, add—or 60,000, consisting of perfons of almost every nation in the East. L. 29, N. lat. 31° 30'. E. long. 48° 39'.

**BAT-Horfes,** in Artillery, are baggage-horfe belonging to the officers when on actual duty; and bat-men were originally fervants hired in time of war to take care of the horfs belonging to the train of artillery, baggage, &c., and who, during their service, generally wear the king’s livery. Thofe who are excufed regimental duty, for the specific purpofe of attending to the horfes belonging to their officers, are called bat-men. Horfes and men of the preceding defcription are sometimes called bow-horfs and bow-men.

**BATARREA,** in Botany, fo named by Pufh, in ho-nour of his learned predeceffor in the study of the Fungus tribe, Antonio Batarrea, prefeffor of philofophy in the Lyceum at Rimini, author of Hifloria Fungorum Agri Ariminensis, published at the neighbouring city of Faenza, in 1759, in 4to., with 40 plates. A preceding edition is indicated in the title-page, which Haller dates 1755. The author was a disciple of Janus Plancus, or Giovanni Bianchi, the conchoflologist, and died in 1789, according to Dryander in Bibl. Bankf. He was, however, an original obferver, and delineated the figures himfelf.—Perf. Syn. Fung. 129.—Clafs and order, Cryptogamia Fungi. Nat. Ord. Fungi.

**Eff. Ch.** Stalk bifling from a wrapper, and elevating the bell-shaped, downy, powdery head, capped with a portion thereof.

1. **B. phaloides.** Tall Brown Batarrea. Perf. n. 1, t. 3, f. 1. (Lycoperdon phaloides ; Dickf. Crypt. f. 1c. t. 24. Woodward in Phil. Trans. v. 74. 423. t. 16. Sm. Spicil. 11, t. 12. Soverb. Fung. t. 390.)—Found on sandy banks about Norwich, by Mr. William Humphrey, and about Bungay in Suffolk, by T. J. Woodward, efq. We have reason to think it may be met with in other parts of England, as Mr. Hudson, author of the Fl. Angl., told the writer of the preffent article, he had seen this fingular production on heaths in Kent, but pafted it by as a biflated or abortive Agarius procerus. We have not heard of this very curious fungus in any other part of the world. The volva, or wrapper, is about the fhape and size of a hen’s egg, originally of three fhightly corrugated layers, hollow internally, where a fpongy flalk is formed, which rides very suddenly (in a few hours) to its full height of about twelve inches. This flalk is hollow, foon becoming dry, and externally filamentous, and carries up, on its fummit, full half the innermost layer of the volva, which is white and smooth within, covered externally with copious brown powdery feeds, intermixed with fibres, as in a Lycoperdon. A smaller portion of the two outer layers, irregularly torn away, forms a double cap to this powdery surface.

**BATAVIA,** in Geography, a poft-townfhip of New York, the capital of Genesee county, 256 miles from Albany, on the great road to Buffalo; about 50 miles long from N. to S., and from 24 to 26 miles wide; bounded N. by lake Ontario, E. by Murray and Caledonia, S. by Warfaw, Attica, and Sheldon, and W. by Niagara county. The whole population of this town, in 1816, was 3,645, with 104 fettlemental electors, and 484,216 dollars of taxable property.

**BATH.** Add—The city of Bath, by the return of 1811, contained 3933 inhabifcnts, and 31,496 perfons; viz. 12,373 males, and 19,123 females. **Batty,** a county of Virginia, &c. add—The total number of inhabitants, in 1810, was 4837, including 882 slaves. **Bath,** a townfhip, &c. l. 2, for 949 r. 2491. **Bath,** in Grafton county, &c. l. 2, for 493 r. 1316. **Bath,** a poft-townfhip, the capital of Steuben county, 245 miles W. of Albany. The whole population, in 1810, was 1096, with 97 electors.

**Batts,** a county of the district of Ohio, in the county of Greene, having 913 inhabitants.

**BATSCHIA,** in Botany, was fo named by prefeffor Gmelin, the compiler of the 13th edition of the whole Syifena Nature of Linnaeus, in honour of prefeffor Batsch of Jena, known particularly by his Elenchus Fungorum, published at Halle in 1783 and 1784, in 4to., with coloured plates, and his Analytic Florum, a work of a fimilar defcription, which appeared in 1790. Gmelin however adopted this genus, like many others, entirely from the Flora Caro- biniana of Mr. Thomas Walter, who had modestly left fuch genera without names, becaufe, though he fuppofed them to be new, he had not the advantage of books, or other helps, to confirm his opinion. In the preffent instance we apprehend their Anonymus, n. 78. Fl. Carol. 91, cannot be supported, but we fhall give its character and fynonym.—Gmel. Linn. Syift. Nat. v. 2. 315. Michaux Boreal.-Amer. v. 1. 129. Pursh 132.—Clafs and order, Pentan- dria Monogynia. Nat. Ord. Aperifolifie, Linn. Borra- giuce, Juff.

**Gen. Ch.** Col. Perranth in five deep, linear, acute, erect segments. Cor. of one petal, falver-shaped; tube straight, longer than the calyx, surrounded at the base, internally, with a ring of hairs; throat pefils; limb orbicular, in five deep rounded segments. Stem. Filaments five, very fhort, inserted into the tube; anthers erect, ovate, concealed within the tube. Pistf. German superior, round-ih, with four prominencef; style capillary, the length of the flaments; stigma minute, flightly clenched. Peric. none. Seeds four, ovate, hard, polifhed.

**Eff. Ch.** Corolla falver-shaped; throat naked; tube with a hairy internal ring at the base; segments of the limb rounded. Calyx in five deep segments. Obs. It appears to us that this genus cannot be kept separate from Lathifpermum. (See that article.) The only mark of diftinction is the hairy ring in the bottom of the tube, which furely is not fufficient. The form of the corolla is as much funnel-shaped as in that genus, and the feeds are acknowledged to be precisely the fame. Michaux alks, (perhaps on account of the yellow flowers,) "whether L. orientale of Linnaeus be not a Basfchia?" We find no traces there of the hairy ring, nor was any fuch character detected by Mr. Bauer, when he made the drawing for Dr. Sibthorp’s Fl. Græca, t. 160. This circumstance does not preclude the fumption of a generic diftinction here indicated by colour. The following are the only reputed fpecies of Basfchia.

1. **B. Gmelini.** Hairy Pucceoon. Michaux n. 1. Pursh n. 1. (Anonymus carolinencis; Walt. Carol. 91.)—Hairy. **Floral**
BAU

2. B. canescens. True Pucoon. Mich. n. 2. t. 14. Purph n. 2. (Anchusa hirta; Muhlenb. Cat. 19. A. virginiana; Linn. Sp. Pl. 191. A. florusbus tparis, caule glabro; Gron. Virg. ed. 2. 24. Lithophorum virginianum, flore luteo duplex; Morif. feci. t. 28. t. 4.)—Downy and hoary. Leaves all oblong. Calyx very short. Segments of the corolla entire.—On dry sunny hills on a sandy soil, in Virginia, Tennessee, &c. perennial, flowering in June and July. Flowers of a deep golden-yellow. The root is covered with a red subsulance, which is the true Pucoon of the Indians, and paints a beautiful red. Purph. With this colour, it seems, the native Americans painted their bodies. The whole herb is clothed with soft hairs, nor is the stem, as Linnaeus says, smooth. He had no specimen of this plant, when he wrote either edition of Sp. Pl., but afterwards confounded herewith a totally different Sibfrican plant, which lies under this name in his herbarium, but without the requisite marks of authenticity. Morison's figure represents a double-flowered variety, which is very unusual in this natural order.

We should presume that all these species belong rather to Lithophorum than to Anchusa, but we have only seen the second, communicated in a dried state, from Pennsylvania, by the late Rev. Dr. Muhlenberg.

BATTAM, the Batta or Strabo, in Geography, a town of Armenia, in the paphalic of Erzeroom, on the Euxine. This is a commercial place; and between it and Akikla are the towns of Ichofteshceoe, Gartzieme, Schwaghaewal, and Kaettaeae.

BAU

BATTING. See Cotton, and Manufacture of Cotton.

BATTLE, 1. ult. r. and in 1811 had 361 houses, and 2531 persons; 1232 being males, and 1299 females. Battle, Order of. Col. 6. 1. 90. to 1. 41. dele.

BATZ. Add.—The florin at Augsburg is divided into 15 batzes, or batzen, or 20 kaylgrochen. A thaler, or rix-dollar, is worth 1½ florin. 22 ½ batzes, or 90 creatorius. At Baf, the thaler, or rix-dollar, is worth 3 lives, 27 good batzes, or 30 Swiss batzes; the florin, 15 good batzes, or 16½ Swiss batzes; the livre, 9 good batzes, or 10 Swiss ditto. A good batze is 4 creatorius; a Swiss batze, 2 sous, or 3½ creatorius. At Bern, accounts are kept in lives of 20 sous; the douze of 12 deniers; also in lives, or francs, of 10 batzes, or 40 creatorius; and in crowns of 25 batzes, or 100 creatorius. A rix-dollar, or ecu blanc, is worth 30 batzes; a crown, 25 batzes; a florin, 15 batzes; a livre, or franc, 10 batzes; a pfund, 7½ batzes, or 15 sous, or 2 batzes, 2 sous, or 4 creatorius.

BAUER, in Botany, received its name, not from Sir Joseph Banks, as Mr. Andrews, by mistake, has recorded, but from the author of the present article; in due commemoration of those excellent botanical artists, and practical observers, Mr. Francis Bauer, so long employed as a draughtsman at Kew, and his brother Mr. Ferdinand Bauer, who after being engaged in the same occupation by Dr. Sibthorp in Greece, accompanied Mr. Brown to New Holland, and is now returned to Germany, having left behind him in England unrivalled monuments of his abilities.—Andr. Repof. t. 1. 198. Ait. Hort. Kew. v. 3. 317. Salib. in Ann. of Bot. v. t. 514. t. 10.—Clafs and order, Polyandria Digniana. Nat. Ord. Saxifraga Juf. Salib. Cunuiones; Brown, Bot. of Terra Auff. 16.

Gen. Ch. Cal. Periander inferior, of one leaf, in eight deep, lanceolate, reflexed, permanent segments. Cor. Petals eight, obovate, equal, concave, alternate with the calyx, and nearly twice as long. Stam. Filaments numerous, thread-shaped, inserted into the receptacle, half as long as the petals; anthers erect, obovate, of two cells, bifurcating at the summit. Pft. German superior, somewhat pyramidal, obtuse; styles two, thread-shaped, longer than the filaments, recurved; stigma simple, obtuse. Peric. Capsule roundish, umbilicate, somewhat compressed, with two short, divericated, pointed lobes, of two cells and two valves, bifurcating at the top, between the points; partition contrary to the valves. Seeds numerous, oval, corrugated, inserted into the central column.

Eff. Ch. Calyx inferior, in eight permanent segments. Petals eight. Capsule inflated, of two cells, with many seeds.

1. B. rubiafolia. Madder-leaved Bauera. Salib. as above. Ait. n. 1. (B. rubioides; Andr. Repof. t. 198. Curt. Mag. t. 715. Ven. Malmafn. t. 96.)—Native of New South Wales. First discovered in that country by Sir Joseph Banks. We received specimens and feeds from Dr. White, among the first communications from the settlement there, and this beautiful shrub was raised by the late anthropologists of Rockingham, at Hillingdon, in 1793. It requires the shelter of a green-house, or conservatory, and flowers during most part of the summer and autumn. The stem is five or six feet high, much branched, woody, but slender and weak; the branches opposite, round, leafy, somewhat hairy. Leaves opposite, or sometimes three together, ternate, nearly pellate, evergreen, widely spreading; leaves three-quarters of an inch long, lanceolate, diastantly serrated, their ribs a little hairy beneath; their upper surface convex, of a deep shining green; under paler. Flowers axillarv, small; hairy, shining, longer than the leaves, a little drooping, scarcely an inch broad, of a beautiful rich rofe-colour, with yellow anthers, inodorous. The branches of the flower vary occasionally in number, from seven to nine or ten. The branches, like the leaves, are sometimes three together, and when young, have, like them, a reddish tinge, which the permanent calyx, and old leaves, likewise assume. We do not very clearly perceive the resemblance to Madder in the leaves, and should have been glad if the specific name originally proposed, formos, had been retained for a plant which so well deserves that appellation.

Another species is mentioned, by the name of B. hamilla, in Ait. Epit. 364, as introduced at Kew, from New Holland in 1805, and flowering in June and July. But not a word is said respecting the specific differences between the two.

BAYAZID, in Geography, one of the Turkish pachalics of Armenia: the city of this name lies at the distance of two days' journey from Erwan, nine from Erzeroom, and four from Khoi, and occupies the declivity of a mountain, the summit of which is strongly fortified. The city is surrounded with walls and ramparts: it has two churches and three mosques; and the monastery of Kuru Killefe is famous for the beauty of its architecture, its antiquity, and its grandeur. The inhabitants are reported to amount to about
about 30,000, and are esteemed the most learned and war-like people in Armenia. The climate is mild, and the city, with the extensive territory attached to it, is under the government of a pasha of two tails, archbishop of Merdin.

McKinne's Persea.

BAYLA, the capital of Lus, a district of the Persian empire, in the province of Meckran, and country of the ancient Orizes, is built on the N.E. bank of the river Pooralie, and contains 1500 houses, and 6000 inhabitants, of whom 400 are Hindus. The present chief can bring into the field 4000 irregular troops, and enjoys a revenue of 50,000 rupees per annum.

BAYOU, a term originally Spanish, signifies the diminutive of bay; but in Louisiana where it frequently occurs, it is synonymous with the word creek, and consequently becomes the diminutive of river.

BEAUNOE. See Anas and Duck.

BEATTIE, James, &c. l. 2, born Nov. 5; l. 12, latter, by the liberality of a mother, (his father having died when he was seven years of age,) by, &c. l. 18, dele at Alloa; and l. 19, dele affiant to the; l. 24, for 1760 r. 1761; l. 41, infant—which was written about the year 1764, though not published till some time after. Col. 2, l. 35, dele following; l. 62, for not long afterwards r. in 1770; l. 65, for 1777 r. 1776, (in consequence of which he obtained the pension above-mentioned.) Col. 3, l. 23, infant.—In 1790 he published a summary of his lectures under the title of "Elements of Moral Science;" the first volume of which contains a very accurate enumeration and arrangement of the perceptive faculties and active powers of man. He has also given a curiously view of what is called natural theology. The second volume, published in 1793, comprehends much miscellaneous information on ethics, economics, politics, and logic, including rhetoric. Towards the latter part of his life, his time, &c.

BEAUAIGRE, l. 7, dele The part of the Rhine is well

BEAVER, in Geography, a county of Pennsylvania, containing 12,168 inhabitants, in which are several townships of the same name; such as North Beaver with 932, Big Beaver with 702, Little Beaver with 1379, Beaver Borough with 426, and South Beaver with 1351 inhabitants.—Allo, a township of Pennsylvania, in Northumberland county, having 502 inhabitants.—Allo, a township of Crawford county, with 236 inhabitants.—Allo, a township of Columbiana county, in the district of Ohio, having 433 inhabitants.—Allo, a township of the same district, in Greene county, having 793 inhabitants.

BEAVER CREEK, a township of Pennsylvania, in Beaver county, with 774 inhabitants.

BEAVER FALL, a township of the district of Maine, in the county of Kennebeck, containing 354 inhabitants.

BEAUFORT, in South Carolina, l. 4. r. 25,887, including 36,914 slaves.

BEAUFORT, (col. 2, after l. 14,) a county of North Carolina, containing 7264 inhabitants, of whom 2568, are slaves.

BEAUFORTIA, in Botany, a truly noble genus, con-fecrated, by Mr. Brown, to the memory of Mary duchess of Beaufort, who died January 7th, 1711, in the 85th year of her age. Her grace cultivated a number of rare plants in the cloues and green-houses at Badminton, Gloucestershire, during the life-time of her husband, Henry, first duke of Beaufort, whose death happened in 1699. The plants introduced by her always therefore bear this date in Mr. Aiton's Hortus Kewensis. Numerous specimens from the Badminton gardens were communicated to Sir Hans Sloane, and if we are not mistaken, a splendid herbarium in the British Museum, bound in several large folio volumes, bears the title of "The Duchess of Beaufort's Plants."—Brown in Ait. Hort. Kew. v. 4. 418. —Clas and order, Polyadelphica leonandra. Nat. Ord. Helseridseae. Linn. Myrs, Jull.

Gen. Ch. Cal. Perianth half superior, of one leaf, tur-binate; limb in five deep, awl-shaped, deciduous segments. Cor. Petals five, elliptical, ciliate, inserted into the rim of the calyx, between its segments, and of equal length. Stem. Filaments very numerous, in five sets, inserted into the calyx, opposite to the petals, the claw of each set linear, hairy at the base internally, much longer than the petals, divided at the top into seven, eight, or more, capillary spreading seg-ments about a quarter the length of the claw; anthers terminal, inserted by the base, of two divergated, conical, deciduous, single-celled lobes. Pet. Germen in the bottom of the calyx, small, roundish, hairy at the summit; style thread-shaped, shorter than the stamens, various bent upwards and downwards; stigma acute. Peric. Capsule coated with the base of the calyx, and firmly united to the branch, roundish, of three cells. Seeds solitary.

Eff. Ch. Calyx in five segments. Petals five. Staminens numerous, very long, in five sets, opposite to the petals; anthers of two deciduous lobes. Capsule clothed with the base of the calyx, three-celled, permanent. Seeds solitary.

Obf. Many of the flowers are said to want the fyle. We are not clear, from the account of the author of this genus, whether more than one seed is perfect in each fruct. The capsules remain in mages surrounding the branches, long after the seeds are gone, perhaps for several years, being firmly united to the bark or wood; a character common to many of this natural order in New Holland, as Melaleuca, (see that article,) and others. The very peculiar ancors seem to afford the most essential character of Beaufortia, and distinguih it from its near ally Calothamnus. See that article hereafter.

1. B. decussata. Splendid Beaufortia. Br. in Ait. n. 1. Sims in Curt. Mag. t. 1733. Leaves opposite, ovate, many-ribbed, croffing each other in pairs. Claws of the stamens very long, their filaments radiating. —Gathered by Mr. Brown, on the south-west coast of New Holland, and sent to Kew by Mr. Good, in 1803. A green-house shrub, flowering in the spring, and increased by cuttings. The branches are angular. Leaves fettile, crowded, half or three-quarters of an inch long, recurved, smooth, rigid, entire, full of pellucid dots; paller beneath. Flowers in dense tufts, surrounding the branches here and there, most conspicuous for their copious spreading tufts of filaments, an inch and a quarter or more in length, all over of a rich scarlet, the petals, as well as calyx, being green.

2. B. parva. Alternate-leaved Beaufortia. Br. in Ait. n. 2. Leaves scattered, elliptical, many-ribbed.—Gathered in the same country, by Mr. Brown, from whence it was likewise sent to Kew, by Mr. Good, in 1803, but does not appear to have flowered in 1812, when the fourth volume of Hort. Kew. was printed.

We premise Mr. Brown's Prodromus, when completed, will make us acquainted with more species of this genus.

BEAUMARIS, col. 2, l. 9, for 1275 r. 1295. Col. 3, l. 1, for 37 r. 57; l. 37; r. Lavan. —Add—The borough of Beaumaris contained in 1811, 295 houses, and 1810 persons; 809 being males, and 1001 females.

BECKET, in Geography, l. 2, for 751 r. 1028.

BEDDOES, Thomas, M.D. in Biography, a distinguished physician and philosopher, was the son of an opulent tanner at Shiffnall in Shropshire, and born in 1760. Indicating at an early age peculiar talents, and disposed to cultivate them by diligent
diligent application, he was defined for a learned profession. With this view, after the requisite previous education, he was entered, in the year 1775, at Pembroke college, Oxford, and in the progress of his studies acquired the reputation of a classical scholar; connecting with his other pursuits the study of the French, Italian, and German languages, as well as of pneumatics, chemistry, mineralogy, and botany. After having taken his first degree of arts, he repaired to London, where he prosecuted the study of anatomy and physiology, and published translations of Spallanzani's Dif- terations, of Bergman's Essay on Elective Attractions, and of Scheele's Chemical Essays. At Edinburgh, where at this time he had commenced his studies, he obtained high reputation among his fellow-students. In 1786 he graduated M.D. at Oxford, and in the following year visited the continent. Upon his return, he was appointed to occupy the chemical chair at Oxford. At this period he formed an acquaintance with Dr. Darwin, which gradually ripened into the intimacy and confidence of friendship. In 1790 he pre- sented to the public an analytical account of the writings of Mayow, well known for his early discoveries in the department of pneumatics. (See his article in the Cyclo- peda.) And he also communicated several papers to the Royal Society. As a chemical professor at Oxford, he was a popular lecturer; and he was much respected in the university on account of the rank he occupied in general literature and science: but interesting himself in the party politics of that period, and avowing his opposition to systems which then prevailed with regard both to church and state, it found him expedient to resign his professorship in 1792. He was adverse, however, to that detestable spirit which blinded itself in France with their struggles for liberty. Among the publications which flowed from the press about this time, our line will only allow the mention of his "Observa- tions on the Nature of Demonstrative Evidence, with Re- flections on Language," intended to facilitate the study of geometry to youthful minds, by showing, in opposition to the doctrine of the author of Hermes, that geometry is founded in experiment, and that its elements may be rendered palpable to the senses. The most popular of his publications was a small work, which appeared under the title of the "History of Isaac Jenkins," a fictitious narrative, exhibiting the character of a labourer immersed in the evils of habitual drunkenness, but reformed to sobriety and in- dustry; of which his biographer (ubi infra) says, that if the author had left no other monument of his ingenuity and benevolence, he would not have lived in vain. Without adverting to his other writings, we shall proceed to mention his pneumatic establishment in the vicinity of the Bristol hot-wells, undertaken and for some time liberally supported for the purpose of curing diseases by the judicious application of different kinds of fœtidous air. For the convenience of superintending this institution he resided at Clifton, and in 1794 formed a matrimonial connection with a lady of the judiciously celebrated Edgeworth family. From this time his medical publications became numerous, and as a physician his advice was in high estimation; and he was con- furred by persons in distant parts, who are said to have derived great benefit from his preceptions. Although his pneumatic institution failed with respect to the degree of success which he might augur, and proved of temporary duration, it served to bring into notice the present Sir Hum- phy Davy, one of the most eminent philosophers of our time, whose talents, refricted in their exercise to a remote town in Cornwall, caused him to be engaged as its manager. In the year 1806, Dr. Beddoes was attacked with some affection of the liver, which, after subsiding for a time, returned with a disaise in the chait in 1808, and rapidly in- creasing terminated in his death on the 24th of December, before he had completed his 40th year. Although his manner, says his biographer, was cold and repulsive, he possessed kind and tender feelings; and in the relations of domestic and private life his conduct was unexceptional. Stock's Memoirs of the Life of Thomas Beddoes, M.D.

**BEDFORD**, col. 3, l. 4, r. In 1811, the borough con- tained 940 houfes, and 4,605 perfonis; 2,057 being males, and 2,548 females.

**BEDFORD**, a township of America, &c. l. 2, for 898 r. 1296.

**BEDFORD**, in Middlesex county, &c. l. 2, for 523 r. 592.

**BEDFORD**, New, l. 2, for 331 r. 561.

**BEDFORD**, in New York, l. 2, for 2,470 r. 2374, with 241 electors, in 1810. Add.—Near the centre of this town is the village of Bedford, where the courts for the county are held one half of the time, and the other half at White Plains. Here are, a court-houfe and prifon, a Preb- leyterian church, an academy, and a small number of houfes.

**BEDFORD**, a county of Pennsylvania, l. 4, for 131,244, including 46 flaves, r. 15,746; fubjoin after 1795: it con- tains 547 inhabitants.

**BEDFORD**, a township in the fame county, includes 1352 inhabitants.

**BEDFORD**, a county of Virginia, &c. l. 5 and 6, for 10,531 r. 16,148, and for 2754 r. 6147.

**BEDFORD**, a county of West Tenefsee, having 8242 in- habitants, including 1156 flaves.

**BEDFORDSHIRE**, col. 2, l. 8 and 9. r. The county, in 1811, contained 13,286 houfes, and 70,213 perfonis; 33,171 being males, and 37,042 females. 9431 families em- ployed in agriculture, and 4155 in trade and manufacture.

**BEDLIS, or Bedlis**, a large town, situated at the opening of the Bowntet of the paffes in the road from Di- beker to Van and Tahe. The river of Bedlis (the Cen- trites of Xenophon) is conducted by Hajy Kalifa through the plain to the southward of Sahert, Sard or Sared (the ancient Tigrancocerta). Betlis is one of the most ancient cities of that part of the kingdom called Kurdtiant; the caflle is on the top of a high mountain, which bounds the plain to the west: the inhabitants of the town and neigh- bouring villages amount to about 26,000 Kurds, Turks, Armenians, and Syrians. The Armenians, who enjoy a considerable portion of liberty, have four churches and four monafteries. The lands around Betlis are highly cultivated, and produce grain of several kinds, cotton, hemp, rice, olives, honey, truffles, and mushrooms. The neighbour- hood abounds with game, and the mountains are infcted by lions, wolves, and bears. In the vicinity are quarries of red and white marble. See Betlis.

**BEDMINSTER**, a township of Bucks county, in Pennfylvania, having 1199 inhabitants.

**BEDRI, a town of the Persian empire, in the pahalic of Bagdad, 13 leagues from Mendeli, and four from the foot of the mountains; is the frontier town, in this quarter, of the Turkift empire. It is surrounded with a number of fine gardens; but its districts are damp and marshy, inter- spersed with pools of water, the receptacles of the torrents, which, in the spring, are continually rushing from the mountains.

**BEER**, col. 2, l. 4, from the bottom, add.—For the excife duty on beer, see Ale.

**BEERING'S STRAITS**, l. 7, after Cook, infert.—He afterwards ascertained, that Cape Prince of Wales was the western extremity of the whole continent of America; and another cape was observed to the northward of this, lying in

fers, Jaff.

Gen. Ch. corrected by Mr. Brown. Common Calyx of one leaf, clothed with many lanceolate, imbricated leaves, with spiny teeth, and spreading points; the lower ones shorted. Cor. compound, radiant. Florets of the disk numerous, perfect, tubular, funnel-shaped, deeply five-cleft, glandular below; of the radius flower, ligulate, lanceolate, four-toothed; glandular below, imperfect. Stam. in the florets of the disk, Filaments five, capillary, very short; anthers forming a tube with five teeth: in thoe of the radius the anthers are short and incomplete. Pfl. in the florets of the disk, German turbinate, short, hairy; style thread-shaped, longer than the filaments; stigmas two, revolute: in thoe of the radius, German small, with hardly any style, and no stigmas. Peric.

one, except the permanent calyx. Seeds of the disk foli-

turbinate, hairy, crowned with from ten to fifteen

chaly, lanceolate, finely serrated, or fringed, scales: of the radius none. Recep. flat, cellular, the cells membranous, jagged and toothed.

The species of this genus, twenty-two in Wildenow, are confined to the Cape of Good Hope and its neighbourhood. Four of them occur under this name in Hort. Kew. as green-house plants, flowering in summer; three others com-

pose Mr. Brown's genus CULLUMIA, to be described hereafter. They are generally perennial, often shrubby. They

embrace Thunberg's whole genus of ROHRIA, (see another
genus of that name in its proper place,) and several of them have been referred by LINNAEUS to Gorteria, Atraphylla, or even Xeranthemum. None has yet appeared in any of our English periodical works. We select a few examples.

B. incana. Hoary Shrubby Berkheya. Willd. n. 1. Ait. n. 3. (B. cristata; Ehrh. Beitr. v. 3. 138. ("Roh-

Lc. Rar. t. 591.) G. fruticoso; Linn. Sp. Pl. 1284. Atracy-

t. 7.)—Leaves alternate, ovate, spinescent-toothed; hoary beneath, like the stem. Calyx-scales with spiny teeth; hoary underneath. Native of the interior regions of the Cape of Good Hope, in dry situations. The stem is various in height, with slender branches. Leaves recurved, three-

ribbed, an inch and a half long, coarsely toothed; tapering at the base. Flowers terminal, solitary, near three inches in diameter, deep yellow.

B. obovata. Smooth Shrubby Berkheya. Willd. n. 2. Ait. n. 2. (Gorteria spinosa; Linn. Suppl. 381. "Ba-

teria aculeata; Houtt. Nat. Hift. v. 6. 158. t. 34. f. 2." Ait.)—Leaves alternate, wedge-shaped-lanceolate, spinescent-

toothed, smooth on both sides. Calyx-scales with spiny teeth. —Sent from the Cape to Kew Garden, by Mr. Maffon, in 1794. Akin to the last, but with narrower leaves, and the whole plant is smooth.

nous-toothed; downy beneath. Calyx-scales with spiny teeth. —Native of hills about Riet-valley and Buffeljags

river, at the Cape. The stem is shrubby, with downy branches. Leaves above an inch long. Flowers terminal, solitary, large, of a full golden yellow, with a downy calyx.

B. cynaroides. Artichoke Berkheya. Willd. n. 19. Ait. n. 1. (Rohria cynaroides; Thunb. Prodr. 140. Gorteria herbacea; Linn. Suppl. 381.)—Stem-leaves alternate, clasping, fringed with prickles: radical ones elongated, entire, unarm: downy beneath. Calyx-scales ovate, straight, spiny, nearly entire. —Sent to Kew, from the Cape, in 1789, by Mr. Maffon. The stems are herbaceous, a foot or more in height, angular, nearly smooth. Leaves rigid, or somewhat coriaceous; the radical ones three or four inches long, tapering at the base. Calyx ovate, smooth, strongly armed; two or three of the lower scales only being fringed, like the adjoining bractes.

B. serca. Drooping Berkheya. Br. in Ait. n. 4. (Gort-

eria serca; Linn. Suppl. 382. Willd. Sp. Pl. v. 3. 2268.)—Leaves alternate, lanceolate, clasping, spiny-toothed, fringed, smooth on both sides. Flowers drooping. Seed-

crown bristly, fringed. —Sent from the Cape, in 1774, by Mr. Maffon. Biennial, flowering from May to July. Leaves slightly cottony when young only. Calyx spinous.

BERKLEY, in Virginia, l. 5, r. 11,479, of whom 1257

are flaves.

BERKLEY, in Massachusetts, r. 1014.

BERKLEY, col. 3, l. 16, for township r. parish; for 99 r. 124; and for 658 r. 616, 266 being males, and 320 females. L. 18, inef after act, in 1811; for 3450 r. 3858; for 9,148 r. 10,144; for 10,074 r. 11,124. Add—1711 families employed in agriculture, and 2215 in trade and manufactures; and for 7584 in trade and manufactures.

BERKSHIRE, a township of Delaware county, in the dis-

trict of Ohio, containing 284 inhabitants.

BERLIN, in Vermont, for 134 r. 1657.—In Con-

necticut, add—the number of inhabitants, in 1810, 123;

2788.—In Worcester county, for 512 r. 591.—In So-

merfield county, infant—the number of inhabitants, in 1810, was 330.

BERNACCHI, l. 13, r. when he was paif his me-

ridian.

BERNARD, Sr., a parish of the territory of Orleans, in the county of Orleans, containing 1026 inhabitants, of whom 382 are flaves.

BERNARDSTOWN, l. 2, r. 1879; l. 4, r. 811.

BERNE, a township of the district of Ohio, in the county of Fairfield, having 976 inhabitants.

BERNARDHARD, in Botany, so named by professor

Wildenow, in honour of Dr. John James Bernardi, of Erfurt, a learned writer on Ferns, and in other respects an excellent cryptogamic botanist.—Willd. in Act. Acad. Erford. for 1802. 11. Sp. Pl. v. 5. 56. Pflanze 655. (See Pflanze, under which name we have treated of this genus in due order.) We know not whether any other genus be dedicated to Dr. Bernardi, but it is to be pre-

sumed that this act of justice will not long be delayed.

BERTIE, l. 5, r. 11,218; l. 6, r. 6559.

BERVIE, l. ult. r. The burgh and parish contain 193

houses,
BERWICK, NORTH. Add—The burgh and parish contain 208 houses, and 1727 persons; 759 being males, and 968 females.

BERWICK, col. 3, l. 26, new ult. r. The town and county of Berwick-upon-Tweed, by the parliamentary return of 1811, contained 934 houses, and 7746 persons; 3325 being males, and 4421 females.

BERWICK, a town of Adams county, in Pennsylvania, having 1799 inhabitants.

BERWICK, in Maine, l. 2, r. 4455 for 3894.

BESANCON, l. 2 and 3, r. capital of Franche Comté, now of the department, &c.

BESANT, l. alt. r. under Henry.

BESTITTOON, a long range of barren mountains, in the province of Irak, in the Persian empire, bounding the plain of Kermanhaw to the N. and terminating abruptly on the E. by a high and perpendicular rock, in one place cut to a smooth surface, and projecting over the road, like a canopy. It receives its name from fittony, signifying, in Persian, a pillar, and be, a negative proposition. Near its projection, on a high and inaccessible part of the rock, is a group of figures, in the form of a procession, of the same age and character with those of Persepolis. The ruins at this place resemble the magnificent ones of that famous city.

BESLICK, a small Turkish silver coin, equal to 5 paras, the para being 3 aperes.

BESSARABIA, col. 2, l. 9, for fourth r. south-west.

BESTIAN, or BOSTANA, a cape of Larillan, in Perifia, which forms one of the most forcible roads to the gulf of Perifia, at the town of Mogoo. The extremity is about N. lat. 26° 30', bearing from Polior N.N.E. 3, and W. from the S. end of Kihma. Shinas and Boltana are small towns that lie between Linga and Cape Boltana.

BETHHEL, in Geography, l. 3, Lowermost Bethel is a township of Northampton county, having 1392 inhabitants; and Uppermost Bethel, in the same county, has 1188 inhabitants. After Dauphin county, add—having 2091 inhabitants; l. 4, r. 1041: at the close, add—a township of Maine, in the county of Oxford, having 975 inhabitants. Alto, a township in Bedford county, containing 1005 inhabitants. Alto, a township of Ohio, in the county of Miami, having 506 inhabitants. Alto, a township of Champaign county, in Ohio, having 484 inhabitants.

BETHLEHEM, col. 4, l. 10, add—Alto, a town of New Hampshire, in Grafton county, having 422 inhabitants; l. 13, r. 1738: l. 15, add—having 1188 inhabitants; l. 26, add—but by the census of 1820, they are flated to be 1436.

BETHLEHEM, E. and W., two townships of Pennsylvania, in Walbington county; the former has 1826, and the latter 1830 inhabitants.

BETLIS. Subjoin—See Bedlis.

BEVERLEY, l. alt. In 1811, the borough and liberties of Beverley contained 1457 houses, and 6731 persons; 3024 being males, and 3707 females.

BEVERLEY, l. 5, r. 4068.

BEVERSTONE, l. 7, r. Edward.

BEWCASLE, l. 35, r. The town includes 35 houses, and 158 persons. 103 being males, and 95 females.

BEWDELY, l. alt. r. The borough contained, in 1811, 632 houses, and 3454 persons; 1583 being males, and 1871 females.

BEZOTZI, col. 2, l. 8, r. The oldest, &c.; l. 18, composition; l. 20, do.; l. 27, for the r. their; after delicacy, insert—there was; l. 40, inferior—a labour exquisite in performance.

BIBIA, FERDINANDO-GALLI, l. 12, r. Alexander; l. 14, r. generosi.

BIBLES, LATIN. See Italic Version.

BICE. Add—see Cast.

BIDDELE, in America, l. 5, r. 1563.

BIDDEFORD, col. 3, l. 2, r. 634 houses, and 3244 persons; 1415 being males, and 1829 females.

BIGELOVIA, in Botany, a genus which we here dedicate to our highly intelligent and scientific correspondent, Jacob Bigelow, M.D. of Bolton in New England, Rumford professor of Materia Medica and Botany in Harvard university, author of the *Flora Botanica*, published in 1814; and of the American Medical Botany, with coloured plates, now publishing periodically; works which, we are confident, will be the forerunners of more ample and valuable communications from the same quarter. We have selected for the commemoration of our friend an American genus, to which the name of Borya, (see that article hereafter,) has been erroneously applied, and which therefore requires a new appellation. We have chosen one as indubitable as the genus itself, whose synonyms are the following. (Borya; Willd. Sp. Pl. v. 4, 711. Pursh 22. Ait. Hort. Kew. v. 5, 365. Adelia; Michaux Boréal-Amer. v. 2, 223. Browne Jam. 361, but not of Linnaeus.)—Chaps and order, Diccia Diania. Nat. Ord. Separia. Linn. Jafiminer, Jul.

GEN, Ch. Male. Cal. Perianthis minute, in four deep, erect, lanceolate segments. Cor. none. Stam. Filaments two or three, thread-shaped, longer than the calyx, inserted into the receptacle; anthers roundish, two-celled.

Female, on a separate plant. Cal. Perianthis in four deep, oblong, slightly spreading, deciduous segments; two opposite ones very minute, and sometimes wanting. Cor. none. Pct. German superior, rounded-ovate, of two cells; style short, cylindrical, thickish; stigma capitae, depressed, obtuse, crenellate. Petals. Berry oval-oblong, of one cell, its inner surface cartilaginous and rugose. Seed almost always solitary, oblong, tapering at each end, furrowed and ribbed longitudinally, with a membranous skin; its embryo bright, in a horny albumen.

Elf. Ch. Male, Calyx deeply four-cleft. Corolla none. Stamens two or three.

Female, Calyx deeply four-cleft; two opposite segments smallish. Corolla none. Stigma capitae. Berry with one seed.

Obf. The description of Michaux, and his hint of the affinity of this genus to *Chionanthus*, have helped us to form, we trust, a correct idea of its characters. Willdenow had seen specimens of Browne's *Adelia*, and he probably had the function of the able Mr. Richard for uniting it with that of Michaux, the latter having already decided this question; nor do we see any reason for a different opinion.

The species are all shrubby, with opposite, undivided, mostly entire, smooth leaves; and minute, tufted, bracteated, flowers. The fruit is probably not edible.

1. B. cassinoides. Elliptical Bigelovia. (Borya cassinoides; Willd. v. 1. Adelia n. 1; Browne Jam. 361. t. 36. f. 3.)—Leaves flat-ted, oblong, obtuse, coriaceous, revolute; reticulated with veins beneath.—Native of the West Indies. Common on low gravelly hills, eastward of Kingston, in Jamaica. Sometimes eight or ten feet high, with
with slender leafy branches. Flowers in little axillary tufts, or clusters. Leaves about an inch and a half long, smooth, entire. Br.

2. B. porulofa. Pierced Bigelovia. (Bory porulofa; Willd. n. 2. Pursh n. 1. Ait. n. 1. Adelia porulofa; Mich. Bor.-Amer. v. 2. 224.)—Leaves soft, oblong-lanceolate, obtuse, coriaceous, revolute; dotted beneath.—On the coasts of Georgia and Florida. The leaves are russet, and as if pierced with little dots, beneath. Michaux.

3. B. liguftrina. Privet-leaved Bigelovia. (Bory liguftrina; Willd. n. 3. Pursh n. 2. Ait. n. 2. Adelia liguftrina; Mich. Bor.-Amer. v. 2. 224.)—Leaves oblong-lanceolate, somewhat membranous, entire, on short stalks. Berry roundish-ovate.—Native of thickets and woods about rivers, in the countries of the Illinois, Tennessee, &c. flowering in July and August. This has the habitat and foliage of our Privet. Michaux.

4. B. acuminata. Pointed Bigelovia. (Bory acuminata; Willd. n. 4. Pursh n. 3. Ait. n. 3. Adelia acuminata; Mich. Bor.-Amer. v. 2. 225. t. 48.)—Leaves ovato-lanceolate, membranous, stalked, slightly serrated, acute at each end. Unripe berry oblong, taper-pointed.—On the banks of rivers in Carolina and Georgia. The taper lateral branches appear to form something like thorns. The leaves are an inch and a half long. Male flowers several together, in small sessile tufts, encompassed with several ovate bracteae; female ones stalked, very small. Berries pendent, elliptical-oblong, near an inch in length.

The three latter species are recorded by Mr. Aiton, to have been brought into England by Mr. John Lyon; the porulofa in 1826, the two others in 1812. They are hardy herbs, but do not appear to have yet flowered.

BIGNONIE, the 45th order in Jussieu's System; the 12th of his 8th clafs, whose characters are given at Gentianace. The following is that author's definition of the order before us.

Calyx divided. Corolla mostly irregular, with four or five lobes. Stamens usually five, one of which is, for the most part, abortive, or imperfect. Style one; stigma either simple or two-lobed. Fruit of two cells; sometimes capular, with many seeds, and with two perfectly separable valves; the seed-bearing partition opposite or parallel to the valves, and separable therefrom: sometimes coriaceous or woody, burling at the top only, with but few seeds, the seed-bearing partition a continuation of the valves, not separable, and often fending off a flight wing, dividing each cell into two. Corculum unattended by albumen. Stem herbaceous, thorny, or arborescent. Leaves opposite, rarely alternate.

Sect. 1. Fruit capular, bivalve. Stem herbaceous. Chelone and Scutum, with Jussieu's Incarnifolia, Lamark Illum. t. 527, compose this section.

Sect. 2. Fruit capular, bivalve. Stem arborescent or fruticose.

Millingtonia of Linnaeus; Jacaranda, Catalpa, and Tecoma of Juss. with Bignonia of Linnaeus.

Sect. 3. Fruit coriaceous, almost woody, opening at the top. Stem herbaceous. Tourrettia of Dombey and Juss.; Martynia, Cranilistoria, and Pedaliunm of Linnaeus.

Mr. Brown, Prodr. Nov. Holl. v. 1. 470, retains the second section only, under the name of Bignoniace, to which he adds the genus Spatiodae. See that article.

BIGNONIA, in Commerce, a liquid manure in Venice. See Amphora.

BILLE, Chemical properties. Bile has been lately denied by Berzelius to contain any resinous or adipocereous matter, as had been maintained by former chemists. The fusibility peculiar to bile, or, as it is denominated by him, the biliary principle, has an exceedingly bitter taste, followed by some sweet-savours. Its smell is peculiar, and the colour in most animals varies from green to greenish-yellow. It is soluble in water, and its solubility is in the leaf; promoted by the alkali of the bile, since when the alkali is neutralized by any acid, the peculiar matter does not separate. It likewise difflates in alcohol in all proportions. Like the albuminous materials of the blood, of which this peculiar matter is composed, it will unite with acids producing two compounds of two degrees of saturation, and hence of solubility. The dilute acetic acid which gives soluble compounds with the albumen of the blood, does the same with the peculiar matter of the bile; and hence this matter is not precipitated on adding this acid to bile, though it falls down on the addition of the sulphuric, nitric, or muriatic acids. It is this sparingly soluble compound of biliary matter with a mineral acid which has been mistaken by many chemists for a resin, since it possesses the external characters of a resin, melts when heated, diffuses in alcohol, and is again partly precipitated by water. The alkalies, alkaline earths, and alkaline acetates, decompose and dissolve it; the former by depriving it of its combined acid, the latter by furnishing it with acetic acid, which renders it soluble in water.

The peculiar matter of bile will also combine with many of the metallic oxides. The degree of the solubility possessed by the compound of acid and biliary principle, varies according to the length of time that the bile has been kept, and also according to the species of the animal.

The biliary matter may be obtained in a state of purity by mixing fresh bile with sulphuric acid diluted with three or four times its weight of water. A yellow precipitate first appears, which is to be allowed to subside, and then removed: more acid is then to be added as long as any precipitate is formed; heat the mixture gently for some hours, and afterwards decant the fluid part, and thoroughly wash the green mass left. This green resinous-like mass reddens limus, and is partially and sparingly soluble in water. It may be deprived of its acid either by the carbonate of barytes, or by the carbonate of potash or lime, and thus obtained pure. It is now soluble in water, and forms a green solution, having all the properties of bile. It is infusible in ether, which converts it into an adipocereous mass. When burnt it yields no ammonia, and consequently contains no azote.

The following are the results of Berzelius's analysis of bile:

The bile of other animals has been but imperfectly examined. It resembles in its general characters the human bile above-mentioned.

BILLARDIERA, in Botany, so named by the writer of this, in honour of his friend James Julian de Billardier, (or, as it is now written, Labillardier,) M.D. author of Icones Plantarum Syriae Rariorum, the fruits of his journey to the Levant, in 1786; and since much better known by his valuable Novae Hollandiae Plantarum Specimen, in two volumes folio, with many plates. An account of his voyage to New Holland, in search of the unfortunate Lapérouse, contains
contains also much botanical matter, and has been published in English, at London, in 1802, with plates. M. Labillardiere has always distinguished himself as a classical botanist, of the Linnean school, preferring the interests of science to those of politics, and following no leader but what he conceives to be true.—Smith Bot. of New Holl. t. Labill. Nov. Holl. v. t. 64. Wildl. Sp. Pl. v. i. 1. 1150. Ait. Hort. Kew. v. i. 5.—Cliffs and order, Pentandria Magnyll. Nat. Ord. uncertain. Akin to Pittosporum, and therefore to the Rhanni of Jussieu, as they stand at present.

Gen. Ch. Calyx inferior, of five lancesolate, coloured, equal, deciduous leaves. Cor. Petals five, inserted into the receptacle, alternate with the calyx, and twice as long, linear-lanceolate, erect; their claws more or less converging in the form of a tube; border spreading, acute, recurved. Nectary none. Stam. Filaments five, inserted into the receptacle, alternate with the petals, the length of the claws, awl-shaped; anthers ovate-oblong, attached by the back of two cells, burking lengthwise, internally. Pet. Germain superior, elliptic-oblong; style awl-shaped, the length of the stamens; stigma obtuse. Peric. Berry roundish-oblong, of two seeds. Seeds numerous, roundish, inserted into the central column.

Eff. Ch. Calyx of five leaves, deciduous. Petals five, alternate with the calyx, converging into a tube. Stigma obtuse. Berry superior, of two cells, with many seeds. The species are all slender, twining, branched fronds, with scattered, simple, undivided, nearly entire, more or less downy, leaves, on short footstalks. Flowers and fruit pendulous, on terminal footstalks.

1. B. scandens. Climbing Billardiera, or Apple-berry. Sm. Bot. of New Holl. t. 1. 1. Wildl. n. i. Ait. n. i. Curt. Mag. t. 801.—Leaves elliptic-lanceolate. Berry cylindrical, obtuse, downy.—Native of Port Jackson, New South Wales, from whence we received specimens and coloured drawings, by the kindness of Dr. White. Sir Joseph Banks sent seeds, or plants, to Kew, in 1793, and we have since seen flowers and ripe fruit in many conservatories. A low frond, with variously twined and climbing branches. Leaves an inch and a half or two inches long, elliptic-oblong, of a dull but not dark green; paler and more downy beneath; their edges somewhat wavy and reflexed, scarcely notched. Flowers on hairy footstalks, pale lemon-coloured, an inch long, with a hairy yellowish calyx. Germin very hairy. Berry above an inch in length, cylindrical, equally obtuse at each end; yellow, downy all over, full of brown seeds, its pulp soft, sweet, but rather impipid in this country, though said, in a wild state, to resemble a roasted apple. The figure in the Botany of New Holland was taken from a drawing made in that country. We readily concur with our friend Dr. Sims, in Curt. Mag. p. 1507, that it is impossible to find a name which will contradict the only known species of a genus, with all that may hereafter be found, and it happens that all the Billardieras are climbers. The appellation above, therefore, serves to shew the present to have been the originally described species. There are several fuch instances in the history of Linnean genera, nor would it be allowable to alter the original specific name on this account.

2. B. mutabilis. Changeable-flowered Billardiera. Salisb. Parad. t. 498. Ait. n. 2. Curt. Mag. t. 1313.—Leaves linear-lanceolate. Berry cylindrical, obtuse, smooth.—Native of New South Wales. Easily cultivated in a greenhouse, and increased by cuttings or seeds. The leaves are narrower and smoother than in the foregoing species. The flowers, at first of a pale greenish-yellow, turn purple before they fall. The germin and fruit are said to be always smooth, the form of the latter agreeing with B. scandens. Flowers and fruit smooth.

3. B. fulfilimentis. Spindle-shaped Billardiera. Labill. Nov. Holl. v. 1. 65. t. 90.—Leaves oblong-lanceolate. Flowers aggregate. Petals spreading. Berry spindle-shaped, pointed, silky, dry.—Gathered by M. Labillardiere at the Cape of Van Diemen, in December. The stem is generally climbing. Leaves somewhat hairy, larger than in the latex. Leaves from two to five at the end of each branch, forming more or less of a cluster, blue, the petals more ovate, and spreading from the base, than in other species. Antehex converging. Berry small and tapering, of a membranous texture, silky, dehitrue of pulp.

4. B. longiflora. Blue-birded Billardiera. Labill. Nov. Holl. v. 1. 64. t. 89. Curt. Mag. t. 1527. Ait. Epit. 364.—Leaves lanceolate. Petals converging. Berry nearly globular, lobed, smooth.—Native of the same country as the last. Raised here by Mefria. Loddiges. The flowers are solitary, pale yellow, longer and more tubular than in any of the reef. Fruit remarkably different, being short and roundish, of a fine blue. Dr. Sims has well observed, that this part affords, in the present genus, the best specific distinctions.

BILLERICA, l. 2. r. 1289.

BILLS, EXCHEQUER. See Exchequer-Bills.

Bill of Health, an account of the health of a crew, given by the captain or master of a vessel.

Bills, India, bills drawn in India on the East India company in London, and payable at the India-house.

Bills, Virtual. See Navy and Virtual Bills.

BILLYMEAD, a town of Vermont, in the county of Caledonia, containing 433 inhabitants.

BILSTON, l. ult. for 1325 r. 1878; and for 6914 r. 6816.

BILTON, l. ult. for 127 r. 120; and for 744 r. 762.

BIR. Add.—According to M. d’Anville this place represents the ancient Birba. The caravans travelling from Aleppo to Orfa pass the Euphrates on a bridge of boats at this place, situated 144 miles from Aleppo, and 67 from Orfa, in N. lat. 36° 58’; A tax is paid at this town, which is in a dilapidated state; and all travellers and merchants cross the Euphrates, which is here deep and rapid, and about 150 yards broad.

BIRDS, Anatomy of. The references to the plates to be expounded. Col. 7, l. 33, after another, infer—a good influence of which is found in, &c. ending heron; l. 35, r. The bulbus in the orich is a long narrow band lying on the front of the stomach. The structure, &c.; l. 53, dele like other, &c. to reception. Col. 9, l. 49, for superficial view r. flight examination. Col. 11, l. 20, after intefine dele to ventricle, l. 34; and infer.—If the cavity of the stomach in the heron be diffused with any transparent fluid and held up to the light, the zone of gallic glands will be plainly seen through its coats. If Spallanzani had employed this expedient, he could not have denied a distinct glandular structure to the heron. The inferior part of the stomach is chiefly composed of muscular fibres, spreading in a radiated manner from a lateral spongosus, which supplies the place of the great tendons of the digastric muscle. The second cavity or stomach in the heron is a small round bag, furnished only with circular muscular fibres; l. 35, for straight r. contracted. Col. 13, l. 34, dele for; l. 15, after respect dele to the end of the paragraph. Col. 14, l. 15, dele after adjoining to the end of the paragraph. for the purpose of securing their quarters, preventing surprizes, and obstructing supplies. When an army does not encamp, but lies under arms all night, it is said to "bivouacke."

BLACKBURN, l. 28, for 24 r. 23. Col. 2, l. 4, r. Blackburn turnip towndship contained, in 1811, 2945 houses, and 15,083 persons; 6953 being males, and 8130 females: 45 families employed in agriculture, and 2861 in trade and manufactures.

BLAIZ, Str., Cape, in Geography. See MOSSET'S Bay.

BLANDFORD, col. 2, l. 39, r. contained, in 1811, 431 houses, with 2425 inhabitants; 1017 being males, and 1408 females.

BLANDFORD, in America, l. 6, r. 1613.

BLANDFORDIA, in Botany, received its name from the writer of the present article, in honour of his grace George duke of Marlborough, at that time marquis of Blandford, an honorary member of the Linnaean Society, and one of the most ardent botanists and cultivators that this country ever possessed in any rank of life. A genus belonging to what Linnaeus terms the Patrician order, was judged peculiarly eligible for this purpose; nor can any one be more distinct, few more beautiful.—Sin. Exot. Bot. v. i. 5.

Gen. Ch. Cal. none. Cor. of one petal, inferior, tubular, straigt, with six marginal lobes, regular, withering. Stam. Filaments six, thread-shaped, inserted into the middle of the tube, decurrent, shorter than the limb; anthers ovate, two-lobed, incumbent, attached by a hood at their base. Fil. Germen superior, stalked, oblong, with three angles, and three intermediate furrows; style vertical,awl-shaped; stigma simple. Peric. Capsule stalked, prismatic, of three cells, furting at their inner angles. Seeds numerous, oval, inserted along the margins of each cell, imbricated, clothed with dense briliy hairs.

1. B. nobilis. Scarlet Blandfordia. Exot. Bot. t. 4. Br. n. 1. Ait. Epit. 364. Curt. Mag. t. 2603.—Bra- teas but half the length of the partial flalks while in flower. Leaves narrow-linear. Br.—Native of the neighbourhood of Port Jackson. The root is woody and perennial. Leaves all radical, four or five inches long, scarcely half an inch broad, entire, smooth, coriaceous, tapering at the base into laciniate footstalks. Flower-flalks radical, two or three feet high, erect, round, each bearing a very handsome corymbose cluster, of drooping, scarlet flowers; yellow, and marked with green, at the border; each near an inch and a half long, on a red partial flalk of the same length, at whose base are two unequal, opposite, tapering bractseas. Capsul pointed twice the length of the permanent withered corolla.

2. B. grandiflora. Large-flowered Blandfordia. Br. n. 2. (Aletes punicce; Labill. Nov. Holl. v. i. 85. l. 111.)—Bracteas nearly as long as the partial flalks while in flower; the inner but one-third as large as the outer.—Observed at Port Jackson by Mr. Brown, who is not quite certain of Labillardiere's plant, found at Cape Van Diemen. We have seen neither, but we should scarcely have thought the latter could be distinguished even from B. nobilis.

BLANDFORDIA cordata, Andr. Repert. t. 343. See GALAX.

BLATTA, col. 2, l. 29, after gigantea, add,—called in the Weft Indies drummer, from the noise it makes, like a smart knocking with the knuckle upon the wainscot; l. 36, del which fee respectively.

BLAYNEY, BENJAMIN, D.D. in Biography, an eminent Hebrew scholar and critic, was educated at Oxford, and graduated M.A. in 1753, at Worcester college, and becoming afterwards fellow of Hertford college, took the degree of B.D. in 1768, and of D.D. in 1787, in which year he was appointed regius professor of Hebrew. As a Scripture commentator and translator, he acquired very considerable reputation. The publications by which he was distinguished were, "A Differtation on Daniel's Prophecy of Seventy Weeks," &c. 1775, 4to.; "A New Translation of
of Jeremiah’s Lamentations, with Notes, &c.” 1784, 8vo.;
“C. The Sign given to Ahaz, A Discourse on Isaiah, v. 14—
16,” &c. 1786, 4to.; “Christ the greater Glory of the
Temple,” 1788, 4to.; “A New Translation of Zechariah,
with Notes,” &c. 1787, 4to. Dr. Blayney was canon of
Chriftchurch, and Archbifher of Pothit, where he died
Sept. 20, 1801, having previously directed by will that
his critical papers should be deposited in the library at
Lambeth.

BLEACHING, col. 10, l. 19, r. For an account of the
progress of discoveries in the new method of bleachings by
the oxygenated muriatic acid, see OXYMURIAC Acid
Gel.

BLECHINGLEY, col. 2, l. ult. r. By the returns in
1811, the borough and parish contained 184 houses, and
1166 persons; 775 being males, and 541 females.

BLECHUM, in Botany, Ext. 1805, an old name for
Pulegium, or Penny-royal, applied gratuitously by Dr. Patrick
Browne to a Jamaica plant, and retained by J. Juff. It
looks, rather than found, too much like Blechum.—Browne
Ait. Hort. Kew. v. 3. 435.—Clafs and order, Dictamnus
Acanthaceae, Brown.

Eff. Ch. Calyx in five deep equal segments. Corolla
funnel-shaped. Capsule imperfectly two-celled, with two
valves, and a contrary partition, at length separating in por-
tions. Seeds several, with awl-shaped props. Br.

These characters exclude Juff. u’s B. anipphyllum, which, with
Ruellia ibrica of Forskall, and several East Indian
as well as tropical African species, compone Mr. Brown’s
new genus of Artelaria, as yet, we believe, merely indi-
cated in his Prodr. Nov. Holl. v. 1. 478. The following
are the only species of Blechum there mentioned.

Ait. n. 1. (Ruellia Blechum; Linn. Sp. Pl. 884. Willid.
173. t. 109. f. 1.)—Leaves ovate-elliptical, slightly toothed.
Spikes quadrangular. Bracteas ovate, downy.—Native of the
West Indies. Perennial. Herbaceous, decumbent, branched,
two or three feet high, with opposite leaves, and white
flowers of no great beauty.

2. B. erinum. Upright Blechum. (Ruellia blechiodes;
Leaves oblong, somewhat toothed, smooth. Spikes ovate.
Bracteas nearly smooth.—Found in shady woods, in the
western part of Jamaica. Stem erect, rather thickest.
Flowers blue. Willdenow misquotes the remarks of
Swartz, which indeed are not very clearly expressed.

3. B. angul dofom. Narrow-leaved Blechum. (Ruellia
363.)—Leaves linear-lanceolate. Spikes oblong. Bracteas
ovate, hairy.—Native of the Caribbe islands. Herbaceous,
a foot high, with fowd leaves. Leaves smooth on both
sides. Flowers small, blue.

BLELIA, so named by the authors of the Flora Per-
viana, after Louis Blet, a Spanish apothecary, whose botan-
icai merits ought to be very great, to entitle him to so fine,
if really distinct, a genus.—“Ruiz et Pavon Prodr. 119.”
Cochinch. 529.)—Clafs and order, Gynandria Monandria.
Nat. Ord. Orchidace.

Eff. Ch. Calyx in five deep segments. Petals five, with
an internal appendage. Style none. Capsule superior, of
tree cells and three valves. Seeds fowd in many, each subtended
by a large fowdy tunica.

1. B. sapidu. Akee-tree. Ait. n. 1. König as above,
571. t. 16. 17. (Akee; Broughton Hort. Ealf. 1792. 10.
“Akeelia africana; Tuffant Antill. 66. t. 3.”)—Native of
Africa, between the tropics, from whence it was transported
to the West Indies in 1778. The fowdy tunica, or support,
of the seed is said to be a delicate article of cookery, ref-
ceming the white fowd of a chicken or frog, like which it
serves to make fowdras for West Indian epicsure.
tree is large, of handsome growth, with abruptly pinnate, ample, smooth, entire leaves, and copious, small, white flowers, in compound, axillary panicles. Some flowers have imperfect flumes, others an abortive germen. Notary a glandular notched ring, surrounding the base of the germen or its rudiment. Capitate elliptic-oblung, three-lobed, fleshy, variegated with red and yellow, about the fize of a goose egg. Sced globular, as big as cherries, dark brown, pohilized, each half funk in a white, turbinate, lobed and corrugated tunic, of the substance of firm fuet, larger than the seed, and attached laterally to the central partition of each vacule.

BLIGHT, l. 25, add—See ANNHS.

BLISTERS, Fluid of, in CHemistry. See FLUIDS, Animal.

BLOCKLEY. Add—It contains 1618 inhabitants.

BLOOD, Chemical Properties of. The chemical properties of the blood have been lately investigated with considerable success by Drs. Marcet and Bolstock, Brande, Berzelius, and others; with a summary view of whole experiments we shall here present our readers.

Of the serum.—The specific gravity of the serum of blood has been stated to lie between 1.028 and 1.029.5. The opinion of De Haen that it contains gelatine, was first shewn to be erroneous by Dr. Bolstock in this country, and about the same time by Berzelius in Sweden. The principles formerly termed gelatine has been variously represented and named by different chemists. Thus Dr. Bolstock endeavoured to prove that it was a species of mucus, Mr. Brande that it was merely an alkaline solution of albumen; Dr. Marcet terms it mucos-extractive matter, Dr. Pearson an animal oxyd, the French chemists ozmazome, &c.; but it is to Berzelius that we owe the knowledge of its real nature. We infer, nearly in his own words, the following account of his analysis of the serum of the blood, as an excellent model for the analysis of all albuminous fluids.

One thousand parts of serum were evaporated to dryness till it could be easily reduced to powder. In this state the residuum weighed 95 parts, and confited of a yellowish fermen-transparent mafs, resembling amber. "Of this mafs," says he, "I digested ro grammes in cold water. The albuminous portion became softened and gelatinous. I separated by the filter the liquid from the insoluble part, and washed the latter repeatedly in boiling water. The undissolved albumen dried on the filter weighed 6.47 grammes, and did not give up its earthly phosphat by subseqent digestion in muriatic acid.

"The solution which passed the filter was evaporated to dryness, during which thick membranes formed at the surface of the solution, and the solution gelatinized before it was perfectly dry. I digested this residue in alcohol whilst it was still gelatinous; the spirit assumed a yellow colour, and on evaporation left an alkaline deliquescent mafs, weighing .92 grammes. This confited of foda holding albumen in solution, of muriate of foda and muriate of potash, of lactate of foda, and of an animal matter which always accompanies the lactate. This animal matter has a brownish-yellow colour, is easily soluble both in water and alcohol, and is precipitated by tannin and submuriate of lead. It is constantly formed, as has been stated, in conjunction with the lactic acid only; and its presence may be taken as a pure indication of the presence of that acid.

"The portion not dissolved by alcohol, when digested with water, left a fresh residue of albumen, weighing 1.95 grammes. The watery solution could not be made to gelatinate, and did not contain the smallest quantity of gelatine. Besides the alkalii, it contained an animal matter, easily precipitated by tannin and by oxymuriate of mercury, and which appeared to me to be extracted from the albumen by the boiling of the water, and to be analogous to the substance obtained by boiling fibrin in water." See FINNT.

Berzelius found only a slight trace of the phosphoric acid, and none of the sulphuric in the serum of ox blood; 1000 parts of which, according to him, consist of

Berzelius remarks on Dr. Marcet’s analysis, “A more perfect agreement cannot be expected in the analysis of substances liable to incidental differences, particularly in the quantity of water, which in the blood depends so much on the proportion of liquid taken into the stomach. It is clear that Dr. Marcet’s extractive matter is impure lactate of foda; and I must also observe, that the sulphate of potash and earthy phosphates found by him in the ashes of the serum are probably, for the reasons above-mentioned, formed by the processes of combustion.” See ALBUMEN.

Of the colouring matter or red particles of the blood.—An opinion long prevalent among chemists, that blood owed its red colour to iron. Badia appears to have been the first who pointed out the existence of this metal in blood; but its presence was more satisfactorily demonstrated by Menghini, whose experiments were repeated and verified by subsequent
frequent chemists. Parmentier and Deyeux supposed, that the 
red colour depended upon the union of iron with the oxygen 
contained in the blood; Fourcroy and Vauquelin, who 
succeeded, denied this, and asserted that it depended upon the 
subphosphate of that metal. Dr. Wells, however, so long ago
as the year 1797, called this opinion in question, and asserted 
that the most delicate tests of iron did not indicate the pre-
ence of that metal in the blood; that other red substan-
ces do not all contain iron; and that, on the other hand, other 
substances that do contain iron are not red. Hence he sup-
poused, that the red part of the blood was an organized 
animal substance. This opinion has been lately revived by 
an eminent modern chemist, Mr. Brande; who affirms, con-
tary to almost every other chemist, that the colouring 
matter of the blood yields no more iron when burnt than 
any other constituent of the blood, and that consequently 
it cannot owe its colour to that principle. Berzelius, how-
ever, though he denies the opinion of Fourcroy and Vauque-
lin, that the red colour depends upon a salt of iron, agrees 
with most preceding chemists, that its affixes contain much 
more of this metal than those of either of its other constituents, 
that is to say, that they contain 50 per cent. of oxyd of iron, 
while the affixes of albumen and fibrin do not yield a trace 
of that metal. Hence he concludes, that iron, somehow or other, 
and in a manner unknown to us at present, probably conduces 
to the colour of the blood. The opinion of Berzelius, and most modern chemists, respecting this prin-
ciple is, that it closely resembles albumen and fibrin in its 
properties. According to Berzelius, the mineral acids act 
upon it nearly in the same manner as upon albumen. It is 
fusible also in dilute acetic acid, and precipitated by the 
prunilacid of potash, like that principle; and hence 
Berzelius is inclined to consider it as a modification of 
albumen. Vauquelin has lately given a method by which 
he thinks the colouring principle may be separated from 
the other principles of the blood, which is a very diffi-
cult task; we do not think, however, that he has been suc-
cessful.

Mr. Brande tried to form a lake, by precipitating its acid 
solution by means of different earthy and metallic salts. 
Neither alumina nor oxyd of tin answered the purpose well. 
Corrosive sublimate or nitrate of mercury succeeded best. 
These gradually precipitated the colouring matter, and 
formed with it powders of a good red colour, not altered by 
exposure to the air. Mr. B. likewise made some attempts 
to employ it as a principle in dyeing, but they were not 
attended with much success.

Some interesting observations have lately been made on 
the size of the colouring particles of the blood by Dr. Young. 
According to this gentleman, they bear no proportion to the 
size of the animal. Thus,

Of the Fibrin.—The experiments of Berzelius shew that 
this substance closely resembles albumen in its chemical 
properties. We do not think it necessary therefore to add any 
things to the subject here, but refer our readers to the article 
albumen. The physical properties of fibrin have been 
already described under blood in the Cyclopaedia. Ac-
Vol. XXXIX.

According to the experiments of Gay Lussac and Thezard, 
fibrin is composed of

The buffy coat of blood is fibrin.

Of the Seraffy.—This term has been generally applied to 
the fats and animal matters existing in the serum of the blood, 
with the albuminous principle. See the description of sera-
fen in the present article.

With respect to the blood as a whole, little has been added 
to our knowledge. M. Vogel has attempted to shew, that 
when placed in the vacuum of an air-pump, it gives out a 
considerable quantity of carbonic acid: and Dr. Gordon has 
asserted, that during its spontaneous coagulation heat is 
emitted; but this has been denied by other observers, and 
especially by Dr. J. Davy.

The blood of other animals, and the blood of perfons 
labouring under different diseases, have been but little exa-
named; indeed this extensive and important field of chemical 
investigation is almost entirely unexplored.

BLOOM, in Geography, a township of Pennsylvania, in 
Northumberland county, having 1285 inhabitants.—Alfo, a 
township of the county of Fairfield, in the district of Ohio, 
having 839 inhabitants.

BLOOMFIELD. Add—Alfo, a township of Penn-
ylvania, in Crawford county, having 114 inhabitants.

BLOUNT, l. l. infant.—Exit Tennessee. Add—contain-
ing 839 inhabitants, of whom 805 are slaves.—Alfo, a 
county of the same state, having 3259 inhabitants, including 
266 slaves.

BLOW-PIPE. We think it proper to notice here the 
important modification of this useful instrument, lately con-
tained by Mr. Brooke, and which, by the intensity of the 
heat it excites, has produced such interesting results in the 
hands of different experimenters, and more especially of 
Dr. Clarke of Cambridge.

Mr. Brooke's blow-pipe consists merely of a strong copper 
or iron air-tight box, to which are adapted a condensing 
syringe and jet-pipe, furnished with a stop-cock. When 
used, the box is to be filled with condensed air by means of 
the syringe; the stop-cock is then to be turned, and the 
condensed air permitted to escape through the jet. From 
the smallness of the aperture of the jet, a constant and 
uniform blast is thus kept up for a considerable time, and by 
the occasional use of the syringe, may be continued for any 
length of time whatever, simply by means of the elasticity 
of the air itself.

A great advantage attending the use of this blow-pipe is, 
that the box can be readily filled with any gas, or mixture 
of gases, we choose. Accordingly advantage was soon taken 
of this property, and a mixture of oxygen and hydrogen 
gases, when inflamed as they issued from the jet, was found 
to yield a more intense heat than any other. From the 
liability, however, of this mixture to explode, great caution 
was required in using it, and this led to the necessity of 
some contrivance for obviating this dangerous circumstance. 
Various means were soon suggested, most of which were 
found on the principle recently discovered by Sir H. Davy, 
that the inflammation of gases will not pass through minute 
apertures (see Wire-gauze): and, at length, we believe 
the
the instrument has been rendered quite safe; and, in this state, may be obtained of any of the philosophical instrument makers.

The public attention was particularly excited towards this instrument by the experiments of Dr. Clarke, who supposed that by its means, and the employment of the gaseous compound above-mentioned, he had succeeded in reducing some of the most refractory metallic oxides and ores. The accuracy of many of Dr. C's results has indeed been since called in question; but they nevertheless demonstrate the extraordinary powers and valuable properties of this modification of the blow-pipe.

BLUEHILL, l. 4, r. 658.

BLUE-WATER River, a river of America, which rises among the southern branches of Dock river, and empties into the Tennessee.

BLUFF, a term used in N.W. America to denote a particular tract of land. The alluvion of the rivers W. of the Alleghanies is considerably lower than the surrounding country, and is of a breadth corresponding to the magnitude of the rivers; that of the Missouri is from 2 to 6 or 8 miles in breadth, and is for the most part from 150 to 300 feet below the general level of the country. The alluvion from this valley into the country is precipitous, and is called "the bluff," and may consist of rock or clay. Between these bluffs, the river runs in a very crooked channel, and is perpetually changing its bed, and the permanent beds are called the bluffs.

BOA, col. 3, l. 27, for Constrictor r. Serpents.

BOARD of Agriculture. See Society.

BOARDMAN, in Geography, a township of Ohio, in the county of Trumbull, containing 343 inhabitants.

BOCCA, a term used both in the Levant and on the N. coast of South America, on the Spanish Main, for a mouth or cleft into any port or harbour; or the entrance into a found which has a passage out by a contrary way.

BOCKFIELD, a town of the district of Maine, in the county of Oxford, containing 1251 inhabitants.

BODMIN, l. ut. r. In 1811, the parish and borough contained 315 houses, and 2353 persons; 158 in the parish and 1008 in the borough being males, and in the former 175 and in the latter 1042 females.

Eff. Ch. Receptacle naked. Seed-down of simple hairs. Calyx double; the inner of eight leaves; outer of many.

1. B. chrysanthenoides. Dwarf Barbarea. Willd. n. 1. Purpur n. 1. (Tagetes papposa; Michaux Boreal.-Amer. v. 2. 132. Vent. Hort. Coll. t. 36. Dylödia glandulosa; Cav. Lecction. 202.)—Native of the overflowed banks of the Missouri and Misflippri, annual, flowering in August and September. Purpur. A branched herb, twelve or eighteen inches high, with the habit of an Anthemis, beakspinkled with glandular pellucid dots, full of a fetid bitter liquid. Flowers of a golden yellow, with eight small rays. Leaves pinnate, toothed, narrow. Cavalmays says this plant grows in every part of America, but especially in the kingdom of Santa Fé, where it is commonly called Ruda, on account of its offensive smell. Venten finds of it as a verminific, and as affording a tolerably durable yellow dye.

BOERO, delo.

BOEFS, Rivière aux, or Ox River, in Geography, is the last and largest branch of Ouachitta. It rises in the angle formed between the Milford and Arkansas, and pursues a course to the S.W. for some distance, then turning southward for 70 or 80 miles, enters the State of Louisiana, and afterwards, at a shorter distance, crosses the N.E. line of Biltrop's grant, pursues a S.W. course, and then resumes its direction to the southward, and after running about 60 miles enters Ouachita, above the west point of the island of Sicily. The Beauf, from its source in the Arkansas lake to the boundary of the State of Louisiana, is about 120 miles, and from thence to its mouth nearly the same distance, producing a length of 240 miles, independently of its windings. It is navigable as far as Prairie Mer Rouge. A strong brake of cane skirts the Beauf nearly along its whole course, through the State of Louisiana. Much land near its banks might be cultivated, but is mostly subject to casual inundation.

BOGAERT, l. 3, r. the Netherlands.

BOILING, col. 4, l. 10, after proceeds, add—Under the ordinary pressure of the atmosphere, with due allowance for its variable density, water does not boil till it is heated to 212° Fahrenheit. However Sir George Shuckburgh found, that when the barometer was at 26 inches, water boiled at less than 205°; but when it was at 31 inches it required before it would boil a heat of nearly 214°. Under the common pressure of the atmosphere, ether boils at 98°; alcohol at 176°; water at 212°; nitric acid at 248°; sulphuric acid at 546°; phosphorus at 554°; and mercury and linseed-oil at 600°. From the experiments of Dr. Black upon several liquids in vacuo, it appears that, in general, they all boiled with about 140 degrees of heat less than when furthering the weight of the atmosphere. Vitriolic ether, if the pressure of the atmosphere be removed, will boil when 52 degrees below the cold sufficient for freezing water.

BOISSÈAUX, a meaure for corn, according to the old fyltem in France, which varies much in different parts of the country.

BOLAX, in Botany, a name of Commerson's adopted by Jussieu, Balsa means a clad, or lump of earth, which this dwarf umbelliferous genus does not ill resemble.—Juss. Gen. 326. Spec. Prod. Umbell. 35. Spec. Umb. 9. (See Chefa.-) The species, though not numerous, are far from being, as yet, accurately determined, either with respect to their permanent differences, or their synonyms.

BOLINGBROKE, l. ut. for 72 r. 745; and for 283 r. 361.

BOLING-GREEN, in Geography, a town of Kentucky, in Warren county, containing 154 inhabitants, of whom 31 are slaves.

BOLL, a corn measure in Scotland, containing 4 firlets, each firlet being = 4 pecks; and 16 bolts = 1 chaldron.

BOLOGNO, a copper coin at Bologna and its neighbourhood.

BOLSÖVER, l. ut. for 435 r. 244; and for 1091 r. 1043.

BOLTON, in America, l. 3, r. 249; l. 6, add—containing 700 inhabitants; l. 8, for 861 r. 1057.

Bolton-u-Moor, l. 30, add—In 1811, the township of Great Bolton contained 3120 houses, and 176750 persons; 7586 being males, and 9082 females. Little Bolton township had 1286 houses, and 7079 inhabitants; 3366 being males, and 3713 females.

BONAVENTURA, l. 2, r. Popayan.

BONDS, India, bonds issued by the East India company of 560l. and 1000l. each, bearing interest of 5 per cent. for
BOR

per annum, which interest is paid at the India-house in London.

BOND, Pay-Obit, a bond payable after the death of the person whose name is therein specified.

BONES, Analysis of, in Chemistry. The analysis of bones was omitted under Bone, but will be found under Teeth, contrasted with the analysis of the teeth.

VOL. V.

BOONE, in Geography, a county of Kentucky, containing 3668 inhabitants, of whom 676 are slaves.

BOONSBOROUGH, 1. 2. r. Madison; and at the close of the manuscript—It contains 68 inhabitants, 15 being slaves.

BOOROOJIRD, a flourishing city of Peria, in the province of Irak, the capital of a wealthy district, subject to the prince, Mahomed Tukkee Mirza, and containing a population of 12,000 souls. The district attached to its government is peopled by the tribe of Lakk, who do not wander far from the spot to which they are partial, but settle in villages, and employ themselves in the improvement of their estates.

BOOTH BAY, 1. 5. r. 1582.

BORACITE. See Mineralogy, Addenda.

BORAX, in Chemistry. See Boron, infra.

BORDI, or Burni, in Commerce, a copper coin in Egypt. 8 borbi being = 6 forli = 3 alpers = a medino, and 40 medini = a piastre current.

Borelli, col. 2. 1. 6. r. 1670.

BORON, or Boracium, in Chemistry, the peculiar elementary bodies of boracic acid. Sir H. Davy, in 1807, first decomposed boracic acid, and obtained this principle by the agency of galvanism. Soon afterwards another method of obtaining it was pointed out by Gay Lussac and Thénard, by means of potash, which was soon verified by Davy and others. One part of pure boracic acid, previously melted and reduced to powder, is to be mixed with two parts of potash, and the mixture put into a copper or iron tube and gradually heated till it is slightly red, and kept in that state for some minutes. At the temperature of 300° the decomposition begins, and the mixture becomes intensely red hot, as may be perceived by making the experiment in a glass tube. When the tube is cold, the matter in it is to be washed out with water, the potash formed is to be neutralized with muriatic acid, and the whole thrown upon a filter. It may be washed and dried at a moderate heat.

BORON thus obtained is a powder of an olive-brown colour, without either taste or smell. In clove vessels, it may be exposed to the most violent heat without being altered, or undergoing any other change than an increase of density. Its specific gravity, before being heated, is less than 1.84, but afterwards greater. It is insoluble in water, alcohol, ether, and oils, whether cold or hot. It does not decompose water even when heated in that fluid. It is a non-conductor of electricity. It undergoes no change when exposed to common air or oxygen at low temperatures; but when heated to about 600° it takes fire, and burns with great splendour; and at the same time absorbs oxygen, and is partly converted into boracic acid. The combustion, however, is soon stopped, from the coating of the boracic acid formed, which prevents the contact of the oxygen. Hence this requires to be frequently removed, by washing, before the whole of the boron can be burnt. The nitric acid also readily converts boron into boracic acid. Boron, heated with molten of the neutral salts, deprives their acids of the oxygen which they contain: thus, when heated in clove vessels with sulphate or sulphite of soda, borate of soda and sulphur are formed. When heated with nitre or oxymuriate of potash, much deflagration ensues, and borate of potash is produced: so also the carbonate of soda is converted into borate of soda and charcoal.

There is considerable difficulty in fixing the proportion of oxygen with which boron combines to form boracic acid, as the results of Gay Lussac, Davy, and others, differ very much. Dr. Thomson, guided partly by these experiments, but chiefly by the analysis of borate of ammonia by Berzelius, fixes the weight of the atom of boron at 6.6, and supposes it combines with two atoms of oxygen to form boracic acid. Upon this supposition, 100 parts of boron will combine with 300 of oxygen.

Boron, when heated in chlorine, takes fire, and burns with a brilliant white flame. A white sub stance coats the vessel in which the experiment is made, and the boron is also covered with a white sub stance, which by washing is converted into boracic acid. It is probable that this white substance is a chloride of boron, but it has not been much examined.

Boron combines with fluorine, (see Fluorine,) and forms with it a powerful acid, which has been named fluoboracic acid. (See Fluoboracic Acid.) It also appears, according to the experiments of Gmelin, to combine with hydrogen. Deccotis has likewise shown that it combines with iron, and Davy with potashium; but, as far as it is known, it combines with no other metal. With respect to the nature of this singular sub stance it may be proper to mention, that some consider the boron described above to be an oxyd of a metallic basis, to which the name of boracium has been given.

BORONIA, in Botany. (See Rutaceae.) Mr. Brown, who could not but be aware of the ill-defined limits of this order, as originally constituted by Jussieu, has, in his General Remarks on the Botany of Terra Australis, 13, proposed to remove the 18th section, under the appellation of Zygo phylles, naming the remainder Diosme, the genus Rut, not being a good type of the order, so limited. This learned Australian botanist informs us that near 70 species have been observed, the greater part of them referable to our Boronia, Correa, Eriogonum, and Zieria, (as also we presume to Cronaca,) and to Phellodium of Ventenar. "Of these genera Boronia is both the most extensive and the most widely diffused, exiling within the tropic, and extending to the south end of Van Diemen's island. Like the others, however, its maximum is in the principal parallel, at both extremities of which it is equally abundant."

BOROUGH, col. 3. 1. 19 from the bottom, after London, r. by a writ bearing date the 12th of December, 1264, in the 49th year of the reign of Henry III.

BOROUGH-BRIDGE, l. 23. r. The borough and township of Borough-bridge contain 131 houses, and 747 inhabitants; 373 being males, and 374 females.

BORRAGINEae, in Botany, the 42d order in Jussieu's system, the 5th of his 8th class; for whose characters, see Gentianae.

This order, equivalent to the Linnaean Asperifolae, (see that article,) is thus characterized.

Calyx in five deep segments, permanent. Corolla softly regular. Stamens generally five. Gynaeceum either simple or four-lobed; style one; stigmas either cloven, or furrowed, or simple. Seeds generally four; sometimes enclosed in a capsular or pulp Wyd-veil; sometimes naked, obliquely attached to the bottom of the style, and for the most part surrounded by the permanent calyx. Calyx without albumen. Stem in the greater number herbaceous; in a few...
few shrubby or arborescent. Leaves alternate, often harth or rough.

Sec. 1. Fruit pulpy. Stem shrubby or arborescent. Patagonula, Cordia, Ebenia, Menais, Varronia, and Tournefortia.

Sec. 2. Fruit of one or two capsules. Hydrophyllum, Phacelia of Julive, Ellia, Dichondra, Mefferichmia, and Centine. Dichondria (see that article) is erroneously placed here.

Sec. 3. Fruit of four naked seeds. Throat of the corolla naked. Plants mostly herbaceous and rough.

Coldenia, Heliotropium, Echium, Lithophragma, Pulmonaria, and Onopordum.

Sec. 4. Fruit of four naked seeds. Throat of the corolla furnished with five scales, hollow like flaps, slightly projecting out of the corolla, at the base of its segments, gaping above. Herbs generally with rough leaves.

Symphylum, Lecopis, Myosotis, Anchusa, Borage, Asperago, and Cynoglossum.

Sec. 5. Genera allied to the Borragineae. Nolana, Sipanthus, and Falkia.

Borreea, is dedicated by professor Acharius, to the honour of Mr. William Borree, F.L.S., one of the most eminent British cryptogamists, whose studies have been particularly directed to the Lichen tribe, and who is also critically versed, as well as Singularly accurate, in every department of British botany — Achar. Lichenogr. 93. t. 9. f. 3–9. Syn. 220. Sm. Prodr. Fl. Græc. Sibth. v. 2. 313. —Cliffs and order, Cryptogamia Algæ. Nat. Ord. Lichenes.

Eff. Ch. Shields italked, coloured, with an elevated, inflexed border, of the substance of the leafy, cartilaginous, elevated, linear frond.

This genus is very natural in habit, comprising the well-known Lichen eilarius of Linnaeus and its allies. Acharius defines fourteen species, among which several are very elegant, such as B. Trulla from Peru, figured in Asch. Meth. t. 4. f. 6. leucomela, (see Engl. Bot. t. 2548,) and ebrapsophalina, t. 1088.

We have ventured in Prodr. Fl. Græc. to remove hither the Evernia prunifera, Ach. Syn. 245, Lichen prunifera of Linnaeus; and feel much inclined to affiocate the whole of that genus with Borreea, there being only two species besides, which are Lichen divorcatus and vulpinus of Linnaeus. We really cannot perceive any distinctive character to keep Evernia separate.

Borrowstonness. Add — The parish contains 352 houles, and 2704 inhabitants; 1102 being males, and 1602 females.

Borya, in Botany, a New Holland genus, thus named by M. Labilliardiere, in honour of the distinguished botanical traveller, M. Bory de St. Vincent. This genus was first made public by its author in 1804. A year or two afterwards, professor Willdenow published a different Borya, in his Sp. Pl. v. 4. 711. The former is adopted, in his Prodrumus, by Mr. Brown, who, nevertheless, has admitted the latter into Ait. Hort. Kew. v. 5. 365. This can only have arisen from the professed plan of the Hort. Kew, being in general to copy Willdenow, and we trust Mr. Brown no more intended to give his function to this error, than to the adoption of Araucaria, to the prejudice of the rightful Dombeya. (See those articles.) However that may be, we feel it incumbent on us to admit the original Borya, against which no valid objection can be raised, having already endeavoured to find a suitable name (see Bigelowia) for the other. — Labill. Nov. Holl. v. 1. 81. Brown Prodr. Nov. Holl. v. 1. 286. — Cliffs and order, Hesandria Monogynia. Nat. Ord. Asphodelae, Brown.

Mr. Brown conceives the present genus to be not very nearly related to any, except perhaps Xanthorrhoea, (see that article,) and his own Johnfonia. In habit it approaches some of the Junceae, but differs in the black crustaceous integument of the seed, and in the soft, fleshy, somewhat oily, albumen.

It confines of perennial herbs, of a harsh dry texture. Roots composed of long, tough, somewhat shining fibres. Stems either simple, or divided and creeping, clothed with very crowded, acerofo, pointed leaves; dilated and half-fleshy at their base. Flower-flats solitary, terminal, simple. Head nearly globular, encompassed with a few short leafy bracts. Scales of the calyx smooth, membranous, the outer one fleshy the inner, which is narrower, and embraces the tube of the corolla.

1. B. niitda. Shining Borya. Labill. Nov. Holl. v. 1. 81. t. 107. Br. n. 1. — Stem much branched, taking root below, with simple polilished fibres. Flower-flats shorter than the ascending branches. Head ovate. — Gathered by both the distingual botanists above cited, on the south coasts of New Holland, and the adjacent islands, in sandy ground. The plant is about a span high, and, except the want of downy radicles, seems calculated to confine the blowing sands of its dreary country, like our Carex arenaria, Elymus arenarius, &c.

Bos, in Zoology, l. 13. after ferus, infant — See Ursus.

Boscawen, l. 4. r. 1829.

Gen. Ch. Cal. Perianth inferior, of one leaf, coriaceous, bell-shaped, two-lipped; upper lip largest, in two rounded, obtuse segments; lower in three deep, lanceolate, equal segments. Cor. papilionaceous. Standard heart-shaped, ascending, as long as the upper lip of the calyx, with a linear, convex claw. Wings half the length of the standard, obovate, each with a tooth at one side. Keel the length of the wings, of two hatchet-shaped, concave, converging petals, each with a lateral tooth, and a prominence on the disk, near the haft. Stem. Filaments ten, united about half way into one fet, separate only along the upper edge; anthers uniform, simple, roundisht. Pfâl. German italked, linear, compefled; style recurved; stigma simple. Peric. Legume italked, oblong, compefled, nearly flat; its valves rigid, thickened at each margin; sometimes internally pungent, and of many cells. Seeds several, oval, compefled, italked, each with a tunid appendage.

Eff.
Eff. Ch. Calyx two-lipped; upper lip largest, crenate, obtuse. Stamens all connected. Legume flaked, compressed, thickened at each edge, with many seeds.

1. B. foledendens. Yellow Flat Bofbia, or Plank-plant. Sm. as above n. 2. Sims in Curt. Mag. t. 1235. (B. Slow-
dendens; Br. in Ait. n. 1. Phatlobium foledendens; Andr. Repof. t. 191. P. foledendens; Vent. Malmai.
t. 55.)—Branches comprefTed, winged, toothed, leaflets; flowering at the teeth. Stem erect. Keel naked. Upper bracteas permanent, imbricated, equal to the footstalks. Calyx very smooth.—Native of New South Wales, from whence it was introduced, in 1792, by Lee and Kennedy. A green-house shrub, flowering early in summer. The winged branchea, in a manner profligate, and bearing handsome, red and yellow, flaked, solitary flowers, from their numerous alternate teeth, give this shrub a very singular aspect. The feeding plants only bear simple, alternate, flaked, ovate, entire leaves. The leaves of this species, (and perhaps the following,) is said by Dr. Sims to want that internal sponginess, which, in those first described by botanists, seemed to yield a good generic character. The texture of the leaf, its thick edges, and the want of a dorsal membranous wing, are still sufficiently to keep the genus distinct from Platylobium. (See that article.) With respect to the specific name, we insist beg leave, like Ventenat and Sims, to consider it as an adjective, comparing this singular plant's branches to the inflorescence of a Scolopendria, or Centipede. It has no connection with the vegetable genus Scolopendria, and still less it has ever been so called.

t. 266, (not 276,) according to Mr. Brown.)—Branches leafy, compressed. Leaves elliptical, obovate, or linear, flat. Legume of many cells, with fpongy partitions.—Native of New South Wales. Imported by Lee and Kennedy in 1792. A branchy bushy shrub, flowering most part of the summer. The branches, though nearly flat, are not dilated like the foregoing, nor are they either toothed, or dentated. The leaves are variable in figure, but on full-grown plants usually linear, alternate, on short flaxls. Flowers axillary, solitary, flaked, large, yellow with a crimson keel, very ornamental.

t. 4.—"Branches leafy, compressed. Leaves linear; recurved at the margin. Legume of one cell."—Observed by Mr. Brown, on the south-west coast of New Holland. Sent by Mr. Good to Kew, in 1803, where it is said to flower from July to September.

t. 5. (B. ovata; Sm. n. 3, excluding the synonyms.)—Branches short, leafy. Stem procumbent. Leaves oval, smooth. Stipules shorter than the footstalks. Legume of a single cell.—Sent from Port Jackson, by Dr. White, in 1793. Mr. Good is mentioned as having sent it to Kew in 1803. The leaves are a span long. Leaves nearly uniform, a quarter of an inch long, their edges thickened, wavy, and somewhat crenate. We had mistaken this for the Platylo-

Bium ovatum of Andrews, t. 266, but Mr. Brown has con-

vinced us of our error.

t. 6.—"Branches round, leafy. Stem cleft, much branched. Leaves ovato-lanceolate; rough above; downy beneath; recurved at the margin."—Found by Mr. Brown in Van Diemen's island, and sent in 1805 to Kew, where it flowers from May to July.

7. B. microphylla. Little-heart-leaved Bofbia. Sm. n. 5. Br. in Ait. n. 7. (Platylobium microphyllum; Sims in Curt. Mag. t. 1863.)—Branches round, leafy, spiny-pointed. Leaves ineradicable-shaped, or wedge-shaped.—Native of New South Wales, from whence Dr. White sent specimens in 1793. Mr. Caley sent seeds to Sir Joseph Banks in 1803. This species is said to have flowered at the present day of Marlborough's, at White Knights, in 1805. The flowers, though smaller than in some other species, are so numerous, and so prettily variegated with yellow, purple, and red, as to render this a very ornamental plant. The leaves are shorter than the flowers, veiny, smooth and entire, very abundant. The tips of the branches finally become spiny.

Mr. Brown is probably furnished with more species of this handsome genus, which have not yet made their appearance in the gardens.

BOSSINEY. Add.—The parish of Tintagel, in which this borough is situated, contained, in 1811, 141 houses, and 730 persons; 339 being males, and 391 females.

BOSTANA. See BESTIAN.

BOSTON. At the close, r. the parish of Boston, in 1811, contained 1712 houses, and 8180 persons; 3805 being males, and 4375 females.

BOSTON, in Massachusetts, l. 17, after augmented, in-\ny.—By the census of 1810, Boston, Chelsea, and the islands within and without the jurisdiction of Boston, included a population of 34,381 souls. The former islands are, Noodle's, Hog, Apple, Deer, Long, Spectacle, Governor's including Fort Warren, and Fort Independence: the latter arc, Greene, Thompson's, Rainford's, George's, Great Brewster, Outer Brewster, Lighthouse, and Califinland. Boston itself is flated as containing 33,250 inhabitants.

BOSTON, a town of the district of Ohio, in the county of Champaign, having 616 inhabitants.

BOSTON, New, l. 12, for 1822 r. 1619.

1. B. glabra. Smooth Boswelia. Roxb. as above, t. 207. (Canarium odoriferum; Rumph. Amboin. v. 2, 156. t. 56. Gugulapootschittoo of the Telingas.)—Leaves smooth, with shallow incisions.—Native of the highest mountains on the coast of Coromandel, flowering in the cool season, and casting its leaves in October. This is one of the largest trees of that country; its wood hard, heavy, and durable. The wounded bark yields a sort of pitch. Leaves crowded at the ends of the branches, a span long, pinuate with an odd one: leaflets all uniform, opposite, ovate-oblong, an inch and a quarter in length. Flowers white, in aggre-
gate, terminal, interrupted, spreading clusters, shorter than the leaves, and coming before them. Nectary red. Antehrs oblong, yellow. Capsule oval, about half an inch long.

2. B. lineata. Hairy Boswelia. (Canarium odoriferum
ferum hispidum;—Rumph. Ambol. v. 2. 157. t. 51, according to Dr. Roxburgh; but the leaflets are represented entire.—Leaflets downy, deeply serrated.—On the Ballagaut mountains. The flowers of this are inserted on the exterior margin of the flavescent. Roxburgh.

BOTETOURT. Add—By the census of 1810, it contained 13,301 inhabitants, of which 2275 are slaves.

5. B. obliquum. Oblique-leaved Moonwort. Willd. n. 5. Muhlenb. Cat. 98.—Fond near the twice ternate; leaflets obovate, finely serrated, unequally heart-shaped at the base. Fruitstalk towards the base of the fruitstalk. In open woods of Pennsylvania and Virginia, in June and July. Refrains the preceding very much, and is probably only a variety. Pursh. This author describes the *jiske* as doubly pinnate; those of the last only pinnate.

6. B. aureum. Southern Moonwort. Brown n. 5. Frond ternate; doubly pinnate; leaflets confluent, cut. Fruitstalk from the base of the fruitstalk.—Sent by Dr. White, from Port Jackson, New South Wales; where, as well as in Van Diemen's Island, it was gathered by Mr. Brown. Leaflets bluntly toothed. Fruitstalk pale, a pan high, being thrice as tall as the leaf, into whole dark-coloured fruitstalk it is inserted, a little above the root. The *jiske* is twice or thrice compound, spreading; the flanks pale. Capsules dark brown.

7. B. ternatum. Ternate Moonwort. Sw. n. 6. Willd. n. 6. (Osmunda ternata; Thunb. Jap. 329. t. 32.)—Fronds in pairs, triply pinnate; leaflets notched and serrated. Fruitstalk from the middle of the common fruitstalk. Spike pinnate.—Gathered by Thunberg once only, near Nagafuki in Japan, in November. A foot high, with two large, opposite, spreading, ternate, then twice pinnate, leaves, half the height of the fruitstalk.

8. B. diffeleum. Cut-leaved Moonwort. Willd. n. 7. Muhlenb. Cat. 98. Ait. n. 3. Pursh n. 3. Sprengel, Crypt. ed. 187. "Schkuhr Crypt. 157. t. 156." (Lunaria botrytes ramosa, gerani Botrytes, floribus, floribus; Pluk. Am. 134. t. 427. f. 5.)—Fond ternate, thrice pinnate; leaflets decurrent, linear-wedge-shaped, sharply toothed at the end. Fruitstalk at the base of the leaf.—In pastures of open dry woods, from New York to Florida, in June. Pursh. We have Pennsylvania specimens from the late Dr. Muhlenberg, very much like Pluteus' figure, but we can discover no essential difference between this plant and the following.

9. B. virginianum. Virginian Moonwort. Sw. n. 3. Willd. n. 8. Ait. n. 4. Pursh n. 4. "Schkuhr Crypt. 157. t. 156." (Osmunda virginiana; Linn. Sp. Pl. 1519, excluding Plumier's synonym. Lunaria americana, folios circitariae, medio eleanter divisa; Moris. sect. 11. t. 4. f. 5. L. multifido,folio crassa, &c; Pluk. Mant. 120. t. 427. f. 8.)—Fond somewhat ternate, twice pinnate; leaflets decurrent, obovate-wedge-shaped, sharply toothed. Fruitstalk at the base of the leaf. In shady woods, on a rich vegetable soil, from Canada to Carolina, in June and July;
July. *Purfa.* That author observes, "this is the largest of the species here described. It is known by the name of Rattle-snake Fern, probably from growing near the places where these venomous animals are generally found." Our specimens, one of which was gathered by Clayton, the other by Kalm, are scarcely so large as the last-described, from which they differ chiefly in having rather less compound leaves. The *inflorescence* is somewhat hairy, as in that. Willdenow, negligently as it seems, changed the termination of the specific name to *virginicum*, which could only cause trouble, and we have therefore restored the original.

10. *B. gracilis.* Slender Moonwort. *Purfa* n. 5. Frond ternate, doubly pinnatisect, smooth; segments cut, acute. Spikes slender, pinnate, erect.—In shady fertile woods of Virginig, in June. This species approaches nearly, at first fight, to the preceding, but is much smaller and more slender, besides the other distinctions. *Purfa.* We have from Dr. Muhlenberg what answers to the above account, but should scarcely have thought it distinct. *The inflorescence* indeed is smooth, and finely pinnate, but this corresponds with the smaller size of every part.

11. *B. cicutaria.* Hemlock Moonwort. Sw. n. 4. Wildl. n. 9. (Omnuda cicutaria; Lam. Dict. v. 4. 650. O. afrophedon radice; Plum. Fil. 136. t. 159. Petiv. Fil. n. 168. t. 9. f. 2.)—Frond triply pinnate; leaflets pinnatisect; terminal ones pointed. Fruitstalk from near the base of the footstalk.—Gathered by Plummer in the woods of Hifripaniola. The root consists of oblong tapering leathery knobs. *Frond* much larger than either of the three last, and essentially different in the nearly radical inflorescence of the fruitstalk. The *spike* is twice pinnate. Plummer records, that the Indians give the name of Serpent-herb to this, and to the *Aenemia adiantifolia,* thinking them useful applications for the bite of a serpent. This may account for the application of Rattle-snake Fern given to *n. 9.*

12. *B. zeylanicum.* Great Ceylon Moonwort. Sw. n. 7. Wildl. n. 10. (Omnuda zeylanica; Linn. Sp. Pl. 1519. O. n. 373; Linn. Zeyl. 178. Ophioglossum laciniatum; Rumph. Amboin. v. 6. 153. t. 68. f. 5.)—Frond ternate; leaflets ternate or somewhate pinnate, lanceolate, pointed, finely crenate. Spike cylindrical, dense; spikelets capitate. —Native of Ceylon and Amboyna, on the fides of hills, in the borders of woods and thickets. The *root* is long and creeping, very deep in the ground, with numerous long fibres. *Fronds* a foot and a half or two feet high, naked, except at the very top of the *stalk,* from whence proceed three slightly-flattened *branches,* each of two, three, or more, equal, uniform smooth leaflets, five or six inches long, and one broad, partly decurrent, light green, with many fine transverse veins. From the same point springs a fruitstalk, with a dense cylindrical compound *spike,* rising rather above the leaflets, the *capsules* about three together, capitate, at the end of each short partial branch.

**BOTRYLITE.** See Mineralogy, Addenda.

1. *B. cinerata.* Ash-colored Chulfler-mould. Perf. n. 1. Disp. Meth. 40. t. 3. f. 9, 10.—Ash-colored, branching, in broad dense patches.—On rotten gourds, pumpkins, and cabbage-stalks, resembling a common *Macor,* tall examined with a magnifier. The *globules* are disposed in irregular oblong masses, and discharge powdery *seeds.*

2. *B. ramosa.* Crofs-headed Chulfler-mould. Perf. n. 2. (B. ramosa cinerea, femininis rotundis; Mich. n. 3. f. 2.) B. alba. (B. non ramosa alba, femininis rotundis; Mich. n. 2. f. 3.) —Ash-colored, branching, with four-rayed spines.—Very common in all kinds of corrupting subjaces. *Micheli.* The minute *flame* are more or less branched and forked, each *branch* terminating in a cros, composed of four dense ovate masses of *globules,* on short horizontal flanks.

3. *B. simplex.* Simple Chulfler-mould. Perf. n. 3. (B. coma grisea, capillis cillati, femininis rotundis; Mich. n. 1. f. 1.)—Grey, simple. Spikes radiating.—On half-rotten wood, or wheat-straw, in winter, not unfrequent about Florence. *Micheli.* Each plant consists of a simple, rather firm, *fem* a line or two in height, crowned with from three to six ovate masses of *globules,* on horizontal radiating flanks.

5. *B. diffusa.* Great White Chulfler-mould. Albert and Schwein. Fung. Nifs. 352.—White, with extensive diffuse branches, and terminal clufers, of about four globules each.—Found on once only on half-rotten flanks of potatoes in November, composing dense, white, cottony, fugal masses, two inches or more in diameter. *The globules* discharge abundant of powdery *seeds* like smoke.

**BOTTOMRY,** col. 4. l. 23, for coarse *r. courts.*

**BOVISTA,** in *Botany,* a name of barbarous origin, being formed by Dilleniis from the German Boßfl. It is adopted by *Perfoon* for a genus separated from *Lycoperdon.* (See that article.)—Perf. Disp. Meth. 6. Syn. Fung. 136.—Claws and order, Cryptogamia Fungi. Nat. Ord. Fungi.

Eff. Ch. Cafe smooth, sillage, burting irregularly at the top; its white external coat (or wrapper?) at length separating in fragments. (Powder or feed brownish-purple.)

*Perfoon.*

The author defines four species.

1. *B. nigrescens,* which is Lycoperdon globosum, Bolt. Fung. t. 118. With. v. 4. 382, and L. arrhizon of *Batfch,* t. 29.

2. *B. plumosa,* figured in Sowerby's Fungi, t. 331, as *L. Boivis,* and judged by that author to be but a variety of the former.

3. *B. psilifera,* "Batfch, t. 41. f. 228;" akin to the first, but only three lines in diameter.

4. *B. surlurata,* figured by *Micheli,* Nov. Gen. t. 97. f. 6, who says it is common on heaths, and fold with other fungi of this tribe, in the market, at Florence. *Perfoon* is doubtful of the genus of this laft, and we should suspect it to belong possibly to *Tuber.*

*Boivis* differs from Lycoperdon in not being elongated at the base into a short *stalk,* but firmly they might, without violence to nature, be united, especially as the species of the present genus are so few and so disputable.

**BOURBON,** in Kentucky, l. 2. r. 11,869; l. 5. r. 2307.

**BOURN,** col. 2. l. 21. r. In 1811, the parish of Bourn contained 308 houses, and 1591 persons; 779 being males, and 812 females.

**BOURSIIPPA,** in Geography, a town of Babylonia, according to Strabo; to which Alexander retired, when warned by the Chaldrans not to enter Babylon. This is supposed to be the present village of Bouria, two leagues
to the S.E. of Hilleh, the site, as it is conjectured, of ancient Babylon. On the road from hence to Mesked Ali, or Neijf, is the tomb of the prophet Ezekiel, where they pretend to show the fiery furnace of Shadrach, Methuchel, and Abednego. It is a large clumsy building, without beauty or ornament; and, like the tomb of Ezra, on the banks of the Tigris, a short way above Korna, is much frequented by Jewish pilgrims.

Eff. Ch. Calyx in four deep segments, with intermediate teeth. Corolla tubular. Anthers within the tube. Capsule of two separable cells, with numerous bordered seeds.

1. B. triphylla. Three-leaved Bouvardia. Ait. n. 1. Salish. Parad. t. 88. (Houtonillia cocinea; Andr. Repof. t. 106. Ixora americana; Jacq. Hort. Schloenbr. v. 3. 2. t. 257. 1. ternifolia; Cavan. f. v. 4. 3. t. 305.)—Native of Mexico. Introduced by Sir Joseph Banks in 1794, and now become common in the English gardens, where, if planted against the front of a green-house, it will stand our ordinary winters, flowering from Midsummer till the end of autumn. The stem is from one to two feet high, shrubby, branched, downy when young. Leaves usually three in a whorl, ovato-lanceolate, varying in breadth, entire, rough-edged, nearly felty. Flowers an inch long, bright scarlet, in dense, terminal, forked panicles, very abundant, and extremely showy, though deficate of scent.

BOW, L. u. t., r. The pariah contains 149 houfes, and 727 perfons; 329 being males, and 398 females.

Bow, in America, L. 4. r. 729.

BOWDOIN, L. u., for 983 r. 1649.

BOWDOINHAM, L. u., for 455 r. 1412.

BOWLESIA, in Botany, so named by the authors of the Flora Peruana, in honour of Mr. William Bowles, a native of Ireland, who published at Madrid, in 1775, an Introduction to the Natural History of Spain, making a 410 volume of 529 pages, in the Spanish language. This work has been translated into French and Italian. The author died in Spain in 1768.—Sprengel Prodr. 24. Spec. Umbell. 13.—Cliffs and order, Peucandria Digynia. Nat. Ord. Umbelliferae.

Eff. Ch. Fruit ovate, quadranular, brilily; concave at the back. Umbel simple.

The author enumerates three certain species in his Prodrumus.

1. B. palmata, of Ruiz and Pavon, of which he gives no character or description.

2. B. Iokata, of the same, "Fl. Peruv. v. 3. t. 251, B." Spreng. Sp. Umb. 13.—Somewhat hairy. Leaves lobed, ribbed; abrupt at the base; lobes entire, pointed. Foot-flakes elongated. Flower-flakes axillary, mostly solitary. Tendrils none.—Native of the loftiest mountains of Peru. Herb slender, green, with some scattered flaky pubescence. Leaves opposite, an inch broad, half an inch long, five-ribbed, on slender zigzag foot-flakes about a finger's length. Stipulas membraneous, linear, in pairs. Flower-flakes about two lines long, reflexed after flowering, the stipulas serving as an involucre. Petals five, cream-coloured. Fruit in pairs, solid, ribbed at the back, clothed with flaky hairs.

FLOWER-flakeS axillary, aggregate. Tendrils axillary.—Native of Peru and Brazil. Our speciem was gathered in the last-mentioned country, by Commerson, and is larger than Sprengel’s figure, being a foot long, though incom- plete. This species seems nearly allied to the last. We discover no tendris in our specim.

BOWLING-Green, in Geography. Add—Allo, a town-ship of Ohio, in the county of Licking, having 379 inhabi- tants.

BOXBOROUGH, L. 2, for 412 r. 388.

BOXFORD, L. u., for 925 r. 880.

BOYU STON, L. u., for 839 r. 802.

BOYTON, Welsh, a town of the same county and state, having 672 inhabitants.

BOZAFA. Add—It contains 960 inhabitants.

BRACCI, plur. BRACCI, a measure for cloth in Italy.

BRACHIONUS. Add—See VERMES and WHEEL-Animals.

BRACHYSEMA, in Botany, so named by Mr. Brown, from brachy, short, and 6em6, a standard, alluding to a striking part of the generic character.—Brown in Ait. Hort. Kew. v. 3. 10.—Cliffs and order, Decandria Mon- gynia. Nat. Ord. Papilionaceae, Link. Leguminose, Jaff.

Eff. Ch. Calyx nearly equally five-echt; with a welling tube. Corolla papilionaceous; standard shorter than the compressed keel, which is equal to the wings. Stalk of the gemen minutely feathered. Style thread-shaped, elongated. Legume tumid, with many seeds.

1. B. laitifolium. Broad-leaved Brachysema. Ait. n. 1. Curt. Mag. t. 2008.—Leaves ovate, flat. Standard oblong-obovate.—Sent by Mr. Good, in 1803, from the south-west coast of New Holland, where it was also gathered by Mr. Brown. A hardy green-soue procumbent or pendulous shrub, easily propagated by cuttings, and flowering in the spring. Flowers scarlet, very hand Some, axillary, nearly celtose, solitary, sometimes two or three together, their small acute standard yellow at the base; wings and keel full an inch long.

There appear to be other species, yet not introduced into the gardens.

BRACKEN, in Geography, a county of Kentucky, having 3451 inhabitants, of whom 295 are slaves.

BRADFORD, col. 2. L. 11. r. In 1811, the houfes in the hundred of Bradford were 1766, and the number of perfons was $9455; 4269 being males, and 5166 females. The parih of Great Bradford contained 548 houfes, and 2959 perfons.

BRADFORD, in Yorkshire, L. 12. The parih of Bradford contains 10 townships, and in 1811 the townhip of East and West Bradford contained 1574 houfes, and 7767 perfons: East Bradford having 725 houfes, and 3559 perfons; 1653 being males, and 1866 females; and West Bradford having 849 houfes, and 4208 perfons: 1986 being males, and 2222 being females.

BRADFORD, East and West. Add—the former contained, in 1810, 1003, and the latter 1219 inhabitants.

BRADFORD, L. 4. r. 1369; L. 9. r. 1054; L. 12, r. 1302.

BRADYPUS,
BRADYPU S, L. 16, for floth r. bear; l. 29, after megaratheriu m, add — (which fee).

BRAIN, Chemical Analysis of. For Adipocere. r. Adipocere.
A new and elaborate analysis of the brain has been lately made by Vaquelin; but it must be confessed that his results throw no light whatever, upon the manner in which its constituents are combined, or to what its peculiar appearance is owing. The following are the results: 100 parts contain

Water - - - 80.
White fatty matter - 4:53.
Reddish fatty matter - .70.
Albumen - - - 7.
Olinazome - 1:12.
Phosphorus - 1:50.
Acids, salts, and sulphur 5:15.

BRAINTREE, in Geography. In 1811, the parish of Braintree contained 508 houses, and 2292 persons; 1082 being males, and 1216 females. The parish of Bocking contained 537 houses, and 2544 persons; 1134 being males, and 1410 females.

BRAINTREE, in America, l. 4, r. 850; l. 12, The inhabitants, in 1810, were 1531.

BRAMPTON, l. 20, r. In 1811, the number of houses was stated to be 265, and of inhabitants 2043; 920 being males, and 1123 females: 52 families being employed in agriculture, and 394 in trade and manufactures.

BRANDON, l. 4, r. In 1811, Brandon parish contained 206 houses, and 1360 persons; 646 being males, and 714 females.

BRANDON, in America, l. 2, r. 1375.

BRANDYWINE. Add—containing 1257 inhabitants.

ALLO, a hundred in the district of Delaware, and county of New-Caflle, containing 2257 inhabitants.

BRANFORD. Add—It contains 1932 inhabitants.

BRANTRIM, a township of Luzerne county, in Pennsylvania, containing 904 inhabitants.

BRASAVOLA, in Botany, has received its name from Mr. Brown, in memory of Antonius Mufa Brafevalus, or Brafevalo, an Italian physician and botanist, born at Ferrara in 1500. Haller, who inaccurately spells his name Brafevalus, speaks of him as not unlearned in books or languages, or in the plants of his own country. His works, which have been often republished, relate chiefly to the Materia Medica. Their author visited France in 1528, and died in 1555.—Brown in Ait. Hort. Kew. v. 5. 216.—Cliffs and order, Gymnandra Monandria. Nat. Ord. Orchidae.

Eff. Ch. Calyx and petals distinct, spreading. Lip undivided, with a fimple claw. Anther a terminal lid. Maffes of pollen eight or more.

We do not feel competent to form an opinion of this genus, having no knowledge but of one species. Mr. Brown, who has more in contemplation, considers the mass of pollen being sometimes more than eight a very remarkable character.

ment of resolvent plasters. Abscesses are to be treated on the principles explained in the article Suppuration.

BRECHIN, in Geography. In 1811, the burgh and parish of Brechin contained 769 houses, and 5559 persons; 2744 being males, and 2845 females.

BRECKENRIDGE, a county of Kentucky, containing 3430 inhabitants, of whom 505 are slaves.

BRECKNOCK, l. 1, for Lancaster r. Berks; and add—containing 723 inhabitants.

BRECKNOCK, col. 3, l. 4, after parishes, add—and in 1811 contained 718 houses, and 3196 inhabitants; 1433 being males, and 1763 females: 205 families employed in agriculture, and 375 in trade, manufactures, and handicraft.

BRECKNOSHIRE, L. 17, r. Théte, with the hamlets, were peopled in 1811 by 37,735 persons, and contained 7555 houses; 4667 families being employed in agriculture, and 2239 in trade and manufactures.—L. 35. The other rivers are the Irvon, which falls into the Wye above the town of Builth; the Tawe, which discharges its waters into the Bristol Channel at Swansea; the Taf; the Llynfi, which passes through Langorfe Mere or Llynfawdadd, and runs into the Wye at Gilabury; the Mellitie or Ildit, remarkable for its subterraneous passage in one part of its course; the Hafpate, celebrated for its beautiful cascade; and the Honduy at Brecknock. The principal lake in this county is Llynfawdadd; which see.—L. 41. The iron-works of this county are objects of great importance, in connection with its commerce and prosperity. The first of these is at Llangywey, in the parish of Llangenau, now forming an appendage to the works at Sirhowy in Monmouthshire: the next works are those in the vale of Clydach, in the parish of Llanelly: there is another in the parish of Llangattock; others are situated near the source of the Rumney river, on the borders of Glamorganshire: and those of Hirwaun, in the parish of Pendergast, at the southern extremity of the county.

BRENTA, in Commerce, a liquid measure in some parts of Italy, as at Bergamo.

BRENTFORD. Add—Old Brentford forms a part of Ealing parish, which in 1811 contained 922 houses, and 5361 inhabitants; 2509 being males, and 2852 females. New Brentford is a distinct parish, and contained 297 houses, and 1733 inhabitants; 809 being males, and 924 females.

BRENTWOOD. In 1811, Brentwood contained 218 houses, and 1238 persons; 575 being males, and 663 females.

BRENTWOOD, in America, l. 2, r. 905.

BRETON, CAPE, l. 6, for 34 r. 84.

BREWER. Add—By 43 Geo. III. c. 69. every common brewer of strong beer shall take out a licence, for which he shall pay according to the quantity of beer brewed by him within the year, as specified in the act, ending 5th July every year; but every person who shall first become a brewer of strong beer, for every such licence 12. 10s., and within ten days after the 5th of July, after taking out such licence, such further additional sum as with the said 12. 10s. shall amount to the duty hereinbefore directed to be paid, according to the number of barrels of strong beer brewed within the preceding year. If he neglect to take out such licence, and to renew it annually, ten days at least before the end of the year, he shall forfeit 50l. 24 Geo. III. c. 41. And every common brewer of table beer, not being a common brewer of strong beer, shall take out a licence and pay for the same yearly 12., to be renewed annually. By 42 Geo. III. c. 58. no person not being a common brewer shall be allowed to retail beer at any higher price than 1/4d. the quart without entering into a recognizance and obtaining a licence as an ale-house keeper, under pain of forfeiting for each offence 50l. over and above the penalty imposed upon selling beer without a licence. By 15 C. II. c. 11. notices of brewing beer or ale shall be given, and also of erecting or altering any implement for this purpose, on pain of 50l. By 5 Geo. III. c. 43. the position of any tun, cooler, copper, &c. shall not be altered without notice, under penalty of 20l. The officer of excise shall enter and examine suspeTed places; and if any person opposes him, he incurs a forfeiture of 20l. 7 & 8 W. c. 30. No common brewer shall use any pipes or other private conveyances from any copper in his brew-house, &c. on pain of 200l. 8 & 9 W. c. 19. 42 Geo. III. c. 58. Search shall be made by the officer, and the penalty of opposing him is 50l. No common brewer, inkeeper, victualler, or other retailer of beer or ale, shall keep any private florehouse or cellar for laying any beer or ale, or worts in calf, on pain of 50l. 15 C. II. c. 11. 1 W. r. c. 24. By 42 Geo. III. c. 38. every common brewer who shall lay off any beer, ale, or worts contrary to the 8 & 9 W. III. shall for each such offence forfeit 100l. Persons inhabiting a market-town, city or town corporate, or parts adjoinning to a city or town corporate, in which there is a common brew-house, who shall suffer liquors to be brewed in their houses, otherwise than for their own families or for purposes of charity or hospitality, and who shall lend out brewing vessels, shall forfeit 50l. 22 & 23 C. II. c. 5. Gaugers shall take an account, and obliterating them in the exercise of their office incurs a penalty of 10l. and forfeiture of double value for beer, ale, or other specified liquors that have been sold or delivered out, without payment of duty. If any brewer shall bribe the gauger to make a false return he shall forfeit 100l., and the officer to bribed shall forfeit the same sum; 5 C. II. c. 11. By 42 Geo. III. c. 38. the penalty on mixing liquors to imitate beer, and to be mixed with or used as beer made from malt and hops, or selling such liquors, is 200l. and forfeiture of liquor and utensils; and the penalty on a brewer's receiving idle beer-grounds, and mixing any liquor with beer, except malt and hops, is 100l. Excise officers are authorized to take samples of suspected liquors, search suspected places, and seize forbidden liquors, ingredients, and utensils; and the person in whose custody they are found shall forfeit 100l. No common brewer shall carry out any ale or beer to his customers in any city or market-town, before notice given to an officer of excise, but between three in the morning and nine in the evening from March 25 to September 25; and between five in the morning and seven in the evening from September 29 to March 25, on pain of 20s. a barrel; 15 C. II. c. 11.

And whereas it is expedient that the quantities to be returned as and for a barrel of beer or ale brewed by the common brewer and the allowances for waffe should be in all places the same, it is enacted that after the 5th day of July 1803 every 36 gallons of beer or ale brewed by the common brewers in Great Britain, whether within the weekly bills of mortality or without the same, taken according to the standard of the ale quart four thereof to the gallon in the exchequer, shall be reckoned and returned by the gauger or other officer of excise for a barrel of beer or ale; and the allowances to be made in Great Britain to the common brewer not selling beer, ale, or worts in any less quantity than a whole cask containing 42 gallons, whether within or without the said limits, for waffe by fillings and leakage, or otherwise, out of the returns by the gaugers, or other officers, shall be three barrels upon every 36 barrels, both of strong beer or table beer and ale, and after that rate for any greater or less quantity; 43 Geo. III. c. 69. A common brewer who shall sell beer, ale, or worts in any less quantity than in a whole cask containing 42 gallons, shall forfeit 50l. for every
such office. And if any person, not being a common brewer, shall retail beer at a higher price than after the rate of 14s. the quart, ale-houfe measure, without obtaining a licence as a common ale-houfe keeper, he shall forfeit 50l. over and above any other penalty for selling beer or ale without such licence; 42 Geo. III. c. 38. Entries shall be made by common brewers once a week, under penalty of 10l., and by innkeepers once a month on pain of 5l.; and also ale-houfe keepers, victualers, and other retailers, shall do the fame on penalty of 20l. Beer and ale above 18s. per barrel shall be deemed strong, and at 18s. and under, table beer; 43 Geo. III. c. 81. The 42 Geo. III. c. 38. regulates the price, &c. of table beer, and repeals as to this beer 22 Geo. III. c. 68. The penalty for selling table beer at more than the barrel price, exclusive of duty, is 100l.

BREWERIA, in Botany, so named by Mr. Brown, in memory of Mr. Samuel Brewer, a Wilshire botanist, the companion of Dillenius in a botanical visit to Wales, Anglesea, and the Isle of Man, in 1726, and subsequently one of his most valuable correspondents, especially for the Cryptogamic department. Mr. Brewer spent the latter part of his life at Bradford, under the patronage of Dr. Richardson, and, according to Dr. Pulteney, was living in 1742.—

There are diffusely herbs, not milky; their leaves undivided; flowers axillary, mostly solitary. The genus appears most akin to Paraca, differing in habit, and in the unaltered calyx of the fruit.

2. B. media. Intermediate Breweria. Br. n. 2.—Slightly villous. Leaves lanceolate; obtuse and somewhat heart-shaped at the base. Style divided half way, into two unequal segments.—From the same country. Br.

We know not whether there be any more species in other parts of the globe.

BRESTER, in Geography, a town of Barnstable county, in the Mafhachusetts, containing 1812 inhabitants.

BRIBIESCA, Del.

BRIDELIA, in Botany, a genus separted from Cluytia by Willdenow, and dedicated by him to the honour of the great systematic museologist, Dr. Samuel El. Bridel. —

Eff. Ch. Calyx inferior, in five deep segments. Petals five, inserted into the calyx. Stamens with a tubular, columnar base. Styles two, divided. Berry with two seeds. Some flowers want the stamens, some others the germen.

The fruit distinguishes this genus from Cluytia. (See that article.) Three species only are described, all East Indian.

1. B. montana. Mountain Bridelia. Willd. n. 1. (Cluytia montana ; Roxb. Corom. v. 2. 38. t. 171.)—Stem erecct, without thorns. Leaves obovate-elliptical, entire, smooth.—Native of Coromandel. On the interior mountains it grows to a tree, but on the lower lands is only found of a small size. The Telingas call it Puntinga. Roxb. The wood is reddish, very hard. Stem short and thick. Branches slender, spreading. Leaves numerous, alternate, two-ranked, an inch and a half long, on short hairs. Flowers small, crowded, axillary. Berry purple, globular, succulent, the faze of a pea.

2. B. sandana. Climbing Bridelia. Willd. n. 2. Ait. n. 1. (Cluytia sandana; Roxb. Corom. v. 2. 39. t. 173.)—Stem shrubby, climbing, without thorns. Leaves oblong-obovate, entire, acute; Downy beneath.—Common on the banks of rivers and water-courses, on the coast of Coromandel, flowering in November and December, and called by the Telingas Dongkhoora. Roxb. Stem climbing; its branches leafy, flowering at their pendulous extremities. Leaves three inches long; those which accompany some of the flowers diminished almost to bracteas. Berry oval, of a rufly black; the fize of a horse-bean. This species was sent to Kew in 1824, by colonel Hardwicke, E.L.S., so well known by his various communications, illustrative of the natural history of India.

3. B. spinosa. Thorny Bridelia. Willd. n. 3. (Cluytia spinosa; Roxb. Corom. v. 2. 38. t. 172.)—Stem arborescent, erect, thorny. Leaves ovate, acute, entire, smooth.—A tree of considerable fize found on the mountains along with the first species, and called by the Telingas Cora-mou. The bark is a strong astringent; wood hard and durable, dark-coloured; leaves eaten greedily by cattle, and said to destroy worms in their bowels. Roxb. The leaves are three or four inches long. Flowers in terminal, or axillary, interrupted spikes. Berry black, the fize of a pea.

BRIDGEFORD, l. u. r. The parish of Newcastle, higher and lower, contains 157 houfes, the former having 40, and the latter 117; and 640 inhabitants, the former including 171, and the latter 469. In the higher, the males are 84, and females 87; in the lower, the males are 216, and females 259.

BRIDGENORTH, col. 2, l. 9, add.—In 1811 the borough of Bridgenorth contained 978 houfes, and 4386 persons; 2006 being males, and 2380 females; 81 families employed in agriculture, and 987 in trade and manufactures.

BRIDGEPORT, a townshif of Pennsylvania, in Fayette county, having 280 inhabitants.

BRIDGEGTOWN, a town of the district of Maine, in the county of Kennebec, containing 214 inhabitants.

BRIDGE-TOWN, l. 5, r. 882.

BRIDGEWATER, col. 2, l. 26, add.—In 1811 the borough of Bridgewater contained 857 houfes, and 4911 persons; 2241 being males, and 2670 females; 87 families employed in agriculture, and 570 in trade and manufactures.

BRIDGEWATER, in America, l. 3, r. 1104; l. 4, r. 2906; l. 5, r. 344; l. 6, r. 5157; l. 10, r. 1154. Add,—Also, a townshif of Luzerne county, in Pennsylvania, having 1418 inhabitants.

BRILDINGTON, l. u. r. In 1811 Bridlington contained 849 houfes, and 3741 inhabitants; 1706 being males, and 2035 females.

BRIDPORT, l. 19, r. 1148, add.—In 1811 the town of Bridport contained 512 houfes, and 3567 persons; 1532 being males, and 2035 females; 20 families employed in agriculture, and 600 in trade and manufactures.

BRIDPORT, in America, l. 3, r. 1520.

BRIGHthemSTON, l. u. r. In 1811 Brighton contained 2077 houfes, and 12,012 persons; 5069 being males, and 6043 females.
BRIGHTON, a town of Massachusetts, in Middlesex county, having 608 inhabitants.

BRIMFIELD, l. 3, r. 1325.

BRISTOL. Add.—In 1811, this city, with Barton Regis hundred, contained 11,940 houses, and 76,433 persons; 32,842 being males, and 43,591 females.

BRISTOL, in America, l. 2, r. 2753; l. 5, r. 37,168; l. 13, r. 5072; l. 23, r. 2693; l. 29, add.—It contains 1458 inhabitants; l. 33, after hovres, add.—The number of inhabitants, by the census of 1810, was 628; l. 36, after county—having 967 inhabitants; l. 39, r. 1179, add.—Alto, a township of Pennsylvania, in Berks county, having 1608 inhabitants.

—Alto, a township of Ohio, in the county of Trumbull, having 202 inhabitants.

BRITAIN, Little, a township of Pennsylvania, in Lancaster county, containing 1708 inhabitants.

BRITAIN, London, a township of Luzerne county, having 403 inhabitants.

BROAD CREEK, a hundred of Delaware, in the county of Suffolk, having 3789 inhabitants.

BROCKLESBY, l. 10, after Ballytore, add.—(which fee,) and dele the remaining part of the sentence.

BRODIEA, in Botany, is named by the writer of the present article, after James Brodie, clg. F.L.S., of Brodie in North Britain, an experienced and liberal British botanist, whose name often occurs in the English Botany, and to whom a genus of the patrician order is with great propriety inferiur.—Sm. Tr. of Linn. Soc. v. 10. i. Pursh 223.

Gen. Ch. Cal. none, unless the bracteae be so called. Cor. of one petal, belf-shaped, cut half way down into fix nearly equal, oblong, rather spreading segments; throat crowned with three erect scales, shorter than the limb, opposite to three alternate segments. Stam. Filament three, inserted into the tube between the scales, and opposite to the other three segments, awl-shaped, erect; anthers vertical, linear, shorter than the scales, cloven at each end. Pijl. Germin superior, elliptic-oblong, triangular; five-celled, nearly the length of the flaments; stigma triangular, three-lobed. Peric. Capsule of three cells and three valves, with central partitions. Seeds numerous, elliptic-oblong, inserted into the inner margin of each partition in two rows.

Eff. Ch. Corolla inferior, tubular; limb regular, in fix deep segments; throat crowned with three scales, alternate with the flaments. Capsule of three cells, with numerous seeds.

1. B. grandiflora. Large-flowered Brodiaea, or Missouren Hyacinth. Sm. n. l. Pursh n. 1. (Hookera cornorata; Sall. Parad. t. 98.)—Scales of the corolla undivided. Partial flarks longer than the flowers.—Discovered by Mr. Menzies in 1792, in New Georgia, on the west coast of North America. Governor Lewis is recorded to have gathered this plant on the plains of the Columbia and Missouren rivers, flowering in April and May. It is reported to have bloomed in Mr. Salkbury's garden, but is not admitted into Hort. Kew. or the Addenda to that work. The root is bulbous, solid. Leaves two, radical, linear, channelled, near a foot long. Flower-stalk solitary, bearing an unequal, braacteate umbel, of upright, handsome, blue flowers, each near an inch long, with yellowish scales, and yellow anthers.

2. B. congesta. Crowded Brodiaea. Sm. n. 2. l. 1.—Scales of the corolla cloven. Partial flarks much shorter than the flowers.—Brought by Mr. Menzies, with a coloured drawing, from New Georgia. The flowers are rather numerous, smaller than the foregoing, and form a dense head, subtended by pointed bracteae.

BROKENSTRAW, a township of Warren county, in Pennsylvania, having 379 inhabitants.

BROMELIACE, in Botany, the 15th order in Jussieu's system, the 6th of his third class. See Junco.

The Bromeliace are thus defined. Calyx (Corolla of Linneas) in fix, more or less deep, segments, either superior or inferior, equal, or mostly unequal, the three alternate divisions being large. Stam, fix, inserted into the bottom or middle of that part, or sometimes into calycine glands, lying over the germin. Germin simple, superior or inferior; style one; stigma three-cleft. Fruit of three cells, either pulpy and not burstin, or capsular and of three valves; each cell containing one or many seeds. The leaves are scathing, all for the most part radical. Flowers spiri, panicled, or more rarely corymbose, each accompanied by a spathe.

Sect. 2. Germin inferior. Xerophyta, Bromidia, and Agave.

BROMSGROVE, in Geography. In 1811, the parish of Bromsgrove contained 1578 houses, and 6932 persons; 3349 being males, and 3583 females: 357 families employed in agriculture, and 1895 in trade and manufactures.

BROONZE. See Mineralogy, Addenda.

BROOK, Hone, in Geography, a township of Pennsylvania, in Chester county, with 1723 inhabitants.

BROOK, a county of Virginia, containing 5843 inhabitants, including 332 slaves.

BROOKFIELD, l. 4, r. 3170; l. 11, for 428 Port. 1384; l. ult., add.—containing 1037 inhabitants.

BROOKLINE, a town of New Hampshire, in Hillsborough county, having 538 inhabitants.—Alto, a town of Vermont, in Windsor county, having 431 inhabitants.—Alto, a town of New Hampshire, with 657 inhabitants.—Alto, a township of Ohio, in the county of Trumbull, having 345 inhabitants.

BROOKLYN, l. 2, 704 inhabitants; l. ult. containing 1200 inhabitants.

BROOME, a county of New York, including 8130 inhabitants.

BROSELEY. In 1811 this parish contained 1026 houses, and 4850 persons; 2448 being males, and 2402 females: 48 families employed in agriculture, and 856 in trade and manufactures.

BROTERA, in Botany, a name applied to two very different plants, in due commemoration of the Rev. Father Felix Avellar Brotero, professor of botany at Coimbra in Portugal, author of the Flora Lusitaniae, and several other learned works. The Brotera of the late professor Willdenow, Sp. Pl. v. 3. 2399, Carthamus corombojus of Linnæus, appears to us founded on a total misconception of the structure of the flower, in which we can find no character whatever different from Carthamus. This genus is, however, adopted in Ait. Hort. Kew. v. 5. 186, according to the general plan of that work, where the editors had no particular object of reformation or illustration in view. The other Brotera is published by professor Sprengel, in Tr. of Linn. Soc. v. 6. 515. Its only species is B. pectinata, brought by Olivier and Bruquière from Peru. We regret to observe that this is manifestly a Hyptis (see that article); and we lament that it was, from full confidence in its learned and distinguished author, too incautiously admitted into the Linnaean Transactions, for which...
which the writer of this acknowledges himself entitled to a
share of the blame.

BROTHERS' VALLEY, in Geography, a township of
Pennsylvania, in Somercounty, having 1314 inhabitants.

BROUGH. In 1811, this township contained 131
houses, and 178 persons; 369 being males, and 389 females.

BROUGHTONIA, in Botany, so called by Mr.
Brown, in memory of the late Mr. Arthur Broughton, of
Bristol, author of an "Enchiridion," or systematical
manual of British plants, published in 1782; and, after his removal
to Jamaica, of the Hortus Elytensis, and of a Catalogue of the

Eff. Ch. Calyx and petals spreading. Column unconnected,
or attached at the base only to the falked lip. Anther a
moveable lid. Mallees of pollen four, parallel, divided by
complete permanent partitions, and extending at the base
into an elastic granulated thread.

Obi. In some instances the base of the lip is elongated
into a little tube, attached to the fermen.

radice bulbos insert, delphinii flore rubro specieo; Slaone
Jam. v. 1. 250. t. 121. f. 2.—Leaves oblong, in pairs
from the top of a bulb. Flower-fstalk divided.—This
 grows on trees and palisades in the woods of Jamaica,
forming tufts of leaf-bearing bulks, the leaves light green,
two inches long. Stalks radical, a foot high, with a few
hairs, corollae, dark crimson flowers.

This is the only species yet known in our flores, nor
have we an account of any other.

BROUSSONETIA, in Botany, (see PAPYRUS),
where the history and description of this curious tree are
given.

BROWN SPAR, or Better SPAR. See MINERALOGY,
Addenda.

BROWNFIELD, I. 2, for York r. Oxford; I. 3, r.
398.

BROWNINGTON, a town of Vermont, in Orles
county, having 236 inhabitants.

BROWNSVILLE. Add.—It contains 608 inhabitants.

BRUCHUS, I. 8. dele which see respectively, and
inert—the infects of this genus are, in general, of a small
kind. The B. granarius is found among leaves, vetches,
and other seeds, the lobes of which it devours. It is about
two lines long, of a black colour, and its wing-flblls are
freckled with white specks; the two fore-legs are reddish,
and the thighs of the hind-legs armed with a tooth and forc
ceps. The B. seminarius is rather smaller than the preceding,
but like it, without the denticle of the hinder thighs.
The exotic species are chiefly natives of America.

BRUNERSTOWN, in Geography, a town of Ken
ucky, in Jeffercon county, with 62 inhabitants, of whom
four are slaves.

BRUNONIA, in Botany, so named by the writer of this,
after his highly-valued friend Mr. Robert Brown, F.R.S.
librarian to the Linnean society, no less eminent for acute
ness of observation, than for deep botanical science, whose
discoveries in New Holland have so often been brought
before our readers, and who met with this new and singular
genius in that country. The memory of Dr. Patrick Brown,
the natural-historian of Jamaica, being already preferred in
the Brownm. (see that article) it has been found neces
sary to adopt the above construction, authorized by prece
dent, to avoid ambiguity.—Sm. Tr. of Linn. Soc. v. oc.
365. Brown Prod. Nov. Holl. v. 1. 589.—Chas and
order, Pentandria Monogynia. Nat. Ord. Aggregate, or
perhaps Campanzaceae. Linn. Dipsaces, Juff.? Goodenovia?
Brown.

Gen. Ch. Cal. Perianth double, both inferior; outer
of four mememious, nearly equal, erect, concave, obtuse
leaves; inner of one leaf, rather the longest, turbinate,
permanent, with five feather teeth. Cor. of one petal,
funnel-shaped, longer than the calyx; limb in five deep
spreading, nearly equal segments, the two upper ones mott
deeply divided; tube separable into five narrow claves.
Stam. Filaments five, capillary, weak, inserted into the
recepracle; anthers linear, united into a cylinder, the
length of the tube of the corolla. Pfl. Germin superior,
roundish; fyle club-shaped, about twice the length of the
flaments; stigma turbinated, obtuse, concealed by two ver
tical, equal, orbital, concave, membranous, converging
valves. Peric. none, except the inner perianth, lined with
the membranous base of the corolla, both together enlarged
and hardened, and crowned with the five feathery teeth
divided and disarticulated, so as to form a seed-crown.
Seed solitary, covered, ovate, delitute of albumen, with
an erect embryo.

Eff. Ch. Corolla funnel-shaped, five-cleft, irregular.
Anthers combined. Stigma with a bivalve sheath. Seed
one, covered with the feathery-crowned inner calyx.

The generic diffinction of Brunonia are abundantly
easy; but to determine its natural order, or affinities, is
very difficult, the latter being so many, and so remote from
each other, that the plant resembles Horaces's imaginary
feathered moniter, with a horse's neck and human head.
Mr. Brown, in the latest view he has taken of the subject,
in a most invaluable paper, on the natural order of Compo
fites, Tr. of Linn. Soc. v. 12. 132, has pointed out Brun
onia as a connecting link between that family and the
Goodenovic; nor are various other links between these very
different tribes wanting. With great candour he neverthe
less admits whatever favours our idea of its relationship
to Dipsaces and Glabolariæ, and moreover adverts to circum
stances approaching it to the Stylijdes, near allies of Gooden
ovic. Two species only have been detected.

2. B. australis. Australian Brunonia. Sm. as above,
367. t. 28. Br. n. 2.—Leaves clothed with spreading
hairs. Segments of the calyx feathery all over.—Native of
the sandy coasts of the south part of New Holland.
Abundant in Van Diemen's istlnd, and observed also on
the opposite shore of New Holland, at Port Phillip, flower
ing in January 1804. Mr. Brown. Herb apparently an
nuai, without a stem, hairy all over, much resembling in
habit, colour, and pubescence, the Linnæan Scabia aetrica.
Root simple, slender. Leaves radical, numerous, spathulate,
pointed, fingle-ribbed, entire, tapering at the base, two or
three inches long, very hairy. Flower-fstalks radical, foli
tary, simple, hairy, especially the lower part, a foot high,
each bearing 3 head of numerous blue flowers, not unlike
the Sheep's Scabious, Jafane montana, but rather larger,
and loofely hairy. The head is subtended by numerous,
neally equal, spreading, permanent, hairy bractees, shorter
than the flowers; the inner ones smallest, foliary under
each flower.

2. B. serticca. Silky Brunonia. Sm. as above, 367.
t. 29. Br. n. 1.—Leaves silky with close-pressed hairs.
Segments of the calyx with naked coloured tips.—Gathered
by Mr. Brown, on the sandy sea-shore at Pine Port, on the
cast coast of New Holland, just within the tropic, flower
ning in August 1802. The aspect and pubescence of this
species
species exactly answer to Scabiosa granitifolia. It differs from the foregoing in having narrower, more numerous, silky leaves, and the flowers differ remarkably in the blunt, coloured, naked pointed of their inner calyx.

BRUSVGIA, so named in 1753, by Heiffer, in compliment to his patron Charles duke of Brunswick Luneburg. What were his serene highness's claims to this honour, we know not, nor is Heiffer any authority in such a cause (see his biographical article); but we hope all Englishmen will ever have reason to hail the name of Brunswick, wherever it appears, and the genus in question, long confounded with Amaryllis, being now restored, the name of Brusvigia appears with peculiar propriety in the royal garden of England.—Heiff. Brunsv. 2. Ait. Hort. Kew. v. 2. 230. Ker in Curt. Mag. under p. 923*—Class and order, Herandria Monogynia. Nat. Ord. Spathaceae. Linn. Narcei, Jaff. Gen. Ch. Col. an oblong, obtuse, compressed, leafy sheath, of two valves, withering. Cor. superior, in six deep, lanceolate, recurved, nearly equal segments. Stam. Filaments six, awl-shaped, about the length of the corolla; anthers oblong, incumbent. Ptil. Germen inferior, obove, with three furrows and as many rounded angles; style thread-shaped, the length and position of the stamens, stigma bluish. Peric. Capsule turbinate, abrupt, with three rounded wings, membranous, somewhat transparent, of three cells and three valves. Seeds spherical, ovate, acute; curved and compressed at the point.

Eff. Ch. Corolla superior, in six deep segments. Capsule turbinate, membranous, with three wings. Seeds several, ovate, acute;

1. B. multiflora. Broad-leaved Brusvigia. Ait. n. 1. (Brunsvigia; Heiff. as above, t. 1. Amaryllis orientalis; Linn. Sp. 422. Willd. Sp. Pl. v. 2. 58. Jacq. Hort. Schoenbr. v. 1. 38. t. 74. Narcissus indicus fpharamicus; Moris. feet. 4. t. 10. f. 35. N. indicus, flore liliaceo, fpharamicus; FERRAR. FL. 125. t. 129. 131. 133.)—Leaves tongue-shaped, depressed, smooth. Flowers somewhat irregular, with ascending stamens and style.—Native of the Cape of Good Hope. The bulb is not uncommon in our flowers, but we never heard of its flowering. That desirable event however happened in the imperial garden at Schoenbrun, and has enabled the late professor Jacquin to adorn his Hort. Schoenbr. with one of the most splendid botanical figures extant. This is perhaps the most flatly of its flatly tribe. The large fealy bulb bears five or six obovate-oblong, dark green leaves, lying over each other in two ranks, and usually a foot long, near three inches broad. Flower-flask earlier than the leaves, erect, round, a foot high, crowned with a broad flabel, of two coloured valves, unequal in breadth, accompanying a very large umbel, of about thirty-five rays, spreading in all directions, each six inches long, bearing a solitary erect flower. All the flaks are more or less of a blood red. Corolla richly varied with crimson and a kind of orange scarlet; its segments an inch and a half long, acute, converging into a tubular form at the base, spreading in the upper part, and reflexed. Capsule two to four inches long, and one broad, pale brown, shining; tapering very much at the base.

2. B. marginata. Red-edged Brusvigia. Ait. n. 2. (Amaryllis marginata; Jacq. Hort. Schoenbr. v. 1. 34. t. 65. Willd. Sp. Pl. v. 2. 59.)—Leaves tongue-shaped, depressed, smooth, with cartilaginous edges. Flowers regular, with erect stamens and style.—Native of the Cape, from whence Mr. Maffon sent bulbs in 1795. Leaves rather narrower than the former, with a hard red border. Umbel erect, dense, of many scarlet flowers, with upright stamens and style, rising high above the reflexed corolla. Anthers purple.

3. B. radula. Rapf-leaved Brusvigia. Ait. n. 3. (Amaryllis radula; Jacq. Hort. Schoenbr. v. 1. 35. t. 68. Willd. Sp. Pl. v. 2. 61.)—Leaves elliptical, depressed, rough with britle tuberces. Flowers ringlet, with declining stamens and style.—From the same country, introduced by Mr. Maffon, in 1790. Leaves two, scarcely more, three inches long, rough-edged, covered on the upper side with britle-pointed warts. Stalks three or four inches high, sometimes in pairs. Umbels of only four or five pink and white flowers, five of whose segments are directed upwards, the fifth deflexed, along with the stamens and style.

4. B. striata. Striated Brusvigia. Ait. n. 4. (Amaryllis striata; Jacq. Hort. Schoenbr. v. 1. 36. t. 70. Willd. Sp. Pl. v. 2. 61.)—Leaves elliptical-obovate, erect; densely striated beneath. Flowers nearly regular, with declining stamens and style.—From the same country as all the rest, introduced by Mr. Maffon in 1795. Larger than the last, and distinguished by its upright red-edged leaves. Umbel of many flowers, whole outside of rose-coloured, inner paler, or white, the segments narrow, nearly or quite regular.

BRUSWICK, in Virginia, l. 3. r. 15. 411 inhabitants, including 9368 slaves; 1. 5. r. 4378; 1. 6. r. 2254; l. 19. add.—containing 143 inhabitants.

BRUSWICK, North, contains 3980 inhabitants.

BRUSWICK, South, contains 2332 inhabitants.

BRUSWICK, in Maine, l. 5. r. 2682.

BRUSWICK, a township in Berks county, in Pennsylvania, having 1770 inhabitants.

BRUSH CREEK, a township of Ohio, in the county of Highland, containing 551 inhabitants.

BRUSSELS, Roger of, r. BRUGES, Roger of.

BRUTON, col. 2. l. 2. r. In 1811, the parish of Bruton contained 553 houses, and 1566 perfons; 658 being males, and 878 females.

BRUTUS, l. 5. r. Cayuga. Subjoin—This is an excellent township of Cayuga county, about 10 miles long, N. and S., by 5 to 6 ½ E. and W. The soil is rich and fertile, and well watered: it contains about 330 families, and 182 senatorial electors. It was erected in 1802, from the N.E. part of Aurelius. In 1810 the population was 2030, and the taxable property amounted to 84,514 dollars.

BRYAN, l. 3. add.—containing 2827 inhabitants, of whom 2264 are slaves.

BUBALIS. See Antelope.

BUBASTUS, dele fee Didyma.

BUCCO, col. 2. l. 1. after cinereus, dele which fee, and add.—These are all inhabitants of Africa, and the warmer parts of Asia and America. Their head is very long, their bills strong and nearly straight, almost covered with bristles; tail-feathers generally ten. They are a solitary rapid race, living in sequestered forests, and subsisting principally on insects.

BUCEROS. Add—Several other species are mentioned by Dr. Shaw.

BUCHEANAN, l. 7. l. 9. infant—in 1532. Col. 3. l. 9. infant—in 1532. l. 10. r. Caflilis; l. 15; r. 1533; l. 18—this happenedprobably in the year 1537; l. 43. after said bargain, but without sufficient evidence; l. ult. but one, infant after admired.—The next in merit is the 137th, in elegiac verse. Col. 3. l. 19, after country; infant.—In 1562, he officiated as clerical tutor to the queen, who was then in the 20th year of her age, and who many afternoons perused with him a portion of Livy. About the year 1566, &c.: l. 30, after York, infant—in 1568; l. 35, after VI, infant—
— in 1570, when the young prince was only four years of age; l. 43, after reading, infert— when the countess of Mar, hearing him walking, hurried and took him up in her arms, reproaching the tutor for having laid his hand upon the Lord’s anointed. Buchanan is said to have replied in terms that contained a very unceremonious anti-theism relative to the part which had received the chaffiment. Col. 4, l. 9, after motives, infert—and it likewise evinces his anxiety for forming a patriot king; l. 15, for 5th of December r. 28th of September; l. 23, after Edin-burgh,—in the cemetery of the Grey Friars. Col. 5, l. 10, after unequal, add—although he maintains the unscientific notion that the earth does not revolve round the sun, he sup-ports his opinion by arguments which must at least be allowed to be plausible; l. 9, from the bottom, after great man, infert—neglected by his ungrateful country, which never afforded his grave the common tribute of a monumental stone. Subjoin—See Irving’s Life of Buchanan.

BUCKENHAM. In 1811, the parish of New Buck-enham contained 127 houses, and 656 inhabitants; 315 being males, and 341 females. The parish of Old Buck-enham contained 200 houses, and 1024 persons; 491 being males, and 533 females.

BUCKINGHAM. In 1811, the borough of Bucking-ham contained 572 houses, and 2987 persons; 1313 being males, and 1674 females: 232 families employed in agriculture, and 466 in trade and manufactures.

BUCKINGHAM, a county of America, l. 3 and 4, for 1790 r. 1810; for 1797 r. 20,059; for 1818 r. 11,675.— Alto, a township of Bucks county, in Pennsylvania, having 1715 inhabitants.— Alto, a township in Wayne county, in the same state, having 1513 inhabitants.— Alto, a township in one county, the same state, having 13933 families employed in agriculture, and 8424 in trade and manufactures.

BUCKLAND, l. 2, for 718 r. 1097.

BUCKS, l. 5, for 25,401 r. 32,171; for 114 r. 11; l. 7, for 27 r. 29.

BUCKSTOWN, a township of Ross county, in the dis-trict of Ohio, containing 781 inhabitants.

BUCKSTOWN, l. 3, for 316 r. 4403.

BUENA, in Botany, Cavan. l. c. v. 6. 49. t. 571, is a genus of the natural order of Rubiaceas, so named by that author, in honour of Dr. Cosmo Bueno, an eminent writer on the natural history and topography of Peru. There is no certain proof of this genus being distinguish from what Ruiz and Pavon had already called Gonolagunia. We are equally unacquainted with both.

BUFFALEO. Add—East Buffaloe contains 2869, and West Buffaloe 2523 inhabitants.— Alto, a township of Penn-sylvania, in Washington county, having 1416 inhabitants.— Alto, a township in Armstrong county, in the same state, having 1150 inhabitants.— Alto, a township of Butler county, with 375 inhabitants.— Alto, a township of Ohio, in the county of Guernsey, having 285 inhabitants.— Alto, a township of Ohio, in the county of Jefferson, having 696 inhabitants.

BUILDING. See 1. 47, for 42d r. 14th.

BUILTH, or Buillett, derived from Bu, an ox, and illt, an eminence, i.e. a wooded eminence, bearing reference to the adjacent country. Col. 2, l. 13, for two weekly r. one good market on Monday; for three r. five; after contains, r. by returns of 1811, 182 houses, and 815 inhabitants; 384 being males, and 421 females. The hundred of Builth included 1086 houses, and 5788 persons; 2698 being males, and 3090 females: 833 employed in agriculture, and 284 in trade, manufactures, and handicraft.

BULLET, a county of Kentucky, having 4311 inhabitants, including 976 slaves.

BULLOCK, a county of Georgia, in America, containing 2305 inhabitants, 420 being slaves.

BULLSKIN. Add— containing 1439 inhabitants.

BUMCOMBE, a county of North Carolina, containing 9277 inhabitants, of whom 695 are slaves.

BUMEN. See Regan.

BUMGALOW, a term used in Bengal for a kind of country-house erected by Europeans.

BUNIUM, col. 2, l. 20, for They r. Ray.

BUPHAGA, l. 6, for legs r. feet.

BUPRESTIT. At the cloke, del which see respectiely, and add—The B. gigantea is the largest of this genus hitherto discovered, being two and a half inches long; a native of India, China, and many other parts of Asia; and found also in South America. The European insects of this genus fall far short of the Indian or American species both in size and splendour.

BURCHARDIA, in Botany, is thus named by Mr. Brown, in commemoration of Dr. John Henry Burchard, author of a letter to Leibnitz, in 1702, in which the found-er principles of botany are developed; the exclusive importance of the parts of fructification, in forming characters, are especially inflected on, and the classification of Linnæus, by the flamos and petals, is anticipated. Heifter published this letter, for the first time, in 1750, probably to deprecate the honour of Linnæus. But as the latter could have heard nothing of Burchard’s sentiments, he has all the merit of originality, and the attempt to deprive him of this credit, serves only to show the high estimation in which his performance was held. Heifter has named a plant Burchardia, but this is Callicarpa of Linnæus, so called many years before.—Brown Prodr. Nov. Holl. v. 1. 272.—Cliffs and order, Hexandra Trigynia. Nat. Ord. Melanthaceae, Br. Eeff. Ch. Petals fix, equal, spreading, with a nectariferous cell in the claw of each, deciduous. Stamens inserted into the base of the petals. Anthers peltate, posterior. German triangular. Stigmas acute. Capsule of three separable boat-like cells, bursting at the inner edge. Seeds numerous, in two rows.

BURG upon the Sands, l. 4, r. as he was preparing for an expedition against the Scots. Hume.

BURICH. For Buderich r. Buderich.

BURKE, in Geography, l. 2, r. 11,007; l. 3, r. 1433; l. 5, r. 10,747 and 4691; l. 9, add— containing 460 inhabitants.

BURKSVILLE, a town of Kentucky, in Cumberland county, containing 106 inhabitants, of whom 20 are slaves.

BURINGTON, l. 6 and 7, for 8,095 r. 24,979, and for 227 r. 93; add—It contains 12 townships; l. 15, r. 2419, and 4 slaves.

BURINGTON, a township of America, &c. l. 3, add—This township is well watered, and bounded with mill-heats; its situation is elevated, and the air salubrious: the population is 3196; the senatorial electors 294, and the taxable property,
property, in 1810, amounted to 178,783 dollars. It has two Baptist meeting-houses, one for Congregationalists, and one for Quakers. The inhabitants are principally farmers.

BURTON, a town of Massachusetts, in Middlesex county, containing 471 inhabitants. — Alto, a town of Hartford county, in Connecticut, having 1467 inhabitants.

—Allo, a township of Lycoming county, in Pennsylvania, having 661 inhabitants.

BURNING, *Extraordinary Casket of.* Col. 3, l. 11, for of the head r. and the head; l. 5, for 332 r. 1690.

BURNLEY, l. ult. after contains, add—by the return of 1811, 807 houses and 4368 inhabitants; 2129 being males, and 2230 females.

BURRILLVILLE, a town of Rhode island, in the county of Providence, containing 1834 inhabitants.

BURSARIA, in Botany, so denominated by Cavanilles, from *Burfsa,* a pure; because the seed-veil resembles that of the common weed called Shepherd's-purse.—Cavan. *L. v.* 4. 30. — Clas and order, *Pentandria Monogynia.* Nat. Or...…..

Eff. Ch. Petals five, inserted into the receptacle. Capsule superior, compressed, of one cell, with four valves. Seeds two, winged.

1. B. *Stipa.* Thorny Burfaria. Cavan. *L. v.* 4. 30. t. 330. Ait. n. 1. (Itea *Stipa* ; Andr. Rep. t. 314.)—Native of New South Wales; first raised in 1793, by the late marchioness of Rockingham. This is a thorny, bushy, green-houfe shrub, flowering from August to December. The leaves are ferrated, ferial, narrow-wedge-shaped, emarginate, smooth, entire. Flowers numerous, white, small, in copious, aggregate, terminal clusters, of considerable elegance.

BURTON in Kendal, l. ult. after contains, add—by the return of 1811, 94 houses and 574 persons; 274 being males, and 300 females. There is another township, named Holme, in the same parish, containing 43 houses, and 283 persons; 137 being males, and 146 females.

BURTON-upon-Trent, l. 4 from the close, add—By the return of 1811, contains 785 houses, and 5979 persons; 1844 being males, and 2135 females.

BURTON, l. 1, for Grafton r. Stafford; for 143 r. 194. Add—Allo, a township of Ohio, in the county of Geauga, having 517 inhabitants.

BURTONIA, in Botany, so named by Mr. Brown, in memory of the late Mr. David Burton, a celebrated collector of plants for the Kew garden, under the patronage of Sir Joseph Banks. He died after a short stay in New South Wales; but Mr. Aiton's work evinces the great diligence of this unfortunate traveller. Mr. Salisbury's original Burtonia proved an Hibbertia. (See that article.)—Brown in Ait. Hort. Kew. v. 3. 12.—Clas and order, *Decandria Monogynia.* Nat. Or. *Papilionaceae,* Linn. *Leguminosae,* Jaff.

(Bompholium scabrum; Sm. Tr. of Linn. Soc. v. 9. 250.)—Leaves ternate. Calyx smooth. Style bearded beyond the middle.—Found by Mr. Menzies, on the south-west coast of New Holland; and sent to Kew by Mr. Good, in 1803. A green-houfe shrub, flowering from May to July. The leaves are ternate, cleft, linear, revolute, rough to the touch. Flowers about the ends of the branches, axillary, dull purple when dried. There is no account of their natural colour. We do not perceive any important difference in character, and there is none in habit, between this plant and *Bompholium* (see that article); but the unpublished species may be more distinct.

BURY, l. 10, after Fleeke, add—created a baronet in 1809, who, about the year 1773; l. 15, add—In the course of his prosperity he purchased a seat at Chamber-hall, in the neighbourhood, which he Afterwards sold; l. 18, for Bolton in Yorksire r. Bolton-de-Moores in Lancashire; l. 23, r. the wheel or fly-shuttle, invented about one hundred years ago by Mr. John Kay, who, on account of the perfection he suffered on this account, was obliged to remove to France, where he died; and the card-making machine, for making several cards at once, invented by Mr. Robert Kay, the son of the former, who died about the year 1804. This machine straightens, &c.; l. 29, after shaft, add—and touching neither the wire nor the leather. The woollen manufactures, confiding of flannels, blankets, and a variety of other articles, were established in this town long before the introduction of the cotton trade, and contributed in no small degree to its prosperity; l. 47, r. In 1811, the number of houses in this township was 1562, and the number of inhabitants was 8762, 4219 being males, and 4543 females. The parish of Bury includes six townships, viz. Bury, Elton, Heap, Higher, and Lower, Tottington, and Walmery.

BURY St. Edmunds, col. 3, l. 3, r. In 1811 this borough had 1474 houses, and 7086 inhabitants; 3539 being males, and 4447 females; 164 families employed in agriculture, and 966 in trade and manufactures.

BUSH. Add—See Coal-Buffel and Weight.

BUTE. The thirc of Bute, by the parliamentary return in 1811, contains 2047 houses, and 12,033 persons; 5545 being males, and 6488 females; 1216 families employed in agriculture, and 530 in trade, manufactures, and handi craft.

BUTLER, r. BUTTER, William.

BUTLER, in Geography, a county of Pennsylvania, containing 7924 inhabitants.—Allo, a township of this county, having 458 inhabitants.—Allo, a township of Ohio, in the county of Columbiana, having 316 inhabitants.—Allo, a county of Kentucky, containing 2181 inhabitants, of whom 274 are slaves.

BUTTER, Chemical Properties of. See Milk.

BUXTON. In 1811 the township contained 180 houses, and 934 inhabitants; 447 being males, and 487 females.

BUXTON, a township of America, l. 5, r. 2324.

BYRAM, a town of New Jersey, in the county of Essex, having 1224 inhabitants.
CAE

CABAL, l. ub. after Shaftesbury, infant—lord Ashley.

CABARRAS, in Geography, a county of N. Carolina, with 6150 inhabitants, of whom 1234 are slaves.

CABELL, a county of Virginia, with 2717 inhabitants, of whom 221 are slaves.

CABINET, col. 2, l. 47, r. whether they be.

CABOS. Add.—The former contains 974, and the latter 1009 inhabitants.

CABOS, in Geography, a town of Caledonias, in the district of Vermont, having 886 inhabitants.

CACHOLONG. See Mineralogy, Addenda.

CADIZ, in Geography, a town of Jefferson county, in Ohio, with 3744 inhabitants.

CADMIUM, in Chemistry, the name of a metal. This metal was discovered by M. Stromeyer in the autumn of 1817, while he was officially examining the apothecaries' shops in Hanover. Cadmium resembles tin in its colour, lustre, softness, ductility, and the sound it produces when bent. Its fp. gr. is 8.6339. It melts and volatilizes at a temperature a little lower than zinc. It prefers its splendour in the air, but by heat it is changed into a yellow oxyd, which is not volatile, and which is very easily reduced. This oxyd does not colour borax; it diffuses very readily in acids, and forms colourless salts, from which it is precipitated white by alkalis. The hydro sulphuric acid (solution of sulphuretted hydrogen) precipitates it yellow, like arsenic. Zinc precipitates it in the metallic state.

This is all which at present we know of this metal, except that it was first obtained from the sublimate which concretes in the chimneys of the zinc furnaces of Saxony; and, consequently, that it exists in the ores of zinc there employed. We understand also that it has been detected in some similar ores of zinc in this country.

CAERFILLY, &c. col. 2, l. 49, add.—It has a market on Thursday, and six fairs in the year. By the parliamentary returns of 1811, the number of houses in this hamlet of Eglwysilan parish was 166, and of inhabitants 1013, viz. 462 males, and 551 females.

CAERLEON, col. 3, l. 18 from bottom, r. The town consists, by the return of 1811, of 170 houses, and 593 inhabitants.

CAERMARTHEN, col. 3, l. 17, after it contains, add—by the parliamentary returns in 1811, 1189 houses, and 1725 inhabitants. The charter allows three markets, viz. on Wednesday, Friday, and Saturday, but the latter is the only one numerously attended by the farmers. It has four fairs in the year, and, &c.

CAERMARTHENSHIRE, l. 7,—others reckon its length 50, and breadth 25 miles. Cary estimates its superficial contents at 512,000 acres; l. 23, The Towy is much celebrated for its fish; its salmon is highly esteemed; as is also its eel. The other rivers, not above enumerated, are, the Llougher, Llologh, or lycher, which separates this county for some distance from Glamorganshire, receiving in its course the Amman, which united streams discharge themselves into Caermarthensbay, by a wide estuary called the Bury river, navigable for small vessels as high as the town of Llologh. Another river, denominated Gwendaethy vawr, or great, has its source in a lake at the upper extremity of Mynudd mawr, and joins the sea below Kidwelly: this is joined by Gwendaethvach, or the left. Other rivers are the Pyccott, which falls into the Dethia, and the Cambwiler, which augments the Towy. The river Bran unites with the Towy below Llandovery. The other tributary streams are, the Saunddy, proceeding from a lake in the Black mountain, and the Cennen, which join the Towy, as well as the Cotsy and Guillyw, already mentioned. The Conwen and the Taf unite at the village of St. Cicsars, and run into the Caermarthensbay at Laughter. The lakes of this county are Llyn Tegwyn, or pull yr Elocob, or the Bishop's pool, situated at the northern extremity, and on the highest elevation of Mynudd mawr, an extensive bleak common, W. of Llandybie, and occupying a surface about half a mile in diameter. Another lake is situated on the Black mountain, at the foot of the almost perpendicular declivity of the Caermarthenshire Fan, or beacon, and extending in form of a parallelogram about one mile in its greatest length. The other lakes are two, which communicate by a faire, and appear like one, situated on the banks of the river Cotty, and near the ruins of the abbey of Talley. The mountains are part of Plinlimmon, and on the E. the long chain called the Black mountain, the summit of which, called Ben Fan, or Ben Sir Gaer, the Caermarthenshire beacon, is the highest ground in the county. The height of this peak has been estimated at about 2600 feet above the level of the sea. It is separated by a chasm from anothereminence, of superior altitude, in Brecknockshire. Both are denominated Bannau Sir Gaer, or Caermarthenshire beacons, in the plural, to disinguish them from those called Bannau Breconhos, or the Brecknockshire beacons. Another mountain lies on the borders of Glamorganshire, called Betwys mountain; it is a chain diverging from the Black mountain, at the upper end of the valley of Tawe, and stretching along the eastern shore of the Amman and Llologh nearly to the sea. —l. 37—The number of parishes has been variously estimated; some having reckoned them at 76, others at 82, and others at 78, besides 12 chapelleries. The number of market towns is fixed at eight. This county, by the last return in 1811, contained 14,856 houses, and 77,217 inhabitants; 9878 families employed in agriculture, and 5256 in trade and manufactures.

CAERNARVON. Add.—In 1811 the parish of Llan-

buhgici.
CÆS

beleg, in which it is situated, contained 1000 houses, and 4595 persons; viz. 1982 males, and 2613 females.

CAERNARVON, a township of America, &c. l. 2, add—
containing 1084 inhabitants.—Also, a township of Berks county, in Pennsylvania, having 723 inhabitants.

CAERNARVONSHIRE, l. 17, r. In 1811 this county contained 1936 houses, and 49,336 persons; viz.
23,379 males, and 25,957 females: 6667 families employed in agriculture, and 2687 in trade and manufactures.

CAERWENT. Add.—The parish of Caerwent, in 1811, contained 60 houses, and 375 persons; viz. 206 males, and 169 females.

CAERYWS. Add.—In 1811, the parish of Caerwys contained 209 houses, and 863 persons; viz. 416 males, and 447 females.

CÆSARIA, r. COHAWZY.

CÆSIA, in Botany, dedicated by Mr. Brown to the memory of Frederico Cæsia, a young Roman nobleman, illustrious for the patronage and cultivation of science, especially of natural history, who founded the academy of the Lycæi at Rome in 1602. This was the first institution of the kind, and is celebrated in various authors of that day. The great Galileo was among its members, as well as that indefatigable botanist Fabio Colonna, better known by his Latin appellation, Colonna. This institution died with its noble founder, in 1630; but the scientific associations of Italy, and thence of all Europe, have sprung from its ashes.

Eff. Ch. Corolla in six deep, equal, spreading segments, deciduous. Filaments bearded, contracted at each end. Anthers attached by their cloven base. Gernmen of three cells, with two seeds in each. Style thread-shaped. Stigma one. Capsule scarcely valvular; tumid and lobed at the summit; or club-shaped. Seeds small, with an appendage to the base.

Herbs generally annual, smooth. Root of clustered, thick fibres, or oblong knobs. Leaves, grisy, Clusters either divided or simple, with aggregate or solitary flower-flanks, jointed under the corolla. Flowers white, or blue, erect, rarely drooping. Corolla becoming spiral after flowering, and soon falling off entire. Anthers yellow.

This genus approaches the Platanium of Jussieu, but differs abundantly in the structure of the germs and seeds.

5. C. lateriflora. Lateral-flowered Cæsia: Br. n. 5.—Stem much branched, falcate. Flowers lateral, drooping, mostly solitary. Capsule club-shaped, pendulous, generally single-seeded. Gathered by Mr. Brown, in the tropical part of New Holland. The filaments are roughish, and the

habit, inflorescence, and capsule differ greatly from all the other species. Brown.

CÆFISE, or CÆFIZ, in Commerce, a measure for corn in Spain, containing 12 fanegas. See Fanega.

CÆFISO, a measure for oil in Sicily, weighing 1-23 rotoli, or about 24 lbs. avoirdupois.

CAHOKIA, in Geography, a township of St. Clair county, in the Illinois country, with 711 inhabitants.

CAJEPUT Oil, l. 2.,—leaves of a species of the Mela- norea, a tree, &c.

CAITHNESS. By the parliamentary returns of 1811, the tilhe of Caithness contained 4301 houses, and 23,419 persons; viz. 10,608 males, and 12,811 females: 3370 families employed in agriculture, and 858 in trade and manufactures.

CAKILE, in Botany, an Arabic name, used by Serapio.

Eff. Ch. Pouch of two single-seeded joints; seed of the uppermost erect, sessile; of the lower pendulous. Oval.

The lower joint is occasionally abortive.

This genus is the real Buniue of Linnæus, nor can we see by that name should be changed for the barbarous Cakile, though we agree with Mr. Brown in removing hither several species of Mycalum, as in the Prodr. Pl. Grex.

CALABOSON, in Geography, a town of South America, in Venezuela, situated between two rivers, viz. Guaro to the W. and Oriuto to the E. which unite their waters four or five leagues below the town. It is situated in a hot climate, in N. lat. 8° 40', 52 leagues S. of Caracas, and at about the same distance N. of the Oronoko, and in the year 1804 its population amounted to 4800 persons.

Eff. Ch. Upper calyx-leaf rather flattened; two lower, with the petals, deflexed under the lip, flat; all glandular at the back. Lip somewhat falked, with rows of glands on its disk. Style winged. Anther a moveable lid. Pollen powdery.

An elegant tribe of small herbaceous plants, clothed with glandular, intermixed with simple, hairs. Bulbs undivided, terminating the defcending base of the stem, inclosed in a scaly coat. Leaf solitary, nearly radical, mostly linear, enclosed by a sheath at the base. Staile bearing one bracteae, besides those immediately accompanying the one, two, or three inodorous, variously-coloured, flowers. Anther most frequently pointed.

Mr. Brown defines thirteen genuine species, from various parts of New Holland. These have, as it were, ringent flowers, the petals nearly equal to the two lower calyx-leaves, and forming with them an under lip, while the upper consists of the upper leaf of the calyx, not quite so flat as the rest. To these are subjoined two species, whose petals are very long, narrow, and directed upwards; and to these, as possibly a distinct genus, the name of Lepotecas is given.

Of the true Caladenes, the first only, C. alba, has been brought alive to England, by Mr. Geo. Caley in 1819, and is marked by Mr. Aiton as a green-house plant, flowering in July and August.—The fifth species, C. alata, is probably Arthutha catarata, Sm. Exot. Bot. v. 2. 89. t. 104.

CALADUIM, a name used by Rumphius, for some kinds

Eff. Ch. Sheath of one leaf; convolute at the base. 
Spadix covered at the summit with petal-like many-celled anthers; glandular in the middle; covered with gerns at the base. Stigma uniloculate. Berries of one cell, with many seeds.

This genus, differing from *Arum* chiefly in the spadix being covered in all its upper part with *flavus*, except, in some instances, a small naked point, is divided like that, (see *Arum*,) into three sections, similarly distinguished. Willdenow has fifteen species in all.

—Native of woods in Martinica and the Caraccas. The flowers are greenish-white, on radical flaks. *Leaves* a foot in breadth, of eleven elliptic, acute leaflets.

Sec. 2. Stem none. Leaves simple. Six species, to which we add one.

2. *C. pinnatifidum*. Pinnatifid Caladium. Willd. n. 2. (Arum pinnatifidum; Jacq. Hort. Schoenbr. v. 2, 31. t. 187.)—Stem none. Leaves pinnatifid. —Native of woods at the Caraccas, where this large species grows on rocks and trees. The leaves are two feet long, and nearly as broad, deeply pinnatifid, with great red ribs. *Flowers* almost sessile; blood-red in their lower half; white, like the spadix, above. The rista are,

5. *C. nympheifolium*. Water-lily-leaved Caladium. Willd. n. 5. Ait. n. 3. (Well-ilia; Rheed H. Mal. v. 11, 43. t. 22.)—Stem none. Leaves peltate, ovate-arboisepalated. Sheath cylindrical, with a lanceolate point, shorter than the spadix.—Native of the East Indies.

6. *C. eufulentum*. Eatable Caladium, or Indian Kale. Ait. n. 4. (Arum eufulentum; n. 11. A. minus, nephys, folius, eufulentum; Sloane Jam. v. 1, 167. t. 166. f. 1.)

7. *C. asecrea*. Acrid Caladium. Br. n. 1.—Stem none. Leaves peltate, heart-shaped. Spadix obtuse, with a very short, occasional, naked point. Sheath lanceolate, twice as long as the spadix.—Gathered in the tropical part of New Holland by Mr. Brown, who remarks that it fearfully differs, except in having *antherae* to the summit of the *spadix*, from the last, which has a consistence of a black trunk of a pointed, and he does not see how the latter is dilliguished from *Arum Colacaha*.

Sec. 3. With leafy stems. Eight species.

—From the Caraccas.

CALAIS, l. 3, for 44 r. 41, a town of Washington county, in the district of Maine, which by the census of 1810 contained 372 inhabitants—Alfo, a town of Caledonia county, in Vermont, containing 841 inhabitants.

CALCULUM, in *Chemistry*, the metallic bals of lime. See LIME.

CALDARA DA CARAVAGGIO, Polidoro, in Biography, an eminent painter, was born in the Milanese, and from the humble station of a labourer became an assistant in Raphael in the works of the Vatican, and at length acquired unrivalled celebrity in his imitation of the antique baso-relievs, which he executed in chiaro-ocuro. His style was so peculiar a feste his own, that, having formed it, it also perished with him. His design was without manner, compact, and correct. He had the art of transporting himself, says his biographer, into the times of which he represented the transactions, the costume and rites, so that nothing modern is discerned in his works. Numerous as his performances once were at Rome, scarcely a fragment remains, if we except the liable of Niobe, left in ruins by time and the rage of barbarians. For these losses we are compensated merely by the prints of Cherubino Alberti, and Henry Golzius, who engraved his gods, the Niobe, and the Brennus, and also by the etchings of Santes Bartoli and Gallefrazzi. On occasion of the pillage of Rome by Bourbon in 1527, Polidoro fled to Naples, where he was patronized by Andrea da Salerno, and gained such reputation that he began to form a school; but declining the prosecution of this undertaking, he removed to Sicily. Having exchanged chiaro-ocuro for colour, he painted at Messina a numerous composition of Christ led to Calvary, which has been highly extolled by Vafari; and not long after the completion of this work, he was strangled in bed by a servant, who wished to get possession of his property. His manner, as a colourist, is said to have been dim and pallid. He died in 1543, at the age of 51 years. Pilkington's Dict. of Painters by Fuseli.

Caldwell, in Geography, a town of Essex county, in New Jersey, containing 2235 inhabitants, of whom 9 are slaves.—Alfo, a county of Kentucky, with 4268 inhabitants, including 579 slaves.

Calestasia, in Botany, from καλαστασις, beautiful, and ἀκατοφρον, an extension, or dilatation, alluding to the elegant star-like expansion of the corolla.—Brown Prodr. Nov. Holl. 3 F 2 v. 1.
CAL

The tube of the *C. cyanet* covered by the sheaths of the leaves; the limb prominent, like a bright blue star, of six equal rays, the three outermost downy underneath. This pretty genus is not very nearly allied to any other, though something like *Aphylantes*, but widely different in structure, and rather approaching *Dasyphugon*, hereafter to be described.

**CALEDONIA**, a county of Vermont, 1. 2, r. 23; add.—In 1810, it contained 18,750 inhabitants.

**CALEDOSCOPE** or *Kaleidoscope*, from *kaleos*, beautiful, *ulos*, a form, and *skopein*, to see, an instrument recently invented by Dr. Brewster, and for which he has obtained a patent, for the purpose of creating and exhibiting an infinite variety of beautiful forms.

The instrument in its simplest form consists of two reflecting planes, inclined to each other, made either of two plates of glass, blackened or silvered, or two metallic surfaces, or the two inner surfaces of a solid prism of glass, or rock-crystal, from which the light sufferers total reflection. The plates may be of any length; but that which is most convenient will be found to be from five to ten or twelve inches, or they may be made only two, three, or four inches long, provided distinct vision is obtained at one end, by placing at the other end an eye-glass, whose focal length is equal to the length of the reflecting-plane; their breadth should be about eight or nine-tenths of an inch when the length is six inches; but it should increase with the length, in order to have the aperture of the same angular magnitude. Two edges of these reflectors, being made perfectly straight, are placed together by a particular contrivance, in such a manner, that their inclination, or the angle which they form, is exactly an even aliquot part of a circle, or a fourth, fifth, eighth, tenth, twelfth, fourteenth, &c. part of 360°. When the plates are thus fixed in a tube, and the eye placed at one end, as near as can be, in the line of the intersecion of the two planes, it will perceive a circular field of view, composed of as many luminous sectors as the number of times the angle formed by the reflectors is contained in 360°. These sectors, excepting the one seen by direct vision, and constituting the angular aperture of the plates, are a series of images of this aperture, formed by successive reflections between the inclined reflectors. These images formed by one reflector from each of the plates lie on each side of the direct aperture, and are inverted images of that aperture; the next two images formed by two reflectors are images not inverted; and so on throughout the whole series, every two direct images being separated by an inverted one.

From these observations, it will be seen that the kaleidoscope is not an instrument which produces beautiful forms by the multiplication of single forms; for it is demonstrable, that a symmetrical and beautiful pattern cannot be produced by the repetition of any single form: and if it were possible to construct a multiplying-glass with mathematical perfection, and free from all the prismatic colours, it would be impossible to produce with it an arrangement of simple forms, marked with symmetry and beauty. The principle of the kaleidoscope, therefore, is to produce symmetry and beauty by the creation and subsequent multiplication of compound forms, each of which is composed of a direct and an inverted image of a simple form.

The tube which holds the reflecting plates moves in another tube; and upon the outer end of the last tube is placed a cell, or cap, for receiving a series of object-plates, containing fragments of differently-coloured glasses and other substances placed at random. When one of these object-plates is placed in the cell, the inner tube is pushed in as far as it will go; and the instrument being held in one hand, the cell containing the object-plates may be removed round with the other, and the eye of the observer being placed at the other will observe the iridescent mazes of colour arranged in an infinite variety of forms, mathematically symmetrical, and highly pleasing to the eye.

If the object be put in motion, the combination of images will likewise be put in motion, and new forms, perfectly different, but equally symmetrical, will successively present themselves; sometimes varying in the centre, sometimes emerging from it, and sometimes playing around it in double and opposite oscillations. When the object is tinged with different colours, the most beautiful tints are developed in succession, and the whole figure delights the eye by the perception of its form, and the brilliancy of its colouring.

The effects, of which we have given a general description, obviously arise from inversion and subsequent multiplication of every object placed before the angular aperture, or the luminous sector seen by direct vision, and from the perfect junction of all the reflected images. When the object is moved, the inverted images all seem to move in an opposite direction, while the images not inverted move in the same direction with the object; and from these opposite motions, as well as from the entrance of new objects, by the revolution or the direct motion of the object-plate, arises that endless variety of forms which affords so much gratification to the eye.

In the preceding form of this instrument, the object must necessarily be placed close to the end of the reflectors; for if it is removed from this position, the symmetry is destroyed, and the deviation from a symmetrical form increases as the distance of the object from the reflector increases. The use of the instrument in this form is, therefore, limited to objects which can be held close to the reflector.

This limitation, however, has been superseded; and the use and application of the instrument indefinitely extended by an optical contrivance. A lens of a short focal length is placed on the object end of the outer tube, and the inner tube is drawn out till the image of objects, whatever be their distance, falls exactly on the outer end of the reflectors. When this is the case, these objects will be arranged into the most beautiful and symmetrical forms, in the same manner as if they had been reduced in size, and actually placed at the end of the reflectors. In this way, every object in nature may be introduced into the picture formed by the instrument, and the observer will derive a new and endless source of enjoyment by the creation of pictures of natural objects, whether animate or inanimate.

As the kaleidoscope is of great use in the ornamental arts, particularly to carpet and lace manufacturers, calico-printing, paper-hanging, jewellery, &c. &c., its adaptation to their purpose is effected by occasionally furnishing the instrument with a stand, in order that the pattern may be fixed whilst...
whilst the artist is engaged in copying it. It is also capable
of being used with Dr. Wollaston's camera lucida, by
which means those who would otherwise be unable to
copy the patterns may do it with perfect facility and
accuracy. The effects of the instrument may also be ex-
bibited to many persons at once, on the principles of the
filar microscope, or magic lantern. The instrument for
scientific purposes is occasionally so constructed as to ad-
mit of the inclination of the reflectors being varied at pleasure.
Under the authority of Dr. Brewster, caleidoscopes of all
the different forms are manufactured by the opticians with
great accuracy and perfection; but the popularity of the
instrument has been such as to induce a great number of
individuals, who have been ignorant of its principles, to
infringe upon the patent, and impose upon the public a
wretched imitation of the original, poaching none of the
properties which are essentially necessary to the production
of beautiful and symmetrical forms; and in order to jus-
tify such proceedings, it became necessary to search out for some
combination of mirrors already described, which might have
some resemblance to Dr. Brewster's instrument: and the
first patented anticipation of it was found in prop. 13 and
14 of Wood's Optics; but professor Wood, in a letter to
Dr. Brewster on the subject, has most handsomely disclaimed
having in contemplation the effects produced by the caleido-
scope in giving the propositions alluded to. The next sup-
pofed anticipation was an instrument proposed and made
by Mr. Bradley in 1711, which consisted of two pieces of
silvered looking-glass, five inches wide, and four inches
high, jointed together with hinges, and opening like a
book. These plates being set upon a geometrical drawing,
and the eye being placed in front of the mirrors, the lines
of the drawing were seen multiplied by repeated reflections.
This instrument had been described long before by Kircher,
and did not receive a single improvement from the hands of
Bradley. It had been often made by the opticians; but no
person ever thought of applying it to any purpose of
utility, or of using it as an instrument of rational amuse-
ment by the creation of beautiful forms: indeed, from its con-
struction, it is quite incapable of producing any of the
singular effects of the caleidoscope. As, however, the
similarity between the two instruments is maintained by
many persons, either from ignorance or interest; in order,
therefore, to render that justice to Dr. Brewster which to
us appears his due, we give the following statement of the
differences between the two instruments, upon the sup-
position of their both being applied to geometric lines upon
paper.

1. In Bradley's instrument, the length is less than
the breadth of the plates.
2. Bradley's instrument cannot be used with a tube.
3. In Bradley's instrument, from the erroneous
position of the eye, there is a great inequality of light in
the sectors, and the last sectors are scarcely visible.
4. In Bradley's instrument, the figures consist of elliptical, and consequently unequal sectors.
5. In the caleidoscope, the equal sectors all unite into
a complete and perfectly symmetrical form.
6. In Bradley's instrument, the unequal sectors do
not unite, but are all separated from one another by a
space equal to the thicknens of the mirror-glass.
7. In Bradley's instrument, the defects in the
junction of the plates are all rendered visible by the erro-
nous position of the eye.

To which it may be added, that professors Playfair of
Edinburgh, and Pictet of Geneva, and the celebrated Mr.
Watt, have each of them borne testimony to the dissimilarity
of the two instruments, and to the unquestionable claim
which Dr. Brewster has to the invention of the caleido-
scope.

CALENDAR. To the French calendar, annex—the
French have abolished their new calendar, and restored the
Gregorian, which was ordered to be used in all their dates
after the 1st of January, 1856.

CALEYA, in Botany, a very distinct and elegant genus,
thus named by Mr. Brown, in full commemoration of Mr.
George Caley, an able and accurate botanist, who has for
several years been employed by Sir Joseph Banks, in the
investigation of the vegetable productions of New South
Wales, but whose discoveries are not all admitted into Mr.
Brown's work, being, we hope, destined to appear in some
more popular, and more amply descriptive, publication.—
Brown in Ait. Hort. Kew. v. 5. 204. (Caleana; Br. Prodr.
Nov. Holl. v. 1. 329.)—Clas and order, Gynandra Monan-

Eff. Ch. Flower reveral. Calyx-leaves and petals linear,
early equal, spreading. Lip stalked, peltate, hollow,
opening outwards. Style dilated. Anther a permanent
lid. Pollen powdery.

There are two species, C. major and minor, both found
near Port Jackson; the former sent to Kew, by Mr. Caley,
in 1810. These are smooth herbs, with simple naked bulbs.
Leaf radical, solitary, linear, sheathed at the base. Flowers
two, brownish-green; the lip and column red. The lip
is moveable, reflexed; but during rain it becomes inflamed over
the column, which Mr. Brown is doubtful whether to at-
tribute to the diminution of light, or to the irritation of the
rain.

CALICUM, from κάλα, a little cup, well ex-
pressing the form of the fructification.—Peri. in Uit. Ann.
fac. 7. 20. Achar. Syn. 55. " Lichenogr. 39. t. 3. f. 1—
Lichenes.

Eff. Ch. Culif uninterrupted, uniform. Receptacles cup-
shaped, cartilaginous, stalked, more or less elevated, con-
taining a compact powdery mass of seeds, forming an even
disk.

Acharius defines twenty-five species of this curious and
beautiful, though minute and inconspicuous genus of the
lichen tribe. They form grey, white, or yellow patches, of
various extent, on old wrought wood, or boards, exposed to
the
the weather; sometimes on the old bark of trees. The receptacles are, most frequently, each elevated on a slender bristle-like 

flatt, usually black, like a horde-hair, and so different from the chalky or granulated crust from whence they grow, as to appear altogether parasitical. Their powder when touched stains the fingers. Sixteen species are described and figured in Eng. Bot. especially in vol. xxxv.

CALLICOMA, Curt. Mag. 1811. See CODIA.

CALLISTACHYS, or rather CALLISTACHYIA. See OXYTHOBUS.

CALNE. The borough and parish of Calne, in 1811, contained 250 houses, and 1547 persons; viz. 1621 males, and 1926 females; 325 families employed in agriculture, and 402 in trade and manufactures.

Eff. Ch. Calyx ringent; two lower leaves under the lip. Petals felsifie, smaller, erect. Lip longer than the calyx, felfife, pointed; beard at the margins and on the disk. Anther parallel to the stigma, permanent.

Herbage smooth. Bulbs undivided, naked. Leaves few, all on the stem; the lower one channelled, much longer than the rest. Spike racemose, lax, with prominent, reddish, rather large flowers. Nearly akin to NEOTRIA; see that article.

1. C. campelis. Br. n. 1.—Lip not much longer than the calyx, with a half-lanceolate point, one-fifth its own length. Column with two glands at the base. Bracteae longer than the germs. Flowers from four to eight.

Gathered by Mr. Brown at Port Jackson, as well as in the tropical part of New Holland.

2. C. paludosus. Br. n. 2.—Lip twice the length of the calyx, with a ligulate zigzag point, half its own length. Column without glands. Bracteae shorter than the germs. Flowers from two to four.—Found by Mr. Brown, at Port Jackson.

Eff. Ch. Corolla in six deep spreading segments; three innermost largest; woolly above, with a smooth spot at the base. Filaments very short, inserted in the bafe of each segment. Anthers erect, arrow-shaped. Stigmas reflexed. Capsule of three cells.

1. C. elegans. Grassy Woolly-flower. Pursh n. 1.—Found by governor Lewis, at the head-waters of the Kookooskia, North America, flowering in May. Bulb solid, globular, eaten by the natives. Leaf solitary, radical, grassy, ribbed, nearly smooth, taller than the flower-stalk, which is simple, round, smooth, bearing two or three very elegant, drooping, white flowers, the size of Hypoxis cerniA, on slender partial stalks, each accompanied by a linear-lanceolate bractea. The three inner segments of the corolla are covered with long down, and marked with a roundish, smooth, purple spot at their base.

1. C. pilosa. Br. n. 1. the only species, found by Mr. Brown in the tropical part of New Holland. An annual hairy plant, smelting when dried like our Anthoxanthum. The leaves are cut or toothed; floral ones anuricled at the base. Stalks axillary, single-flowered, without bracteae; reflected as the fruit ripens.

This plant is separated from Goodenia, (see that article,) solely on account of the three-cleft style, and three filaments, and Mr. Brown hesitates about the propriety of the measure.

CALOMERIA. See HUMA.

Few orchidaceous genera are more natural.

Eff. Ch. Petals six. Nectary with twelve segments, bearing the flamens. Berry globose, with one or two seeds. Diffiguished from Pancratium, as Mr. Brown observes, chiefly by the structure of the single-celled germs and pericarp. The flowers are small, not an inch long, either white or purple. The seeds germinate in the berry.

2. C. purpureum. Br. n. 2.—Flower-flalk earlier than the leaves. Barren segments of the nectary triangular.

Found on the southern coast of New Holland.

Gen. Ch. Cal. Perianth half-superior, of one leaf, turbinate; limb in four or five short, broad, deciduous segments. Cor. Petals four or five, ovate, twice the length of the calyx, and alternate with its segments. Stamina. Filaments very numerous, in four or five sets, opposite to the petals, the claw of each flattened, oblong, many times longer than the corolla, some of them either combined together, or partially imperfect, pinnate, or otherwise many-cleft, in the upper part, with capillary segments; anthers terminal, inserted by their base, linear-oblong, undivided. Pist. Germs in the bottom of the calyx, small, roundish; style thread-shaped, erect, shorter than the flamens; stigma acute.

Peric. Capsule coated with the base of the calyx, and firmly united to the branch, roundish, of three cells. Seeds numerous, small, oblong.
CAL

Eff. Ch. Calyx in four or five segments. Petals four or five. Stamens numerous, very long, in several various sets, opposite to the petals; anthers linear, undivided, vertical. Capsule coated by the calyx, three-celled, permanent. Seeds numerous.

Obs. The flaments in some species consist of uniform sets, answerable to the number of the petals; in others, two or more of those sets are partially combined laterally, the remainder being divided into simple threads, without anthers, and this last is the character of the genus as M. Labillardiere underfoot and described it. But Mr. Brown has, in conformity to nature and analogy, not limited it so strictly. We adopt his views of the genus, only begging leave to construct the essential character without exception, such paraphrasis being best avoided. The genus before us comes next to Beaufortia, (see that article,) and is full as splendid, differing from it essentially in the structure of the anthers, and in having numerous seeds. From Melaleuca, (see that article in vol. xxii,) the difference is less striking, but we believe very essential, confiding in the vertical, not in-ternal, anthers. To this Mr. Brown adds that the infrutescence is unilateral.

1. C. fangula. Blood-red Unequal Calothammus. Labill. Nov. Holl. v. 2. 255. t. 164. —Flowers four-cleft. Sets of flaments equal combined; two of them imperfect, distinct. Adult leaves linear-awl-shaped, compacted, smooth. —Native of Lewin's land, flowering in December. A fbrul, fix feet high, with round, scarred branches. Leaves scattered, slender, acute, entire, rather above an inch long; hairy when young. Flowers in small lateral fellite tufts, about the length of the leaves, conspicuous for their blood-red flaments, two feet of which unite to form a broad, wedge-shaped, cone-c każdy, divided at the top into numerous, vertical, parallel flaments, each bearing an upright linear anther; the two remaining feet diminished to simple, thread-like threads, without any anthers. Capsule small, globose.

2. C. quadrifida. Four-cleft Equal Calothammus. Br. in Ait. n. 1. Sims in Curt. Mag. t. 1556. —Flowers four-cleft. Sets of flaments equal and distinct, with many anthers. Adult leaves smooth, as well as the fruit. —Gathered by Mr. Brown, on the south-west coast of New Holland. Sent to Kew in 1803, by Mr. Good, along with the two following. This bears splendid scarlet flowers, whose beauty however depends on the large flaments, an inch and a half long, the petals being small, pale, and inconspicuous. The leaves are linear-oblanceolate, or somewhat spatulate, but extremely narrow, hardly more than an inch in length.

3. C. willoa. Hair-Hair Five-cleft Calothammus. Br. in Ait. n. 2. —Flowers five-cleft. Sets of flaments equal and distinct, with numerous anthers. Adult leaves villous, as well as the fruit. —Found by Mr. Brown on the south-west coast of New Holland. A green-house fbrul, flowering at Kew, from July to September.

4. C. grecolis. Slender-leaved Calothammus. Br. in Ait. n. 3. —Flowers five-cleft. Sets of flaments equal and distinct, with only three anthers to each. Leaves elongated, smooth, as well as the prominent capsule. Stem branched. —Native of the same country as the last.

No other species have been hitherto described.

Eff. Ch. Corolla. Crown of the flaments fimple, of five keel-shaped leaves, attached lengthwise to the tube of the flaments; recurved at the base. Manipes of pollen ren, smooth, pendulous. Stamina pointefs. Follicles tumid, smooth. Erect smooth milky fbrul, with broad opposite leaves, and handsome large flowers, in lateral corybofhe panicles, immersed between the footstalks. Only two species are described.

1. C. procrera. Bell-flowered Auricula-tree. Ait. n. 1. (Afiepia procrera; Ait. ed. 1. v. 1. 305. Wild. Sp. Pl. v. 1. 1263. Schneee. ic. 1. 18. (See A.fiepia, n. 25.) —A. gigantea. Andr. Repof. t. 271. "Zia-rect; Le Brun Voy. 315. t. 184."") —Segments of the corolla spreading. —Native of Persia. A fbrul shrub impotent of damp and cold, flowering from July to September. The whole plant is glaucous, fix or seven feet high, with broad, felfie, entire leaves. Flowers irregularly corybofhe, numerous, larger than in most of this tribe, an inch or more in width, of a rich brownish-purple, powdered like an Auricula; pale beneath.

2. C. gigantea. Curled-flowered Auricula-tree. Ait. n. 2. (Afiepia gigantea; Linn. Sp. Pl. 312, excluding the fynonym of Plunckent and Alpinis. Wild. Sp. Pl. v. 1. 1264. (See A.fiepia, n. 6.) —Erica; Rheede Hort. Mal. v. 2. 53. t. 31.) —Segments of the corolla reflexed, with twisted points. —Native of sandy ground on the coast of Malabar. Very like the foregoing, but the corolla is differently shaped, as expressed in the character, and is laid to be variegated with white and purplish-red, smelting like a lily. We beg leave to observe, that if priority of date were to determine generic names, without regard to the found regulations of Linnaeus, Mr. Brown's elegant Calotropis must give way to Rheede's Erica, as the appellation of this genus, in spite of law, fense, taste, and convenience.

Vol. VI.

CALVERT, in Geography. Add—This county contained, in 1811, 8003 inhabitants, including 3937 slaves.

CALYPSO, in Botany, an elegant botanical name of Mr. Salisbury's, from καλυψω, to cover or conceal, not merely alluding to the covering of the stigmas, but preserving a poetical analogy between this botanical beauty, so difficult of access, and the secluded godfells, whose life was fabled to be protected miraculously from the observation of observers.—Salibb. Parad. 85. Brown in Ait. Hort. Kew. v. 5. 268. Purf. 593. —Clasf and order, Gynandria Meteoria. Nat. Ord. Orchidaceae.

CALYSTEGIA, a genus separated by Mr. Brown, Prodr. Nov. Holl. v. 1. 483, from Convolvulus, and chiefly distinguished by the great fire of the two fcalp tribes, including
inflating the calyx, whence the name, from καλύς, and τον, to cover. Convolutus septum and C. Soldatiella of Limneus, with several others, constitute this genus, which appears to us better omitted.

CALY-YUG, denotes, according to the chronology of the Hindoos, the present or fourth age of the world.

CAMALODUNUM, 1. 3, r. Trinidantes.

CAMBERWELL, a parish of Brixton hundred, in the county of Surrey, which includes the hamlets of Dulwich and Peckham, and in 1811 contained 1849 houses, and 11,309 persons; viz. 4854 males, and 6455 females; but since that time much increased in buildings and inhabitants.

CAMBIUM, l. 51, for CORTICAL LAYERS r. Cortex; l. 39, for PITH and MEDULLARY CANAL r. MEDULLA. Col. 2, l. 5, r. MONOCOTYLEDONES.

CAMBRIA, in Geography, a county of Pennsylvania, containing 2117 inhabitants.—Also, a township of the same county, having 868 inhabitants.

CAMBRIDGE, col. 4, l. 7, add—By the return in 1811, the borough and university of Cambridge contained 991 houses, and 11,108 persons; viz. 5288 males, and 5820 females: 80 families employed in agriculture, and 1600 in trade and manufactures.

CAMBRIDGE, in Washington county, &c. l. 2, r. census of 1810, 6732 inhabitants, and 650 senatorial electors; l. 10, for 2115 r. 2523; l. 38, r. 990.

CAMBRIDGE, a town of Guernsey county, in Ohio, having 474 inhabitants.

CAMBRIDGE, Wis., a township of Middlesex county, Massachusetts, having 971 inhabitants.

CAMBRIDGESHIRE, col. 1, l. ult. r. In 1811, this county contained 17,489 houses, and 101,109 persons; viz. 50,756 males, including 2946 local militia, and 50,393 females: 12,811 families employed in agriculture, and 5330 in trade, manufactures, and handicraft.

CAMDEN, a county of North America, l. 3, for 4033 r. 5347.

CAMDEN, a county in Georgia, &c. l. 3, r. containing 3941 inhabitants, of whom 2681 are slaves.

CAMDEN, in the district of Maine, contains 1607 inhabitants.

CAMDEN, a post-township of Oneida county, in the state of New York, watered by the W. branch of Fitch creek, containing about 1100 inhabitants, principally farmers from Connecticut.

CAMELINA, in Botany, an old name of French origin, used by Dodonaeus, but whether it alludes to this plant's being the companion of flax, Linum, as Crantz seems to intimate, is hardly worth enquiring.—Crantz Auftr. f. 17. Brown in Ait. Hort. Kew. v. 4, 93.—Clasf and order, Tetragonion Siliculose. Nat. Ord. Siliculose, Limn. Cruciferae, Jaff.

Brown.

Mr. Brown founds this genus on the Mygrum fatuum of Limneus, and the M. (not Alysum) austriacum of Jacq. Auftr. t. 111. The first is the only Camelina of Crantz above cited, who distinguishes it from Alysum, (see that article,) by the connection between the style and the valves of the pouch, the style of Alysum being connected with the position only. Mr. Brown's distinction depends chiefly on the position of the cotyledons; for every Alysum has not toothed filaments. Of Mygrum austriacum we do not feel competent to judge, but we are disposed to keep the fatuum an Alysum, as in Fl. Brit. and Engl. Bot. t. 1254, unlefs it could be set apart along with Alysum utriculatum of Limneus.

Curt. Mag. t. 130, one species of Mr. Brown's and Lamarck's "Vesicaria," very different from the original Vesicaria of Tournefort; see that article.

CAMPBELL, l. 3 and 4, r. 11,001 and 5368.

CAMPBELL, a town of Kentucky, containing 5306 inhabitants, of whom 438 are slaves.

CAMPBELL-Town. Add—The burgh and parish, in 1811, contained 1010 houses, and 7807 persons; viz. 3367 males, and 4440 females.

CAMPDEN, col. 2, l. 23 from the bottom, add—In 1811, it was stated to contain 273 houses, and 1214 persons; viz. 594 males, and 612 females.

CAMPION, l. 5, r. 873.

i. C. linearis. Br. Mag. t. 121. N. H. Cape Van Diemen. A smooth herb, with a root of several tapering fibres. Leaves gritty, alternate, half-clasping the stem. Flowers terminal, erect, either solitary, or from two to four in a lax cluster. Anthers variable, heart-shaped. Stigmas simple. Seeds in a simple row, attached to the inner angle of each cell. Nothing is said of the colour of the flowers.

CAANAH, l. 2, for Lincoln r. Somerf. l. 4, r. 1757; l. 7, r. 1810 and 1094; l. 12, add—In 1810, it contained 2233 inhabitants; l. 13, add—With 232 inhabitants.—Also, a township of Wayne county, in Pennsylvania, having 829 inhabitants.

CAANAH. New, a town of Fairfield county, in Connecticut, having 1599 inhabitants.

CANAL, col. 14, l. 44, add—The principal interior canals that are already (1818) completed in the United States are, the Middlesex canal, uniting the waters of the Merrimack river with the harbour of Bolton, and the canal Carondelet, extending from Bayon St. John, a post of delivery in the Missippifi district, to the fortifications or ditch of New Orleans, and opening internal communication with lake Pontchartrain. The union of this canal by lakes with the Missippifi would, independently of other advantages, enable the government to transport with facility and effect the same naval force for the defence both of Missippifi and lake Pontchartrain, the two great avenues by which New Orleans may be approached from the sea. In 1816 or 1817, the flate legislature of New York passed acts, appropriating funds for opening a navigable communication between the lakes Erie and Champlain and the Atlantic ocean, by means of canals, connected with the Hudson river. When this scheme, actually begun, is accomplished, and a communication opened by canals and lakes between lake Erie and the navigable waters of Hudson's river, and also between lake Champlain and these waters, the flate of New York will soon become, in itself, a powerful empire.

Sheet Q 9, instead of CANAL at the head of the page, insert in col. 1 and 2, CAN.

CANAL, p. 44, col. 2, l. 6 from the bottom, for thereon r. therein. P. 49, col. 1, l. 20, add.—Mr. Chapman has lately (viz. in 1816) suggested to the editor, that this method, without complicated collateral aid, not had in contemplation, will be found to be impracticable; because the moment the defending criffen entered the lower canal, the equilibrium
equilibrium would be lost, and all counterbalance when the chaff had entered to such depth as to allow its contained vessel to go out.

For Hartlepool Canal r. Hartley Canal; for Durham r. Northumberland; and for Hartlepool r. Hartley. Canal, Bafing-broke, col. 2, l. 3, after commences in, infect—Cooper’s meadow, adjoining to the town of Bafing-broke, and enters the river Wey about two miles above Weybridge; de&, l. 3, 4, 5, from Wey to Bafing-broke; l. 18, after Loddon, add—The proprietors are prohibited from touching the Loddon, or any of the springs or streams that feed it.

Canandaqua, or Canandaigua, l. 11, r. In 1810, this township had 415 families, 256 fanatorial electors, and 2392 inhabitants.

Candarine, a money of account in China, where 1 mile is = 10 marcs = 100 candaries = 1000 cash.

Candles, Law relating to, col. 2, l. 2, add—By Geo. III. c. 98. duties of calumies are likewise imposed: 1 l. 8, r. c. 9.

Candy, a weight in the East Indies. At Madras the candy is 500 lbs. avoirdupois, = 20 maunds. See Maund.

Canfield, in Geography, a township of Trumbull county, in Ohio, having 494 inhabitants.

Canhada, a liquid measure in Portugal, 6 canhadas being = 1 pote, or 20 liters.

Canicular Year, c. 2, l. 16, for r. on.

Canua, or Canxe, a measure for cloth in Italy, and the south of France, Spain, &c. each canua at Barcelona being = 6.4 English inches; at Florence, = 9.1 English inches for woollen, and 9.15 for silk; at Genoa, = 11.7 English inches; at Majorca, 67.5; at Malta, 81.9; at Messina, 95; at Montpellier, 75.8; at Morocco, 75.4; at Naples, 83; at Palermo, 76.2; at Saragossa, 81.55; at Toulon, 68.25.

Canannaghquanesing, in Geography, a township of Butler county, in Pennsylvania, having 1284 inhabitants.

Canoe, l. 3, r. 1621; l. 7, after Seville, and under Juan Martinez Montanes; l. 26, infect—In 1643 he removed to Toledo; and upon, &c.

Cantbury. This city, by the return of 1811, contained 2093 houses, and 10,200 inhabitants; viz. 4606 males, and 5593 females; 508 families being employed in agriculture, and 1195 in trade and manufactures.

Cantbury, a township of America, &c. l. 5, for 1578 r. 1526, including 7 lakes; l. 8, add—It contains 1812 inhabitants.

Cantharidin, in Chemistry, a name given by Dr. Thomson to a peculiar principle extracted from cantharides in the following manner.

Boil cantharides in water till every thing soluble in that liquid be taken up. Concentrate the solution by evaporation, and when reduced to a thick syrup, boil it repeatedly in alcohol, till that fluid ceases to act upon it. Evaporate the alcoholic solution to dryness, and digest the dry residue in sulphuric ether. When the ether has assumed a yellow colour decant it, and expose it in an open vessel to spontaneous evaporation. Small crystalline plates mixed with yellow matter will soon separate. The yellow matter may be separated by alcohol, which leaves the crystals of cantharidin quite pure.

Cantharidin thus obtained exists in the form of shining micaceous plates. It is insoluble in water, and in cold alcohol. Boiling alcohol dissolves it, but the cantharidin again separates on the cooling of the alcohol. Ether dissolves it, but not in large quantities. It readily dissolves in oils, and when applied to the skin, acts as a vesicatory with great energy. The solution of it in oils is equally efficacious. This principle seems to have been first separated by Thouvenel. See Cantharides.

Cantharis, l. alt. dele which see respectively.

One of the most elegant insects of this genus is the scarlet cantharis; entirely of a vivid red, except the body, legs, and antennae, which are coal-black. It is somewhat more than half an inch in length. The C. bipustulata is a beautiful insect, somewhat smaller than the preceding, of a very dark but elegant gilded green, with the tips of the wing-shells red, and on each side of the thorax a triple velle of a bright red colour, capable of extension or retraction at the insect’s pleasure, and by the microscope exhibiting an alternate inflation and contraction, like that of the lungs in the larger animals. This species is found in the middle of summer on various plants, and particularly on nettles. Shaw.

Canticles, col. 3, l. 16, r.—The causes of the apparent, &c.

Canton, in America, add—and containing 1353 inhabitants.—Alto, a town of Hartford county, in Connecticut, having 1374 inhabitants.—Alto, a township of Luzerne county, in Pennsylvania, having 417 inhabitants.—Alto, a township of Washington county, in the large state, containing 1345 inhabitants.—Alto, a town of Stark county, in Ohio, having 846 inhabitants.

Canton, in China, l. 17, after houfes, infect—built of brick. Col. 2, l. 1, add—These sampans, as they are called, accommodate, at the very lowest computation, 40,000 people: l. 13, after 40,000, add—The accounts of the population of Canton are very various and contradictory. The exaggerated statement above given is that of Le Comte. Da Halde estimates it at a million; and Sommav, erring in the other extreme, reduces the number to 75,000. But according to data, collected by captain King, in “Cook’s Third Voyage,” (vol. iii.) he apprehends, that the city and its suburbs may probably contain about 150,000.

Cauutchouc, in Chemistry. In addition to what has been said of this singular substance, we may observe that Surinam has been lately itated to exist in a great variety of plants, though it has been hitherto usually confounded with other substances. It may be separated from resins by means of alcohol. It may be extracted from the different species of millet by water, with which it readily combines, whilst in that fluid it exists in the plants. When mixed with gum or extractive, it may be separated by distilling a part of the plant containing it, first in water, and then in alcohol, till all the substances soluble in these liquids be extracted. The residue is then to be dried and digested in four times its weight of rectified petroleum. Express the liquid part by fusing the substance in a linen cloth. The liquid is then to be put by for some days to settle, and after the clear part has been poured off, the remainder is to be mixed with a third part of water, and distilled. The caoutchouc remains behind.

According to Bucholz, a considerable proportion of caoutchouc exists in opium. Malick also is flated to contain a substance very similar to caoutchouc.

Capelet, or Capellat, a name sometimes given by followers to a swelling of a wensy kind, which grows on the back of a horse, and on the point of its elbow. It often arises from bruises, and in this case should be bathed with hot vinegar and alum; but when they grow gradually on both hee’s and elbow, blood is extravasated. When this happens, suppuration should be promoted by rubbing the part with stimulating unguents; and when matter is formed, the skin should be opened with a lancet, in more dependent parts.
CAR

parts towards one side, for avoiding a fear. The subsequent dressings may be turpentine, honey, and tincture of myrrh.

CAPE MAY, in Geography, a county of New Jersey, containing 36,322 inhabitants, of whom 18,110 are slaves.

CARAGE of Lime, denotes the quantity of sixty-four bushels.

CARALLIA, in Botany, Caralle of the Telingas, or natives of Hindoostan; being one of those barbarous names which some modern botanists have ventured to tolerate, but which no classical one can approve. — Roxb. Coromandel. v. 3. 8. — Chal. and order, Isocrypta Monogynia. Nat. Ord. Hesperides, Linn. Myri. Jull.

Ell. Ch. Calyx in five or seven segments, superior. Petals five or seven. Stigma three-lobed. Berry of one cell, with a solitary seed.

1. C. lucida. Shining Carallia. Roxb. as above, t. 211.

—Native of the lower region of the Cazar mountains. A small, handlike, evergreen tree, flowering in March and April. Leaves on short flanks, opposite, elliptical, acute, finely serrated, smooth, four or five inches long, and two or three and a half broad. Flowers small, yellow, in little, aggregate, axillary, falked heads. Berry the size of a pea, red. Seed large, with a strongly curved embryo. Nothing is recorded of the qualities or uses of this plant. It is evidently next akin to Eugenia; see that article.

CARAWAY, r. Carum, &c.; at the end of the next article r. Carum.

CARBON, in Chemistry. The progress of chemical knowledge enables us to date, with greater accuracy and precision, the nature of some of the compounds of carbon, than at the time this period in the Cyclopedia was written.

Carbonic Oxid.—It has been flown by Gay Lussac, that 100 measures of this gas require for complete combustion 50 measures of oxygen, and that the product is 100 measures of carbonic acid; hence it must be composed of one atom of carbon and one atom of oxygen, or 100 parts by weight will consist of

<table>
<thead>
<tr>
<th>Oxygen</th>
<th>Carbon</th>
</tr>
</thead>
<tbody>
<tr>
<td>57.14</td>
<td>42.86</td>
</tr>
</tbody>
</table>

And its true specific gravity must be 0.9722, and 100 cubic inches of it weigh 16.99 grains. Carbonic oxir has the property of combining with chlorine, and forming a peculiar compound, which its discoverer, Dr. Davy, has named Phosgene gas; which see.

Carbonic Acid.—When pure charcoal is burnt in oxygen gas, it has been shown that the original bulk of the oxygen suffers no change. Hence it is obvious, that, by subtracting the specific gravity of oxygen from that of carbonic acid gas, we shall obtain the quantity of carbon existing in it. The specific gravity of oxygen gas is 1.11, and that of carbonic acid 1.52. Hence 100 parts, by weight, of carbonic acid will consist of

<table>
<thead>
<tr>
<th>Oxygen</th>
<th>Carbon</th>
</tr>
</thead>
<tbody>
<tr>
<td>72.73</td>
<td>27.27</td>
</tr>
</tbody>
</table>

which correspond with two atoms of oxygen and one of carbon. See Atomic Theory.

Carburetted Hydrogen.—The specific gravity of carburetted hydrogen, according to Dr. Thomson, is 0.5555, and 100 cubic inches of it weigh 16.99 grains. It requires for its complete combustion twice its volume of oxygen gas, and produces exactly its own volume of carbonic acid; the only remaining product is water. Hence 100 parts, by weight, of this gas are composed of

<table>
<thead>
<tr>
<th>Carbon</th>
<th>Hydrogen</th>
</tr>
</thead>
<tbody>
<tr>
<td>75</td>
<td>25</td>
</tr>
</tbody>
</table>

which correspond with one atom of carbon and two of hydrogen.

Olelfant Gas.—The specific gravity of this gas, according to Dr. Thomson's experiments, is 0.974, and 100 cubic inches of it weigh 29.72 grs. It requires for its complete combustion three times its volume of oxygen gas, and produces, when burnt, twice its volume of carbonic acid gas, and a certain proportion of water. Hence 100 parts, by weight, of this gas are composed of

<table>
<thead>
<tr>
<th>Carbon</th>
<th>Hydrogen</th>
</tr>
</thead>
<tbody>
<tr>
<td>85.71</td>
<td>14.29</td>
</tr>
</tbody>
</table>

which correspond with one atom of carbon and one of hydrogen.

The curious oil-like compound formed by the union of this gas with chlorine, has been lately examined by MM. Robiquet and Colin. They found that it is composed of one volume of chlorine united with one volume of olefiant gas, and of course that its constituents, by weight, are

<table>
<thead>
<tr>
<th>Olefiant gas</th>
<th>Chlorine</th>
</tr>
</thead>
<tbody>
<tr>
<td>16.28</td>
<td>83.72</td>
</tr>
</tbody>
</table>

This oily liquid, which Dr. Thomson considers as a sort of ether, and hence names it chloric ether, burns with a green flame, and at the same time gives off copious fumes of muriatic acid and much foot. Its specific gravity at 45° is 1.2201, water being 1.000. It boils at 152°. At the temperature of 45°, its vapour is capable of supporting a column of mercury 24.66 inches in height. The specific gravity of this vapour was found by experiment to be 3.4434, which very nearly coincides with the above account of its composition. When passed through a red-hot porcelain tube it is decomposed and converted into muriatic acid, and an inflammable gas containing hydrogen and carbon, while a copious deposit of charcoal is found in the tube. It is also decomposed when passed through red-hot oxide of copper.

With respect to the carbonates, the numbers representing them will of course require a little adjustment; this can be easily done from the composition of carbonic acid stated above, and from the data given under Atomic Theory.

CARBONIC Acid Gas, col. 2, l. 5, add—According to the accurate experiments of Mells. Allen and Pepsy, recorded in the Phil. Trans. the weight of a cubic inch of this gas is .464 of a grain. Col. 3, l. 46, r. milikins.

CARDAMOM, l. 2, inset after Cardamom, anguifolia, grana Paradisa, &c.

CARDIFF, col. 2, l. 9, inset after canal.—The townhall of Cardiff is a respectable, modern building, and near it
is the county gaol, built upon Mr. Howard's plan; 1. 14—
By the parliamentary return in 1811, the number of inhab-
habitants is stated at 2457. The only manufactory established
here is that of iron hoops; the trade, however, is very
considerable, in consequence of the numerous collieries up
the vale, and the iron and tin works of Methyr, Melin
Gruffydd, &c. the produce of which is conveyed here by
the canal for exportation, and which creates a large import
trade from Bristol, &c., in shop goods to supply the con-
sumption of the interior country. There are regular passage-
boats twice a week from this place to Bristol.
Cardiff is a borough-town, and in conjunction with the
contributory boroughs of Cowbridge, Llantrifflant, Caerphili,
Aberavon, Neath, Swansea, and Loughor, sends one mem-
ber to parliament.

CAREX, col. 4. l. 11, r. banata.
CAREYA, in Botany, named by Dr. Roxburgh, "after
its discoverer Mr. William Carey, a good botanist, and a pro-
founder of natural history in general."—Roxb. Coromand.
v. 3. 13. Ait. Hort. Kew. v. 4. 236.—Claws and order,
Myrti, Juf.
Germens of four cells. Berry with numerous seeds, imbedded
im in pulp.
1. C. herbeca. Herbaceous Careya. Roxb. as above, l.
217. Ait. n. 1.—Herbaceous. Flowers stalked. Outer
filaments longiit and without anthers.—Native of Runnpore,
in Bengal, flowering in February. Root woody, perennial.
Stems a span high, annual, round, smooth. Leaves opposite,
ovate, crenate, smooth, from four to eight inches long,
on short stalks. Flowers terminal, corymbose, few, large
and very beautiful, the calyx and petals greenish, tinged with
red; the outer row of their innumerable filaments crimson,
capillary, two inches long, recurved, without anthers, about
twice the length of the ovobate petals. Berry brown, the
fizze and texture of a medlar.
(Pelou : Rheed Hort. Malab. v. 3. 35. t. 38.)—Arbo-
reous. Flowers small. Inner filaments short, and without
anthers.—Native of the valleys, in various mountainous parts
of India. A large tree, with obvate, slightly ferrated, smooth,
deciduous leaves, from six to twelve inches long. Flowers
crowded, pale yellow, appearing with the young leaves in
March. Fruit the size of a small orange, soft and juicy till
quite ripe, when the pulp becomes sweetish, but Rheedede
reports it to be poisonous, which, considering its affinity to
Pfidium, is not credible. Dr. Roxburgh gives no account of
this plant, but describes the wood as the colour of mah-
ogany, though less hard and close. The fibrous bark
makes tough and durable ropes.
CARGA, a measure for wine and oil at Barcelona,
equal to 2½ quarters.
CARGADOR, in Portugal and Holland, denotes a
shipbroker.
CARGILLA, in Botany, is dedicated to the memory of
Dr. James Cargill of Aberdeen, a contemporary of Culpin
Baulhin, in whole Prodrornus, p. 154, 155, (Mr. Brown by
mistake refers to his Theatrum,) several descriptions of Fuci,
communicated by Dr. Cargill in 1653, may be seen.—Brown
Prodr. Nov. Holl. v. 1. 250.—Claws and order, Polynem
Juf. Br.
Eff. Ch. Calyx inferior, half-four-cleft. Limb of the
corolla four-cleft. Stamens inserted into the bafe of the
corolla; filaments doubled. Germen of four cells, with
two seeds in each. Berry globose, closely invested with
the cup-shaped calyx.—Some flowers have fewer, and im-
perfect, filaments; others only the rudiment of a pistil.
This genus is intermediate between Diospyros and Maba.
See those articles.
of the male flowers four-toothed, half as long as the tube of
the corolla. Style in three or four deep segments. Young
branches lax.—Found by Mr. Brown in the tropical part
of New Holland.
2. C. apera. Leaves oblong, smooth, obtuse, paler
beneath; acute at the base. Calyx of the male flowers four-
cleft, as long as the tube of the corolla. Style undivided.
Found by Mr. Brown, in New South Wales.
CARL P'Or, a gold coin of Brunnick, of which there
are double, flange, and half car d'ors; since 1802 con-
taining 92 gr. of pure gold, and equal 16s. 3d. sterling.
The double in proportion. See Coin.
CARLIN. Add.—See Taro.
CARLISLE, col. 5. l. 27; add.—By the return of 1811,
the city of Carlisle contained 16,528 houses, and 12,531
persons; vis. 628 males, and 6593 females: 134 families
employed in agriculture, and 2301 in trade, manufactures,
and handicraft.
CARLISLE, the chief town of Cumberland county, &c. —
I. 6. By the census of 1810, Carlisle borough contains
2491 inhabitants, including 78 slaves. Alto, a town of
Middlesex county, in Massachusetts, having 672 inha-
bitants.
CARMELEITES. Add.—see Manchetter Memoirs,
vol. v.
CARN, or CAIRN. See Carnezzarella.
CARNESVILLE. Add.—see Franklin.
CAROLIN D'OR, or CAROLIN, a gold coin of Bavaria,
Hefte Darmstadt, and Wurttemberg, valued at 11 florins.
See Coin.
CAROLINA, N. and S. See United States.
CAROLINE, l. 4, r. 17, 544; l. 5, r. 10, 743; l. 8, r.
9453; l. 10, r. 1520.
CARORA, l. 2, infert.—15 leagues E. of Maracaybo
lake, in N. lat. 10°. The town is tolerably well built; the
streets are large and on a line; the air is flyfarious, though
the soil is parched; the inhabitants, amounting to about
6200, live on the produce of their flocks and herds, and em-
ploy themselves in tanning and trefenting the hides and
skins, which are used in the tins for boots, shoes, saddles, bridles,
and curriers. The surplus of the local consumption is spread
over the province, or is conveyed to Maracaybo, Cartha-
gena, and the island of Cuba. They also make, with a
kind of fibre (aole djsiilia) very good hammocks, which far-
thigh an article of commerce. Depons.
CARPATHIAN MOUNTAINS, l. 22, r. Zemnit.
CARPHA, in Botany, so named by sir Joseph Banks
and Dr. Solander, from saxa, dry forests, cattania, in allusion
to the habit of this genus.—Brown Prodr. Nov. Holl. v. 1.
Calamaria, Linn. Cerepera, Juf. Br.
Eff. Ch. Spikelet single-flowered; scales imperfectly
two-ranked, the lower ones empty. Brifles three to fix,
beneath the germen, as long as the fertile scale. Style awl-
shaped, without a joint, crowning the prismatic nut. Stigmas
two or three.
1. Sect. 1. Spikelets two-ranked. Stigmas three. Nut trian-
gular. Brifles feathery.
1. C. alpina. Spikelets in a corymbose cluster. Brifles
fix, feathered nearly to the top. Stem leafy, smooth.
Leaves rough.—Native of Van Djeems's island.
2. C. dufta.—Tuft terminal. Involucrum of two elon-
ated
gated leaves; dilated and membranous at the base. Brites three, feathery at the base. Stem leaflets. Leaves radical, almost bristle-shaped.—Native of Port Jackson.

Thefe, with a non-descript species from Terra del Fuego, conftitute, in Mr. Brown’s opinion, the genuine genus of Carpho, the following being perhaps entitled to form one by themselves.

**Sect. 2. Spikelets awl-shaped. Style elongated, in two divisions.** 

**CARRICK.** See Trankey.

**CARTER, l. i.,** infect E. Tennekece. **Add**.—It contains 1142.

4190 inhabitants, 202 being花钱.

**CARTS, Laws relating to,** col. 3, l. 49, for 14. 4s. r.

CARTHAMUS, Chemical Properties of. Many experiments have been made on the colouring matter extracted from this plant. The leaf and most interesting are those of Dufour and Marchais, of which we shall present our readers with a short account.

The flowers of the carthamus contain two colouring matters; a yellow, which is soluble in water, and has hitherto been applied to no use; and a red, which is employed by the dyers, &c., and which constitutes the pigment called rouge. The yellow colouring matter readily dissolves in water, but it is difficult to separate the whole of it. Dufour effected this by expounding the carthamus wrap up in a piece of linen to the action of a flame of water. To separate the red colouring matter, he macerated for an hour the carthamus, after it had been washed, in a weak solution of carbonate of soda. Into this solution was put a quantity of cotton, and lemon-juice was then dropped into it till the liquid assumed a fine cherry-red colour. After standing twenty-four hours, the liquid lost its red colour, the whole colouring matter having combined with the cotton, and dyed it red. The cotton was taken out and well washed, to separate a little of the yellow colour adhering to it. It was then put into a very dilute solution of carbonate of soda. This alkali separated the colouring matter from the cotton, dissolved it, and assume a yellow colour; the cotton being removed and lemon-juice dropped into the solution, a fine red-coloured powder gradually separated, and at last precipitated. This was the red colouring matter. This red colouring principle is insoluble in water and oils, but is soluble in alcohol and ether. The alkalis also dissolve it, but destroy its colour. When diffused, it yields a little water, scarcely any gas, but a little oil, and a portion of charcoal, equal to one-third of the original weight. When this charcoal is burnt it leaves no ashes. One thousand parts of carthamus yielded only five of this red colouring matter, but no less than 268 of the yellow colouring matter above-mentioned. Carthamus also contains a great variety of other subiances according to Dufour, many of which, such as alumina, laud, &c., are evidently foreign. It is probably in some such manner as the above that the pink flowers are prepared from carthamus, though we believe the exact process is kept secret.

**CARTILAGE, Chemical Properties of.** See Bone.

1. C. ficatum.—Found by Mr. Brown in the tropical part of New Holland. Root perennial, tuberous below the fibres. Herb clothed with bar hairs, much resembling Phylidrum in appearance. Stem leafy, simple, or slightly branched. Leaves linear, clasping, elongated. Spike terminal, of many yellow flowers, each with two unequal, leafy, permanent bractes. The habit, as well as the permanent flaments and style, lead Mr. Brown to suspect some affinity to Phylidrum. Hence perhaps the true place of that puzzling genus may be discovered.

**CARVER, in Geography.** Add.—It contains 358 inhabitants.

**CASBIN, infect or CASWEEN, l. 11, after broad, add**—it may fill, however, be regarded as one of the largest and most populous towns in the kingdom, and carries on a great trade with Ghilan.

**CASEY, a county of Kentucky, containing 3252 inhabitants, of whom 257 are flowers.**

**CASH, a small coin in China, and India beyond the Ganges.** See TAL.

**CASHIERING, in Military Language.** An officer sentenced by a general court-martial, or peremptorily ordered by the king, to be dismissed from the service, is said to be cashiered.

**CASSAVA, or TAPIoca, Chemical Properties of.** This is prepared from the roots of the Jatropha manihot, an American plant. (See Jatropha.) These are peeled and subjected to prebure in a bag made of rushes. The expressed juice is a virulent poison, and is employed by the Indians for poising their arrows; but it deposits gradually a white powder, which has all the properties of starch, and which, when washed and dried, is perfectly harmless and highly nutritious. What remains in the bag also confits chiefly of the same starch. It is dried in stove, and afterwards pressed through a kind of sieve. Of this substance, the cassava bread, so much employed in the West Indies, is made.

1. C. aurea. Yellow Cassinia.—Native of the south coast of New Holland. Br. Seeds were lent to Kew, by Mr. Good, in 1803. The plant is marked as a green-houfe perennial herb, flowering in July and August, but we have no account of its habit or appearance.

**CAST, for BRAHMINS r. BRACHIMANS.**

**CASTELLANO, a weight for gold in Spain, 50 castellanos**
CAV

lanos being = 400 tomiones or 4800 grains. Silver is weighed by the same mark of 50 castellanos, divided into 8 ounces, 64 oehavos, 128 adaranes, 384 tomiones, or 4608 grains.

CASTINE. Add—It contains 1036 inhabitants.

CASTLE, New. See NEWCASTLE.

CASTLE-CARY, l. 8, add—By the returns of 1811, the parish contained 281 houses, and 1406 inhabitants; 650 being males, and 756 females.

CASTLE-RISING. By the returns of 1811, the borough and parish contained 46 houses, and 297 persons; viz. 148 males, and 149 females.

CASTLETON, l. 9, r. 1420.

CASTLE-TOWN, a township of America, &c. l. 2, which contained, by the census in 1810, 1301 inhabitants, and 121 senatorial electors. Here are three houses for public worship, and some school-houses.

CASTOR. By the returns of 1811, the parish contained 185 houses, and 1051 persons; 487 being males, and 564 females.

VOL VII.

CASWELL, l. 3, r. 11757 and 4299.

CATAHULA, a parish of the territory of Orleans, having 1164 inhabitants.

1. C. syringifolia. Common Catalpa. Sims in Curt. Mag. 1. 1894; and

2. C. longiflora. Wave-leaved Catalpa. (Bignonia longiflora ; Willd. Sp. Pl. v. 2. 290.) are the two described species. (See Bignonia n. 1 and n. 22.) We have heard that Dr. Solander, who was first aware of this genus, and who would certainly never have admitted it unauthorized a name as Catalpa, was very desirous of having it called Solandra.

CATAWESSY. Add—It contains 1914 inhabitants.

CATHARINE II., col. 3. l. 40, for Prussian.

CAT'S-EYE. See MINERALOGY, Addenda.

Catty, a weight at Canton, in China, and in some parts of India. The catty or gin of 16 langes or taels weighs 19 oz. 6 dwt. 4 grs. English Troy, so that 10 taels would weigh 5792 English grains. See TALE.

CAVALLO, THOMAS, F.R.S., in Biography, the son of an eminent physician of Naples, where he was born in 1759. Definied for commerce, he came to England for the purpose of acquainted himself with the principles of commerce in 1771; but literature and philosophy diverted his delination and enjoyed his preference. To those who were engaged in pursuits similar to his own, and to the editor of this Cyclopedia, he was a very useful coadjutor. His publications on a variety of philosophical subjects, and his communications to the Royal Society, were numerous, and are well known; particularly his "Elements of Natural and Experimental Philosophy," 1803, 4 vols. 8vo. He died, much respected and esteemed, and with the editor's sincere regret, in London in 1810.

CAUCUS, a term used in North America for a kind of electioneering committee; caucusing, as it is said, denoting electioneering. Of the origin of this uncoutth term we have the following account in Gordon's Hist. of the Amer. Rev. London 1788, "About the year 1738, the father of Samuel Adams, and twenty others who lived in the north or shipping part of Boflon, used to meet to make a caucus, and lay their plan for introducing certain persons into places of trust. Each distributed the ballots in his own circle, and they generally carried the election. As this practice originated in the shipping part of Boflon, caucus might have probably been a corruption of Caulker's meeting."

CAVEDONIA, l. ult. r. 80.

CAVEER, or CAVER, a money of account at Mocha, in Arabia, where accounts are kept in piasters of 80 cavers current.

CAVELLO, a copper coin of Naples.

CAVENDISH, The Honourable Henry, in Biography, was the son of Lord Charles Cavendish, and born in London in 1731. In literature, mathematics, chemistry, and philosophy, he was eminently distinguished; but his temper and habits were through life singularly recluse and economical; so that he appeared to those who were not honoured with being his intimate associates to great disadvantage. In early life his fortune was small; but by the retired manner in which he lived, and by subsequent accumulation of property, he died very rich. His library was very valuable; and easy of access to all his literary friends; but it is to be lamented that, in other respects, he was not emulous of following the example and acquiring the reputation of his eminent friend, Dr Joseph Banks, the president of the Royal Society, whose Sunday evening meetings he constantly attended, being generally there as well as at the meetings of the Royal Society, where he was almost always present, more ready to hear than to speak. A similar reserve and taciturnity marked his character in all his ordinary social connections and secular concerns. As a philosopher, his ruling temper was not without its beneficial effects. His contributions to the Royal Society, and which may be found in its Transactions, relate to chemistry, electricity, meteorology, and astronomy. This eminent philosopher died on February 4th, 1810, in the 79th year of his age; and at that time was reckoned the greatest proprietor in the Bank of England, his wealth being estimated at near 1,500,000 pounds, which he left entirely among his relations.

CAVENDISH, in Geography, a town of Windsor county, in Vermont, having 1295 inhabitants.

CAUK, l. ult. add—and BARTYES.

This genus is founded on Zyglera ocinica of Linnaeus, see Cavol, Monogr. translated in Ann. of Bot. v. 2. 77. t. 6. To this Mr. Brown adds a New Holland species, C. ferrulata, with three doubtful ones, among which is Rupia antarctica, Labill. Nov. Holl. v. 2. 116. t. 264. We are not informed why this genus supercedes the Cavolinia we have already described; see that article.

CAULO-
CAULOPHYLLUM, Michaux Bor.-Amer. v. 1. 204. Pursh 218. See LEONTICE.

CAUSTIC, Lunar, l. 18, r. revived.

Eff. Ch. Spikelets nearly single-flowered. Scales fallucited, the empty ones numerous. No bristles beneath the germen. Style dilated at the base. Stigmas three or four. Nut tumid, crowned with the bullous base of the style.

Obs. One species has five flaments, a circumstance marked by Mr. Brown as very extraordinary.

The are rigid rufby plants, growing on dry heaths in New Holland. Their flaments are leaflets; round and undivided in the lower part; panicked and semi-cylindrical above; the ultimate branches awl-shaped and leaf-like. The flaments are clothed with entire withered sheaths, extended on one side into an awl-shaped point, of the fame colour. Spikelets panicked, small, sometimes dioecious. Nut ovate, white, opaque. Brown.

1. C. flexuosa.—Panicles loose, zigzag; their ultimate branches smooth. Scales of the spikelets smooth.—Found at Port Jackson.

2. C. dioica.—Panicles zigzag, rather dense; ultimate branches rough-edged. Scales of the spikelets downy.—Native of the south coast of New Holland.

3. C. pentandra.—Principal and partial branches bif. Stamens five.—Found near Port Jackson.

CAWZI, or CADI, denotes in India a Mahometan judge, or justice, who also officiates as a public notary by affixing his seal. This is the same name as that which the officer named Cadi in Turkey.

CAYUGA, in Geography, a county of New York, containing 20,843 inhabitants, of whom 75 are flaves.

CECIL, l. 3, add—In 1810, 13,066 inhabitants, of whom 2,469 are flaves. Add at the close—Containing 1167 inhabitants.

CEDAR CREEK, a hundred of Sussex county, in Delaware, having 3874 inhabitants, of whom 310 are flaves.

CELEBINE, a corn measure in Spain. See CAFIIS.

CELESTEINE Sulphate of Strontian. See STRONTIAN.

CELSIUS, Andrew, in Geography, an eminent Swedish astronomer, was born at Upsal in 1701, and distinguished by his knowledge of mathematics, and more especially of astronony, to which his attention was principally devoted. In 1730 he was appointed by the king professor of astronomy, and he contributed very much to the revival of the study of this science in his native country, where it had been much neglected. With this view, he travelled into foreign countries, visiting Germany in 1732, and Italy in 1733. From Bologna he went to Rome; and having an opportunity of measuring the power of light, he concluded from his experiments on this subject, that the light of the moon, at new moon, is eight times weaker than at full moon; and that the light of the sun is 320,000 times stronger than that of the moon, and when in the meridian, thirty times more powerful than in the horizon. From Rome he removed to Paris in 1734, and was there engaged to accompany Maupertuis and other eminent astronomers, who were appointed to measure a degree under the polar circle; a problem of great importance in determining the figure of the earth. To the success of this mission he very much contributed by his journey to London in 1736, in order to procure instruments of Graham's construc-
Cephaeanthus, a genus of the cartilaginous order of fishes, the species of which have been united with those of the genera of Diodon and Tetronod; which see. Dr. Shaw has given the following character of this genus: jaws bony; body terminating abruptly, so as to resemble the head of a fish. The species enumerated by Shaw are, C. brevis, or tetronod mola of Linnaeus; C. oblongus, or Tetronod trunculus, or oblong dionod of Pennant; C. ovatus, with body variegated by whitish undulations and spots; C. Pallaflanus, the dionod mola of Gmel. Linn.

Ceratium, in Chemistry, a name given by Dr. John to a peculiar vegetable subfusible, which has always been hitherto confounded as a variety of gum. Its properties are the following.

It is a solid subfusible, having the general appearance and taste of gum; though it is usually harder than gum, and not so easily reduced to powder. When put into cold water it imbibes that liquid and swells up very considerably, and becomes semi-transparent and gelatinous, but is not in the least soluble, a property by which it is distinguished from gum. It diffuses in boiling water, but again precipitates as the liquid cools, and remains in the state of jelly. This gelatinous mass may be used like gum to pave together pieces of paper, &c. It is insoluble in alcohol and ether; but cold water, acclimated with either of the mineral acids, diffuses a small portion of it, and if heated, the whole. When an alkaline solution is dropped into the nitric solution of cerasin, a portion only of the cerasin is precipitated. If the liquid be evaporated, the remainder is obtained converted into a peculiar bitter-subsalubrious.

Tragacanth gum may be confounded as an example of pure cerasin. (See Tragacanth.) Cerasin also confounds a portion of the gummy matter that exudes from the prunus cerasin, (hence the name,) prunus ebulium, prunus domestica, xanthera hallisi, &c.

Ceratochis, in Botany, from xipho, a spur, and affinis, an anchor.—Brown Prodr. Nov. Holl. v. 1. 438.

Eff. Ch. Calyx split at one side; five segments cohering at the other. Corolla funnel-shaped; limb spreading, five-lobed, unequal. Stamens within the tube. Lobes of the anthers spurred at the base. Stigma lancesolate. Capsule with two cells, two valves, and a contrary partition bearing the receptacle of the base, at length separating from the valves.

1. C. hipida. Br. n. 1.—Found by Sir Joseph Banks, in the tropical part of New Holland. An upright bristly herb, with opposite, undivided, narrow leaves, and a terminal spike. Flowers purplish, alternate, nearly upright, each with three bractlets. Capsule ovate, rather pointed, its valves sometimes divided. Seeds minute, with a lax reticulated skin. Albumen but small. Embryo round. Calyx at length separable into two divisions. Akin on the one hand to Buchnera and Euphrarita, on the other perhaps to Digitalis, being also allied to Sefianum, but distinguished by the structure of the calyx, and the preference of albumen. The stigma requires further examination. Mr. Brown thinks there is another species found in the East Indies.

Ceratium, in Chemistry, a name given by Dr. John to a peculiar vegetable subfusible, which has always been confounded as a variety of gum. Its properties are the following.

It is a solid subfusible, having the general appearance and taste of gum; though it is usually harder than gum, and not so easily reduced to powder. When put into cold water it imbibes that liquid and swells up very considerably, and becomes semi-transparent and gelatinous, but is not in the least soluble, a property by which it is distinguished from gum. It diffuses in boiling water, but again precipitates as the liquid cools, and remains in the state of jelly. This gelatinous mass may be used like gum to pave together pieces of paper, &c. It is insoluble in alcohol and ether; but cold water, acclimated with either of the mineral acids, diffuses a small portion of it, and if heated, the whole. When an alkaline solution is dropped into the nitric solution of ceratin, a portion only of the ceratin is precipitated. If the liquid be evaporated, the remainder is obtained converted into a peculiar bitter-subsalubrious.

Tragacanth gum may be confounded as an example of pure ceratin. (See Tragacanth.) Ceratin also confounds a portion of the gummy matter that exudes from the prunus ceratin, (hence the name,) prunus ebulium, prunus domestica, xanthera hallisi, &c.
which he gave the name of ocherita. (See OCHROITE.) About the same time this mineral was examined with more attention by Hifinger and Berzelius, who gave it the name of cerit, and detected in it a peculiar substance, which they considered as a metallic oxyd, to which they gave the name of Cerium, from the planet Ceres, later discovered by Piazzi. They did not succeed in reducing this oxyd; nor was Gahn, who made the experiment some time afterwards, more successful. Vaquelin, however, who had formerly examined the mineral, turned his attention to the subject a second time, and he succeeded in reducing it so far as to show that its basis is a metallic.

In 1814 a new set of experiments was made upon it by Laugier. He appears to have reduced it to the metallic state, but combined with carbon. Oxalic acid, according to Laugier, separates the whole of the oxyd of cerium from iron. The affections of this chemist, however, that its oxyd is not volatile, has been denied by Dr. Thomson.

To procure the oxyd of cerium in a state of purity, the Swedish chemists employed the following method. The mineral was reduced to a fine powder, and digested in nitric acid till every thing soluble was taken up. The solution was then evaporated to dryness, and the residue diffused in water. Into this solution ammonia was poured, till every thing precipitable by its means was thrown down. The precipitate being well washed, was redissolved in nitric acid, the acid neutralized, and then tartrate of potash added to the solution. The precipitate thus formed was then heated to reduce, well washed with vinegar, and dried, and was considered as pure oxyd of cerium.

The oxyd of cerium, when first prepared, is white; but when it has been heated it becomes reddish-brown. Formed into a paste with oil, and heated in a charcoal crucible, it loses weight: when urged by a strong fire on charcoal, it does not melt but continues in powder. It exhibits, however, brilliant particles, which were proved to be of a metallic nature.

According to Vaquelin and Hifinger, cerium combines with two proportions of oxygen. The protoxyd is white; the peroxyd reddish-brown. The peroxyd contains 15 times as much oxygen as the protoxyd. The protoxyd, according to Hifinger, is composed of

| CERIUM   | 100 |
| Oxygen   | 17.41 |
| Cerium   | 100 |
| Oxygen   | 28.115 |

From Hifinger's experiments, it appears that the equivalent number for the protoxyd of cerium is 67.5, and of the metal 57.5. But if with Dr. Thomson we suppose the per oxyd to be a compound of two atoms of cerium and three of oxygen, the weight of the atom of per oxyd will be 145.

No compound of this metal with hydrogen, azote, chlorine, or fluorine is known. The carburet formed by Laugier was a black matter, which took fire spontaneously when exposed to the air. The phosphuret, which appears to have been formed in one instance by Hifinger and Berzelius, was a hard, brown, tenacious substance, which thione in the dark, and took fire when heated.

Hydrosulphuret of ammonia throws down cerium at first of a brown colour, but it becomes deep green if the reagent be added in larger quantity. When dry, the hydrosulphuret formed is a bright green, and burns when heated, leaving a yellow oxyd of cerium. The colour of the precipitate varies, however, according to the state of oxidation of the cerium held in solution.

No alloy of cerium is known, except one with iron, obtained by Vaquelin; this was white, brittle, and diffused with great difficulty in nitro-muriatic acid.

Salts of Cerium. Nitrate of Cerium.—Nitric acid unites with both the oxyds of cerium; with the white oxyd it combines more readily. The solution is colourlefs, crystallizes with difficulty, retains an excess of acid, and has a sweet aulfer tafte. The red oxyd diffuses with difficulty in cold nitric acid, but the solution may be readily effected by heat. The solution is yellow, and if an excess of acid be present, it yields small white deliquescent crystals. Both the nitrates are soluble in alcohol, and are decomposed by heat.

Muriate of Cerium.—This salt exists in the form of small four-sided prismatic crystals of a yellowish-white colour. They are soluble in alcohol, and deliquesce on exposure to the air. When exposed to heat they are decomposed.

Sulphate of Cerium.—Sulphuric acid diffuses the red oxyd of cerium with difficulty. The solution when obtained is of an orange-colour, and yields by evaporation small octahedral and needle-formed crystals of per sulphate of cerium. Their colour is partly lemon-colour and partly orange. This salt is not soluble in water without excess of acid. When exposed to the air, the crystals soon assume the form of a yellow powder. Sulphuric acid combines readily with the white oxyd of cerium, especially when in the state of carbonate. The solution is colourlefs, and readily crystallizes. There is a triple sulphate of potash and cerium.

Phosphate of Cerium.—This is a white powder insoluble in water, but soluble in the nitric and muriatic acids.

Arseniate of Cerium.—This salt is insoluble. There is a soluable super arseniate which does not crystallize.

Acetate of Cerium.—This salt exists in the form of small granulated crystals, readily soluble in water, but sparingly soluble in alcohol, and not altered by exposure to the air.

Oxalate of Cerium.—Oxalic acid and oxalate of ammonia precipitate cerium from its solution. The precipitate with the per oxyd is red, with the protoxyd white. It is not soluble in excess of acid, but readily in ammonia.

Tartrate of Cerium.—The tartrate of potash throws down cerium from its solutions in the form of a white insoluble tartrate. This tartrate, however, is soluble in nitric, muriatic, and sulphuric acids, and also in pure alkalis.

Citrate of Cerium.—The citrate of cerium is insoluble, without an excess of acid, when it is readily soluble. The solution does not crystallize. The other salts of this metal are unknown, or devoid of interest. With respect to these salts in general, it may be observed, that they are either of a white or yellow colour, according to the state of oxidation of the metal, and their solutions have a sweetish taste. The hydro sulphate of potash, prussiate of potash, and oxalate of ammonia, produce in them white precipitates; while the gallic acid and infusion of galls occasion no precipitate, when added to solutions of their salts.

CERIUM. See MINERALOGY, Addenda.

CERNE, or CERNE-ABBAS, l. 36, add—In 1811 the parish contained 145 houses, and 795 persons; viz. 538 males, and 437 females.

CERUMEN, or Ear-Wax. Chemical Properties of. This substance is nearly insoluble in water. Alcohol, when diffused by heat, diffuses five-eighths of the cerumen; the remainder is flaked by Vaquelin to pool the properties of albumen mixed with a little oily matter: when the alcoholic solution is evaporated, it leaves a deep orange-redudium of a very bitter taste, having the smell and consistence of turpentine. It melts when heated, evaporates in a white smoke, without leaving any residuum, and in short resembles the resin of bile.
bila. Ether also dissolves this oily body; but the solution is much less bitter, and lighter coloured. From these and other experiments, Vauquelin considers cerasum as composed of

Albumen,
An infusigated oil,
A colouring matter,
Soda and phosphate of lime.

CESAR'S CREEK, a township of Greene county, in Ohio, having 640 inhabitants.

CETIC ACID, in Chemistry. A name given by Chevreul to a substance obtained by taponifying fpermacti. It may be procured by adding an acid to a soap composed of spermaceti and potash. Cetic acid is a white solid substance, without taste or smell. It melts at a temperature of about 113°, but does not crystallize on cooling, a circumstance in which it differs from spermaceti. It is insoluble in water, but boiling alcohol dissolves more than its weight of it, and as the solution cools, the cetic acid separates in brilliant lamellar crystals. The solution in alcohol redness litmus. It combines readily with the different Salifiable bases, and forms salts or rather soaps, none of which appear to possess any striking properties.

CETARIA, in Botany, Achar. Syn. 226, a natural, but not very easily defined genus of Lichenes, comprising eleven species, among which are L. juniperinus, glauces, nitulitis, and isidaticus of Linnaeus. See Lichenes, n. 19 in the arrangement of Acharius.

CÉYLANITE, or Pleenaste. See Mineralogy, Addenda.

CHASE, col. 2, l. 32, for vizier r. veneur.

This genus is distinguished from Leptocarpus (fee that article) by the undivided flake, and the minute facetous form of the inner scales of the very short calyx. The only species is

1. C. leptocarpus, found by Mr. Brown, on the south coast of New Holland.

CHÆTODON, col. 2, l. ult. for Japan r. Java. Add —See Teuthis.

CHÆTODON Arcanus. Add—Perhaps from the Aro islands among the Moluccas.

CHÆTOPORA, in Botany, from χαζη, a bristle, and αψης, a feed.—Brown Prodr. Nov. Holl. v. i. 232.—This genus is founded by Mr. Brown, on those species of the Schoenus of Linnaeus, and other authors (see that article), whose seed is subgutted by bristles, which are not fo long as the scales of the flower. Fifteen species are natives of various parts of New Holland, one of which, C. lanata, Br. n. 4, is Schoenus lanatus, Labill. Nov. Holl. v. i. 19. t. 20. The rest appear to have been first described by Mr. Brown. Schoenus compressus and rufus of Fl. Brit. belong to Chetopora. See Rhyhchospora for a genus similarly characterized.

CHAIN, col. 2, l. 4 from bottom, r. Plate XII.

CHALK, French r. See SLATE.

Female, Calyx deeply three-cleft. Petals three. Nectary

three scales, between the petals and germen. Styles three. Drups succulent, with one seed.

1. Ch. gracilis. Slender Chamedorea. Willd. l. n. 1. (Boraxius pinnatifrons; Jacq. Hort. Schoenbr. v. 2. 65. t. 247, 248.)—Native of the Caracas and of Guiana. An elegant palm, whose trunk is ten feet high, an inch in diameter, very smooth, crowned with alternate pinnate leaves, two feet long, and spreading out near the bottom several long, slender, aggregate spikes, of numerous small yellow flowers; the male ones long-stalked, and pendulous. Fruit scarlet, the size of a pea.

Eff. Ch. Calyx of two valves, two-flowered; the outer valve very small. Corolla of two valves. Outer floret male, its outer valve like the inner valve of the calyx: inner female, smaller, membranous. Scales two beneath the germen. Stigmas feathery. Seed included in the hardened corolla.

CHASE, in Architecture, l. 5 from the end, r. ought not to be, &c.

CHANCE, col. 2, l. 32, for vizier r. veneur.

CHÆTODON Arcanus. Add—Perhaps from the Aro islands among the Moluccas.

CHEILANTHES, in Botany, a genus of ferns, first distinguished from Adiantum, (see that article in the present volume,) by Professor Swartz, and named from χείλος, margin, and ωλιν, a flower, because the fructification is really inserted into the margin of the frond, not into the scales which conceal it. Such indeed was the idea hitherto conceived of Adiantum; but this not being the case with the original and best-known species, Capillus Veneris, the generic appellation was properly allowed to remain with that and its allies, under a corrected character.—Swartz Syn. Fil. 126. t. 3. Willd. Sp. Pl. v. 5. 455. Brown Prodr. Nov. Holl. v. 1. 155. Ait. Hort. Kew. v. 5. 526. Sm. Prodr. Fl. Græc. Sibth. v. 2. 278. Pursh 670.—Clafs and order, Cryptogramia Filices. Nat. Ord. Filices annulata.

Dr. Swartz defines sixteen species; Professor Willdenow, nineteen, the latter disposing the whole in three sections, though marked as two only, according to an inaccuracy which we have often noticed in him. The following are sufficient examples.

Sec. 1. Frond simply pinnate. One species.

Ch. micropteris. Small Cheilanthes. Willd. n. 1. Sw. n. 1. 324. t. 3. f. 5.—Frond pinnate, linear; leaflets hairy, nearly orbicular, with wave-like notches.—Native of Quito.

Fronds narrow, a finger's length, with several, alternate, finely flaked leaflets, about a line in diameter.

Sec. 2. Frond doubly pinnate. Ten species.

Ch. pterisides. Pteris-like Cheilanthes. Willd. n. 2. Sw. n. 12. Ait. n. 1. (Adiantum pteroides; Linn. Mant. 130.) Pteris orbiculata; " Hoff. Nat. Hill. t. 96. f. 3.c."—Frond doubly pinnate; lower branches somewhat compound; leaflets ovate-elliptical, obtuse, rather heart-shaped, finely crenate. Dots crowded. Coverings imbricated. Common fl Milk polifoliate.—Native of the Cape of Good Hope. A handsome fern, a foot or more in height, with stout, black, shining flanks, and firm dark-green leaflets, half an inch long; paler beneath. This and the following have been referred to the next section.

Ch. spicules. Aromatic Cheilanthes. Willd. n. 5. Sw. n. 6. " Schkuhr Crypt. 116. t. 19." Sm. Fl. Græc. Sibth. t. 966, unpublished. (Polypodium fragrans; Linn. Mant. 357. Desfont. Atlant. v. 2. 408. t. 257. Petiv. Gazoph. t. 73. f. 4.)—Frond doubly pinnate, smooth; lower branches more or less compound; leaflets ovate, obtuse, somewhat revolution. Common fl Milk thread-shaped, roughish with slender scales.—Found on rocks and old walls in Barbary, Madeira, Cyprus, &c. An elegant little fern, three or four inches high, very fragrant when first dried. The capacious hair-like twanny scales of the flanks are sometimes almost entirely wanting.

Ch. fragrans. Sweet-scented Cheilanthes. Willd. n. 7. Sw. v. 4. 325. t. 3. f. 6. " Hoff. n. 22."—Frond doubly pinnate, smooth; leaflets elliptic-lanceolate, obtuse, pinnatifid, with incurved, partly cloven segments. Common fl Milk somewhat hairy.—Native of the East Indies, from whence Kenig sent specimens, which remain unnamed in the Linnean herbarium. The Madeira plant, gathered by the same botanist, is, as Dr. Swartz suspected, a different species, being the Polypodium fragrans of Linneus, our Ch. spicules, which is probably also Mr. Aiton's Ch. fragrans. The East Indian fern before us is excellently delineated by professor Swartz, and has a more oblong frond, with curiously pinnatifid leaflets, or can those who have seen both species ever confound them. We are unacquainted with Ch. odorata, Willd. n. 6.

Sec. 3. Frond triply or quadruply pinnate. Eight species.

Ch. dichotoma. Forked Cheilanthes. Willd. n. 15. Sw. n. 15. 335. t. 3. f. 7.—Frond three or four times pinnate, smooth; leaflets three-lobed, obtuse, somewhat crenate.—Native of mountains in Quito. A span high, slender and delicate, with alternate, wavy, almost capillary branches, and minute round-lobed leaflets.

Ch. tenifolia. Fine-leafed Cheilanthes. Willd. n. 16. Sw. n. 15. 332. " Schkuhr Crypt. t. 125." Br. n. 1. (Trichomanes tenifolia; Burm. Ind. 237. Dryopteris campbellii; Rumph. Amboin. v. 6. 74. t. 34. f. 2.)—Frond triply pinnate, smooth; leaflets ovate-oblong, slightly crenate; upper ones confluent.—Native of the East Indies. This has the habit of fragrans; and its allies, but is much larger.

Ch. dillatata. White-leafed Cheilanthes. Pursh n. 2.—" Frond triply pinnate; leaflets oval, distinct, crenate or emarginate at the end; white beneath."—On rocks, on the banks of the Mopsfouri, in July. A very delicate small fern, much resembling Ch. tenifolia. Pursh.

CHEKIE, or Chequeé, a Turkish weight: that with which gold, silver, diamonds, and precious stones are weighed, is divided into 400 drachms, and the drachm into 16 kilots, or carats, or 64 grains. A cheque weighs 10 oz. 5 drs. 3 grs. troy weight; and a drachm 492 grs. troy; so that 48 cheques = 41 lbs. troy nearly. The kiks = 4 cheques, or 460 drachms; and the cheque = 11 oz. avoidance. The cheque of goats' wool is 800 Turkish drachms, or 5 lbs. 10 oz. avoidance; the cheque of opium 250 Turkish drachms = 27 oz. 10 drs. avoidance.

CHELMESFORD, col. 2. l. 12 from the bottom, r. 469 and 822.

CHELMESFORD, in America, l. 4. r. 1306.

CHELSEA, in America, l. 3. r. 5941. l. 8. r. 1527.

CHELNTHAM, col. 2. l. 19 from the bottom, r. 325. l. 12, r. 1568.

CHELTHAM, a township of Montgomery county, in Pennsylvania, having 783 inhabitants.

CHEMIN CREUX, r. RAVINE.

CHENANGO, a county of New York, containing, by the census of 1810, 21,704 inhabitants, of whom 13 are slaves.

CHEPSTOW, col. 4. l. 48, for wall r. walk. Add—The parish of Chepswell contained, in 1813, 421 houses, and 2581 persons; 1158 being males, and 1423 females.

CHERRY, or CHURAY, a weight in Perse; the batman of Churay being double the batman of Taurus, and weighing 12 lbs. 4 oz. 13 drs. avoidance.

CHERBOURG, l. ult. r. N. lat. 49° 38' 31". W. long. 1° 37' 18".

CHERRYFIELD, in Geography, a town of Washington county, in the district of Maine, with 181 inhabitants.

CHERRY-
CHERRY-TREE, a township of Venango county, in Pennsylvania, having 391 inhabitants.

CHESHAM. The parish of Chesham, in 1811, contained 417 houses, and 2071 persons; 924 being males, and 1147 females.

CHESIRE, col. 2, l. 4 from the bottom, r. 41,187 and 227,031.

CHESIRE. By the returns of 1811, Ashton-upon-Mersey in this county, and in a parish of the same name (omitted in its alphabetical arrangement), appears to have then contained 150 houses, and 918 persons; 467 being males, and 451 females.

CHESHIRE, in America, del. l. 5 and 6, and add—and 409,988 inhabitants.

CHESNUT HILL. Add—containing 1128 inhabitants.

CHEST, in Anatomy, l. 2, infr.—LUNGS.

CHEST of Viois, del. SIX-STRINGED BASE.

CHESTER, col. 6, l. 17. In 1811, the city of Chester contained 3296 houses, and 16,140 persons; 7007 being males, and 9133 females; 397 families employed in agriculture, and 2256 in trade and manufactures.

CHESTER, in Nova Scotia, l. 8, r. 1534; l. 13, r. 2030; l. 17, r. 2370; l. 30, after assistants, add—It contains 1956 persons; l. 32, r. 40; l. 33, r. 39,596; l. 34, r. 7; l. 57, r. 11,479; l. 58, r. 2743. At the close, add—Alfo, a town of Clinton county, in Ohio, having 1254 persons. Alfo, a town of Burlington, in New Jersey, having 1839 inhabitants. Alfo, a town of Morris county, in New Jersey, having 1175 inhabitants. Alfo, a borough of Chester county, in Pennsylvania, having 471 inhabitants.

CHESTER, WEB, a county of New York, containing 30,272 inhabitants, of whom 982 are slaves.

CHESTERFIELD, col. 2, l. ult. In 1811 the parish of Chesterfield contained 951 houses, and 4476 persons; 2025 being males, and 2451 females.

CHESTERFIELD, l. 3, r. 1408; l. 7, r. 1839; l. 15, It contains 5564 inhabitants, of whom 1639 are slaves; l. 17, r. 9979, and 6015. Add—Alfo, a town of Burlington county, in New Jersey, having 1839 inhabitants.

CHESTER-LE-STREET. In 1811, the township of Chester-le-Street contained 245 houses, and 1726 persons; 800 being males, and 926 females.

CHESTERVILLE, a town of the district of Maine, in the county of Kennebec, with 430 inhabitants.

CHETWERT, and CHEWTWICK, two corn measures in Raffia; the former or cool being 2 omissions = 4 pâkjacks = 8 chiewerts = 64 garnity. The latter measures 1555.92 cubic inches, and contains 53 Wincheffer gallons nearly. In buifines the usual calculation is, that 100 chwerts produce 72 quarters, and 1 chewart 53 buifhles, Wincheffer meafure.

CHIAROSTOLITE. See Mineralogy, Addenda.

CHICHESTER, in Geography. In 1811, the city of Chichester contained 1083 houses, and 6425 persons; 2878 being males, and 3547 females.

CHICHESTER, Upper and Lower. Add—The former contains 457, and the latter 511 inhabitants.

CHICHESTER, l. 4, r. 951.

CHILLISQUAQUE. Add—Northumberland county, having 1505 inhabitants.

CHILLIKOTHE. Add—By the census of 1810, it contained 1460 inhabitants.

CHILMARK, l. 3, r. 723.

CHILODIA, in Botany, perhaps from χίλιος, in allusion to its longer and more conspicuous lip.—Brown Prodr.

1. Ch. feutellariana. Br. n. 1.—Gathered by Mr. Brown at Port Jackson, New South Wales. A little shrub, agreeing with Proflanthera in habit, but differing in calyx and anthers. The leaves are linear, revolute. Flowers axillary, solitary, flaked. We venture to rid the specific name of its termination, odes, which might be done with advantage in many other similar instances.

CHILOGLOTTIS, from χίλιος, a lip, and γλώττις, the tongue, alluding to the tongue-shaped appendage to the lip.

Eff. Ch. Calyx ringent; two lower leaves under the lip, channelled, with cylindrical points. Lip flaked; glandular in the disk; with a tongue-shaped appendage at the base. Column cloven at the top. Anther a terminal permanent lid; the cells close together. Maffes of pollen two in each cell, powdery, comprefsed.

1. Ch. diphylla.—Native of Port Jackson, New South Wales. Bulbi folitary, naked, terminating the defending caudex. Herb smooth. Leaves two, oval, many-ribbed, heathed at the base. Flower folitary, reddish, with a foliary bracteate half way up the flalk. Akin to CYRTOSTYLL and PTEROSTYLL. Brown. See those articles.

CHIMBORAZO, l. 9, add—according to Humboldt, its summit is 21,430 feet above the level of the sea; and consequently a great part is above the circle of perpetual congelation, which, in this latitude almost under the line, is situated higher than the summit of Mont Blanc.

CHINA, col. 3, l. 19 from the bottom, r. Mandhurs. Col. 24, l. 4, r. flicks or poles.

CHIODECTON, in Botany, from χιος, snow, and δεκτος, to receive, alluding to the whiteness of the warts or aggregate receptacles.—Achar. in Tr. of Linn. Soc. v. 12, 43. t. 3.—A genus of crassulaceous Lichens, found on the banks of trees in South America, thus defined.

Eff. Ch. Warts convex, of the substance of the crust. Receptacles numerous, imbedded in the warts, globular, aggregate, black, powderly throughout.

Two species are described, Ch. spharele, f. 2, and feriale, f. 3.

CHIPPENHAM, l. 30.—In 1811, the borough and parish contained 668 houses, and 3410 persons; vis. 1580 being males, and 1830 females: 145 families employed in agriculture, and 632 in trade and manufactures.

CHITTENDEN, l. 6, r. 1810; l. 24, r. 1820. At the clofe, add—It contains 446 inhabitants.

Eff. Ch. Calyx bell-shaped, equally five-leafed. Corolla tubular, ringent; throat dilated; upper lip cloven; lower in three deep segments, the middle one longist. Stamens prominent. Stigma cloven, acute. Drupa dry. Nuts two, each of three cells; two lateral cells single-seeded; middle one abortive, obliterated.

Downy shrubs, with opposite, fimple, decurrent, linear, blitary leaves. Stalks axillary, folitary, single-flowered, 5 H 2 each.

1. Ch. flocculata. Br. n. 1.—Back of the leaves, and outside of the calyx, snow-white, downy. Bracteas in the middle of the flower-flasks.—Native of Port Jackson, New South Wales.

2. Ch. glandulosa. Br. n. 2.—Back of the leaves glandular, and clothed, like the outside of the calyx, with featered hairs. Bracteas at the base of the flower-flasks. —From the same country.

CHLORATES, in Chemistry. See Chlorine.

CHLORIC Acid. See Chlorine.

Chlorine. This name was given by Sir H. Davy to the principle formerly termed Oxymuriatic Acid, under which head its leading properties are detailed. We have only therefore to notice here fome important compounds of this principle lately discovered, especially those with oxygen.

The protosyd of chlorine, or euclosoine, has been already decribed under the article above alluded to. For its correct composition, see Table II. Atomic Theory.

The deutosyd of chlorine was discovered about the same time by Sir H. Davy and the count Von Stadion of Vienna, but Davy’s account of it was firt published. It may be prepared by mixing together a small quantity of chlorate of potash (not more than fifty grains) in powder, with fulphoric acid, till the whole forms a dry paff of an orange colour. Put this paff into a small glafs retort, and pfinge the belly of the retort into hot water, and keep it in that poftition for fome time, taking care that the temperature of the water never becomes fo high as 212°. A bright yellowish-green gas separates from the paff, which must be received in small glafs jars over mercury. This gas is the deutosyd of chlorine. Its colour, as above fated, is a bright yellowish-green. Its fmal is peculiar and aromatic, without any mixture of the fmal of chlorine. Water abfors at leaf seven times its bulk of this gas. The solution is deep yellow, and has an atrigent and corrosive tafl, leaving a difagreement and lafling imprefion on the tongue. It defroys without previously reddening vegetable colours, provided they are moifi. It does not act upon mercury, nor any other combustible substance tried, except pholphorus, which, when introduced into the gas, occasions an explosion, and burns with great splendour. When heated to 212° it explodes with more violence than euclosoine, and emits a great light. Two volumes of deutosyd of chlorine, when thus exploded, are converted into three volumes, according to Davy, which confit of two volumes or four atoms of oxygen and one of chlorine, or per cent. of

</table>

And its fp. gr. will be 2.361, that of chlorine being fpupofed to be 2.5. According, however, to the count Von Stadion’s analysis, this deutosyd is composed of one atom chlorine, and only three of oxygen.

Chloric Acid. —The eifillence of this compound of chlorine with oxygen was fpupofed by Berthollet, but it was firft obtained by M. Gay-Lussac. It is the acid which exits in what was formerly termed oxymuriate, but now chlorate of potash. It was procured by diffoving the chlorate of barytes in water, and cautiously adding dilute fulphoric acid to the solution, till the whole of the barytes was fpaped.

The chloric acid remained in solution. This acid has a strong foul taste, but no fenfible smell. Its aqueous fpolution is colourles, and reddens vegetable films without defroying them. By a gentle heat it may be concentrated without being decomposed, or volatilized with the water. When thus concentrated, it has an oily confistency. When the heat is raised, it is partly volatilized, and partly decomposed into chlorine and oxygen. Muriatic acid decomposes it fimilarly without heat: the nitric acid does not affect it. It combines with the different bales forming chlorates, formerly termed oxymuriates, the most important of which will be previouly decribed. Chloric acid has been proved to be composed of

Or of one atom chlorine and five of oxygen. See Atomic Theory, Table II.

Chlorate of Potash. —This is the best known and moft important of the chlorates. Se a Table briefly decribed under Hypertoxynuriatic Acid.

Chlorate of Soda. —This salt was firft accurately decribed by Chenevix. It may be prepared by the fame process as the chlorate of potash; but the easiest mode of obtaining it is, to diffove carbonale of soda in chloric acid. It does not readily cryfaliize, but its cryfals when formed are square plates. Its tafle is sharp and cooling. On burning coals it melts into globules, and emits a yellow light. When diftilled it gives out oxygen, mixed with a little chlorine, and the falt left behind has alkaliene properties.

Chlorate of Ammonia. —This salt may be formed by diffoving carbonate of ammonia in chloric acid, or by mixing a fpolution of carbonate of ammonia with a fpolution of an earthly chlorate. It cryfaliizes in fine needles, and is very foule in water and alcohol. Its tafle is sharp. Thrown on burning coals, it fulminates with a red flame. When strongly heated, it is decomposed, chlorine is evolved mixed with azote and oxygen, and some muriate of ammonia remains behind.

Chlorate of Barytes. —The earthly chlorates are formed with more difficulty than the alkaline. The chlorate of barytes may be formed by pouring warm water on a quantity of the pure earth prepared by Vauquelin’s method, and paffing a current of chlorine through the mixture. To separate the chlorate from the muriate, which are both equally foulable, and otherwife resembie each other, Mr. Chenevix had recourse to the ingenious expedient of boilsphating of filver with the compound fpolution; thus muriate of filver and phophate of barytes are formed and easily seperated, while nothing but the chlorate of barytes remains in the fpolution, and may be easily obtained. This falt cryfaliizes in square prifms, terminated by an oblique face. It diffoles in about four times its weight of cold water. The fpolution is neither precipitated by nitrate of filver nor muriatic acid. It is insoluble in alcohol. When heated it gives out oxygen gas, and an alkaline reftedium is left.

Chlorate of Strontium. —This falt was formed by a process similar to the above, and resembies it in many of its properties, but is deliquefcent, and rather more fonluble.

Chlorate of Lime, and Chlorate of Magnesia, may be formed as above. They are both deliquefcent, and very fonluble both in water and alcohol.

The metallic Chlorates may be formed by diffoving the oxyds...
oxys of the different metals in chloric acid. They do not
possess any very remarkable properties, except those common
to all the chlorates; viz. of giving out oxygen when heated,
and of detonating when thrown on burning coals. The
chlorate of silver, mixed with a little sulphur, and struck
lightly, fulminates with prodigious violence.

CHLORIDIC ACID. See Iodine and Simple Sub-
stances.

CHLORITE. See Mineralogy, Addenda.

CHLOROCYANIC ACID. See Cyanogen.

CHLOROPHANE. See Mineralogy, Addenda.

CHLOROPHYTUM, in Botany, from chlo-nes, green,
and phytos, a plant, because of the green hue of the flowers,
as well as herbage, in the original species.—Ker in Curt.
Mag. t. 271. Brown Prodr. Nov. Holl. v. 1. 276.—Clafs and
order, Hexandria Monogynia. Nat. Ord. * Bromeliea,
Jufh.' Ker. Albipedale, Brown.

Eff. Ch. Corolla inferior, in fix deep, equal, spreading,
permanent segments. Filaments thread-shaped, fmooth.
Style thread-shaped. Stigma fimple. Capsule with three
different compefled lobes, three cells, and three valves with
central partitions. Seeds feveral, compefled, with a naked
scar.

Herbage smooth. Root fagiculated; the fibres occa-
sionally fthiny. Leaves radical, ribbed, linear, sometimes
lanceolate. Flowers racemofe green or white, their partial
flalks united in the middle. Capsule membranous, venous.

Curt. Mag. t. 271. Ait. Epit. 365.—Stem none. Leaves
lanceolate, nearly as tall as the flalk. Partial flalks foltary.
—Native of Sierra Leone, from whence, and not from the
West Indies, its seeds were brought to the late Mr. Fair-
barn, at Chelms, if we mistake not, by Francis Borone, in
1793. It is a fiove plant, flowering and feeding in fummer.
Several radical, many-ribbed, pointed leaves, five or fix
inches long, pater beneath, are accompanied by an eretf,
simple or branched, leaves flalk, a fpan high. Flowers pale
green, fenteet, each with a pointed bractea. Corolla
infeared, three-quarters of an inch wide.

2. Ch. laxum. Loofe-cluftered White Chlorophytum.
Br. n. 2.—*Stem none. Leaves linear, nearly as tall as the
flalk. Clufers lax, elongated, fimple or divided; partial
flalks foltary or in pairs.*—Found by Mr. Brown, in the
tropical part of New Holland.

3. Ch. elatum. Tall Chlorophytum. (Anthericum
Asphodelus folis planis, 8c.; Mill. Ic. 58. t. 56.
Phalangium elatum; Redout. Liliea 1. 391.)—Stem much
branched, almost leafless, much taller than the linear-lanceo-
late radical leaves.—Native of the Cape of Good Hope.
A perenual green-fhoue plant, flowering in August and
September. The flowers are copied, white, fmalier than in
the flalk species, foltary and almoft felfe.

Mr. Brown mentions a fourth species, found at the Cape,
but without any name or character.

226, a genus confifting of only one species, diftinguifhed by
its inflorefcence alone from CHORIZENA; fee that article.

CHORD, col. 2, l. 13, for EO r. ED.

v. 1. 354.—Clafs and order, Penniadia Monogynia. Nat.
Ord. Santalaceae, Br.

Eff. Ch. Calyx superior, in five deep, vaulted, coloured
flgments, each with an interior defcding keel, permanent,
with a minute five-toothed calyfe at the base. Stamens in
the hollows of the flgments. Anthers with four cells and
four valves. Stigma radiated. Drupa?

CHORISPERMUM, from yepes, separately, and "petra,
feed, fee the character.—Brown in Ait. Hort. Kew. v. 4.
129.—Clafs and order, Tetradynamia Silico". Nat. Ord.

Eff. Ch. Pod of two cells, without valves, separating in
little infeared clofed fragments. Cotyledons flat, accufent.
Stigma fimple.

(Raphanus tenellus; Wild. Sp. Pl. v. 3. 561. Pallas
Voy. v. 3. 744. t. L. f. 3.)—Leaves, as well as pods,
smooth; upper ones lanceolate, toothed; lower almost pinna-
tifid.—Native of deferts near the Capflan fea. A little
annual herb, with small purple flowers. Mr. Brown's
specific character indicates the eflence of another species,
not known to us.

CHORIZANDRA, from yepes, to separate, and "tena,
a male, because the flaments are individually grouped by
separates.—Brown Prodr. Nov. Holl. v. 1. 222.—A genus con-
ftiting of two species, natives of Port Jackson, nearly akin
to CHORDRACHNE of the fame author, and to the Linnean
CHRIS'TIAX, fee those articles. From the latter it differs
in inflorefcence and habit. How far they could with propriety
be united, we have not materials to form a defcife opinion.

CHORIZENA, a name of which there have been vari-
ous explanations, (see Tr. of Lin. Soc. v. 9. 252,)
most probably derived from yra-"petra", to separate but certainly
not in allusion, as De Thieuf fuppofes, to any division of
the fruit. We rather believe the author of this name had in
contemplation the separate flaments, of which fo few
inflances were known in papilionaceous flowers, at the time
he wrote, and may place to their dafi-like figure.

Holl. 1. 9. 391.)—Clafs and order, Penniadia Monogynia.

Eff. Ch. Calyx five-feled, two-tipped. Corolla papil-
lonaceous. Style curved. Stigma obtufe. Legume
oblong, tumid, of one cell, with many seeds.

1. Ch. ilicifolia. Holly-leaved Chorizena. Labill., as
above, t. 21. Sm. n. 1. Ait. n. 1.—Leaves alternate,
oblong, pinna"ifid, with spinous teeth; point entire, longer
than the teeth. Bractea close to the flower.—Brought by
M. Labillardiere, at the foot of the mountains, on the south
coal of New Holland, flowering in December. Sent to
Kew in 1803, by Mr. Good. Stem shrubby, hardly a foot
high, branching from the root. Leaves alternate, fefile, fmal-
ler, smooth, coriaceous, with sharp spines. Flowers in fmal
clufers.

Mag. t. 1032. Ait. n. 2. (Pultenilia nana; Andr. Repof.
1. 343.)—Leaves alternate, elliptic-oblong, bluntish, fmal-
er, with spinous teeth. Bractea rather fmall from the
flower.—From the fame country. We profit by Mr. Brown's
remarks for diftinguifhing hisfepecies, hitherto confounded
by us with the foregoing. Its nature is more humble.
Flowers in lateral clufers, orange, with purple winges, and
a short, white, purple-tipped kef. We know not difinftly
the colour of ilicifolia.

3. Ch. rhombea. Few-flowered Chorizena. Br. n. 3. —Leaves entire, flat, pointed; lower ones orbicular,

somewhat
somewhat rhomboid; upper elliptic-lanceolate. Stalks with few flowers.—Native of the same country. Mr. Brown.

4. Ch. triloba. Three-lobed Chorizema. Sm. n. 2. (Podolobium trilobum; Ait. Hort. Kew. v. 3. 9. Curt. Mag. t. 1477. Putenaeia ilicifolia; Andr. Repof. t. 320.)—Leaves opposite, somewhat halate; entire or toothed, spinose. Chlusters axillary, shorter than the leaf. German filky.—Found near Port Jackson, New South Wales. (See Podolobium.) Young branches and leaves downy. Flowers copious, yellow, with a red radiating spot, and red keel, the latter nearly as long as the wings.

5. Ch. feonda. Climbing Chorizema. Sm. n. 3.—Leaves nearly opposite, elliptical, undivided. Chlusters terminal, elongate. Calyx rather hairy.—Found by Dr. White, at Port Jackson. Stem twining. Flowers in loose pendulous clusters, yellow variegated with red.

6. Ch. fritida. Silky-leaved Chorizema. Sm. n. 4.—Leaves mostly alternate, elliptical. Chlusters axillary, the length of the leaves. Calyx filky. Standard narrow.—Gathered by Mr. Menzies, at King George’s Sound. Stem twining. Leaves more filky at the back than in C. feonda; flowers three as large as that species.

7. Ch. coriacea. Leathery-leaved Chorizema. Sm. n. 5.—Leaves roundish-elliptical, abrupt, coriaceous, scattered. Umbels axillary, filky. Calyx hairy.—From the same country. A stout, upright, rigid shrub. Leaves beautifully veiny; filky beneath. Umbels on filky stalks, much shorter than the leaves.

CHOUT, denotes in India a fourth part; and the Maharatta chout is a fourth of the revenues, exacted as a tribute by the Maharrattas.

CHOWAN, 1835, 5. 5297 and 2780.

CHRISTCHURCH. In 1811 the borough and street contained 203 houses, and 1535 persons; 682 being males, and 871 females.

CHRISTIAN, a county of Kentucky, containing 10,889 inhabitants, of whom 1708 are slaves.

CHRISTIAN d’Or, a Danish gold coin, current in Holstein since 1775, worth about 13 marks hub, or 26 marks Danish currency.

CHRISTIANA. Add.—By the census of 1810, it contained 6698 inhabitants, 47 being slaves.

CHRISTINA, SANTA,—for CHRISTIANA, r. CHRISTIANA.

CHRISTOPHER’S, St., col. 2, l. 13 from bottom, r. W. long. 62º 45’.

CHROMATE of Iron. See Mineralogy, Addenda.

CHROMIE, or CHROMIUM, in Chemistry, the name of a metal. (See CHROME.) Since that article was written, however, some facts have been ascertained respecting this metal and its compounds, which deserve to be briefly mentioned here.

Chrome seems capable of combining with three different proportions of oxygen, and of forming three oxides, the green, the brown, and the yellow or chronic acid. The green oxide may be formed by exposing chronic acid to heat in close vessels, by which means a portion of the oxygen is expelled. It may be also formed in other modes, as by precipitation; in which case it has a dark green colour, and contains water. In this state it readily dissolves in acids, but if exposed to a heat a little below redness, it becomes ignited, diminishes in bulk, and its colour changes to a lighter green. It is now no longer soluble in acids, though it has lost no weight. The brown oxide may be formed by dissolving the above green oxide in nitric acid, evaporating the solution to dryness, and exposing the dry mass to heat, till it ceases to give out nitrous fumes. A brown brilliant powder remains, which is soluble in alkalies but not in acids. It is not improbable, that this will be found hereafter to be a substantia instead of an oxide. Chronic acid, the third oxide of chromium, is easily reduced to the state of green or protoxide, by the action of sulphuretted hydrogen, sulphurous acid, and protoxides of iron, copper, and tin. The chromates have been already described. The chromate of lead is the only one much used, which has been lately employed as a paint with great success.

CHRONOLOGY.

1813.—Concordat signed between pope Pius VII. and Buonaparte, at Fontainebleau, Jan. 25.—At Bejar, in Spain, the French were defeated by general Hill and the allied Spaniards, Feb. 20.—At Lunenburg, the French were defeated by the united army of Ruffians and Prussians, with the loss of general Morand, 100 officers, and 2200 privates, and two pieces of cannon, April 2.—At Fort George, on the Niagara, the British were defeated by the Americans, May 27.—At Vittoria, the French, under Joseph Buonaparte, were defeated by lord Wellington and the allied Spaniards, June 21.—Pyrenees, Soult was defeated, with immense slaughter, by lord Wellington and the Spaniards, July 28.—St. Sebastian was taken by force, by general Graham, July 31.—Before Dresden, the allied army of Austrians, Ruffians, and Prussians, was defeated by the French, Aug. 28.—At Toplitz, the French were defeated by the allied Austrians, Ruffians, and Prussians, Aug. 30.—At Dennewitz, the French were defeated with great loss by the Crown Prince of Sweden, Sept. 8.—At a Moravian village on the Thames in Canada, the British were defeated by the Americans, Oct. 5.—At Mockero, a desperate conflict occurred between the French and the allied army of Austrians, Ruffians, and Prussians, the place having been taken and re-taken five times, terminating in a defeat of the French, Oct. 11.—Before Leipsic, a second general engagement took place, the result of which was, a loss to the French of 10,000 men, in killed, wounded, and prisoners, with 63 pieces of artillery, and the defection of 17 German battalions, Oct. 19.

1814.—At Rothiere, the French, under Napoleon, were defeated by the allied Ruffians and Prussians, with the loss of 3000 prisoners, and 26 pieces of cannon, Feb. 21.—Bourdeaux entered by lord Wellington, March 12.—At Tarbes, Soult was defeated by lord Wellington, March 20.—Paris entered by the emperor of Ruffia, at the head of his troops, March 31.—Buonaparte renounced, for himself and heirs, the throne of France, and accepted the Isle of Elba for his retreat, April 5.—The states of Parma, Placentia, and Guelfica, conferred on Maria-Louisa by treaty, April 5.—At Touloufle, the French were defeated by lord Wellington, April 10.—Buonaparte embarked for Elba, April 28.—Treaty of Paris signed by the ministers of the allied sovereigns for the protection of France, May 30.—Pope Pius VII. returned to Rome, and resumed his functions in May.—The emperor of Ruffia, with the king of Prussia, prince Blucher, and other illustrious personages, entered London amidst great rejoicings, June 8.—Inquisition of Spain restored by Ferdinand VII. July 21.—A grand jubilee on celebrating the peace, and the centenary of the accession of the house of Brunswick, Aug. 1.—Trafalgar, after having been ebulated to Buonaparte in 1807, restored in 1814.—Washington, in North America, taken by the British, and the principal buildings destroyed by fire, Aug. 24.—Hackney chariots licenced in London, not to exceed 200.

1815.—Buonaparte quitted Elba, and landed at Cannes, March 1.—King of Candy deposed, and the crown regency vested in Great Britain, March 2.—Buonaparte arrived at Fontainbleau, March 20.—Treaties for the maintenance of the treaty of Paris, between England, Ruffia, and Prussia, signed at Vienna, March 25.—Buonaparte abolished the slave trade, March 29.
1816. — Treaty with the Nepau!le in India, ratified March 15. — princefs Charlotte of Wales married to the prince of Saxe-Cobourg, May 12, the annual sum of 60,000L. per annum having been previously settled upon him by parliament. — Declaration of independence of the representatives of the United Provinces of South America in general congress, published at Montevideo, July 19. — Generals transferred to the king of Sardinia. — Lotteries prohibited, on account of their immoral tendency, by the grand duke of Hesse, October.

1817. — Inhabitants of Chili restored to freedom by the Buenos Ayres army, under general San Martin in February. — A revolutionary insurrection in Fernambuco in March. — Above 600 petitions for parliamentary reform, presented by sir Francis Burdett, fired up the floor of the house of commons, March 4. — The measure for repealing the penal laws against Catholics, which had been negatived in the house of commons by 213 against 105, June 1, 1816, and again by 146 against 83, and in the house of lords by 121 against 62, in 1811; and again in the former house by 300 against 215; and in the latter by 174 against 102, in 1812; and again in the former house by 251 against 247, May 15, 1813; — and again in the same house by 228 against 147; and in the house of lords by 86 against 65, in 1816; — and again in the house of commons by 172 against 141, and in that of the lords by 73 against 69, in 1816; — and again in the former house by 245 against 221, and in the latter by 142 against 90, April 1817. — A bill admitting Catholics to promotion in the army and navy passed June 1817. — Loan of twelve millions advanced to the French government by English merchants.

Vol. VIII.

CHRYSPORASE. See Mineralogy, Addenda.

CHUDLEY, 1, 3, r, contains, by the return of 1811, 370, &c.; 1, 14, r, being 1832.

CHUKOTSKIA, for Tschutski r. Tschusktskia.

CHUMLEIGH, 1, 10, r, by the return of 1811 is 282, of inhabitants 1340.

CHURCH-STREETON. In 1811, the township contained 100 houses, and 398 persons; viz. 184 males, and 214 females.

CHURDER, signifies, in India, a staff-bearer, or an attendant on a man of rank. He waits with a long staff plated with silver, announces the approach of visitors, and runs before his master, proclaiming aloud his titles.

CHUSISTAN, 1, 14, add.—Chuhitan, or Kuzistan, the ancient Susiana, is now divided between the territories of the Chab Sheikh, and those that form the government of Shutter. The former extend from the banks of the Tab to the confluence of the Karoon and Abzal, and from the shore of the Persian gulf to a range of hills which skirt the valley of Ram Hormuz to the south. This country, though watered by the Karoon and the rivers Zab and Jerahi, does not abound, as some travellers have asserted, in grain, rice, and dates; the greatest part of it consisting in wild sandy plains and morasses, wholly destitute of cultivation. The most fertile parts are those in the environs of Dorak, the capital, and on the borders of the Hafar and Shat-ul-Arab, which produce dates and rice, and scanty portions of wheat and barley. The northern and western parts of the country afford tolerable pasturage, and here the wandering tribes pitch their tents. The principal towns are, Dorak, Alwaz, Endian, Maiboor, Goban, and Jerahi. Dorak, or more properly Pelahi, is situated in low marshy ground, on the banks of two of the branches of the Jerahi. The walls of mud are two miles in circumference, sixteen feet thick, and flanked with round towers. The majority of the inhabitants, amounting to about 8000, prefer living in the suburbs, under the shade of the date-trees. Dorak is the residence of the Sheikh, who has in it a miserable palace. Its manufacture is the abaa, or Arabian cloak, which is exported to foreign countries, and exported to foreign countries, and the Arabian, or Ahous, formerly a flourishing city, and capital of a province of the same name, is reduced to a wretched town containing 600 or 700 inhabitants, situated on the banks of the Karoon, 48 miles S. of Shutter. Endian lies in N. lat. 36° 28', 20 miles from Zaitoon, and 72 from Dorak, occupying both banks of the Tab, and nearly two miles in circuit. This town trades with Baffora and Bahban, and has a population between 4000 and 5000 souls. Maiboor lies half way between Endian and Dorak, in the desert, and two miles from the sea, containing about 700 persons, trading with Baffora and the Arabians. The revenue of the Chab Sheikh amounts to five lacs of piastres, or about 50,000l. sterling, and he can bring into the field 5000 horse and 20,000 foot. The territories attached to the government of Shutter constitute the finest portion of Susiana.

M'Kinzie's Persian Empire.

CHYAZIC ACID, in Chemistry. See CHYANOCIN.

CHYLE, and CHYMP, Chemical Properties of. These
have been already described under Digestion, and we have here only to notice briefly the late experiments of Dr. Marcet and Dr. Prout on the subject. These gentlemen were furnished by Mr. A. A. Cooper with specimens of chyle and chyme taken from different dogs, some of which had been fed on vegetable and others on animal food. Their experiments coincide almost exactly in every respect, so that it will be necessary only to mention Dr. Marcet’s results. 1. The specific gravity of the ferous portion of chyle appears to be between 1021 and 1022, whether formed from vegetable or animal food. 2. The quantity of solid residue, comprehending both fatine and animal matter, left by the evaporation of chyle at the heat of boiling water, may be generally flated to vary between 50 and 90 parts in 1000. 3. The quantity of fatine matter appears to be about 9 parts in 1000, being the same proportion of fats which is found in all other animal fluids. 4. The chyle from vegetable food appears to yield, by analysis, about three times as much charcoal as that from animal food. 5. The chyle from animal food is much disposed to putrefy, and generally begins to undergo that change in three or four days; while that from vegetable food can be kept for weeks, or even sometimes for months, without undergoing putrefaction. 6. The coagulum of chyle is more inclined to putrefy than the ferous part. 7. The chyle formed from animal food alone is always milky; and in standing, an unctuous white creamy, turbid substance collects on the surface; its coagulum is opaque, and has a pink hue. 8. The chyle from vegetable food is commonly transparent, or nearly so, like common serum. Its coagulum is nearly colourless, like an oyster, and no creamy sub stance rises to the surface. 9. The principal ingredient of the animal matter of chyle is albumen; but besides albumen, chyle, especially when derived from animal food, contains globules of an oily substance, which bears a strong resemblance to cream. 10. By the destractive distillation, chyle gives rise to a liquor impregnated with carbonate of ammonia, and afterwards a heavy fixed oil. The chyle from animal food yields a greater proportion of both these products, but the residue, whatever the mode of analysis be, contains less charcoal than the chyle from vegetable food. Iron is readily detected in the residue of chyle, mixed with the fats and carbonaceous matter. 11. Chyme from vegetable food yields much more solid matter than any other animal fluid, though it appears to contain rather less fatine matter. 12. Chyme contains albumen. 13. It yields about four times as much charcoal as chyle from vegetable food. 14. Neither chyle nor chyme contains any gelatine.

Dr. Prout ascertained the curious fact in different animals, that albumen never exists in the blood, even when the food is perfectly digested, but that an albuminous principle is formed the moment it enters the duodenum and comes in contact with the bile. He was also induced to conclude, that this albuminous principle becomes more abundant, and more perfectly albuminous, the nearer it approaches the gurgulous syphum, so that it seems to undergo important changes between the intestines and thoracic duct. See Med.-Chir. Transf. vol. v. and Annals of Medicine and Surgery, vol. i.

CICCA, dele See Termie at the close.
CICUTA. Annex—See Conium.
CIGOLI, r. Ludovico Cardi. CIMEX, col. 2, l. 35, add—This offensive creature was in a great degree unknown in the days of our ancestors. Its origin is traced to the year 1679, when it was imported among the timber used for rebuilding the city of London after the great fire of 1666; but it was known at a much earlier period than this, though it was much less common.

Vol. XXXIX.

A circumstance is mentioned by Mouflet, which proves that these insects were known at Mortlake, in Surry, in the year 1583. They live entirely by suction, employing for this purpose their sharp and fine trunk and proboscis, which lies in a straight direction beneath the breast. Like the gnat and some other insects, they probably infuse some quantity of irritating fluid into the wound they make before they suck the blood of the animal, which they attack, as the feeling is often very considerable, and attended with severe itching. In winter they conceal themselves behind the walls, wainscot, and in other neglected places; and on return of warm weather they emerge from their concealment. Mr. Baker says, in his "Microscope made easy," that the bug is one of the best subjects for exhibiting a microscopic view of the circulation of the blood.

CIMOLIA, dele Pipe-clay.
CINCHONA. Chemical Properties of. Vauquelin some time ago published a set of comparative experiments on all the different species of cinchona which he could procure, in order to determine, if possible, how far they differ from each other, and what the constituents are on which their virtues depend. They may be divided into three distinct sets.

1. Those whose infusions precipitate the infusion of nutgalls, but not that of glue.
2. Those whose infusions precipitate glue, but not the infusion of nutgalls.
3. Those whose infusions precipitate glue, nutgalls, and tartar emetic.

The following table exhibits the effects of the different re-agents upon all the barks tried. It is difficult, however, as Dr. Thomson has remarked, to determine, in all cases, the real name of some of the specimens, as Vauquelin has not given us the botanical name.

</table>
It is very probable, that several specimens in the above Table are duplicates, though we have no means of ascertaining this with certainty. All the above barks produced a green colour with iron, and most of them produced a green precipitate with that metal.

The substance which precipitated tannin was brown, of a bitter taste, and left soluble in water than alcohol. It precipitated tartar emetic, but not glue. It resembled the resins in some respects, though it gave out ammonia when distilled.

Upon the whole, these experiments, though they establish the fact that differences exist among the various species of cinchona, throw very little light upon the nature of their active ingredient or its mode of operation.

CINCINNATI, dele l. 9 and 10, and after paper, add — The number of public buildings, or dwellings, is from 1300 to 1400; of inhabitants, in 1810, 2540, and in 1817, 8000, all whites; the laws of Ohio prohibiting slavery, and even the settlement of free negroes, in the state, except in certain cafes. About 400 houses are built of stone or brick, many of which are three stories high, and in a superior style. The public edifices are of brick. Numerous manufactories are already established, and a very extensive commerce is carried on by river navigation with Pittsburg, New Orleans, and all the western states; and by wagons with the interior country. The manners and dress of the inhabitants resemble those of the English. Cincinnati is said to be the border of the western world, and will probably be the largest city in America at no very distant period. Forty years ago it was the resort of Indians; and the whole surrounding country was a wilderness, full of wild beasts and fowls.

CINNAMON STONE. See Mineralogy, Addenda.
CIONE, ORGANIZATION, dele.
CIPHER, col. 36, l. 35, for syllables r. letters.
CIRCAR. At the close, add — Circar denotes generally the head of affairs, or the state and government, as well as the great division of a province. It is also a name used by Europeans in Bengal to signify the Hindoo writer and accountant, employed by themselves or in the public affairs.
CIRCLE, col. 5, l. 27 from the bottom, for 1854 r. 1571-43. Col. 6, 1, 3, Plate 1. add of Astronomical Instruments. Col. 68, l. 5 from the bottom, for cannot be read.
CIRENCESTER, col. 31, l. penult. By the return in 1811, the borough of Cirencester contained 902 houses, and 4540 persons; viz. 2030 males, and 2510 females: 207 families being employed in agriculture, and 526 in trade and manufactures.
CISTOTOME. See Cystotomy.
CITRIC Acid, in Chemistry. This acid has been lately analyzed by Gay Lussac and Thenard, and still more recently by Berzelius. The results obtained by the able chemists differ considerably, which are partly to be ascribed to the presence of water in the acid analyzed by Gay Lussac. (See Analysis of Organized Substances.) The following Table exhibits these results.

<table>
<thead>
<tr>
<th>Hydrogen</th>
<th>Carbon</th>
<th>Oxygen</th>

<td>6.330</td>
<td>33.811</td>
</tr>
<tr>
<td>Berzelius</td>
<td>3.800</td>
<td>41.369</td>
</tr>
</tbody>
</table>

If we consider the numbers of Berzelius as most accurate, citric acid may be supposed to consist of two atoms hydrogen, four of carbon, and four of oxygen, and the weight of an integrant atom will be 7.25. Dr. Thomson, however, is disposed to consider another atom of hydrogen, or three atoms, to be present in citric acid, which supposition he states will render the weight of its integrant atom more accordant with the best analyses of the citrates.

CLACKMANNAN. Add — In 1811, the parish of Clackmannan contained 693 houses, and 3605 persons; viz. 1677 males, and 1948 females.
CLACKMANNANSHIRE. By the returns of 1811, this parish contained 1995 houses, and 12,010 persons; viz. 5715 males, and 6295 females: 280 families being employed in agriculture, and 893 in trade and manufactures.
CLADION, in Botany, a term, a thing, alluding to its habitat. — Browne, Jam. 114. Brown Prodr. Nov. Holl. v. i. 326. — A genus founded on Schoenus Mairiensi of Linnaeus. (See Schoenus.) This plant grows in the West Indies and New Holland, as well as in Europe. Mr. Brown, who defines thirteen New Holland species, gives the following
Eff. Ch. Glumes imbricated every way, one or two-flowered; the outer ones empty. Germen without brittle or scales underneath. Style decidous, without a joint at the base. Nut naked and smooth, with a smooth kernel.
CLADONIA, from its twiggy habit, a name given by Hoffmann to a tribe of Lichens, now sunk in Cenomyc; see that article.
CLABORNE, in Geography, a county of East Tennessee, having 17598 inhabitants, of whom 327 are slaves. — Allo, a town of Musquippi territory, in Adams county, containing 1538 inhabitants, of whom 14 are slaves.
CLAIR, a county of the Illinois territory, containing nine townships, and 5007 inhabitants, of whom 40 are slaves.
CLAIR, St. Add — It is a town of Butler county, having 1180 inhabitants. — Allo, a town of Columbian county, in the same state, having 1003 inhabitants. — Allo, a township of Pennsylvania, in Alleghany county, containing 5080 inhabitants.
CLARCKIA, in Botany, so named by Mr. Pursh, in honour of general Daniel Clark, the companion of the late governor Lewis, in his botanical travels. — Pursh 260. — Class and order, Cistandria Monograph. Nat. Ord. Calycanthem, Linn. Omegae, Juss.
CLAREMONTE, l. 6, r. 2094. — Allo, a town of Massachussetts, in Hampshir county, having 987 inhabitants.
CLARENDON, a townhip of America, l. 1, after contains, infect — 1799.
CLARKE. Add — The county contains 10,981 inhabitants, of whom 2695 are slaves; and the town has 538 persons, includin 230 slaves.
CLARKSBURG. Add — Allo, a town of Massachussets, in Berkshire county, having 291 inhabitants. — Allo, a county of Georgia, whose town is Athens, containing 2405 inhabitants, of whom 30 are slaves: its town contains 134, including 4 slaves.

CLAUSENBURG. See Colosvá.
CLAY, in Geography, a county of Kentucky, containing 2398 inhabitants, of whom 141 were slaves in 1810.
CLAY-STONE. See Mineralogy, Addenda.
CLEAR CREEK, in Geography, a township of Fairfield county, in Ohio, containing 1126 inhabitants.
CLEARFIELD, a county of Pennsylvania, containing a town of the same name, which in 1810 had 875 inhabitants.
—Alfo, a township of Butler county, in Pennsylvania, containing 288 inhabitants.
CLEARING, denotes a method adopted by the city bankers for exchanging the drafts on each other’s houses, and settling the differences. In pursuance of this method, at half-past three o’clock in the afternoon, a clerk from each banker attends at the clearing-house, where he brings all the drafts on the other bankers which have been paid into his house during the course of the day; and he deposits them in their proper drawers (a drawer being here allotted to each banker) :—he then credits their accounts separately with the
articles which they have against him as found in his drawer. Balances are then struck from all the accounts, and the claims transferred from one to another, until they are too wound up and cancelled, that each clerk has only to settle with two or three others, and their balances must be immediately paid either in cash or Bank of England notes. Such drafts as are paid into a banker's too late for clearing, are sent to the houses on which they are drawn to be marked, which is understood as an engagement that they will be paid the next day. Kelly'sCambilt.

CLEAVELAND, in Geography, a town of Cayhogue county, in Ohio, having, in 1810, 547 inhabitants. CLERGY, col. 5, l. 44. By 41 Geo. III. c. 63, no person ordained a priest, or deacon, or being a minister of the church of Scotland, shall be capable of being elected to serve in parliament as a member of the house of commons. Such person's election shall be void; and if after his election he shall be ordained a priest, &c. he shall vacate his seat; and if he sit or vote as a member of the house, he shall forfeit 500l. for every day in which he shall sit or vote; provided such profession be commenced within twelve calendar months after such penalty shall be incurred. L. 54, after canon law, add.—But now by 43 Geo. III. c. 84, certain provisions of 21 Hen VIII. are repealed, and other provisions made in lieu thereof; and it is enacted, that after the passing of this act (7th July 1803) (spiritual persons against whom no action shall have been brought under the recited act are indemified; and contrasts which would have been good after passing this act are valid notwithstanding that act; and proceeding may be fixed under certain conditions. And any spiritual person may take to farm to himself or to any person or persons, to his use, by lease, grant, words, or otherwise, for term of life or of years, or at will, any meafetion, manor, or dwelling-house, with or without orchards, gardens, and other appurtenances, although not in any city, borough, or town, notwithstanding the said first recited act or any other.

And it shall also be lawful for any spiritual person, having or holding any donation, perpetual curacy, or parochial chapelry, not having sufficient glebe or demesne lands annexed to or in right of, or by reason of his benefice or cure, or chapelry, or for any stipendiary curate or beneficed spiritual person, with the consent in writing of the bishop of the diocese, to take to farm to himself, or to any person to his use for a limited number of years, any farm or farms, lands, tenements, or hereditaments, which may under all the circumstances appear to such bishop proper to be taken by such spiritual person, for the convenience and accommodation of his hospitality only, without being subject to any pains, penalties, or forfeitures, under the said first recited act or any other: provided that nothing herein contained shall extend to authorize any non-residence of such spiritual person.

CLERMONT, a county of America, l. 5, r. 1810, 9965. CLIFFORD, a township of Luzerne county, in Pennsylvania, having 675 inhabitants. CLINTON, l. 12, r. 1810, 8002; l. 13, of whom 29 are slaves. CLINTON, col. 2, l. 21, after Hallowell, add—containing 1030 inhabitants.—Also, a county of Ohio, containing 2674 inhabitants.—Also, a township of Knox county, in Ohio, including 714 inhabitants.—Also, a town of Georgia, in Jones' county, containing 6023 inhabitants, of whom 13 are slaves. CLITHEROE. In 1811 this borough contained 299 houses, and 1767 persons; viz. 826 males, and 941 females.

CLITOMACHUS, l. 2, for Carthage r. Athens. CLOCK. In col. 53, l. 18 from bottom, we have referred to Pyrometer for the description of Troughton's new instrument, by which he tries the compensation of his tabular pendulums; but on application both then and recently made to him for permission to describe it, we were informed that this instrument has not yet been completely finished, and consequently not described by him. We can, however, now give our readers some idea of its principle and construction without a drawing. The pendulum is suspended vertically in an enclosed box of wood, made fast to a wall, and heated with lamps placed within; then a horizontal metallic bar, about thirty inches long, has one of its ends inserted through the side of the box into a hole made in the centre of cleftion of the ball, while the middle of it is supported by a short bearing-piece driven into the wall, and projecting a few inches therefrom: on the remote end of this bar, a micro-meter-screw is fixed, that adjusts a delicate spirit-level, borne by it; so that whenever the interior end of this horizontal bar is depressed by the elongation of the pendulum, the bubble runs to the exterior end of its tube, and indicates the quantity of elongation by its run, as measured by the micro-meter during its re-adjustment; and on the contrary, when a contraction takes place in the pendulum, the bubble runs to the interior end; but when it remains stationary, on the application of heat to the pendulum, it is considered that the compensation is perfectly adjusted. Two thermometers are placed at a distance from each other in the box, and are viewed through slips of glass inserted in the front of the box near the top and bottom, to shew that the heat is equally diffused; and thus the expansion of any simple rod may be taken, while the apparatus is removed sufficiently from the heat applied within the box, while the least quantity of expansion may be ascertained, without danger of error, by means of the micrometrical level. It is hardly necessary to remark, that when a simple rod has its expansion thus ascertained in different degrees of temperature, its inferior end must rest on the inner end of the horizontal bar, while its superior end must be pressed upwards against a pin in the wall instead of being suspended; in which case, a counterpoise must be placed on the horizontal bar near the level, to hold the vertical rod up to its bearing. The peculiar advantage of trying the final adjustment of a pendulum of Troughton's construction for compensation after it has been brought to time, is, that the spring by which the pendulum is suspended is included in the determination of the total result of all the contrary expansions; which cannot be ascertained of any other method, except that which results from actual experience, in observing the variations of rate at opposite eonons of the year, which is a tedious method, accomplished only at the expense of much observation and loss of time after each new adjustment.

CLOCK-MAKING, col. 2, l. 13 from bottom, for radii r. diameters.

CLOWES, l. 2, for fifteen r. sixteenth.

CLUNCH. This is also a name given to Stourbridge clay, which lies at a great depth in the earth, under the bed of coal: it is a grey clay, of a sandy nature, and better adapted for making large crucibles and fire-brick than perhaps any in Europe. Parke's Eff. v. i.

CLUPEA ALOSA, col. 2, l. 39, for it is not of r. it is one of.

CLYSTERS, in Farriery, are of great use in allaying many acute complaints to which horses are subject; and Mr. Clark recommends for this purpose simple clysters of warm water or thin water-gruel. The ingredient which he
COBALT, col. 7, l. 6 from bottom, for or r. on.

COBALT, in Chemistry, the name of a metal. Some circumstances omitted in their proper place require to be mentioned here.

The specific gravity of pure cobalt, according to Taffet, is 8.5384; according to Lampadius it is 8.7. It melts at about 135° of Wedgwood's scale, and is not capable of being volatilized by any degree of heat we can excite. Like iron, it is attracted by the magnet, and according to Wenzel is capable of being converted into a magnet, precisely similar in its properties to the common magnetic needle.

There are two oxys of cobalt, the protoxyd or blue, and the peroxoyd or black oxyd.

The protoxyd dissolves in acids without effervescence, and seems to form the basis of most of the salts of cobalt. According to Rothoff, it is composed of

| Cobalt | 100 |
| Oxygen | 27.36 |

Proust found the proportion of oxygen considerably less, that is to say, only 19.8 with 100 of the metal; and Klaproth still less, or about 18.0. If, with Dr. Thomson, we consider Rothoff's analysis most entitled to confidence, the weight of the atom of cobalt will be 29.25.

When the protoxyd of cobalt, newly precipitated from an acid, is dried by heating it in the open air, it assumes a flesh-brown colour, which gradually deepens till it becomes black. This is the protoxyd of cobalt. It dissolves with effervescence in muriatic acid, and a great quantity of chlorine is evolved. From the experiments of Rothoff, it appears that this oxyd is composed of

| Cobalt | 29.25 |
| Oxygen | 27.36 |

Hence it appears to be composed of two atoms cobalt, and three of oxygen; and on this supposition, the weight of its atom will be 59.75.

COCALICO. Add—containing 4024 inhabitants.

COCALM, r. Lee Maynas.

COCCINELLA, l. 39, add—These insects are commonly known under the name of lady-birds. The C. 7-punctata, or that of a 7-spotted body, makes its appearance in the advanced state of spring and middle of summer, and in every field and garden. One of the most beautiful of the English species is C. 18-punctata of Linnaeus, which is little more than half the size of the common red head, and is of a bright yellow colour, with numerous (generally 18) black specks.

COLBERT, JOHN BAPTIST, l. 16, r. XIV.

COLCHESTER. In 1811, the borough of Colchester contained 2111 houses, and 12,544 persons; 5400 being males, and 7144 females: 480 families employed in agriculture, and 1152 in trade and manufactures.

COLCHESTER, in America, l. 7, add—containing, in 1810, 2697
COL

2697 inhabitants, of whom 7 are slaves; 1. 10, add—containing 257 inhabitants.

COLCHICUM, col. 2, add—See Phil. Trans. for 1817, pt. ii. p. 262; and for Meadow v. Saffron.

COLDINGHAM. In 1811 the parish contained 462 houses, and 24,244 per sons; 1774 being males, and 1250 females.

COLDSTREAM. In 1811, the parish contained 397 houses, and 2384 persons; 1103 being males, and 1281 females.

COLEBROOK, l. 2, for Grafton r. Coos; l. 6, add—containing, in 1810, 325 inhabitants; l. 10, add—In 1810, it contained 1243 inhabitants.

COLEBROOKA, in Botany, so named, by the writer of this, in honour of Henry Thomas Colebrooke, c.f., chief judge in the courts for the natives of Bengal, a practical and accomplished botanist.—Sm. Exot. Bot. v. 2. 111.—Clas and order, Didynamia Gymnosperma. Nat. Ord. Vitice, Jaff.

1. C. oppositifolia. Opposite-leaved Colebrokea. Sm. as above, t. 115.—Leaves opposite.—Found by Dr. Buchanan, by road fides in Nepal. A downy, slightly aromatic, fibrous, with thalke, elliptic-lanceolate, serrate leaves, and terminal, aggregate, whorled spikes, of immemorial minute white flowers.

2. C. ternifolia. Three-leaved Colebrokea. Roxb. Corom. v. 3. 40. t. 245.—Leaves three or four in a whorl.

—Native of Myfro. The leaves are narrower and more drooping; the spikes much thinner than in the foregoing. Dr. Roxburgh lays the germs are four, sometimes all perfumed; the flowers aggregate, with many common bracttes.

COLEFORD. In 1811, this tything in Newland parish contained 253 houses, and 1551 persons; 849 being males, and 702 females.

COLERAIN, l. 2, add—containing 834 inhabitants; l. 20, add—Allo, a township of Bedford county, in Pennsylvania, containing 1847 inhabitants.—Allo, a township of Belmont county, in Pennsylvania, containing 471 inhabitants.

—Allo, a town of Rof county, in Ohio, having 846 inhabitants.

COLERAINE, l. 3, r. and in 1810, 2016 inhabitants.

COLESHILL. In 1811, this parish contained 390 houses, and 1639 persons; viz. 780 males, and 850 females; 119 being employed in agriculture, and 196 in trade and manufactures.

COLICA, or Colic, in Ferrvry, a difeae to which brute animals are subject; for which Mr. Taplin recommends a ball made of the following ingredients; viz. 1 oz. of pulvized aniseeds; 1 oz. of mithridate; ginger and grains of paradise, of each, in powder, 2 drs.; oil of aniseed and oil of juniper, of each, 1 dr.; and fryup q. f.: the ball to be given, according to the state of the diseae, every two, four, or six hours. In some cases, a mixture of ginger, pepper, aniseeds, &c. 1 oz. of each, with the addition of a little brandy or gin, will give relief. In flatulent colics, a ball made of 6 drs. or 1 oz. of Venice turpentine, purified opium from 1 to 1½ dr., 1 dr. of oil of aniseed, and 2 drs. of powdered ginger, may be administered every two, three, or four hours, according to the urgency of the symptoms.

COLLEMA, in Botany, γōλυκης, a glutinous substance. The name appears to have originated with Hill, and is adopted by Hoffmann and Acharius. The latter has only admitted this genus in two his last publications.—Ach. Lichenogr. 129. t. 14. f. 8—11. Syn. 302. Sm. in Engl. Bot. 2284. (Pameliae, f. 6; Arch. Meth. 221.)—Clas and order, Cryptogamia Alg. Nat. Ord. Lichenes. Eff. Ch. Shields orbicular, horizontal, nearly fylline, superficial, with a gelatinous ascyfie border. Acharius reckons up sixty-four species. These are the gelatinous Lichens of former authors. (See Lichenes, f. 1.) They are all more or less pulpy, olive-green, or blackish; their fronds various in form and direction. Twenty-three Britifhe species are figured in Engl. Bot.

COLLEMORE'S RIDGE, in Geography, a township of America, in the district of Maine, and county of Lincoln, having 40 inhabitants.

COLLETON, a district of South Carolina, containing 26,359 inhabitants, of whom 5238 are slaves.

COLLISION, col. 9, three half lines, for Z r. E.

COLNE. By the return of 1811, this township contained 990 houses, and 5336 persons; viz. 2531 males, and 2805 females; 58 families being employed in agriculture, and 928 in trade and manufactures.

COLNAYSAY, l. 21. By the last act 786, and the number of houses 138.

COLOUR, col. 12, l. 11, for cold r. colour. Col. 22, l. 18, for tube r. tub.

COUBER, l. ult. r. See Hydrus.

COUGO, in Zoology. See Galeopithecus.

COLUMB, St. In 1811, the parish of St. Columb major contained 410 houses, and 2070 persons; viz. 968 males, and 1082 females; 223 being employed in agriculture, and 108 in trade, &c. : and the parish of St. Columb minor contained 229 houses, and 1126 persons; viz. 550 males, and 576 females; 147 families being employed in agriculture, and 72 in trade, &c.

COLUMBIA, a military order, l. 2, r. 1379. Add—See Dove.

COLUMBIA, l. ult. r. in 1810, 32,390 inhabitants, of whom 879 are slaves; l. 8, add—It contains 12,422 inhabitants, including 5980 slaves; l. 11, add—It contains 518 inhabitants; l. 31, add—It contains 2507 inhabitants.—Allo, a township of Cayugha, in Ohio, having 250 inhabitants.

COLUMBIANA. Add—It contains 17 townships, and 10,878 inhabitants.—Allo, a town of Kentucky, in Adair county, containing 175 inhabitants, of whom 45 are slaves.—Allo, a district of America, containing 24,023 inhabitants, of whom 5395 are slaves.

COLUMBIUM, Columbic Acid, in Chemistry. See Tantalus.

COMBUSTION, Theory of, in Chemistry. See Acid, and Acification.

COMEPHORUS, in Ichthyology, a genus of the apodes, the
the characters of which are, head large, with depressed
snout; mouth large, with small teeth; body elongated,
comprefled, the second dorsal fin surrounded with several
long naked rays.
This fish is a genus of Cepede, and referred by Pallas to
the genus of Callionymus among the jugular fishes. It is a
native of the lake Baikal; and from its conformation feems
to be capable of fweeming up and down, and of springing out
of the water like the flying-fish. See Callionymus Baikalen-
sis of Gmelin's Linnaean fytem.
COMIMPHORA, in Botany, from comm, gum, and phyte,
to bear, Jacq. Hort. Schnebr. v. 2, 66, t. 249, a dioecious
oantocladous thraub, of which the male only is known, found
in Madagascar, and faid to produce that kind of elastic
gum, of which Fourcroy has given an analysis. More in-
formation on this subject is very defirable.
COMMON PRAYER, l. 15, add—2 & 3 Edw. VI.
COMPAGNIE ECOUSOISE. See GENDARMES, &c.
COMPASS, col. 6, l. 37 and 38, r. See MAGNETICAL
DECLINATION, and MAGNETICAL VARIATION.
COMPENSATION, col. 18, l. 39 from the bottom,
for but broader r. and narrower.
COMPOSTELLA, l. 2, after capital, infert—(see CORUNNA).
COMPOUNDS, in Chemistry, are divided into primary
and secondary.
Primary compounds, according to Dr. Thomson, are
thofe formed by the union of combifible with the four
supporters of combination, oxygen, chlorine, iodine, and
fluorine, and with curagen. Dr. Thomson also includes
under this division certain compounds of combifibles with
one another, and with oxygen.
Secondary compounds are thofe formed by the union
of two or more primary compounds. These include the four
claffes of fiabtions, termed hydrates, faltis, hydrofphate-
s, and foaps.
COMREE, in Geography, a township of Berks county,
in Pennsylvania, containing 2017 inhabitants.
CONCORD, l. 10, infert—and had, in 1810, 2396.
At the clofe, add.—Alfo, a town of Grafton county, in
New Hampshire, containing 1126 inhabitants. At the
clofe of the next article, add—containing 677 inhabitants;
3:4 from the bottom, after upwards, add—By the census of
1810, the number of inhabitants was 1633.
CONCORD, in Delaware county, add—containing 1061
inhabitants.—Alfo, a township of Miami county, in Ohio,
having 679 inhabitants.—Alfo, a town of Rofa county, in
Ohio, containing 1277 inhabitants.
CONCORDIA. Add.—Alfo, a county and parifh of
the territory of Orleans, containing 2895 inhabitants, of
whom 1581 are flavfs.
CONEMAUGH, a township of Indiana county, in
Pennsylvania, containing 1167 inhabitants.—Alfo, a town-
ship of Somerset county, in the fame flate, having 381
inhabitants.
CONESTOGA. Add—containing 1506 inhabitants.
CONEWAGO, a township of Adams county, in Pennsyl-
vania, containing 531 inhabitants.
CONEWANGO, a township of Warren county, in
Pennsylvania, having 448 inhabitants.
CONELTON, 2 half lines, r. at 944, the inhabitants
4616, of whom 2023 are males, and 2593 females.
CONGOON, a port of Larifian, in Perflia, containing
6000 or 7000 inhabitants, and having an excellent road-
field, where a frigate may ride fafiely in the most tempeftuof
weather, and good water and fire-wood be procured.
CONIC SECTIONS, Lemmas. Def. l. 1, r. A E;
1, D and B; 2, A B. Cor. l. 1, r. A E in D; l. 3,
and D and in B: l. 51, DB and D'E.
CONNECTICUT. At the clofe, add—See UNITED
STATES.
CONNELSVILLE, l. 2, for Washington r. Fayette;
1, r. 93 inhabitants.
CONNIOTT, a township of Pennsylvania, in the county
of Crawford, having 285 inhabitants.
CONON, thron mon r. father; l. 2, after Athens, r.
who died in the year B.C. 393.
CONOPLEA, in Botany, Perf. Syn. Fung. 234, an
obfcur genus of Fungi, confifting of compact, rigid, perma-
nent fubftances, generally black or brown, intermixed
with powder. Four species are defcribed, found on rotten
wood, branches, or leaves.
CONOSTYLIS, from the conical form of the flyle.
Br. Prod. Nov. Holl. v. 1, 360. Pursh 224.—Clafs and
order, Hexanaria Monogynia. Nat. Ord. Hemiiniozoeis,
Brown.
ENT. Ch. Corolla superior, in fix deep equal segments,
woolly with branched hairs, permanent. Anthers erect.
Style conical, separable into three parts. Stigma fimple.
Capsule of three cells, burbling at the top, with a triangular
central receptacle, and many feeds.
Roots perennial, fibrous. Stem fcarce any. Leaves
sword-shaped, equitant, rough or fhrilly at the edges. Stalk
many-fawed, capititate or corymbose, often woolly.
Four species are natives of the south coast of New Hol-
land; and 039, C. americana, of the pine-barrens of New
Jersey and Carolina, bearing flowers of a golden yellow,
in July. The genus is almost entirely superior in this species.
Pursh.
CONSTRUCTION of Boats. The plate referred to
under this article has been fuperfeded by Plate XIV. of
Naval Architecture; and for the defcription of the latter,
as far as it relates to Boats, the reader is referred to the
article WHOLE-MOULDING.
CONVOCATION, col. 3, l. 36, after representatives,
add—The fummons to the convocation must not be con-
found with that which we now mention, though the con-
venient parts are the fame; and by modern ufage the affently
of both is fupposed to have been on the fame day. But
the one may be fufly distinguished from the other by this
difference; viz. that the convocation is provincial, and fum-
moned by the metropolis of Canterbury and York;
whence the clause, commonly denounced preeminenter,
(from its firft word,) in the writ to each bishop proceeds
from the crown, and enjoins the attendance of the clergy at
the national council of parliament.
CONWAY, col. 3, at the clofe—Population in 1811
was 1953; the number of houses 218.
CONWAY, in America, l. 8, r. 1080. Col. 4, l. 1, r. 1784.
COOLING Powers of the Gales. It is difficult to
afcertain the precise conducting powers of gafeous fubftances,
as the cooling of hot bodies in gales is influfed by a
variety of circumstances besides their conducting properties.
Count Rumford found, that a thermometer cooled nearly
time times as falt in water as in air of the fame tempera-
ture. The fame philofopher also faid, that rarification
much diminishes the conducting power of air, and that hot
bodies cool more foon of all in a Torrefelian vacuum. This
fubjeét, however, has been investigated more lately with greater
precision by Leftie and Dalton. Mr. Leftie afcertained,
that the conducting power of all gases is diminished by rare-
faction. He has endeavoured to deduce from his experi-
ments,
ments, that the conducting power of air is nearly proportional to the fifth root of its density. Mr. Dalton, however, has rendered it probable, that it varies nearly as the cube root of its density. Vapours of all kinds, and every thing that has a tendency to dilate air, diminish their conducting powers. The conducting powers of common air, oxygen, and azote, as might be expected, are nearly equal. The conducting power of carbolic acid is rather inferior to that of air, but bodies cool in hydrogen more than twice as fast as in common air; and Mr. Leffel has endeavoured to shew, that the actual conducting power of hydrogen is no less than four times greater than that of common air.

Mr. Dalton's experiments were made with a strong phial filled with the gas to be examined, into which he introduced a delicate thermometer through a perforated cube, and observed the time it took to cool 15° or 20°. The following table exhibits the result of his experiments:

COOLSPRING, in Geography, a township of Pennsylvania, in the county of Mercer, having 521 inhabitants.

COOS, in Ancient Geography. Add—See Cos.

Coos, in Geography. Add—Coos is a county of New Hampshire, containing 24 townships, and 3991 inhabitants.

COPAL. Add—See Vateria.

COPPER, in Chemistry, the name of a metal. Some circumstances omitted in our account of this metal require to be inferred here.

There are two oxyds of copper, the protoxyd of an orange or red colour, and the peroxyd or black oxyd.

The protoxyd was observed by Proult; but Chenevix, who found it native in Cornwall, first accurately described its properties. It may be formed by mixing together 57.5 parts of black oxyd of copper, and 50 parts of copper in a flake of powder, formed by precipitating it from muratic acid by an iron plate. This mixture is to be triturated in a phial, and put with muratic acid into a well-rounded phial. Potash dropped into this solution precipitates the oxyd of copper of an orange colour. It may be also formed with much less trouble by adding excess of copper to the muratic acid, and letting the whole remain till the green colour disappears, and the solution becomes dark brown and opaque. In this state, dirty-white crystals like sand are deposited. If potash be added to the brown solution, or a solution of the crystals above-mentioned, the protoxyd is precipitated in abundance. According to Berzelius, this oxyd is composed of

\[
\begin{align*}
\text{Copper} & = 100 \\
\text{Oxygen} & = 12.5
\end{align*}
\]

Hence the weight of the atom of copper will be 80.

The peroxyd or black oxyd of copper has been already described. It is composed, according to Proult and Berzelius, of

\[
\begin{align*}
\text{Copper} & = 100 \\
\text{Oxygen} & = 25
\end{align*}
\]

Hence the quantity of oxygen in these two oxyds is as one to two; or the protoxyd may be considered as composed of one atom copper and one of oxygen, and the peroxyd of one atom copper and two of oxygen. From these determinations, the composition and weights of the atoms of the different salts of copper may be accurately estimated.

Eff. Ch. Calyx none. Petals five or six, deciduous. Nectaries as many, hooded. Follicles membranous, stalked, beaked, with many seeds.

1. C. trifolia. Three-leaved Coptis. Pursh n. 1.—Leaves ternate, obovate. See HELLEBORUS, n. 3.

2. C. aphlenfola. Fern-leaved Coptis. Pursh n. 2.—Leaves twice ternate, pinimatif.—Found by Mr. Menzies, on the west coast of North America, and by Thunberg in Japan, this being actually Thalictrum japonicum of that author, and of Wildl. Sp. Pl. v. 2. 1303! The flowers are greenish.

CORACHIE, in Geography, a good sea-port in the country of Seind; which see.

CORAL, Chemical Properties of. See VERMES.

CORALLORHIZA, in Botany, an old name, alluding to the branching coral-like form of the root.—Hall. Hift. v. 2. 159. t. 44. Brown in At. Hort. Kew. v. 5. 209. See CYMBIDIUM.

We do not doubt the propriety of separating this plant, and another of American origin, (see Pursh 393, n. 4.) from CYMBIDIUM; but we have some nearly allied Orchideae from Nepaul, which require to be examined before the limits of Corallorrhiza can be clearly defined.

CORDILLERAS. Add.—The great body of the Cordilleras, as it extends from Quito northward, approaching the gulf of Mexico, and entering the kingdom of New Granada, is divided into three chains, which are almost parallel, and of which the two lateral branches are covered with sand-flume, and other secondary formations, to a very considerable height. The eastern chain divides the valley of the river Magdalena from the great plains that are drained by the Orinoco and its branches. Inclosed by a circle of mountains belonging to this chain is the high valley of Bogota, the bottom of which is no less than 7460 feet above the level of the sea. The waters of this valley are collected by the single stream of Rio de Bogota, which finds its way through the mountains to the S.W. of the town of Santa Fé; the stream where it leaves the valley is about 144 feet wide; it then enters into a rocky channel not more than 40 feet wide, apparently formed, says M. Humboldt, by an earthquake. From this crevice, the river precipitates itself at two bounds to the depth of 574 feet; and after this fall pursues its course to the Magdalena, about 50 miles, still descending with great rapidity, and at the rate of 150 feet to a mile. The natural bridges of Icononzo are on the western declivity of this ridge. The central chain is the highest of the three, and often attains the limits of perpetual snow, and greatly furfades it in the collossal suns of Guaneas, Baragan, and Quindiu. The western chain separates the valley of Cauca from the province of Choco, and the coasts of the South sea. This is lower than the others, and rises so much as it approaches the isthmus of Panama, that its course can hardly be ascertained. In our ordinary
ordinary maps, there is no trace of the highest or central chain; and Mr. Arrowsmith's map of America, in 1802, makes the valley of Magdalena occupy the whole interval between the eastern and western chains. The most difficult passage of the Andes is that by the mountain Quindiu. It lies through a thick uninhabited forest, which cannot be traversed in the finest season, in less than ten or twelve days. The summit of the pass is at the prodigious height of 11,499 feet above the level of the sea, and the passage from ten to sixteen inches in breadth. Humboldt's Researches, etc., by F. M. Williams, 1814.

CORDYLINE, in Botany, an old name of Van Royen's, from xopkw, a club or staff, sufficient enough to the Dracaena and {Punica} to which it was originally applied, and which we presume are included in the genus which now bears it.—Comm. in Jull. 41. Brown Prod. Nov. Holl. v. 1. 286.

The stem is shrubby. Leaves lanceolate, finely ribbed, elongated. Panicle terminal, of numerous, many-flowered, alternate spikes, with two unequal-"bracteas under each flower.

1. C. canisfolia. Br. n. 1.—Leaves flaked, pointed. Chilfers divided. Outer bracteas acute, twice as large as the inner, which hardly equal the partial flacks.—Found by Mr. Brown, in the tropical part of New Holland.

See DRACENA, of which our first and second species belong to this genus.

CORMECASTLE, l. 29, r. after return—of 1811 was 161, and of inhabitants 741.

CORINTH, a township of America, l. 2, r. 1876.

CORINTHIAN ORDER, l. 8, for convex r. concave. CORN, col. 3, l. 18 from the bottom, del l. 18 to l. 14.

Vol. X.

CORN, Opacities of. Opacity of the cornea is one of the world consequences of obliterative chronic ophtalmie. The slight, recent, and superficial form of the disease is usually known under the name of nebula; and it is proceeded by and attended with chronic ophtalmie. The iris and pupil are discernible through a sort of cloudiness, and the patient is not entirely deprived of the power of vision. The veins of the conjunctiva are greatly relaxed, turgid, irregular, and knotty, which change first affects their trunks, and then gradually extends to their ramifications near the union of the cornea with the telerotica, and ultimately to their most minute branches returning from the delicate layer of the conjunctiva, spread over the front of the cornea. When this happens, a milky albuminous secretion begins to be superficially effused in the interstices between the red flakes, and the specks thus produced may cover only a part or the whole of the cornea.

The opacity of the cornea sometimes occurring in violent ophtalmies is essentially different from the nebula, and arises from a deep extravasation of coagulating lymph in the cellular texture of the cornea, or from an absence between its layers. In the treatment of the nebula, the curative indications are to refire the varicose veins to their natural diameters; and if that be impracticable, to cut off all communication between the trunks of the most prominent veins of the conjunctiva and those on the cornea. The first object is performed by using Janin's ophtalmic ointment, or the ung. hydrarg- nitrat, together with affringent collyria. The second defedraterum is fulfilled by the excision of the falciformis of varicose veins, just at the base of the opacity, with a pair of dissecting scissors and forceps. With respect to the deeper and more oblitimate opacities, which are frequently called allugu and leucoma, they are consequences of severe acute ophtalmie, though sometimes the effects of an ulcer or wound of the cornea, when they are commonly known only by the latter appellation.

The recent allugu may sometimes be disfigured by the same treatment, which is applicable to violent ophtalmie; and when the inflammation has been subdued, the ung. hydrarg. nitrat. is the best local remedy for promoting the absorption of the extravasated opaque lymph. The eye may also be frequently washed with a collyrium, composed of two scruples of the muriate of ammonia, and four grains of verdigras, in eight ounces of lime-water. The treatment must be continued three or four months before the cafe is to be abandoned as hopeless. With respect to the leucoma arising from a cicatrix, Scarpa fets it down as absolutely incurable.

CORNISH, l. 5, r. 1810, and 1606. Add—Alfo, a town of York county, in the district of Maine, having 974 inhabitants.

CORNWALL, a town of America, in the district of Maine, and county of Somerset, having 504 inhabitants.

CORNWALL, col. 8, l. 31, r. 1811; l. 32, r. 37971, and 216,667.

CORNWALL, in America, l. 3, r. 1279; l. 8, add containing 1622 inhabitants.

CORO, l. 7, after persons, add. The little commerce that is carried on in males, goats, hides, sheep-skins, cheefe, &c. obtained from the interior of the country, and more particularly from Carora. At the close, r. N. lat. 18° 8' from Paris.

CORSHAM, l. 17, add. By the return of 1811, the number of houses was 478, and that of inhabitants 2395.

CORTLANDTS, a county of New York, having 8890 inhabitants.

CORUNDUM. See Mineralogy, Addenda, and Adamantine Sær.

CORUNNA. Add. See Constantina.

CORVUS, col. 2, l. 20, add. The African or Captian, described by Le Vaillant, is, according to Dr. Shaw, the only variety worth of notice.

CORNWEN, l. ult. r. 51 Geo. III. 288 houses, and 1417 inhabitants.

Eff. Ch. Calyx ringent; upper lip vaulted, very large; lower in two linear segments, combined with the linear petals. Lip dilated, concave. Anther terminal, of one cell, and two connected valves, permanent. Nodes of pollen four. Curious little smooth plants, each with a single bulb, one roundish radical leaf, and a large, deep red, solitary flower. Nearly related to Limperanthes nigricans; see that article.

3 K
COT

fue of the Andes, a longitudinal valley separates the Cordilleras into two parallel chains; the bottom of this valley is 9843 feet above the level of the ocean, so that Chimborazo and Cotopaxi appear no higher than the Col du Géant, as measured by Saulliere. The summit of the mountain of Chimborazo is 21,430 feet above the level of the sea, and therefore a good part is above the circle of perpetual congelation, which, in the latitude almost under the line, is somewhat higher than the summit of Mont Blanc. Humboldt's Researches. See Volcano.

COTTAGE, col. 13, l. 15 from the bottom, for feed r. reed.

COVENTRY, by the return in 1811, this city contained 3448 houses, and 17,293 persons; viz. 8197 males, and 9296 females; 123 families being employed in agriculture, and 3207 in trade, manufactories, and handicraft.

COVENTRY, in America, l. 4, add—containing 1938 inhabitants; l. 6, r. 2928; l. 8, r. 162; l. 12, add—In 1810 it contained 178 persons; l. 13, r. having 1608 inhabitants.

COUGHING, in Physiology. See Lungs.

COUNSEL, col. 2, l. 5, r. the king's premier, &c.

COURONNE des Tifes, an apparatus constructed by professor Volta, in which he arranges the component parts of the galvanic pile in a different form. (See Galvanism.)

This apparatus consists of a set of small glass plates, placed side by side, one another, and containing water or some saltness solution. Metallic arcs are then procured, having one end composed of zinc, and the other of silver or copper: these arcs are inserted into the glass plates in an uniform order; each glass having the zinc leg of one arc, and the copper or silver leg of another arc immersed in the fluid. The zinc and copper legs are not in contact, and they are always to be disdised in the same situation with respect to each other: i.e., one is always to be at the right-hand, and the other at the left. The pile and this apparatus operate in the same manner, and their operation is referred by the professor to his new principle (see Voltaism), by which he conceived different metals, when placed in contact, to destroy the electric equilibrium, or, in his phrase, to become movers of electricity, producing that electric motion which is supposed to be the primary and essential cause of the galvanic action.

COURT, University, col. 2, l. 4, r. 14th.

COURUPITA for Courapita.

COWBRIDGE. In 1811, the parish contained 158 houses, and 850 persons; 425 being males, and 425 females.

COW-TAIL RIVER. See Wau-ca-hatcho.

CRACKS, col. 4, l. 15, for bone r. cone.

CRAFTSBURY. In Geography, a town of Orleans county, in the state of Vermont.

CRAIN. In 1811, the burg and parish of Crain contained 316 houses, and 1600 persons; viz. 673 being males, and 927 females.

CRANBERRY. Add—Also, a town of Butler county, in Pennsylvania, having 543 inhabitants.

CRANBORNE. In 1811, the parish of Cranborne contained 144 houses, and 816 persons; viz. 429 being males, and 387 females.

CRANBROOK. Add—The parish of Cranbrook, by the return of 1811, has 511 houses, and 2994 persons.

CRAVEN, l. 4 and 5, r. 12, 676, and 5050.

CRAWFORD, a county of Pennsylvania, containing fourteen townships, and 6178 inhabitants.

CRAFFORD. In 1811, the parish contained 233 houses, and 1553 persons; viz. 759 being males, and 784 females.

CREAM,
CRO

CREAM. *Chemical Analysis of.* See Milk.

CREDITON. *Chemical Analysis of.* See Milk.

CREDITON, l. 3 from the end, r. and the hundred contains, by the return of 1811, 2130 houses, and 10,548 inhabitants; l. 5, after extent, add—But the borough of Crediton contains only 425 houses, and 1846 inhabitants.

CROKHERE, col. 2, l. 4, for 41 r. 51 l. 5, r. of houses was 589, and of persons 3021, of whom 1346 are males, and 1765 females; 281 families employed in agriculture, and 308 in trade, &c.

CRIADERA, in Botany, from its perforated structure, Perf. Syn. Fung. 189; one of those beautiful, though minute, genera of *Pungi,* whose *head* is formed of reticulated fibres, enclosing the powdery *feels.* Person reckons up eleven species.

CRICKHOWEL. In 1811, the parish contained 137 houses, and 611 inhabitants. In the hundred of Crickhowel is a Roman encampment, called the Gaer, situated at the extremity of the vale, on a rising ground. The dimensions are much the same with those of Caer-Bannau (see Bannium), and it is nearly of a square form. It lies on the Via Julia, which passed in this direction from Caerleon to Caermarthen. We are informed that the old practice of fusing carols in the church at cock-crowing, or the earliest dawn of the morning, on Christmas-day, is still continued in the church at Crickhowel; but it merits any other appellation than that of a religious rite.

CRICKLADE, l. 14, r. 51 l. 15, r. 1939, and 2095; l. 16, 10,403; l. 17, 4804, and 5599; 1483 families chiefly, &c.; l. 18, r. 411.

CRIADRIA, in Botany, from the wings or *crests* of the aggregate capsules, by which alone it is distinguished from *Seida* (see that article).—Cavan. Ec. t. 5. 10. Pursh 453. Sims in Curr. Mag. 1675. We can hardly ascribe to the establishment of this genus, its character being entirely artificial, and unaccompanied by any thing discriminative in the habit. The only species mentioned are, 1. *C. glaucescens,* Cavan. Ec. t. 348. 2. *C. multifidus,* which is our *Seida meroformis,* the last species but one in that article. 3. *C. cocinea,* Pursh n. 1. Curr. Mag. t. 1675, a native of the dry plains of the Mifouri, perennial and hardy in our gardens, adorned with beautiful scarlet flowers. 4. *C. botanisefolia,* Cavan. as above, 11, which is Malacochites botanica folio, &c.; Feuill. Voy. p. 3. 40. t. 27.

CROMER. At the close, add—the parish contains, by the returns of 1811, 170 houses, and 848 inhabitants.

CROSBY, a township of Hamilton county, in Ohio, having 981 inhabitants.

CROSS-CREEK. Add—containing 1847 inhabitants—Alto, a township of Ohio, in Jefferson county, having 1152 inhabitants.

CROSS-WORT. Add—and *Valentia.*

CROTALUS, col. 3, l. 19, r. to have them come, &c.

CROTONEOPSIS, in Botany, from *kronos,* Croton, and *opsis,* appearance; but the principle of the name is incorrect, infasmuch as the Greek *kronos* is our *Ritinus,* to which the genus in question bears no resemblance; and if the Croton of modern botanists be intended, such a comparative appellation is contrary to rule.—Michaux Boreal.—Amer. v. 2. 183. Willd. Sp. Pl. v. 4. 350. Pursh 206. Cliffs and order, *Monodia Pentandria.* Nat. Ord. 1.

Eff. Ch. Male, Calyx in five deep segments. Petals five. Female, Cal. and Cor. like the male. Stigmas divided.

Cupule inferior, not burfting, with one seed.

1. *C. argentea.* Silverly Crotoneops. Pursh n. 1. (C. linearis; Michaux 188. t. 46. Willd. n. 1. C. elliptica; Willd. n. 2.)—Native of North America, in sandy ground near the coast, in the Illinois country and on the Mifouri,

CRY

flowering in July. *Pursh.* A slender annual herb a span high, with opposite or alternate entire leaves, variable in breadth, and loose *flowers* of minute white *flowers.* The pubescent calyx consists of fringed silky scales, as in Croton.

CROUPADE, r. See Ballotaede.

CROW'S Nest, in Naval Language, is a kind of box, sufficient to hold a man; generally a cask, fixed near the main-head, to protect the observer from cold, and enable him to look out for whales, or open pieces of water.

CROYDON. The parish of Croydon, in 1811, contained 1594 houses, and 7801 inhabitants; 5616 being males, and 1485 females; 397 families employed in agriculture, and 662 in trade, &c.

Croydon. Add—and in 1810, 802 inhabitants.

CROYDON Canal, l. 5, r. Surrey.

CUCIBROSTRA, *Cross-bill,* in Ornithology, a genus of birds of the order Pheiferes; the characters of which are, beak thick and forked; mandibles, when at rest, inerribly curved; neither small, rounded, situated at the base of the beak; tongue entire. Mr. Stephens, the compiler of Dr. Shaw's Zoology, mentions and describes two species; one of which, or common cross-bill, with a variable red body, quills and tail-feathers brown, beak externally olive-green, and tail forked; the *Loxia curvirostra* of Linnaeus; and the cross-bill with a dull crimson body, wings black, with two white feathers, secondary quills white at the tips, and tail black, the *Loxia leucotera* of Gmelin, and white-winged cross-bill of Latham and Pennant.

CRUSTA, Animal, Chemical Properties of. See VERMES.

CRYPHIA, in Botany, *cypris,* *clandestine,* alluding to the concealed corolla.—Br. Prodr. Nov. HOLL. v. 1. 502. A genus, of which there is perhaps but one certain species, a small thyme-leaved herb, with solitary axillary flowers, found on the south coast of New Holland, intermediate between *Chlodia* and *Prostanthera;* see those articles. The ringent corolla is shut up in the closed two-lipped calyx. Possibly the flowers were not fully evolved, owing to the climate or season.

CRYPTOCARYA, Brown Prodr. Nov. HOLL. v. 1. 502, a genus of the order of *Laurine,* resembling the Cinnamon-tree in habit, as well as inoreforebence, but differing from *Laurus* in having only two cells in each other, and from the whole order in having the nut concealed, (whence the name,) in the enlarged tube of the calyx, become closed above it at the top. *C. glaucescens* and *obovata* are natives of Port Jackson; *C. triflinervis* of the tropical part of New Holland.

CRYPTOSTEMMA, *xerophyton,* concealed, and *segoa,* a crown, the sealy crown of the feeds being involved in wool.

2. *C. hypochondriacum.* Divided-rayed Cryptostemma. Ait. n. 2. (Arctostis hypochondriaca; see sp. 1. &c. Willd. Sp. Pl. v. 3. 2428.)—Radiant flowers in three or five deep segments. Leaves lyrate, downy.

3. *C. rumicatum.* Dandelion-leaved Cryptostemma. Ait. n. 3.—Radiant florets in three or five deep segments. Leaves runcinate; toothed; downy beneath.

All the species are natives of the Cape of Good Hope.
CRY

rather tender annuals in our gardens, of no striking appearance.

Eff. Ch. Calyx-leaves and petals linear, spreading. Flower recurved. Lip crest, felliie, dilated, undivided; concave at the base, concealing the very short column. Anther parallel to the stigma, subtended at each side by a lobe of the column.

Bulbs clustered. Leaves few, radical, stalked, flat. Flowers in a terminal spike, dull red, scented.

1. \textit{C. longifolia}. (Malacca subulata; Labill. Nov. Holl. v. 2. 62. p. 212.) found at Port Jackson, as well as on the south coast;

2. \textit{C. ovata}; and 3. \textit{C. cretica}; are the only described species.

CRYSTAL, col. 5, l. 19, for changed r. charged.

CRYSTALLOGraphy is the science which treats of the form and structure of crystals. (See Crystal.) The beautiful symmetrical forms, which frequently occur in the deep recesses of mines or the fissures of alpine rocks, cannot fail to strike the most common observer with surprise. Amidst the almost infinite variety which they present, it will be found, on a more attentive examination, that there are certain definite forms which some minerals most frequently assume, and which are rarely, if ever, seen in other minerals. Hence we might at first be led to infer, that crystallization depends on the definite action of some general law, by which the constituent parts of each mineral species are invariably arranged in the same form. When, however, it is farther discovered that, besides the prevailing forms peculiar to certain minerals, the same species are not unfrequently crystallized in a variety of different forms, and that minerals of different species often present crystalline forms of the same form, we must retract our first conclusion, and shall be more disposed to believe that the mineral kingdom has not yet emerged from a chaotic state, or that the reign of order is subject to the invasion of disturbing forces, the extent of which we have no means of ascertaining.

The labours of a few enlightened and indefatigable philosophers have recently removed, in a great degree, the obscurity in which this department of science was involved, and have demonstrated that the laws by which the particles of the minutest crystal are arranged act with unerring precision, and are not less regular than those which govern the motions of the planets or the solar system.

Under the article Crystal (which see), some account is given of the discoveries of Romé de Liége, Bergman, and Häüy. The latter has ably demonstrated that all the varieties of crystalline forms are reducible to a few simple primitive forms, one of which may be regarded as the nucleus of each crystal, however complicated its form may be. The constituent particles, or what Häüy denominates the \textit{integrant molecules}, of all crystals, may be conceived as arranged in rows, and a number of these rows as forming thin laminae or plates. When these laminae are parallel with all the faces or planes of a crystal, they may be removed without changing the form of the crystal; but if the laminae divide in any other direction than that which is parallel to the faces, a change of form will be produced by every division, until at last we obtain a nucleus which is divisible in a direction parallel to its sides.

In the former case, the primitive form is the form of the crystal itself. Thus, if a cubic crystal be divisible only by laminae parallel to its six sides, we may continue diminishing the magnitude of the crystal, as long as mechanical division is possible without any change of form.

When the laminae of a crystal divide in any other direction than parallel to its faces, it is called a secondary or derivative crystal.

The primitive forms of all crystals which have been hitherto examined are fix.

1. The parallelopiped, bounded by six planes, the opposite planes being parallel. This includes the cube, and varieties of the rectangular prism, the oblique angular prism, and the rhombohedron.

2. The octahedron. This is a double four-sided pyramid. When the triangular faces are equilateral, it is called a regular octahedron. (Plate VII. fig. 27, Cry stallography.) There are, besides this, other varieties of the primitive octahedron, in which the pyramids are longer or shorter than the regular one, or have a rhombohedral base, or a rectangular base, longer in one direction than the other.

3. The regular tetrahedron (Plate VII. fig. 13.) is bounded by four equilateral triangles.

4. The regular hexahedral prism, or equiangular six-sided prism, fig. 5.

5. Rhombohedral dodecahedron, bounded by twelve equal rhombs, fig. 12.

6. The pyramidal dodecahedron, confiding of two six-sided pyramids joined base to base, fig. 14.

The primitive forms which most frequently occur are, the parallelopiped and the octahedron. The tetrahedron and dodecahedron are very rare as primitive forms, though common as the secondary forms of crystals.

The division of secondary crystals by sections in the direction of the lamina is, in some minerals, effected with facility; in others, the joints are indiffusely and require the crystal to be heated and plunged into cold water to make them visible. The direction of the lamina is frequently rendered obvious by turning a mineral slowly round in the furnace, when the reflections from the internal parts will shew its structure. Where no joints are discoverable, Häüy determines their direction and the form of the primitive nucleus by conjecture, from the appearances offered by the secondary crystal.

The actual mechanical division of an hexahedral crystal of calcareous spar, and the extraction of the primitive, is represented in Plate II. figs. 17, 18, 19, 20, Crystallography, and is described under the article Crystal; but the references are erroneously made to Plate I. figs. 1, 2, 3, 4, 5.

The primitive nucleus is represented fig. 21, E A, O T, G H, A K. The discovery of it in this crystal was first made by the abbé Häüy in looking over the cabinet of M. Defiance, a hexahedral prism of calcareous spar having fallen from the group to which it was attached. M. Defiance made him a present of it. One of the corners being off from the base, he attempted to detach similar corners from the other angles, and after some time he succeeded in bringing to view its rhombohedral nucleus. This first suggested to him the theory of the structure of crystals. The situation of the primitive form, in another variety of calcareous spar, called the dog-tooth spar, may be seen Plate II. figs. 22 and 23. This is described under the article Crystal, with the mode of extracting the nucleus; but the reference is erroneously made to Plate I. figs. 6 and 7.

The angles of the primitive rhomb are invariably $105^\circ 5'$ and $75^\circ 55'$. Rhombohids of calcareous spar, indeed, occur with different angular admeasurements; but these are secondary crystals, and will not split in directions parallel to their faces. One of these, with the primitive nucleus, is represented
The diieAioa parallelopiped, but figure because composed that be a and cubes, the firm conceive graphy, which represents the base of a fix-edided prism, divided by sections parallel to each of its sides: from this division the ultimate form which we can ever obtain must be that of a triangular prism; for by carrying on the division we may conceive the particles to become smaller, but their form will remain the same. We have therefore obtained the form of the integrant molecule. In parallelo-pipeds, the form of the nucleus is also that of the molecule itself.

Thus in the cube, as represented Plate IV. figs. 48 and 49, the divisions parallel to the sides produce a series of smaller cubes, which must be the form of the integrant molecule. In some instances, the primitive forms themselves admit of division by lames not parallel to that of the faces, from which must necessarily result a new form of the integrant molecule.

Plate II. fig. 26, represents a primitive rhomboid of tourmaline A E, O I, G H, A K, which is divisible both in the direction of its fix faces and in that of the short diagonal A O, I A, K A. These latter sections divide the rhomboid into fix tetrahedrons, which are represented surrounding the nucleus. Hairy conceives, that by these divisions, we obtain the form of the integrant molecule, or of the ultimate integrant atom of the crystallized mineral. It has been observed, that no proof can be advanced to confirm this conjecture, except the impossibility of altering the form, how far ever we carry the divisions; and the obvious consequence is, that if these divisions be carried far enough, we must at last reduce the crystall to its integrant particles. It is not, however, necessary to suppose, that the constituent particles themselves have any other form than that of spheres; because all the forms of the integrant molecule, which are the tetrahedron, the triangular prism, and the cube, may be readily conceived to be constructed with four, fix, and eight spherical particles, arranged in their forms by crystalline polarity. It deferves attention, that the forms of the integrant molecule are the most simple which can exist among solids with plane surfaces, being bounded respectively by the smallest possible number of sides, viz. four, five, and fix.

If we conceive the integrant molecules to be arranged in rows, and a number of these rows to be arranged in the same plane, they will form lames of any conceivable size. Now by a succession of plates increasing in size, the magnitude of the primitive crystal will be increased; but if these lames decrease in extent by one or more rows of particles, the result will be a change of form, or the production of a secondary crystall. Now the lames may either decrease on the edges by one or more rows, or may decrease diagonally on the angles by a determinate number of rows; or the decrease may take place in some intermediate direction. These are called by Hairy, decrements on the edges, decrements on the angles, and intermediate decrements. Sometimes decrements take place at once on all the edges, sometimes upon all the angles, and sometimes only upon certain edges and angles. In some instances the decrements are uniform, and the same number of rows decrease from the different edges or angles. Sometimes the law of decrement varies from one edge to another, or from one angle to the other; and this happens chiefly when the nucleus has not a symmetrical form, or when it is a parallelo-pipied, whose faces differ in the respective inclination of their faces, or in the measure of their angles. In certain cases, the decrements on the edges concur with those on the angles to produce the same crystalline form. It happens also, that the same edge, or the same angle, sometimes undergoes different laws of decrement that succeed each other; and, finally, there are a great many cases where the secondary crystal prefers faces parallel to those of the primitive form, and which combine with the faces produced by the decrement, to modify the figure of the crystal.

If, in the midst of such a variety of laws, sometimes acting solitarily, and sometimes in combination upon the same primitive form, the number of ranges subtracted were likewise variable; if, for instance, there were decrements of twenty, thirty, forty, or a greater number of ranges of molecules, of which it is very possible to conceive, the multitude of forms which might exist in each mineral species would be sufficient to appal the imagination, and the study of crystallography would present an immense labyrinth, from which even the affilience of theory could not extricate the learner.

But the force which produces the decrements of range appears to have a very limited action. Generally these subtractions take place by only one or two rows of molecules. None have hitherto been found beyond fix rows; but furnish the facies limited with this simplicity, that were we to confine ourselves to decrements by one, two, three, and four rows, and to exclude those that are mixed or intermediate, we find that the rhomboid is susceptible of 8,508,624 varieties of crystallization. Doubtless many of these varieties do not exist in nature; but there is reason to expect that discoveries in the field of inquiry will be made for many years to come.

The tetrahedron and the triangular prism, when they occur as integrant molecules, are always arranged in such a manner in the interior of crystals, that, taking them in groups of two, four, fix, eight, they compose parallelo-pipeds. These parallelo-pipeds are, by Hairy, named integrant molecules. They are always substituted in the place of tetrahedrons and triangular prisms in considering the decrements where they produce the secondary forms.

Decrements of the Edges.—The most simple case of change of form produced by the superposition of decreasing lames, is that which supposes ranges of molecules to be taken away on all the edges of a parallelo-piped, in a direction parallel to the edges. Yet this case, so simple in appearance, may give rise to forms of confiderable complexity. Thus the rhomboidal dodecahedron (Plate II. fig. 27, or Plate III. fig. 28. Crysrallography) may be formed in this way from a cubic nucleus. If the integrant molecule of this species be a cube, it follows that the primitive crystal E A, O I, and E' A', O' I', is formed by a congeries of cubes. Suppose these cubes of such a size, that an edge of the primitive crystall is composed of a row of seventeen cubes, placed side by side, as represented fig. 29. I O, O E: of course each face of the primitive crystall will be a congeries of 289 squares, consisting of so many integrant molecules; and the primitive crystall or cube will be a congeries of 4913 cubes. Let us suppose that a square surface or plate, of the thickness of one integrant molecule, be applied to every face of cube; that is, instead of being of the same size as the face of that crystall it is less by a single row of molecules all round; so that the sides, instead of containing seventeen little cubes, contain only fifteen each (see fig. 29.); of course this square will contain only 225 little cubes, instead of the 289 that form the surface of the primitive crystall. Upon each of these first plates applied to every face,
face, let another plate be applied similar to the first, but less than it by a row of integrant molecules; so that each side contains only thirteen squares, and the whole only 169 squares. Let six other plates be applied in succession to each of the faces, decreasing by a row of little cubes all round; so that the sides consist of eleven, nine, seven, five, three, and one squares respectively. It is obvious, that by this process we have raised upon each of six faces of the cube a four-sided pyramid, the faces of which, instead of being smooth, will, by their constant diminution of bulk, represent the steps of stairs. If, however, we conceive the molecules to be extremely small, and the number of decreasing laminae to be increased, the steps of the stairs may be so small as to be imperceptible to the eye, in which case the surfaces of the pyramids will appear smooth.

These pyramids having each four faces constitute twenty-four triangular faces, so that the cube is converted into a new crystal. Instead, however, of having twenty-four faces, the decrements having been equal on each edge, the triangular faces in each adjacent pyramid will be in the same plane, and form together a rhomb, which will be evident from the inspection of figs. 28 and 29; the cube will therefore be converted into a rhomboidal dodecahedron. The cubic nucleus I', O', O, E, fig. 29, is represented with the pyramids raised on three of its faces. When complete, it will have the form represented in Plate II. fig. 27. If the decrement had taken place by two ranges on each of the lamina, when applied to the cube the pyramids would have been lower; and their adjacent faces being no longer in the same plane, the secondary crystal would have terminated in twenty-four distinct triangles.

In the example given (fig. 29) it will be seen, that as each of the laminae decreases by one row on each of its edges, viz. one on I'O, and another on the inferior row I'O', and the same on the other edges, it is obvious that the pyramid decreases by two rows in breadth for every row in height; therefore the height will be equal to half the breadth at the base.

The terms decrement in breadth, and decrement in height, are thus explained by Haidy. Decrements in breadth are those in which the thickness or height of each plate or lamina is only equal to one integrant molecule; and the result of the decrement is by one, two, three, or more ranges in the direction of the breadth. Decrement in height implies a decrement of one row in breadth on each of the successive plates; but each of these rows may have the thickness or height of two, three, or more molecules. In the latter case, the decrement is said to take place by two, three, or more ranges in height.

These two kinds of decrement are often combined together, of which we have an example in iron pyrites with twelve pentagonal faces. (Plate III. fig. 32.) This variety has a cube for the nucleus, as represented fig. 31; and may be conceived to be formed, as represented fig. 32, by decrements of two ranges in breadth in one direction, and by decrements of two ranges in height in the other. The decrements in breadth by two ranges tend to produce a more inclined face than the decrements by two ranges in height; the consequence resulting is, that the crystal will not terminate in pyramidal points, but in wedges, as is seen at $q$, fig. 32. The structure of this crystal is more particularly described under the article Crystal; but for Plate I. Nos. 14, 15, 16. r. Plate II. figs. 30, 31, 32. Crystallography.

Another example of decrements on the edges is deferring particular attention: it is afforded by that peculiar kind of crystal of calcareous spar, commonly called dog-tooth spar, or which Haidy denominates the metaflatic crystal. (Plate II. fig. 22.) In this crystal, the edges E O, O I, I K, where the two opposite pyramids join, coincide with the edges of the primitive nucleus, as may be seen in fig. 23. The decrements set out from these edges, and do not take place on the other six edges of the nucleus. Now it is easy to conceive, that the edges of the plates, laid upon the primitive nucleus, form as many triangles, E O I, I O E, &c. resting upon the edges from which they set out; and as there are six in number, there will be twelve triangles, six above and six below; and these will all be scalene, in conformity of the obliquity of the edges from which they set out. With respect to the other edges of the plates of superposition, so far from experiencing any decrement they will increase; because they must always remain contiguous to the axis of the crystal, which is an imaginary line drawn from s to s. It is from calculation combined with observation, that we must determine the law of decrement on which this dodecahedral form depends. If we suppose a decrement by one range, it may be demonstrated, that the two faces produced on each side of the edge from which the decrement takes place will be in the same plane, and parallel to the axis of the primary crystal, conditions which do not apply to the present form. The most simple hypothesis is that which supposes a decrement by two ranges in breadth. This will be more clear from inspecting Plate III. fig. 33: it represents the upper pyramid of the crystal, placed on the upper planes of the primitive nucleus, which being partly visible, admits us to perceive more clearly the progressive effects of the decrement by two ranges.

Each edge of the nucleus, as K I, I O, O E, is divided into ten; from whence it follows, that each face is an assembly of one hundred small rhombs, which are the exterior planes of so many molecules. This construction requires only eight plates of superposition for each face of the nucleus; and these plates being joined to each other, three and three on the edges, which correspond with the upper edges of the nucleus, form decreasing envelopes, covering each other in succession; the last of which is composed of eight little rhombs. If we consider the position of the line E s, which represents an edge of this pyramid, as it appears to the eye, and E s', such as it really exists, we may observe that the geometrical summit of the pyramid s is placed a little above the true summit s'; but this difference is imperceptible, on account of the extreme minuteness of the molecules: and for the same reason, the channels or steps upon the pyramid are not visible. There are darts, however, in which the channels may be perceived by the naked eye.

For determining the form of secondary crystals by calculation, it is only necessary to take the decrements at their commencement, in order to have as many planes, which, if we conceive them to be extended until they meet, would form a complete polyhedral crystal; and in this manner we only consider the initial effects of decrements mathematically, a method more simple and expeditious than that of reasoning. It is useful, however, to explain in detail the structure of a crystal, in such a manner as may enable us to arrange a number of small solids similar to primitive molecules to form a nucleus, in an order conformable to that of nature, and thus to imitate the process of crystallization. We shall give another example from that variety of calcareous spar, called by Haidy equiaceous.

This variety, the secondary crystal, is a rhomboid, much more obtuse than the nucleus, the greater angle being $114^\circ 18' 56''$. It is represented (Plate III. fig. 34) surrounding the nucleus. To extract the latter at once, it is only
only necessary to make sections cutting through the oblique diagonals of the different faces of the secondary rhomboid.

One of the sections, for instance, that paffes through the diagonals drawn from \( a \) to \( t \), and from \( a \) to \( u \), and which cuts off the solid angles \( a, b, d, f \), of the nucleus. But there are six lateral solid angles \( a, b, c, y, z \), and \( t, m, u \). We have, therefore, six sections to make, inclined three and three towards each summit; and because the upper solid angles alternate with the inferior, the sections which cut them off prefer the same alternation, and crofs in such a manner as to present the six rhomboidal faces of the nucleus.

To conceive the structure of this secondary rhomboid, let us refer to the rhomboidal dodecahedron (Plate III. fig. 29.) before described. We have seen that by a decrement of one range in breadth on all the edges, there reffulted two triangular faces on each edge, which being in the fame plane formed a rhomb, the short diagonal of which is \( I _0 \).

Let us suppose, that the nucleus was the primitive rhomb of carbonate of lime \( (a b, d f, f g, 34.) \), and that the lamine of superposition due by one range of little rhomboids similar to the nucleus; but the decrements to take place only on the edges \( a b, b f, f c, c a, a m, \) which meet at the summit \( a \), and on the opposite edges, which meet at the opposite point \( d' \). Then instead of twelve rhombs there will only be six, of which the shorter diagonals will coincide with the edges \( b d, d f, f x, g c, \) &c. The other parts of the lamine of superposition, that is, those which are situated near the lower edges, \( b d, d f, f x, g c, \) &c. will not undergo any decrement, but will suffer variations that will tend to prolong the faces produced by these decrements, until they interfect each other. From hence it refults, that the lamina, instead of preferring the figure of a rhomb, as would have been the cafe if the decrement had taken place on all the edges, will, as they are further and further removed from the nucleus, pass successively from the figure of a pentagon to that of a triangle.

(Plate III. fig. 35, \( a, b, c, f, d, \) is the face of the fame nucleus or rhomb as in fig. 34, and what is said of this face may eafily be applied to the others. Suppose this face divided into \( 8 \) rhombs, which repreffent the faces of so many molecules, or \( 729 \) in the whole. The firft lamine of superposition, which we apply to the face \( a b, b d, f, \) will be \( B, G, \) in which \( U I, Z, d, \) repreffent the upper face, and \( C U, B, X Z, b, \) the faces of the two upper edges. We muft place this lamine in such a manner on the face \( a b, b d, f, \) that the point \( b \)' shall unite with the point \( b, \) the point \( A^1 \) with the point \( A, \) and the point \( B^1 \) with the point \( B. \) We shall perceive immediately, that the two upper ranges of the face \( a b, d f, \) fig. 35, \( A, \) that is, those included between \( a b, A, b, \) on one side, and \( a f, B, b, \) on the other, will remain uncovered, the neceffary reffult of a decrement by one range of molecules. The lamine \( B \) is a pentagon reffulting from the subtraction of the three little rhombi neceffary to complete the rhomb. This subtraction was required, that the lamine by its figure might aid the effect of the decrement, as will be afterwards explained.

The two ranges of rhomboids on each side of the lines \( D d', E d', \) are added, that the nucleus may be covered and continue to increase on the edges \( b d, f d, A, \) fig. 35, which correspond with these lines. These two ranges being fufficient to fill up the void, it is not neceffary to add similar ranges towards the adjacent edges of the lamine of superposition, applied on the neighbouring faces. The operation will indicate of itself what is required in these kinds of additions.

The fig. C, 35. represents the second lamine of superposition, which is to be applied to the former in such a manner, that the points \( d', D, E, d, \) shall unite with those which are marked with the fame letters in fig. B. As the cryftal will receive another increment towards the edges, which correspond with \( F, D, C, d', \) we may conceive that instead of one range added on each side \( D d', E, d', \) it will be neceffary to add two on each of the two lines \( E d', C d', \) fig. C, 35.

We muft place in the fame manner, in succession, the two laminae represented \( D \) and \( E, \) fig. 34; obferving that the letters marked with an accent in each figure shall coincide with the fame letters not accented in the foregoing figure. Beyond the feries which answers to fig. \( E, \) the lamine of superposition will ceafe to envelope the lower edges of the cryftal, and will be reduced to fimple triangles, which may be perceived on examining the figures \( E, F, G, H,\) whose position will be determined according to the conditions before stated.

The number of rhomboids which compofe the lamine being now progreffively decreafing, is reduced at last to a fingle rhomboid \( d' \) (fig. D, 35.), which being applied on that which is designated by the fame letter in fig. \( H, \) will form the summit of one of the lateral solid angles of the secondary rhomboid. It will now be seen why the laminae of superposition take fucceffively pentagonal and triangular faces as they recede from the nucleus. For example, every lamina, detached from the cryftal (fig. 34.) by a fection which paffes any where between the angle \( z, \) and the middle of the lines \( Z, I, Z, u, \) is neceffarily triangular, and has the fame structure as \( P' R', \) fig. 35; namely, it is really furred at its bafe, but the ridges are imperceptible on account of their extreme minutenefs.

Decrements of the Angles.—To explain the formation of secondary cryftals, in many instances it is neceffary to admit that the decrements take place on the folid angles. The formation of the regular octahedron formed on the cube is repreffented Plate III. fig. 35. Crystallography, and an account of it given under the article Crystal, but the reference is erroneously to Plate I. fig. 20.

The effect of decrement on the angles by one range of molecules in breadth is explained in the article Crystal, and a reference made to Plate I. fig. 21, for which see Plate II. fig. 21, Misellaneous, O I, U O; where the face of a cubic nucleus is repreffented as divided into a number of feries of figures; and fig. 23, A, B, C, D, E, F, G, H, I, in the fame plate, repreffent a fucceffive feries of plates, or lamine, placed on the cubic nucleus, each decreafing by one row on the angles. These are defcribed under the article Crystal, but referred to Plate I. fig. 23: by applying that description to the proper figures as here given, the reader will be able to comprehend this cafe of decrement, where a regular octahedron is formed on a cubic nucleus. The arrangement of the integrant molecules on one of the triangular faces of the octahedron is repreffented Plate IV. fig. 37. Crystallography.

If the decrements on the angles of a cube were to flop before they terminated in a point, there would remain faces parallel with that of the cube, which will be evident from inspecting Plate III. fig. 36. The cryftal would then have fourteen faces, eight thole of the octahedron, and fix thole of the cube. Nothing is more common than to find fuch cryftals both in iron pyrites and in galena.

As another example of decrements on the angles, let us take the rhomboid (Plate IV. fig. 38.), which differs fome what from the cube. If the plates applied fucceffively upon all the faces of this rhomboid fuffer decrements only at the angles contiguous to the summit A and O, and that of
thee decrements take place by two ranges, then instead of twenty-four faces, only six would be formed; and if we conceive these prolonged till they meet each other, they would conjoinly form a very obtuse rhomboid (Plate IV. fig. 45.), encircling the nucleus. The summits A, O', coincide with the summits of the nucleus, from which the decrements commenced, and each of the faces A e i o corresponds with one of the faces of the nucleus; so that the diagonal which passes through the points e i is parallel with the diagonal E I of the nucleus, but somewhat more elevated. This kind of crystal is found among the secondary crystals of olivine iron-ore.

As a further illustration of the different variations of which the decrements, whether of the superior or inferior angle, are susceptible, let G g be any rhomboid whatever (Plate IV. fig. 45.), the summits of which are S, S'. Let S g\(\prime\), G g' be a quadrilateral figure formed by cutting through the rhomboid G g in the direction of a plane, formed by the two oblique diagonals G g', S g', fig. 45., and the edges S G, G g'. This quadrilateral figure, termed by Haüy the principal section of the rhomboid, is divided in the figure into a number of small quadrilaterals representing the principal section of as many molecules. Let S G, G g', fig. 47., be the face of the rhomboid, fig. 45., marked with the same letters, and subdivided into the bafes of the molecules of which it is composed. If we supposing that the angle e g' undergoes a decrement by a single row of molecules, the small rhomboid represented by e o n z g' will be wanting; hence it is obvious, that the edges of that plate will have the direction e z, and that the distance between the angle e g', from which the decrement sets out, and the edge o z, will be measured by the semi-diagonal of a molecule, or e g'. If the decrement took place by two ranges, the edge g, the first plate of superposition, will correspond with e d, and the distance between it and the angle e g' will be measured by the diagonal molecule g n. Hence we may conclude, that in the decrements on the angles, the distance between one plate and the succeeding one, which is the same as between the point of departure and the edge of the first lamina, is equivalent to as many semi-diagonals of a molecule as there are ranges taken away, as will be further evident by inspecting fig. 37. But in decrements on the edges, the distance between two consecutive plates is equal to the breadth of as many molecules as are taken away.

This being understood, let us suppose a decrement of two rows upon the angle g'. In that case, the quadrilateral n c p, fig. 46, being a section made in the first plate of superposition, the decreasing edge of this plate will coincide with the little edge e n, since g n is the same diagonal as in fig. 47; therefore if we draw the slanting line g' e b, it will coincide with the face produced by the decrement. But g' d being, in this case, parallel to the axis S, S', as may be demonstrated geometrically, hence it follows that the secondary faces constitute the faces of a prism. If the decrements went on more rapidly, the faces of the secondary crystal would have different angles of inclination to the axis, as will be evident from inspecting Plate IV. fig. 46. If the decrement were by four ranges, for instance, the edge of the first plate of superposition would coincide with the line y g; then the line g q S' indicates the position of the face produced by the decrement. What has been stated, where the plane is parallel to the axis, holds true with respect to all possible varieties of the primitive rhomboid.

**Mixed Decrements** are those in which the number of ranges taken away in breadth and height give ratios, the two terms of which lapen unity. As, for example, decrements by two ranges of molecules in breadth, and three in height, or by three ranges in breadth and two in height, &c. It is easy to see, that the theory may with facility be reduced to that of decrements, in which there is only one row of molecules taken away in one of the two directions.

**Intermediate Decrements.**—These will be best explained by references to the figures.

Let A A', Plate IV. fig. 48, be a parallelipiped of any kind, which undergoes a decrement by two ranges on the edge E O I of its base A E O I. It is obvious, that the edges of the plates of superposition will have the directions b c, r s, parallel to the diagonal E I, and so situated that these will be upon the sides O E, O I, two rows of molecules comprehended between the angle O and the line b c, and likewise between b c and r s. But as it has already been said, the plates applied upon the adjacent faces I O, A K, A E, A H, undergo likewise auxiliary decrements, which continue the effect of the decrement upon the angle E O I. But such, in this case, are the effects of these decrements, that the edges of the plates applied upon I O, A K have the directions c g, s t, and those of the plates applied upon E O, A H, the directions b g, r t; for since the lower edge of the first plate applied upon E O I coincides with b c, and the height of this plate corresponds to that of a single molecule, a little attention will satisfy us, that the plane b e g, which, on one part, coincides likewise with b c, and, on the other, separates from the base A E, O I by a quantity measured by O g, the height of a single molecule, is necessarily parallel to the face produced by the decrement. The fame holds with the plane r I s. From this it follows, that if we suppose the part situated above r I s, we shall have a solid on which the face r I s will represent the effect of the decrement which we are considering.

Now the direction c g, s t, of the plates applied upon the face I O, A K, (and the same may be said of the face E O, A H,) in consequence of the auxiliary decrements, are neither parallel to the edge, nor to the diagonal of the face, but intermediate between the one and the other. This want of parallelism will become still greater, if we suppose the decrements upon the angle of the base E O I to take place by one or four ranges. This is the kind of decrement to which the name of intermediate has been given. It is obvious, that it may take place in an infinite number of different directions, according as it deviates more or less from its two limits, the parallelism with the edge and the diagonal of the face.

In cases similar to those of Plate IV. fig. 48, we avoid the complication introduced by these intermediate decrements, by supposing them comprehended under the principal decrement. But certain crystals exist in which all the three decrements round the same solid angle are intermediate. In such a case, the simplicity of the three is chosen as the principal decrement, and the other two considered as auxiliary. Fig. 49. represents a case of this kind: c n, which is the edge of the first of the plates applied upon A E, O I, is so situated, that on the side of O I there are three molecules subtracted, while on the side O E there is only one: n p, which is the edge of the first plate applied upon I O, A K, indicates three molecules subtracted from O I, and two from O A': c p, which is the edge of the first plate applied upon E O, A H, shews the subtraction of two molecules on O A', and only one on O E.

It is easy to see, that the decrements take place relatively to the different faces situated round the angle O, as if the molecules that compose the different plates of superposition were united invariably several together, compose other molecules of a higher order, and as if the subtraction took place by single ranges of these compound molecules. Thus there will...
will be on the base AE, OI, a decrement of triple molecules by two ranges in height, since on one part, the quadrilateral figure \( \epsilon ONz \), which represents the base of a compound molecule, is equivalent to the bases of three simple molecules; and on the other, the line \( OP \), which corresponds to the height of a superposition, is equivalent to the height of two simple molecules. It is easy to conceive likewise, that the decrement relative to the face EO, A'K, takes place by two ranges in height of double molecules, because \( \epsilon OPx \) contains the bases of two simple molecules, and \( ON \) is equal to the length of three simple molecules. In the decrement which takes place upon IO, A'K, there is a subtraction of one row of molecules, triple in one direction, and double in the other.

Among these three decrements, the one which it appears natural to adopt as the principal is the second which takes place upon the face EO, A'H; because it is the one whose direction deviates least from that of the diagonal EA', or because it takes place by double molecules, which is a more simple decrement than the other two.

To give some further examples of intermediate decrements, let us suppose OI, I'O, one of the faces of cubic nucleus (see Plate IV. fig. 50. Crystallography); and that the decrement took place on the angles by the subtraction of double molecules: in this case, the edges of the lamina of superposition will be in the direction of the lines \( dn, km, a, b, \epsilon, &c. \)

Let \( E'I', \) fig. 51, be a cubic nucleus, and suppose the decrements are made parallel to the lines \( km, l, k, lr \), always by subtraction of double molecules, but in such a manner, that there shall be three ranges taken away in the direction of the breadth, and one of that in the height: in this case, the decrements will be both intermediate and mixed. Suppose also that the edges of the superposition, situated around one solid angle, \( O \), had directions which crossed, so that with respect to the face OI, I'O, the greatest number of the faces of the molecules should be taken away on the sides OI', but on the face EO, OI', it should be on the side O'O', and with respect to face EA, IO, it should be on the side EO; the effect of these different decrements would produce three faces round each solid angle, which would be situated in an inclined manner with respect to the faces of the nucleus; and because the cube has eight solid angles, the secondary crystal would have twenty-four faces, which would tend to unite four and four, and form the summit of a pyramid round each face of the nucleus. But if we suppose the decrement to cease before these are completed, there will remain six faces parallel to those of the nucleus, and we shall have a polyhedral crystal of thirty faces, as represented fig. 52. The angles \( km, lr \), corresponding with those of the nucleus, are rhombs; and the faces \( m, l, r, a \), are equal and similar trapeziums. This form is that of one of the varieties of iron pyrites.

Suppose intermediate decrements on the two lateral angles of a rhomboid \( G'O' \), Plate IV. fig. 47, and that these decrements take place by ranges of double molecules, parallel to the faces \( um, s, t, u' \). It is evident, that these decrements will produce above each rhomb of the primitive nucleus \( S, G, G' \), two faces, which, commencing at the angles \( G \), will converge towards each other, and come in contact in a line situated above the diagonal \( S \), but inclined to that diagonal; so that the complete result of the decrement will be the formation of twelve faces, disposed six and six towards each summit. Plate IV. fig. 53, represents one of these folids, with its nucleus inscribed. It is a variety of calcareous spar which some-times occurs. The lines \( a, b, d \) show the direction of a fracture parallel to the face \( G'' \), \( C'' \), of the primitive nucleus. It appears from this figure, that the nucleus does not touch the secondary crystal, except by its lateral angles, which are situated in the edges \( BS, ED, C'T, &c. \), while in the dodecahedron of Bergmann, represented in Plate II. fig. 22, and called by Haüy metabasitic calcareous spar, the lateral edges of the nucleus coincide with those edges of the secondary crystal that confine the common basis of the two pyramids, as is evident from inspecting Plate II. fig. 23.

Hitherto immediate decrements have been observed only in a small number of infinities, but they lead to forms as simple as the other, and give some curious results, which deserve to be studied in a mathematical point of view, without any reference to crystallography.

**Compound Secondary Forms.**—Simple secondary forms are those which proceed from a single law of decrement, the effect of which covers and conceals the nucleus, which only touches the secondary crystal by certain angles or edges. Compound secondary forms are those which are produced by several simultaneous laws of decrement, or by one law which has not reached its limit: so that faces remain parallel to the original faces of the nucleus, which further modify the faces of the crystal.

Suppose, for instance, the law which produces the octahedron from the cube (Plate III. fig. 36.) should concur with that from which results the dodecahedron with pentagonal faces. (Plate III. fig. 31.) The first of these laws would produce eight faces, which would have for centres the eight angles of the cubic nucleus. Each of these faces, as, for instance, that whose centre coincides with the solid angle \( O, \) fig. 31, will be parallel to the equilateral triangle, whose sides pass through the points \( p, t, i, \) fig. 34: in like manner, the centre that coincides with the front \( O' \) will be parallel to the equilateral triangle, whose sides pass through the points \( s, n, p, \) Plate IV. fig. 54. But the second law produces faces situated as the pentagon, cut by the sides of the triangles \( p, t, i, \) fig. 34. Now the section of these triangles upon the pentagon \( t, O, \) \( O'n, \) fig. 31, reduces the pentagon to an isosceles triangle, which has the line \( in \) for the base: the two other sides are those which pass through the points \( t, n. \) The same takes place with the other pentagons. Hence it follows, that the secondary crystal produced would be an icosahedron, bounded by eight equilateral triangles, and twelve isosceles triangles. (See Plate IV. fig. 54.) This icosahedron occurs in iron pyrites; it is different in its form from the regular icosahedron of geometers: the latter form does not exist among crystals, and cannot be produced by any law of decrement. The same remark applies to the dodecahedron, bounded by twelve regular and equal pentagons.

Another illustration of a compound secondary form is offered in the regular fix-sided prism of calcareous spar. (Plate II. fig. 17.) From the manner of dissecting this prism, (see CRYSTAL,) it is easy to conceive that the rhombohedral nucleus, fig. 21, has a fix of its solid angles \( E, O, L, K, G, H, \) situated in the middle of the lateral faces of the prism: it follows, that these angles are the points from which the decrements set out from the three plane angles of the rhomb \( E O I, E O A', I O A', \) which form the solid angle \( O \); but it is only necessary to consider the decrements on one of them, supposing the same decrement extends on the two adjacent planes that form the solid angle. Let us then refer all the decrements to the fix angles \( E O I, E H G, I K G, H K G, O I K, H G O, \) the first of which are turned towards the summit \( A, \)
and the three left to the summit \( A' \). If we suppose a decrement by two ranges of rhomboidal molecules on these different angles, fix faces will be produced parallel to the axis, as has been already observed.

The plates of superposition, at the same time that they undergo a decrement towards the inferior angles, will extend by their superior parts, so as to remain always contiguous to the axis, the length of which will progressively be augmented. The small faces produced by the decrements on the angles will gradually increase till they touch each other; we shall then have the solid represented \( AA, fig. 2o, \)

where each of these small faces, as \( 000 \), is marked with the same letters as the angle to which it belongs, and which is now situated in the middle of the triangle, because it constitutes the point from which the decrements set out. As new plates are applied, the points or line \( oo \) rise up, and the point \( O \) links down; so that at a certain period we shall have the solid represented \( fig. 19, \) where the faces produced by the decrements become pentagons \( ooO, Oo. \)

Let us now suppose a second decrement to concur with the first, and to take place by a single range upon the superior angle \( E A I \) and the inferior angle \( H A K, \) and also on the other faces of the rhomb which form the solid angles \( A \) and \( A' \); the effect of this will be to produce two faces perpendicular to the axis; and when it has reached the point at which these faces cut the six faces parallel to the axis which are produced by the first decrement, the secondary solid will be completed, and will be a regular fix-fided prism. (Plate II. fig. 17.) It has been already said, that the result is general, whatever be the form of the primitive rhomboid. It may now be seen why, in the mechanical division of the prism, the section \( pp, oo, \) has the sides \( pp, oo, \) parallel to each other, and to the diagonal of the nucleus \( E F, fig. 21. \) Since the two decrements taking place, one upon the angle \( E O I, \) the other upon the angle \( E A I, \) the plates of superposition ought to have the edges formed by the decrements parallel to the same diagonal, or to \( E I. \)

In the case we have been considering, and which is the most common, the axis of the secondary crystal is longer than that of the nucleus; but if we suppose the two decrements to commence at the same time, then the axis of the prism being equal to that of the nucleus, both the lateral angles and the summits of the nucleus would touch the prism, the one on the sides, and the other the faces. If the decrement were to commence on the superior angles prior to the lateral decrements, the summits of the nucleus would then be contiguous to the bases of the prism, whilst its lateral angles would be wholly within the prism, between its planes and axis. This is the case with certain crystallinos, in which the prism is very short, and resembles an hexagonal plate.

Another remarkable example is offered in that variety of calcareous spar, called by Halyi analagous. (See Plate IV. fig. 55.) It is composed of twenty-four trapezoidal faces, of which six are vertical faces, as \( d a b \), \( d a d b, \) and twelve others, disposed fix and six, as \( d e p a, \) and \( c e p a b, \) \&c. and six terminal faces, as \( p a e. \) The vertical trapezoids result from the same law that produces the hexahedral prism (Plate II. fig. 17.); the second result from the law which produces the metallic crystal, fig. 22. In comparing fig. 55 with fig. 21, we may see that the vertical faces cut those of the metallic crystal, so as to intersect the lateral solid angles \( E O I, K, \&c. \) figs. 22 and 23; and, lastly, the terminal faces result from a decrement similar to what produced the equiax crystal. (Plate III. fig. 34.)

Fig. 55. \( A, B, C, D, \) represents the different trapezoidal faces of this crystal. Various relations of proporation between their sides and angles are given by Halyi, Mineralogie, tom. i. p. 85, 86.

It is a character common to all the primitive forms to be divisible, parallel to their faces. In the parallelepiped, where this division is not joined with some other in a different direction, it leads us obviously to the form of molecule similar to that of the primitive crystal. In the regular fix-fided prism, it gives us for a molecule the triangular prism, as has been before observed. (See Plate V. fig. 56.) In the octahedrons, it appears to produce two kinds of molecules, tetrahedrons and octahedrons. Halyi, in this case, conceives that the tetrahedron is the integrant molecule, and that the octahedrons are empty spaces between them. The difficulty is removed, by conceiving the molecules to be an assemblage of spherical particles, as we have before observed. The dodecahedron, with itsolcal triangular faces, cannot have molecules extracted, without dividing it in directions different from those which are parallel to the face. The cutting-planes must pass through the axis, and through the edges contiguous to the summits, from whence will result irregular tetrahedrons. Some other primitive forms divide also in directions which are not parallel to the faces, as we have seen in the case of the tourmaline. See Plate III. fig. 26.

Thus, besides parallelepipeds, there are two other forms which form molecules alike, namely, the tetrahedron and the triangular prism; but it depends particular attention, that the tetrahedral and prismatic molecules are always arranged in such a manner in the interior of crystals, that, taking them in groups of two, four, six, or eight, they compose parallelepipeds, so that the ranges subtracted by decrements are no other than these parallelepipeds; and we may consider such decrements as taking place by one or more ranges of rhomboidal molecules. If, for example, we take the regular fix-fided prism (Plate V. fig. 56.), suppose one base of this prism divided by sections parallel to its sides into small triangles, which form the bases of the integral molecule; it is evident that any two adjoining triangles, \( A pi, A O i, \) compose a rhomb, and by their union the two little triangular prisms to which these bases belong would form by their union a rhomboidal prism or parallelopiped. It is obvious, therefore, that we may conceive the larger prism to be composed of similar rhombics. Now, if we conceive a series of plates piled upon the hexagon \( A, B, C, D, F, G, \) and which undergo, for example, on their different edges, a subtraction of one range of thefe parallelepipeds, these edges will successively correspond with the lines of the hexagon \( 1m n r b, k u x s y z e, \&c. \) from which we see that the quantity by which each plate decreases is a sum of parallelepipeds, or prisms with rhomboidal bases; and if the decrement attains its limit, we shall have a right fix-fided pyramid, which will have for its base the hexagon \( A, B, C, D, F, G. \) These parallelepipeds, composed of tetrahedrons or triangular prisms, are called by Halyi \( subtrahentes molecules; \) and as far as the theory of crystals is concerned, we may conceive all crystals to be composed of parallelepipeds.

Plate V. fig. 58. refers to a particular case described in a note by Halyi (tom. i. p. 96.) to explain the vacuities on the edges \( b, c, f, m, \) but being of less importance, we proceed to state the observations of M. Halyi on some apparent anomalies in crystallization.

In common crystals, the faces adjacent to each other always form families, and never re-entering angles; but certain cryshalline forms exist, which present the latter angles. Let \( B d, \) Plate V. fig. 6c, represent an oblique prism with rhomboidal
rhomboidal bafes, situated in such a manner, that the faces A D, a d, and C D, c d, are vertical, and B, D, are the acute angles of the base, and that these proceed in an ascending direction from A to C. Let us suppose also, that the prism is cut into two equal parts by a plane which passes through the diagonals drawn from B to D, and from b to d, and that one half remained fixed, whilst the other is reversed without being separated from the former. The crystal will then be presented under the aspect seen in fig. 61. Where the triangle B, d', c, which was one of the halves of the inferior base, fig. 60, is now situated in the upper part, fig. 61, and forms a palient angle or projecting edge with the triangle A B D. Whilft the triangle B D C, fig. 61, which was one of the halves of the superior base, fig. 60, is transported into the lower part, fig. 61, and forms a re-entering angle with the triangle a b d, we may easily conceive that the plane of junction D B, b d, of the two halves of a rhomboid is situated like a plane drawn, formed by a decrement on one range or other of the edges A a, C c, fig. 62, and thus the manner in which these halves join is in strict relation with the structure.

Now if we imagine a secondary form, which has for its nucleus a similar prism to the above, and if we suppose that it has been cut in the direction of the plane D B, b d, and that one of the halves has been reversed as in fig. 61, the arrangement may be such, that there will still be a re-entering angle at one termination, and a palient angle at the other, resulting from the mutual incidences of the faces produced by the decrements.

In certain cases, the plane of junction on which the two halves of the crystals are joined is situated parallel to one of the faces of the nucleus, and the arrangement does not admit of presenting a re-entering angle opposite to a palient one.

These crystals which are here described are called by Hauy *hemiplies*, or half reversed. Romé de Lisle has called such crystals marles.

Another accident extremely common is the manner in which crystals in groups are inferred into each other. This kind of penetration is subject to many diversities; but on accurate examination, we shall find that they are subject to certain laws always analogous to those of structure, and that these crystals, instead of being precipitated confusedly on each other, have a certain kind of arrangement. In illustration of this, let Plate V. fig. 62. be a cube, and M N a such triangular facet, produced by a decrement of one range round the angle A: let us suppose a second cube modified in the same manner, and attached to the former by a facet resulting from a similar decrement; we shall have the combination represented fig. 63.

We may also conceive that one of these cubes, for instance the lower one, is increased in all its dimensions, except in those places where the other forms an obstacle to its progression. As the increment continues increasing, it will more and more envelope the upper crystal, and may finish by covering it entirely. We observe crystals sunk into each other at different degrees of depth, but always in such a manner, that their plane of junction has a position analogous to planes resulting from decrement; so that both follow their common progress to this plane, which serves as their respective limit. Cubes of flor spar inserted into each other have the laminae of each extended without interruption, until they are stopped by the common plane of junction.

The example here stated relates to a very simple and regular law of decrement. But frequently the laws which determine the plane of junction are more or less complicated, and there are a few which are rather extraordinary. When two prisms cross towards the middle of their axis, there are two planes of junction which unite crossing each other, as in the mineral called fluorite, and these planes have positions analogous to those which would be determined by the known laws of decrement.

In the preceding theory of crystallography it has been constantly supposed, that the laminae composing crystals of the same species proceed from a common nucleus, undergoing decrements subject to certain laws, on which the forms of these secondary crystals depend. But this, says Hauy, is only a conception adopted to make us more easily perceive the mutual relations of the forms we are treating of.

Properly speaking, a crystal taken as a whole is only a regular group of similar molecules. It does not commence by a nucleus of a size proportioned to what it afterwards acquires, or that which we can extract from it by mechanical division; and the laminae which cover this nucleus are not applied successively over each other in which the theory considers them. The proof of this is, that among crystals of different sizes that are often attached to the same support, those which can only be distinguished from the microscopes are as complete as the largest; from whence it follows that they have the same structure, that is to say, they have already within them a small nucleus proportioned to their diameter, and enveloped by the requisite number of decreasing laminae to form the faces of the secondary crystal. We must therefore conceive, that from the first commencement a crystal similar to the rhomboidal dodecahedron is already a small dodecahedron, and contains a cubical nucleus proportionally small, and that this kind of embryo continues to increase without changing its form by the addition of new laminae on all the sides, so that the nucleus increases on its part, always preserving the same relation with the entire crystal.

We shall render this idea distinct by a construction which refers to the dodecahedron, and represented by a plane figure. What is said of this figure may easily be applied to a solid, since we can always conceive a plane figure to be a section made in a solid: let t s, a d', Plate V. fig. 59. A, be an assemblage of small squares, in which the square B N, D G, composed of forty-nine squares, represents a section of the nucleus, and the extreme square f p b f c s, &c. the slips formed by the laminae of superposition. We may conceive that the assemblage commenced by the square B N, D G, and that different piles of small squares are afterwards applied on each of the sides of the central square; for instance, on the side B N, the five squares comprehended between f and d, afterwards the three squares contained between c and s, and then the square s. This progression corresponds with what would take place if the dodecahedron commenced with a cube proportioned to its volume, and which afterwards increased by an addition of laminae constantly decreasing.

But we may also suppose, that the assemblage of molecules commenced as represented Plate V. fig. 59. C, in which the square B N, D G, is only composed of nine molecules, and had on each side of it only a single square, s t, t s. If we refer this assemblage in imagination to the solid, of which it is a section, we shall easily perceive that this solid had for its nucleus a cube composed of twenty-seven molecules, and that each face composed of nine squares had placed on the middle one a little cube, so that the decrement of one range is already seen in the initial dodecahedron.

By the addition of new squares, this assemblage will become that of B, fig. 59, in which the central square B N, D G, is formed of twenty-five small squares, and supports on each of its sides a range of three squares, besides the terminal squares s t, t s. Here we have already two laminae of superposition instead of one only. Lastly, by a further
The instrument by which the angles of crystals are measured is called a goniometer. For a description of Dr. Wollaston's reflecting goniometer, see Goniometer. A more simple instrument was employed by Haüy. (See Plate VI. fig. 53. Crystallography.) It consists of a semi-circle of brass divided into degrees. At the centre is fixed a pin, upon which slide the two arms A B, G F. The last of these, by means of a screw, may be fixed in any position, so that the distance between the end G and the centre may correspond with the face of the crystal to be measured. The other arm A B is drawn up till the distance between B and the centre corresponds as nearly as possible with the size of the other face of the crystal. It is then turned round till the angle of the crystal to be measured corresponds exactly with the angle B C G; the arm A B then cuts the semi-circle in the angle, which corresponds with that of the crystal. This instrument is found to be not sufficiently accurate for delicate observations, but it is truly surprising that Haüy was enabled by it to approximate so nearly to the correct dimensions of the various crystals which he has described. The instrument for determining the electricity of crystals (Plate VI. fig. 92.) is described in the article Mineralogy, Addenda.

On the Notation of Crystals.—To facilitate and abbreviate the description of the structure of secondary crystals, Haüy has invented symbols which denote the particular laws of decrement, that produce the various forms that may occur. This mode of notation will be easily understood by a reference to the figures in Plates V. and VI. Crystallography. Let Plate V. fig. 64. represent any oblique parallelopiped, the faces of which have angles of different measures; let it be the primitive form of some mineral, as selenite. The vowels are to represent the solid angles. The four first, A, E, I, O, are placed at the four angles of the upper base, following the order of the alphabet. The confonants are chosen to designate the edges. The six first are placed on the middle of the edges of the upper base, and upon the two longitudinal edges of the lateral faces, B C, D F, G H. The letters P, M, T, which are the initials of the syllables of the word Primitives, are placed in the middle of the upper base, and of the two lateral planes or faces exhibited to view.

Each of the solid angles, or of the six edges marked by letters, is susceptible of undergoing particular laws of decrement, on account of the irregular form of the parallelopiped. For this reason, they are marked each with a different letter. But as the laws of decrement act with the greatest possible symmetry, every thing which takes place with respect to the angles and edges that undergo distinct decrements, takes place also on the angles and edges that are diametrically opposite, and are perfectly equal, but which are not visible, or are not marked. Thus in fig. 66. the edges A I, E J, A E, and E F, and the solid angles I and J, O and P, are equal. It is, therefore, only necessary to mark the number of solid angles or edges that have different decrements, because these are understood to include all those which take place on analogous edges or angles.

In some cases, it is necessary to indicate the analogous edges and angles; this is done by similar small letters: the angles analogous by A E, I O, are represented by a r, i o, and the same with the edges. But it is seldom necessary to mark these small letters in the figure; it is sufficient to introduce them into the symbol of the crystal, because the place which every one should occupy in the figure may easily be conceived.

To indicate the effects of decrements by one, two, three, or more ranges in breadth, the figures 1, 2, 3; 4, &c. are employed in a manner to be immediately explained; and to indicate the effects of decrements by two, three, &c. ranges in height, the fractions 3, 1, 4, &c. are employed.

The three letters P, M, T, serve to distinguish either the form of the nucleus without any modification when they alone constitute the symbol of the crystal, or the faces parallel to those of the nucleus in the figure where the decrements do not reach their limit; and these letters are combined in the symbol of the crystal with those which relate to the angles or edges that have undergone decrements.

Let us suppose that one of the solid angles O, fig. 64., is intersected by a single additional face. The decrement which produces this face may take place either on the upper base P, or on the plane I, which is on the left of the observer, or on the face M, which is on the right. In the first place, the figure marking the decrement is placed above the letter O; in the second case, the figure is placed on the left-hand, a little above the letter; and in the third case, it is placed on the right-hand. Thus O denotes the effect of a decrement by two ranges in breadth, parallel to the diagonal of the base P, that passes through I, E; O indicates the effect of a decrement by three ranges in breadth, parallel to the diagonal of the face M, which passes through the angle E; and O indicates the effect of a decrement by four ranges in breadth, parallel to the diagonal of the face T, that passes through the angle O.

When the decrement takes place on one of the three other solid angles A, E, the observer is supposed to move round the crystal till he is opposite to that angle, or to turn round the crystal till the solid angles E, A, I, are exactly opposite to him; and it is relative to that position that the decrement is said to take place to the right or the left.

For example, if we are speaking of the solid angle A, the sign A will represent a decrement by two ranges on the surface A E, i r, fig. 66. or opposite to T; and A will represent the effect of a decrement by three ranges upon the face A I r, opposite to M.

As to the decrements on the edges, those which take place towards the boundary of the upper base B, C, F, D, are expressed by a letter placed above or below the letter as the effects occur above or below the terminal edge, supposing them to set off from the edge to which they are referred, whilst those which take place on the lateral edges are conducted by an exponent placed on the right or the left of the letter, according as they occur in one direction or the other.

Thus O expresses a decrement by two ranges proceeding from D towards C: O, a decrement by two ranges proceeding from C towards D; O, a decrement by two ranges descending upon the face M: H, a decrement by three ranges, proceeding from H towards G: and G, a decrement of four ranges proceeding from G towards the edge opposite to H, or A r, fig. 66. When it is necessary to denote by a small letter, such as d, a decrement upon the edge u r, fig. 66. opposite to the edge denoted by the capital letter D, fig. 64.
CRYSTALLOGRAPHY.

D, fig. 64, we must suppose the faces of the crystals reversed. Hence, \(d\) will express a decrement by two ranges upon the other base, just as \(D\) expresses a similar decrement on the base \(P\). For the same reason, \(c\) will express a decrement by three ranges proceeding from \(r\), to \(E\), to \(O\).

If the same solid angle, or the same face, undergo several succeffive decrements on the same side, or different decrements which take place on different sides, the letter pointing out the angle or edge is repeated as often as the decrements, varying the figure each time, to make it correspond with the particular decrements denoted. Thus, \(D\), \(D\), will denote two decrements upon the edge \(D\), one of two ranges on the base \(P\); and another of three ranges upon the face \(M\); and \(H\), \(H\), \(H\), will denote two decrements, one by two ranges on the left, the other by four on the right of the edge \(H\).

Mixed decrements are marked according to the same principles, employing the fractions \(\frac{3}{4}\), \(\frac{1}{2}\), which represent them; the numerator referring to decrements in breadth, and the denominator to decrements in height.

The intermediate decrements are thus described. Let \(A\), \(E\), \(I\), \(O\), (Plate V, fig. 67.) be the same face as in fig. 66., but divided into rows or ranges; let us suppose a decrement by one range of double molecules, according to the lines parallel to \(x\); so that \(O\) measures the double length of a molecule, and \(O\times\frac{1}{2}\) that of a single molecule.

This kind of decrement is thus expressed, \((O, D, F, \ldots)\) the parentheses indicate that the decrement is intermediate;

\(O\), that it takes place by one range on the solid angle marked by that letter in fig. 64.; \(D\), that there is one length of a molecule taken away along the edge \(D\); and \(F\), that two lengths are taken away along the edge \(F\).

The written language to denote the symbols, that they may be easily expressed when dictated, would be thus; for \(O, O, o, O\) read, \(O\) under two, \(O\) above four. And the symbol \((O, D, F, \ldots)\) read, in a parenthesis, \(O\) under one, \(D\) one, \(F\) two.

The order in which these letters must be placed to denote a secondary crystal remains to be explained. If the alphabetical order was adopted, there would result a degree of confusion in the picture which the formula presents. It is more natural to conform to the order that would direct an observer in the description of the crystal, that is, to begin with the prism or middle part, and to indicate its different faces as they present themselves successively to the eye; then to pass to the faces of the summit or the pyramid.

Suppose (Plate VI. fig. 68.) that variety of sapphire which Hauy calls binary, viz. where there are two decrements by two rows each. The primitive form is represented fig. 64. and 66. In this form of the crystal, the face \(l\) results from a decrement by two ranges on the edge \(G\), fig. 64. going towards \(H\); the face \(M\), fig. 66. corresponding with \(M\), fig. 64.; the face \(T\), fig. 68., is parallel to \(T\), fig. 64.; the pentagon \(x\) comes by a decrement of two ranges on the angle, corresponding with the angle \(I\), fig. 64., and parallel to the diagonal \(A\). O. As this decrement does not reach its limit, the summit exhibits a second pentagon \(P\), parallel to the base \(F\), fig. 64. All this description may be exhibited by five letters in symbolic language: thus \(G M T\)

\(\top\) denoting a decrement by two ranges on the edge \(G\), and a decrement by two ranges on the angle \(I\), fig. 68. It is customary, in order to prevent any ambiguity, to place under the different letters that compose the symbol those that correspond to them in the figure. Thus in the binary felspar, fig. 68. \(G M T\) the letters in the line below those of the symbol enable us to compare the symbol with the figure, and thus to decipher the meaning with facility; however, complicated it may be.

Where the primitive form has great simplicity, as in the cube and rectangular prism, when the opposite angles are equal, one letter will denote them both, and when the opposite edges are equiangular, the same letter will denote either: for every thing that denotes one of them, takes place also in the other. If, for instance, we suppose fig. 64. to become more symmetrical, and that certain solid angles which were before unequal are become equal, they should be marked with the same letter. If, for instance, the primitive form be a rectangular prism, which has oblique-angled parallelograms for its bases, one side of which is longer than the other, fig. 69.; in this case, we have the angle \(O\) = \(A\), \(I\) = \(E\); we may substitute in each case the second letter for the first, as is done fig. 69.

If we review the different kinds of parallelograms we shall find them acquire different degrees of simplicity, which occasions new equalities in the angles and edges, and new subtiltations of letters. The oblique prism with rhomboidal bases is represented fig. 70. The rectangular prism with rectangular bases fig. 71. The rectangular prism with rhomboid bases fig. 72. The rectangular prism with square bases fig. 73.

The cube is represented fig. 74.; here only the superior base is marked, because what takes place with respect to this may be applied indifferently to any of the other faces.

The same mode is employed in writing the symbols for these regular forms, only the letters that have the same name and the same figure are not repeated. An example will render this method evident. Fig. 75. represents the most common variety of the chrysoberyl, or cymophane, (see Chysoberyl.); the nucleus of which is a rectangular parallelopiped, such as represented fig. 71. The symbol of the secondary crystal, fig. 75. will be \(M T^1 G^1 B^2 A^2 A\). This variety is called by Hauy annular cymophane.

To understand this expression better, let us mark each angle and edge with a particular letter, as in fig. 76. In this case, the symbol would become \(M T^2 G^2 H^1 B^2 F^2 E^2 O^2\); but if we compare fig. 71. with fig. 76., we shall see that \(H = G\), \(F = B\), \(O = A\); hence if we substitute instead of their first letters their equal values, we get \(M T G B B^2 A^2 A\), which becomes the same as the one before given, when the useless repetition of \(B\) is suppressed.

From the preceding statement, it is evident that we must not confound such symbols as \(G G^2\) with \(G^2 G\); the first symbol indicates the decrements which take place on the face \(T\), fig. 71., and on the edge opposite to it, going from the edges \(G\) towards those that correspond with them behind the parallelopiped. The second symbol indicates the decrements which take place upon the face \(M\), and which meet each other in the middle of that face.

If these two decrements took place simultaneously, these symbols would be \(G^2 G\).
In the preceding symbols, each letter, such as on G or G, can only be applied to a single edge situated to the right or left, as the letter is itself; but G G applies differently to the one edge or the other: hence it is needless to repeat the letter.

If we take Plate VI. fig. 77, as another example, and suppose fig. 70, to represent its primitive form, we shall have for the symbol of the variety of crystal here represented, 

\[ G^3 M B B E \]

If we place in this symbol, G indicates two distinct faces formed on each side of each edge G, but it is not necessary to place two letters under that symbol, because all the faces situated in the same manner being distinguished by the same letter in the figure; it is sufficient to point out that the symbol G applies to the faces marked with the letter G, and this requires only to write the letter G under the symbol.

From the same principles it follows, that the rhomboidal dodecahedron derived from the cube, fig. 74, is expressed by the symbol B B. The octahedron derived from the cube is thus expressed A A.

The rhomboid, supposing it placed in the most natural aspect, so that the two solid angles, composed of three similar flat angles, are in the same vertical line, has properly speaking, no base, but merely bifurcites, which are the extremities of its axis. Its angles and edges are marked as in Plate VI. fig. 78.

If all the lateral angles were indicated by letters, those that are nearest the summit A would have the letter E, and those which are nearest the inferior summit the letter e. As the rhomboid has six faces equal and similar, it is only necessary to consider the decrements relative to one of these faces; as, for example, that marked P, fig. 78, because all the others are mere repetitions of this. The decrements which set out from the superior angle A, or the superior edge B, will have the figure indicating the number of ranges placed below A and B. Those which set out from the lateral angles E, will have their figures situated at the side and towards the top of the letter. Those decrements which set out from the inferior angle e, or the inferior edge D, will have the figure placed above the letter e or D.

Suppose, for example, that fig. 79, represents the variety of calcareous spar, called analogie by Häüy, its symbol would be \( e^2 D B \), the interpretation of which will be easy. What has been said of the rhomboid may be applied to the other primitive forms, of which we shall give examples: fig. 80, represents the octahedron with equilateral triangles; fig. 82, the regular octahedron. In placing the figures that accompany the letters in the symbols in fig. 80, the figure denoting the decrement is placed below the letter A or B, to represent decrements setting out from the angle A, or the edge B. The figure is placed above for those which set out from the edge D, and at the side for those which set out from the angle E.

If we want to denote a decrement by one range upon all the angles of the regular octahedron, fig. 82, we have only to write A A. To indicate a decrement by one range on all the edges we write B B. The first of these decrements produces a cube, the second a rhomboidal dodecahedron. In some mineral species, as in the nitrate of potash, the primitive octahedron, which is composed of eight isosceles triangles, similar four and four to each, ought to have the position represented as in fig. 83, that the secondary crystal may have the most natural attitude. The edges which join the two pyramids ought to have two of them a vertical direction, as F, F; and two an horizontal direction, as B. By comparing fig. 83, with fig. 84, in which the letters are placed as if all the edges and angles had different functions, it will be easy to conceive the arrangement of the letters adopted in fig. 83; for in the present case we have E=A, D=B, G=F.

The tetrahedron being always regular when it becomes a primitive form, it will be expressed as in fig. 85, and the decrements marked as in the octahedron.

In the regular four-sided prism, fig. 86, the figures are written precisely in the manner already described for the four-sided prism. But it happens sometimes, that three of the solid angles taken alternately are replaced by faces, whilst the intermediate angles remain untouched. In that case, the prism is distinguished as in fig. 87. In the rhomboidal dodecahedron, fig. 88, each solid angle composed of three planes may be distinguished from the opposite rhomboid; hence it is only necessary to give letters to one face, as may be seen in the fig. A A, E E, B B, P. Where the parts of crystals opposite to those which undergo certain decrements remain untouched, it is easy to mark this peculiarity by zeros. This case belongs chiefly to the tourmaline. One variety of the tourmaline is represented fig. 90, and the primitive form fig. 89. The prism, which is nine-sided, has fixed its faces, namely s s, produced by the subtraction of one range upon the edges D D, fig. 89, and the three others, as l, by the subtraction of two ranges only on three angles e. The inferior summit has simply three faces parallel to those of the nucleus; while on the superior summit the three edges B, fig. 89, are replaced each by a facet n n, fig. 90, in consequence of a decrement which has not reached its limit. This crystal is represented by the following symbol:

\[ D e E P B b \]

\[ E b \]

indicates, the one that the angles E, fig. 89, opposite to e, undergo no decrement; the other, that the edges parallel to B remain also untouched. If these edges underwent a different law of decrement, for instance, that which produced a subtraction by two ranges, the symbol would be:

\[ D e E P B b ; \]

hence it may be understood, that the decrements represented by a capital letter, accompanied with a figure, do not always include similar decrements represented by a small letter of the same name. Thus B does not implicitly imply b, or vice versa; it is only when the second letter is not introduced into the symbol with a different figure, or a zero, that we imply that the same decrements take place on the analogous sides or angles.

In the symbol \( D e E P B b \), by B is implied a decrement by one range, which takes place only on the edges contiguous to the superior summit A, fig. 89: b indicates a decrement by two ranges, which only takes place on the edges contiguous to the inferior summit. The quantities \( e \) and \( E \) indicate two ranges on the angles e only, and that no decrement whatever takes place upon the opposite angles E.
The preceding illustrations of M. Hauy’s mode of de-
noting the structure of crystals by symbols, are given in
detail to enable the student to make a figure of a crystal
from the symbol representing the laws of its formation.
Shorter rules for enabling the student merely to read and
understand this mode of notation will suffice.
1. The letters P, M, T, denote the faces of the nucleus or
primitive crystal, or indicate that the faces are parallel to
the faces of the primitive crystal marked with the same letters.
2. Every vowel in the symbol indicates a solid angle,
marked with the same letter as in the nucleus. Every con-
sonant indicates the edge which has the same letter in the figure.
3. Each letter contained in the symbol is understood with
the figure belonging to it to represent all the same letters,
and the angles or edges which have the same function.
4. Every number joined to a letter indicates a decrement
setting out from the angle or the edge denoted by that
letter. If the number be a whole one, it indicates the
ranges in breadth, supposing each plate to have only the
thicknes of one molecule. If the number be a fraction, the
numerator indicates the number of ranges subtracted in
breadth, and the denominator the number of ranges sub-
tracted in height.
5. The number is placed above the letter to shew that
the decrement ascends, or below it to shew that it descends,
setting out from the angle or edge marked by the letter.
If it be placed either on the right or left hand of the letter,
it indicates a decrement to the right or left of the edge or
angle marked by the letter.
6. When a letter is twice repeated with the same number
placed on different sides, as 4 G G , the two edges or two angles which it marks should be
considered in the figure in the same relative positions.
Thus, 2 G G indicates the effect of decrement by two
ranges on the edge G situated at the left, and of a similar
decrement on the edge G situated at the right.
7. When a letter has the same number both on the right
and left side, as 3 G 3 , it applies equally to all the edges G.
The same applies to the letters which denote the angles.
8. The parentheses, as, for example, ( O D , F ) indi-
cates an intermediate decrement. The letter O indicates
that an ascending decrement of three ranges takes place on
the angle O ; D , that one molecule is subtracted along the
edge D ; and F 2 , that two molecules are subtracted on the
edge F .
9. Every small letter in the symbol indicates the angle or
the edge diametrically opposite to that which has the same
capital letter in the figure, where the small letter is omitted as
superfluous. The letter e is, however, never omitted in
the rhomboid; it indicates, according to the principle, the
letter opposite to E.
10. When the large and small letters of the same name
are introduced into the symbol with different numbers attached to them, the two opposite edges or angles denoted by
these letters are considered to undergo exclusively the
law of decrement, indicated by the number attached to the
letter.
11. Every letter, whether large or small, marked by a
number having a zero attached to it, as E, indicates that the
decrement denoted by that number does not take place on
the angle or edge which the letter represents.

The above account of the theory of crystallization, and
the notation of crystals, may suffice with what has been
before given under the article Crystal, to convey ample
information of the abbe Hauy’s ingenious system, so far as
relates to the structure of crystals, and the symbolic mode
of describing the decrements by which the secondary crystals
are formed. The figures in Plates II, III, IV, V, VI,
Crystallography, which we have described, are copied from
Hauy’s Traite de Mineralogie, tom. i., and contain what he has
given in illustration of the theory of crystallization. The
application of geometry and analysis, to determine the laws
of decrement from the measurement of the angles, which has
been so ably made in the above-named work by this illustri-
ous crystallographer, would require for its explanation a
more ample space than would be consistent with the present
article, which is intended to supply what was defective in
the explanation of the plates under the article Crystal, and
to correct the references that were there erroneously given.
(See Crystal.) We omitted to state, that Plate II, fig. 25,
represents the secondary rhomb, fig. 24, with the three
superior edges, and the three inferior ones cut off or truncated
r, r, r ; by cutting other laminae parallel to each of the faces r, r, &c. we shall at length extract the
primitive nucleus A, E, O, I, fig. 24.

C SHATRIYA, or CHATTERIE, denotes in India a
man of the second or military cast. See Cast.

CUCKFIELD. In 1811, the parish of Cuckfield
contained 300 houses, and 2088 perons ; viz. 1065 males,
and 1023 females : 251 families being employed in agricultu-
role, and 123 in trade, &c.

CUCKOW-SPIT. Add—This cuckow-spit en-
compasses the larva of a species of cicada, which is denomi-
nated C. fumaria, or cuckow-spit cicada, from the circumstance
of its larva being constantly found enveloped in a mass of
white froth adhering to the leaves and stems of vegetables.
This froth, called cuckow-spit, is found during the ad-
vanced state of summer, and is the production of the in-
cluded larva, which, from the time of its hatching from
the egg deposited by the parent insect, continues occasion-
ally to suck the juices of the item on which it resides, and to dis-
charge them from its vent in the form of very minute
bubbles, till it covers itself with a large mass of froth, and
it is sometimes so overcharged with moisture that a drop
may be seen hanging from its under surface. Shaw’s Zool-
ology, vol. vi.

CUCULUS, I. 4. add—Dr. Leach, however, observes
that this property does not belong to this kind of feet,
which can be considered merely as simple feet, having two
toes before and two behind. Col. 2, 1. 21, after insects,
add—and on larvae or caterpillars; 1. 35, add—for the
natural history of this bird, see Dr. Jenner’s curious paper
in the Phil. Trans. for 1788, pt. ii.

CUD-BEAR. See LICHEN Tartaricus.

CULLUMIA, in Botany, dedicated by Mr. Brown, to
the honour of the late sir John Cullum, bart., an elegant
and accomplished scholar and botanist; as well as of his
brother the present sir Thomas Cullum, bart. F.L.S.
a very excellent British botanist, one of the most ardent
cultivators of this lovely science, whose friendship alone can
be more valued than his various and extensive information.—Br. in
Ait. Hort. Kew. v. 5. 137.—Clafs and order, Polygnia-
Common calyx of one leaf, covered with imbricated scales.
1. C. ciliaris. Fringed Cullumia. Ait. n. 1. (Berckheya
ciliaris ; Willid. Sp. Pl. v. 3. 2273.) Gorteria ciliaris ; Linn.
Sp. Pl. 1884. Carlina folis imbricatis, &c.; 151. t. 54.
f. 1.)—Leaves ovate, smooth, imbricated, fringed with a
double row of bristles, and tipped with a reflexed spine.

n. 2. (Berckheya fruticosa; Willid. ibid. excluding Commic-

in't

C U R I A Aduifare sult, a deliberation which the court sometimes takes, before judgment is given in a cause, with regard to which there seems to be any point of difficulty.

C U R R I E, James, M.D., in Biography, distingushed both as a physician and a writer, was the fon of an eftab-lished minister at Kirkpatrick-Fleming, in Dumfriesshire, in which parish he was born in the year 1756. Originally de signified for commerce, he was educated with that view; but upon a change of his defination, he commenced, in 1776, a course of medical study at Edinburgh: and having graduated in that university, settled, in 1781, at Liverpool, where he soon rose to eminence in his profession and in his literary character. His first performance as a writer was an elegant tribute to the memory of his intimate friend, Dr. Bell of Manchefter, published in 1785 in the first volume of the Manchefter Transactons. His paper on Tetanus, &c. was published in the Memoirs of the London Medical Society, vol. iii. In 1792 he was elected a member of the Royal Society; and his curious paper on the lamentable effects of a shipwreck was printed in the Phil. Trans. for that year. Disapproving of the war between this country and France in confluence of the revolution, he was sup-posed to be the author of an interesting pamphlet, which appeared in 1793 under the title of "A Letter, Commercial and Political, addref fed to the Right Honourable William Pitt, by Jafper Wilfon." In 1797 his medical reputa-tion was much advanced by a treatife in 8vo., entitled "Medical Reports on the Effects of Water, cold and warm, as a Remedy in Febrile Difeaſes," by which the practice of effufion of cold water in fevers, fugges ted by Dr. Wright's narrative in the London Journal, was much extended. With a view to the relief of the dif turbed family of the rufic poet, Robert Burns, with whom he became acquainted in 1792, he published in 1800 an edition of his works, with an account of his life, &c. in 4 vols. 8vo. It is with real regret we farther report, that Dr. Currie's health began to decline in 1824, and that his friends and patients in Liverpool were deprived of the pleafure of his society, and advice by his removal, towards the clofe of the year, to Clifton and Bath. His diforder, which was of the pulmonary kind, somewhat abated in con-quence of the change of his situation, and at the com- mencement of the following year he began to profecute in his profeflion with encouraging prospects of success. But it again re cured with alarming symptoms, and he was under a neccessity of removing to Sidmouth, where his valuable life terminated on the 31st of August, 1805, in the 50th year of his age. The caufe of literature and fience, and the interefts of humanity and benevolence, suffered great loss by his death.

C U R V O, in Geography, a township of America, in the district of Maine, and county of Somerset, containing 275 inhabitants.

C U S E R U N D, a town of Mekran in Persia, situated in a fertile valley, about 21 miles broad, with a river running through it. It contains 500 huts, and a large mud fort. Wheat, rice, and dates, are abundant; and the town belongs to an in dependent chief, whose revenue is about 1000 rupees a year.

C Y A N O G E N, in Chemsfry, the name given by M. Gay Lussac to the recently-discovered basis of the pruffic acid, and which he has demonstrated to be a compound of carbon and azote. The name is derived from κυανος, blue. Cyanogen may be obtained by exposing dry pruflic mercury in a small retort, to a heat rather under rednes. The salt blackens, and a gaseous fluid is extracted in abundance, which muft be collected over mercury. This gas is cyanogen. It is colourfefs, and polifhes the mechanical properties of common air. Its smell is quite peculiar, and very strong and disagreeable. Its specific gravity, as ascertained by Gay Lussac, is 1.8064. It is inflammable, and burns with a purplish-blue flame. It is not decomposed by exposure to a red heat. Water dissolves 44 times its volume, and alcohol 23 times its volume of this gas. It reddens tincture of lnutus. Phosphorus, sulphur, and iodine, may be volatilized in it without alteration. Potaffium burns in it, and abfors it. For complete combufion, it requires twice its volume of oxygen gas; and the products are twice its volume of carbonic acid, and its own volume of azotic gas. Hence it is obviously
obviously composed of two atoms or volumes of carbon, and one atom or volume of azote, or per cent. of

See Atomic Theory, Table III.

Cyanogen is capable of combining with chlorine, and forming an acid which has been named chlorocyanic acid. It also combines with hydrogen, forming hydrocyanic acid; with sulphur, forming sulphiocyanic acid; and with iron, forming ferrocyanic acid: of each of which acids we shall here give a brief account.

Chlorocyanic Acid. — This is the oxyprussic acid of Berthollet, who first demonstrated its existence. Its properties were afterwards more thoroughly investigated, and its true composition pointed out by M. Gay Lussac, who gave it the above name. The acid was formed by M. Gay Lussac by diffusing a current of chlorine gas through a solution of hydrocyanic acid (prussic acid, see below) in water, till the liquid was discoloured indigo dissolved in sulphuric acid. To separate the excess of chlorine, the mixture was agitated with mercury. The chlorocyanic acid was subsequently separated by an ingenious process. A glass cylinder, filled two-thirds with mercury, was filled to the brim with the above mixture, and then inverted into a basins of mercury. The apparatus was put under the receiver of an air-pump, and the exhaustion carried on till the whole of the mercury and liquid was displaced, and the cylinder filled with chlorocyanic acid in a state of vapour. On letting the air again into the receiver the vapour was condensed into a liquid, and thus collected upon the surface of the mercury in the cylinder. Chlorocyanic acid thus obtained is a colourless liquid, having a strong and peculiar odour, which excites such irritation as to induce a flow of tears. It reddens litmus, is not inflammable, and does not detonate when mixed with hydrogen or oxygen. Its solution in water does not precipitate nitrate of silver, nor barytes water. The alkalies absorb it rapidly, but it requires an excess of them to destroy its odour completely. It throws down iron from its solution of a green colour. But some of its compounds appear of a very permanent nature. Gay Lussac has shown that this acid is a compound of one atom or volume of cyanogen, and one atom or volume of chlorine, united together without change of bulk. Hence it will be composed per cent. of

And its specific gravity in a state of vapour will be 2.152.

Hydrocyanic Acid. — This was formerly denominated Prussic Acid; which see. Hydrocyanic acid may be prepared in the manner pointed out in the above article; but the method more lately recommended by Gay Lussac consists in decomposing the prussiate of mercury by means of muriatic acid in a retort with heat. The products are to be passed through a tube two feet long, the first one-third of which length is to be filled with fragments of marble, to retain the muriatic acid that may come over, and the remaining two-thirds with dry muriate of lime. A small receiver covered with ice is to be adapted to the end of this tube in which the hydrocyanic acid may be collected on application of a moderate heat to the retort. The properties of this acid are correctly described under Prussic Acid. It is a most virulent poison. From Gay Lussac's experiments, it appears to be composed of one atom or volume of cyanogen, and one atom or volume of hydrogen, united together without condensation. Hence it is composed per cent. of

And the specific gravity of its vapour will be .9367.

Hydrocyanic acid cannot be preferred for any length of time without undergoing decomposition, ammonia is formed, and a quantity of chary matter is deposited. Iodine volatile in this acid suffers no change. Oxygen decomposing it with combustion. Chlorine displaces the hydrogen, and forms chlorocyanic acid. Neither azote, hydrogen, carbon, boron, silica, nor phosphoruses, have any known action upon it. Sulphur decomposes it, appearing to displace the hydrogen and combine with the cyanogen, and thus forming sulphiocyanic acid. Potassium, iodum, potash, soda, and barytes, combine with the cyanogen and liberate the hydrogen. The vapour of hydrocyanic acid is decomposed when passed through red-hot iron or platina; also when passed through the peroxide of copper. The peroxid of manganee completely absorbs the vapour of hydrocyanic acid in a few hours, water is formed, but cyanogen is not evolved. When the red oxygen of mercury is heated in hydrocyanic acid vapour, so much heat is evolved from the violent action that takes place that the compound is destroyed. If heat be not applied, the vapour is absorbed by the oxyd, and when the compound is afterwards submitted to heat, water is diffregenaged, and the cyanide, or prussiate of mercury, as it was formerly termed, is left behind. See further under Prussic Acid.

Sulphiocyanic Acid. — This is the sulphuretted chyazic acid of Mr. Porrett, who discovered it in 1808. It may be formed by dissolving one part of sulphuret of potash in water, and boiling in this solution three or four parts of prussian blue, added at intervals. Sulphuret of iron is formed, and a colourless liquid containing a considerable quantity of sulphiocyanic acid combined with potash. This liquid is then to be rendered decidedly acid by sulphuric acid, and the mixture kept at the boiling point for some time. When cold, a little peroxid of manganee is to be added, which will give to the solution a fine crimson colour. This crimson liquid is to be filtered, and a solution composed of two parts of the perfulphate of copper and three of the protufulphate of iron is to be added, till the crimson colour disappears. A copious white precipitate, composed of sulphiocyanic acid and protuoxid of copper, takes place. The copper may be separated by boiling with a solution of potash, and the sulphiocyanate of potash thus formed afterwards decomposed by sulphuric acid; the sulphiocyanic acid may be then obtained by distillation in a retort. If any sulphuric acid adheres to it, this is to be separated by a little carbonate of barytes.

Sulphiocyanic acid thus formed is a transparent colourless liquid, having an odour as strong, and somewhat resembling acetic acid. Its specific gravity when most concentrated was 1.022. According to Mr. Porrett's analysis, it is composed of

Dr. Thomson seems inclined to consider this acid as composed of 3 M.
posed of cyanogen and sulphur, but it is probable that Mr. Porrett's view of its composition will hereafter be found correct.

The *fulphocyanate* of potash, soda, ammonia, barytes, flint, lime, and magnesia, are all deliquecent salts soluble in alcohol. The *fulphocyanate* of soda, lime, barytes, and flint, are capable of crystallizing, the others are not. The *fulphocyanate* of alumina is not deliquecent, and readily crystallizes. The *fulphocyanate* of the protosyd of iron is colourless, and very soluble. The *fulphocyanate* of the peroxysyd of this metal is of a beautiful crimson colour, deliquecent, and does not crystallize, and this is one of the most striking characteristics of this acid. The *fulphocyanate* of the peroxysyd of copper is a white powder insoluble in water and most acids. The other salts are not remarkable, and consequently posefles little interest. The following is a short account of some of the salts formed by this acid.

**Ferrocyanic Acid; the Ferreutted Gleyacic Acid of Mr. Porrett its Discoverer.**—This is the acid which combines with different bases, and forms what were formerly denominated *triple prusslates*, iron being supposrd to form part of their base, whereas Mr. Porrett has demonstrated that this metal forms a con*l*uent of the acid itself. This acid may be obtained by the following simple process:—

Dissolve in cold water any quantity of the *triple prusslate* of baryte, and form for every ten grains of the salt add about 2.5 grains of real fulphuric acid, agitate the mixture and let it abide some time. The baryte will be precipitated in union with the fulphuric acid, and leave the ferrocyanic acid in solution in the water. When obtained, it has a pale lemon colour, and is deliquescent of smell. It is decomposed by a gentle heat and exposure to a strong light, hydrocyanic acid being formed, and the white *triple prusslate* of iron deposited. When combined with the different bases, it forms at once the salts formerly termed *triple prusslates*. It displaces acetic acid from all its combinations without heat, and displaces all other acids when it forms insoluble compounds with the bases to which they were united. Mr. Porrett, from his analysis, concludes that this acid is composed of

\[
\begin{align*}
\text{Hydrocyanic acid} & \quad 63.79 \\
\text{Black oxyd of iron} & \quad 36.21 \\
\text{Total} & \quad 100.00
\end{align*}
\]

Dr. Thomson, however, from analogy, is disposed to consider it as a compound of cyanogen and iron, but it is probable that Mr. Porrett's views are correct. Most of the *fulphocyanates* have been already described under the different bases, by the old name of the *triple prusslates*, see Iron and Prussian Blue.

**CYTHODES, in Botany, a cup-like, alluding to the shape of the nectary.**—Labill. Nov. Holl. v. 1. 57.

Eff. Ch. Calyx five-cleft, with numerous scales at the base. Corolla funneld-shaped; tube scarcely longer than the calyx, naked and smooth within; limb spreading. Filaments within the tube. Drupa pulpy. Nut with five or ten cells.

*Stem* shrubby, erect, branched, sometimes almost arborescent. *Leaves* stiituated at the back. *Flowers* axillary, erect, or febragdrooping, small. *Nuts* a five-toothed cup-shaped disk, beneath the germ. Mr. Brown differs from Labillardiere in his ideas of the species which properly belong to this genus. He defines six New Holland species. 1. *C. gunacus*, Labill. t. 81; 2. *C. fruticosa*, 3. *C. dealbata*. All these have some degree of hairiness on the corolla. 4. *C. parvifolia*; 5. *C. oxycoccus* (Stephelia oxycoccus, Labill. t. 69); and 6. *C. abietina* (Stephelia abietina, Labill. t. 68). These have a smooth corolla. *Arabia aerocera*, Garn., t. 94, belongs to this second fection, and Mr. Brown has seen three Southsea species in Sir Joseph Banks's herbarium.

The present genus stands between *Melicurus* and *Lisanthe*; see those articles.

**CYTHODES, a cup.**—Perf. Syn. Fung. 256, a genus of rather small Fungi, to which some botanists have given a still more expressive name, *Nidularia* (see Sowerby, Fung. t. 29). The whole plant consists of a leathery cup, containing several ventricous bodies, supposed to contain the seeds, and all together resembling a bird's nest with eggs. *Peronoo* has seven species.

Eff. Ch. Calyx five-cleft, unequal; intruded at the bafe. Corolla papilionaceous; stamens furrowed lengthwise; wings with a transverse plait. Stamens deciduous. Stigma biserate at one side. Legume compressed, with many seeds.

Of the remaining species we have no account.

**CYNODON, from *wod4, a dog, and *on*, a tooth, a genus founded by some authors on the Panicum Dactylon of Linnaeus, a graps known in molt of the temperate or warm parts of the globe, to which Mr. Brown adds two tropical New Holland species. See his Prodr. v. 1. 187. This genus is closely related to the Chloris of Swartz. See *Panicum*, at the end of sect. 1. of that article.

**CYTHEANEA, in Geography, a town of Kentucky, inarrison County, containing 369 inhabitants, of whom 116 are slaves.**

**CYRSTYLLIS, in Botany, from *wod5, curved, or convex, and *cya, the eye, or column.**—Brown Prodr. Nov. Holl. v. 1. 322. Claws and order, *Cynandra Monandra*. Nat. Ord. *Orchideae*.

Eff. Ch. Calyx ringent, pointlets. Petals spreading, nearly equal to the lower calyx-leaves. Lip dissimilar, direct, flat, obtuse, undivided, with two calliotes at the base. Anther a terminal permanent lid; the cells close together. Maffe of pollen two in each cell, powdery, compressed.

1. *C. reniformis*.—Gathered by Mr. Brown, at Port Jackson, New South Wales. Habit like *Acianthus*, (see that article,) to which this plant is perhaps too near akin. Leaf kidney-shaped, many-ribbed. Flowers generally turned, or, in one sense, reversed. *Malaxis bifolia* (see that article, n. 11.) is thought by Mr. Brown to approach this plant in structure of flowers, though different in habit. We have already observed how imperfectly that species, with our Cordifolia and Locelli, answer to *Malaxis.*

**CYSANTHAE,**
CYSTANTHE, from κυστής, a bladder, and ῥύς, a flower, expressing the appearance of the corolla.—Brown Prodr. Nov. Holl. v. i. 555.—Clafs and order, Pentandria Monogynia. Nat. Ord. Eparidræae, Br.

Eff. Ch. Calyx leafy. Corolla closed, like a lid, splitting transversely; the torn base permanent. Stamens inserted into the receptacle, permanent, Neptuniferous scales none. Capsule with many seeds; receptacles pendulous from the top of the central column.

1. C. sprengeliana.—Native of Van Diemen’s island. A shrub, resembling Sprengelia, Ponceletia, and Cosmeya, except the branches being marked with annular scars after the fall of the leaves. A short-leaved variety grows on the mountain tops, but on their shady sides the plant bears more elongated, spreading, recurved leaves.

CYSTITIS. Inflammation of the bladder is rarely a primary disease, but generally comes on as a consequence of some other affection in the neighbouring parts; or of lithotomy, accidental injuries, &c. The symptoms attending it are, tension and pain over the pubes, with a frequent desire to make water, difficulty in voiding it, or a total retention, with tenesmus and fever.

The treatment recommended for NEPHRITIS is here also applicable. In particular, venesection, leeches to the hypogastric region, the warm bath, aperient medicines, and emollient clysters, must be employed. When the bladder and peritoneum inflame after wounds, or the surgical operation of lithotomy, blisters are often of great service; but bleeding should be first practised. In chronic inflammation and thickening of the bladder, the symptoms and pain may be allayed with anodyne emollient clysters, which are far better than injections into that organ itself. Opium, cicuta, hyoscyamus, the uva ursi, &c. with a perpetual blister, may also be tried.

CYSTOTOMY, CYSTOTOMIA, from κυστής, the bladder, and τομή, to cut, the operation of cutting into the bladder. See LITHOTOMY.

Vol. XI.

DAGESTAN, l. 2, after Asia, infert—almost entirely mountainous, as its name implies.

DAGOTTI. See Gauthier.

DALIBARDA, in Botany, a genus originally dedicated by Kalm and Linnaeus to M. Dalibard, author of the Flore Parisiensis Prodromus, classed in the Linnean method.—Linn. Gen. ed. 5. 217. Sp. Pl. ed. i. 491.—It was afterwards reduced to Rubus, but is since restored by Michaux and others. (See the two species under Rubus, n. 54 and 55.) The specific names of Michaux are inadmissible, for several reasons.

DALTON, col. 2, l. 15, after government, dele to houfes in l. 18; and infert—in 1811, the parish of Dalton in Furnefs contained four townships; viz. Dalton having 156 houfes, and 643 inhabitants; Hawcoat having 107 houfes, and 583 inhabitants; Ireleth with 75 houfes, and 445 inhabitants; and Yarleside with 68 houfes, and 403 inhabitants.

DALTON, in America, l. 3, r. 779; l. 7, for Grafton r. Coos; l. 8, for 62 r. 235.

DALTONIA, in Botany, so named in juft commemoration of the Rev. James Dalton, F.L.S., an eminent British botanist.—Hook. and Tayl. Mufc. Brit. So. t. 3.—However defirous we may be to admit this genus, it affords a fresh proof in support of the opinion we have always maintained, that the inner fringes of Mollis give, in general, no found generic characters. Nothing can be lefs exclusively allied than the two suppos’d species, either in habit or character. They are, Neckera spalchnoides, Engl. Bot. t. 2564; and N. heteromalla, Hedw. Crypt. v. 3. t. 15; Engl. Bot. t. 1180. The teeth of their inner fringe, it seems, want the slight connecting base, more or lefs visible in several species of Neckera (see that article), and are attached, scarce visibly, to the teeth of the outer fringe.

DANGAN. See SUMSUM.

DAMPIERA, in Botany, dedicated by Mr. Brown, to the memory of William Dampier, the famous navigator, who first brought one of the species, D. incana, Br. n. 7, from the west coast of New Holland, along with several other specimens preserved at Oxford, the earliest botanical tribute from that remote country.—Br. Prodr. Nov. Holl. v. i. 587.—Clafs and order, Pentandria Monogynia. Nat. Ord. Goodeniaceae, Br.

Eff. Ch. Corolla two-lipped; tube split at one side; segments of the upper lip auricled at their inner margin. Anthers clofely combined. Cover of the stigma naked at the edge. Nut inferior, crustaceous, with a solitary kernel. Dry, downy, perennial herbi, or shrubs, with undivided, alternate, often toothed, coriaceous leaves. Flowers blue or purple. Calyx small, or none. Stamens permanent, sheathing the style.

Thirteen species, from various parts of New Holland, are described, among which is D. fricta, Goodenia fricta; Sm. Tr. of L. Soc. v. 2. 349. Willd. Sp. Pl. v. i. 955.

DANA. Add—containing 625 portions.

DANBURY, l. 3, r. 345; l. 8, r. 3636.

DANBY, l. 2, r. 1730.

DANTHONIA, in Botany, so named by M. De Candolle, after M. Danthon, a French botanist, is a genus separated by that eminent writer, in his Flore Franaise, v. 3. 321, from Avens, on account of the three awns to the outer valve of the corolla, and, as far as we can perceive, for no other reason. He is however followed by Mr. Brown, Prodr. 3 M 2.
Prod. Nov. Holl. v. 1. 176, who defines eight New Holland species, and mentions having gathered ten or more in Southern Africa; but with a hint that this genus is too near to *Avena*, which it almost entirely resembles. The term being acknowledged very treacherous in grusses, we would presume to offer another hint, that Anisopogon (we wish to lay nothing of Diplopogon and Amphipogon, see those articles,) may possibly require revision.

DANVERS, I. uhl. r. 5127.

DANVILLE, l. 6, r. 432 and 166; l. 9, r. 2240.

DAOURIAN. See Neitkrinskel.

DARABGERD. Add—Although a great part be in ruins, it is said to contain between 15,000 and 20,000 inhabitants. It is beautifully situated on an extensive plain, and surrounded with groves of orange and almond trees, the juice of which is exported to every part of Persia. Its tobacco is highly esteemed for its mildness.

DARBY. Add—The former containing 966, and the latter 1085 inhabitants.

DARIEN. Add—It contains 107 inhabitants, of whom 10 are females.

DARK-RAYS, l. 17, r. see Heat and Rays of Heat.

DARLINGTON, l. 6 from bottom, after Darlington, infert—ward, confiding of three divisions, contained 7184 houes, and 39,001 persons; 18,725 being males, and 20,276 females: and the township of Darlington contained 818 houes, and 5059 persons; 2351 being males, and 2708 females.

DARLINGTON, in Carolina. Add—It contained, in 1810, 9874 inhabitants, of whom 2731 are females.

DARRYFIELD. Add—See Deerfield.

DARTAN, in Rural Economy, a kind of scabs or ulcers to which lambs are subject, and which extending to the mouth often prove fatal. The remedy proposed is washing the fores with vinegar, and applying a false made with equal parts of tar and hog's-lard.

DARTFORD, col. 1, l. ult. r. 1811; col. 2, l. 1, r. 526 and 3177.

DARTMOUTH, l. 31, after houes, infert—in the parishes of St. Petrox, St. Saviour, and Townfall, which form the borough of Clifton Dartmouth Hardness, was 364 houes, and that of inhabitants 3595.

DARTMOUTH, in America, l. 9, for 2660 r. 3219.

1. D. bromeliifolius. Br. n. 1. Terr. Aufr. 76. t. 8.—Found on the shores of King George's found, New Holland. Herb one and a half or two feet high, somewhat shrubby, with rigid, simple, sharply and finely toothed leaves. Flowers in a dense, globular, bristly head. The figure seems to exhibit three seeds.

DATOLITE. See Mineralogy, Addenda.

DAVENTRY, l. 2, r. Faviley l. 4 and 5, infert—51 Geo. III., 534 houes, and 2758 inhabitants.

DAVID'S, Sr. col. 2, l. 3, infert after act—51 Geo. III. In 1811, the number of houes for the parih, containing four hamlets, was 437, and that of inhabitants 1816.

DAVIDSON, l. 2, infert—Weft Tenn妃ee; l. 6, r. 15,608, and 6305.

DAUM, or Dam, a copper coin in India, equal in value to the fourth part of a rupee.

DAUPHIN, in America, l. 6, for nine r. fifteen; l. 8, for 22,270 r. 31,883, of whom, in 1810, 26 were slaves.

DAWLISH. Add—By the returns in 1811, the parish of Dawlish contained 328 houes, and 1882 persons.

DAWSONIA, in Botany, a new and most curious genus of Mosses, dedicated, by Mr. Brown, to our valued friend Mr. Dawson Turner, an eminent English botanist, particularly distinguishing himself by his cryptogamic writings. —Br. Tr. of Linn. Soc. v. 10, 316.—Clas and order, Cryptogamia Musci. Nat. Ord. Musci.

Eff. Ch. Fringe a tuft of very numerous, straight, equal hairs, originating from the central column, as well as from the mouth of the calyptra. Outer veil of entangled hairs; inner rough at the summit. Capsule flat at one side.

1. D. polytrichoides. Br. t. 23. l. 1.—Found by Mr. Brown, on the shady banks of rivers, at the foot of the mountains, near Port Jackson, New South Wales. This moss exactly resembles some of our larger species of Polytrichum, (see that article,) while the figure of the calyptra approaches Buschmania. The fringe is totally unlike every thing previously known. The leaves are linear, flat, fringed with sharp teeth.

DAYTON. Add—It contains 1746 perons.

DEAL, col. 3, l. 14, r. 7351, and 1340.

DEAN, Michael. In 1811 the parish contained 121 houes, and 559 perons; viz. 270 males, and 265 females: 31 families being employed in agriculture, and 77 in trade, &c.

DEBENHAM, l. ult. r. 167 and 1224.

DECADIA, in Botany, a tree of Amboina and Cochinchina, so named by Loureiro on account of its ten petals. —Loureiro. Cochinch. 315. (Arbor alumnifera; Rumph. Amb. v. 3. 160. t. 100. Loureiro moreover cites Bobu; Burn. Zeyl. 26, which is also Laurus ferrata, floribus fipicatis, ex foliorum alis proveniuntibus; ibid. 139. t. 62; Eugenioidei; Linn. Zeyl. 192: but this does not agree with the plant of Rumphius.)—Clas and order, Leofandria Monogynia, according to Loureiro, but by his description it belongs to Polyandria. Nat. Ord. Gutiferis affinis. It seems nearly allied to Elcocarpus.

Gen. Ch. Col. Perianth of three permanent, roundish, hairy, keeled, spreading, unequal leaves. Cor. Petals ten, nearly ovate, somewhat serrated, erect, longer than the calyx; the outer ones larger. Stam. Filaments about 30, almost as long as the petals, into whose baiies they are infected; anthers two-lobed, roundish, permanent. Pyll. German roundish, superior; fylle thread-shaped, the length of the filaments; stigma rather thick. Peric. Drupa ovate, rugged, small. Seed an ovate nut, of three cells.

1. D. alumnifera, called in Cochinchina Cay Deung fe, is the only species. This is a middling-sized tree, with a smooth bark and spreading branches. Leaves alternate, filaked, lanceolate, serrated, smooth, of a bright green.

Flowes
DEE

Flowers in small, nearly simple, clusters, about the ends of the branches, white minute. Rumphius relates that the bark and leaves, which may be preferred dry for the purpose, are of great use, instead of alum, in dyeing, to improve and fix the red colours afforded by several Indian woods and roots.

DECAGON. Add.—See Dodecagon.

DECANDRIA, in Botany, from δέκα, ten, and ανή, a man, the tenth clas of the sexual or artificial system of Linnaeus, containing such plants as have ten separate or distinct stamens, in the same flower with the pistil. Hence it admits several papilionaceous plants so circumstanced, notwithstanding their natural affinity to others which belong to the seventeenth class, Diadelphia, the latter containing only such as have some form of union or combination in their filaments, and those filaments are moreover of a peculiarly flat membranaceous structure, altogether different from those of proper decandrous flowers. (See Diadelphus.) The tenth class is divided into five orders, and comprises various natural tribes or families, many of which have allies in other parts of the system, and several of the genera have species whose parts of structur are irregular in number.

A genus of elegant shrubs, found on the south coast of New Holland, with scattered upright leaves, and terminal drooping spikes of red flowers. Berries violet.

1. D. difficilis, (Cyathodes difficilis); Labill. Nov. Holl. v. 64, 1, and 2. D. thymifolia, are all the species mentioned.

DEDDINGTON. In 1811, the parish contained 252 houses, and 1256 persons; 635 being males, and 621 females.

DEEDHAM. In 1811, the parish contained 264 houses, and 1,432 persons; 697 being males, and 735 females.

DEEPING-MARKET. In 1811, the parish contained 166 houses, and 899 persons; 426 being males, and 473 females.

DEER, in America, l. 2, r. 674. Add.—Alfo, a township of Weftmoreland county, in Pennsylvania, having 2380 inhabitants.

' DEER Creek, a town of Ohio, in the county of Pickaway, having 853 inhabitants.

DEER, Ill, col. 2, l. 1, r. 1857.

DEERFIELD, l. 10, r. 1252; l. 16, r. 1851. Add.—Alfo, a town of Ohio, in Portage county, having 394 inhabitants.—Alfo, a town of Ohio, in Rens county, having 625 persons.—Alfo, a town of Ohio, in Warren county, having 1181 persons.

DEERING, l. 32, r. 1363.

DELAGOA, col. 2, l. 8, r. Kaffers.

DELAWARE. Add.—See United States.

DELAWARE County, l. 4, r. 14734.—In New York, l. 2, r. 20, 303 inhabitants, 55 in 1810 being slaves.

DELAWARE Township, l. 2, r. 472. Add.—Alfo, a township in Mercer county, in Pennsylvania, having 218 inhabitants.—Alfo, a county of Ohio, containing seven townships, and 2000 inhabitants.—Alfo, a township of the same county, having 200 inhabitants.

DELI, a river of Persia, in Shirvan, which has its source in the Legean hills, and dilemogues into the Caflian sea, about 20 miles S. of the Samur.

DELMER, a township of Tioga county, in Pennsylvania, having 884 inhabitants.

DELOS, col. 6, l. 21, r. ruin.

DEMBEA, col. 2, l. 16, r. Gorgora.

DE MURIS, John, for Muri, John De.

DENBIGH, col. 2, l. 45 and 46, r. 617 and 2714.

DENBIGHSHIRE, col. 2, l. 22, r. 13,078 houses, inhabited by 64,240 persons; 31,129 being males, and 33,111 females; of whom 3447 families are employed in trade and manufactures, and 7973 in agriculture.

DENMARK, a town of America, in the district of Maine, and county of Oxford, containing 436 inhabitants.

DENNIS, l. 4, r. 1739.

DEPTFORD, col. 3, l. 24, r. 1811, 19,833; l. 25, r. 3463.

DEPTFORD, in America, l. 2, add—containing 2978 inhabitants.

DERAGUZ, a district of Khorassan, which, as well as that of Cotchung, is situated between Meshed and Merv. Cotchung is governed by an independent chiefman, who can bring into the field 12,000 men, and who resides in the town of Cotchung, 23 furlongs from Meshed. The district of Deraguz touches on the W. the dependencies of Kast; on the N. the country of the Turkomans of Tek, sometimes called Attok; and on the E. a branch of the Alhind. Koh. It is the property of Lahli Ali Khan, whose subjects are reckoned the bravest and most polite of the natives of Khorassan; and the soil which they inhabit is so fruitful, that dry grain yields a hundred, and rice four hundred fold.

DERBANE, a beautiful little river which rises in the lake of Louisiana, and has its principal source in N. lat. 32° 30'. W. long. 93° 30', and pursues nearly an easter course of 60 miles, entering Ouachita from the west. It is navigable about one-half of its course for large boats. Its water, which is very pure, is supplied from numerous fprings by many creeks, that are bordered by fine land.

DERBY, col. 6, l. 5 from the bottom, r. 2644, and 13,043.

DERBY, in America, in the census of 1810, probably called Derby by mistake. It has 114 inhabitants.—L. 11r. 2051. Add.—Alfo, a township of Ohio, in Madison county, having 257 inhabitants.—Alfo, a township of Ohio, in the county of Pickaway, having 475 inhabitants.

DERBY. See DARBY.

DERBYSHIRE, l. 12 and 13, r. 35,658, and 185,487.

DEREHAM, East, l. 4 and 5, r. 551 houses, and 2888 inhabitants.

DEREM, a village in the hundred of Clackclove, having 58 houses, and 428 inhabitants.

DERLEY. See Derby.

DEREY, in America, l. 4, r. 2431; l. 5, 1341; l. 7, 2283; l. 8, 2380.

DESERT,
DESSERT ISLAND, Mount. Add.—Mount Defect contains 1,047 inhabitants. See Eden.

DESMANTHUS, in Botany, so called by the late professor Wilder, who first separated the genus we are about to describe from Mimosa; see that article, and Acacia of the present volume. This name seems to be composed of brown, a bandage, and when a flower; alluding perhaps to the strap-like filaments of the neutral flowers, common to every species.—Willd. Sp. Pl. v. 4. 1044. Ait. Hort. Kew. v. 5. 457.—Clas and order, Polygonia Monococia; or rather perhaps Decandria Monogynia. Nat. Ord. Lomentaceae, Linn. Leguminosae. Jaff.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, with five teeth. Cor. of one petal, funnel-shaped, regular, more or less deeply five-cleft, sometimes of five petals. Stam. Filaments ten, rarely but five, capillary, equal, very long; anthers incumbent, oblong. Pet. Germen superior, ovate-oblong; style thread-shaped, the length of the filaments; stigma dilated, abrupt. Peric. Legume oblong, compressed, of two flat valves, and one cell, separated into several by transverse opposite striae in the valves. Seeds numerous, oblong, flaked. Several flowers, below the perfect ones, are neuter, having dilated lanceolate flaments, without anthers, no efficient pistil, and sometimes no corolla.

Obf. Although the definition of this genus is not to flinking as could be wished, it seems to us tolerably natural, being distinguished from Acacia by the definite number of its flaments, always twice as many as the divisions of the corolla, and by the presence of several neuter flowers, in the lower part of each tuft, or spike, known by their dilated, strap-shaped flaments, destitute of anthers, and more or less different in colour from the perfect flowers. We are neverthelbaw aware, that generic characters founded on such anomalies or imperfections, are always the least solid; these neutral flowers, apparently created for no end, being doubtless liable to become, according to circumstances, perfect in one organ of impregnation or the other. The habit of the genus before us is pretty uniform, having doubly pinnate leaves, with numerous, oblong, obtuse, crowded leaflets; axillary, solitary, flaked, oblong spikes, of crowded fistel-like flowers; and flat, generally broad, elliptic-oblong, smooth legumes, whose transverse striae make them resemble the jointed fruit of what now remains as Mimosa, but their valves do not split at those striae. As only ten species of Desmanthus are described, we shall give the whole. They are all of tropical origin; partly herbaceous, and sometimes annual, with felvise leaves; partly shrubby.

Sec. 1. Without thorns.

1. D. lacufris. Lake Desmanthus. Willd. n. 1. (Mimosa lacustris; Humb. and Bonpl. Pl. equinocst. t. 16.)—Thorns none. First division of the leaves of three pair; second of many pair. Spikes ovate. Stalks bracteated. Stem round, creeping. Native of marlhes in South America. Root perennial. Stem herbaceous. First divisions of the leaves an inch and a half long. Leaflets numerous, linear, obtuse at each end. Spikes barren in their lower part, each supported by a flalk longer than the foliages, furnished with two or three ovato-lanceolate dichotous bractees. Legume oblong, pointed, with from four to five seeds. Very narrowly related to the following. Willdenow.

2. D. natans. Floating Desmanthus; or Aquatic Sensitive. Willd. n. 2. Ait. n. 1. Andr. Repol. t. 629. (Mimosa natans; Vahl Symb. v. 3. 102. Roxb. Coro-
Stem prostrate, compressed. Stamens five.—Gathered in stagnant waters at Vera Cruz by Dr. Houltoun, who sent seeds to Miller. The latter records that the *flamen*, though naturally floating, grew more erect when the plant was cultivated on dry ground. The *rostr* is annual, according to Willdenow, Alton, and Linnæus, who had this species in the flowe of Upsal. *Stems* herbaceous, smooth, a little zigzag, a foot or two in length, floating or decumbent, slightly branched. *Leaves* needle-like, longer than those of *D. natans*. *Stipulas* acute, obliquely and broadly ovate. *Spikes* as large as Common Clover, yellow, recurved, on *flails* nearly as long as the leaves, bearing two, three, or four, ovate, flattened *bracteas*. *Stamens* but five, those of many of the flowers changed to long lanceolate petal-like leaves, which give the flowers a double appearance, and render them truly so, according to the analogy of flowers in general. Hence the specific name given by Linnæus; but this circumstance is common to the whole genus of *Desmanthus*, as above described. In this and similar cases it seems best to retain the original name, as indicating the first known species, and therefore the history of the genus. *Legume* is drawn by Houltoun elliptic-oblong, slightly curved, with a furrow, or double edge, along the back. *Seeds* numerous, ovate. The *leaves* are needle-like in this and the three preceding.

Thorns none. First division of the leaves of two pair; second of eight or ten pair of linear obtuse leaves. *Spikes* capitate, of a few decandrous flowers. *Legumae* linear. *Stem* prostrate. —*Found by Humboldt and Bonpland, in South America. Roset* woody, perennial. *Stems* several, from a spæn to a foot long, diffuse, smooth; branched and round at the bottom; obliquely quadrangular above. *Spikes* flaked, without *bracteas*. *Legume* an inch and a half long, pointed, with many seeds. *Akin* to the following, as to the shape of the *spike* and of the *legume*, though easily distinguishable by the specific characters. *Willdenow.*

6. *D. diffusus*. Prostrate Desmanthus. Willd. n. 6. Ait. n. 3. (Mimosa perambucana; Linn. Sp. Pl. 1502. *M. inermis* decumbens, foliiis duplicato-pinnatis, spicis cernuis, floribus pentandris, inferioribus calicatis; Linn. Hort. Ups. 145. n. 4. *M. americana* pigræa, foliis longis angulis, allium olentibus; Pluk. Amag. 252. t. 307. f. 3.)—Thorns none. First division of the leaves of four or five pair; second of twelve pair. *Spikes* capitate, of a few pentandrous flowers. *Legume* linear. *Stem* prostrate.—*Native of South America. Stem* shrubby. *Willdenow*, who had examined dried specimens, says this species is extremely similar to the following, but differs in having more coarsely five primary divisions in the *leaves*, a *prolimate *flamen*, and only five *flamines*. We have never seen the present species, which probably has not appeared in the gardens since Miller's time, but we venture to transfer the synonym of *Zanoni* to the next, on account of the upright flex of his plant. Hence the Linnæan specific name *perambucana*, taken from *Zanoni*, becomes peculiarly unsuitable, and is fortunately changed by Willdenow.

7. *D. virgatus*. Upright Angular Desmanthus. Willd. n. 7. Ait. n. 4. (Mimosa virgata; Linn. Sp. Pl. 1502. Jacq. Hort. Ind. v. t. 34. t. 80. *M. purpurea* of *Perambuco*, detta Mimosa italica; *Zanoni*. l. 151. t. 60. *M. inermis*, foliis duplicato-pinnatis, spicis lineariis glabris; *Linn. Hort. Cliff. 209.*—Thorns none. First division of the leaves of four pair; second of twelve pair. *Spikes* capitate, of a few decandrous flowers. *Legume* linear. *Stem* erect, angular.—*Native of South America, where Jacquin observed it in various places; and not of the East Indies, Burmann's *M. virgata* being properly our *D. natans*, at least according to the synonyms of Plukkenet and Rheedes, cited by that author. The late professor Jacquin sent seeds of this present species to Kew, in 1774, where it flowers in the flowe in July and August. His plant is certainly that of Linnæus, mentioned in the *Hortus Cliffortianus* as of American origin, but confounded with several other things in his *Pl. Zeylanicus*, 216, n. 505. *D. virgatus* has an erect shrubby *flamen*, with wand-like *bracteas*, angular when young, but less so as they become older. *Stipulas* bristle-shaped, with a round auriere. Common *flawflaks* with a round depreessed gland between the first pair of subdivisions. *Legflas* linear, obtuse, fringed, glaucous beneath. *Flower-flakes* the length of the leaves, erect, with small deciduous *bracteas* near the top. *Heads* slightly drooping while young, pale or whitish. Several of the lower-most *flowers* furnished with ten linear, very narrow, almost thread-shaped, abortive filaments, in the place of *flamines*. *Anthers* of the upper *flowers* roundish, yellow. *Legumae* about five from each head, almost erect, full two inches long, linear, not one-eighth of an inch broad, acute, thick-edged, smooth. *Seeds* very numerous, elliptic-oblong, obliquely disposed in a central row. Miller's remark, cited by Willdenow, after Linn. Mant. 2. 503, does not belong to this species, and is excluded by Linnæus himself in his MSS. Probably it may relate to *D. plenus*.

8. *D. punctatus*. Spotted-flaked Desmanthus. Willd. n. 8. Ait. n. 5. (Mimosa punctata; Linn. Sp. Pl. 1502. *M. trutceens* media inermis, foliis compressis falcatis et umbellatis, pedunculo longifimo; Browne Jam. 255. Aecephyromene mitis prima; Comm. Hort. v. t. 61. t. 31.)—Thorns none. First division of the leaves of four or five pair; second of many. *Spikes* ovate. *Flower-flakes* bracteated at the bafe. *Legume* oblong, obtuse, wavy.—*Native of Jamaica*, from whence it was introduced very early into the European Thames. Our specimen was sent by Dr. Browne to Linnæus. The *flamen* is beprinkled with small callous points. *Branches* angular. *Leaves* a spæn long, with a gland on the common *flawflaks* between the first pair of wings. *Legflas* about twenty pair, senitive, linear-oblong, smooth, obtuse with a small point. *Flower-flakes* scarcely so long as the leaves, each bearing, near the bafe, two large ovate, or heart-shaped, *bracteas*. *Spikes* drooping, ovate, of numerous, crowded, pale *flowers*, the lower ones with thin lanceolate *petals*, in the place of the ten *flamines* of the more abundant upper ones. *Legumes* about three from each *spike*, *flaked*, horizontal, compressed, oblong, obtuse at each end, with a small terminal point; their length an inch and a half; breadth one-third of an inch. They betray an inclination to split across, like the true *Mimosa*. *Seeds* about twelve, ovate. This species does indeed, as *Willdenow* observes, much resemble *D. plenus*; but is nevertheless much too different to be confounded therewith.

Sect. 2. Thorny.

owing to the smallness of the tree, of little use. Miller cultivated this plant at Chelsea in 1739, and it is marked by Mr. Aiton, as flowering in the fiover about June and July. A low, irregular, rigid frur, with a grey bark, and zigzag branches, whose short, alternate, lateral shoots spread horizontally, and each finally becomes tipped with a hard sharp thorn. These branches bear very fine and delicate foliage, whose very minute oblong leaflets are smooth above, hairy at the back, and appear to be sensitive; their common flulk also is hairy. Spike axillary, flalked, an inch or two long, swelling upward, obtufe, dense, and many-flowered. Perfect flowers numerous, yellow, with ten fiamens, whose anthers are ovate, of two cells, and tipped with a small round gland. The lower flowers, fleshy, are pale rose-coloured, abortive, having ten linear, obtufe, strap-like leaves instead of fiamens. Legume falcate, linear, compressed, but not flat, about three inches long, and one-fourth of an inch broad, fmooth, obtufe. Seeds ten to fifteen, oblong, yellow.

10. D. divergens. Spreading-branched Defmannthus. Wild. n. 10. ("Ergett Dimmo ; Bruce's Travels, v. 5: 34, with a plate.") — "Branches becoming foliary spines. First division of the leaves of eight pair; second of many. Spikes in pairs, cylindrical, pendulous. Legume twisted."—Native of Abyssinia? A frur, six feet high, with diverications furrowed branches, bespangled with white warts. First divisions of the leaves from fix to nine pair. Lcflits numerous, linear, angular at the base, and fringed at the edges. Thorns rigid, straight, awl-shaped, sometimes in pairs. Legume linear, contorted. Wildenow, who made this description from a living specimen, says the gardeners call this species Mimosa divericata. But what is so denominated in Donn's Hort. Cont. ed. 5: 240, comes from Carolina, and, as far as we can discover, does not occur in Hort. Kew. Bruce's figure above quoted was thought by Wildenow to answer exactly to his own garden frur, except the want of thorns; but as these occur on the older branches only, they might be overlooked. We have not seen specimens of either Bruce's or Wildenow's plant.

DEI'OTO. Add.—The civil distrit of Detroit, which is one of the divisions of the territory of Michigan, contains, by the census of 1810, 2227 inhabitants, of whom 17 were slaves.

DEVAUXIA, in Botany, so named by Mr. Brown, in honour of M. Devaux, author of a dissertation on the natural family of Jumé, in the Journal de Botanique. M. Labillardiere had previously published this same genus under the appellation of Centrolepis, from which, the centre, and =e, a scale; which, giving an erroneous idea of the structure of the flower, it was found necessary to change.—Brown Prodr. Nov. Holl. v. 1: 252. (Centrolepis; Labill. Nov. Holl. v. 1: 7.)—Close and order, Monardia Polygynia. Nat. Ord. Reflections, Brown.

Gen. Ch. Col. Sheath of two concave, keeled, permanent, alternate valves, clasping each other at the base, containing an indefinite number of flowers. Cor. of two oblong, membranous valves, sometimes accompanied by small accessory scales. Stem. Filament one, capillary, drooping, rather longer than the largest valve of the corolla; anther simple, oval. Pfil. Germens several, from three to twelve, ovate-oblong, superior, inserted into one side of a central oblong receptacle, and all turned one way; styles as many, thread-shaped, either distinct at the bottom or combined, spreading or deflexed at the summit; stigma linear, downy. Peric. Capsules as many as the germs, membranous, oval, of one valve and one cell, burbling along one side. Seed solitary, obovate, pendulous.

This genus, of which we have already spoken as akin to Alepyrum, (see that article,) consists of small herbaceous plants, growing in tufts, and resembling the lesser species of Scirpus. The roots are fibrous and tufted. Stem none. Leaves radical, bristle-shaped, half sheathing at the base. Flower-flarks radical, thread-shaped, undivided, naked. Seed solitary, terminal, its valves either awned or not. Nine speciferes are described by Mr. Brown, as follows.

Sec. 1. Receptacle sealy. Styles five or seven, distinct. Sheath pollenless; lower valve hispid; upper smooth. Leaves nearly as tall as the flower-florks.—Gathered by Mr. Brown, in Van Diemen's island.

2. D. Paterfani. Paterfani's Devauxia. (Centrolepis aemula; Rudge Tr. of Linn. Soc. v. 10: 284, t. 12. f. 2.) — Receptacle sealy. Styles eight or nine, distinct. Sheath pointed, many-flowered; upper valve nearly smooth; lower hispid. Adult flower-florks hairy, as well as the leaves, which are only one-third as tall.—Gathered by Col. Paterfani and Mr. Brown, near Port Jackson, New South Wales. Leaves very narrow, an inch long. Flower-florks above two inches high. Seed tumid, scarcely rising above the flowers.

3. D. frigida. Britty Devauxia.—Receptacle sealy. Styles from five to seven, distinct. Seed pollenless; both valves hispid. Adult flower-florks smooth, thrice as long as the finely hispid leaves.—Found by Mr. Brown, on the southern coast of New Holland.

Sec. 2. Receptacle without scales. Sheaths bispsi. Styles sealy.

4. D. tenior. Slender Devauxia.—Receptacle naked. Styles four or five, combined at the base. Seed almost pollenless, bristle as well as the leaves. Flower-florks lightly hairy.—Found in the island of Van Diemen, by Mr. Brown.

5. D. Billardierii. Labillardiere's Devauxia. (Centrolepis saecularis; Labill. Nov. Holl. v. 1: 7; t. 1. C. cupidigera; Rudge Tr. of Linn. Soc. v. 10: 283, t. 12. f. 1.)—Receptacle naked. Styles two or three, combined at the base. Sheath seealy; bristles nearly as long as the valves. Leaves rather hairy. Stalks smooth.—Native of Port Jackson, as well as of Van Diemen's island. Brown, Labillardiere. The numerous bristle-shaped leaves are about an inch and a half long, erect; those which clasp the base of each flower-flork, which is half as tall again, are toothed at their inner margin towards the base. Valves of the sheath twice as well as the flowers. Corolla toothed, obtuse.

6. D. esentrica. Prominent-flowered Devauxia.—Receptacle naked. Styles from seven to ten, distinct. Sheath pollenless, brily, not quite so long as the flowers. Stalks and leaves downy.—Gathered by Mr. Brown, in the tropical part of New Holland.

Sec. 3. Receptacle without scales. Sheaths smooth.

7. D. Bankfield. Bankfield Devauxia.—Receptacle naked. Styles from eight to ten. Seed pollenless, very smooth, many-flowered, membranous at the edges. Stalks three or four times the length of the leaves.—Gathered by Sir Joseph Banks, in the tropical part of New Holland.

8. D. papsila. Little Devauxia.—Receptacle naked. Styles fix or seven. Seed pollenless, very smooth, membranous at the edges, with but few flowers. Stalks and leaves
leaves both smooth, and nearly equal in length.—Observed by Mr. Brown, in the tropical part of New Holland.

Mr. Rudge, very commendably anxious to retain, if possible, Labillardiere's original generic name, has, by taking *calyces* for a *prickle*, as it undoubtedly means a *point*, or *sharp spike*, made *Centropis* to express a *prickly scale*, alluding to the hairy *leaves* of some species. But this is not apposite, the scales, or glumes of the *flower*, to which the original name applied, being, in no sense, pointed, or prickly; nor do we see that the same name can be forced into any appropriate meaning, the *scales* being acknowledged on all hands not to be central.

DEVIZES, col. 2, l. penul. r. 606, and 3750.

DEVONSHIRE, col. 6, l. 11 and 12, r. 62,318, and 383,308.

DEW. To this article we shall subjoin some appropriate remarks, selected from an "Essay on Dew," &c., by the ingenious Dr. Wells, lately (sic. 1819) republished in an edition of his works, to which is prefixed a Memoir of his life written by himself. To this author it occurred in 1784, that the formation of dew is attended with the production of cold. The fame opinion was announced in 1788 by Mr. Wilfon of Glaifgow (vol. i. Edinb. Traln.), and alfo by Mr. Six of Canterbury (Phil. Trans. for 1788, and in a posthumous work printed at Canterbury in 1794.) All these writers at firft concurred in regarding the cold which accompanies dew as an effect of the formation of that fluid. Dr. Wells, however, upon mature consideration of the subjeft, was led to fufpect that this opinion was erroneous; and his fufpicion was afterwards justified by a variety of observations and experiments. Although Dr. Wells agrees, in general, with Arifotle and other writers, and maintains that dew appears only on calm and ferene nights, yet this opinion is not universally true; for he frequently found a small quantity of dew on grafs, both on windy nights, if the sky was clear or nearly fo, and on cloudy nights, if there was no wind; but he never perceived dew on nights both cloudy and windy. Dew, he fays, probably begins, in this country, to appear upon grafs, shaded from the fun, during calm and temperate weather, foon after the heat of the atmosphere has declined; and it continues to form, in shaded places, after fun-fife; the interval between fun-fife and its ceafing to form being coniderably shorter than that between its firft appearance in the afternoon and fun-fife. If the weather be favourable, however, more dew forms a little before, and in shaded places a little after fun-fife, than at any other time; whereas Muifchenbroeck afferts, that dew does not form after the fun has rifen. Our author also maintains, in opposition to the opinion of M. Prieur, that dew, after it has once commenced, continues during the whole night, if the weather remain flill and ferene. During nights that are equally clear and calm, whether they be longer or shorter, dew often appears in very unequal quantities; the quantity of moifure in the atmosphere serving to increase the production of dew; and, accordingly, in equally clear and calm nights, dew is more abundant foon after rain than during a long continuance of dry weather: it is also more abundant in Europe, and in fome parts of Asia and Africa, with fouthery and weffery winds, than with thofe which blow from the north and the efl. Another circumstance upon which the quantity of dew depends, is the diminution of the weight of the atmosphere; for though the falling of the mercury in the barometer is commonly attended with wind or clouds, both unfavourable to the production of dew, yet the greatest dew obferved by our author occurred while the barometer was rifen. M. De Luc alfo has obferved, that a light rain may be foretold when dew is uncommonly abundant in relation to the climate and feafon. We have already obferved, that dew is commonly more plentiful in spring and autumn than in summer, a fact which our author alfo has noticed; it is always very copious on clear and calm nights which are followed by miffy or foggy mornings; and on a clear morning which precedes a fudden night. Heat of the atmosphere, if other circumstances are favourable, occasions a great formation of dew; and upon the fupposition of the fame clearnefs and allottedness of the atmosphere, more dew is formed between midnight and fun-fife than between fun-fife and midnight; the cold of the atmosphere being greater in the latter than in the former part of the night. Our author's experiments ferve to shew, that various differences with regard to situation, mechanical state, and real nature of bodies, have a very coniderable influence upon the production of dew. As to situation he obferves, that whatever diminishes the view of the sky, as foon from the expofed body, diminishes the quantity of dew that is produced; thence the quantity is greater when the expofure to the sky is more complete. There are other circumftances, regarding fution, which ferve to augment or diminish the quantity of dew that is produced, when the fubftances that are used for indicating it are the fame.

It is obferved farther, that when other circumstances are similar, a difference in the mechanical state of bodies has an effect with regard to the quantity of dew which they attract; and hence it is, that fine raw filk, fine unwrought cotton, and flax, were found to attract more dew than the wool employed by our author in his experiments; the fibres of wool being thicker than thofe of the other fubftances mentioned. Bright metals also attract dew much less powerfully than other bodies: this fact was obferved by Muifchenbroeck and Dufay; but they erroneously afferted, that dew never appears on the upper surface of bright metals. There are others, and our author in particular, who have known dew to be formed on gold, filver, copper, tin, plaffia, iron, flleet, zinc, and lead. This inaptitude of metals to attract dew is communicated to bodies of a very different nature, which touch or are near to them. With wool, fays our author, laid upon a metal, will acquire much less dew than an equal quantity laid upon grafs in the immediate vicinity. It is maintained, that the upper surfaces of metals are most readily and mop copiously dewed on those nights and in thofe parts of the night, during which other fubftances are the moft readily and the moft copiously dewed. All metals, our author remarks, do not refit the formation of dew with the fame force. "I faw," he fays, "for example, plataina one night distinctly dewed, while gold, fliver, copper, and tin; though similarly situated, were entirely dry; and I have alfo feveral times seen three four metals free from dew, while iron, flleet, zinc, and lead, were covered with it."

Our author proceeds to investigate and aflertain the degree of cold connected with the formation of dew. Mr. Wilfon, he thinks, is the firft philofopher who ever fuspected the exifence of fuch a conjunction; though dew is often fproken of as cold by our popular writers. Hero- dotus mentions it as poifonifying this quality; Cicero and Virgil apply to it the epithet of "gelidus;" Milton that of "chill;" and Collins that of "cold." With thermometers adapted to the purpose, he has, in ferene and fit nights, examined the temperature of dewed griffs, and con-
Dew.

The next subject to which Dr. Wells directs his attention is the theory of dew. According to Aristotle among the ancients, and many philosophical writers among the moderns, dew is a species of rain, formed in the lower atmosphere, in consequence of its moisture being condensed by the cold of the night into minute drops. But opinions of this kind have been found erroneous, by the consideration of a fact first noticed by Erigena in 1733; viz. that bodies a little elevated in the air often become moist with dew, while similar bodies, lying on the ground, remain dry, though necessarily, from their position, as liable to be wetted, by whatever falls from the heavens, as the former. It was soon afterwards observed by Moscowbrook, that metals will be free from dew, while other bodies attract it copiously: hence Dufay concluded, that dew is an electrical phenomenon, since it leaves untouched the bodies which conduct electricity, whilst it appears upon those which cannot transmit that influence. Against this hypothesis several objections have been urged, however plausibly it has been supported. It has been alleged that charcoal, which next to the metals is the best solid conductor of electricity, attracts dew very powerfully; and dew, as we have seen above, frequently forms upon metals themselves. It has also been urged against this hypothesis, that dew forms in different parts of the night, in quantities disproportional to the degrees of electricity found in the atmosphere at the same time. Thus, it is commonly more copious in the morning than in the evening, though the air is observed to be, in the latter season, more highly electrically than in the former. But another argument applies alike to all the theories which have hitherto been made public on the cause of dew; and this is, that none of them include the important fact, that its production is attended with cold. Mr. Wilfon and Mr. Six have indeed maintained, that the formation of this fluid is the cause of the cold that accompanies it. Dr. Wells once held the same opinion; but finding that bodies would sometimes become colder than the air without being dewed, and that when dew was formed, its quantity, and the degree of cold which appeared with it, were very far from being always in the same proportion to each other, he first doubted its truth, and at length became convinced that it was erroneous; and by further inquiry he was led to conclude, that dew is the production of a preceding cold in the substances upon which it appears; and that it has precisely the same immediate cause as the presence of moisture upon the outside of a glass or metallic vessel, when a liquid considerably colder than the air has been poured into it shortly before. This fact is applied by our author, to the explanation of several atmospheric appearances.

"I. The variety in the quantities of dew, which were found by me upon bodies of the same kind, exposed to the air during the same time of the night, but in different situations, is now seen to have been occasioned by the diversity of temperature, which existed among them.

"II. Agreeably to the opinion of Mr. Wilfon and Mr. Six, the cold connected with dew ought always to be proportional to the quantity of that fluid; but this is contradicted by experience. On the other hand, if it be granted, that dew is water precipitated from the atmosphere, by the cold of the body on which it appears, the same degree of cold, in the precipitating body, may be attended with much, with little, or with no dew, according to the existing state of the air in regard to moisture; all of which circumstances are found actually to take place.

"III. The
III. The formation of dew, indeed, not only does not produce cold, but like every other precipitation of water from the atmosphere, produces heat.

IV. In very calm nights, a portion of air, which comes in contact with cold grases, will not, when the surface is level, immediately quit it, more especially, as this air has become specifically heavier than the higher, from a diminution of its heat, but will proceed horizontally, and be applied successively to different parts of the same surface. The air, therefore, which makes this progress, must at length have no moisture to be precipitated, unless the cold of the grases which it touches should increase. Hence in great measure is to be explained, why, on such nights as have been just mentioned, more dew was acquired by substances placed on the raised board, than by others of the same kind on the grases, though it began to form much sooner in the latter than in the former situation, tho' on the raised board having received air, which had previously deposited less of its moisture.

A reason is now also afforded, why a slight agitation of the atmosphere, when very pregnant with moisture, should increase the quantity of dew; since fresh parcels of air will hence be more frequently brought into contact with the cold surface of the earth, than if the atmosphere were entirely calm.

V. Dew, in agreement with the immediate cause which has been assigned by me for its production, can never be formed, in temperate climates, upon the naked parts of a living and healthy human body, during the night; since their heat is never less in this season, in such climates, than that of the atmosphere. I have, in fact, never perceived dew on any naked part of my own body at night, though my attention was much occupied, for three years, with every thing relative to this fluid, and though I had been, during that period, much exposed to the night air. On the other hand, in very hot countries, the uncovered parts of a human body may sometimes, from being considerably colder than the air, condense the watery vapour of the atmosphere, and hence be covered with a real dew, even in the day-time.

VI. Hygrometers formed of animal or vegetable substances, when exposed to a clear sky at night, will become colder than the atmosphere; and hence, by attracting dew, or, according to an observation of Sauflure, by merely cooling the air contiguous to them, mark a degree of moisture, beyond what the atmosphere actually contains. This furnishes to explain an observation made by M. De Luc, that in serene and calm weather, the humidity of the air, as determined by an hygrometer, increases about, and after sun-fet, with a greater rapidity, than can be attributed to a diminution of the general heat of the atmosphere.

Having established the fact, that bodies become colder than the neighbouring air, before they are dewed, and applied this fact to the explication of many atmospheric appearances, we shall now proceed with the author to complete the investigation of his theory with respect to the cause of dew; and hence he avails himself of the discoveries on heat and its radiation, that have been made by professor Leflie, Dr. Herschel, and count Rumford. (See Heat.)

"The experience of most persons," says Dr. Wells, "reflecting the communication of heat among bodies in the open air, is confined to what happens during the day; at which time, those that are situated near to one another are always found to posse the same temperature, unless some very evident reason for the contrary should exist. To many, therefore, it may appear incredible, that a perfectly dry body, placed in contact, on all sides, with other bodies of the same temperature with itself, shall afterwards, without undergoing any chemical change, become much colder than they are, and shall remain so for many hours; yet these circumstances are found to occur in substances attractive of dew, when laid on the surface of the earth, in a still and serene night, and are in perfect agreement with the doctrine of heat, now universally admitted to be just.

"To render this more easy of apprehension, let a small body which radiates heat freely, and posse the temperature, in common with the atmosphere, higher than 32°, be placed, while the air is clear and still, on a slow conductor of heat lying on the surface of a large open plain, and let a fragment of ice be supposed to exist at any height in the atmosphere; the consequences must be, that the small body will, from its situation, quickly become colder than the neighbouring air. For, while it radiates its own heat upwards, it cannot receive a sufficient quantity from the ice to compensate this loss; little also can be conveyed to it from the earth, as a bad conductor is interposed between them; and there is no solid, or fluid except the air, to communicate it laterally either by radiation or conduction. This small body, therefore, unless it shall receive from the air, nearly as much heat as it has emitted, which, considering the little that can be communicated from one part of the atmosphere to another, in its present calm state, must be regarded as impossible, will become colder than the air, and condense the watery vapour of the contiguous parts of it, if they should contain a sufficient quantity to admit of this effect. But events similar to these occur, when dew appears in an open and level grass field, during a still and serene night. The upper parts of the grases radiate their heat into regions of empty space, which consequently send back no heat in return; its lower parts, from the smallness of their conducting power, transmit little of the earth's heat to the upper parts, which at the same time receiving only a small quantity from the atmosphere, and none from any other lateral body, must remain colder than the air, and condense into dew its watery vapour, if this be sufficiently abundant, in respect to the decreased temperature of the grases.

"This subject may be further illustrated by a reference to what happens in the experiment, which has been used to prove the reflection of cold.

"In the simplest form of this experiment, a small body, the bulb of a thermometer, posse the temperature of the atmosphere, is placed before a larger cold body, rendered equal in effect to one still larger, by means of a concave metallic mirror. In this situation, the small body radiates heat to the larger, without receiving an equivalent from it, and, in consequence, becomes colder than the air through which its heat is sent, notwithstanding that it is continually gaining some heat, both from the air which surrounds it, and from the walls and contents of the apartment, in which the experiment is made. Dew, therefore, would as readily form upon the thermometer in this experiment, as it would upon one suspended in the open air at night, under a clear sky, provided that the two instruments were equally colder than the atmosphere, and that this was in both cafes equally near to being replete with moisture.

"Regarding now as established, that bodies situated on or near to the surface of the earth become, under certain circumstances, colder than the neighbouring air, by radiating more heat to the heavens, than they receive in every way, I shall in the first place offer a few remarks on the extent and use of this occurrence, and shall afterwards apply the knowledge of it to the explication of several more of the appearances described in the former part of this Essay. and
DEW.

of some others, which have not hitherto been mentioned by me.

"Radiation of heat by the earth to the heavens must exist at all times; but, if the sun be at some height above the horizon, the degree of which is hitherto undetermined, and probably varies according to season, and several other circumstances, the heat emitted by it to the earth will overbalance, even in places shaded from its direct beams, that which the earth radiates upwards.

"In a calm and serene night, however, when concomitantly little impediment exists to the escape, by radiation, of the earth's heat to the heavens, and when so heat can be radiated by the fun to the place of observation, an immense degree of cold would occur on the ground, if the following circumstances did not combine to lessen it. 1. The incapacity of all bodies to prevent, entirely, the palling of heat, by conduction, from the earth to substances placed upon them.

2. The heat radiated to these substances by lateral objects.

3. The heat communicated to the same substances by the air.

4. The heat which is evolved, during the condensation of the watery vapour of the atmosphere into dew.

"The extent of the effect of all these checks upon the production of cold, by the nightly radiation of heat from bodies on the surface of the earth, cannot, in the present state of our knowledge, be properly estimated; but facts shew that, notwithstanding their operation, the cold originating in this source must be often very considerable.

"I shall add, with the greatest diffidence, a few words upon a final cause of the radiation of heat from the earth at night, and upon some of the circumstances which modify its action, though fully conscious of the danger of error, which is always incurred in the attempt to appreciate the works of our Creator.

"The heat which is radiated by the sun to the earth, if suffered to accumulate, would quickly destroy the present constitution of our globe. This evil is prevented by the radiation of heat by the earth to the heavens, during the night, when it receives from them little or no heat in return. But, through the wise economy of means, which is witnessed in all the operations of Nature, the prevention of this evil is made the source of great positive good. For the surface of the earth, having thus become colder than the neighbouring air, condenses a part of the watery vapour of the atmosphere into dew, the utility of which is too manifest to require my speaking of it. I may remark, however, that this fluid appears chiefly where it is most wanted, on herbage, and low plants, avoiding, in great measure, rocks, bare earth, and considerable masses of water. Its production too, by another wise arrangement, tends to prevent the injury, that might arise from its own cause; since the precipitation of water, upon the tender parts of plants, must lessen the cold in them, which occasions it. I shall observe in the last place, that the appearance of dew is not confined to any one part of the night, but occurs during its whole course, from means the most simple and efficacious. For after one part of the air has deposited its moisture, on the colder surface of the earth, it is removed, in consequence of that agitation in the atmosphere which exists during its elevated states, and gives place to another having its quantity of water diminished; and, again, as the night proceeds, a portion of air, which had before deposited all the moisture, which circumstances at that time permitted, is rendered fit, by the general increase of the cold of the atmosphere, to give out a fresh parcel, when it comes anew into contact with the ground.

"The first fact, which I shall here attempt to explain, is the prevention, either wholly or in part, of cold, from radiation, in substances on the ground, by the interposition of any solid body between them and the sky. This evidently appears to arise in the following manner. The lower body radiates its heat upwards, as if no other intervened between it and the sky; but the loss, which it hence suffers, is more or less compensated by what is radiated to it, from the body above, the under surface of which possesse always the same, or very nearly the same temperature as the air.

"No direct experiments can be made to ascertain the manner, in which clouds prevent, or occasion to be small, the appearance of a cold at night, upon the surface of the earth, greater than that of the atmosphere; but it may, I think, be firmly concluded, from what has been said in the preceding article, that they produce this effect, almost entirely, by radiating heat to the earth, in return for that which they intercept in its progress from the earth towards the heavens. For although, upon the sky becoming suddenly cloudy during a calm night, a naked thermometer, suspended in the air, commonly rises two or three degrees, little of this rise is to be attributed to the heat evolved by the condensation of watery vapour in the atmosphere, as was supposed by Mr. Wilton; since, in consequence of the cooling of that part of the cold indicated by the thermometer, which was owing to its own radiation to a clear sky, the temperature of the atmosphere may seem to increase 2°, or more, notwithstanding that it has received no real addition. Besides, the heat which is extricated by the condensation of vapour, during the formation of a cloud, must soon be diffused; whereas the effect of greatly lessening, or preventing altogether, the appearance of a superior cold on the earth to that of the air, will be produced by a cloudy sky, during the whole of a long night.

"Dense clouds, near the earth, must possess the same heat as the lower atmosphere, and will therefore tend to the earth as much, or nearly as much, heat as they receive from it by radiation. But similarly dense clouds, if very high, though they equally intercept the communication of the earth with the sky, yet being, from their elevated situation, colder than the earth, will radiate to it less heat than they receive from it, and may, consequently, admit of bodies on its surface becoming several degrees colder than the air. In the first part of this Effay, an example was given of a body on the ground becoming at night 5° colder than the air, though the whole sky was thickly covered with high clouds.

"Islands, and parts of continents close to the sea, being, by their situation, subject to a cloudy sky, will, from the smaller quantity of heat lost by them through radiation to the heavens at night, in addition to the reasons commonly assigned, be less cold in winter, than countries considerably distant from any ocean.

"Fogs, like clouds, will arrest heat, which is radiated upwards by the earth, and, if they be very dense, and of considerable perpendicular extent, may remit to it as much as they receive. Accordingly, Mr. Wilton found no difference at night, in very foggy weather, between the temperature of the surface of snow, and that of the air.

"In mists and low fogs it was found by professor Leslie, that the diminution of the sun's heat is small, when compared with what occurs, when the sky is obscured by a dense body of clouds; and it will, I presume, be readily granted, that the dense flate of the atmosphere, which allows the heat of the sun to pass copiously, will also give a ready transit to heat radiated by the earth."

From previous reasoning, the author concludes, therefore, that "fogs do not in any instance furnish a real exception to
DEW.

depressions in the earth are artificially made, for the purpose of increasing the cold, which appears in serene nights. On this subject, however, it is to be observed, that if the depressed or hollow places be deep, in proportion to their horizontal extent, a contrary effect must follow; as a cave will occur more or less similar to that which existed in some experiments formerly related by me, in which a small portion of grass was surrounded by a hollow cylinder.

"An observation closely connected with the preceding, namely, that in clear and still nights, frosts are less frequent upon hills, than in neighbouring plains, has excited more attention, chiefly from its contradicting what is commonly regarded an established fact, that the cold of the atmosphere always increases with the distance from the earth. This inferior cold of hills is evidently a circumstance of the same kind, with that ascertained by Mr. Pictet and Mr. Six, respecting the increasing warmth, in clear and calm nights at all seasons of the year, of the different strata of the atmosphere, in proportion as these are more elevated above the earth. As the greater cold of the lower air is the less complicated fact, I shall attempt to explain it in the first place. Mr. Pictet, indeed, furnishes an explanation himself, by ascribing it to the evaporation of moisture from the ground. But to shew that this is not just, it need only be mentioned, that the appearance never occurs in any considerable degree, except upon such nights as are attended with some dew, and that its great degrees are commonly attended with a copious formation of that fluid; since it cannot be thought, that the same stratum of air will deposit moisture on the ground, from an insufficiency of heat, at the very time it is receiving moisture from the ground, in the state of pellicul vapour, as this presupposes, that it is not yet replete with water."

Aristotle and Plutarch, and of late Mr. Jefferson, (Notes on Virginia,) have observed that dew is much more copious on hills than it is upon plains. In order to account for this fact, we may allow, at first, that the surface of the ground is in both situations equally colder than the air contiguous to it; yet, "as the production of dew must be in proportion to the whole depression of the temperature of the air which furnishes it, below what its heat had been in the preceding day, and as one part of this depression, the general cooling of the atmosphere, is much more considerable on the plain than on the hill, moisture must necessarily be deposited more copiously in the former than in the latter place. If the greater agitation of the atmosphere, and the less quantity of moisture, during clear weather, in its higher region than in the lower, be added, it may readily be inferred, that dew shall sometimes be altogether wanting on a hill, though abundant on a plain at its foot, agreeably to what has been actually observed by Mr. Jefferson."

"The leaves of trees often remain dry throughout the night, while those of grass are covered with dew. As this is a familiar fact to the inhabitants of the hill, I shall in accounting for it do little more, than enumerate the circumstances on which it depends.

"1. The atmosphere is several degrees warmer near the upper parts of trees on dewy nights, than close to the ground. 2. The air in the higher situation is more agitated, than that in the lower. 3. The air at a little distance from the ground, from being nearer to one of its sources of moisture, will on a calm evening contain more of it, than that which surrounds the leaves of elevated trees. 4. Only the leaves of the very tops of trees are fully exposed to the sky. 5. The declension of the leaves from an horizontal position will occasion the air, which has been cooled by them, to slide quickly away, and be succeeded by warmer parcels. 6. The
6. The length of the branches of the trees, the tenderness of their twigs, and the pliancy of the footstalks of their leaves, will cause in the leaves an almost perpetual motion, even in the air that may be denominated calm. I have hence frequently heard, during the stillness of night, a fluttering noise in the trees, which formed one of the boundaries of the ordinary place of my observations, while the air below seemed without motion.

"Nearly in the same manner is to be explained, why shrubs and bushes also receive dew more readily than lofty trees.

"Bright metals, exposed to a clear sky in a calm night, will be less dewed, on their upper surface than other solid bodies; since all bodies will, in such a situation, lose the smallest quantity of heat by radiation to the heavens, at the same time that they are capable of receiving, by conduction, at least as much heat as any others from the atmosphere, and more than any others from the warmer solid substances, which they happen to touch.

"If the exposed pieces of metal be not very small, another reason will contribute somewhat to their being later and less dewed than other solid substances. For, in consequence of their great conducting power, dew cannot form upon them, unless their whole mass is sufficiently cold to condense the watery vapour of the atmosphere; while the same fluid will appear on a bad conductor of heat, though the parts a very little beneath the surface are warmer than the air."

It appears from the discoveries of professor Leflie, that the metals differ in their capacities of radiating heat; and hence will arise a difference among themselves with regard to their attraction of dew. Gold, silver, copper, and tin, as we have already said, reflect the formation of dew more strongly, than other substances of the same class; but these metals, according to Mr. Leflie, radiate heat the most sparingly. On the other hand, lead, iron, and steel, which, according to the same author, radiate heat more copiously than the former metals, were found by Dr. Wells to acquire dew more readily. The fame observations may probably be applicable to platina and zinc. In the article "Dew," we have already taken some notice of the opinion of those who maintain, that it rifies from the earth at night. The first trace of this opinion, according to Dr. Wells, occurs in the Hist. Acad. Sci. for 1687, Gersten advanced it anew in 1733. It was embraced by Muelichenbrock and Dufay; though the former soon admitted that dew sometimes falls. Mr. Whitter of New England has adopted the same opinion. We refer those who wish to see the arguments for and against this opinion fully stated to Wells' "Effay."

Agreeably to another opinion on the origin of dew, that which is found upon growing vegetables, is said to be the condensed vapour of the plants on which it appears. "But this seems," says our author, "to be erroneous for several reasons. 1. Dew forms as copiously upon dead as upon living vegetable substances. 2. The transpired humour of plants will be carried away by the air which passes over them, when they are not sufficiently cold to condense the watery vapour contained in it; unless, which is almost never the case if mist does not already exist, the general mists of the atmosphere be incapable of receiving moisture in a pellicul form. Accordingly, on cloudy nights, when the air, consequently, never can be cooled more than a little below the point of repletion with moisture, by bodies in contact with it, the dew is never observed upon any plants, that are elevated a few feet above the ground. 3. If a plant has become, by radiating its heat to the heavens, so cold, as to be enabled to bring the air in contact with it below the point of repletion with moisture, that which forms upon it, from its own transpiration, will not then, indeed, evaporate. But other moisture will, at the same time, be communicated to it by the atmosphere; and when the difference in the copiousness of these two sources is considered, it may, I think, be safely concluded, that almost the whole of the dew, which will afterwards form on the plant, must be derived from the air; more especially when the coldness of a clear night, and the general inactivity of plants in the absence of light, both lessening their transpiration, are taken into account."

"An experiment, however, has been appealed to in proof, that the dew of plants actually does originate from fluid transpired by them; that, namely, in which a plant, shut up in an air-tight cafe, becomes covered with moisture. But this experiment, if attentively examined, will be found to have little weight. First, the inclosed plant being exempt from the cold, which its own radiation would have produced in its natural situation, on a dewy night, will transpire a greater quantity of fluid, than a similar plant exposed at the same time to the open air. Again, the small quantity of air, contained in the cafe, might be replenished with moisture, after which, the whole of what is further emitted by the plant will necessarily assume the form of a fluid, whatever may be the condition of the external atmosphere; whereas, during even the clearest night, only a part of the smaller quantity of moisture, emitted by the exposed plant, will be condensed on its surface. In the last place, notwithstanding the circumstances which favour the appearance of moisture upon inclosed plants from their own transpiration, still the quantity observed on them is said to be for, I have made no experiment myself respecting this matter, much less considerable, than what is seen upon plants of the same kind, exposed to the air for the same time, during a calm and serene night." For several appearances connected with dew, we are under a necessity of referring to the third part of Dr. Wells' "Effay."

DEWAN, or DIAN, a term which has various significations in India. It denotes a place of assembly, a native minister of the revenue department, and chief judge of civil causes within his jurisdiction, and receiver general of a province. The term is also used to designate the principal revenue servant under an European collector, and even of a Zemindar. By this title, the East India company are receivers of the revenues of Bengal, under a grant from the Great Mogul. Accordingly Dewanu denotes the office or jurisdiction of a Dewan.

DEWEYSBURG, in Geography, a town of Caledonia county, in Vermont, having 200 inhabitants.

DEZFOUL, a town of Perfa, in Kuziflan, or Chufitan, 28 miles W. of Shufter, containing nearly as many inhabitants as that city, and situated on the eastern bank of the Abzal, on a beautiful and spacious plain. Its only ornament is an elegant bridge of twenty-two arches, erected by command of Sapor, notorious for destroying as well as famous for building cities. The bridge is 450 paces in length, 20 in breadth, and about 40 in height. The piers are made of large stones, and the arches and upper parts of burnt brick.

DIAL. Work of a Clock, col. 2, l. 24, for Plate XXIII. r. Plate XVIII.

DIALlage. See Mineralogy, Addenda.

DIAMOND, col. 4, l. 43, add—With a small portion of oxygen, as for Humphrey Davy has lately discovered.

DIAMOND. See Diamond, and Mineralogy, Addenda.

DIANA, col. 3, l. 20 from the bottom, for 27 r. 30.

DIANELLA, in Botany, a poetical name, in honour of the sylvan goddess Diana, to whom Commerford its author thought so beautiful an inhabitant of the woods peculiarly appropriate.
from *Saccharum*, (see that article,) by the flowers being all sessile, on a permanent, not jointed, *flato*.

D. *acinaeformis* was found by Br. J. Banks, in the tropical part of New Holland, and Mr. Brown has an East Indian species:

**DINAS-MAWDDY.** In 1811, the hundred of Tallybont and Mawddwy contained 834 houses, and 4287 persons; 1964 being males, and 2323 females: 531 families employed in agriculture, and 200 in trade, &c.

**DINGAAS.** Add— *See SCIND.**

**DINGWALL.** In 1811, the burgh and parish contained 278 houses, and 1500 persons; 647 being males, and 853 females: 158 families employed in agriculture, and 153 in trade and manufactures.

**DINWIDIE.** 1. 4 and 5. r. 12,524 inhabitants, of whom 7442 are whites.

**DIOPSIDE.** See *Mineralogy, Addenda.**

1. D. *cardinum.* Br. n. 1.—Native of the tropical part of New Holland. Banks. A little gassy bog plant, with a leafy stem, and axillary as well as terminal tufts of flowers. Akin to *Scelonia* and *Carex*; see those articles.

1. D. *tetraphyllus.* Br. n. 1. Banks l.c. ined. in Bibl. Linn.—Native of the tropical part of New Holland. A tree, with an irregular spreading head, of round downy branches. Leaves four on a whorl, stalked, large, oblong, entire; cloven, and marked with two glands, at the base. Flowers numerous, large, and handsome, yellow, with long prominent *flamats* and *flatoes*, in dense terminal panicles. Ripe fruit not known.

Eff. Ch. Sheath of two leaves. Three inner segments of the corolla small; upper one vaulted. Stamens distinct; two of them converging under the vaulted segment.
of the corolla; the third imperfect. Stigma two-lipped, in three deep segments. Seeds depresse.

1. D. Morea. Labill. as above, t. 15. Br. n. 1. (Morea diandra; Vahl Enum. v. 2. 154.)—Native of the south coast of New Holland, flowering in May. The flowers are very short-lived, white; their inner segments variegated. This plant differs from Patersonia, (see that article,) chiefly in the irregularity of its flower.

Eff. Ch. Calyx of two lax, membranous, awned valves, single-flowered. Corolla of two valves, outer with three awns, of which the middle one is twisted, unlike the rest; inner with two awns.

1. D. Jactaeus. Setaceous Dippedogon.—Gathered by Mr. Brown, on the southern coast of New Holland. A graft perfectly resembling Amphiagon lagaroides, (see that supplementary article,) in habit and of appearance, the spike being capitated, and the outermost flowers like wide white absciss, asling of a kind of ionic or vonculum. Brown.

DIP-MICROMETER, and METECTION, instruments invented by Dr. Wollaston, to correct the variation of the real dip from that given in the tables, arising principally from the difference between the temperature of the sea and that of the atmosphere.

DIPIDIUM, in Botany, from δίπλος and δίπλος, alluding to the two separate flowers, or sp., by which the maffes of pollen attach themselves to the stigma.—Brown Prodr. Nov. Holl. v. 1. 330.—Cliffs and order, Cynandra Monandra. Nat. Ord. Orchidace.

Eff. Ch. Calyx-leaves and petals uniform, spreading, lip three-lobed; disk bearded; base with a short spur. Column semi-cylindrical. Anther a terminal deciduous lid. Masses of pollen solitary in each cell, with an inner lobe, each attached by a separate thread to the gland of the stigma.

Leaflets smooth herbae, growing on the ground, with a thick, branching root. Base of the stem sheathed with imbricated scales, more distant on its upper part, where they become broader. Flowers numerous, in a simple clump, purple, very handsome. Two species are mentioned.

DIPSAEE, 1. 3, after cotyledon, insert—two.

1. D. turbinatus. Wood-oil Dipterocarpus. Roxb. as above, t. 213.—Native of various countries easterly of Bengal, flowering early in the hot season, and famous for its liquid balsam, much used for painting houses and ships. This is copiously procured by wounding the trunk, and lighting a fire near the part. The tree is very large. Leaves alternate, falcate, ovate, acute, wavy or serrated, smooth, from four to twelve inches long. Flowers in simple, axillary clusters, large, white, with yellow anthers. Wings of the calyx in fruit erect, oblong, three inches in length.

DISCHARGED WORK. See Paste-Work and Discharging of Colour.

DISS, l. 6, r. 348, and 2592.

Vol. XII.

DISTHENES. See Mineralogy, Addenda.

DISTILLATION, col. 7, l. 22, &c. for Wetter r. Welt.

DISTILLED WATERS, col. 2, l. 3 from bottom, for macerated water r. macerated in water.

DISTILLER, col. 2, l. 12 from bottom, r. 24 Geo. II. c. 40. Col. 3, l. 10, r. 14 Geo. III. c. 73. Col. 5, l. 24, r. 43 Geo. III. c. 81.

DIXFIELD, l. 2, for Cumberland r. Oxford. Add—it contains 403 inhabitants.

DIXMONT. Add—Also, a town of Maine, in the county of Hancock, having 337 inhabitants.

DIXVILLE, a township of Coos county, in New Hampshire, having 12 inhabitants.

DOAB, or Dooab, denotes in India any tract of country included between two rivers.

DOCKING, in the Mange. See Curtailing.

DODECAGON. The demonstration annexed is misplaced, and belongs to Dicagon.

DOEMIA, in Botany, Brown Tr. of the Wern Soc. v. 1. 50. (Daemia; Ait. Hort. Kew. v. 2. 76.) a genus of the Afclepiadace, differing from Sarcostemma, (see that article,) in having the outer crown of the flamin in ten deep segments. It consists of Cynandra extensum, Jacc. Br. 3. rar. t. 54. (to which C. bicolor, Andr. Rep. t. 562. is very nearly related,) and Afclepias cordata, Forr. Egypt. Arab. 49.

DOLGELLY, col. 2, l. 21 and 22 from bottom, r. 537 and 5064.

DOLOMITE. See Mineralogy, Addenda.

DONCASTER, col. 2, l. 26 from bottom, r. 1438 and 6935.

DONEGAL, in America, l. 1, r. four; l. 3, r. 3156 and 2147; l. 4, 1327. Add—And one in Butler county, having 671 inhabitants.

DONIA, in Botany, so named by Mr. Brown, in memory of the late Mr. George Don, of Forfar, a most acute and indefatigable Scottish botanist.—Br. in Ait. Hort. Kew. v. 5. 82. Pursh 559.—Cliffs and order, Syngenesia Polygynia-sperma. Nat. Ord. Compositae. Linn. Corymbosae, Jaff.

1. D. glutinoa. Glutinous Donia. Ait. n. 1. (After glutinosus; Cavan. Ic. v. 2. p. 53. t. 168. Doronnum glutinosum; Willd. Sp. Pl. v. 5. 2115.)—Leaves ovate-oblong, sharply serrated, glutinous, as well as the upright-scaled calyx.—Native of Mexico. A green-house fibrous, raised from Spanish feeds by Mr. Lambert, flowering in August and September. The leaves are felie. Flowers terminal, solitary, two inches broad, yellow, with many rays.

herbaceous. Leaves much narrower than the foregoing. Flowers yellow, with a balamic scent.

DONNINGTON, l. 19, r. 1811; l. 20, r. 316; l. 21, r. 1528.

DOODIA, in Botany, named after Mr. Samuel Doody, F.R.S. one of the earliest and best British Cryptogamists. He was an apothecary in London, and died in 1706.—Brown Prodr. Nov. Holl. v. 1. 151. Ait. Hort. Kew. v. 5. 523.—We fear this genus cannot be separated from Woodwardia; see that article.

DOOSHAK, in Geography, the present capital, and the residence of the prince of Sind, in N. lat. 31° 8'. Long. 63° 10', eight or nine miles from the river Hermand. See Zarang.

DORAK. See Felahi.

DORCHESTER, col. 4, l. 29, r. 1811; l. 20, r. 3020 and 15,980.

DORCHESTER, in America, l. 10, r. 18,108 and 5032.

DORCHESTER townships, l. 2, r. 537; l. utl. r. 2930.

DORCHESTER, a town, or rather a village, formerly a city, of Oxfordshire, between Benfon and Oxford. By the returns of 1811, the parish contained 148 houses, and 754 persons; 358 being males, and 396 females: 93 families employed in agriculture, and 47 in trade, manufactures, and handicraft.

DORKING, l. 29, r. 1811—589—3529.

DORSET, l. 4, r. 1294.

DORSETSHIRE, l. 15 and 16, r. 23,210 and 124,693.

DOVER, col. 9, l. 21, r. 9674 and 17,800.

DOVER, in America, l. 3, r. 543; l. 11, r. 2228; l. 26, r. 1882; l. utl. r. 1882 inhabitants. Add—Alto, a township in the district of Ohio, in the county of Tuscarawas, containing 461 inhabitants.

DOUGLAS, in America, l. 5, r. 1142; l. 11, r. 687.

Add—Alto, a township of Bucks county, in Pennsylvania, having 660 inhabitants.

DOWNE. Add—containing 1501 inhabitants.

DOWHANN, l. 25 and 26, r. 1811—361—1771.

DOWNTON, l. 24, r. 543—2624.

Some flowers are fix-cleft, as Labillardiére observed in his D. verticillatum, found in New Caledonia. Mr. Brown, who met with four species in New Holland, remarks, that Forster's Eparis longifolia and rosinariifolia, Prodr. 13, natives of New Zealand, belong to this genus.

DRACUT, l. 2, after county, r. and state of Massachusetts; l. utl. r. 1301.

DRAG. See Drowning.

DRAMATIC Music of the Greeks, col. 2, l. 5 from the clofe, r. maft.

DRAYTON. Add—The part of this parish that lies in Salop county contained, by the return in 1811, 599 houses, and 3370 persons; the other part, formerly denominated Tivelt, now Drayton-in-Hales, situated in the hundred of North Pirehill, in the county of Stafford, consists of three townships, having 104 houses, and 607 inhabitants.

DRESDEN, in America. Add—It contains 1095 inhabitants.

DRESSING, in Rural Economy, and the Mange, de—Vol. XXXIX.
petal, in four deep linear segments, at length separating more or less completely, slightly dilated and concave at their funnics. Nectary four scales at the base of the germen. 

Filaments four, very short, inflected into the base of the cavity of each petal, and another linear-oblong. 

Germen superior, very small, of two single-feeder cells; style cylindrical, rigid, erect, about the length of the corolla; stigma undivided. 

Peric. Follicle woody, obliquely turbinate, two of two shallow cells; the partition unconnected, deeply cleft, a nema tranversely, clastic. 

Seeds solitary, compressed, oblong, with a lateral crescent-shaped membranous wing. 

Common receptacle flat, befit by oblong scales or bristles, rarely wanting.

Eff. Chl. Corolla of one petal, four-cleft, bearing the flammers in the hollows of the segments. Nectary four scales at the base of the germen. Follicle woody, of two single-feeder cells, with a close moveable partition. Common calyx imbricated, many-flowered. 

Receptacle flat.

This genus confits of New Holland thubs, mostly of humble growth; their branches, if any, either scattered or umbellate. 

Leaves scattered, pinnatifid or cut, alike in young or old plants. 

Flowers solitary, sessile, terminal, rarely lateral, encased with crowded leaves, of which the innermost are sometimes dimidiated, or as it were imperfect, and accompanied at the base with close-pressed bracts, some of them occasionally furnished with a terminal appendage. 

Style for the most part hardly longer than the corolla, and not forced into a curve as in Bankia.

We follow Mr. Brown’s names and numbers throughout.

—Leaves wedge-shaped, deeply and sharply serrated. 

Calyx-scales flirait, the outermost nearly smooth. 

Tips of the corolla smooth. 

Stigma obtuse, slightly club-shaped. 

Native of Lewin’s land, growing on stony hills. 

Mr. Menzies admired us with a specimen from King George’s found. 

This shrub flowers at Kew most part of the year. 

The branches sometimes bear a few long, loose, spreading hairs. 

Leaves sessile, rigid, an inch and a half or two inches long, finely reticulated on both sides, the minute intericles of the veins curiously depressed beneath. 

Flowers terminal, in a close cylindrical head, resembling some Thistle or Sarracena, shorter than the crowded surrounding leaves. 

Calyx brown, of many sharp imbricated scales, the inner ones gradually long and hairy. 

Corolla thrice as long, yellow, externally hairy, except at the tips lodging the stamens, which are white, keeled, obtuse, minutely haired. 

Mr. Brown observes that the scales of the receptacle, separating the flowers, are sometimes wanting.

Leaves wedge-shaped, deeply serrated, pinnate, flaked. 

All the calyx-scales even and silky. 

Tips of the corolla bearded. 

Stigma slender, awl-shaped, acute. 

—Found by Mr. Brown, on stony hills in Lewin’s land. 

He notices some variety: one with leaves scarcely an inch and a half long, whose three terminal teeth are all nearly equal; another, which may possibly be a distinct species, with leaves two inches long, whose dilated extremity has the middle tooth short, the adjoining finites broader.

Leaves pinnatifid; lobes triangular, flat, divaricated, straight, pinnate-pointed; reticulated with naked veins beneath; the terminal one longer than the next. Branches, and tips of the corolla, smooth. 

Style downy at the base. 

Stigma awl-shaped, flaked. 

—Found by Mr. Brown, on rocky hills in Lewin’s land. 

Mr. Good sent this species to Kew in 1803, but it has not yet flowered there, nor have we seen a specimen.

Leaves pinnatifid; lobes triangular-awl-shaped, divaricated, falcate and recurved, pinnate-pointed; reticulated with naked veins beneath; the terminal one shorter than the next. 

Branches downy. 

Tips of the corolla, as well as the style, longitudinally smooth. 

Stigma club-shaped, without furrows. 

—Found by Mr. Brown, in the same country as the last.

Leaves linear, elongated, deeply pinnatifid; lobes unequally triangular, pointed, flat; downy beneath. 

Calyx-scales hairy; the innermost linear-oblong, reflexed. 

Receptacle chaffy. 

—Discovered by Mr. Menzies, near King George’s found. 

Mr. Brown met with it likewise, in barren ground near the coast of Lewin’s land. 

This truly beautiful species was sent to Kew, by Mr. Good, in 1803, and it is marked by Mr. Aiton as flowering there most part of the year. 

The leaves are falked, from four to six inches long, and barely one-third of an inch broad, cut to the middle, into numerous, close, regular segments, whose upper margin is direct, lower curved; the under side finely downy, snow-white, turning rufily with age, or long keeping. 

Stem branched, downy. 

Flowers terminal, two or three inches in diameter, embofomed in leaves. 

Calyx-scales purplish-brown, fringed and naked on the inside. 

Flowers of a tawn yellow, clothed with long thin hairs to the very point. 

Style yellow, fvvant and smooth. 

Stigma cylindrical, furrowed. 

Follicles small; tapering and hairy at the base; rounded at the margin; gaping widely, overtopped by the linear scales of the receptacle.

Leaves linear, elongated, deeply pinnatifid; lobes equally triangular, pointed, flat; downy beneath. 

Calyx-scales downy; inner ones linear, pointed. 

Receptacle chaffy. 

Stem firmly branched. 

—Gathered by Mr. Brown at Lewin’s land, in low stony ground.

Leaves linear, elongated, deeply pinnatifid; lobes equally triangular, pointed, flat; downy beneath; slightly revolute at the margin. Inner calyx-scales with feathery tips. 

Receptacle without scales. 

—Discovered by Mr. Brown, on the rocky sides of hills, in Lewin’s land. 

Sent to Kew by Mr. Good, in 1803, but has never blossomed there.

Leaves linear, pinnatifid, longer than the downy recumbent stem; lobes triangular, obtuse; downy beneath; thickened and recurved at the edges. 

Outer calyx-scales ovate; inner linear-oblong. 

—Gathered by Mr. Brown in Lewin’s land, in dry open situations near the shore. 

This also was sent to Kew, at the same time as the last, but has never yet produced flowers.

—Leaves linear, pinnatifid, about as long as the smooth stem; lobes unequally triangular, acute, pointed; white and mealy beneath; recurved at the margin. 

Calyx-scales linear-lanceolate, smooth, fringed. 

Corolla hairy from top to bottom, much shorter than the style. 

—Gathered by Mr. Menzies at King George’s found; by Labillardiere and Brown in rocky places near the coast of Lewin’s land, flowering in December. 

The stem is usually from one to three inches high, greatly overtopped by the very long, narrow, erect leaves, which are not quite so deeply pinnatifid as most of the foregoings; each lobe has two or three prominent ribs beneath, and is clothed on that side with a snow-white mealy pubescence, unaltered by time in our original specimens. 

Flowers solitary, fleshy among the leaves,
leaves, smaller than those of *D. formosa*, with a purplish-brown *calyx*, and yellow, or tawny *corolla*. *Style* purplish, angular, smooth. *Stigma* small, pyramidal, obtuse, not well represented in the plate; at least not in our English edition. This *flowers* at Kew from July to September. Mr. Brown notices a variety in which the lobes of the *leaves* are somewhat disfigured, finger-ribbed, and the *stigma* hardly thicker than the *style*.

—Leaves linear, pinnatifid, very long, acute; *downy beneath*; tapering and entire at the base; *lobes* triangular, acces- sorily recurved, recurved at the margin. *Calyx*-scales linear, awl-pointed, smooth, fringed. *Corolla* woolly at the base; *downy upwards*; rather hairy at the tips; *stem* downy.—*Discovered* by Mr. Brown, on rocky hills in Lew- in's Land. The pubescence of the backs of the leaves is greyish, not white. This plant was raised at Kew in 1805, but has not yet borne any *flowers*.

—Leaves linear, elongated, pinnatifid, rather abrupt; *snow-white beneath*; entire at the base, and tapering into a foot-flake; *lobes* triangular, recurved, disfigured, recurved at the margin. *Calyx* as long as the flowers, *downy*; *outer scales* ovato-lanceolate. *Corolla* almost as long as the *style*; *woolly at the base*; *smooth upwards*; slightly hairy at the tips. *Stem* smooth.— *Gathered* by Mr. Brown, in heathy ground at Lewin's Land. *It flowers* at Kew from March to May.

—Leaves deeply pinnatifid, longer than the *downy stem*; *lobes* linear, acute, pointed, *revolute, dilated* at the base. *Calyx*-scales *downy, ovate*.—*Gathered* by Mr. Brown, in Lewin's Land, on the *flanks* of hills.

—Leaves deeply pinnatifid, longer than the *downy stem*; *lobes* linear, obtuse, slightly pointed, three-ribbed, somewhat *revolute*, scarcely dilated at the base.—*Gathered* near King George's *found* by Mr. Menzies, to whom we are obliged for a specimen, without flowers, with which Mr. Brown likewise was unacquainted; but the resemblance of the plant to the *laff-described*, induced him to consider it as belonging to the present genus. The *short stem* is clothed with dense, soft, *woolly pubescence*. *Leaves* reflexing a *Cycas* in texture, as well as form, though only 3 feet high; the early *ones* smaller, with very broad rounded *lobes*, clothed beneath with white *woolly down*; the pubescence of the more *full-grown leaf* only, in our specimen, is become *woolly*.

**DUBASH**, a name applied at Madras to the fame person who is denominated Banian in Bengal: it signifies a person who can speak two languages.

**DUBLIN**, in America, l. 4, r. 184; l. 8, r. 2194; l. 10, r. 970. Add—*Alfo*, a township of Bedford county, in Pennsylvania, having 820 inhabitants.

**DUBOISIA**, in Botany, in memory of Mr. Dubois, a botanist of the time of Dillenius, who appears, by Ray's

**DUBLIN**, in America, l. 4, r. 184; l. 8, r. 2194; l. 10, r. 970. Add—*Alfo*, a township of Bedford county, in Pennsylvania, having 820 inhabitants.

**DUBUQUES**, in Botany, in memory of Mr. Dubois, a botanist of the time of Dillenius, who appears, by Ray's *Synopsis*, ed. 3. 17, to have had a garden at Mitcham in Surrey, and whose son, or brother, Charles, was an affiduous cryptogamist. His copy of Buxbaum is in our hands. —Br. Prodr. Nov. Holl. v. i. 448.—*Clas and order*, *Dip- dyna Angiospermae*. Nat. Ord. Luride, Linn. Solanaceae, Brown.

**DUBBIDU.** See DUBBU.

**DUCHESENA**, in Botany, a genus announced at the end of our article *Fragaria*, and since published in Tr. of Linn. Soc. v. 10. 371. It was suppos'd to differ essentially from *Fragaria* and *Potentilla*, (with both which the *calyx* agrees, and with the latter more particularly the *habit*,) in having the compound *berry* of a *Rubus*. Some garden *specimens* have led us to fepulchre an error in botanists who have described the ripe *fruit*, which in those *specimens* was certainly that of *Fragaria*, a succulent *receptacle* fluided with *dry seeds*. Whether the latter becomes pulpy at any more advanced period, remains to be proved. Meanwhile this plant flanks as *F. indica*, in Alt. Hort. Kew. v. i. 273.

**DUCU CREEK**, in Geography, a hundred of Kent county, in Delaware, containing 3092 inhabitants, of whom 167 are *flaves*.

**DUDLEY**, l. 3621 houses, and 13,925 inhabitants. Add—*Dudley* is partly in Old hundreds, Staffordshire, in which *Dudley* is locally situated.

**DUDLEY**, in America, l. 2, r. 1220.

**DUEL.** At the close, add—*Duellng*, says a late excellent writer, in the modern sense of the word, exclusive of casual frays and finge combats during war, was unknown before the 16th century. But we find one anecdote, which seems to illustrate its derivation from the judicial combat. The dukes of Lancaster and Brunswick, having some differences, agreed to decide them by duel before John, king of France. The lists were prepared with the solemnity of a real trial by battle; but the king interfered to prevent the engagement. The barbarous practice of wearing swords as a part of domestic drefs, which tended very much to the frequency of duelling, was not introduced till the latter part of the 15th century. Our author says, that he can find only one print in Montfaucon's *Monuments* of the French Monarchy where a sword is worn without armour before the reign of Charles VIII; though a few as early as the reign of Charles VI. have short daggers in their griddles. Hallam's State of Europe during the Middle Ages, vol. ii. ch. 9, part i. p. 441. London, 1818.

**DUREN.** See DEUREN.

**DUFOUREA**, in Botany, so named in honour of a French botanist.—Achar. Syn. 246. "Lichenogr. 103. t. 11. f. 2." A genus of the order of *Lichenes*, composed of *L. Flanneus*, Linn. Suppl. 451. Hoffm. Pl. Lich. t. 3. f. 1.; *L. madreporiformis*, Wulf. in Jacqu. Coll. v. 3. t. 3. f. 25; and three other species. The *frond* is tubular, branched, membranous; *fronds* terminal, with a border from the *frond*. We must shelter ourselves under the doubt, expressed by the author himself, respecting this genus.

**DUKE'S COUNTY**, l. 5, r. 3290.

**DULVERTON**, l. 11, r. 204 and 1035.

DUN

DUMBARTON. By the return of 1811, the burgh and parish of Dumbarton contained 363 houses, and 3121 persons; 1,373 being males, and 1,748 females: 93 families employed in agriculture, and 524 in trade and manufactures. The shire of Dumbarton contained 3213 houses, and 24,189 persons; 11,369 being males, and 12,820 females: 1,123 families employed in agriculture, and 2,689 in trade, manufactures, and handicraft.

DUMFRIES. In 1811, the burgh and parish contained 1445 houses, and 9262 persons; 4103 being males, and 5159 females.

DUMFRIESSHIRE. By the return of 1811, this county contained 11,660 houses, and 62,960 persons; 29,347 being males, and 33,613 females: 3862 families employed in agriculture, and 4435 in trade, manufactures, and handicraft.

DUNMORE, l. 2, for Graffon r. Coos; add—containing 7 inhabitants.

DUNMORESTOWN, l. 3, r. 1704.

DUNBAR, in Scotland. The burgh and parish, in 1811, contained 664 houses, and 3965 persons; 1661 being males, and 2304 females: 263 families employed in agriculture, and 305 in trade and manufactures.

DUNBAR, a township of Fayette county, in Pennsylvania, containing 2066 persons, of whom, in 1810, 7 were slaves.

DUNBARTON, l. 3, r. 1256.

DUNDEE, col. 2, l. 7 from the bottom, r. 1811—29,614, and add—the number of houses 2482.

DUNFERMLINE, col. 2, l. 41, r. 1811—11,649; add—and the number of houses in the burgh and parish 1810.

DUNKARD, a township of Greene county, in Pennsylvania, having 1055 inhabitants.

DUNKELD. The town and parish, in 1811, contained 126 houses, and 1360 persons; 651 being males, and 709 females. The parish of Little Dunkeld contained 637 houses, and 2982 persons; 1448 being males, and 1534 females.

DUNMOW, Great, col. 2, l. 14 and 15, r. 1811—397—2013.—Little, l. 4, add—The number of houses, in 1811, was 45, and of persons 264.

DUNNET. In 1811, the parish contained 311 houses, and 1398 persons; 698 being males, and 700 females.

DUNSE. In 1811, the parish contained 462 houses, and 2424 persons; 1174 being males, and 1250 females.

DUNSTABLE. l. 6, r. 1049; l. 9, r. 475.

DUNSTABLE. In 1811, the parish contained 296 houses, and 1616 persons; 690 being males, and 926 females.

DUODENUM. See Intestines.

DUPLIN, l. 4, r. 1769—2416.

DURSELEY, l. 15, for town r. parish, 489; l. 16, r. 2820—365 families.

DUTCHESS COUNTY, l. 7, r. in 1810, was 51,363—1262.

DUXBOROUGH, or DUXBURY, l. 5, r. 2201.

DUXBURY, l. 3, r. 326.

DYEBERRY, a township of Wayne county, in Pennsylvania, having 318 inhabitants.

DYSART, l. 15, infert.—The borough and parish, by the return of 1811, contained 777 houses, and 5506 persons. The town of Dysart contained 136 houses, and 1578 persons: the lower, &c.

1. D. littoralis. A tropical New Holland herb, smooth, very diminutive, with alternate entire leaves, and axillary tufts of white flowers, twenty of which would hardly make the bulk of a pin's head. One only in each tuft is furnished with stamens.

EAGLE, in Geography, a township of Adams county, in Ohio, containing 801 inhabitants.—Allo, a township of St. Clair, in the Illinois territory, having 384 inhabitants.

EAGLE, Bold, a township of Centre county, in Pennsylvania, having 1146 inhabitants.—Allo, a township of Lycoming county, in the same state, having 246 inhabitants.

EAGLE ISLAND. Add—Allo, an island in the district of Maine, and county of Hancock, having 9 inhabitants.

EAR, Difficult of. See Deafness, Tympanum, Tube, Eufachian, and Otaelpa, the latter of which articles will be found in the Addenda.

EARN, in Geography, a township of Lancaster county, in Pennsylvania, containing 4218 inhabitants.—Allo, a township
township of Berks county, in the same state, having 794
inhabitants.

EARTH, col. 19, l. 12 from bottom, for 7935 r. 39711, and
for 7882 r. 3941.

EARTHEN WARE. See Delf and Pottery.

EASTBOURNE, l. 13, after parish, infert—which con-
tains 120 houses, and 720 inhabitants.

EAST DISTRICT, a township of Berks county, in Penn-
sylvania, having 805 inhabitants.

EASTHAM, l. 9, r. 752.

EASTON, col. 2, l. 1, r. 1657.

EASTON, l. 5, r. 1557.

EAST PORT. Add—It contained, in 1810, 1511 in-
habitants.

EAST TOWN, l. 2, r. 587.

EAST WHITELAND, l. 2, r. 779.

EATON, l. penult. r. 535.

EATONTOWN, a town of Putnam county, in Georgia,
having 73 inhabitants.

ÉCHENIES, l. 4, add—Or, according to Dr. Shaw,
head furnished above with a flat, ovate, transversely falcated
shield, gill-membrane six-rayed, and body without scales.

ECLIPSI. Obliquity of, col. 2, l. 6 from bottom,
add—And he found the obliquity of the ecliptic at the
summer solstice to be 23° 27' 51" 35', and at the winter sol-
stice 23° 27' 47" 37'. The difference he conceives to depend
upon refraction. At the observation of the summer solstice
in 1812 with the new mural circle, he found the obliquity of
the ecliptic to be 23° 27' 52" 45'; and from that of the winter
solstice he deduced it 23° 27' 47" 35'.

ECTROSIA, in Botany, from excessive, an abortion, allud-
ing to the number of abortive florets.—Brown Prod. Nov.
Holl. v. i. 185.—A genus of grasses, allied to Eleusine,
(see that article,) and to Chloris or Swartz, all whose charac-
ters require investigation.

EDDINGTON, in Geography, a town of America, in
Maine and county of Hancock, having 205 inhabitants.

EDDYSTONE, col. 2, l. 1, for 8vo. r. folio.

EDEN, in America, l. 4, add—containing 657 inhabi-
tants; l. 5, add—containing 224 inhabitants.

EDESSA. Add—Edessa, at present denominated Orfa,
after having been the residence of the Courtneys, counts of
Edessa, and having been taken by Zenghi or Zangi, was facked
by the Moguls in the 13th century, and by Timur in the 8th
year of the Hegira. It is now subject to the grand feignor,
and the residence of a pacha of two tails. It is situated in a
barren country, 67 miles from Bir, and 232 from Diar-
beik. It is surrounded by a double wall, and defended by a
cidetale. The houses are well built, and the inhabitants,
composed of Turks, Arabs, Armenians, Jews, and Nettorians,
are said to amount to about 25,000 souls. The chief orna-
tments of this city are a mosque, consecrated to Abraham,
and the cathedral of the Armenians, now decayed.

EDGARTON, l. 7, r. 1365.

EDGCOMB, l. 3, r. 1288; l. 9, r. 12,423 and 5107.

EDGEFIELD. Add—It contains 23,160 inhabitants,
of whom 8576 are slaves.

EDGEMONT, l. 2, r. 611.

EDINBURGH, col. 7, l. 7, add—By the parliamentary
return of 1817, the city and burgh of Edinburgh contained
7110 houses, and 102,987 inhabitants; 43,982 being males,
and 59,005 females. The fluire of Edinburgh contained
8679 houses, and 45,620 inhabitants; 21,022 being males,
and 24,598 females.

EDINGTON. In 1811 the parish contained 85 houses,
and 417 persons; 195 being males, and 222 females.

EDISTO, r. Pen Pon.
part happens with all new remedies. The disappointment to which this necessarily led soon brought it into disrepute, and latterly it has been treated with unmerited neglect. There can be no doubt, however, that when judiciously applied, it is a remedy possessing very considerable powers.

It is not our intention to detail here all the difficulties to which electricity and galvanism are applicable, as the remedy, when proper, will be found, for the most part, to be recommended in the different articles treating professedly of such diseases. Our object is merely to describe the best and most approved methods of applying electricity, and to state a few remarkable facts which have been lately observed respecting its use.

Electricity may be applied in the form of shocks, sparks, or of a continued stream or current. The first of these forms was generally had recourse to by the older electricians, but it has been long since laid aside, except in particular cases of great general, or local debility. In such cases, the shock must be proportioned to the degree of the disease, but the size of the jar employed seldom or never ought to exceed a quart. The second form, or that of sparks from the chief conductor, is an excellent mode of applying electricity in many instances. It is, however, much less used than formerly. Sparks may be applied by the medium of balls of brais or other metal, and their strength is determined by the magnitude of the prime conductor, of the balls, and of the machine in general, and by the distance at which the balls are removed from the patient's body. The nearer the balls, the less powerful and more frequent are the sparks, and vice versa. The third method of applying electricity is in the form of a continued stream or current, and this perhaps is the most generally useful and important form of the whole. This method requires a very powerful apparatus. The current is directed through the different parts of the body by means of a simple apparatus placed in contact, or nearly so, with the body, and connected with the prime conductor. Besides these three forms of administering electricity, there is a fourth, which may be considered as intermediate in its nature between the two last; this is the application of what is termed the electrical aura. It is effected nearly like the last, only the electric fluid is permitted to pass off from points of metal or wood placed at some distance from the body, or sometimes instead of points, the edges of hollow metallic or wooden cylinders, more or less sharp, are employed in a similar manner.

Of these different methods of applying electricity, the two last are undoubtedly in all ordinary cases preferable to the others. They are equally, if not more, beneficial in most instances, if properly applied; and besides have the great advantage of exciting no dread or alarm in the patient, a circumstance which often operates powerfully in deterring timid individuals from having recourse to this remedy, besides being productive of actual injury. These methods, however, as we before observed, require a powerful apparatus, so that the electrician may be enabled to send a very copious stream of the fluid through the whole or any part of the body, if required, as it is chiefly upon this circumstance that the good effects of these modes of applying electricity depend. We would not, however, be under the impression that the good effects of these modes of applying electricity depend. We would not, however, be under the impression that these modes of applying electricity exclusively of all others. The application of shocks, and particularly sparks, is often of great use when judiciously employed. Even the alarm they excite may not be without its use in particular cases; but such cases are rare, and the application of the remedy with advantage in these forms requires great judgment and practical knowledge on the part of the medical electrician.

For the phenomena of that modification of electricity termed galvanism, and its general effects upon the animal economy, we refer our readers to Voltaism, where they will find these subjects discussed; we shall therefore chiefly confine our attention here to the exhibition of galvanism as a remedy. The general principles of the employment of galvanism differ in no respect from those of the application of electricity, nor do the effects of this form of electricity upon the animal economy differ perhaps in any respect whatever from those produced by common electricity; from the mode, however, in which this variety of the electric energy is excited and brought into action, a little difference in the mode of applying it is necessary. The application of galvanism in the form of shocks and sparks is out of the question. It is always applied in the form of a continued or interrupted stream, or sometimes in the form of aura; hence the conductors generally require to be in contact with the skin of the patient, which should be kept moist. The greater the surface of the conductor in contact with the skin within certain limits, ceteris paribus, the greater the effect produced, and vice versa. The interrupted stream, or that produced by the frequent removal and re-application of the conductor in contact with the skin, or by otherwise breaking the chain of communication, approaches in its nature more to that of the electric shock than the continued stream, a circumstance which should be kept in mind by the operator. Indeed with an apparatus composed of small plates, the stream requires to be occasionally interrupted, otherwise the effects will be very much diminished. See Voltaism, last section.

With respect to the magnitude of the battery proper for medical purposes, no very general rule can be given. The greater the number of plates, especially when of small size, the more do the effects produced upon the animal economy resemble those produced by common electricity. Large plates are best adapted for keeping up the continued stream, which is double the first modes of exhibiting galvanism, and of enduring its specific operation, if it extorts any. A medical galvanist can seldom require a battery composed of more than fifty or sixty pairs of plates, from four to fix inches square, and a greater or less proportion of these must be employed according to the energy of action in the battery, and the circumstances of his patient. Dr. Wilton Philip states, that few patients can bear, for any length of time, more than from eight to sixteen pairs of plates fourteen inches square, when administered as described below. The same author, however, remarks, that patients can often bear double this number, for a short time, before any disagreeable sensation is produced.

Dr. Wilton Philip has lately attempted to show that the galvanic battery may be subsituted for the nervous energy in animals. His experiments on this subject are extremely interesting, and their results led him to employ galvanism as a remedy in several diseases to which it was never previously applied. These therefore remain to be briefly noticed.

_Asthma and Dyspnœa._—Dr. Philip states, that he has employed galvanism in many cases of habitual asthma, and almost uniformly with relief. The good effects began to appear usually from five to fifteen minutes after the application of the remedy. His battery consisted of thirty plates fourteen inches square, more or less of which were employed according to the degree of sensation produced; and his rule was to begin with a low power, and gradually increase it by moving one of the wires from one division of the trough to another. His method of exhibiting it in this disease was to apply two thin plates of metal, about two or three inches in diameter, moistened with water, one to the nape of the neck, and the other to the pit of the ro-
mach, or a little lower, which plates were connected with the wires leading to the opposite ends of the battery. He directs that the wires should be constantly moved upon the metallic plates, particularly the negative wire, otherwise the cuticle is apt to be injured where they rest. The relief seemed much the same whether the positive wire was applied to the nape of the neck, or the pit of the stomach. The different effects, therefore, ascribed by some to positive and negative electricity seem doubtful. When relief was obtained, nothing appeared to be gained by continuing the operation longer.

The galvanism was seldom used more than once a day, except in some severe cases. About a sixth part of those on whom it was tried received a permanent cure. It gave decided relief in all cases, and only failed to give considerable relief in about one-tenth of the whole number of cases.

Similar good effects are stated by Dr. Philip to have been experienced in dyfpepsia, provided no inflammatory symptoms were present. Dr. Philip, however, seems to doubt if it will be found useful in phthisic asthma.

In *Dyspepsia*, likewise, Dr. Philip thinks it will prove an excellent remedy; also in porosis of the liver and bilary ducts; and a recent writer states, that he has found it very advantageous in chronic hepatis, *confiption*, 

See an Experimental Enquiry into the Laws of the Vital Functions, by Dr. A. P. Wilton Philip.

**ELECTROPHORUS**, col. 2, l. 19 from bottom, for hair-skin r. hair-skin.

**ELEOCHARIS**, in *Botany*, l. 45, a marth, and *scapes*, an ornament or favourite, from its general place of growth. Brown Prodr. Nov. Holl. v. 1. 224. — A genus separated from Scirpus by Mr. Brown; near akin to *Deichromena*, in character, but very different in habit; see those articles.

Though the definition is not without exceptions, the genus is thought a natural one by its learned author, embracing Scirpus palustris, geniculatus, mutatus, and acteolus of Linnaeus with several others. There are eight New Holland species.

**ELEPHAS**, col. 10, l. 21 from bottom, for thirteen r. three.

**ELETTARIA**, in *Botany*, so called by Dr. Maton, V.P.L.S., from the Malabar name Elettari, or Ela-tarti, which has always been appropriated to this very plant. If any names of barbarous origin may be retained, and many are now established, even by Linnaeus himself, who in the vigour of his judgment and authority protected against them, the above may well be admitted, for the following reasons. It exclusively belongs to a very important plant, constituting, as far as we know, a genus by itself, and it is perfectly unquestionable both in form and construction, as well as free from all ambiguity. Were this name nevertheless to be finally rejected, we should gladly subtilitate in its stead that of Matonida, in honour of our learned and valued friend, who has first clearly established the genus. — Maton Tr. of Linn. Soc. v. 10. 254. Rheede Hort. Mal. v. 11. 9. — Clas and Order, Monandria Monogynia. Nat. Ord. Scitamineae, Linn. Canne Jull.

Gen. Ch. Cal. Perianthis superor, of one leaf, tubular, cylindrical, elongated, minutely and irregularly toothed at the margin, permanent. Cor. of one petal; tube longer than the calyx, cylindrical, slender, curved; outer limb in three equal, oblong, recurved segments, not half the length of the tube; inner a somewhat obovate, large, notched, crenate, undivided lip, with a short claw. Stam. Filament one, rather longer than the claw, stout, erect, with a lanceolate, acute, horizontal lobe, about its own length, on each side at the base, the filament simply notched, without any crest or extension beyond the anther, which consists of two oblong, dilated, marginal lobes, about half the length of the filament, attached by their backs, their extremities on a level with the top of the filament. Fil. Germen inferior, nearly globose; style thread-shaped, lying close to the filament, between the lobes of the anther; stigma funnel-shaped, small, erect, nearly on a level with the top of the filament. Peric. Capsule fully, elliptic-oblong, or somewhat ovate, triangular, fringed, of three cells, and three coriaceous valves. Seeds numerous, roundish, somewhat angular, rough, each with a fine, membranous, evanescent tunic. Recept. central, shorter than the capsule when dry, winged with three longitudinal membranes, originally connected with the central ridge of each valve.

Eff. Ch. Anther of two distinct lobes. Filament with two transverse lobes at the base; emarginate and simple at the summit. Outer limb of the corolla in three oblong lobes; inner a single lisp. Capsule of three cells and three valves, with a central receptacle. Seeds rough, tunicated.

Native of the mountainous parts of Malabar, on lofty cloudy hills, flowering when the rainy season begins, in April and May, ripening feed in October and November. White, Roxburg. Root perennial, tuberous, with many fibres. Leafy stems from six to twelve feet high, erect, flat, bright, green, not red or brownish, at the base. Leaves elliptic-lanceolate, pointed, from nine inches to two and a half feet long, and from one to five inches broad, spreading, dark green, smooth, entire, palmate, and more or less toothed beneath. Stipula emarginate, rounded, smooth. Petals entire, lateral, several from the tuberous base of each stem near the root, a span long, much branched, many-flowered, spreading horizontally on the ground, jointed, smooth. Bracteas alternate, ovate-oblong, acute, at the base of each partial stalk, withering; partial ones solitary, tubular, closely embracing the germex and calyx, almost as long as the latter, and resembling it in shape, but deciduous. Outer limb of the corolla green; lip white, veined with crimson. Capsule when fresh flat, smooth, nearly globose, but becoming bluntly triangular, coriaceous, and pale brown, when dry. Seeds blackish, gratefully aromatic and pungent, with a flavour of Camphor, esteemed more agreeable and useful in food and medicine, than any others of this tribe. (See Cardamom, excluding what regards Cardamomum majus, &c.)

This subject will be found explained under our supplementary article Amomum. Mr. White, who has given a most accurate and correct history of this plant and its cultivation, under the name of Amomum Cardamomum, in Tr. of Linn. Soc. v. 10, above quoted, speaks of its seeds as "one of the most valuable articles of modern luxury, regarded as a necessary of life, by most of the inhabitants of Afi
Afa—a grateful and fabulious accasy of diet—whose general adaption by the civilized nations of the other quarters of the world is prevented only by its limited importation." This is certainly a new idea to us Europeans, who value this drug merely as a grateful and wholesome fire-bringer, on which account it becomes an article of commerce, having supplanted all its relatives in the apothecary's shop. Its general use in Afa, indeed, renders the plant a very important and profitable object of cultivation, though the harvest, occurring at the most unhealthy season, is not attended by serious dangers. Fevers, fluxes, the bite of innumerable minute leeches, and the instantly fatal sting of the whip-snap, are mentioned as not uncommon mishaps, to which is added the caustic quality of a shrubby plant, whose botanical characters have not been ascertained, but whose leaves produce dangerous, and sometimes fatal, ulcerations of the skin. The profit of the Cardamom farms, however, is so considerable, as to overcome all difficulties in their cultivation, and Mr. White thinks they might easily be greatly extended.

2. E. major. Greater Oblong Cardamom. (Cardamomum major;) Dale Pharm. 276. Bout. Nat. 127, the fruit only? C. majus officinarum; Buh. Pin. 413. C. majus vulgare; Ger. Em. 1542. Cluf. Exot. 1817. Lob. t. v. 2. 204. C. medium; Matth. Valgr. t. 1. 25. Camer. Epit. 11. f. 2. Barrel. 1c. obf. 1395. t. 971, the longest fruit. C. cum filiquis five theica longis; Buh. Nat. v. 2. 205. Enfalin; Herm. Muf. Zeyl. 66. Zingiber Enfalin; Goertn. t. 12. f. 5.)—Capsula lanceolate-oblong, acutely triangular, with flat sides. Calyx three-lobed.—Native of Java, according to Dale, who remarks that this kind of Cardamom was, even in his time, rare, used, some substituting it for Grains of Paradie, others the Amomum verum. (See Amomum.) Specimens of this species are indeed, at present, only to be found in the cabinets of collectors. We are perfused they must belong to the same genus as the Malabar Cardamom. They appear to have a similar panined inflorescence, and the structure of the fruits, with its central receptacle, coriaceous fluted valves, and angular rough or rugged feeds, are the same in this as in the last. These feeds, however, are of a brighter, or reddish hue, and very inferior in favour, far less powerful and less agreeable. The shape of the capsule is essentially different, being usuallly thrice as long, and much more acutely and strikingly triangular, flattened at the sides, and more evidently curved. It is similarly crowned with a long, cylindrical, permanent calyx, decidedly three-lobed, whereas that of the former is only crenate, or jagged. This part is unfortunately often rubbed off by those who collect the fruits for sale. If Bontius be right, there is so wide a difference between these two plants in the situation of their flowers, as would almost overturn their generic identity. He gives, under the title of Cardamomum major, a figure with large, terminal, finely racemose inflorescence, which he compares to that of a Hyacinth, describing the plant as taller than a man, with very large leaves, flowers white with a purple limb, and the whole very beautiful. Two capsules, unlike our plant, though by no means very like it, being represented cylindrical, not triangular, and described as long as the finger, accompany the above figure. We cannot, on mature consideration, think the synonym of Bontius rightly applied. Nevertheless, he speaks of the qualities as agreeing with his C. minus, supposed to be our Amomum Cardamomum, or Amomum verum of old writers, not the preceding Elettaria Cardamomum. Clafius, Gerard, &c. rather copy the fruit from Bontius than from nature, and seem to take the calyx for the stalk.

ELEVATION. Angle of, for A R B r. R A B
(Plate I. Mechanics, fig. 3.)

ELGIN, l. alt. By the return of 1811, the number of houses in the burgh and parish was 562, and of inhabitants 4602.

ELHAM, l. 3 from bottom, infer after London—and the parish contains 174 houses, and 962 inhabitants.

ELOCUTION. Add to the references—Action, Articulation, Passion, Pronunciation.

ELSENBOROUGH, a town in Salem county, in New Jersey, having 517 inhabitants.

ELTHAM, l. 3, r. 285 houses, and 1813 inhabitants.

ELWUND, Mount, a range of mountains in Irak, in Perisa, most probably the mount Oroentes of Diodorus, about twelve miles in length. Near its summit, which is tipped with continual snow, and seldom obscured by clouds, is a beautiful valley, perfumed by a thousand sweet-scented flowers. This mountain is famous in the East for its mines, waters, and vegetable productions. The natives of Hamada, which is situated at the foot of this mountain, believe that some of its gracles have the power of tranfmuting the bafel metals into gold, as well as of curing any dillemper to which the human frame is exposed; and the Indians suppose that it contains the philosopher's stone.

ELY, col. 2, l. 4, after includes, infer—5977 houses, occupied by 32,443 inhabitants, &c. Col. 4, l. 43, r. 4249; l. 44, r. 928.

ELY, or Ely. In 1811 this parish contained 157 houses, and 886 persons; viz. 365 males, and 521 females.

EMBANKMENT, col. 25, l. 14 from bottom, infer—In 1809 about 6000 acres of land were obtained by an embankment of the sea upon Cartmell lands, in Lancashire. The embankment at Tre-Madoc, in Carnarvonshire, was completed in 1811.

EMDEN, in Geography, a township in the district of Maine, and county of Somerset, having 351 inhabitants.

EMERY,
EMERY, l. 11, after Tennant, infert.—(Phil. Trans. for 1802, p. 401.)

EMETIN, in Chemistry, a name given by MM. Majendie and Pelletier to a substance extracted by them from ipecacuanha, and so called because it constitutes the principle to which that root owes its emetic qualities. Emetin may be obtained by digesting ipecacuanha in sulphuric ether, and afterwards in alcohol. The alcoholic solution is then to be evaporated to dryness, redissolved in water, and acetate of lead dropped into the solution. The copious precipitate thus obtained being well washed and diffused through water is then to be exposed to the action of sulphuretted hydrogen. The lead is thus precipitated while the emetin remains dissolved in water; and the liquid being filtered and evaporated to dryness, the emetin will be obtained in a state of purity.

Emetin thus obtained exists in the form of brownish transparent scales. Its taste is bitter and a little acrid, but not disagreeable. It has no smell. At the temperature of boiling water it is not changed. When exposed to a higher heat it does not melt, but swells, becomes black, and is converted into water, carbonic acid gas, a little oil, and acetic acid, but yields no trace of ammonia, which indicates that it does not contain azote. A very spongy and light coal remains. When exposed to the air, emetin undergoes no change, except the air be very damp, when it deliquesces. It diffuses readily in water and alcohol, but not in sulphuric ether. It does not crystallize.

Sulphuric and nitric acids, when concentrated, decompose it. Murcuric and phosphoric acids diffuse it without alteration, and it may be separated from them by saturation with an alkali. Acetic acid is one of the best solvents of it. Gallic acid and infusion of galls precipitate it immediately, as do solutions of most of the metallic salts.

Half a grain of this substance occasions violent vomiting, followed by sleep, and the animal awakes in a state of health. A larger quantity, as twelve grains, or even six grains, produces violent vomiting and sleep, followed by death, which appears to take place in consequence of the severe inflammation of the lungs and intestinal canal, produced by large doses of this solution.

ENAMEL of the Teeth, Chemical Properties of. See TEETH.

Procumbent shrubs, very much branched, with alternate fleshy leaves, and axillar, solitary, fefuline flowers, without bracteas. There are two New Holland species.

ENDIAN. Add.—It lies in N. lat. 30° 18', 20 miles from Zeitzoon, occupies both banks of the Tab, and is nearly two miles in circuit. It trades with Bafiora and Behaban, and its population is between 4000 and 5000 souls.

ENDIANDRA, in Botany, Br. Prodr. Nov. Holl. v. 1. 402, a triandrous genus, perhaps hardly distinct from Ginnosmaönium, which Mr. Brown separates from Laurus of Linnaeus; and also very near his CRYPTOCARYA, see that article.

ENFIELD, l. 4, after parliament, infert—in 1811, 1115 houfes, and 6630 inhabitants. The town has only 524 houses, and 3055 inhabitants, and is one of the four quarters into which the parish is divided.

ERATOSTHENES, col. 2, l. 9 from bottom, r. Bib. ERBILLE, in Geography, a town of Peria, which is probably that Arbelo so famous for the final victory obtained by Alexander over Darius, and the capital of the province of Adiabene, is now reduced to a wretched mud town, with a population not exceeding 3000 souls. N. lat. 36° 14'.

Eff. Ch. Calyx in five deep segments; changed and membranous in the fruit. Corus... Stigma undivided. Drupes dry, with four cells, and four seeds.

Two rough-like shrubs, E. opposifolia and alternifolia, found on the inhospitable south coast of New Holland. Their leaves are semicircular. Flowers solitary, stalked.

3 P.

ERIACHNE,
ERK

Stigmas feathery.

A genus of tropical grasses, akin to Aria, generally downy, their leaves narrow, flowers panicked. Mr. Brown describes ten New Holland species, none of them in any other author. In fix of them, the outer valve of the corolla has a terminal awn.

ERIE, l. 2, r. 3758; after Erie, add—borough, containing 394 inhabitants, of whom, in 1810, 16 were slaves.

Eff. Ch. Calyx ringer; lower leaves flaked, under the lip. Petals smaller, crept. Lip flaked; dilk downy, without glands. Column femicylindrical; simple at the top. Anther terminal, permanent, pointtles; cells close together. Malefs of pollen four in each.

1. E. autumnalis. Br. n. 1. (Epipactis ceculata; Labill. Nov. Holl. v. 2. 61t. f. 2.)—Native of the calf and southern parts of New Holland. Bulb globular. Leaf radical, enclosed in a sheath, with the bale of the flatk, which is four or five inches high, naked, bearing from one to three white or purplish flowers. Akin to Caladenia.

ERIVAN. Add—By various siege, the last of which was in the year 1808 by the Russians, this town is reduced to a ruinous condition. It has been repeatedly taken both by the Turks and Perians, and has remained in the possession of the latter from the peace of Nadir Shah in 1748. This city, which gives name to a province bounded on the N. and W. by the Moflian hills, on the S. by the Araxes, and on the E. by the districts of Kabaunga and Karadung, is situated on the banks of the river Zengui, and defended by a fortress, of an elliptical form, upwards of 6000 yards in circumference. The N.W. side of the town is built on a precipice, overshadowing the river 100 toises in height; but is surrounded by the fort which is encompassed by two strong walls, flanked with towers.

ERKOM, in Ornithology, a bird of Abyssinia, which belongs to a large tribe, differing principally in the beak and horn. The horn is sometimes seen upon the back, and sometimes upon the forehead, above the root of the beak. In the calf part of Abyssinia, it is called Alba Gumbus; in the language of Tigré; but on the western side of the Tacaçê, it is called Erkoom. Its graceful note gives occasion to the name of its sexes. By naturalists, this bird is called the Indian crow or raven. The colour of the eye is a dark brown, or rather of a reddish call; the eye-lusses are large; its length from the tip of the beak to the extremity of the tail is three feet ten inches; the length of the beak is ten inches, and the length of the horn three and a half inches. The colour of this bird is footy-black; the large feathers of the wing are ten in number, milk-white both without and within; the tip of his wings reaches nearly to his tail; and at his neck he has those protuberances like the turkey-cock, which are light blue, but turn red upon his being chafed, or when the hen is laying. He seems to prefer running on the ground to flying; but when he is roused, he flies to a considerale distance. Its smell is rank, and he is said to live in Abyssinia upon dead carcasses; but this Mr. Bruce conceives to be a mistake, as he never follows the army like birds of prey. His food seemed to be the green beetles that are found upon the tops of the tuff, and in order to obtain them, he frequents fields of this grain.

EROLI, l. 2, for Grafton r. Coos. Add—and in 1810, contained 58 inhabitants.

ERVING'S GORE, in Geography, a town of Hampshire county, in Massachusetts, having 160 inhabitants.

ERZERUM, l. 11, after church, add—Mr. M'Kinnell estimates the whole number of inhabitants at 105,000, of whom are Armenians, and the rest Turks, with the exception of 200 or 300 Greeks. Here are nearly 40 mosques, four of which are hansome, a Greek church, a large Armenian chapel, and at a distance from the city three celebrated monasteries. The bazzars are extensive. In winter the cold is intense; but the air being pure, and the water good, the natives are stout and healthy. N. lat. 39° 57'; E. long. 46° 51'. The pachale of Erzerum is the most considerable in Armenia; it is divided into twelve districts, and governed by a pacha of three tills, who refides at Erzerum.

ESCAPEMENT, Ispocrinal for a Pendulum, col. 2. 14 from the bottom, for CN r. 1. 13, for ND r. N.Q.—Eefcapement by Alex. Cumming, col. 1. 10 from the bottom, for D r. H.

ESSEX, in America, l. 7. r. 8.; l. 8, r. by the census of 1810, 71,888 inhabitants.

ESSEX, in Virginia, l. ult. r. 9376 inhabitants, of whom, in 1810, 5659 were slaves.

ESSEX, in New Jersey, l. 4, for 3 r. 9.; l. 5, r. 25984 and 1129.

ESSEX, in New York, add—containing 9477 inhabitants.

ESSEX, in Vermont, add—containing 14 townships, and 307 inhabitants.

ESTLE, a township, &c. l. 2, r. 957.

ESTLE, a county of Kentucky, containing 2082 inhabitants, of whom, in 1810, 133 were slaves.

ETHER, in Chemistry. The specific gravity of sulphuric ether, as recently determined by M. Theodore de Sauffrre, is .7153 at 68°; and it boils in vacuo at — 26°, and not at 20°, as it is given in the Cyclopaedia. The specific gravity of the vapour of sulphuric ether, according to Mr. Dalton, is 2.25; according to M. Gay Lussac, whose experiments were made with great care, it is 2.586, that of air being 1. M. Theodore de Sauffrre has lately published an analysis of sulphuric ether: according to this ingenious chemist, it is composed of

<table>
<thead>
<tr>
<th>Substance</th>
<th>Specific Gravity</th>

</tr>
</tbody>
</table>

Dr.
Dr. Thomson, however, seems to doubt the perfect accuracy of this analysis, and supposes rather that it is a compound of four atoms of olefiant gas and one atom of water, which supposition nearly agrees with the specific gravity of the vapour of ether above-mentioned, as determined by M. Gay Lussac. Thus the fp. gr. of olefiant gas being .974.

Two volumes of it will weigh 1.948
The fp. gr. of the vapour of \[
\text{water is } \frac{1.948}{2} = 0.974\]

which certainly differs but little from 2.586, the true fp. gr. according to M. Gay Lussac.

Nitrif Ether.—The properties of this singular subflance have been lately investigated by Thenard. This eminent chemist found the following to be the best mode of preparing it. Equal parts of alcohol and nitric acid, of the fp. gr. 1.283, were put into a retort, to the beak of which was luted a glass tube, which was plunged to the bottom of a long narrow glass jar, half filled with a saturated aqueous solution of common salt. From the top of this jar passed another tube, which went to the bottom of another similar jar, filled with the same solution. In this manner, five other similar jars were connected with each other, and from the last a tube passed to a water-trough, to receive the gaseous products in proper vessels. Each of these jars was surrounded with a mixture of snow and salt, to keep it as cool as possible. A moderate heat was then applied to the retort, which produced to violent an effervescence, that it became necessary to moderate it by withdrawing the fire, and applying cold water to the outside of the retort. At the end of the operation, the ether was found floating on the surface of the solution in the different jars, but more especially in the first. It was separated, and to remove the nitrous and acetic acids with which it was contaminated, it was agitated in a close phial with a sufficient quantity of chalk. Thus purified, it possesses the following properties.

It has a slightly yellow colour, and a very strong ethereal odour. Its taste is likewise strong and peculiar. It is rather heavier than alcohol. It is much more volatile than sulphuric ether, the heat of the hand being sufficient to make it boil; hence it produces a very considerable degree of cold by its evaporation. It is lighter than water, and requires about forty-eight parts of that fluid to dilute it. The solution has an agreeable odour, like that of apples. It is soluble in alcohol in every proportion. It is very inflammable. When kept for some time, both nitrous and acetic acids are formed in it. The same acids also are produced if it be heated, or even agitated with water. It has also the property of absorbing these acids very readily, and acquiring the property of reddening vegetable bleeks. Its vapour is much more elatite than that of sulphuric ether.

According to Thenard, it is composed of

<table>
<thead>
<tr>
<th>Element</th>
<th>Weight</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hydrogen</td>
<td>8.54</td>
<td>-</td>
</tr>
<tr>

<tr>
<td><strong>Total</strong></td>
<td><strong>100.00</strong></td>
<td></td>
</tr>
</tbody>
</table>

But Dr. Thomson does not seem to place much reliance on the accuracy of this analysis.

Muriatic Ether.—Since the article Ether was written for the Cyclopaedia, this species of ether has been examined with great care by Gehlen, and still more recently by Thenard, which latter chemist has given the following as the best mode of preparing it.

A retort is to be nearly filled with a mixture of equal bulks of muriatic acid and alcohol, both as strong as possible. To prevent the effects of the violent chullition which would otherwise take place on the application of heat, a few grains of sand are to be introduced into the retort. From the beak of the retort a tube passes into a glass jar, twice the size of the retort, and furnished with three mouths. This jar should be half filled with water of the temperature of about 70°. Into the second mouth a short tube of safety is to be luted; and into the third, a tube which passes into a water-trough to receive the gas. On the application of heat, the ether escapes in the form of gas. This gas is colourless, does not affect vegetable colours nor lime-water. Its fp. gr. is 2.193, that of air being 1. At the temperature of 64° water dissolves its own bulk of it. At the temperature of 52°, it becomes liquid ether.

Muriatic ether in its liquid state is colourless like water, very liquid, has no action on vegetable bleeks, and has the same smell and taste as in the gaseous state. At the temperature of 41°, Thenard ascertained its fp. gr. to be .874. It is much more volatile than alcohol, or even sulphuric ether. None of the usual tests indicate the preence of muriatic acid in it. When burnt, however, a considerable proportion of this acid is diffegaded, a fact first observed by Gehlen, and since fully confirmed by Thenard. From Thenard's analysis, it appears that this singular compound is composed of

<table>
<thead>
<tr>
<th>Element</th>

<td></td>
</tr>
</tbody>
</table>

Dr. Thomson is disposed to consider it as a compound of one volume of olefiant gas, and one volume of muriatic acid gas, condensed into one volume; or, what is the same thing, of four atoms olefiant gas, and one atom of muriatic acid. On this supposition, its constituents will be

Hydriodic Ether.—This ether was discovered by M. Gay Lussac. He formed it by mixing together two volumes of absolute alcohol, and one volume of hydriodic acid of the fp. gr. 1.73, and distilling in a water-bath. Hydriodic ether, after being well washed with water, is perfectly neutral. Its odour is strong, and analogous to that of other ethers. In a few days it acquires a reddish colour, which is instantly removed by mercury or potasa. Its fp. gr. at 72° is 1.9206. It boils at the temperature of 148°. It is not inflammable, but merely gives out purple vapours when put upon burning coals. When passed through a red-hot tube, it is decomposed, an inflammable carburetted gas is obtained, hydriodic acid evolved, and some charcoal deposited. This ether has not been analyzed; but Dr. Thomson is disposed to believe, from analogy, that it has a composition similar to that of muriatic ether, or that

\[ 3 \text{P} \]
it is composed of four atoms olefiant gas, and one atom of hydriodic acid.

Acetic Ether.—The original experiments of Lauraguais and Scheele have been lately repeated by other chemists, and particularly by Thénard. Thénard succeeded in forming this ether, by repeatedly distilling together very concentrated acetic acid and alcohol. No graceful product was evolved. The superfluous acid was neutralized by potash, and the ether finally obtained by a cautious distillation of the resulting liquid from acetic of potash. Acetic ether thus procured is limpid and colourless. Does not redden vegetable blues. Possesses a peculiar taste, quite different from that of alcohol. Its fp. gr. at 44° is .866. It boils at the temperature of 163°. It burns with a yellow-white flame, and acetic acid is evolved during its combustion. At the temperature of 65°, it requires more than seven times its weight of water to dissolve it. It appears from these and other properties to be a compound of acetic acid and alcohol.

Formic Ether.—This was first formed by Gehlen. It may be prepared precisely in the same way as acetic ether, merely sublimating the formic for the acetic acid. Formic ether has an agreeable odour, similar to that of peach blossoms. Its taste is likewise similar, leaving an impression of ants. At a temperature of 65°, its fp. gr. is .9157. It burns with a blue flame, having yellow edges, and at the above temperature is soluble in nine times its weight of water. This ether has not been analysed.

ÉTON, col. 3, l. 25, r. to be seen; l. 57, r. 314 and 2279.

Eff. Ch. Spikelets generally single-flowered; scales imbricated, mostly empty. Stamens twelve or more. Nut cylindrical, crumblative, without bristles at the base; kernel smooth. Tall bog-plants, from the south coast of New Holland. Scales blackish externally; upper ones silky internally. Somewhat allied to Chrysétrix. There are two species.

EUCHILUS, Brown in Ait. Hort. Kew. v. 3. 17, seems to us a Poltenia; see that article.

EUCHLORINE, in Chemistry. See OXYMURIATIC Acid.

EUCLID, in Geography, a township of Cuyahoga, in Ohio, containing 284 inhabitants.

EUCLIDIUM, in Botany, from v. and well, and vailov, to float up, because of the firmly-closed seed-vellum.—Br. in Ait. Hort. Kew. v. 4. 74.—Cliffs and order, Tetradynamia Silicifiu, Linn. Nat. Silphace, Linn. Cruciëfæ, Juss.

1. E. syriacum. Syrian Euclidium. Ait. n. 1. (Añatatica syriaca; Linn. Sp. Pl. 865; Jacq. Añ. 7.)—Pouch rough. Style awl-shaped, twisted. Leaves lanceolate, flaked.—Native of the warmer parts of Europe. What other species may be the same we are not informed.

Eff. Ch. Calyx four-toothed, superior. Petals closely united into a deciduous lid, with four furrows. Stamens in four fets, alternate with the calyx-teeth, combined at the base. Capule of four cells, opening at the top. Seeds numerous.

1. E. tetragonum. Br. as above, t. 3.—In exposed barren places near the shore, about Lucky bay, on the south coast of New Holland, flowering and bearing fruit in January. Br. A fúlbus, three to five feet high, with square, bordered branches. Leaves flaked, ovate-oblong, mostly opposite, coriaceous, four or five inches in length, entire, glaucous, dotted with reniform points. Umbels axillary, flaked, of three or four flowers, whose numerous white flames spread conspicuously after the lid is fallen. We believe this fine plant is living in the green-houf of the Comtesse des Vandes, at Baywater.

EUDIOMETE. See LABORATORY.

EUDIOMETRY. Add.—See LABORATORY.

EVELYN, l. 1. inerf after Surrey.—October 31st; l. 4, for Christchurch r. Bialoi college; l. 5, infert much of his time. At the close of his article, add—For a farther account of the life and writings of this excellent perfon, we refer to the "Memoirs," published from original MSS. in 2 vols. by William Bray, eqq. Lond. 1818.

EVEISHAM, col. 2, l. 10, from the bottom, r. 674 houfes, and 3068 inhabitants.

Evesham, in America, add—In 1810, it contained 3445 inhabitants.

1. E. laurelia. Br. as above, t. 2.—In mountainous woods, and about great rivers, at Port Jackson, flowering in December and January. A slender fréulibus, from five to ten feet high, very smooth. Leaves alternate, on short stalks, obvate-oblong, acute, entire, coriaceous, four or five inches long. Flower-flasks axillary, short, bearing two or three small leaves, and one flower, whose numerous, pale yellow, perfect fíamus spread, in a radiant manner, after the lid is gone, displaying the broad imperfect ones, united with them below, overlapping the fíamus. These superfusious intruders are observed, by Mr. Brown, to be usually eaten away by insects. Berry three-quarters of an inch broad. Seeds oval, wrinkled.

EURYALE, the name of one of the Gorgons, adopted here to express the thorny menacing habit of the plant. It might likewise be underfooted as alluding to the angle area of the leaves.—Salif. in Ann. of Bot. v. 2. 73. Añt. Hort. Kew. v. 3. 295.—Cliffs and order, Polyandra Monogynia. Nat. Ord. Rhoeaceae, Linn. Hydrocharitides, Juss. Nymphæe, Salif.

1. E. ferox. Prickly Euryale, Ait. n. 11. Roxb. Corom. v. 3. 39; t. 244. Annélae lapina; Andr. Repof. t. 618.—Native of lakes and ponds in India, to the east of Calcutta. Roxb. This has the habit of a Nymphæa. The floating peltate leaves, cloven at the base, are from one to four feet wide; purple beneath; their ribs, veins, and stalks, like the flower-stalks, calyx, and fruit, armed copiously with sharp prickles. Flowers comparatively small, purple, with yellow flaments. Fruit about two inches in diameter. Seeds, or nuts, the size of a large pea, each in a loose coloured tunic.

EXTRACT—Extractive Principle, in Chemistry.

Great confusion exists in different chemical authors respecting these terms. Formerly the term extract was applied to all those substances which were extracted from plants by means of water or spirits; but of late it has been confined by many to a substance which is supposed to exist in many plants, and which may be obtained tolerably pure from the bark of the cinchona officinalis, according to the experiments of Schrader. Other chemists, however, still use the term extract in its original sense; hence Dr. Thomson, to prevent ambiguity, has chosen to distinguish the principle of Schrader by the term extractive. The following are the properties of extractive, according to Dr. Thomson:

1. Soluble in water, and the solution is always coloured. When the water is slowly evaporated, the extractive matter is obtained in a solid state, and transparent; but when the vaporization is rapid, the matter is opaque.

2. The taste of extractive is always strong, but it is very different according to the plant from which it is obtained.

3. It is insoluble in absolute alcohol and in ether, but soluble in alcohol when it contains water.

4. By repeated solutions and evaporations, the extractive matter acquires a deeper colour, and becomes insoluble in water. This change is considered as the consequence of the absorption of the oxygen of the atmosphere, for which the extractive principle has a great affinity. But if the solution be left to itself, exposed to the atmosphere, the extract is totally destroyed in consequence of a purer fraction which speedily commences.

5. When chlorine is poured into a solution containing extractive, a very copious dark yellow precipitate is thrown down, and the liquid retains but a light lemon colour. These flakes are considered as oxygenized extractive; it is now insoluble in water, but hot alcohol dissolves it.

6. The extractive principle unites with alumina, and forms with it an insoluble compound. Accordingly, if sulphate or muriate of alumina be mixed with a solution of extractive, a dark, insoluble precipitate appears, at least when the liquid is boiled; but if an excess of acid be present, the precipitate does not always appear.

7. It is precipitated from water by concentrated sulphuric acid, muriatic acid, and probably by several other acids. When the experiment is made with sulphuric acid, the fumes of vinegar generally become sensible.

8. Alkalis readily unite with extractive, and form compounds insoluble in water.

9. The greater number of metallic oxys form insoluble compounds with extractive. Hence many of them, when thrown into its solution, are capable of separating it from water. Hence also the metallic salts molly precipitate extractive. Muriate of tin polishes this property in an eminent degree. It throws down a brown powder, perfectly insoluble, composed of the oxyd of tin and vegetable matter.

10. If wool, cotton, or thread, be impregnated with alum, and then plunged into a solution of extractive, they are dyed of a fawn-brown colour, and the liquid loses much of its extractive matter. This colour is permanent. The same effect is produced if muriate of tin be employed instead of alum. This effect is still more complete if the cloth is soaked in chlorine, and then dipped into the infusion of the extractive. Hence we see that the extractive matter...
matter requires no other mordant than oxygen to fix it on cloth.

11. When distilled, extractive yields an acid liquid impregnated with ammonia.

It cannot be doubted, continues Dr. Thomson, that there are many different species of extractive matter, though the difficulty of obtaining each separately has prevented chemists from ascertaining their nature with precision. Watery extracts, when obtained by slow evaporation to dryness, always have an acid taste, and redden litmus. They all yield a precipitate while liquid on the addition of ammonia. This precipitate is a compound of lime and insoluble extractive. Lime always causes them to exhale the odour of ammonia. It has been ascertained, that the extractive principle is more abundant in plants that have grown to maturity than in young plants.

All the extracts prepared by apothecaries are compounds of the extractive principle with several others, even as many as eight or more, according to Dr. Thomson. In short, this department of vegetable chemistry is at present in a very confused and imperfect state.

Vol. XIV.

EYE, Physiology of the, col. 6, l. 26 from bottom, for an inch r. one-tenth of an inch.

EYE, Humours of, Chemical Properties of. Some experiments have been made on these fluids, the results of which defer to be briefly mentioned.

Aqueous Humour.—Mr. Chenevix found the fp. gr. of the aqueous humour of the sheep at 60° to be 1.009. This fluid scarcely affects vegetable blues while fresh. On exposure to heat, a slight coagulum is formed. Tannin occasions a precipitate in it, both before and after boiling. Nitrate of silver likewise produces a precipitate, but no other metallic salt. According to Berzelius, 100 parts of it consist of

| Water               | -      | 98.10 |
| Muriates and lactic | -      | 1.15  |
| Soda with animal matter, soluble | - | 0.75 |
| only in water      | -      |       |
| Total              | 100.   |       |

Vitreous Humour.—This possesses very nearly the same properties as the aqueous. Even its fp. gr. is the same, or only a very little heavier. According to Berzelius, it is composed of

| Water               | -      | 98.40 |
| Albumen             | -      | 1.16  |
| Muriates and lactic | -      | 1.42  |
| Soda with animal matter, soluble | - | 0.02 |
| only in water      | -      |       |
| Total              | 100.   |       |

Crystalline Lens.—The fp. gr. of this is 1.100. When fresh it has little taint. It putrefies very rapidly. It is almost completely soluble in water. The solution is partly coagulable by heat, and gives a copious precipitate with tannin both before and after boiling. According to Berzelius, it is composed of

| Water               | 58.0   |
| Peculiar matter     | 35.9   |
| Muriates, lactate, and animal matter soluble in alcohol | 2.4 |
| Animal matter, soluble only in water, with some phosphates | 1.3 |
| Portions of the remaining insoluble cellular membrane | 2.4 |
| Total              | 100.   |

The peculiar matter of the lens possesses all the chemical properties of the colouring matter of the blood, except colour.

The humours of the human eye are composed of the same ingredients as those of the sheep; but they differ in their fp. gr. Thus the fp. gr. of the human aqueous and vitreous humour is 1.0053; that of the crystalline 1.0790. The humours of the eyes of oxen also resemble those of the sheep. The fp. gr. of the aqueous and vitreous humors is 1.0088; that of the crystalline 1.0765. The crystalline of the ox weighed thirty grains. When the whole was pared away, except six grains in the centre, the fp. gr. was found to be 1.194.

Sir H. Davy found the same constituents in the eyes of birds; but the fp. gr. of the vitreous humour of these animals is greater than the fp. gr. of the crystalline.

Pigmentum Nigrum.—This curious substance has been examined by Gmelin. From 500 eyes of oxen and calves he collected 75 grains. Its colour is blackish-brown. It is tafleless, and adheres to the tongue like clay. It is soluble in water, alcohol, ether, oils, lime-water, and acetic acid. It dissolves in potash and ammonia by the affinities of heat, and is again precipitated by acids. Sulphuric acid dissolves it, and becomes black. Muriatic acid also forms an imperfect solution. Nitric acid dissolves it, and changes its colour to reddish-brown. When distilled it yields water, brown oil, and carbonate of ammonia. The residuum consists almost entirely of charcoal.

EYE, col. 2, l. 6, r. In the year 1811, the town and parish consisted of 326 houses, and 1893 inhabitants.

EYMOUTH. Add.—By the return of 1811, the town contained 115 houses, and 962 inhabitants.

EYNSHAM, or Ensham, l. 1st.—In 1811, the number of inhabitants was 1418, and of houses 246.

FAYSTON, a town of Chillendon county, in Vermont, having 140 inhabitants.

FEARING, a town of Ohio, in Washington county, having 454 inhabitants.

FEATHERS, dry-pulled, beaded, dele the reference to Bed.

FELAHI,
FER

FERAHI, or DORAK, one of the principal towns of Chuftlian or Kuzftlan, in Persia, founded by Sheikh Soliman when the ancient Dorak, one of the eight cities of Susiana, was abandoned. It is situated on marshy ground, on the banks of two of the branches of the Zerashi, surrouned with mud walls, sixteen feet thick and two miles in circumference, flanked at intervals with towers. The inhabitants, amounting to 8000, live chiefly without the walls in the suburbs. This town is celebrated for the manufacture of the abba, or Arabian cloak, which is transported in great numbers all over Persia and Arabia.

FELSAR. See FELSAR and MINERALOGY, Addenda.

FELUGIA, or ABBAS, in Geography, a town in the pachalic of Badagd, which, under the appellation of Perifabur, is ranked, in the history of the campaigns of Julian, as the head city in Asia. The city was reduced to ashes, and on its ruins a palace was erected by Soliman the Great, pacha of Bagdad. Pilgrims going to Kerbele generally cross the river at this spot, on a bridge of boats.

FENCE, col. 2, l. 20, dele low. Col. 3. dele hedge, last word, and the comma in 1. 2. Col. 21, l. 3, for thus above r. thus formed above; l. 34, 35, for under the plough r. into grafts.

FEREDUN, in Geography, a small district of Irak, in Persia, behind the S.W. ridge of the mountains of Khonfar, peopled with Georgians and Armenians, brought hither by Abbas the Great. The former, amounting to 1000 families, are Mahometans, who never intermarry with either Persians or Armenians. The capital of the district is Paashih.

FERGUSON, a township of Centre county, in Pennsylvania, having 1666 inhabitants.

FERMANAGH, l. 2, r. 1954.

FERMENTATION, VINUS, in Chemistry. The recent observations of chemists enable us to state with greater precision the changes which fugar undergoes during its conversion into alcohol, than could be done when this article was written for the Cyclopaedia.

Sugar is composed, according to Dr. Prout's analysis, of

<table>
<thead>
<tr>
<th>Element</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hydrogen</td>
<td>6.66</td>
</tr>
<tr>
<td>Carbon</td>
<td>4.00</td>
</tr>
<tr>
<td>Oxygen</td>
<td>5.33</td>
</tr>
</tbody>
</table>

= 100.

which correspond with 1 atom of each element.

Alcohol, according to Dr. Thomson, is a compound of about

<table>
<thead>
<tr>
<th>Element</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hydrogen</td>
<td>13.04</td>
</tr>
<tr>
<td>Carbon</td>
<td>52.16</td>
</tr>
<tr>
<td>Oxygen</td>
<td>34.80</td>
</tr>
</tbody>
</table>

= 100.

which correspond with 3 atoms of hydrogen, 2 atoms of carbon, and 1 atom of oxygen; and carbonic acid gas is composed of

<table>
<thead>
<tr>
<th>Element</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>Carbon</td>
<td>27.27</td>
</tr>
<tr>
<td>Oxygen</td>
<td>72.72</td>
</tr>
</tbody>
</table>

= 100.

or of 1 atom of carbon and 2 atoms of oxygen.

Hence, if we suppose (for the sake of round numbers) 3 atoms of fugar to be decomposed during the process of fermentation, they will be converted into 1 atom of alcohol and 1 atom of carbonic acid; for

<table>
<thead>
<tr>
<th>Element</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hydrogen</td>
<td>3 atoms + 2 atoms + 1 atom</td>
</tr>
<tr>
<td>Carbon</td>
<td>1 atom + 2 atoms</td>
</tr>
</tbody>
</table>

which make together

3 + 3 + 3

or three atoms of fugar.

Now this determination very nearly coincides with the actual experiments of Lavoisier, and the more recent determination of Thenard, respecting the proportional quantities of these two products obtained by the fermentation of fugar. Thus 100 parts of fugar (as deduced by Dr. Thomson from Thenard's experiments) were converted into

<table>
<thead>
<tr>
<th>Compound</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alcohol</td>
<td>57.44</td>
</tr>
<tr>
<td>Carbonic acid</td>
<td>42.56</td>
</tr>
</tbody>
</table>

= 100.

Whereas the proportions, according to the above calculations, ought to have been

<table>
<thead>
<tr>
<th>Compound</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alcohol</td>
<td>51.12</td>
</tr>
<tr>
<td>Carbonic acid</td>
<td>48.88</td>
</tr>
</tbody>
</table>

= 100.

A coincidence as near as could have been expected, considering the very difficult nature of the experiment.

With respect to the modus operandi of ferments, we have nothing to add, but that the subject still remains a mystery. See WINE, and YEAST.

FERRABAD, in Geography, a town of Mazendaran, in Persia, situated at the mouth of a river, 3 miles E. of the village of Meshed Sir, which carries on a small trade in rice, salt, and pottery.

FERRISBURGH, a town of Addison county, in Vermont, having 1647 persons.

FIRMANESS, l. ult. after gold, add—or platina. Col. 2, l. 7, for motion r. notion.
FIROZABAD, an ancient city of Fars, in Persia, founded by Artaxerxes Bæbeon, which became the capital of Firoze Shah, the grandson of Nachivran. Its ruins occupy a large space in a plain about 17 miles in length, and half as wide. Here are the remains of Attaf Kudda, or fire-temple of Firoze Shah.
FIRUZABAD. See the preceding article.
FISCARD, l. ult. r. 250. Col. 2, l. 2, r. 1811—391—1572; l. 14; dele lately and received; l. 15, for Fridays r. Thursdays; l. 22, dele having been recently assailed by the erection of a pier; l. 28, for about fifty r. severally; l. 29, r. from 50 to 100 or more tons burlen; l. 40 and 41, r. at a distance near St. David's is a wall, &c.
F. lanceolata. Lanceolate Fischera. Sprn. n. 3. (Azorella lanceolata; Labill. 74. t. 99.)—Leaves linear-lanceolate, keeled.—Native of Port Jackson, New South Wales, Dr. White; of Levin's land, Labillardiere. Stem shrubby, twelve or eighteen inches high, roughish branches. Leaves scattered, numerous, spreading, entire, smooth, an inch and a half long; tapering at the base. Umbel terminal, flalked, compound, many-flowered.
F. ovata. Ovata Fischera. Sprn. n. 4. (Azorella ovata; Labill. 74. t. 100. Trachymene ovata; Sprn. Umb. 8.)—Leaves elliptic-ovate, triple-ribbed.—From the same countries. Differs from the foregoing chiefly in the broader shorter figure of the leaves, and the more evident combination of their ribs. We suspect Labillardiere has confounded a more lanceolate variety of the present with his real lanceolata.
F. linearis. Linear Fischera. (F. linearifolia; Sprn. n. 2. Azorella linearifolia; Cav. 1. c. v. 5, 57. l. 485.)—Leaves linear-awl-shaped.—Native of Port Jackson, Dr. White. Like the two former in habit, but the small, narrow, heart-like leaves seem to distinguish it, if the foliage of this genus can at all be trusted for specific characters.
We conceive the compound umbels, totally different habit, more oblong less flattened fruit, and other characters above indicated, must keep these plants generically distinct. Both from the original Azorella, (see BOLAN,) and from Mr. Rudige's Trachymene, hereafter described, though the learned Sprengel now refers them to the latter. His T. composita (Azorella composita; Labill. t. 101.) appears not well to accord with either, in character or habit. The fruit is broader than long, tumid and reticulated, not rough, Umbels compound.

FLOYD,

a town of Berkshire county, in Massachusettts, containing 92 inhabitants.

FLORIN, col. 2. l. 19, after divisions, a florin is a silver coin in Holland, Flanders, and Germany, called also "Guilder," or "Gulden." Accounts are kept in Holland in guilders or florins of 20 frances, each subdivided into 16 pences. A rix-dollar is worth 2 ½ florins, and a pound Flemish is equal to 6 guilders; hence, the rix-dollar being = 32. 4d. Flemish, the gilder is = 32. 4d. Flemish. A gold gilder, with which accounts are kept in the corn-trade, is worth 28 florins. Among the coins are stamped gold guilders at 28 florins, unslamped do. at 26 florins. A gold gilder of 28 florins must weigh 407 Dutch attes, or 301 English grains. In Germany, they have gold florins, or gulden, which are chiefly current in the countries on the banks of the Rhine, passing generally for 2 rix-dollars current, and they are to contain 18½ carats of fine gold, 3½ carats of fine silver, and 1½ carats of copper. The Hanoverian gold florins contain 18½ carats of gold, 3½ carats of silver, and 1½ carats of copper. The gold florin is a gold coin in Hanover, and other parts of Germany; but the gold gilder in Holland is a silver coin. See Table of Coins under Coin and Exchange.

FLOYD, l. 4. p. 3452 and 113.

FLUATES, in Chemistry. See FLORIC Acid.

FLUGEL-MAX, in Military Language, a well-drilled intelligent folder, advanced in front of the line to give the time in the manual and platoon exercises. The term flugel is derived from the German, and signifies a wing; the man having been originally polled in the front of the right wing.

FLUIDS, Animal, Chemical Properties of. The blood is the general source of all other animal fluids, most of which, more or less, resemble it in their properties. The operation by which other fluids are formed from the blood is termed secretion. See Blood and Secretion.

Berzelius divides secreted fluids into two classes; namely, the secretions properly so called, or the fluids intended to fulfil some exterior purpose in the animal economy; and the excretions, which are directly discharged from the body. The fluids of the former class, according to this distinguished chemist, are all alkaline; of the latter, all acid. The excretions are, the urine, the perspirable fluid, and the milk; all the other fluids appear to belong to the former class. The alkaline secreted fluids may be divided into two very distinct species. The former of these contains the fame quantity of water as the blood, so that the charge induced by the nervous influence seems to be confined to that of altering the chemical form of the albuminous materials, without affecting their relative proportions to the water and other substances dissolved in the blood. The bile, spermatic fluid, &c. are of this kind. The latter species consists of fluids, in which the influence of the nervous system has separated a large por-

The above are the results of Dr. Bolck's experiments, with the exception of the fluid from a blister marked *, which is taken from Margueron.

With respect to the nature of the incoagulable matter and salts, they are the same as those constantly found in the serum of the blood; we refer our readers therefore to the chart on this subject under the article Blood.

FLUORIC Acid. FLUORIC Acid. Since this article was written for the Cyclopædia, many important additions have been made to our knowledge respecting fluoric acid, which defer to be mentioned here.

Pure fluoric acid, according to Gay Lussac and Thénard, may be obtained by distilling together in lead vessels a mixture of one part of white fluor spar in a flake of powder, and two parts of concentrated sulphuric acid. The lead receivers must be kept as cool as possible by a mixture of common salt and snow or ice.

FLUORIC Acid thus obtained is, at 32°, a colourless liquid, like water. It remains a fluid between 4° and 66°. Its boiling point has not been determined, but it is low. When exposed to the air it smokes violently, giving out a smell similar to that of acetic acid, but much stronger. It is very speedily diffused in the open air, and can only be preferred in metallic vessels. Those best adapted for the purpose are made of pure silver, with air-tight silver stoppers. This acid, according to Davy's experiments, when as concentrated as possible,
possible, contains no water. In this flate, its specific gravity is 1.2699. When united to a certain portion of water, its specific gravity becomes as high as 1.250. When a drop is let fall into water, a hissing noise is heard, similar to that occasioned by a hot iron. When a few drops of water are let fall into fluoric acid, it enters into ebullition. A large proportion of water may be added without destroying its fuming property. Care must be taken not to breathe the fumes of this acid, as they are very deleterious. When a drop of it falls upon the skin, it acts as a powerful corrosive, and occasions a sore which does not soon heal.

Refecting the nature of this acid, the opinion of the older chemists, and even of Gay Lussac and Thenard, was, that it is composed of an unknown base and oxygen. M. Ampere, however, started the notion that it is analogous to muriatic acid, or a compound of hydrogen, and a supporter of combustion, to which the name of fluorine has been given; and this opinion has been since supported by Sir H. Davy, and though its truth has not been absolutely demonstrated, yet upon the whole perhaps it is the most probable. On this supposition, fluoric acid is a compound of one atom fluorine, and one atom hydrogen. See Simple Bodies.

Fluoric acid combines with all the bases forming fluoates.

Fluate of Ammonia.—This salt may be formed by saturating pure fluoric acid with ammonia. It is neutral when first formed, but becomes acid when evaporated. It does not crystalize, but when heated, flies off in thick white vapours.

Fluate of Potash.—This salt may be formed in the same manner as the last. It has a very sharp taste, crystallizes with difficulty, is very deliquescent, and of course soluble in water. When heated, it undergoes first the aqueous, and afterwards the igneous fusion. Sulphuric acid decomposes it, driving off fluoric acid in vapour.

Fluate of Soda.—This salt may be formed as above. It has much less taste than fluate of potash. It is not altered by exposure to the air, and is rather more soluble in hot than in cold water. On cooling, therefore, it separates in small crystals, or more frequently in the form of a solid and transparent crust on the surface of the water.

Fluate of Lime.—This salt exists abundantly native. It is called Fluor spar (which see), and is the fusible substance from which this acid is always obtained. It is composed, according to Davy’s analysis, of

Fluorine - 20 - 100.
Calcium - 26.25 - 131.25.

Fluate of Borate.—This salt is taletels, insoluble in water, but soluble in excess of fluoric acid, and likewise in nitric and muriatic acid. It is composed of

Fluorine - 20 - 100.
Barium - 87.5 - 437.5.

Fluate of Strontian.—This salt possesses the same properties as fluate of barytes.

Fluate of Magnesia.—This is a taletels powder, insoluble in water, and scarcely soluble in acids.

Fluate of Titania, Fluate of Alumina, and Fluate of Zirconia, are likewise white insoluble powders. The

Fluate of Glaucia is soluble in hot water, and precipitates in small crystals as the water cools.

It is extremely probable, as Dr. Thomson remarks, that the above salts are in reality fluorides, or compounds of fluorine, with the metallic bases of the earths.

The metallic fluates are not upon the whole an interfering class of bodies. The fluates of iron, manganese, zinc, and tin, are white insoluble powders. The fluate of cobalt is of a red colour. The fluate of lead exists in the form of brilliant plates. The fluate of copper, of small blue-coloured soluble crystals. The fluate of mercury of small lamellar yellow crystals. The fluate of silver is very soluble in water, and does not crystallize. It cannot be formed by the direct union of fluoric acid and silver, but it is formed when fluate of mercury is made to act upon silver.

Fluoboric Acid.—Fluorine has the property of combining with boron, and forming an acid which has received the above appellation. It may be formed by mixing together in a retort one part of finely pounded fused boracic acid, and two parts of fluor spar in powder, and twelve parts of sulphuric acid. The heat of a lamp is then to be applied, and the acid comes over in the form of a gas, which must be received over mercury. For this procés we are indebted to Dr. John Davy, but the acid itself was first discovered by Gay Lussac and Thenard in 1808.

Fluoboric acid thus obtained is colourless, and possesses the mechanical properties of common air. Its smell is similar to that of muriatic acid, and its taste is exceedingly acid. It instantaneously gives a red colour to vegetable blues. Its specific gravity, as determined by Dr. Davy, is 2.3709. Water absorbs about 700 times its bulk of this gas, and becomes slightly viscid, like sulphuric acid, and like it requires a high temperature to make it boil. It also changes animal and vegetable substances, and is capable of forming an ether when distilled with alcohol. It combines with the different bases, and forms a class of salts called fluoroborates, which have been little examined. On the supposition that it is a compound of fluorine and boron, which seems to be the most probable opinion, its composition will be

| Fluorine | 20 | 100 | 228.57 |
| Boron | 8.75 | 43.75 | 100. |

Fluosilicic Acid.—Fluorine has also the property of combining with silicon, and forming a powerful acid. This compound was first discovered by Scheele, but it is to Dr. J. Davy that we are principally indebted for the correct account of its properties. It may be formed by putting a mixture of equal parts of pounded fluor spar and glafla into a retort, and pouring over the mixture sulphuric acid sufficient to convert the whole into a paste. Heat is then to be applied, and the acid speedily comes over in the form of a gas, and may be collected over mercury. Fluosilicic acid gas is colourless, and possesses the mechanical properties of common air. Its smell resembles that of muriatic acid. It smokes when allowed to escape into the atmosphere. It instantly reddens vegetable blues. Its specific gravity, according to Dr. Davy, is 3.5735. Water absorbs about 263 times its bulk of it, but at the same time it is partly decomposed, and silica is deposited. When passed through liquid ammonia, the whole of the silicil is deposited in the form of silica: this enabled Dr. Davy to effect its analysis, the result of which appears to shew that it is a compound of one atom silicil and one atom fluorine.

The fluosilicates have not been much examined. The fluosilicate of lime exists abundantly native, and has not hitherto been distinguished from fluor spar. It may, however, be readily recognised by fheating it in metallic vellums with sulphuric acid, when it yields fluosilicic acid gas, while fluor spar does not.

FORFAR, l. 21, r. 1811; l. 22, r. 759—5652.

FORFARSHIRE. Add—By the return of 1811, this county had 16,135 houses, occupied by 107,264 persons; 48,151 being males, and 59,113 females; 4980 families employed in agriculture, and 13,616 in trade and manufactures.

FORFICULA, col. 2, under Auricularia, add—The popular dread in which this insect is held, from an apprehension of its entering the cavity of the ear, and piercing the tympanum, is now generally considered as an ancient and vulgar error.

FORMIC Acid, in Chemistry. The distinct nature of this acid appears now to be generally admitted by chemists. In its sensible properties, it approaches the acetic acid. But Sucreus has shown, that it has the property of neutralizing much leas of alkaline bodies than acetic acid. Gehlen also has shown, that the formates of soda and copper, differ altogether from the acetates of the same bases. Berzelius has lately analysed this acid with his usual precision; according to him, it is composed of

Hydrogen 2.84%, which nearly cor—

| 1 atom hydrogen. |

Carbon 30.24%, with

2 atoms carbon. |

Oxygen 67.92%, with

3 atoms oxygen. |

Hence it appears to resemble oxalic acid closely in its composition.

Fungi, Chemical Properties of the. Braconnot has lately detected three different new principles in this class of plants. Two of these are acids, one of which he has denominated boletic acid, the other fungie acid; the third is a principle neither acid nor alkaline, to which he has given the name of fungin. We shall briefly describe here the leading properties of each of these principles.

Boletic Acid.—This was obtained from the juice of the boletus pseudio-ignarius. Its colour is white; it is not altered by exposure to the air, and its crystals are irregular four-sided prisms. Its taste is similar to that of tartar. It is soluble in 180 times its weight of water at a temperature of 68°, and in 45 times its weight of alcohol. The aqueous solution reddens vegetable blues. It combines with the different bases forming boletates, which have been but little examined. The boletate of ammonia crystallizes in flat four-sided prisms, and is soluble in 26 times its weight of water at 68°. The boletate of potash is very soluble in water, and crystallizes with difficulty. The boletate of lime crystallizes in flat four-sided prisms, and is soluble in about 110 times its weight of water at 72°. No one hitherto appears to have repeated the experiments of Braconnot on this acid.

Fungie Acid.—This was extracted from the boletus juglandis, and other fungi. This acid is colourless, does not crystallize, has a very thick taste, and when evaporated to dryness, deliquesces on exposure to the air. The fungate of potash and soda do not crystallize, are very soluble in water, but not in alcohol. The fungate of ammonia crystallizes in regular four-sided prisms. The fungate of lime is not altered by exposure to the air, and is soluble in about 18 times its weight of water at 73°.

Fungin.—This substance approaches woody fibre in its properties, but seems to be sufficiently distinguished from it by various characters, particularly by constituting a nourishing article of food, and by being less soluble in alkaline leys.

Fungus of the Anturum, l. 13, for he r. the.

Eff. Ch. Petals fix, superior, spreading. Filaments shorter than the corolla, obvolute in their lower part. Style triangular, thickened at the base.

F. gigantea, De C. Pl. grafs. (Agave fertilis, Linn.) and F. tuberosa, (A. tuberosa, Willd. Sp. Pl. v. 2. 194.) are the only species.

 lanceolate. Scales of the seed-down awned, entire.-Found
in dry landy soil, from Canada to Florida. Annual.

FLOWERS handsome, orange, variegated with red and purple.

We have already announced this genus under the VIRGILIA
now classified. There are two more species, G. minimaria
and ariflata, from N. America.

GALEOPTHETUS, CUTILGO, in Zoology, a genus of
the order Primates, the characters of which are, that it
has no front teeth in the upper jaw; that those in the lower
are six, short, broad, dilated, and perforated; that the
canine teeth are very short, triangular, broad, sharp, and
ferrated; that the grinders are four, truncated and muriated
with conical protuberances; and that it has a flying-kin
surrounding the body, limbs, and tail. For the description
of this genus with appropriate figures, naturalists are
indebted to Dr. Pallas; and it may be found in the Trans-
actions of the Academy of Philadelphia for the year 1788.
The galeopithicus volans, or flying colugo, is the lemur
volans of the Linnean system, and the flying macaco of
Pomian's quadrupeds. It is a native of the Molucca and
Philippine islands, where it feeds principally on fruits, and
almost constantly resides on trees. It has two young ones,
which are said to adhere to its breasts by the mouth and claws.
Its whole length is about three feet, and of the fame breadth
when expanded; the tail is slender, and about a span long.
Its expandile skin, which enables it to fly, is continued on each
side from the neck to the back-foot; thence to the hind-foot,
and again to the tip of the tail. It is covered with fur, like
the body of the animal; the upper side of which is generally
of a deep ash colour; the back, in animals that are full
grown, is crossed transversely with blackish lines, having
towards the edges a tinge of yellow; and the whole under-
side, both of the body and membrane, is of a yellowish colour.
The head is long, the mouth small, and the tongue fleshy,
broad, rounded, and ciliated on each side, and with papilae,
and also slightly bevel with papilae on its surface.

The legs are clothed with a soft yellow down, and on each
foot are five toes, united by a common membrane, and
terminating in very sharp crooked claws. The animal is
called by the Indians caguan, colugo, and gigua. It is
a gregarious animal, flies chiefly in the evening, and its
body is said to be about the size of a cat. M. Geoffroy says
there are two varieties; one of the colour usually
described; the other of a fine cinereous or ferruginous colour,
vivid on the back and paler beneath, and without any
variegations. It is suggested, that these may be merely
sexual differences. Dr. Shaw has availed himself of Pallas's
description and figure in the first vol. of his Zoology, to
which we refer.

2. G. trilobata, ib. t. 282. - Both natives of South
America.

GALLIUM, col. 2. l. 54, for dried r. fresh.
GALLATIN, l. 2. r. 3559, and 664.
GALLIC Acid, in Chemistry. This acid has been
recently analyzed by Berzelius. He found it composed of
Hydrogen - - 5.90
Carbon - - 56.64
Oxygen - - 38.36

According to which analysis, the constitution of gallic
acid is as follows:

3 atoms hydrogen - - 3.75
6 atoms carbon - - 45.
3 atoms oxygen - - 30.

and the weight of its atom will be 78.75

Gallic acid has been found in the following plants, in the
different proportions stated.

Elm - - 7 Sallow - - 8
Oak, cut in winter 8 Mountain-ash - - 8
Horfe-cheefnut - 6 Poplar - - 8
Beech - - 7 Hazel - - 9
Willow (boughs) - 8 Ald - - 10
Elder - - 4 Spanish chestnut - - 10
Plum-tree - - 8 Smooth oak - - 10
Willow (trunk) - 9 Oak, cut in spring 10
Sycamore - - 6 Huntingdon or 10
Birch - - 4 Leicelpher willow 10
Cherry-tree - - 8 Sumach - - 14

GALLICIA, New, l. 3, r. Zacatecas.
GALLIPOLIS, a township of Ohio, in the county of
Galla, containing 448 inhabitants.

GALVANISM, col. 3. l. 25, after inch, inch—a part.
GALVANISM, Medical. See VOLTAISM, and particu-
larily Electricity, Medical.

GALVANOMETER, an apparatus constructed by
Mr. Pepsy, by an alteration in Bell's electrometer,
adapted for measuring very minute quantities of electricity,
and which perhaps could not be rendered reusable by any
other means. This apparatus consists of a glass cylinder,
covered with a lid, which is composed of two circular
plates of brass, attached to a cork that fits into the cylinder.
When the lid is fixed a thin slip of silver, the end of which
hangs down in the body of the cylinder, and has a pair of
gold leaves attached to it; and the whole is so contrived as
to be capable of being moved nearer to, or farther from,
the piece of zinc which stands up from the bottom of the
cylinder. The pieces of zinc are so contrived, that the
parts of them which project upwards from the bottom of the
cylinder may be fixed at different distances from each
other by means of a slide and screw. See a description and
figure of this instrument in Biot's "History of Gal-
vani." 8vo. 1819.

GAMING, col. 3. l. 30, r. 8 Geo. I.
GARDENING, l. 177, r. London.
GARDINER. Add.—containing 1029 persons.
GARDNER, l. 3, r. 815.

GARGLE, a disease of horned cattle, which consists of
an external hard swelling in the dewlap, which afterwards
spreads to the breast and throat. For the cure, profuse
bleeding is recommended; and then an opening is to be
made in the dewlap at the seat of the swelling, into which are
are introduced the leaves of bear's-foot pounded: the opening is then few with two or three stiches, and thus will be produced a running which will cure the diseahe; or a common rowel will answer the purpose.

GARRARD. Add—It contains 8926 inhabitants, of whom, in 1810, 2000 were slaves.

GARUGA, l. 3. r. 178 and 790.

GARUGA, in Botany, a very barbarous Indian name.

Eff. Ch. Calyx bell-shaped, five-cleft, bearing the filaments and the five equal petals. Stigma five-lobed. Drupa with several nuts.

GAS, col. 2, l. 25, after atmosphere, add — will be found under Air, Atmosphere, &c.; delineated under the head of Pneumatics.

GAS, in Chemistry. Great revolutions have taken place in the chemistry of the gases since this article was written for the Cyclopedia. Not only have their number been increased, but the laws of their combination, expansion by heat, &c. have been further investigated, and in many instances found very different from those flated under the above article. Several of these particulars have been already given under the article Atomic Theory, a few others remain to be mentioned here. The following table from Dr. Thomson includes the gases at present known.

d. Chlorine, hydrogen, and cyanogen with a base. Fluoric acid, chloroacetyc acid, hydrocyanic acid, chlorocarbonic acid.

e. Two solid bases. Sulphuret of carbon.

f. Triple or quadruple compounds. Hydriodic ether, chloric ether, sulphuret ether, muriatic ether, alcohol, oil of turpentine.

Combination of Gases with one another. — The important law first observed by Gay Lussac respecting the combination of gaseous bodies, and alluded to in our original article, is now, we believe, nearly universally admitted. This law is, that gaseous bodies always unite with reference to their volumes; that is to say, that either equal volumes of different gases combine together, or one volume of the one, with two, three, or more of the other, and not with any intermediate proportion; and further, that when a gaseous result is obtained by such union, the volume of this is either equal to the united volumes of the two gases, or to half, one-fourth, or some other submultiple of the original volumes.

The combinations of gases with one another have been arranged by Dr. Thomson under the following heads.

1. Gases that unite by mere mixture, such as: Oxygen with nitrous gas, forming nitrous or nitric acid. Ammonia with vapour, forming liquid ammonia— with muriatic acid, forming muriate of ammonia— with fluoric acid, forming fluoborate of ammonia— with fluofuscic acid, forming fluofuscate of ammonia— with carbonic acid, forming carbonate of ammonia— with sulphureous acid, forming sulphilte of ammonia— with sulphuretted hydrogen, forming hydrofulphuret of ammonia.

2. Gases that may be mixed without any flaring combination, though they are capable of uniting in certain circumstances, such as: Oxygen with hydrogen, forming water— with carbonic oxyd, forming carbonic acid— with azote, forming nitric acid— with chlorine, forming chloric acid— with sulphureous acid, forming sulphureous acid— with nitrous oxyd, forming nitric acid. Hydrogen with chlorine, forming muriatic acid— with iodine, forming hydroiodic acid— with cyanogen, forming hydrocyanic acid. Chlorine with carbonic oxyd, forming chloro-carbonic acid.

3. Gases which mutually decompose each other when mixed together, such as: Oxygen with sulphuretted hydrogen. Chlorine with ammonia— with sulphuretted hydrogen— with carburetted hydrogen— with olefiant gas— with sulphuretted hydrogen— with nitrous gas. Sulphuretted hydrogen with nitrous gas—with sulphureous acid.

4. Gases which mix without spontaneous decomposition, but which may be made to decompose each other in particular circumstances, as on the approach of an ignited body, when electric explostions are passed through them, &c. These are more numerous than the preceding, and are as follow: Oxygen with sulphuretted hydrogen— with carburetted hydrogen— olefiant gas— vapour of ether— vapour of alcohol. Nitrous oxyd with hydrogen— with sulphuretted hydrogen— with carburetted hydrogen— with carbonic oxyd— carburetted hydrogen— olefiant gas— vapour of ether— vapour of alcohol— sulphureous acid. Nitric acid with hydrogen, and probably all the preceding combustible gases and vapours— with sulphureous acid. Nitrous gas with hydrogen— with sulphureous acid. Hydrogen with sulphureous acid— with carbonic acid. Vapour of water with carburetted hydrogen— with olefiant gas.

Combination of Gases with Liquids. Gases may be considered with reference to their combination with water and other fluids. With respect to water, by far the most important of all fluids, gases may be divided into two classes; those that are absorbed in a small proportion, and those that are absorbed in a great. Almost all gases belong to the first class. In the following list of this class, the gases are arranged in the order of their absorption, beginning with the least absorbable: azotic gas— hydrogen gas— arlenical hydrogen— carburetted hydrogen— carbonic oxyd— pholphuretted hydrogen— oxygen gas— nitrous gas— olefiant gas— carbone deoxyd— sulphuretted hydrogen.

The following laws seem to be pretty well established respecting the absorption of gases by water.

1. When the pressure, temperature, and purity of the water, are the same, water absorbs a determinate quantity of every individual gas.

2. Water
GAS

2. Water of the same temperature always takes up the same bulk of each gas, whatever be its density.

3. The proportion of any gas absorbed by water depends greatly upon the nature of the gaseous residue.

4. The proportion of gases absorbed by water is considerably influenced by the temperature.

All the very absorbable gases belong to the classes of supporters, acids, or alkalis. The following is a list of such of them that have been hitherto examined, arranged in the order of their absorbability. Chlorine, cyanogen, sulphureous acid, fluoric acid, muriatic acid, fluoric acid, ammoniacal gas.

When water is saturated with the above gases its bulk is augmented. Thus one cubic inch of water saturated with Cubic Inches.

With respect to the absorption of gases by other fluids little is known. It appears, however, that in general alcohol and oils absorb a much greater proportion of gases than water.

Our limits will not permit us to enter upon this subject so much as its importance demands, we must therefore content ourselves with submitting our readers with the following table of the proportions of different gases absorbed by water, according to the best experiments.

GENEVIEVE, l. 7. add—and district. In 1810, it contained 4620 inhabitants, of whom 988 were slaves. This town is famous for its lead-mines, which occupy an extent of country, commencing about 30 miles W. of the Mississipi, and extending W. and N.W. It was the discovery of these lead-mines that gave rise to the famous Mississipi scheme, projected by Law in 1719, which ruined hundreds of families in France, as they were then supposed to be a silver-mines; and though the bubble burst immediately, yet Du Pratz, who wrote thirty-nine years afterwards, perished in the error, and speaks of a silver-mines on the Maremis in his account of Louisiana. The Maremis is now called the Muraraahl, on a branch of which, called the Negro-Fork, the mines of St. Genevieve are situated. These mines have been worked since about the year 1725, and they belong to a number of proprietors mostly held by grants from the Spanish governors, formerly residing about St. Louis. Bradford's Travels, &c.

Vol. XXXIX.
GEOLGY.

This, we believe, is now admitted by all those who have had the most extensive range of observation.

The secondary strata are local formations, and some of the upper strata were evidently formed in detached lakes or inland seas. A still more comprehensive view will prove that even all the stratified rocks above the red sandstone and alpine lime-stone are also local formations, which had their origin in detached hollows or seas of great extent, but which were limited to certain portions of the globe. The observation of travellers in different parts of the world incontrovertibly proves that these formations are local. I am even inclined to consider the red sandstone and alpine lime-stone as local formations, but of greater extent than any of the strata above them. If this view of the subject were admitted, geologists would be relieved from the great difficulties under which the science labours at present, and it would go far to establish a simple and perspicuous system, which will at once account both for the similarity and diversity of rock formations in various parts of the world. If the mountains were once much higher than at present, it must be admitted, that before the formation of the secondary strata the valleys and hollows were deeper in a far greater proportion, because to the height of the surrounding mountains we must add the whole depth of the secondary strata which were then wanting. By whatever process the secondary strata were formed, the existence of organic remains in them incontrovertibly proves that they were deposited in succussion, and the regular manner in which they are spread over each other further proves that the greatest part of them were deposited in a fluid medium. As there are incontrovertible proofs that water once covered nearly all the existing continents, it follows, that when the ocean retired, or, which is the same thing in effect, when the dry land emerged from the sea, vast inland lakes or seas would be left at the bottom, of which the secondary strata were formed. As the sea retired farther, the higher grounds being left dry, these inland seas or lakes would become contracted, and a number of smaller lakes would occupy the lowest cavities and depressions, in each of which separate depositions of strata might take place. The lower strata would be the most widely spread, and the upper would constitute detached or laminated formations of greater or less extent, in which there might be a great similarity in some situations, and a great diversity in others. Now fuch is found to be the fact." (Bakewell’s Introduction to Geology, 2 ed. chap. x.)

This view of the subject, we think, receives much support from the position of the mountain ranges in Europe, as may be seen in Mr. Arrowmith’s excellent map, in which the phyleis of the mountain ranges is distinctly marked. These ranges form the borders of numerous bays, which must evidently have once been the boundaries of inland seas when the ocean retired from the present continents.

Though great diversity may prevail in the succussion of the strata in different parts of the world, yet there are certain rock formations that we may regard as universal, without asserting that they were formed at the same epoch in very distant countries; for it is only where organic remains of the same species occur in rocks that we may infer that their formation was contemporaneous. In the present state of our information, we may regard granite as the lowest and most extensive rock, forming the foundation of all other rocks or strata, where we have opportunities of tracing their succussion. With granite we include gneiss, and also mica-flake, which may be regarded as granite in a schistose form, but with one or other of the ingredients nearly wanting, or occurring in a very small proportion. (See Rocks, Granite, Gneiss, and Mica-Slate.)

Clay-slate (see Slate) generally covers the granite, gneiss, or mica-flake, and may be regarded as a universal formation, or, perhaps more correctly, as a general covering of granite, gneiss, and mica-flake. The slate formation contains various anomalous beds of porphyry, compact felspar, lime-stone, hornblende, serpentine, and felspar. (See Porphyry, Felspar, &c.) No observable regularity has yet been discovered in the succussion of these latter rocks in different countries, and some of them may often be observed passing by gradation into each other. They have generally a crystalline structure in the vicinity of granite (see Rocks), and have not been observed to contain organic remains.

The beds of rock which cover slate appear, many of them, to be a coarse kind of slate, with an intermixture of quartz, or other minerals, until at last they lose the character of slate, and become sandstone. This coarse slate, in its passage from slate to sandstone, forms that kind of rock which has been denominated grey wacke or wacke. Various beds of lime-stone occur in the coarser slate. Of these, the most considerable in England is called the mountain lime-stone: it has a fuchrytalline structure; it abounds in organic remains in many parts, and contains metallic veins, principally of lead and zinc. This lime-stone lies below all the principal coal formations in England and Wales. (See Strata.) Between this lime-stone, and a dark grey compact lime-stone called lias, occur the coal strata, with the various beds of sand-stone and slate. The order of succussion of these beds is not similar in different districts. The lias stratum is the most remarkable in England, both for its regularity and extent, and the organic remains which it contains. The fame stratum occurs in Flanders. The strata above the lias are still correctly described by Mr. Farey, whose account we have given in the article STRATA. (See STRATA.) The strata above the lias occur with remarkable regularity over a great part of the eastern side of England, described by Mr. Bakewell, in his Geology, as the 'low district,' extending in a waving line from Dorsetshire to the county of Durham, and delineated in his map. These strata consist of a succussion of beds of roe-stone, or oolite, (fée Roe-stone), and coarse lime-stone, with thick beds of flint and clay, over which occurs the chert. These beds are arranged with great regularity compared with the beds that occur between the lias and the mountain lime-stone; but the order of succussion and thickness, particularly of the oolite, is variable; for in many parts, beds of vaft thickstones occur which are not found in other situations, and in some situations the oolite is entirely wanting, and the green sand, instead of covering it, rests immediately on the lias. See Mr. Bakewell’s section of the strata, Plate III. fig. 2. Geology.

A tabular arrangement of the strata of England, given by Mr. Buckland, professor of mineralogy at Oxford, has recently been published, which we shall present to our readers. At the same time we must observe, that they would be greatly mistaken were they to suppose that the whole of these rock formations had ever been observed in any one situation in England or elsewhere, or that the strata prefer the thickstones here given throughout their whole extent. There is no part of England, we believe, in which all the strata here enumerated could be found, were it possible to perforate through them. The table may be regarded as an approximation to the true order of succussion whenever several of these formations occur in the same district, and the localities annexed will make it both interesting and useful. Perfons who study nature in their closets are disposed to believe, that the thickstones of the strata
GEOLOGY.

Flratum between the chalk near London, and the granite of Devonshire, is much greater than what it really is, taking it for granted that the dip of the flratum is always regularly to the east; but this is not the case. A flratum of any considerable extent has waves and irregularities, by which it is generally spread over a large space compared with its true thickens and supposited angle of inclination. A flratum not more than seventy yards in thickens may extend in the line of its dip ten miles or more, and may appear to have a considerable dip when observed in certain situations; and were we to calculate its thickens from the extent of ground, which it covers, and from the dip, we might infer that it exceeded two thousand yards or more. More accurate observations will convince us, that the numerous fractures or bendings of the flratum in the line of their dip generally spread them over a much wider space than the angle of inclination and thickens would lead us to believe; and the comparison which has been made of sliding a number of books under each other to represent the supposited thickens of the whole flratum of England is utterly inappropriate to the cafe. In sections of particular districts, to represent the arrangement and dip of the flratum, it is impossible to delineate the irregularities and wave of the flratum on a small scale. In the section of England by Mr. Bakewell, (See Plate IIII, fig. 1.) the various flratum from the German ocean to Croydon are represented rising regularly from under each other, like a number of books in a slanting position, it being impracticable to represent on such a small scale all the irregularities of each flratum. In Plate IIII, fig. 2, the section is on a larger scale, and the thickens flratum, d, d, d, d, is represented rising from under the green sand b, b, near Bridport in Dorsetshire, and continued to the valley, M, at Axmouth; whereas had not the flratum been dislocated by a great number of fractures, as represented in the section, the flratum of d would have terminated or cropped out east of the letter L, which represents the situation of the town of Lyme. The aggregate thickens of all the beds of flratum cannot be more than two hundred yards, and the regular inclination is at least one yard in twenty, which would make the lowest bed of flratum crop out about four thousand yards, or two miles and a quarter west of its first appearance near Bridport.

Plate IIII, fig. 6. Geology, represents the waving structure of the beds of flate, provincally called shillet in Devonshire. In some situations, as near Moreton, beds of black lime-flate are interposed, and take the twilled form of the flate. Now in passing from Exeter to Dartmoor over the fractured edges of the flratum, as represented fig. 6, the traveller may cross portions of the same flratum as, a, a, a, repeatedly at a considerable distance from each other, and were he to suppose each of these portions to be a separate flratum, and to calculate accordingly, the thickens of the whole bed of flate, from the red ground on the east, to Dartmoor on the west, he would make it not less than ten miles; whereas in all probability it may not exceed three or four hundred yards. On a smaller scale, the flratum are often extended over a large space by fractures in many of the coal districts; by which a bed of coal is brought near the surface several times in the line of its dip, as represented Plate I. fig. 1. Geology, and described in the article Coal. See Coal, and Veins, Mineral.

It too frequently happens that geological observers measure nature by the standard of their own limited experience in passing through a country, and describe certain rock formations as definite of organic remains, because they have not found them in travelling through a district. The alpine part of Westmoreland and Cumberland near the lakes consists of grey wacke, clay-flate, compact felspar, porphyry, sienite, trap, chinkstone, and granite; a thin bed of flratified lime-flate is interposed, and runs through a space of fifteen miles, containing organic remains of coralloids, though the rocks which cover this lime-flate, to a great depth, and the rocks on which it rests, contain no observable vestiges of organic life. Their relative position in the valley of Long Sleddale in Westmoreland, is represented Plate IIII. fig. 5. Geology. The flate which covers the lime-flate appears to dip at an angle of seventy degrees; but on more attentive examination it will be found, that what might be mistaken for regular flratum are merely the fchistofce laminae of the flate arranged in the direction of the cleavage, the dip of the flate being in reality the same as that of the lime-flate on which it rests. Under the lime-flate occurs a bed of horn-flate, resembling compact felspar, but infusible; this is eighty yards thick, and rests on other beds of shillet, as represented Plate IIII. fig. 5. Geology. This shillet and horn-flate contain no organic remains, and appear to be connected with the granite, which makes its appearance in the adjacent valley at no great distance. The discovery of organic remains under rock formations of great extent which are definite of them is a circumstance of great interest to the geologist wherever it occurs, and proves the necessity of caution in deciding whether certain rocks were formed prior to the existence of organic beings. Baffalt or trap rocks, whose formation is not conformable with the general dip or position of the flratum, and which bear a near similarity to volcanic rocks in appearance and composition, are described under the articles TRAP, ROWLEY-RAGG, WHINSTONE, and VEINS, Mineral; and also the article BASALT, Addenda; which see. Plate IV. fig. 2. Geology, represents the arrangement of a series of columnar and amorphous beds of bafalt placed over regular flratum in an unconfomable position, and interfaced by veins or dykes of bafalt b, b, in which the structure is columnar; but the columns or bafaltic prisms in these dykes are arranged horizontally.

Fig. 4 represents a bafaltic rock on the coast of the county of Antrim, which inclines a bed of chalk that it appears to have broken and enveloped; an effect which seems to require that the bafalt should once have been in a melted flate like lava. The bafalt is represented in the fig. immediately beneath the above, as it occurs in veins in another situation on the same coast, cutting through the chalk, and changing it to a certain distance into crysalline lime-flate or marble. See TRAP and WHINSTONE.

Plate IV, fig. 1. Geology, represents the section of a regular metallic vein, which divides into two, and meets again, leaving an intervening space filled with earthy minerals called rider. The vein is represented as separated from the rock by a thin lining of clay c, which generally accompanies veins. The interfection of metallic veins in the same plate represents two veins containing the same kind of ore, and having the same dip as a, a, a, a, the first, by a vein of a different kind b, which has cut through and displaced the former: in these interferences, the vein b b is supposited to be of posterior formation to the veins a, a, a, a. In the same fig. is shown the displacement of a vein without any interfection of other veins. (See VEINS, Metaltic.) For an account of volcanic rocks, see the articles VOLCANO and VOLCANIC PRODUCTS, and also SYSTEMS of Geology. For an account of the organic remains in rocks, see PETRIFICATIONS, ROCKS, STRATA, and FLATE ROCKS. For an account of the organic remains of extinct species of large quadrupeds in alluvial soil, see MAMMOTH, MASTODON, MEGALONIX, and MEGATHERIUM, Addenda.
A Tabular Arrangement of all the Rock Formations in England.

**CLASS I.**—Primary Rocks.

**Granite Formation.**

**No. 7.**
In the preceding part of the present article we have stated, that this arrangement of the strata may be taken as an approximation to the truth with certain limitations. It must be observed also, that the trap rocks, No. 9, most frequently occur covering or between many of the lower secondary rocks, precisely similar to what would have been the case had they been formed like volcanic rocks at different and distant epochs. The occurrence of basalt in or over chalk, or any of the formations above the lias, is extremely rare. See Systems of Geology.

GEORGE, St.l. 15, add.—The hundred of St. George's, in Delaware, contains 2880 inhabitants, of whom 314 are slaves.—Also, a town of Maine, in the county of Lincoln, having 1168 inhabitants.

GEORGE-Town, col. 2, l. 14, r. 1998; l. 29, add.—Also, a district of North Carolina, containing 15,679 inhabitants, of whom 13,867 are slaves.

GEORGE, a township of Fayette county, in Pennsylvania, having 2086 inhabitants.

GEORGIA, in America, l. 2, r. 1760.

GERMAN, l. 2, r. 2079.

GERMAN-Town, col. 2, l. 1, r. Macon county, in Kentucky, containing 36, &c.; add.—Also, a town of Ohio, in the county of Montgomery, having 1256 inhabitants.

GERRY, l. 3, r. 839.

GEYSERS, celebrated fountains situated on the side of a hill, about 16 miles to the N. of Skahall, for an account of which we refer to the article UXAMBER.

GEZANGABEEN, or Perian Manna. This substanee has been lately affected by Capt. E. Frederick, of the Bombay Establishment, to be the production of insects. It is obtained, according to the same gentleman, from a small shrub somewhat resembling the broom, on which the insects refuse, by beating the bushes with a flick. When first separated, it is a white ficky substance, not unlike hoar frost, of a very rich sweet taste. It is purified by boiling, and then mixed up with rose-water, flour, and pistachio-nuts into cakes, and in this form constitutes the sweetmeat, called in Perian gezangabeen, and which by the Persians is highly valued. This substance, in its original state, is said to liquify at a temperature of about 69°. The Persians, however, themselves consider this substance as a spontaneous exudation from the tree on which it is found; hence the term gezangabeen, a term meaning literally juice of the gez, which is the Persian name of the tree producing it. Thomson's Animals of Philosophy, vol. xiii. See MANNA.

GHONI, a large market-town of Mingrelia, carrying on some trade, situated between the Arascha and the Hippas.
GLU

GHURZI, a well-built and populous town of Mingreia, on the left bank of the Taghuriz.

GILBERT, col. 2, l. 32, r. 1759.

GILDER, or GUILDER. See Florin.

GLEAD, in Geography, a town of Maine, in the county of Oxford, having 215 inhabitants.

GILES, a county of Virginia, containing 3475 persons, of whom 242 are slaves.

GILL, l. 4, r. 762.

GILLINGHAM, l. 4 and 5, r. 875, and 5135.

GILMONT, l. 4, r. 4338.

GILSON, or GILSOM, l. 2, r. 513.

GIRARDEAU, Cape, a district of Louisiana, containing 3888 inhabitants, of whom 589 are slaves.

GIRVAN, l. 4, r. 762.

GLASGOW, col. 2, l. 11 from the bottom, add.—By the parliamentary returns of 1811, the city and burgh of Glasgow contained 27,543 houses, and 100,749 inhabitants; 45,125 being males, and 45,702 females; of whom 7915 families were employed in trade and manufactures, and 8217 in agriculture.

GLANCE Coal. See Mineralogy, Addenda.

GODALMING, l. 2, r. 2474, and 5343.

GOFFSTOWN, l. 5, r. 2000.

GOLD. See Gold, and Mineralogy, Addenda.

GOLDEN, in Chemistry. A few particulars lately ascertained respecting this metal deserve to be briefly noticed here.

GOLDEN, or GUSBOROUGH, l. 5, r. 1811—435 l. 12, r. 2094.

GLAMORGANSHIRE, last paragraph.—Glamorganshire is divided into ten hundreds, exclusive of the two towns of Cardiff and Swansea, and 118 parishes, which, in 1811, contained 85,057 inhabitants; 41,305 being males, and 43,752 females of whom 7915 families were employed in trade and manufactures, and 8217 in agriculture.

GLASS. Laws relating to, l. 14, add.—By 49 Geo. III. c. 63, the former duties upon crown glass and broad glass were repealed, and new duties were imposed. This act also contains directions and regulations with regard to the construction and use of the annealing arch or oven.

GLASTONBURY, col. 2, l. 42, r. 1811—448 l. 43, r. 2337—121.

GLASTONBURY, in America, l. 2, r. 76; l. 5, r. 2766.

GLOUCESTER, col. 6, l. 6, r. 1811; l. 7, r. 1599—2380; del the next paragraph, and insert—3726 being males, and 4554 females; of whom 1312 families were employed in trade and manufactures, and 12 families in agriculture.

GLOUCESTER, in America, l. 3, r. 5943; l. 21, r. 2319. Col. 2, l. 2, for Woodbury insert—Weymouth; l. 9, r. 19744; l. 10, r. 74; l. 17, after Philadelphia, add—having 555 inhabitants.—Alfo, a town of the same county, having 1726 inhabitants;—l. 25, r. 10,427 inhabitants, of whom 5708 were slaves in 1810.

GLOUCESTER, New, a town of Maine, in the county of Cumberland, having 1640 inhabitants.

GLOUCESTERSHIRE, col. 2, l. 26, insert after amounted to—52,042, of inhabitants 285,514, of whom 133,192 were males, and 152,322 females; 29,985 families were employed in trade and manufactures, and 20,782 in agriculture.

GLOVER, l. 3, r. 378.

GLOUCINA, in Chemistry, the name of an earth. (See GLYCINE.) Dr. Thomson, from the experiments of Berzelius and others, estimates the weight of the atom of glucina at 22.5.

GLUCINUM, the metallic basis of gluicina. When glucina was heated by Sir H. Davy with potash, that metal was converted into potash, and grey metallic particles were observed mixed with the potash, which, when put into water gradually evolved hydrogen gas, and were converted into glucina. This is all we know at present respecting this metal.

GLUTEN, supposed to be the active principle of yeast. See YEAST.

GLUTTON, r. Ursus Gulo.

GLYN, l. 4, r. 3417, of whom, in 1810, 2845 were slaves.

GLYPHIS, in Botany, from ἔγγαρον, to emboss, expressing the appearance of the warty crust.—Achar. in Tr. of Linn. Soc. v. 12. t. 2, 3.—A genus of crustaceous Lichens, of which four species are described and figured, found on the banks of different tropical trees. See CHIODECTON.

Eff. Ch. Watts flatfish, of the subfamily of the crust. Receptacles superficial, numerous, irregular, black, solid, each with a depressed disk, and tumid margin.

The species are, G. labyrinthisca, t. 2. t. 1. Ach. Syn. 107: tricocca, l. 2: cicatricocca, l. 3: favulocca, l. 3 t. 1.

GODALMING, l. 2, r. 672, and 3543.

GOFFSTOWN, l. 5, r. 2000.

GOLD. See Gold, and Mineralogy, Addenda.

GOLD, in Chemistry. A few particulars lately ascertained respecting this metal deserve to be briefly noticed here.

 Sulphur is flated in the Cyclopaedia to exert no action on gold, and this is true in ordinary cales. But if an alkaline hydroxyl are diffused into a solution of gold, a black powder falls to the bottom, which is found to be a fulphurat of gold, and which, according to the experiments of Bucholz and Oberkampf, is composed of

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

With respect to the oxyds of gold, there are still very great confusion and uncertainty. According to Berzelius, who is one of the most recent experimentalists on gold, the purple oxyd is a compound of 100 gold + 12,077 oxygen; and the protoxyd of 100 gold + 4,026 oxygen. On this supposition, the weight of an atom of gold, as estimated by Dr. Thomson, will be 248.75, and this determination agrees tolerably well with Oberkampf’s analysis of the fulphurate of gold above-mentioned. Still, however, these results are by no means satisfactory.

GOLDSINNY, r. GOLDFINNY.

GOMPHOSUS, in Ichthyology, a genus of fishes of the Thoracici order, instituted by Count de Cepede from the MSS. of Commeron; the characters of which are, that the jaws are strengthened into a tubular snout, and that the teeth are small, thole in front being larger. There are two species, both natives of the Indian seas, viz. G. carinus, or G., entirely of a blue colour, about the size of a tench, with a blackish cast on the pectoral fins; body arched above, and in a greater degree beneath; snout about one-sixth of the whole fish; upper jaw larger than the lower; the sides of the mouth smooth and blue, head and gill-covers plain, the rest of the body covered with scales, the lateral line through its whole course marked with small streaks like Chinefe characters: and G. variegatus, or variegated with red, yellow, and blue; a beautiful fish, observed by Commeron about the coasts of Otaheite.

GOOCHLAND, l. 4, r. 10,203 inhabitants, of whom 5664 were slaves in 1810.

GOODYERA, in Botany, dedicated by Mr. Brown, to the worthy memory of Mr. John Goodyer, a Hampshire botanist, celebrated in various parts of Gerard’s Herbal, (see ed. 2. 1018, 228, &c.)—Br. in Ait. Hort. Kew. v. 5: 197.
197.—This genus founded on Satyrium repent, Linn. we have not as yet ventured to separate from Neotria; see that article.

GORHAM, l. 4, r. 2632.

GOSHEN, in America, l. 4, r. 692; l. 7, containing 86 inhabitants; l. 8, r. 1273; l. 10, r. 1641. At the close, add—Allo, a town of Cheshire county, in New Hampshire, having 563 inhabitants. —Allo, a town of Lincoln county, in Georgia. See LINCOLN.—Allo, a township of Columbiana county, in Ohio, having 277 inhabitants.—Allo, a town of Ohio, in Tuscarawas county, having 320 inhabitants.

GOSPORT, col. 2, l. 30, r. 1811—7788; l. 31, r. 1439.

GOSPORT, in America, l. 3, r. 72.

GOTHEBOURG, col. 2, l. 5, r. amounted in 1811 to 24,858 persons, &c.

GOULDSBOROUGH. Add—the town contains 471 persons.

GRABS, the name of vessels peculiar to the Malabar coast, generally with two masts, and of 180 tons burthen, but sometimes with three masts, and about 300 tons burthen. They are fo constructed as to draw little water, being very broad in proportion to their length, becoming narrow from the middle to the end, and having a prow projecting like that of a Mediterranean galley; others are constructed with a strong deck fixed with the main-deck of the vessel, from which, however, it is separated by a bulk-head that terminates the forecastle; on the main-deck under the forecastle are mounted two pieces of cannon, of nine or twelve pounders; the cannon of the broad-side are from six to nine pounders.

GRAFTON, l. 4, r. 1365; l. 8, r. 33; l. 9, r. 28,462; l. 12, r. 931; l. 18, r. 946.

GRAIN, as a weight, l. 11, del. bread.

Grains of Paradise. See Amomum and Cardamom.

GRAINGER, l. 6, r. 6397 and 537.

GRAMPOUND, l. penult. r. 601 and 96.

GRANDBY, l. 5, r. 850; l. 8, r. 2696.

GRAND ISLE. Add.—It contains 3445 inhabitants by the census of 1810.

Grand Junction Canal, l. 16 from bottom, for began r. begun.

Grand View, a township of Ohio, in Washington county, having 463 inhabitants.

GRANLEY, a township of Essex county, in Vermont, having 120 inhabitants.

GRANTHAM. In 1811, the borough and parish contained 673 houses, and 3646 persons; viz. 1677 males, and 1969 females: 61 families being employed in agriculture, and 430 in trade and manufactures.

GRANVILLE, l. 2, r. 15576; l. 3, r. 7746; l. 9, r. 1594.

GRANVILLE, a township of Licking, in Ohio, having 674 inhabitants.

GRAPHITE. See Plumbago, and Mineralogy, Addenda.

GRAVESEND, col. 2, l. 3, r. 3119; l. 4, r. 525.

GRAY, l. 3, r. 1310.

GRAYSON, l. 2, r. 4941 inhabitants, of whom 270 were slaves in 1810; add—Allo, a county of Kentucky, containing 2301 inhabitants, of whom 103 were slaves in 1800.

GREEN, l. 4, r. 19536 inhabitants, of whom 367 were slaves; l. 10, r. 12544; l. 14, r. 6663; of whom 1354 were slaves; l. 16, r. 4567 and 1842; l. 19, r. 1277; l. 23, r. 1497; l. 24, for Franklin county, add—Allo, a township in Washington, r. 36, adding after State—with 1708 inhabitants; then add—Allo, a township of Ohio, in Fayette county, with 295 inhabitants. —In Gallia county, with 421. —In Hamilton county, with 916. —In Jefferson county, with 875. —In Rens county, with 1185. —In Scioto county, with 507. —In Trumbull, with 559. —In Columbiana county, with 338 inhabitants; all in the district of Ohio.

GREEN Brier, l. 4, r. 5914 inhabitants, of whom 494 were slaves in 1810.

GREEN Earth. See Mineralogy, Addenda.

GREENE, l. 2, r. 9713 and 655; l. 7, containing, together with Greenborough towns, 11,769 inhabitants, the county having 4992, and the town 244 slaves, included in the above number; l. 12.—By the census of 1810, it contains six townships, and 5870 persons.

GREENE, in Pennsylvania. See GREEN.

GREENE, in Maine. See GREEN.

GREENE, a town of Adams' county, in Ohio, having 393 inhabitants.

GREENFIELD, l. 5, r. 1165; l. 7, r. 980; add—Allo, a township of Bedford county, in Pennsylvania, having 855 inhabitants. —Allo, a township of Ohio, in Fairfield county, having 743 inhabitants.

GREENLAND, in America, l. 3, r. 592.

GREENLAW, col. 2, l. 2. In 1811, it contained 253 houses, and 1260 inhabitants.

GREENOCK, l. 3, after Glasgow, add—The parish, including East, Middle, and West Greenock, contained, in 1811, 1138 houses, and 19,042 persons.

GREENSBOROUGH, in Georgia. See GREEN;

l. 6, r. 5166-

GREENSBURGH. Add.—It contains 132 inhabitants, including 47 slaves.

GREEN-STONE, in Geology, granulite, Werner, a species of granular trap or basalt, composed of hornblende and feldspar, and described in our article Trap. (See Trap.) It has recently been discovered, that the mineral called augite, or pyroxene by Hauy, is a constituent part of many rocks of green-stone, which confirms still further the similarity between volcanic and bafial rocks. See Volcanic Products.

GREENSVILLE, l. 4, r. 6853 inhabitants, of whom 4599 were slaves in 1810.

GREENVILLE, l. 3, r. 13133 and 2353.

GREENUP, a town of Kentucky, containing 2569 persons, of whom 484 were slaves in 1810.

GREENWICH, col. 4, l. 28, for bottom, r. 16947 and 2315.

GREENWICH, in America, l. 3, r. 1225; l. 6, add—containing 2858 persons; l. 9, in 1810, 2528; l. 13, add—In 1810, 858 inhabitants; l. 12, r. 3533. Add—Allo, a township in Berks county, in Pennsylvania, having 1104 inhabitants.

GREENWICH, East, l. 3, r. 1530.

GREENWICH, West, a township in the same county and State, containing 1619 inhabitants.

GREENWOOD, l. 1, r. Northumberland; l. 2, r. 1028; add—Allo, a township in Cumberland county, having 1102 inhabitants.

GREGORY, David, l. ult. It appears by the inscription on his monument in St. Mary's church, Oxford, that he died Oct. 10, A.D. 1708; and not, as the writer of his life in the Biog. Brit, says, in 1710, whence this date is cited. He died at an inn at Maidenhead, in his way to London from Bath, and was buried in this town.

GRENATITE. See Mineralogy, Addenda.
GUADALAJARA, col. 2, l. 39. — The population is estimated at 75,000, but according to Humboldt, 19,500 in 1803, and that of the administration 5,615,500. N. lat. 20° 50'. W. long. 105°.

GUAICUM, Chemical Properties of. — Guaiacum was formerly considered as a resin, though in its properties it differs considerably from resins. Guaiacum always assumes a green colour when exposed to the light in the open air. When heated, it melts and diffuses at the same time a fragrant odour. Its fp. gr. is 1.2289. It is very sparingly soluble in water, but imparts to that fluid a greenish-brown colour, and a fetid, nauseous odour. Alcohol diffuses it with facility, and forms a deep brown coloured solution. Sulphuric ether also diffuses it; but not in such large proportions as alcohol. It is readily soluble in alkaline solutions. Most of the acids also act upon it with considerable energy; thus sulphuric acid diffuses it, and forms a deep red solution. Nitric acid diffuses it completely with effervescence, and when the solution is evaporated, it yields a very large proportion of oxalic acid, but no artificial tannin. Muratic acid acts but slightly on guaiacum. When guaiacum is submitted to defractive distillation, it yields a little acridulous water, a considerable proportion of brown empyreumatic oil, some gaseous products, and a quantity of charcoal is left on the retort nearly equal to one-third of the original weight of the guaiacum.

GUANAJUATO, l. 2, r. Quaratéaro, and between 21° 30' and 22° 30' N. lat., and 100° and 103° W. long., extending from N. to S. 75 miles, from E. to W. 85 miles. Humboldt estimates the population of the administration at 517,300, and of the capital, in N. lat. 21°. W. long. 105°, at 41,000.

GUANARE, at the end, r. Deponts &c.

GUAXACA, l. 5, after distance, add—between 16° and 18° N. lat., 98° and 112° W. long.; from E. to W. 230 miles, from N. to S. 175 miles. — L. 32, after perons—that of the province 534,800. At the clofe—W. long. 96° 25'.

GUERNSEY, a county of Ohio, containing 9 townships, and 3,050 inhabitants.

GUGA, a town of Scind, in the Perian empire, built at the foot of a hill, at the bottom of which runs a small creek in N. lat. 24° 45'. E. long. 68° 7'; and containing 600 inhabitants.

GUILDER, or GILDER. See Florin.

GUILDFORD, lat lines, r. 495 and 2974.

HANIFAH, Abou, in Biography, a celebrated Mahometan doctor of the 8th century, who was the founder of the sect denominated Hamitites, and who was imprisoned at Baghd by the caliph Almanfor, because he would not subscribe to the doctrine of absolute predestination. He was born at Cufa in the year 700, and died in prison in the 76th year of his age. After his death his doctrine acquired so much reputation; and in the year 1092 a maneulium was erected to his memory, and a college for the votaries of his sect. This college according to his will was not to be unmanfully closed with the following anecdote:—Having received from an adversary a rude blow on his face, he said to the person who thus assaulted him, “I could return you outrage for outrage, but I will not; I could accuse you to the caliph, but I will not; I could pray to God to avenge the affront, but I will not: if the day of judgment were now come, I would pray to God that I might enter heaven with you.” D’Herbelot, Bibl. Orient.

HANOVER, col. 3, l. 6, after Pennsylvania, add— with 63 inhabitants; l. 9, add— the former having 1387, and the latter 2461 persons; l. 14, r. 1171; l. 16, add— containing 2135 inhabitants; l. 22, add— having 3843 inhabitants. — Also, a town of Burlington county, New Jersey, having 2576 persons:— l. 25, r. containing 15282 persons, of whom 8454 are slaves.

HANOVER, a township of Ohio, in Columbiana county, having 735 inhabitants. — Also, a township of Ohio, in Licking county, having 651 inhabitants.

HANOVER, New. Add— Also, a county of New Orleans, having 11465 persons, of whom 6442 are slaves.

HANOVER, Upper, a township in Montgomery county, in Pennsylvania, with 725 inhabitants. — Also, a township in Northampton county, in the same slate, having 939 persons.

— Also, a township in Beaver county, in the same slate, having 1090 persons.

HARAN. Add— This is a town of the pachalic of Orfa, inhabited by wandering Arabs, who were led hither by a plentiful supply of water, and situated in N. lat. 36° 52'. E. long. 36° 52', on a flat sandy plain. See CHARRE.

HARBOROUGH, col. 2, l. 30, r. 1811—335—1704.

HARDEN. See HARDIN.

HARDIN, or HARDEN, r. 7330—803; add— Also, a township of Preble county, in Ohio, having 802 inhabitants.

HARDISTON, a town of Suffolk county, in New Jersey, having 1702 persons.

HARDWICK, l. 2, r. 734; l. 4, r. 1657; l. 6, add— containing 2561 persons.

HARDWICKIA, in Botany, so called in honour of a most able and indefatigable botanist and zoologist, Col. Thomas Hardwicke, F. L. S. long resident in the East Indies. Roxb. Corom. v. 3: 6. — Clavis and order, Deca-

Eff. Ch. Calyx none. Petals five, nearly equal. Legume with one seed.

1. H. binata. Roxb. l. 299. — Native of the mountains of the coast of Coromandel. A large and handsome tree, yielding valuable timber. Leaves alternate, flatked, binato; leaflets unequally elliptical, entire, smooth, from one to three inches long. Flowers numerous, rather small, yellowish, in axillary and terminal panicles. Legume lanceolate, an inch and a half long. Seed wedge-shaped, inferted at the summit.

HARDY, l. 2, r. 5525, of whom 749 are slaves.

HAREWOOD, l. 5. r. In 1811, its five townships contained 259 houses, and 1315 persons.

HARFORD, l. 3, r. 21, 258—4431; add— Also, a township of Luzerne County, in Pennsylvania, having 478 inhabitants.

HARLEM, l. 2, r. 939.

HARLOWE, l. 17; r. 1811; l. 18, r. town and Reddenhall; r. 277—1516.

HARLOW. In 1811, the parish contained 256 houses, and 1663 persons; 883 being males, and 181 females: 191 families employed in agriculture, and 102 in trade, manufactures, and handicraft.

HARMONY. Add— It contained, in 1810, 80 persons. — Also, a township of Ohio, in Champaign county, having 595 inhabitants. — Also, a township of Maine, in the county of Somerset, having 351 inhabitants.

HARP, col. 2, l. 10 from the bottom, for lyre r. liar.

HARPER'S FIELD. Add— Also, a township of Genega county, in Ohio, having 490 inhabitants.

HARPSWELL, a township of America, in Maine, and county of Cumberland, having 1190 inhabitants.

HARRAN. See HARAN.

HARRINGTON, l. 3, r. 469; at the close, add— It contains 2187 inhabitants.

HARRISON, l. 6, r. 9938 inhabitants, of whom 458 were slaves in 1810: l. 9, r. 7883, of whom 989 were slaves.

Add— Also, a town of Maine, in Cumberland county, having 439 inhabitants. — Also, a township of Ohio, in Pickaway county, having 291 inhabitants. — Also, a county of Indiana, containing 2338 inhabitants; of whom, in 1810, 15 were slaves. — Also, a township of the said county, the other being Exeter. — Also, another county in the same territory, which, with its township, Washington, contains 1257 persons, including 6 slaves.

HARROW, col. 2, l. 9, insert— The town, with the hamlet of Roxath and Sudbury, contains 283 houses, and 1689 inhabitants.

HARROWGATE, l. penult. add— The township of Bilston and Harrowgate contains 286 houses, and 1583 persons.

HARTFORD, l. 3, r. 1831; l. 6, r. Oxford for Cumberland; l. 7, r. 720; l. 12, r. 191; l. 13, r. 44773; Hartfort City, l. 11, r. 3955. — Add— Hartford, except the city, a township of Hartford county, Connecticut, contains 2048 inhabitants.

HARTFORD, East, l. 4, r. 3240.

HARTLAND, l. 5, r. 2352. — Add— Also, a town of Hartford county, in Connecticut, having 1284 inhabitants.

HAY, l. 4, r. The parliamentary return of 1811 states the number of inhabitants to be 1599, and that of houses 231. It has one market on Thursday, and five fairs. A woollen manufacture has latter been established here.
HAYLING, l. 5, r. 1811—110—620.
HAYNES, a township of Centre county, in Pennsylvania, having 1757 inhabitants.
HAYTI, a name given by the natives to the island of St. Domingo (which see). The dimensions are differently stated by different writers. Some say, that it extends 140 or 150 miles in breadth from N. to S., and about 400 miles in length from E. to W. Mr. R. Edwards alligns 400 for the length: Rainford says, that it is more than 450. The abbe Raynal represents it as 250 leagues in length, and 60, in some places 80, in breadth. When the French had this island, a proclamation, announcing its independence, was published, signed by Deffalines, Christophe, and Cherveaux, dated Nov. 29, 1803. The liberated blacks now determined on discarding the appellation which the island had received from Europeans, and reviving the name of Hayti, by which it was designated by the aboriginal inhabitants when first visited by Columbus. On the 11th day of the year 1804, the general and chiefs of the army, in the name of the people of Hayti, signed a formal declaration of independence, and took a solemn oath to renounce France for ever, pledging themselves to each other, to their posterity, and to the universe, to die rather than submit again to her dominion. At the same time, they appointed Deffalines governor for life, with power to enact laws, to make war and peace, and to nominate his successor. One of the first acts of his government was to arrange the return of negroes and mulattoes from the United States of America. He also treated with the British agent for Jamaica, offering to open his ports to slave ships, and to allow the people of Jamaica the exclusive privilege of selling negroes in Hayti; intending these not for slavery, but for military service. Some of the French inhabitants had remained upon the general evacuation of the island, confiding in the favour and mercy of Deffalines. But their confidence was misplaced; for in a few weeks he meditated their destruction, and issued mandates, no less pernicious than cruel, for a general massacre. He then proceeded to the subjugation of the few Spaniards who inhabited the eastern part of the island, and with laying siege to the city of Domingo, which was possessed by a small detachment of French troops. In this siege he was unsuccessful; and after his return from it, he assumed the title of emperor. The empire was divided into fixing military divisions, with a general over each, independent of one another. The generals of division and brigade composed the council of state, and they had a minister of finance, another of war, and a secretary of state. All persons decided their differences by arbitration, military crimes were subjected to special jurisdiction: no predominant religion was admitted, nor was the state to provide for the maintenance of any religious institution. Marriage was declared to be an act purely civil, and divorce in private cases was allowed. A census, taken in 1805, of the inhabitants of the part of the island under the power of Deffalines, the returns were about 380,000, to which some incidental omissions of 10,000 were added, making the whole number 400,000. The regular army consisted of 15,000 men, of whom 1500 were cavalry. Considerable attention was paid to the subject of education. The young Haytiens were generally taught to read and write. Deffalines, whilst he possessed several good qualities, was ferocious and cruel; and at length his atrocious acts of tyranny caused an insurrection of the army, which was followed by his premature death by violence, on the 17th of October, 1806. Christophe, who, since the expulsion of the French, had been second in command, immediately assumed the supreme power. He had been a slave in St. Domingo at the revolution in 1791, and an early friend and faithful adherent of Toussaint, whom he resembled in character. Discarding the pompous title of emperor, he modestly designated himself "chief of the government of Hayti." He made several enactments, and issued proclamations favourable to commerce. Petion, however, soon appeared as a candidate for the sovereign power; the struggle between him and Christophe was fierce, and in a battle fought January 11, 1807, between the two armies, Petion was defeated, and felled himself by his own hand. In a council convened at Cape Francois, a new constitution was published Feb. 17, 1807, in which slavery was for ever abolished in Hayti; and the government was vested in a chief magistrate for life, who appointed his successor. The council of state consisted of nine members, two-thirds of whom were generals; so that the government approached nearly to an oligarchy. The struggle for sovereignty still continued, and was carried on for several years; many battles being fought, in some of which Christophe, and in others Petion was victorious. In the spring of the year 1811, Christophe changed the title of president for that of king, and the royal dignity was established by a constitutional act in his person and family. In July 1816, after Louis XVIII. was restored to the throne, commissioners were sent to St. Domingo, entrusted with the administration of all the affairs of the island, both civil and military. These commissioners addressed letters to Christophe, which gave offence. Although the two governments which rule the northern and southern districts have not established any relations of mutual amity, they have remained in
in a state of perfect tranquillity, and have devoted their attention to the cultivation of their respective territories, and to the civilization and improvement of their people. Schools upon a Lancasterian plan have been established. From the zeal manifested by both chiefs in this noble cause of public instruction, and the progress already made in carrying their wife and benevolent designs into effect, there is great reason to hope, that in a few years the island of Hayti will exhibit a population as generally educated as that of any country on the face of the globe. See History of the Island of St. Domingo, &c. London, 1818.

HEARING, col. 2, 1. ult. infrer after CAR. — (see EAR.)

HEAT, col. 2, 1, 2, infrer after CALORIMETER — in the sequel of this article.

Heat. Many important additions have been made to our knowledge respecting heat and its effects, which our limits will only permit us to mention very briefly here. In doing this, we shall follow the same arrangement as that adopted in the original article, and confine ourselves chiefly to the results.

Capacity for Heat, or Specific Heat. — In the year 1813, a malaria elaborate set of experiments was published by Delaroche and Berard, on the specific heat of the gaseous bodies. The results of former experimentalists respecting this part of the subject were not, as we remarked, very satisfactory; but from the care with which the present experiments were made, philosophers in general appear inclined to admit their accuracy.

From the recent experiments of Dulong and Petit it appears, that the capacity of solid bodies follows the same law as that of liquids, that is to say, it increases with the temperatures measured by an air-thermometer. They would be even increasing according to these experimentalists, if we were to employ a mercurial thermometer. See the section Expansion by Heat below. Thus, The mean capacity of iron, from 0° to 100° = 0.192

In the following table, for the other metals they have only given the measures taken at 100°, and at 300°.

Combustion, Heat produced by. — A great number of laborious experiments were made by the late count Rumford on this subject, the general results of which we shall briefly mention, as they differ in some degree from those of his predecessors. Thus, according to him, 1 lb. of

This philosopher likewise extended his experiments to the combustion of woods, with the view of ascertaining which gave out most heat, and under what circumstances. The general results were, that the wood of the lime-tree gives out most heat, and that of the oak the least, during combustion. The extreme limits of his long table, which we regret we cannot give, were, that 1 lb. of lime-wood, highly dried over a chaffing-dish, melted 54.210 lbs. of ice, while 1 lb. of oak, similarly dried, melted only 39.728 lbs.

Expansion of Bodies by Heat. — The law, as recently established by Dulong and Petit, respecting the expansion of the gaseous bodies, has been given under Gas. We confine our attention here, therefore, to the expansion of liquids and solids. The experiments of Dulong and Petit shew, that the expansion of bodies by heat is not uniform, and that the laws of expansion, as laid down by Mr. Dalton, are not to be depended upon. Thus, in the following table of the absolute dilatation of mercury, it will be found that the expansion above the boiling point of water increases as the temperature increases according to the air-thermometer, which from the uniform expansibility of the gaseous is the only one that indicates equal measures of temperature.

In the above table, on the dilatation of glaís, the third column shews that its expansion is not uniform, but increases, except between 0° and 100°, where it is the same as that of Lavafourier and Laplace. The last column contains the degrees which would be indicated by a thermometer formed of
of a glass plate, whose incrustation in length would serve as a measure of temperatures.

When we compare these results with those obtained from gla's, it is seen that the expansibility of solids referred to an air-thermometer is increasing, and that it is unequally so in each of them.

Our readers will observe, that MM. Dulong and Petit used the centigrade thermometer. See further on this subject under Refrigeration.

See an Effay which gained the prize voted by the Academy of Sciences in 1815, entitled Remarks on the Measurement of Temperatures, and on the Laws of the Communication of Heat, by MM. Dulong and Petit.

Animal Heat.—The above determinations of the specific heats of oxygen gas and carbonic acid by Delacroche and Berard, very much diminish the probability of Dr. Crawford's theory of animal heat. But the most formidable objections to this theory reful from the experiments of Mr. Brodie. This gentleman found that when artificial respiration is kept up in the lungs after decapitation, the usual proportion of carbonic acid gas is formed, and the circulation continues nearly as usual, yet that in these animals the heat diminishes more rapidly than in the dead animal in which artificial respiration is not kept up. From these experiments, Mr. Brodie concludes that the production of animal heat is owing to the action of the brain, and not to respiration. See Respiration.

HEATH, in Geography, a town of Hampshire, in Massachusetts, containing 917 inhabitants.

HEAVY Spear. See Mineralogy, Addenda.

HEBRON, l. 2, r. 563; l. 3, r. Oxford for Cumberland; l. 5, add, after Portland—containing 2121 inhabitants; l. 8, r. 2002.

HEIDELBURG, l. 3, r. 3532; l. 6, r. 1433. Add—Alto, a township in Pennsylvania, in Berks county, having 2806 inhabitants.

HEMATIN, in Chemistry, the name given by Cleft to the peculiar matter constituting the colouring matter of the hematoxytan campechianum, or logwood. Hematin may be obtained by digesting, for several hours, logwood-powder in water, of the temperature 125°. The liquid is then to be filtered, evaporated to dryness, and digested for a day in alcohol of the fp. gr. .837. Filter the alcohol, concentrate it by evaporation, then add a little water, evaporate a little further, and leave it to itself. Crystall of hematin are deposited in abundance. Thus prepared, it is in the form of small brilliant crysals, of a reddish-white colour, and a slightly astringent bitter and acrid taste. It is readily soluble in boiling water, and the solutio is of an orange-red colour when warm, which becomes yellow as it cools, but heat again restores the original colour. Acids render it at first yellow, then red; sulphurous acid destroys it altogether. The alkalies and alkaline earths give it a purplish-red colour, and if in excess appear to decompose it. Most of the metallic oxys unite with hematin, and give it a blue colour. Gelatine throws it down in reddish flocks. The other properties of this substance do not appear remarkable.

HEMER-HEMSTED. At the close,Infert—The population of the parish, by the return of 1811, amounted to 3245, and the number of houses to 638.

HEMIQUUS. See Equs.

HEMLOCK, in Geography, a township of Northumberland county, in Pennsylvania, having 879 persons.

HEMPFIELD. Add—The former contains 3431, and the latter 3344 inhabitants.

HENDERSO/N, in Kentucky, l. 2, r. 4544; l. 5, r. 1457. At the close, add—containing 159 persons; of whom 47 were slaves in 1810.

HENLEY upon-Thames, l. 1, r. 1811—522—3177.

HENLEY in Arden, l. 5, r. 1811—242; l. 6, r. 1935.

HENNIKER, a town of Hillsborough county, in New Hampshire, having 1608 inhabitants.

HENRY, l. 4, r. 5611 inhabitants, of whom 1755 were slaves in 1810; l. 6, r. 6652 inhabitants, of whom 1103 were slaves.

HEPATIC, in Botany, so named by the earlier botanists and physicians, from a resemblance in the lobes of these to those of the human liver, is referred to a distinct genus from Anemone, (see that supplementary article,) by professor De Candolle, in his Syl. v. 1. 215, merely because the involucrum is placed very near to the flower, (some have thought it an actual perianth), and its leaves undivided. We hesitate to follow our learned friend in this measure, the certain species of Hepatica being scarcely more than one or two, so that nothing is gained as to convenience, nor is the character very decisive. These species are,

2. H. angulata. Angular, or Serrate, Hepatica. Lamarck Dict. v. 1. 160.—Leaves palmate, with five serrated lobes. Cultivated formerly at Paris, but now lost. It is much to be wished that we could learn more concerning this plant.

3. H. integrifolia, with ovate entire leaves and very hairy stalks, found by baron Humboldt in South America, is not clearly an Hepatica.

HÉPATITÉ. See Mineralogy, Addenda.

HERAT. Add—The ancient Aria or Artacaana, capital of Ariana; l. 4, after name, infert—or Herioccod; l. 5, after which, add—gives fertility to the plain, 30 miles long and 15 broad, upon which Herat is situated, and which,
which, though surrounded with lofty mountains, is highly cultivated, and covered with villages and gardens. The Herat, or Hericoord, afterwards runs, &c.; l. 5, for it. Herat embraces an area of four square miles, and, &c.; l. 6, add—This cattle is of a square form, elevated on a mound, flanked with towers at the angles, and built of burnt brick. The city has a gate in each face, and two in that which fronts the north, and from each gate a spacious and well-supplied bazaar leads up towards the centre of the town. It is well supplied with water, every house almost having a fountain independent of those that are public on either side of the bazaar:—l. 23, add—The residence of the prince is a mean building, having a gallery in the centre of the square, which is situated in its front; and the chief mosque, once a noble edifice, enclosing an area of 800 square yards, is falling into decay. Herat is computed to contain 100,000 inhabitants, 10,000 being Patans, and the rest Afghans, a few Jews, and 600 Hindoos, the last-mentioned of whom are highly respected, and they only pose their capital or credit; hence they derive a very considerable influence. The trade of this city, as we have already said, is extensive, and accordingly it is the emporium of the commerce carried on between Cabul, Cashmere, Buchara, Hindooftan, and Peria. From the former, they receive flax, indigo, sugar, chintz, muslin, leather, and Tartary skins, which they export to Mehded, Yazd, Kerman, Ispahan, and Tehran, receiving in return chiefly dollars, tea, china-ware, broad-cloth, coffee, pepper, and sugar-candy; dates and figs and dates from Kerman and carpets from Ghao. The staple commodities of Herat are, silk, coffee, and assafetida, which are exported to Hindooftan. The gardens are full of mulberry-trees, cultivated merely for the sake of the silk-worm, and the adjoining plains produce assafetida. The winters here are very severe, and the cold often injures the crops; but the fertility of the plain is such that it affords an immense produce both of wheat and barley, and almost of every kind of fruit known in Peria. The cattle are small, but not plentiful, and the broad-tail sheep are abundant. The revenue of this city is estimated at one-third of the revenues of Heran. The prince in possession pays a tribute to his Persian majesty of 50,000 rupees a year. N. lat. 34° 12'. E. long. 63° 14'.

HEREFORD. At the close, add—By the return of 1811, Hereford contains 1539 houses, and 7306 inhabitants. HEREFORD, a township of Berks county, in Pennsylvania, having 1140 inhabitants.

HEREFORDSHIRE, col. 2, l. 7 from bottom, r. 1811—18,572—94,073.

HERKIMER, a county of New York, containing 22,046 inhabitants, of whom 64 are slaves.

Eff. Ch. Calyx spreading. Petals three-lobed, like the lip, which has no spur. Anther fixed, nearly terminal.

HESUS, in Mythology. See Druids.

HEXHAM, l. 4. In the year 1811, Hexham parish, divided into four wards, or townships, comprehended 478 houses, and 3518 persons; and Hexham shire, including four quarters or townships, had 251 houses, and 1328 persons.

HEYNE, CHRISTIAN GOTTLIEB, in Biography, was born at Chemnitz, in September 1729, and ruled from humble life, after struggling with many difficulties, on account of the penury of his condition, to an eminent rank, as a critical scholar and philologist. Although his parents were hardly able to derive a scanty subsistence from their labours, he was sent to school, and made such proficiency in learning, that in his tenth year he was able by teaching others to defray the expences of his own education, and by the affittance of a neighbouring clergyman, he entered himself at a grammar-school; and having acquired a competent knowledge of the Latin and Greek languages, he was sent to the university of Leipzig. Private teaching, however, was his resource for further supplies, and thus furnished he devoted himself to the prosecution of the law; and inductious in his study of the Roman law and history, he was qualified for reading lectures, which were much approved, on the Roman antiquities. Under the patronage and recommendation of count Bruhl, the Saxo minifter, which he obtained by a Latin elegy, he was invited to Drefden, whither he repaired in 1752 with flattering expectations, which were eventually disappointed, so that he was reduced to a state of indigence and distress, without the means of providing either food or lodging. At length necessity compelled him to become a writer, and by one of his performances as a translator of a Greek romance, he acquired that taste for criticism which raised him to that eminence in this department of literature which he afterwards occupied. His next work was an edition of Tibullus, which was followed in 1756 with his first edition of Epictetus. But his prospects, which appeared promising in consequence of his access to the Brulian library, were again precluded by the incursion of the Prufhians into Saxony, which occasioned the sudden removal of count Bruhl from Drefden, and the dispersion of his library. After some changes of situation, he repaired to Drefden in the year 1760; and in the following year married a lady, named Thertha Wels, to whom he had for some time been affectionately attached. In 1763 he was invited to Gottingen to supply the vacant professorship of John Matthias Gfener. The subjects of his first academic lectures were, Horace, the Georgics of Virgil, and some parts of the Tragic writers. In 1766 he explained the Illiad, and afterwards the Greek antiquities. His leisure hours, after his first settlement at Gottingen, he employed as a writer and translator. Having been appointed, in 1763, first librarian to the university, he obtained, in 1770, the title of aulic counsellor, and became secretary to the Royal Society of Sciences, and editor of the Literary Gazette. In 1771, he collected the papers presented to the society for sixteen years, which had been neglected, and published the first volume of the "Commentarii Novi," which was dedicated to the king. The first edition of his Pindar appeared in 1773. His "Catalogue of the Library," begun in 1777, was completed in 1787, and extended to about 150 volumes in folio. But his opus majus, on which he
he bestowed the greatest part of his attention and time, was his edition of Homer, which he began in 1787, and which was presented to the public in 1802. A second edition of his Virgil appeared in 1788; in the revival and improvement of which he derived great assistance from his literary friends, particularly Van Santen in Holland, and Jacob Bryant in England. During the autumn of this year, he made a tour to Switzerland, and formed an acquaintance with several of the most eminent literary characters in that country; and on his return he was offered the place of chief librarian at Dresden, and a professorship at Copenhagen, both of which he declined. The principal object of his attention was the Royal Society of Gottingen, of which he was secretary; and which was enlarged by the admission into the number of its members of several French literati. By means of his reputation and influence, he preferred the society, in 1803, from the miferies incident to a state of war, and from any molestation on the part of the French army. After a tour to Arnitzdt in 1806, on a visit to one of his daughters recently married, his infirmities increased, so that in 1809 he resigned his office as professor of eloquence. In 1810 he was made a knight of the Wellington order of the crown, and died in the month of July 1812. Few persons have been more diligent in the improvement of their time than Heyne, or devoted more time in the day to literary occupations, without excluding himself from domestic and social enjoyments. He was twice married; by his first wife he had one son and two daughters, one of whom was married to George Forster, son of the celebrated Dr. John Reinhold Forster, and on his death to Mr. Huber. By his second wife, who was daughter of George Frederick Brandes, aulic counsellor, he had two sons and four daughters. His works were too numerous for recital within our limits. We refer for an account of them to the General Biogrophy, Appendix.

Vol. XVIII.

HICKMAN, in Geography, a town of Weft Tennessee, containing 2383 persons.

HICKUP, l. 7. add—See Lungs.

HITIANS, the name of a people of North America, who traverse a region extending from the limits of the state of Louisiana to the Rio Gila, and to the eastern declivity of the Californian coast, within a short distance of the shores of the Pacific ocean. In following the herds of buffalo, which change their pasture with the seasons, they resemble the wandering tribes of Tartars and Arabs, who have no settled residence. Encamped where they find water and their prey, they remain as long as they can obtain a supply. The Hitians have domesticated the horse, and vie with the most civilized people in their management of this useful animal, in mounting it and applying its force to the purposes of chase or war. They are the only people, aborigines of this continent, who seem to have acquired the ability to withstand the shock of cavalry furnished with the principles of European tactics.

HIGHAM FERRERS, col. 2, l. 8, r. 1250, and 6627.

HIGHGATE, in America, l. 5, r. 1374.

HIGHWORTH, col. 2, l. wait. r. 1811, contained 480 houses, and 2514 inhabitants.

HILLSBOROUGH, in America, l. 6, r. 49249; l. 11, r. 1592.

HILLCITY, l. 4, r. 1355.

HINEKLEY, col. 2, l. 5 from bottom, r. 1811—6598, and 1697.

HINDON. Add—By the returns of 1811, the borough and parish contained 170 houses, and 781 persons.

HINDSDALE, a town of Berkshire, in Massachusetts, containing 822 inhabitants.

HINESBURGH, a town of Chittenden county, in Vermont, having 1258 persons.

HINGHAM, l. 3 and 4, r. 241—1657.

HINGHAM, l. 1, r. Plymouth for Suffolk; l. 7, r. 2382.

HINSDALE, l. 4, r. 740.

HIRAN, l. 2, r. Oxford for York, and 336; add—Allo, a township of Ohio, in Portage county, having 171 inhabitants.

HIRUNDO. At the close, for Swallow r. Migration.

HITCHIN, l. ult. r. 1811, the hundred of Hitchin and Pilton contained 1520 houses, and 7732 inhabitants.

HOCKSTETT. Add—See Battle.

HOKING, a town of Fairfield county, in Ohio, having 1078 inhabitants.

HODSON, a township of Portage county, in Ohio, having 793 inhabitants.

HOLDEN, l. 3, r. 1072.

HORDERNESS, l. 4, r. 335.

HOLLAND, in America, l. 3, r. 420. Add—Allo, a township of Orleans county, in Vermont, having 126 inhabitants.

HOLLES, l. 4, r. 1529.

HOLLISTON, l. ult. r. 1810—989.

HOLLOW SPAR. See Mineralogy, Addenda.

HOLLY, Mount, in Geography, a town of Rutland county, in Vermont, having 922 inhabitants.

HOLOCENTRUS, in Ichthyology, a genus of the Tho- racic order of fishes; the characters of which are, habit of the genus Pecra; gill-covers scaly, serrated, and aculeated; and scales, in most species, hard and rough. The species enumerated and described by Dr. Shaw are as follow: viz.

1. With forked or lined tail.

SACO. Silvery-red H. with longitudinal yellow lines on each side, very beautiful, about a foot long, resembling a carp, but of a more square form, and becoming suddenly slender near the tail, eyes large and gold-coloured, scales large, and dentilicated at the edges. Native of the Indian, American, and Mediterranean seas, and held in high estimation for the table.

CHRAETER. Brownish H. with four longitudinal black lines on each side, silver abdomen and naked head; the perca character of Gmelin's Linnaeus. Native of the Danube, and of its tributary streams, esteemed for food.

RADULA. H. with the body lineated with white specks; P. radula of Gmelin's Linnaeus. Native of India.

GATERINA. Bluish H. with black specks and scattered spots; Sciencia gaterina of Gmelin's Linnaeus. Native of the Arabian seas, varying in size and colours.

QUINQUILINEATUS. Yellowish H. with brownish back, and body marked on each side by five longitudinal blue lines. Native of Japan.

BENGALENSIS. Subfuscous H., silvery beneath, and marked on each side of the upper part by five longitudinal blueish bands, margined with black. Native of Bengal.

TIGRINUS. White H. with the body tranverse bands, and fins spotted with black. Native of the Indian seas, and esteemed for the table.

DECUSATUS. White, with brown back, and body marked by
by two longitudinal and seven transverse brown bars. Native of the American seas.

**Striatus.** Subluteous H. with brownish back, body marked by transverse brown bands, dorsofin ramentose behind, and marked by a black spot. Native of unknown regions.

**Argentinus.** Brownish H. with silvery sides. Native of regions unknown.

**Niger.** Black H. with extremely minute scales: found about the coast of Cornwall.

**Acerinus.** With fourteen soft and seventeen spiny rays in the dorsofin; perca acerina of Gmel. Linn. Native of the Euxine sea, and esteemed as food.

**Ceruleocrensit.** Blueish H. with all the fins yellow. Native of the Indian seas.

2. With undivided or rounded tails.

**Variegatus.** Red H. with seven transverse black lines, and the head and abdomen varied with blue streaks; perca marina of Linn. Gmel. Native of the Mediterranean and northern seas.

**Cottoides.** With all the fins marked by two speckled lines. Native of the Indian seas.

**Forskalii.** Red H. with four broad transverse whitish bands; perca falcata of Linn. Gmel. Native of the Red sea.

**Tauvinus.** Linear-oblong H. with blackish fimbrious spots; perca tauvina of Linn. Gmel. Native of the Arabian seas.

**Ongo.** Brown H. with the body marked transversely by elongated spots, and the dorsofin, anal, and caudal fins spotted with yellow. A native of Japan.

**Auratus.** Gold-yellow H. with red specks. Native of the East Indies.

**Quadrilineatus.** Silvery H. with brownish back, and body marked above by four longitudinal black lines on each side. Native of the East Indies.

**Fasciatius.** Green-yellowish H. with transverse brown bands divided beneath. Native of a region unknown.

**Punctatus.** Yellow H. sprinkled over with black spots and red points. Native of the Brazilian seas.

**Calcarifer.** Subargentous H. with brownish back, large scales, and spotted gill-covers. Native of Japan.

**Surnamensis.** Brownish H. with subluteous clouds, red head, and anterior gill-covers pimple-ciliated. Native of Surinam.

**Afer.** Oblong-ovate brown H. with small scales and short tail. Native of the coasts of Guinea, in high estimation for food.

**Japanicus.** Red H. with small scales, and blue and yellow irides. Native of Japan.

**Merra.** White H. spotted on all parts with brown. Native of the Japanese seas.

**Testudineus.** Subluteous H. with slightly branching brown bands, blue-striped gill-covers, and blackish fins. Native of the northern seas.

**Marginatus.** Blueish H. with brownish back, red fins, and dorsofin edged on the fore-part with black. Native place unknown.

**Sonnerathii.** Yellowish H. with three transverse silvery bands, edged with brown. Native of the Indian seas.

**Lanceolatus.** Silvery H. transversely banded with brown, and with the dorsofin, anal, and caudal fins subluteous. Native of the East Indies.

**Ceruleopunctatus.** Blueish H. with pale yellow clouds, and deep-brown fins spotted with blue. Native country unknown.

natives of New South Wales. Our *P. elliptica*, L. Tr. v. 9. 305 may be doubtful.

**Houghton-Le-Spring**, in Geography, a township in a parish of the same name, and in Eaglesfield Ward, in the county of Durham. In 1811, it contained 221 houses, and 1356 persons: viz. 663 males, and 693 females; 44 families being employed in agriculture, and 68 in trade and manufacture. The parish includes 18 townships.

**Howard**, a township of Centre county, in Pennsylvania, having 761 inhabitants.

**Howden.** In 1811, this township contained 344 houses, and 1812 persons; viz. 830 males, and 982 females. **Howell,** a township of Monmouth county, in New Jersey, having 2780 inhabitants.

**Hubbardston.** See Hubbardston.

**Hubbard,** a township of Ohio, in Trumbull county, having 674 inhabitants.

**Hubbardston, l. 3, r. 1127.**

**Hubbardston, or Hubbardston, l. 2, r. 734.**

**Huddersfield, l. 27,** r. 1811—1871—6971.

**Hull,** col. 5, l. 9 from bottom, r. 1811; l. 8, 4611; l. 7, 26,792—11,998—14,794.

Hull in America, l. 1 and 2, for Suffex r. Plymouth; l. 3, r. 132—167—943.

**Humeite.** See Mineralogy, Addenda.

**Hummock, l. 12 from bottom, dele the reference (see that article).**

**Humours of the Eye, Chemical Properties of.** See Eye.

**Humphries, in Geography, a county of West Tennesse, having 1511 persons, of whom 132 were slaves in 1810.**

**Hungary, col. 2, l. 33, after inhabitants (in 1810, 7998, 184).**

**Hungerford, l. 2 from bottom, r. 1811—167—2397—454.**

**Huntingdon, col. 3, two last lines, r. 1811—522.**

**Huntingdon,** in America, l. 7, r. 16,778; l. 14, r. 4775; after Philadelphia, add—the township contains 1698 persons; l. 22, r. 2770.

**Huntingdon, North, South, and East, three townships, &c. the former containing 2345, the second 1656, and the last 1267 inhabitants.**

**Huntingdon, a township in Luzerne county, in Pennsylvania, having 1114 inhabitants.**—Alfo, a township of Adams' county, in the same state, having 1014 inhabitants.

—Alfo, a township of Adams' county, in Ohio, containing 1375 persons.

**Huntingdonshire, l. 14, r. 7566 houses, 42,208 inhabitants: 20,402 males, 21,806 females.**

**Huntington, l. 5, r. 514.**

**Huntington, in Connecticut.** See Huntington.

**Huntsburg, l. 3, r. 714.**

**Hurd, Richard, in Biography, an eminent English prelate, was the fon of a reputable farmer, in the parish of Tetherhall, in the county of Stafford, and born in January 1710-20. After a preparatory school-education, he was sent to Emanuel college in the university of Cambridge, where he was graduated M.A., and was elected a fellow in 1742. In 1744 he received priest's orders. As a writer, he began his career by an anonymous work, which was, "Remarks on a late Book, entitled an Enquiry into the Rejection of the Christian Miracles by the Heathens, by William Wetton, B.D. &c." which was highly commended by Dr. Warburton. As a literary critic, he first laid the foundation of his future fame in 1749, by an anonymous publication, entitled "Horace's Epistles to the Pifos, with an English Commentary and Notes," and also of his fortune by a compliment paid in the preface to Warburton, whom he afterwards resembled, not only in his advancement, but in his mode of thinking and of writing. By his recommendation to Bishop Sherlock, he was appointed, in 1750, one of the Whitchall preachers. In 1751, he published a "Commentary on Horace's Epistle to Augustus," referring in learning and ingenuity his former commentary. Both these Commentaries were reprinted in 1753, with two dissertations on dramatic poetry and poetical imitation. This volume was dedicated to Warburton in a high style of pædagogy; and it was followed, in 1755, by a piece, entitled "Delicacy of Friendship," in which the anonymous author, known to Hurd, paid homage to his patron by an attack on Dr. Jortin, who, in his "Six Dissertations," had not treated Warburton with that respect to which, in the estimation of his admirers, he was thought to be entitled. By this pamphlet he gained no reputation, and it is said, that in consequence of some remarks on his subfervient disposition, he was deisirous of supressing it, though it has been since reprinted in a late edition of his works. His first church preferment was a college living at Thurcaston in Leicestershire, to which he was inducted in 1756, and here he lived for several years in retirement. Soon after Hume's "Eflay on the Natural History of Religion" was published, a pamphlet of "Remarks" upon it appeared, of which Hurd was thought to be the author, and which Hume notices in the following terms: "Dr. Hurd wrote a pamphlet against this work, with all the illiberal petulance, arrogance, and frivolity which distinguished the Warburtonian school." These Remarks have been thought to be the joint production of the master and disciple. Dr. Hurd's "Letter to Mr. Mafon on the Marks of Imitation," published in 1757, is represented by his biographer as "one of the most agreeable and ingenious of the writer's works on elegant criticism." Our author's "Moral and Political Dialogues," which appeared in 1759, contributed to the increase of his literary reputation; and those in particular that relate to the English constitution evince the writer's attachment to Whig principles. In 1762 appeared, without his name, an amusing work, entitled "Letters on Chivalry and Romance," 12mo. and in 1764 was published another dialogue on "The Uses of Foreign Travel." The several dialogues now recited were published in 1765, in 3 vols. 8vo. introduced with a preface on the manner of writing dialogue. The defence of his patron and friend had in the mean time occasioned a "Letter to the Rev. Dr. Leland of Dublin College;" in which he vindicates Warburton's idea of an inspired language, stated in his "Doctrine of Grace."

Hurd's preferments in the church had not corresponded to his growing literary fame; but in 1765 he was recommended by bishop Warburton and Mr. C. York to the office of preacher at Lincoln's-Inn; and in 1767 he was collated by the bishop to the archdeaconry of Gloucester. In the following year, he was graduated D.D. at Cambridge, and appointed to preach the lectures on prophecy, embellished at Lincoln's-Inn by Warburton; these were comprized in twelve discourses, which formed a volume of highly valuable theological literature, published in 1772, 8vo. with his explication of the double sense of prophecy, called by him "a divine artifice." With that excess of ingenuity which in some cafes seems to derogate from the simplicity of the gospel, some have been dissatisfied. Having embellished his reputation both as an elegant writer and an ingenious theologian, Dr. Hurd was promoted without solicitation to the see of Lichfield and Coventry in 1775; and in his first charge to the
the clergy of his diocese, the subject to which he directed their attention was the excellence of the liturgy, inculcating at the same time the duty of submitting all alterations to the wisdom of the church, and thus guarding against that disposition to reform which was manifesting itself among those who formed a considerable party pertaining to the establishment.

In the following year, the learned prelate had the honour of being preceptor to the Prince of Wales and his brother the duke of York. In the same year, he published a volume of sermons preached at Lincoln’s-Inn; to which, in 1780, he added two additional volumes, containing a variety of elegant discourses, orthodox with regard to their theology, and conformable to the articles of the church, which he professed highly to venerate. His translation to the fee of Worcester took place in 1781, when he was also nominated clerk of the cefet; and though he was offered the primate in 1783, he declined the acceptance of this high dignity. In his retired station at the episcopal seat of Hartlebury, he passed the remainder of his life in attending to the concerns of his diocese, pursuing his literary avocations, and collecting a noble library, which he bequeathed as an heirloom to the fee of Worcester. Of his minor publications, both before and after this period, we shall take no notice; but content ourselves with mentioning his edition of the works of his esteemed friend the bishop of Gloucester, presented to the public in 7 vols. 4to. in 1788; adding afterwards, v. 2 in 1794, an account of the life, writings, and character of the author. With this performance he terminated his literary labours; and after a gentle and easy decline, he expired, in his sleep, in May 1808, four months after the completion of his 88th year. The literary character of this prelate may be duly appreciated by a perusal of his writings; but with respect to his private character and conduct, we shall adopt the opinion and language of a candid biographer, who says of him, “if a fair abatement be made on account of some literary arrogance and acrimony, probably derived from the same source,” (referring to familiarity with the writings of Warburton) “they will merit unqualified praise. His strict regard to decorum, his liberal courtesy, his warmth of friendship, his moderation and disinterestedness, rendered him equally an object of regard and esteem.” Gen. Biog.

HURON, in Geography, a town of Cayahuga county, in Ohio, having 424 inhabitants.

HUTCHINSON, in Botany, dedicated to the memory of the late Mr. Hutchins, of Ballylickey, near Bantry, in Ireland, a most intelligent and accomplished botanist.—Br. in Ait. Hort. Kew. v. 4. 82. Sm. Compend. 98.—Cliffs and order, Tetradyrrama Siliculofa. Nat. Ord. Siliculofa, Linn. Crucifers, Jaff.

HYDE, I. 4, p. 6029—1882.

HYDE-PARK, I. 2, p. 261.

HYDRODATES, HYDRIODIC Acid, in Chemistry.

See Simple Bodies.

HYDROCHLORIC Acid. See Muriatic Acid, and Chlorine.

HYDROCYANIC Acid. See Cyanogen and Prussic Acid.

HYDROGEN. For the recent determinations respecting the specific gravity, &c. of this gas, see Atomic Theory.

HYDROGEN, Arsenical. See Arsenic.

HYDROGEN, Boruretted, the name of a gaseous compound of hydrogen and boron. The existence of such a gas, however, seems somewhat uncertain. Dr. Thomson thinks Gmelin succeeded in forming it by mixing together four parts of iron-dustings, and one part of boracic acid, and exposing the mixture to a strong heat for half an hour. When this fused mass was dissolved in muriatic acid, an effervescence took place, and a gas, supposed to be boruretted hydrogen, was extracted; but it was not satisfactorily examined. Sir H. Davy endeavoured in vain to unite boron with hydrogen by heating them together.

HYDROGUERET of Carbon, Phosphorus, and Sulphur, the names by which some have chosen to distinguish compounds of hydrogen with these respective substances, and which were formerly called carburetted, phospburetted, and sulphuretted hydrogen.

HYDROPHILUS. At the close, add—The genus hydrophilus, like that of dytiscus, has been greatly increased by the perverting researches of modern entomologists. Mr. Marsham enumerates twenty-eight British species.

HYDROPHOSPHORIC Acid, HYDROSULPHURIC Acid, HYDROTHIONIC Acid, in Chemistry, names which have been given, the first to phospburetted hydrogen, the last to sulphuretted hydrogen.

HYGROMETRY, col. 13, l. 22, add—Mr. Leflie's improved hygrometer is composed of a tube of ivory, containing quicksilver, with a glass tube adapted to it, to which a scale of equal parts is attached. When the ivory yields moisture to the air, which it does according to the dryness of the atmosphere, it contracts, and presses the quicksilver higher in the tube; when it imbibes moisture from damp air, it swells, and allows the quicksilver to subside. Mr. Leflie finds, however, that these variations do not correspond with the real measures of atmospheric dryness or humidity; near the point of extreme dryness, they are much augmented; while they diminish rapidly towards the other extreme. The addition of another scale, therefore, corresponding to this inequality, is necessary; and even with this, it cannot be regarded as either an accurate or delicate instrument.

There are other circumstantialties, fays the professor, connected with evaporation, on which an hygrometer may be constructed; particularly the dilatation imparted to the air by the vapour, and the depression of temperature produced on the humid surface.

On the fift of thefe he has invented an hygrometer consisting of a small tumbler, the mouth flat, having a hole ground through the bottom, in which is cemented a flender recurved tube, like a pyphen, containing a portion of coloured oil. A few drops of water being put on a glass plate, and the tumbler being printed upon this, the included air diffuses moisture proportional to its dryness; and the increased elasticity, thus communicated to the air, causes the column of oil in the tube to ascend. This instrument, however, requires adjacent in its management, which renders it difficult to obtain with it results perfectly precise.

On the other principle, Mr. Leflie has constructed what

3 T. 2

He
he regards as the most accurate hygrometer. It is a happy application of the differential thermometer. One of the balls is coated with fine cambric paper, and the paper is moistened with pure water. Evaporation takes place; and, from the cold which accompanies this, the liquid falls in the opposite item. The extent of its defect is measured by the scale attached. This indicates the degree of cold; this, again, the extent of evaporation; and this, lastly, indicates the relative dryness of the air, the evaporation being proportionally greater as the air is more free from moisture. The full effect is very soon obtained—generally in about two minutes; and it continues permanent under the same circumstances, as long as moisture is supplied to the covered ball.

This ingenious author observes, in consequence of experiments adapted to the purpose, that the condition of the atmosphere, with regard to dryness, is extremely variable.

In our climate, the hygrometer will, during winter, mark from 5 to 25 degrees; but, in the summer months, it will generally range between 15 and 55 degrees, and may even rise, on some particular days, as high as 80 or 90 degrees. In thickest fogs, the instrument flanks almost at the beginning of the scale; it commonly falls before rain, and remains low during wet weather; but it states powerfully in continued tracts of clear and warm weather. The greatest dryness yet noticed was at Paris, in the month of September, when it reached 120 degrees. But for want of observations, we are totally unacquainted with the real state of the air in the remote and tropical climates.

When the indication of the hygrometer does not exceed 15 degrees, we are directed by our feelings to call the air damp; from 30 to 40 degrees we begin to reckon it dry; from 50 to 60 degrees we should account it very dry; and from 70 degrees upwards we might consider it as intensely dry. A room is not comfortable, or perhaps wholesome, if it has less than 30 degrees of dryness; but the atmosphere of a warm occupied apartment will commonly produce an effect of upwards of 50 degrees.

Mr. Leflie has invented another instrument, which gives indications of the quantity of evaporation from a humid surface in a given time—which he has named the atmometer. It consists of a thin ball of porous earthen-ware, two or three inches in diameter, with a small neck, to which is cemented a long and rather wide tube, bearing divisions, each of them corresponding to an internal annular section, equal to a film of liquid that would cover the outer surface of the ball, to the thickness of the thousandth part of an inch. To the top of the tube is fitted a braze car, having a collar of leather, which, after the cavity has been filled with distilled or boiled water, is screwed tight, to prevent the tranfusion of the liquid from being fo copious as to drop from the ball. Evaporation of the water takes place from the external surface, the instrument being suspended in the air; and the quantity evaporated in a given time, is discovered by the defect of the liquid in the tube. The use of this instrument will require some dexterity, particularly in adjusting the pressure of the collar; and its indications are slow,—but it may often be employed with advantage, where it is of importance to ascertain the actual rate of evaporation.

From a variety of observations on the subject of evaporation he infers, that air has its dryness doubled at each rise of temperature, answering to 15 centesimal degrees. Thus, at the freezing point, air is capable of holding a portion of moisture represented by 100 degrees of the hygrometer; at the temperature of 15 centigrade, it could contain 200 such parts; at that of 30, it might diffuse 400; and at 45 on the same scale 800. Or, if we reckon by Fahrenheit's divisions, air absolutely humid holds, at the limit of congelation, the hundred-and-fiftieth part of its weight of moisture; at the temperature of 59 degrees, the eightieth part; at that of 86 degrees, the fortieth part; at that of 113 degrees, the twentieth part; and at that of 140 degrees, the tenth part. While the temperature, therefore, advances uniformly in arithmetical progression, the diffusing power which this communicates to the air mounts with the accelerating rapidity of a geometrical series.

The theory of the precipitation of rain, which he founded on this principle, requires, as he says, the affirmation, not merely of the mixture of two mists of air at different temperatures, saturated with moisture, but the continued contact of two currents of air under these conditions; as it is thus only that a sufficient quantity of water will be furnished to form that copious precipitation which constitutes rain. And he adds a calculation, founded on the preceding law, which illustrates this, and illustrates exceedingly well, the general theory.

We shall here take occasion to observe, that as the capacity of air for heat is increased by its rarefaction, its disposition to hold moisture in solution appears to be increased by the same cause; and at the same time the removal of pressure, which is the consequence of the rarefaction, facilitates the transition of water into vapour. From these causes, if the hygrometer be suspended within a large receiver, from which a certain portion of air is quickly abraded, it will sink with rapidity. But the effect is only momentary, for the rarefied air soon becomes charged with moisture, and consequently ceases to act on the wet ball of the thermometer. Hence there is every reason to believe that the higher regions of the atmosphere are drier than those beneath; and, without this condition, Mr. Leflie remarks, our globe must have been shrouded in darkness; for the cold which reigns in the upper strata, would have prevented the humidity from ascending to a great elevation, and have precipitated it in continual fogs or clouds. In the actual state of things, the diminution of temperature, in ascending, predominates at first over the augmented power of aqueous solution; and the air becomes damper till a height be reached, at which the opposite effects of cold and rarefaction are balanced. Above this, which is the proper region of the clouds, the influence of the rarity of the medium exceeds that of the cold, and the air therefore becomes progressively drier, until it melts away into the clear ethereal expanse.

On this principle is founded the very beautiful experiment invented by Mr. Leflie, of causing water to freeze by the cold produced by its own evaporation. The peculiar arrangement for this consists in placing water in a porous earthen cup, suspended within the receiver of an air-pump, and placing, at a short distance beneath it, sulphuric acid in a broad shallow vessel, so that an extensive surface of the acid shall be presented. On rarefying the air, the evaporation of the water is accelerated, and of course the degree of cold produced by that evaporation is increased. This, however, would soon be checked by the presence of the watery vapour; but this the sulphuric acid absorbs, almost as quickly as it is formed; keeps, therefore, the rarefied air always dry; and thus allows the evaporation to proceed with the same rapidity. The temperature, therefore, continues to fall, until the water freezes into crystals of ice; and even after it is entirely congealed, the ice continues to suffer evaporation, until it wholly disappears. See Leflie's Short Account of

HYPERSTONE. See MINERALOGY, Addenda.

HYPOCHLORHYDRIC ACID. See PHOSPHORUS.

HYPERUS, in Ornithology, a genus of birds of the order Passeres; the characters of which are, beak conic, straight and ferrated; nostrils ovate; tongue short and obtuse; feet with three toes, two before and one behind. There is one species, viz. H. Abyssineus, or black plant-cutter, with the head, throat, and jugulum red, wing-coverts brown, with white margins. It is found in Abyssinia, and, according to Mr. Bruce, it is a solitary species, and subsists on the kernels of almonds and other seeds, which it easily breaks with its strong ferrated beak. It frequents woods, and is called "Guifso batim dimmo-won jerck."

Ice, col. 4, l. 43, add—clouds and frequent changes of wind being certain preventives of its formation; l. 44, Dr. Wells, in his Essay on Dew, &c. has given an account of the processes described by Mr. Williams, which, from its extent, 300 persons being employed in it, must have been carried on for profit, and of course would be conducted in the most economical manner. "A piece of ground, nearly level, containing about four acres, was divided into square plots, from four to five feet wide, which were surrounded by little mounds of earth, four inches high. In these inclosures, previously filled with dry straw, or sugar-cane haum, were placed as many broad, shallow, unglazed earthen pans, containing unboiled pump water, as they could hold. The air was generally very still, when much ice was formed; wind prevented its formation altogether. In the morning, between five and six o'clock, at which time alone, Mr. Williams made his observations, a thermometer, with its bulb naked, placed on the straw, amidst the freezing vessels, was never found by him lower than 35°; and he has observed ice, when a thermometer placed was 42°. Another thermometer, suspended five feet and a half above the ground, was commonly 4° higher than that among the pans. It is possible, therefore, that Mr. Williams may have seen ice, a little before sun-rise, when the temperature of the air was 40°. But granting this were the fact, it would not hence follow, that the ice was formed, while the air polflefeled that heat. For, although the air is generally held to be in all countries colder about sun-rise than at any other time, I know, from my own observations, that this is not always the case in England; and similar exceptions may occur in Bengal."

The formation of ice in the circumstances above specified is ascribed by Dr. Barker wholly, and by Mr. Williams in great measure, to cold produced by evaporation; and this opinion has been adopted by bishop Watson, Thompson, Young, Davy, and Leslie. Dr. Wells, however, is of opinion, that they have not fully considered the subject, alleging several reasons against it. He conceives, agreeable to his sentiments respecting the formation of dew (see Dew), that the formation of ice in Bengal depends upon the radiation of heat to the heavens. This cause, he says, not only exists, but exists in a degree sufficient for the production of the effect which he attributes to it. To this purpose he observes, that according to Mr. Leslie (on Heat, p. 80.) the power of water to radiate heat exceeds, perhaps, that of
all other substances. Ice, he adds, is chiefly formed in Bengal during the clearest and calmest nights; and on such nights the greatest cold, from radiation, is perceived on the surface of the earth. Moreover, the cold that produces this effect in Bengal appears, in its greatest degree, like cold from radiation in other substances, on those mild and serene nights, during which little dew is deposited by the atmosphere. He further adds, that clouds and wind prevent the formation of ice in Bengal; and that the same flates of the atmosphere either prevent, or considerably diminish, the occurrence of cold from the radiation of heat at night by bodies on the ground. From experiments, in procuring ice in the manner of Barker and Williams, Dr. Wells found reason for inferring, that water may freeze at night, in air of a temperature higher than 32°, not only without any loss of weight from evaporation, but with a gain of weight from an opposite process: and he concludes in general, that the formation of ice in Bengal, in the circumstances described by Barker and Williams, must be attributed, in far the greater measure, if not altogether, to a loss of heat, which the water suffers by its own radiation, while situated in such a manner, that it can receive little heat from other bodies, either by radiation or conduction. Our author, in the course of his experiments, found, that evaporation from water of 32° produces very little cold, even in the day-time: and he thinks it much more probable, that on a clear and calm night, though in a dry winter of Bengal, water at the temperature of 32° will acquire warmth from the formation of dew upon it, than that it will become cold from evaporation.

ICHNEUMON. Add—The characters are, mouth with jaws, without tongue; antennae with more than thirty joints; abdomen in most species foot-flaked; piercer exserted, with a cylindric-bivalve sheath. The animals of this genus deposit their eggs in the bodies of other living insects, and generally in the hofe of caterpillars. Here they hatch, and the young larvae, resembling small white maggots, nourish themselves with the juices of the unfortunate animal, and at length the young brood of ichneumon larve creep out by perforating the skin in various places, and each spinning itself up in a small oval flaken case, changes into chrysalis, the whole number forming a group on the shrivelled body of the caterpillar which had afforded them nourishment, and, after a certain period, emerge in the state of complete ichneumons. The principal species are, glomeratus, eumerus, ovum, uramidus, lutes. See Vespa, and Wasp.

ICTUS SOLARIS, A Stroke of the Sun, denotes the effect of a too violent influence of the sun upon the head. It is ranked by Dr. Cullen as a variety of apoplexy, under the name of "Carus ab infolatione."

IDA. Add—The summit of Ida is denominated Gar- garius; and it affords a level surface, of no great extent, but of an oblong form, with a rudely-built wall around it, in which are small blocks of marble. This inclosure, if conjectured, may have been a Greek church, or perhaps only a sheep-pon, united for the protection of the flocks in the summer months.

IDOCRASE. See Vesuvian.

IDOLATRY. col. 5. l. 15 from the bottom, for even r. ever.

JEDBURGH. In 1811, the burgh and parish contained 669 houses, and 4454 persons; vis. 1957 males, and 2497 females: 399 families being employed in agriculture, and 405 in trade and manufactures.

JEFFERSON. (See Jackson.)—Also, a county of the Missippiri, containing 4001 inhabitants, of whom 1792 were slaves in 1810.—Also, a township of Clarke county, in the Indiana territory.

JEFFERSON, in Kentucky, l. 3, r. 11, 611; l. 4, r. 5746; l. 7.—It contains, together with Louiville, 6111 inhabitants, the slaves in the county being 2080, and in the town 256; l. 9, r. 7309 inhabitants, of whom 783 are slaves; l. 14, r. 1971; l. 11 towns with 17,260 inhabitants, of whom 6001 are slaves; l. 14, after St. Clereville, add—Also, a town of Adams' county, in Ohio, having 494 inhabitants.—Also, a town of Fayette county, in Ohio, having 327 persons.—Also, a township of Madison county, in Ohio, having 246 inhabitants.—Also, a township of Montgomery county, in Ohio, having 1343 inhabitants.—Also, a township of Muskingum county, in Ohio, having 962 persons.—Also, a township of Preble county, in Ohio, having 385 inhabitants.—Also, a township of Scioto county, in Ohio, having 258 persons.—Also, a township of Geauga county, in Ohio, containing 168 inhabitants.—Also, a town in Maine, in Lincoln county, having 1205 inhabitants; l. 16— also, a county of Virginia, containing 11,581 inhabitants, including 3552 slaves; l. 17, for Grantham r. Coos, New Hampshire; do. r. 197; l. 19, after Scottville, add—Also, a county, containing 161 inhabitants.—Also, a township of Greene county, in Pennsylvania, having 1124 inhabitants.—Also, a county of New York, containing 15,140 inhabitants.

JERICO, l. 4, r. 1185.

JERSEY, New, after the table, add—By the census of 1810, the whole number of its inhabitants is rated to be 245562, and that of slaves 10851. See each county, and United States.

JESSAMINE, l. 2, r. 8219 and 2466.

Vol. XIX.

INCUBATION, dele the account of the figures.
INDEPENDENCE, in Geography, a town of Suffolk
county, in New Jersey, containing 1224 inhabitants.
INDIANA. After the table, add—According to the
census of 1810, Indiana is divided into five counties, viz.
Dearborn, having 7210 inhabitants; Clark, with 5070;
Harrison in two divisions, having in one 2338, and in the
other 1257 inhabitants; and Knox in two cantons, one
having 4907, and the other 3848. See United States.
INDIANA, in Pennsylvania. Add—Indiana contains nine
townships, and 6214 inhabitants.—Alto, a township of
Alleghany county, in Pennsylvania, containing 692 inha-
bitants.

INDICATOR, Honey-guide, in Ornithology, a peculiar
genus formed of the Cuculus Indicator; the characters of
which are, beak strong, conical, dilated at the base, narrow
towards the tip, the upper mandible bent and carinated, the
lower one recurved at the tip; nostrils slightly covered with
feathers, feet simple, with two toes before and two behind.
The external hinder toe longest, armed with a stout claw.
See Cuculus, and for Dr. Sparrman's account of it, Phil.
Trans. vol. lxxxv. p. 38.

INDIGO, Chemical Properties of. The indigo of com-
merce is exceedingly impure, and seldom contains more
than half its weight of real indigo. Thus, Bergmann could
only obtain 47 per cent. of real indigo from the purest speci-
men he could procure; and more lately Chevrel from the belt
Guatamala could only obtain 45 per cent. The following
analysis of Chevrel will give some idea of the substances
with which the indigo of commerce is adulterated.

Substances separated by water

| Substance                           | ... | ...
|------------------------------------|-----|-----
| Ammonia                            | 5   | 2   |
| Dióxygenified indigo               | 12  | 16  |
| Green matter                       | 46  | 46  |
| Bitter matter                      | 13  | 13  |
| Red matter                         | 7   | 7   |
| Muriatic acid                      | 1   | 1   |
| Alumina                            | 1   | 1   |
| Silica                             | 1   | 1   |
| Pure indigo                        | 1   | 1   |
| Total                              | 100 | 100 |

The principal properties of indigo have been already
detailed. The effects of nitric acid upon indigo, however,
as ascertained by Mr. Hatchett, have been omitted, and are
so interesting that they deserve to be mentioned.

Nitric acid acts on indigo with great violence, so as even
to set fire to it when concentrated, as was long ago observed
by Woulfe. When the acid is dilute, the action is less
violent. Mr. Hatchett, however, found, that when diluted
with an equal quantity of water, the action of the acid was
still so violent as to require further dilution. When the
effervescence had nearly subsided, the liquid was placed on a
sand-bath for some days, and evaporated to dryness. Water
poured upon this redfluid dissolved a considerable portion of
it, and formed a beautiful deep yellow solution of an
intense bitter taste. This solution contains only a very
small portion of oxalic acid; but with a solution of if you
or its it forms a copious yellow insoluble precipitate, and hence
contains a portion of artificial tannin; with ammonia, crystals
precipitate, consisting of bitter principle combined with
ammonia.

When four parts of nitric acid are poured upon one part
of indigo, the pigment soon loses its colour, and is dissolved.
The solution becomes yellow, and a thin layer of a renin-
like substance appears on the surface. This substance
becomes solid on cooling if the procures be now flopped. If
it be removed, and the solution be evaporated to the con-
fistency of honey, redissolved in hot water, and filtered,
pa-day throws down yellow iscopical crytals, consisting of
bitter principle combined with potash. These crytals have
the property of detonating with a purple light when wrapped
up in a paper, and struck with a hammer; the reyn by
further treating it with nitric acid may be converted into the same
bitter principle. If the procuses be flopped sooner than the
point above-mentioned yellow crytals are obtained, which
on solution become white, and appear to posses the prop-
erties of benzoic acid. Thus it appears, that by treating
indigo with nitric acid, it is converted into tannin, oxallic
acid, benzoic acid, and bitter principles.

INDRA, col. 2, 1, 32 and 33, read thus, without a
break; and omitting INDRA Malwa.—Malwa, the hereditary
person of, &c.

INDUSTRY, in Geography, a township of America, in
Maine, county of Somerfet, having 562 inhabitants.

INFLAMMATION of the Breast. See Breast, In-
flammation of, in the Atlcida.

INGA, in Botany, an American name, recorded by
Marcgrave, and adopted by Plumiier. It was funk in
Mimosa by Linnaeus; but Humboldt and Bonpland have
separated from the original genus of Plumiier, have
retained the appellation he had chosen, and they are followed
by Willdenow, as well as by Brown and Aiton in Hort.
Kew. If any barbarous name be tolerated, and they
can hardly be all expunged, the present is unexceptional.

Hort. Kew. v. 5. 15. Clasf. and order, Polygania Mon-
ocica ; rather Monadelphia Polyandria. Nat. Ord. Lamen-
taces, Limn. Leguminosae, Jutt.

Eff. Ch. Calyx five-toothed. Corolla tubular, five-
toothed. Stamens united into a cylindrical tube. Legume
of one cell. Seeds imbedded in pulpy tunics. Some
flowers without a pistil.

Obv. If Mimosa be divided at all, the present numerous
genus may commodiously be separated from it, though the
inflorescence, and structure of the flowers, come, in many
instances, very close to Acacia; see that article, as well as
Mimosa and Desmamthus. From the last, Inga is truly
distinct, in having monadelphous indefinitely numerous
flowers, no neuter, though so many male, flowers, and in
every instance a very different fruit. The greater size of the
leaflets is characteristic of Inga, and they are, for the most
part, differently compounded from those of the other genera.
Willdenow enumerates fifty-eight species, some of them truly
superb in their flowers. We shall give examples of this
writer's fix sections. The leaves of this whole genus are
compound; some of them sensitive.

Sect. 1. Leaves twice yoked. Eleven species.
1. dulcis. Sweet Inga, or Sappan Fruit. Willd. n. 3;
Ait, n. 1. (Mimosa dulcis; Roxb. Corom. v. 1. 67. t. 99.)

2. Thorns bipetalous, straight. Leaflets elliptic-oblong,
somewhat pointed. Fruits with few glands. Cluster
compound, terminal. Flowers capitatis. Legume twifled.

—Native of the Philippine islands. Cultivated on the coast of
of Coromandel, for the sake of its sweet pulpy red fruit, which is six inches long, wholesome, though rather impish. Flowers small, white.

Sect. 2. Leaves thrice pinnate. Five species.

Sect. 3. Leaves pinnate; common flake winged. Thorns none. Twelve species.
I. vera. Common Inga. Willd. n. 17. Ait. n. 3. (Mimofa Inga; Linn. Sp. Pl. 1498. Inga flore albo cimbratio, fructu dulci; Plum. Ic. 14. t. 25. Arbor; Merian. Surin. t. 51.)—Leaflets about five pairs, ovate-oblong, pointed, smooth, with a gland between each pair. Corolla hairy. Legume furrowed, downy. Native of South America and the West Indies, where the legumes are esteemed for their agreeable sweetmeats.
I. furtuofa. Stately Inga. Willd. n. 25. (Mimofa furtuofa; Jacq. Fragnm. 15. t. 10.)—Leaflets about four pairs, ovate, pointed; hairy beneath; with a flaked gland between each pair. Corolla hairy. Legume hairy, compressed, twisted.—Native of the Caraccas. We have from Dr. Merter a fine dried speciem, such as that from which Jacquin's plate is taken. This is a truly magnificent plant, whose copious large tawny flowers, with long crimson filaments, make a splendid appearance. The leaflets are from two to five inches long. Legume broad, flat, but containing a sweet pulp, with large oval seeds.

Sect. 4. Leaves pinnate; common flake simple. Thorns none. Ten species.
I. nodofa. Knobbed Inga. Willd. n. 29. Ait. n. 6. (Mimofa nodofa; Linn. Sp. Pl. 1498. Phaeolus arbores, &c.; Phil. Phyt. t. 121. f. 5.)—Leaflets two pair, ovate-oblong, smooth, undivided by the rib; the lower ones smaller, with a gland between.—Found in Ceylon and Cochinchina. It appears to have been raised in the English and Dutch flaves, but not preferred. The leaflets are from one to two inches long, their two fides very unequal.

I. purpurea. Purple Inga, or Soldier-bush. Willd. n. 42. Ait. n. 8. (Mimofa purpurea; Linn. Sp. Pl. 1500. Andr. Repol. t. 372. Acacia frutescens, &c; Plum. Ic. 6. t. 10. f. 2, the Linnaean character misapplied.)—Leaflets four pairs, oblong, obtuse; unequal at the base. Footstalks without glands. Heads of flowers flaked.—Native of the West Indies. The leaflets are half an inch long, smooth. Flowers copious, very conspicuous for their long tassels of crimson filaments.

Sect. 6. Leaves doubly pinnate. Eleven species; some thorny.
I. Saman. Great Downy-leaved Inga. Willd. n. 49. (Mimofa Saman; Jacq. Fragnm. 15. t. 6.)—Thorns none. Leaves with five pair of primary divisions; leaflets five or six pair, elliptic-obovate, obtuse; terminal ones unequalied; all downy beneath as well as their flake.—Native of the Caraccas. One of the largest and floutest trees of the Mimofa tribe. Leaves two feet, or more, in extent, with a impressed gland at every subdivision. Legume flat, seven or eight inches long.

INGESTONE, l. 5, r. 98 and 640.

INSTITUTE, National, &c. col. 2, after line 6, add—By a royal edict, passed the 26th of March, 1816, the first clafs refumes the name of the Royal Academy of Sciences, preferving the organization and distribution of ftentions.

INVERARY, col. 2, l. 8 and 7 from bottom, r. 103 and 113.

INVERKEITHING. Add—The burgh and parifh of Inverkeithing, by the last returns in 1811, contained 581 houfes, and 2400 perfons.

INVERNESS, col. 2, l. 7, 8, 9, r. The burgh and parifh was returned, under the act of 1811, containing 577 houfes, and 10,775 inhabitants.

INVERNESS-SHIRE, l. 10 and 11, r. comprehended, in the year 1811, 78,336 perfons, occupying 14,646 houfes; 35,722 being males, and 42,614 females.

INVERURY. In 1811, the burgh and parifh contained 205 houfes, and 907 perfons; 453 being males, and 454 females.

INULIN, in Chemical, a name given by Dr. Thomson to a flubstance extracted by Rofe, from the Inula helenium, or Elecampane. This flubstance is extracted by boiling the roots in water, and putting by the decoction to cool, when the inulin is deposited in the form of a white powder. Inulin resembles flarch in its appearance, and some of its properties. It is principally distinguished from flarch by separating from water after boiling in the form of a white powder. Inulin has been found by Dr. John in the roots of several other plants.

IOANNA. Add—In 1809, this ifland was visited by the favages of Madagascar, called Malagacars, who laid fiege to the principal town, and defroyed the crops, and thus reduced the inhabitants to the moft deplorable flate; fo that nearly 200 women and children perihed of hunger, and numbers of the latter were actually eaten by their parents, fo that these favages have nearly defolated the Comorof iflands. The once happy and flourishing ifland of Ioanna, with its 370 towns and f Villages, so enchantingly defcribed by Sir William Jones, is now reduced to two walled towns, and a population of 5000 fows.

IOANNINA, a city of Albania, the capital of Ali's dominions, situated on the weftern banks of a lake of the fame name, at about two miles from its eaftern extremity. In its uptem length, it may be, perhaps, about two and a half miles, and in breadth nearly a mile. Near the lake it flands on a flat, but the northern and weftern parts are built on flpes of rising and uneven ground. A triangular peninfula juts into the lake, and contains the reftidence of the pacha, being defended by a fortification at each angle. The entrance into these forts is over a draw-bridge. There is one ifreet which runs nearly the whole length of the town, and another that intercefs it at right angles, extending to the forts; there are the principal ifreets. Many of the houfes are large and well built, containing a court-yard, and having warehouse or flables on the ground, and the apartments of the family above. A flight of wooden flies and a gallery connect the under and upper parts of the houfes. Although gloomy in appearance, with small windows fatted with crofs bars of wood, the yard is furnifhed with orange and lemon trees; and the bell houfes communicate with a garden, and the galleries are sufficiently spacious to allow scope for walking in rainy weather. The bazaar, or principal ifreet, inhabited by trademen, has a fhowy appearance; the bizelefen, or covered bazaar, is of confiderable size, and would put one in mind of Exeter Change in London. Beside the palace of the pacha, and two houfes allotted to the sons of Ali, there is another fummer refidence of the vizier's in the fruburbs, at the N.W. end of the town. Beyond the pavilion,
pavilion, there are gardens belonging to the principal inhabitants of Ioanna, most of whom have summer-houses. The population is variously stated: some compute the number of houses at 8000, and others estimate the number of inhabitants at no more than 35,000. From the commercial transactions of this city, the vizier draws a revenue of 250,000 piastras. Hobhoue's Journey through Albania, &c.

IODATES, IODIC ACID, IODIDE, in Chemistty. See Simple Bodies.

IODINE. This newly discovered elementary substance has been correctly described under Simple Bodies, to which, therefore, we refer our readers.

JOHN of Gaunt, l. 2, for third r. fourth.

JOHNSBUROUGH, Sr. 1, 3, r. 1330.

JOHNSON, l. 2, r. 4867; l. 3, r. 2330. Add—Alfo, a town of Franklin county, in Vermont, having 494 inhabitants.

JOHNSTON, l. 3, r. 1516. Olee the last paragraph, and insert—See Johnson.

JOLITE. See Mineralogy, Addenda.

JONES, l. 3, r. 4968 inhabitants, of whom 2375 were slaves in 1810.—Alfo, a county of Georgia, which, with its town Clinton, contains 8597 inhabitants; the number of slaves belonging to the county being 2574; and to the town 63, in 1810.

JONESBOROUGH. Add—a township of Washington county, in Maine, having 523 inhabitants.

JOSEF, Sr. 1, 6, r. Tucuman.

IPECACUANHA, l. 33, add—The plant is now known to be the Calliococa.

IPECACUANHA, Chemical Properties of. See Emetin.

IPSCHW, l. 6. In the year 1811, by the parliamentary returns, it contained 2732 houses, and 13,670 persons.

IRA, a town of Rutland county, in Vermont, having 519 inhabitants.

IRAC, l. 17, after wine, add—This province is divided into five great districts, and each of these into halloows, or leffer districts. The five districts are, Ipaavan, Tehraun, Naen, Mullagar, and Kermaunhaw. See each. At the clofe, add—See Yezd, Kom, Tehraun, &c.

IRAVAT, l. 15, for thunder, bearer r. thunder-bearer.

IREBY. In 1811, the parish, comprehended High and Low Ireby, contained in the former township 26 houses, and 130 persons, viz. 62 males, and 68 females; and in the latter, 41 houses, and 269 persons, viz. 137 males, and 132 females.

IRIDIUM. See Mineralogy, Addenda.

IRITIS, or Inflammation of the Iris. Professor Schmidt, of Vienna, first accurately discriminated this disease from other kinds of ophthalmia, and applied it to the foregoing name. The iris often becomes inflamed in consequence of artificial or accidental wounds of the eye-ball. Constitutional syphilis frequently affects the eye, producing a peculiar and characteristic iritis. The iris is the texture, which is the seat of inflammation in the diffusel kind of ophthalmia; frequently meeting with in gouty constitution. In the rheumatic ophthalmia, the inflammation, though never originating in the iris, frequently extends to it. And, lastly, an inflammation of this membrane sometimes accompanies cutaneous eruptions; particularly tho' which, though not syphilitic, have succeeded fores of the genitals, and are generally sup- posed to be connected with the abuse of mercury.

besides the common symptoms of ophthalmia, there are changes which occur at the very commencement that indicate the seat of the inflammation. The pupil is contracted, the motions of the iris are less free, and the pupillary opening loses the bright black colour which it naturally possesses. The colour of the iris is next observed to alter; this happens first in the lesser circle, which gets of a darker hue; and afterwards in the greater, which grows green if it has been greyish or blue, and reddish if it has been brown or black. The iris afterwards swells and projects towards the cornea; and the margin of the pupil loses its sharply defined edge, and is turned back towards the posterior chamber. The redness accompanying these changes is by no means considerable, and is at first confined to the sclerotic coat, in which a number of very minute rose-coloured vesicles are seen running in straight lines towards the cornea. The pupil, at the same time, loses its circular form, becomes somewhat irregular, and presents a greyish appearance. Examined with a magnifying glass, this appearance is seen to be produced by a substance very like a cobweb, occupying the pupil, and which is soon afterwards distinguished as a delicate flake of coagulable lymph. Into this, the processes and dentations of the margin of the pupil seem to shoot, and it is afterwards found, that at these points adhefions are apt to be established, in consequence of which vision is rendered more indistinct, and only one side or parts of objects can be discerned.

The effusion of lymph into the pupil continues to increase; it is likewise poured into the posterior chamber, and adhefions between the iris and capsule of the lens are formed. The quantity of lymph effused is sometimes so great, as to fall in a curdled form from the pupil to the lower part of the anterior chamber. The pupil, the size of which is considerably diminished, now derives a greyish-white colour from that of the lymph by which it is filled; the morbid fen- bility to light, which prevailed at the commencement of the inflammation, is diminished; the powers of vision become gradually more and more limited; and, at length, merely the perception of light remains.

By this time, the redness of the eye has increased, and partly arises from vesicles which are now developed in the conjunctiva. The redness is deepest all around the cornea; towards the periphery of the eye-ball it fades. The cornea loses somewhat of its peculiar brilliancy; and lymph now appears to be effused into the substance of the iris; for, while it projects more and more towards the cornea, its fibres are collected into bundles, and its surface exhibits a puckered or plaited appearance. A yellowish-red tuberle then forms on some part of its surface; it is at first small, but enlarges and projects forwards, and, according to Schmidt, is distinctly seen to be an abscess, which finally bursts, and discharges its contents into the anterior chamber. At this period of the disease, a small quantity of blood is sometimes extravasated into the anterior chamber. The inflammatory symptoms now abate, and, as the abscess subsides, both the pus and blood in the anterior chamber are absorbed. The throes of the eye of the abscess, which were floating in the aqueous humour, in a few days disappear. The anterior chamber regains its transparency; the iris remains permanently expanded; its aqueous appearance continues, the pupil is closed, and the power of vision is entirely lost. When the termination is somewhat more favourable, the pupil is not entirely closed, and the iris retains some degree of motion. The piece of coagulable lymph which occupies the pupil is reduced to the state of a thin membrane, which is opaque towards its centre, but somewhat transparent at the edges; the margin of the iris is only adherent
at some points to this membrane; and vision is impaired, but not destroyed.

Sometimes the inflammation of the iris extends to other textures of the eye. When the cornea is attacked, it becomes cloudy and thickened; and the iris, projecting, the two inflamed textures come into contact, and adhere before any visible effusion of lymph takes place. Should the inflam-

mation spread more deeply, and attack the membranes of the lens, and of the vitreous humour, the choroid coat, 

&c. then the violent symptoms of deep-seated inflammation of the eye take place. Even if the form of the organ is

preferred, vision is totally destroyed; but often the eye suppures, bursts, and almost entirely disappears.

In the Syphilitic iritis, a pale redness all round the cornea is the first symptom which is perceived. It is at first feated in the fcelerotic coat alone; but the conjunctiva very soon shares in it, and afterwards becomes even redder than the preceding membrane. However few the vessels may be elsewhere, there is always a broad zone of them all round the cornea, a zone formed at this place, not only by the vascular net-work in the conjunctiva, but by the ciliary vessels on the external surface of the fcelerota. The redness has a peculiar tint; for instead of being bright red, it is brownish, something like the colour of cinnamon. The whole cornea becomes uniformly hazy. The pupil also becomes con-

tracted, and the iris limited in its motions, as in common iritis; but the pupil does not preserve its natural situation. It is removed in a direction upwards and inwards towards the root of the nose, and is irregular. At the same time, the iris loses its natural colour, and projects forwards.

Towards evening, there is always an aggravation of the symptoms; the intolerance of light and painful sensibility of the whole eye increasing, and a gush of tears following every change of light and temperature. At length, a reg-

ular nightly pain sets in, of an extremely severe kind, but strictly limited to that part of the cranium which is imme-
diately above the eye-brow. It usually begins between six and seven in the evening, gradually increases, reaches its utmost height about midnight, and then diminishes till about four or five in the morning, when it ceases. After every such attack of pain, the pupil is found more contracted, drawn farther upwards and inwards, the iris more altered both in colour and form, the quantity of lymph increased, and consequently vision more impaired.

Peculiar appearances then take place in the iris; for, either on its pupillary or ciliary margin, or on both, one or more reddish-brown tubercles arise, which have a spongoy look. Their growth is pretty rapid. Lardy-looking ulcers sometimes appear on the cornea and white of the eye, or on the eye-lids. Even when syphilitic iritis terminates in the most favourable manner, the eye for a long time afterwards is peculiarly sensible to the influence of cold and moisture. On every exposure to the cold, the organ becomes morbidly sensible to light, of a reddish colour, and discharges tears. Indeed, frequently for more than a year afterwards, on every sudden change of temperature, a pale violet-coloured zone appears around the cornea, but goes off when the eye has remained for some time exposed to an equal temperature.

In the iritis which appears in conjunction with the eru-
tions supposed to be connected with the abuse of mercury, the inflammation feems less active than in the other kinds. The pupil is not much contracted, and lymph is less apt to be effused. A vehicle full of yellow matter sometimes rives on the iris, without any other alteration on this mem-

brane than that of colour, the pupil remaining almost un-

changed. By the use of proper remedies, this vehicle, even when it seems quite ready to burst, can generally be made to disappear in a few days, without any rupture taking place. The blood-vessels of the conjunctiva are large and dilated, without being varicose; they have a more livid colour than in the iritis of arthritic persons, and run quite to the edge of the cornea.

The treatment of iritis is conducted on the same prin-
ciples as that of inflammation in general, with one differ-
ence, which is deduced from the important fact so well explained by Dr. Farre and Mr. Travers, viz. that in iritis, the free exhibition of mercury is the most effectual means of preventing the effusion of coagulating lymph, and promoting its absorption after it has taken place, from which effu-

sion the thickening and adhesions of the iris, the formation of opacities in the pupil, and other mischievous and deftruc-
tive effects upon vision, are principally derived. According to Mr. Travers, indeed, whatever may be the cause of iritis, mercury is the grand remedy for retarding the progress and consequences of the effusion of lymph in the eye. According to professor Schmidt, of Vienna, general bleeding is necessary only where there is a great degree of sympto-
matic inflammatory fever. Hence, it is principally in the idio
topathic iritis that large bleedings from the arm are requi-
site. In the syphilitic species, he says, it is never necessary to open a vein. In the arthritic, it is sometimes attended with benefit; but in patients of this description, a small bleeding, repeated next day if necessary, is found to answer much better than a large bleeding at once, even though the constitutional disturbance be considerable. In the rheumatic iritis, it is also sometimes highly beneficial to bleed from the arm. Local bleeding, by means of leeches to the forehead, produces the most decided benefit in all the varieties of iritis.

Purgatives, given so as to act copiously, professor Schmidt describes as being useful only in the idiopathic iritis; and as for cold local application, he tells us that they are in all cases quite useless.

In the idiopathic iritis, he recommends us to take fifteen or twenty ounces of blood from the arm; and to repeat the bleeding if circumstances should require it. Six or eight leeches are to be applied to the eye-brow or temple. A smart purgative should then be given. The application of leeches, but in smaller number, should be continued every day, or every other day, until an abatement of the inflam-
mation has evidently taken place. In the first stage of the disease, blisters and blisters to the temple, or behind the ears, have little or no effect; though sometimes a large one on the nose seems to be of service. According to Schmidt, the only topical treatment which is admissible is the fomenta-
tion of the eye with water made as hot as the patient can bear it, which sometimes procures a mitigation of the vio-

lence of the pain. Care, however, must be taken to dry the eye-lids and circumference of the orbit well after using this application.

When the discharge passes into its second stage, or that in which the effusion of coagulating lymph commences, mercury is to be given with the views already mentioned. Two grains of the submuriate of mercury, and half a grain of opium, made into a pill, are to be given every evening and morning; or common mercurial fomentations may be employed. Externally, professor Beer applies a solution of the oxymuriate of mercury in water, to which mucilage and a considerable quantity of the vinum opii have been added. When this collyrium loses its effect, or the eye cannot bear any fluid application, which is sometimes the case, then he inserts daily between the eye-lids a small quantity of a face compos-
ed of two drachms of fresh butter, five grains of red precipitate, and eight grains of extract of opium. According to
to the same eminent oculist, frictions once a day over the eye-brow with mercurial ointment, opium being added to it, very much contribute to the absorption of the lymph effused in the posterior chamber.

It is seldom necessary to continue many days the exhibition of mercury; for such is the efficacy of this mineral in producing a removal of the lymph, and clearing away all opacities about the pupil, that in less than eight or ten days these objects are generally effected, and the medicine then may be omitted.

The form of iritis, usually named syphilis, or unquestionably one of those diseases which does not require more mercury for its cure than the common idiopathic iritis; and although it was suppos'd by professor Schmidt that it could not be radically cured without removing the constitutional disease, modern experience fully proves, that it may often be entirely and permanently relieved by freely exhibiting mercury for only a few days. This is another fact tending to confirm the opinions which have recently been examined and promulgated with so much ability by severals of our army surgeons, in relation to the curability of all the forms of syphilis without mercury. For, even in the syphilitic iritis, we are not to imagine that the complaint is stopped and cured by a few grains of calomel, on the principle of eradicating a specific disease: the thing is more rationally explained by the peculiar efficacy of the medicine in producing an absorption of the lymph, which thickens the iris, obstructs the pupil, and even serves for the formation of preternatural adhesions, and new opaque membranes destructive of vision. Besides the use of mercury, however, other means are advisable. When there is severe pain in the eye with violent headache, three or four leeches should be applied on the eye-brow, and a mild purgative administered. The nightly attacks of pain, which so invariably follow by an aggravation of all the symptoms, are most effectually prevented by rubbing into the part just over the eye-brow a small quantity of mercurial ointment with opium, a short time before the pain is expected to begin, and then covering the eye with a folded piece of warm linen. Generally speaking, calomel given in small doses two or three times a day, is the best preparation of mercury for internal exhibition.

The iritis which accompanies cutaneous eruptions was thought by Schmidt to be the most easy of cure; local bleedings are said to be in this case strikingly beneficial. According to some writers, when the eruptions have arisen from the previous abuse of mercury, calomel has not the least effect on the accompanying iritis. But at the London Infirmary for diseases of the eye, this form of the disease, though originally it may have been caused by the effects of a mercurial course, is said to be benefited as much as the other varieties of iritis by the exhibition of mercury; a circumstance which no mode of reasoning would ever have led us to anticipate. If, however, it be an unequivocal fact, the voice of experience must direct us in practice, and we must be silent on things which we cannot explain.

The best account of iritis is contained in professor Schmidt's valuable work, entitled "Ueber Nachbarlauf und Iritis nach Staar-Operationen," 4to. Wien. 1801. Additional information is also published in Beer's "Lehre von den Augenkrankheiten," b. 1. p. 350. Wien. 1813. Saunders on Diseases of the Eye, edit. 3. by Dr. Farre; B. Travers, in "Surgical Essays," part I. Carmichael in "Observations on the Symptoms and Specific Distinctions of Venerial Diseases," 8vo. 1818. The Quarterly Journal of Foreign Medicine, No. 1. contains a well-written analysis of professor Schmidt's work on Iritis; and at the same time that we acknowledge our obligations to that periodical publication for every thing which is valuable in this article, we cannot refrain from expressing our full wishes for the success of a journal, the principal object of which is to make us acquainted with the contents of all the best modern books which appear on the subject of medical science in different parts of the continent.

IRON, in Chemistry. According to the recent determination of Dr. Thomson, the black or protoxyl of iron is a compound of

\[
\begin{align*}
\text{Iron} & \quad - \quad - \quad - \quad 100. \\
\text{Oxygen} & \quad - \quad - \quad - \quad 28.5
\end{align*}
\]

Hence the weight of the atom of iron will be 35. The red or peroxyl of iron, according to the same chemist, is a compound of

\[
\begin{align*}
\text{Iron} & \quad - \quad - \quad - \quad 100. \\
\text{Oxygen} & \quad - \quad - \quad - \quad 42.955
\end{align*}
\]

Or it is composed of 1 atom iron + 1/2 atoms oxygen, or, to get rid of fractions, of 2 atoms iron + 3 atoms oxygen, on which latter supposition the weight of an atom of peroxyl will be 100.

KAMA, col. 2, l. 3 from bottom, for magry r. magry.

KAMAL, col. 2, l. 3, and 4 from the bottom.

KAMAWKA, in Geography, a county of Virginia, containing 9366 perons, of whom 352 were slaves in 1810.

KARLY, col. 2, l. 8, for ball r. bafe; l. 15 from bottom, for as r. or.

KARPOOT, a large and ancient town in the pachalic of Diarbeik, built on the summit of a hill, at the western extremity of a fertile valley, about three or four miles broad, and from twenty to twenty-five miles long.

KASAWAGO, a township of Crawford county, in Pennsylvania, having 384 inhabitants.

KASHEKA, for Vifnaviira r. Vifnaviitra.

KASI, l. 4, for nari r. naf.

KASKASKIAS, l. 5, r. 622, and 48.

KASYAPA, l. 7, for all r. ufe.

KAYKIYA, l. 4, for Lucina, his half brother r. twins, his half brothers.

KAZAMEEN, a town of Periia, in the pachalic of Bagdad, three miles north of Bagdad, and on the western bank of the Tigris, inhabited by about 8000 Periians, who reside here because this town is the burying-place of Imam Mofa Cafim, and Imam Mahomet Tonky, holy men for whom they had great respect, and to whose memory a noble mosque is erected. About nine miles north-west of Kazameen, and at some distance from the river, a pyramidal structure is erected, called by Europeans the Tower of Babel, Nimrood by the natives of Bagdad, and Agerkaft by the Arabs, and supposed by fome to be coeval with the remains of ancient Babylon. It is 190 feet high, and 100 in diameter.

KAZARON, or KAZEROON, r. nearly seventy miles W.S.W. of Schiras, E. long. 51° 45'. This town is situated in a valley about thirty miles long, and seven or eight broad, bounded on the N. by a falt lake, and fertilized by many freams of excellent water. From the depopulation it has suffered, its preent inhabitants do not exceed 3000 or 4000.

JUNGLE, denotes, particularly in India, a wood or thicket, in a country overrun with shrubs or long grasses.

JUNIATA, in Geography, a township of Cumberland county, in Pennsylvania, having 1233 inhabitants.

Eff. Ch. Recept. chaffy, Seed-down none. Calyx imbricated; inner scales radiating, coloured.

K. A. n. 1.—Native of the fourth coast of New Holland. A green-houfe fhrub, flowering molt part of the year.

KEARSARGE GORE, a township of Hilliborough county, in New Hampshire, having 125 inhabitants.

KEENE, l. 3, 1810; l. 4, r. 1046.

KEITH. In 1811 the parifh contained 755 houfes, and 3352 perons; 1391 being males, and 1961 females; 173 families employed in agriculture, and 295 in trade, manufactures, and handicraft.

KELAT, the capital of Balouchiftan, &c.; add—It is immediately encompassed by a low mud wall, and contains 4000 houfes: the inhabitants are estimated at 7000, of whom 500 at least are Hindus. The palace of the Khan is feated on a very high hill, and commands a view of the whole place and neighbouring country. The bazaar is well supplied, and the town has the appearance of opulence, being frequented by merchants, and enjoying a confiderable trade. N. lat. 26° 6'. E. long. 67° 57'.

KELLY VALE, a township of Orleans county, in Vermont, having 40 inhabitants.

KELSO. In 1811 the parifh of Kelso contained 529 houfes, and 4408 perons; 1079 being males, and 2429 females; and the district of Kelso, comprehending twelve parifhles, contained 2173 houfes, and 12,378 perons; 5592 being males, and 6786 females; 1268 families employed in agriculture, and 797 in trade, manufactures, and handicraft.

KENDAL, l. alt. In the year 1811, Kendal ward contained 2710 houfes, and 13,674 perons; and the town of Kirkby Kendal contained 1496 houfes, and 7508 perons.

KENERA, 1. 9, for there r. thefe.

KENFIG. In 1811, the parifh contained 55 houfes, and 242 perons; 110 being males, and 153 females; and Higher Kenfig, which is a hamlet in Mengan parifh, contained 24 houfes, and 129 perons; 69 being males, and 60 females.

KENILWORTH. In 1811 the parifh contained 463 houfes, and 2279 perons; 1145 being males, and 1134 females; 155 families employed in agriculture, and 264 in trade, manufactures, and handicraft.

KEN-
KERNEBECK, l. ult. It contained, in 1810, 32,564 inhabitants.

KENNEDIA, in Botany, so named in honour of Mr. Kennedy, the well-known cultivator at Hamfermath, whose skill and experience have so much enriched the works of his son-in-law, Mr. Andrews.—Venten. Malmais. 104. Brown in At. Hort. Kew. v. 4, 299.—Claths and order, Delphina Decandra. Nat. Ord. Papilionaceae. Linn. Leguminosae, Jaffi.

3. K. profusara. Few-flowered Scarlet Kennedia. Br. in Ait. n. 3. (Glycine coccinea; Curt. Mag. t. 270. Willd. Sp. Pl. v. 3. 1606.)—Leaves ternate, ovate, hairy. Stalks one or two flowered. Stem prostrate.—Native of New South Wales, from whence its seeds were brought about 1790.

Mr. Brown appears to have some unpublished species.

KENNET. Add.—It contained, in 1816, 947 inhabitants.

KENNINGTON, l. 4. 1811—1379—19,886.

KENTUCKY. Add.—See United States.

KERBALA. See VOLGOLESIA.

KERRUK, or KERKOUK, the largest town in the lower Kuriditan, in N. lat. 35° 29', 59 furlongs from Bagdad, and 41 from Mosul, on the road from one place to the other. It was formerly a military station, called by Strabo, Demetrias; and by Ptolemies, Cercura. Its population is estimated at 18,000 souls, Turks, Armenians, Nettorkians, Kurds; this estimate, however, is supposed to exceed the truth by 5000. The city is defended by a mud wall, has two gates, seven mosques, fourteen coffee-houses, one harem, one caravansera, one Armenian church, and twelve pieces of udefles artillery mounted on the bastions. In the suburbs, are five mosques, nine small caravanseras, thirteen coffee-houses, three convents, and three Catholic churches. Near it is a number of naphtha pits, which afford an abundant supply of that commodity.

KERMANSHAW, one of the five distritcs of the province of Irak in Peria; the capital of this extensive and fruitful distritc of the same name, and the residence of Mahomet Ali Meerza, the king's eldest fon, and the most able and warlike of the princes of Peria. It is a flourishing town, containing about 12,000 houfes, at the extremity of a fine plain, through the centre of which runs the Karatu. It is adorned with many gardens, and fourteen hummums or public halls, four mosques, and yields a revenue of 15,000 tomans a year.

KERRIA, in Botany, so named after Mr. William Kerr, a gardener, who has introduced the shrub in question, with many other Chinese plants, into the English gardens. —De Candolle Tr. of Linn. Soc. v. 12. 156.—Claths and order, Kennedia Polygynia. Nat. Ord. Senticf, Linn. Rosaceae, Jaffi.

KESWICK, l. 7. r. 352—168. See KET, 1. 14.

KETU, l. 4, for Karyapa r. Kalyapa. Col. 2, l. 4, for r. a.

KEW, l. 4 and 5; r. 1811—73—560.

KEYNSHAM, l. 4 and 5; r. 1811; the parish contained of 318 houfes, and contained 1748 inhabitants.

KHARASAM, col. 2, l. 3; r. (See KIHEVA.)

KHOE, a town of Peria, in the province of Persia, with 22 furlongs from Tebrz. This town is the capital of a rich and extensive district, and the emporium of a considerable trade carried on between Turkey and Peria. It is said to contain a population of 25,000 souls, and is situated on a plain, famous for a battle fought, in 1514, between Shah Ismail and Selim I, in which 30,000 Perians encountered 300,000 Turks. There is no town in Peria better built or more beautiful than Khoee: the walls are in good repair; the streets are regular, shaded with avenues of trees; and the ceilings of many of the houfes are painted with extraordinary talke.

KHONSAR, a town of Peria, in the province of Irak, situated at the base of the two ranges of mountains, running parallel with each other, and fo close that the houfes occupy the bottom and also the declivity of the hills to some height. The town, placed in a beautiful and romantic situation, and formed of houfes and gardens, connected by means of its plantations, is about six miles in length, and about one-fourth of a mile in breadth. It contains 2500 families under a chief named Ali Shah, and yields an annual revenue of 3000 tomans, exclusive of the fadir, which generally consists of dried fruits and a kind of cotton chintz. Although they have no corn in the valley, fruit is fo abundant, that the inhabitants procure for it every article which they can want or desire. Of their apples, they make a kind of cyder, but it will not keep above a month. The women are celebrated for their beauty and vivacity.

KOHASSAN. Add.—Khorassan is a level country, interspersed with fancy islands, and irregular ridges of lofty mountains; the climate is accordingly various; in some parts temperate, but in others very cold; and the "had-a-fennum," which blows in the defects for 40 days in the year, proves

instantan—
KILMAURS, a parish of Ayrshire, which, in 1811, contained 248 houses, and 1,432 persons; viz. 685 males, and 747 females: 61 families being employed in agriculture, and 142 in trade and manufactures.

KILPATRICK. The parish of New or East Kilpatrick contained, in 1811, 205 houses, and 1,643 persons; viz. 746 males, and 897 females. The parish of Old or West Kilpatrick contained 370 houses, and 3,428 persons; viz. 1,595 males, and 1,833 females. In the former, 81 families were employed in agriculture, and 120 in trade and manufactures; in the latter, 95 families were engaged in agriculture, and 577 in trade, &c.

KILSYTH. In 1811, the parish of Kilcony contained 626 houses, and 3,206 persons; viz. 1,488 males, and 1,718 females.

KILWINNING. In 1811, the parish contained 561 houses, and 3,521 persons; viz. 1,607 males, and 1,684 females.

KIMBOLTON, l. 4 r. 1811: l. 5 r. 260—1400.

KINCRINE. By the parliamentary returns of 1811, the parish of Kinbrace, in Montrose, with Thornhill, contained 479 houses, and 2,419 persons.

KINCRINE, col. 2, l. 8, after Bervie, and which burgh and parish, in 1811, contained 193 houses, and 927 persons; l. 46 r. 1811: l. 47, r. 578—27,439: add—12,580 being males, and 1,485 females.

KINETON, l. 12, r. 1811, the hundred contained 4,666 houses, and 19,459 persons; and the parish 166 houses, and 801 inhabitants. Add—See KINGTON.

KING and Queen, l. 5 r. contains 10,989 inhabitants, of whom 6023 were males in 1810.

Kings, George, l. 3 r. 6456, of whom 3876 were males in 1810.

KINGHORN. Add—In 1811, the burgh and parish contained 326 houses, and 2,204 persons.

KINGSBRIDGE, l. 9, r. 1811—156—1242.

KINGSCLEERE, l. 9, r. 1811—398—1803—50 families; l. 15 r. 1137.

KINGTON, in America, l. 12 r. 324. Col. 2, l. 3 r. 746. Add—Allo, East Kington, a township of the same county and state, having 442 inhabitants; l. 12 r. 832.

KINGSTON, on the Thames, l. ult. r. 1811—716—414.

KINGTON, l. 2, r. Huntingdon; l. 11 r. 1811—1617—329. See KINGTON.

KING WILLIAM, a county of Virginia, containing 31,925 inhabitants, of whom 3788 were males in 1810.

KINGWOOD, l. 1 r. Hunterdon; l. 2 r. 2605—48.

KINROSS, l. 4 r. The number of inhabitants of this parish, in 1811, was 2940, of whom 287 families were employed in trade and manufactures, and 92 in agriculture; the number of houses was 396.

KINROSS-SHIRE, col. 2, l. 9 r. 1811, as containing 1364 houses, and 7245 persons.

KINTORE, l. 11 r. 1811, the burgh and parish contained 218 houses, and 863 persons.

KINTRYE, l. 1 r. fix for three; l. 2 r. fix for three; l. 3 r. after this: Argyll, Corrall, Illay, Kintyre, Lorn, and Mull. The first district contained, in 1811, 2702 houses, and 15,637 persons; Corrall, 2121 houses, and 6887 persons; Illay, 2636 houses, and 14,161 persons; Kintyre, 2959 houses, and 18,286 persons; Lorn, 2721 houses,
houses, and 13,779 persons; and Mull, 3,012 houses, and 16,834 persons.

KIRCALDY, col. 2, l. 25, r. In 1811, the number of inhabitants in the burgh and parish was 37,471, occupying 31,488 houses, of whom 453 families were employed in trade and manufactures, and 46 in agriculture: the number of houses in the whole district was 38,999, and of inhabitants 31,958.

KIRKBY-LONSDALE, l. 5, r. In the year 1811, the town contained 271 houses, and 1,568 persons.

KIRKBY-STEPHEN. Add—By the return of 1811, the township contained 250 houses, and 1,235 persons.

KIRKUDBRIGHT, l. ult. r. In 1811, the number of houses in the burgh and parish was 302, and of inhabitants 2,073.

KIRKUDBRIGHTSHIRE, col. 2, l. 8, r. 1811—33,684 persons: 15,788 being males, and 17,894 females: the number of houses being 6,223.

KIRKHAM, l. 6, r. 1811—424—2214.

Kirkham, a township of Amounderness hundred, in Lancashire, part of Kiffen parish, containing, in 1811, 424 houses, and 2,214 persons; viz. 1,039 males, and 1,175 females.

KIRKINTULLOCH, l. penult. r. In 1811, the number of houses was 605; and of persons 3740; of whom 573 families were employed in trade and manufactures.

KIRK-OSWALD. At the end, add—In 1811, the number of houses in this township was 116, and of inhabitants 636.

KIRKWALL. Add—The burgh and parish of Kirkwall contained, in 1811, 287 houses, and 1,715 persons.

KIRKMANSHA. Add—See Kirkmanshaw.

KIRRIEMUIR, l. 12 and 13—1811, the town and parish were returned as containing 955 houses, and 4,791 persons.

KIRTON, l. 6, r. In 1811, it contained 307 houses, and 1,531 persons.

KIRTON Lindsay, l. 5, 1811—258—1152.

KILBERRY, l. 3, r. 1919.

KIZIL-OZAN. Add—This river, called the Golden Stream, is the natural boundary of Irak and Azerbijan, and, according to Renell, the Gozan of Scripture.

KNARESBOROUGH, col. 4, l. 13, r. The population of the borough and township, as returned to parliament in 1811, was 2,934, occupying 688 houses.

KNEE, in the Mange, add—Broken knees very much depreciate the value of a horse; and therefore various methods have been proposed for repairing and correcting this injury. Mr. Tepelin recommends, first of all, to wash the injured parts well with a sponge and warm water, so as thoroughly to cleanse them from gravel or sand; and then plentifully embrocating them with camphorated lead-water, and bandaging over them a pledget of towel moistened with the same, repeating the operation once or twice, if necessary. This treatment should be continued, that a crust or cicatrix may be formed, which will render unctuous or greasy applications unnecessary. But if the laceration be considerable, suppuration will ensue, and should be encouraged by a common poultice, and the cure completed by digestive ointments. Mr. Lawrence proposes to make the hair grow after such accidents, by, binding a piece of fleet-lead on the part after the wound is healed; and he also mentions a contrivance by which the knees of a valuable horse may be preserved from this accident. (See Hose.) He advises to wash the wound clean with a linen rag and warm soap-fands, and having wiped the parts dry to apply brandy. Friar's balsam (compound tincture of benzoin) will, he says, heal broken knees very speedily. A kind of hofe, or boots, is used to defend the legs of race-horses in travelling; and some kind of guard, latten'd above and below the knee, would be very useful to pit-horses. For broken knees, Mr. Ryding recommends a mixture of 1 dr. of cantharides in fine powder with 1 oz. of olive-oil, which should be applied occasionally with the hand to the wounded part. This, he says, by its gently stimulating power, will brace the parts, promote the fore, and facilitate the growth of hair.

KNIGHTIA, in Botany, so named by Sir Joseph Banks and Mr. Brown, in honour of Thomas Andrew Knight, eqq., the able president of the Horticultural Society, well known by his numerous writings on vegetable physiology.—Br. Tr. of Linn. Soc. v. 10. 193.—Clubs and order, Tetrapedia Monogynia. Nat. Ord. Proteaceae, Juff. Br.

K. excelsa. Br. as above, t. 2.—Found by sir J. Banks, in New Zealand. A large tree, often eighty feet high. Leaves scattered, flaked, elliptic-lanceolate, ferrated, five or six inches long; downy beneath. Flowers red, in dense lateral clusters, with red falks. This genus comes very near Aublet's and Schreber's Rhopala, (see that article,) differing only in having four seeds winged at the apex, instead of two winged all round.

KNOWLTON, l. 2, r. 2.064 inhabitants, including 17 slaves in 1810.

KNUFSORD, l. 5 from the bottom, r. In 1811 there were in the township of Nether Knutsford 448 houses and 2,114 persons, and in Over Knutsford 49 houses and 243 persons, of whom in the former township 276 and in the latter 37 were employed in trade, manufacture, and handicraft.

KOM, l. 4, add—It is said to have been built in the year 203 of the Hejira, from the ruins of seven towns, which had composed a small sovereignty under Abdalrahman, an Arabian prince:—l. 19, after khan, add—It was taken by the Afghans, when they invaded Persia in 1722, and completely destroyed. Part of it has been since rebuilt, but it still appears like a vast ruin.

KORASAN, or Khorassan. Add—See Khorassan.

KORNA. See Siat-ul-Arab.

KOUMISS, an intoxicating drink, prepared by the Tartars from mare's milk. See Milk.

KRISHNA, l. 21 and 24 from the bottom, for Gapia r. Gapia; l. 18, for Tafuda r. Yafuda.

KROOK. See Regan.

KUFA, a kind of boat in use on the Euphrates and Tigris; it is perfectly round, made of wicker-work, covered with bitumen, and generally about seven feet in diameter.

KUFRI, in Geography, a town of Persia, in the pashalic of Bagdad, between Bagdad and Kerkook, containing about 2,000 inhabitants.

KUPRI-ALTUN. See Altun-Kupri.

KURMAVATARA, l. 18 from the bottom, for beautiful r. bonuful.

KYANITE. See Mineralogy, Addenda.

K. calycina.
1. K. calycina. Roxb. t. 215.—Outer calyx four-leaved, longer than the corolla.—Native of the banks of rivulets, in Coromandel and Hindooften, flowering in the cool season. A tree, with long-talked, roundish, mealy, slightly three-lobed leaves. Flowers small, white, in terminal panicles.

2. K. fraterna. Roxb. t. 216.—Outer calyx six-leaved, shorter than the corolla.—Native of the Cercul mountains, flowering in the rainy season. A larger tree than the foregoing. Flowers more conspicuous. Leaves whiter underneath.

LABORATORY. Woulfe's Apparatus, Plate V.

LAC, in Coinage. See Lack and Rupee.

LACKAWANNA, a township of Mercer county, in Pennsylvania, having 379 inhabitants.

LACTATES, in Chemistry. See Lactic Acid.

LACTIC Acid. The description of this acid has been omitted, we shall therefore introduce a brief account of it here.

The lactic acid was first obtained by Scheele from four whey. He considered it as analogous to the acetic acid. Bouillon Lagrange afterwards instituted a series of experiments upon it, from which he drew the conclusion that it is merely acetic acid, contaminated with some fatty and animal matter. Four years afterwards, Thenard advanced a similar opinion. Both these chemists, however, had obtained the acid which they examined by distillation, though Scheele had expressly stated that lactic acid, when distilled, was converted into acetic acid. The existence of lactic acid, therefore, was by no means disproved by their experiments. Soon afterwards, Berzelius took up the subject, and in an elaborate set of experiments proved that Scheele's original opinion was correct, and thus fully established the peculiar nature of lactic acid.

Berzelius obtained the lactic acid by the following complicated process. The extract obtained by evaporating whey to dryness was dissolved in alcohol, and mixed with alcohol holding 2/3 of its weight of concentrated sulphuric acid in solution, till there was an excess of sulphuric acid present. Sulphate of potash was precipitated. To get rid of the other acids, it was digested over carbonate of lead till the liquid acquired a sweetish taste. By this means, the sulphuric acid, the phosphoric acid, and most of the muriatic acid, were separated; but the lactic acid forming a soluble compound with lead remained in solution. A current of sulphuretted hydrogen gas being passed through the liquid threw down the lead. The liquid was digested over quick-lime till all the animal matter was separated. It now contained only lactic acid, muriatic acid, and lime. A portion of it was freed from lime by means of oxalic acid. This portion was then saturated with carbonate of silver; by means of this solution, the remainder of the liquid was freed from muriatic acid. Finally, the lime was thrown down by means of oxalic acid, so that nothing remained but lactic acid dissolved in water. To get rid of a small portion of oxalate of lime which it held in solution, it was evaporated to dryness, and redissolved in water.

Lactic acid thus obtained has a brownish-yellow colour, and a sharp four taste, which is much weakened by diluting the acid with water. While cold it has no smell, but when heated it acquires a sharp four odour, not unlike that of sublimed oxalic acid. It does not crystallize, but when evaporated to dryness forms a smooth varnish, which gradually attracts moisture from the air. It dissolves readily in alcohol. When heated it boils, emits a four smell, and leaves a bulky charcoal, not easily burnt. When distilled it gives out empymatic oil, water, acetic acid, carbonic acid, and inflammable gas.

Lactates.—All the lactates are more or less soluble in water, and hardly any of them can be made to crystallize. The lactate of potash and lactate of soda form a light yellow transparent gummy mass, which cannot be easily made hard. The lactate of ammonia has some tendency to crystallize. It forms a gummy mass, which acquires in the air an excess of acidity. When heated, most of the ammonia is driven off. The lactates of barytes, lime, and magnesia, are divided by alcohol into superlactates of those earths which are soluble in alcohol, and into sublactates which are insoluble. The metallic lactates do not possess remarkable properties. There are three lactates of lead; the superlactate which does not crystallize, the lactate which exists in grey crystalline grains, and the sublactate which is insoluble. The lactate of zinc crystallizes.

Dr. Thomson estimates the weight of the atom of lactic acid from Berzelius's experiments at 57.5.

Such are the chief properties of lactic acid and its compounds. We have entered further into the description than we should otherwise have done, on account of the importance of the subject,—the lactic acid existing both in a simple and combined state in most of the animal fluids. See Blood, and Fluids, Animal.

LACTODORUM, in Ancient Geography. See Towcester.

LACTUCARIUM, a name given by Dr. Duncan to the impregnated juice of the lactuca salia, or common lettuce, and which has been found beneficial in various disorders, especially consumption, as an anodyne, where opium disapproved and could not be taken.

LADY-BIRD. See COCCINELLA.

LAFOURCHE, in Geography, a county of the territory of...
of Orleans, containing in its interior, and in the parish of Assumption, 4467 inhabitants.

LAHORE, l. 10, for Schaugruve r. Shah Jehan.

LAKE, a town of Champaign county, in Ohio, containing 180 inhabitants.

LAKSHMI, col. 3. l. 4. for deities r. deity's wives.

LALESTON, Higher and Lower, in Geography, form a parish of Newcastle hundred in Glengarnshire. The Higher in 1811 contained 34 houses, and 157 persons; 81 being males, and 76 females; and the Lower contained 62 houses, and 271 persons; 111 being males, and 160 females.

LAMBETH, l. 25, r. 1811—7201; l. 24, r. 4144, and 4491; l. 27, r. 338.

LAMBOURN, l. 13 and 14, r. In the year 1811, the population of the parish, with its dependent hamlets, viz. Bрагgrave and Halsey, Eastbury and Bockhampton and Upper Lambourn, was 2674 persons, and the number of houses 527.

LAMP, Aphiologic. Sir Humphrey Davy, during his researches on flame with the view to the construction of his safety-lamp for coal-mines (see Wire-Gauze), observed, that a fine platinum wire heated red hot and held in the vapour of ether would continue ignited. Soon after this curious fact was made known, Mr. Ellis of Bath thought of extending the principle, and found that a coil of fine platinum wire, flung into the wick of a common spirit-lamp (being previously heated), might be kept red hot for any length of time. The lamp so constructed received the appellations of aphiologic lamp, lamp without flame, &c.

The platinum wire for this experiment should not exceed \( \frac{1}{8} \) of an inch in diameter. About twelve coils of this (the coil being about \( \frac{1}{8} \) of an inch in diameter, and as close together as possible without touching) are to be placed upon the wick of a common spirit-lamp, in such a manner that half be on the wick and half above it; the lamp is then to be lighted, and when the wire has become red hot the flame is to be blown out; the wire will then remain red hot for any length of time required, and in a dark room, if properly constructed, will emit a considerate light. Instead of alcohol, ether may be employed, or a similar effect may be produced by flicking the ignited wire into a piece of camphor.

LAMP, Safety, for coal mines. See Wire-Gauze.

LAMPETER, l. 2, r. 2501.

LAMPIC Acid, in Chemistry. The name recently given by Mr. Daniell to an acid generated by the combustion of alcohol, &c. by the aphiologic lamp.

Sir Humphrey Davy observed, during the combustion of ether in the manner above described, the formation of a peculiar acid pungent vapour, which he considered as a new product. Mr. Faraday soon afterwards described some of the properties of this acid, and more recently Mr. Daniell has given us a more full description. Mr. Daniell prepared Vol. XXXIX.

it for his experiments by burning the aphiologic lamp under an alembic head, and collecting the products; but we understand it may he formed much more readily by palling the vapour of ether through a tube containing platinum wire. The lampic acid, when as pure as possible, is a colourless fluid, of an intensely taint and pungent odour. Its vapour when heated is extremely irritating and disagreeable, and produces an oppression on the chest, something like that produced by chlorine. It reddens vegetable blues, and decomposes all the earthy and alkaline carbonates. Its ip-kr. when rectified as highly as possible, according to Mr. Daniell, is 1015.

The Lampates of Potash and Soda are deliquecent salts, and do not readily crystallize. The lampate of ammonia is volatile, and easily decomposed. The lampate of barite readily crystallizes in colourless transparent needles. The lampates of lime and magnesia are deliquecent.

The lampic acid has the property, according to Mr. Daniell, of reducing many of the metallic oxides; this is particularly the case with the oxides of gold and mercury. When warm nitrate of mercury, according to Mr. Daniell, is mixed with lampic acid, a metallic flower takes place, and brilliant globules of mercury soon accumulate at the bottom of the vessel.

Mr. Daniell estimates, from his experiments, the weight of the atom of lampic acid at about 64, and confers it as composed of 1 atom hydrogen + 1 atom carbon + 1 atom water. How far these determinations are to be depended upon we cannot say, though we think it probable that they are incorrect.

LANARK, l. ult. r. 1811—5677—658.

LANARKSHIRE, l. 13, r. according to the parliamentary returns in 1811, the population of the county consists of 191,532 persons, occupying 32,870 houses; the males are 88,688, and the females 102,844: the families employed in trade, manufactures, and handicraft, are 27,672, and those employed in agriculture 5387.

LANCASHIRE, l. 21, r. 1811—14,283—828,309; l. 22, r. 114,222; l. 23, r. 23,305. The number of males was 394,104, and that of the females was 434,205.

LANCASHIRE. This county contains several villages and parishes, which, by the prevalence of its manufactures, are become populous, but which our limits will not allow us to mention.

Abston-under-Lime (omitted in its proper place) defers a particular notice as a parish in the hundred of Salford, which in 1811 contained 3042 houses, and 19,052 persons, viz. 9146 males, and 9906 females; 213 families being employed in agriculture, and 2727 in trade, manufactures, or handicraft.

Abston-in-Mankerfield is also a township in the hundred of Well Darby, and parish of Winwick, which contains 864 houses, and 4747 persons; viz. 2342 males, and 2405 females: 163 families being employed in agriculture, and 726 in trade, manufactures, &c.

LANCASTER, col. 4, l. 26 from bottom, r. 1811; l. 25, r. 1694 and 9247.

LANCASTER, in America, l. 5, r. 3927—44. Col. 2, l. 5, r. 5592 inhabitants, of whom 312 were slaves in 1810; l. 7, r. 6318; l. 8, r. 1646; l. 18, add,— and by the census of 1810, 5405 inhabitants, including 700 slaves; l. 31, add.—Also, a township of the same county, containing 592 inhabitants:—l. 43, r. 1694; l. 44, for Grafton r. Coos; l. 47, r. 1810; and 517.

LANDAFF, l. 2, r. 550.

LANDGROVE, a town of Bennington county, in Vermont, having 299 inhabitants.

3 X STRANDSCAPE,
LANDSCAPE, 1. penult. r. wherein. Col. 2, l. 6 from bottom, r. aims.

LANESBOROUGH, 1. 3, r. 1302.

LANGAYA, a genus of serpents, the characters of which are, that it has abdominal plates, caudal rings, and terminal scales. Of this genus there is only one species, differing from all the rest of the serpent tribe in having the upper part or beginning of the tail marked into complete rings, or circular divisions, resembling those on the body of the amphid, while the extreme or terminal part is covered with small scales, as in the genus anguis. This species is called Langaya nacha, or large-mouted Langaya, has 184 abdominal scales, and 42 caudal rings; it is a native of Madagascar, and was first described by M. Bruguier of the Royal Society of Montpellier. The natives of Madagascar are much afraid of this serpent; as they conceive it to be very poisonous.

LANGDON, l. 3, r. 632.

LANGHOLM, l. 5, r. 1811, 2636 persons, occupying 522 houses.

LANGPORT, col. 2, l. 3, r. 1811—112; l. 4, r. 861.

LANFITT, Major, a parish of Cowbridge hundred, in the county of Glamorgan, containing, in 1811, 179 houses, and 786 persons; viz. 357 males, and 429 females.

LAN WTIT, Lower, a parish near Neath, which, in 1811, contained 116 houses, and 564 persons; viz. 265 males, and 299 females.

L A R, l. 6, add.—It still contains about 12,000 inhabitants, celebrated for the manufacture of muskets, and cotton cloth. It has very handsome buildings, and particularly a bazaar, that is reckoned the noblest structure in Persia. N. lat. 37° 30'. E. long. 52° 45'. See TAMREM.

LARIISTAN, L. 1, after Perfa, add—extending along the Northern shore of the gulf from E. long. 55° 10'.

LARUS, col. 3, r. RIDIBUNDUS.

LASCAR, a term in India, denoting a camp-follower, but applied to native sailors and artillerymen.

LASCQ, JOHN, Add.—A brief account has already been given of this famous reformer under ALASCO.

LASSUS. See ORLANDO.

LATIMORE, in Geography, a township of Adams' county, in Pennsylvania, having 666 inhabitants.

LAUD, l. 16 from bottom, r. Stanford.

LAVENHAM, at the close, r. 1811—398, and 1711.

LAUGHTER, l. 15, add—See LUNGS.

LAVINGTON, Ed. l. 11, r. 1111; l. 12, r. 899—184; l. 16, for Whirlond r. Potturn and Cannings; l. 17, r. 1811—127; l. 18, r. 582.

LAUNCESTON, col. 2, l. 4 and 3 from the end, r. 1811—1758, and 262.

LAUREAT, POET, l. 5, add.—In anciently conferring degrees in grammar, which included rhetoric and verification, at our universities, particularly at Oxford, a wreath of laurel was presented to the new graduate, who was afterwards usually styled "Poeta Laureatus." These scholastic laureations seem to have given rise to the appellation:—l. 19, after Edw. IV, infert—who appointed John Kay poet laureat, and who, according to Warton, was the king's first poet under this appellation. The only composition he has transmitted to posterity is a profe English translation of a Latin history of the siege of Rhodes. In the dedication, addressed to king Edward, or rather in the title, he styles himself by humble poet laureate. The same appellation occurs under, &c. At the close, add—Warton's Hift. of English Poetry, vol. i. p. 128.

LAUROPHYLLUS, in Botany, an exceptional compound name.—Thumb. Prodr. pref. n. 16. Willd.

1. L. caprifol. Thumb. Prodr. 31. Willd. n. 1. Ait. n. 1.—Found at the Cape of Good Hope. A tree, with round, brown, lining branches; alternate, oblong, serrated, smooth, coriaceous leaves; and minute flowers, in terminal panicles.

LAWLANSE, in Geography, a township of Northampton county, in Pennsylvania, having 157 inhabitants.

LAWSVILLE, a township of Luzerne county, in Pennsylvania, having 166 inhabitants.

LEAD, in Chemistry. According to the most recent determinations, mafficot, or the protosxil of lead, is a compound of 100 lead + 7.593 oxygen; and the brown or persyil, of 100 lead + 7.2534 oxygen. Hence the weight of the atom of lead will be 136, oxygen being 16. From these data, the composition of all the other compounds of lead can be easily estimated. See Atomic Theory.

What is usually called minium, or red-lead, is a combination of these two oxyds, or of 2 atoms lead + 3 atoms oxygen. Red-lead does not appear capable of combining with acids, at least no salt of which it forms a constituent is at present known.

LEAD, page 10, c. 2, l. 3, after gallic, read acid.

LEAD-ORES. See LEAD, and MINERALOGY, Addenda.

LEATHERHEAD. In 1811 the parish contained 312 houses, and 1290 persons; viz. 580 males, and 629 females: 75 families being employed in agriculture, and 101 in trade, manufactures, and handicraft.

LEBANON, in America, l. 3, r. 1810; l. 4, r. 1993; l. 8, r. 2580; l. 11, r. 1810; l. 12, r. 1808. Col. 2, l. 3, add—containing 1434 inhabitants. Also, a township in the same county, containing 2473 inhabitants. Also, a town of Hunterdon county, in New Jersey, containing 2490 inhabitants.

Eff. Ch. Calyx in five deep acute segments, with rounded sinuæ. Stamens all connected. Legume cylindrical, with many seeds.

Thunberg and Wildenow describe three species with simple, and five with ternate, leaves, all shrubs, found at the Cape of Good Hope. Three are in Hort. Kew. L. contaminata, ferrica, and cytisoides, all previously referred to Spartium; see that article.

LECANA, Ach. Synt. 146. "Lichenogr. 77. t. 4. f. 3—7." a new genus, confining of 139 species, of the Lichen tribe, being the crustaceous species of Parmelia; see that article.

LECLOADE, l. 16 from bottom, r. 1811; l. 15, r. 993; l. ult. r. 195.

LECIDEA, in Botany, Ach. Synt. 111. "Lichenogr. 32. t. 2. f. 1—7." A genus of Lichenet, chiefly the tuberculata of Linnæus, whose shields have no border from the fulness of the frond or cupa, 153 species are now described, whose fronds are various.

LEDBUY, col. 2, l. 17, r. 1811—316; l. 18, r. 604.

LEDYARD, col. 2, l. 39, r. Ochotok.

LEE, in Virginia, l. 6, r. 4694 inhabitants, of whom 336 were slaves in 1810; l. 10, r. 1329; l. 12, r. 1305.

Lee, a long measure in China, rather more than one-third of a mile.

LEEDS, col. 2, l. 25; r. 1811, the town and liberty contained
LEP

1. contained, &c.; l. 26, r. 12,449 and 62,534; l. 27, r. 11,739 families were flated, &c.

2. Leeds, in America, l. ult. r. Kennebeck for Cumberland; after county, add—containing 1273 inhabitants.

3. LEKEE, l. 7, r. 1811—832; l. 8, r. 3703.

4. LEELITE. See MINERALOGY, Addenda.

5. LEGEND, col. 2, l. 34; r. Sybaris. Col. 3, l. 36, for found. r. secret; l. 8 from bottom, r. Coningham.

6. LEHI, in Geography, add—Allo, a township containing 1185 inhabitants.

7. LEICESTER. At the close, r. 1811, 4699 houfes, 23,146 inhabitants.

8. LEICESTERSHIRE, col. 3, l. 24, r. 1811—150—419; add—of whom 10,801 were males, and 12,345 females; 17,027 families were employed in trade and manufactures, and 11,700 in agriculture. The number of houses was 30,019.

9. LEIGH, West. In 1811, this township contained 341 houses, and 1960 perfons; viz. 927 males, and 1033 females.

10. LEIGHTON-BUZZARD, l. 5, r. 1811—408 houses, 2114 inhabitants; of whom 187 families were employed in trade and manufacture, and 283 in agriculture.

11. LEITH. At the end, add—By the parliamentary return of 1811, North Leith had 1085 houfes, and 4875 inhabitants; and South Leith had 838 houfes, (if not a millake in the number,) and 15488 inhabitants.

12. LEMINGTON, or LEMINGTON, l. 2, add—containing 1774 inhabitants.

13. LEMINGTON-PRIORS, a parish of Warwickshire, in the hundred of Knightlow and Kenilworth division, contained, in 1811, 125 houfes, and 543 perfons; viz. 275 males, and 268 females. But since that period, it has been much referted to as a watering-place refembling Cheltenham; and the number of private houfes, baths, hotels, and public buildings, for the accommodation and amufement of its visitors, has been very much augmented, and is every year increafing.

14. LEMNIAN EARTH. See PEARLIDE.

15. LEMON, a township of Ohio, in Butler county, having 1308 inhabitants.

16. LEMPSTER, l. 3, r. 1810 and 854.

17. LEMUR, col. 3, l. 17 from bottom, r. MACAO.

18. LENIOR, or LENORE, l. 3, r. 5572, of whom 2449 were flaves in 1810.

19. LENOIX, l. ult. r. 1310.

20. LENS, Cryallifline of the Eye, Chemical Properties of. See EYE.

21. LEOMINSTER, col. 3, l. 19, r. the population of the borough and parifh, &c.; r. 1811—3238; l. 20, r. 730.

22. LEMINSTER, in America, l. 5, r. 1814.

23. LEONINE, l. 12, after Leonius, add—A French monk of St. VIdor, at Marseilles, about the year 1153; l. 14, after III.—But rhymes in Latin verses were in use much earlier. See Warton’s Hist. of Poetry, vol. i. diff. ii.

24. At the close, add—See Rhyme.

27. Anther a deciduous lid.

28. Four West Indian species are described, small plants, each with a thick, solitary, roundifh leaf, and one or two clusfers of minute flowers.

31. L. criepata, Wildenow’s only species, from the East Indies, bears aggregate, sessile, scaly balls of flowers, chiefly about the crown of the root. The numerous flons are decumbent, eighteen or twenty inches long, leafy, square. Leaves simple, oblong, rough-edged. Mr. Brown has refoaected the character, as above, from various Chinefe and tropical species, in Sir J. Banks’s herbarium.

32. LEPIDOLITE. See LEPIDOLITE, and MINERALOGY, Addenda.

33. LEPSIA. Add.—It is now called Lippo.

34. LERIA, l. 2, after Strabo, add—This little ifland has three harbours, and is faid to produce abundance of the wood of aloes, fo much esteemed in Turkey as a perfume; though others have doubted this fact, on account of the high price of this wood at Constantinople. In this iflad is a monaftery, and it has a town called Lera.

35. LERWICK. At the close, r. 1811—1049; add— the number of houfes was 252.

36. LESGESTAN, one of the small iflats of Daghestan, confifting of a fupenous range of mountains, very long but narrow, and forming the whole N.E. frontier of Georgia. The Lefghi or Lefghans, who inhabit this country, are a wild and favage banditti, divided into different tribes and fpeaking a different dialect. Their houfes are situated on the loftic iflands, and on the moft tremendous precipices; they are connected by fone or wooden bridges, and roads carried through rocks; and they are fupplied with water by pipes or canals cut out of the rocks. The foil is featy, and in order to furnish themselves with the means of fubfiflence, the surface is increafed to the fummits of the elevated ground by graduated terraces, the intermediate spaces being filled up with rubbish, and covered with earth. These people are the bravest, as well as the moft turbulent, of all the nations of mount Caucasus, exciting terror in their neighbours, laying waste their cottages, and carrying away the inhabitants into fervitude. They have long preferred their liberty and independence, and rendered their country inaccessible to any foreign invaders. Moft of them are Mahometans; and the few tribes that continue in ignorance, never change the object of their veneration, which is either the fun, moon, or stars; or indeed any thing that has made an impression on their minds. They hire themselves to fight the battles of their neighbours, at the price of twelve roubles the campaign, which is to ceafe at the end of three months from the appointed day. They often take different fides, not caring againft whom they fight; and thus it often happens, that the Lefghan falls by the fword of his brother or moft intimate friend. They are lightly defroed, after the manner of the Tatars, and armed with a gun, pilfols, dagger, and fable. Their women far- pas in Symmetry and beauty all the females of mount Caucasus, and fetch the largest prices in the markets of Constantinople. M’Kinney’s Peria.

37. LESSERTIA, in Botany, named in honour of the late Mr. Stephen Deloffert, to whom whole mother Roufcaul’s celebrated Letters on Botany were adreffed, and who, like all his family, was no lefs endeared, to those who knew him, by perfonal worth than by talents.—“De Cand. Afragal.

L. annua. (Colutea herbacea; Linn. Sp. Pl. 1245.), and L. perennis. (C. perennians; Jacq. H. Vind. v. 3. t. 3.), see Colutea, n. 11 and 12; with L. diffusa. (Galega dubia; Jacq. 1c. Rar. t. 576; are the only species in Hort. Kew. all natives of the Cape of Good Hope, composing a very natural genus.

LEVERT, in Geography, a township of Gallia county, in Ohio, having 501 inhabitants.

LETTERKENNY, l. 2. r. 1549.

LEVER, col. 2. l. 3, dele (See Plate Surgery.)

LEVERETT, l. 4. r. 760.

LEWES. At the close, r. The population of the rape of Lewes was settled, in the parliamentary return of 1811, to be 18,659 persons, occupying 2932 houses.

LEWIS XVI. col. 10. l. 44, r. the son, Lewis XVII, died very miserably June 8th, 1793, and his father, Maria Theresa Charlotte, was delivered up in exchange for deputies, December 26th, 1793. The queen was brought to the scaffold on October 16th, 1793, and Elizabeth, the king's sister, May 12th, 1794. Col. 11, l. 2, add—Lewis XVIII, on whom the crown devolved after the death of Lewis XVI. and his son Lewis XVII, retired, during the subsequent period of the Revolution, (which flee,) first to Vienna, and was allowed a provision by the emperor of Russia, April 30th, 1798; he afterwards sought an asylum in this country, and landed at Yarmouth, under the title of the Count de Lille, October 6th, 1807; and before returned to the throne of France, made his public entry into London from Hartwell, where he had resided, April 21st, 1814; and having failed from Dover April 23d, made his entry into Paris May 3d, 1814; but quitted this city again in consequence of the landing of Buonaparte in France, March 21st, 1815. After the battle of Waterloo, he returned to Paris, and resumed the government, July 8th, 1815.

LEWIS, in Geography, a county of New York, containing 6433 inhabitants, of whom 4 were slaves in 1810.—Alfo, a township of Ohio, in Clermont county, having 903 inhabitants.—Alfo, a county of Kentucky, containing 2357 persons.

LEWISBURG; a town of Kentucky, in Mason county, having 19 inhabitants.

LEWISHAM. In 1811, the parish contained 1105 houses, and 6625 persons; 2923 being males, and 3702 females.

LEWISIA, in Botany, in memory of Meriwether Lewis, e. q. late governor of Upper Louisiana, the discoverer of several new American plants.—Pursh 368.—Clas and order, Polyandria Monogynia. Nat. Ord.....

1. L. redorvar. Pursh. n. 1.—On the banks of Clark's river, perennial, flowering in July. Leaves radical, linear, rather succulent. Stalk radical, bearing one or two handsome white flowers, whole calyx is elegantly veined with red.

LEWIS TOWN, l. 3. r. 1038; l. penult. r. 474.

LEXAWASCEIN, a township of Wayne county, in Pennsylvania, containing 165 inhabitants.

LEXINGTON, l. 2, add—containing 6641 inhabitants, of whom 971 were slaves in 1810; l. 19, after university, add—or college, a Lancasterian school, and other well-regulated seminaries; l. 22, r. in 1810, were 4326, of whom 1509 were slaves. In 1817, it amounted to 6000, though in 1773 it was merely a hunting camp; l. 28. after Georgia, add—in Oglethorpe county, having 113 inhabitants; l. 34, add—in 1810, the inhabitants were 1052.

LEYDEN, l. ult. r. 1009.

LEYLAND, a township of Leyland hundred, in Lancashire, which, in 1811, contained 459 houses, and 2646 perons; 1263 being males, and 1383 females; 97 families employed in agriculture, and 391 in trade, manufactures, and handcraft.

LIBEL, col. 4, l. 30, dele pilory.

LIBERTY, l. 12. r. 6228 inhabitants, of whom 4898 were slaves in 1810. At the close—Alfo, a township of Butler county, in Ohio, containing 1790 inhabitants.—Alfo, a township of Ohio, in Delaware county, containing 206 inhabitants.—Alfo, a township of Highland county, in Ohio, having 1120 inhabitants.—Alfo, a township of Ohio, in Trumbull county, having 473 inhabitants.

LICHEN ISLANDICUS, Chemical Composition of. This has been submitted to a rigorous and curious analysis by Berzelius. Our limits will not permit us to enter into the details, but the following are the results:

We premise in the above analysis the excels of weight (if not an error) was owing to water.

This indefatigable chemist afterwards examined other species of lichen, such as the L. barkatus, L. fuscatus, and the L. fraxinse. He found them all characterized by the presence of a species of starch which posesses several peculiur properties.

LICHFIELD, l. 4. r. 1811—1010 houses, 5022 inhabitants, 509 families employed, &c.

LICK, a township of Ohio, in Ross county, having 334 inhabitants.

LICKING. Add—Alfo, a county of Ohio, containing 7 towns, and 3832 inhabitants.—Alfo, a township of the said county, having 632 inhabitants.—Alfo, a township of Ohio, in Meukgum county, containing 756 inhabitants.

LIEOU-KIEOU, or Loo-choo, or Great Loo-Choo, l. 2, after number, add—or rather innumerable. At the close, add—The belt maps are wrong in the situation of Loo-choo. They place its town between 23° 45' and 27° 53' N. lat. and between 128° 5' and 129° 2'E. long. The island is also made to extend about 130 miles from N. to S. with an uniform breadth of about 30 miles. Its true direction is nearly N.E. by N. and S.W. by S.; its length is only 56 miles, and its breadth about 11. The longitude of the western extremity is 126° 34' E., and of its easter 128° 19'. The latitude of the S. point is 26° 4' N. and of the N. point 26° 52' N. See an interesting account of these islands in Capt. Hall's Voyage to Loo-choo, or Edinburgh Rev. N° 58. p. 460, &c.
LIMESTONE. Add—Allo, a town of Georgis, in Lincoln county.

LIMON, col. 6, l. 4, from bottom, r. 1811—1813—1861.

LIMON, in America, l. 14, after Warren, add—The number of inhabitants, in 1810, was 42,992; l. 22, r. 16,339—2,489. Col. 2, l. 5, r. 4,555; l. 4, 2212; l. 5, r. 8676—2,341; l. 11, r. 109; l. 13, r. 221; l. 15, r. 713. Add—Allo, a county of Well Tennessee, containing 6104 inhabitants, of whom 720 are slaves.

LIMKHURSHIRE, l. 8, r. 1811—46,368—237,891; l. 9, r. 117,022 males, 120,869 females, 13,184 families; l. 11, r. 29,831.

LIMKQNTOFT. Add—Allo, a town of Georgis, in Lincoln county.

LIMDLWNVILLE. Add—It contains 1013 inhabitants.

LINE, in Fortification. Add—See Field-Fortification. LINGA, col. 2, l. 2, for fire r. fine.

LINLITHGOW, l. ut. r. 1811—40,222—535; the country part having 229 houses, and 1465 persons; and the town part having 306 houses, and 2357 persons.

LINLITHGOWSHIRE, col. 2, l. 15, r. 1811—19,451, occupying 3908 houses: the number of males is 8874; and that of females 10,577; of these 1506 families are employed in trade and manufactures, and 1132 in agriculture. Col. 4, l. 18, after town add—The number of houses in the parish is 354, and of persons 2704.

LINNEUS, col. 5, l. 24, r. journal. Col. 8, l. 19, r. Caper. Col. 11, l. 12, r. Oeland. Col. 15, l. 7, r. Hemmavley.

LINOZSTAS. Add—See Mercurialis.

LIQUIDS, Expansion of. See Expansion and Heat. LISBON, in America, l. 3, r. 1128. Add—Alfo, a town of Maine, in the county of Lincoln, having 1614 inhabitants.

LISKARD, l. 32, r. in the year 1811, the borough and parish were returned to parliament as containing 523 houses, and 2884 persons; the borough having 361 houses, and 1072 persons.

LISMORE. At the close, add—By the returns of 1811, the parish of Lismore, in the district of Lorn, contains 252 houses, and 1323 persons.

LITAMO. Eff. Ch. Calyx and petals spreading. Lip without a spur, cloven, not embraced by the calyx. Column without wings. Anther parallel to the stigma.

L. ovata, and L. cordifolia; see Epipactis, n. 10 and 11.

LITCHFIELD, l. 2, r. 1847; l. 6, r. 1810—382; l. 9, r. 22; l. 10, r. 4,137; l. 20, r. 4,639.

LITHON, LITHO, or rather Lithina, in Chemistry, the name of a fixed alkali recently discovered in Sweden, and so called from $\frac{\text{SiO}_2}{\text{K}_2}$, a flax, because obtained only from mineral substances. This alkali was first detected by Mr. Arvedson, a young Swedish chemist, and pupil of Berzelius. He obtained it from a mineral found at Uten, in Sweden, and which had been some time before described, and named pentalite (see Pentalite) by M. D'Andrada. He found it likewise soon after in tripahne (or fudnmen) and in crystallized lepidolite, all minerals from the same place.

Lithina is principally distinguished from the other alkaline metals, by its great capacity for saturating acids. Sir H. Davy has succeeded in reducing it to the metallic state. Lithium, as this metallic base may be called, bears a strong resemblance to the other alkaline metals, especially to soda, to which it seems most nearly allied.

With respect to the salts of lithina, they have not yet been rigorously examined. The sulphate crystallizes with sufficient facility, and the crystals contain no water of crystallization. Their solution is not precipitated by the muriate of platinum, nor by the tartaric acid. The muriate deliquesces like the muriate of lime, and melts below a red heat. The nitrate crystallizes in rhomboeds, but readily attracts moisture. The carbonate crystallizes in prisms, and the crystals which are commonly very minute are not very soluble in water. The sulphate of lithia is very soluble, and of a yellow colour.

According to Vaquerin, 100 parts of lithia contain 43.5 of oxygen; hence the weight of the atom of lithium will be very nearly 13, and of lithia 23, from which data the composition of all its salts can be easily ascertained.

LITHOMARGE. See Mineralogy, Addenda. LITHONTRIPHT. See Lithotomv, and Urinary Calculi.

LITTLE BRITAIN, l. 14, r. 1700.

MADRID,
MADRID, in America. At the close, add—The district, by the census of 1810, contains 2103 inhabitants, of whom 287 were slaves.

MAD-RIVER, a township of Champaign county, in Ohio, having 1008 inhabitants.

MAGIC, Superstitious, insect—has been supposed to confest; in l. 2, after its—hupposed; l. 7, dele half.

MAGNIFIC SQUARE, col. 5, l. 18 from bottom, dele and.

MAGNESIA, in Chemisty. According to the latest determinations, the weight of the atom of magnesia is 25.7, that of oxygen being 10; from this, the composition of its salts can be easily ascertained. See Atomic Theory.

Separation of Magnesia from Lime.—We may take the opportunity of mentioning here an ingenious method of effecting this difficult chemical problem lately proposed by Mr. R. Phillips, and originally suggested, we believe, by Mr. T. Cooper. The two earths are to be reduced to the state of flatus, and then well washed with a saturated solution of sulphate of lime, which readily diffuses, and thus separates the sulphate of magnesia, but which, from its being already saturated, can take up no more sulphate of lime.

MAGNESIAN LIME-stone. See Mineralogy, Addenda.

MAGNESITE. See Mineralogy, Addenda.

MAGNESIUM, in Chemisty, the metallic basis of magnesia. See Magnesia.

MAGNOTS. At the end, add—See MAINA.

MAHNING, a township of Northumberland county, in Pennsylvania, with 829 inhabitants.

MAHIM, for 17 miles N. of Bombay r. 7 miles N. of Bombay fort.

MAHONING. Add—In Indiana county, having 552 inhabitants.—Also, a township of Mercer county, in the same state, having 1316 inhabitants.

MAHONTOGO, Lower and Upper, two townships of Berks county, in Pennsylvania: the former having 557, and the latter 489 persons.—Also, a township of Northumberland county, having 1608 inhabitants.

MAIDSTONE, in America, l. 2, r. 177.

MAINA, a district of the Morea, including that part of the country anciently called Laconia, that lies between the gulf of Melone and Gythium, bounded on the N. by the highest range of Taygetus, from which a chain of rugged mountains attends to Cape Matapan, the southern termination of the country. It is watered by Pamfius, now the Pirena, the broadest river of the Peloponnesus. The plains round Calamata, a town towards the N.W., are fertile and well cultivated, abounding with the cactus, a prickly pear, the white mulberry affording food for great numbers of silk-worms, and various fruit-bearing trees. The town is built on a plan that is well adapted for defending the inhabitants against the attacks of the pirates that infest the coast. The government of the Maina, in 1705, resembled that of the Scottish islands in former time. Over each district prefixed a capitan, whose residence was a fortified tower. Each chief, besides his own domain, received a tithe from the produce of the land of his retainers; and the different chiefs were independent of each other. Because the Mainots were reluctant to submit to the chajarch, or poll-tax, they had been repeatedly attacked by the Turks, but without success; when an enemy appeared, the coast was immediately deserted, and the inhabitants retired to the strongholds of Taygetus. Expert also in the use of the rifle, besides the advantages of their situation, they have been able to defend the Turkish forces. Some of the chiefs were found by Mr. Morritt to be tolerably vered in Roman literature, and some capable of reading Had, and Xenophon. The laws of hospitality were observed amongst them with the strictest punctiliousness, and letters of recommendation secured to travellers a friendly reception. The religion of the Mainots is that of the Greek church, with all its mummery. Their women were never secluded nor enslaved, and therefore neither corrupted nor ignorant. They distinguished themselves by attention to domestic management, and the education of their children. Influences of conjugal infidelity were rare. In case of necessity, it is said that the Mainots can bring 12,000 men into the field. See Walpole's Memoirs on Turkey, &c. 1817.

MAINE, at the close, add—See United States.

MAINOTS. See MAINA.

MAKEFIELD dele: add—See Wakefield.

MAKONGO, one of the states of Loango in Africa, of which Malemba is the port. The king of Makongo, or Malemba, resides inland at a town called Chingale, the Kinkole of the charts.

MALABAR, l. 11, add—The Malabar language prevails on the western coast of Cape Comorin, extending over Travancore and Malabar, formerly named Kera, as far N. as Nilgirian. See Toolava.

Eff. Ch. Pod nearly cylindrical, of two valves. Stigma simple, acute. Cotyledons incumbent, flat. Calys clooted. This appears to us a very natural and well-defined genus, though hitherto confounded with Cheiranthus. The three species in Hort. Kew. are,

1. M. maritima. See Cheiranthus. n. 14; a pretty annual, frequently and easily cultivated.

2. M. africana. (Hefersis africana; Willd. Sp. Pl. v. 3. 532. Leucojum gallicum, folio balini; Boce. Sic. 77. t. 42. f. 1.)

3. M. littorea. See Cheiranthus. n. 21. (Leucojum marinimum minus; Cluf. Hift. v. 1. 298. f. 2.)

MALDEN, col. 2, l. 12, r. 1811; l. 13, r. 505—2559.

MALDEN, l. 4, r. 1584.

MALEMBO, or MALEMA. Add—See Makongo.

MALIC Acid, in Chemisty. See Sorbic Acid.

MALKOHA. See Phenicopifus.

MALLENDERS, a cutaneous dis ease, commonly confined to draught-horses: it is an inflammation of the skin below the hock, producing cracks which discharge a fetid matter. For the cure of this disorder, owing to want of cleanliness and friction, the hair should be clipped, and the parts well washed with soaps and water; and Mr. White recommends the following ointment: viz. a composition of 2 oz. of wax ointment, 1 oz. of olive-oil, oil of turpentine and camphor, of each 1 dr., and 2 drs. of acetated water of litharge. Mr. Ryding recommends a mixture of 1 oz. of strong quicksilver ointment, and 10 grs. of muriated quicksilver.
The greatest number of the teeth of the mammoth that have been examined resemble at first sight those of the Indian elephant; but, according to Cuvier, the structure, on more attentive observation, will be found somewhat different. In the living species of elephants, the size of the tusk varies with the species, the sex, and the varieties; and as they continue to grow during the life of the animal, age determines their dimensions more than any other cause. The tusks of the African elephant are larger than those of the Indian; they are harder, and preserve their whiteness better. According to Pennant, Mofambique furnishes tusks of living elephants ten feet in length, which are the largest that are known. The degree of curvature in the tusks differs as much as the size; some occasionally occur in a spiral form, and some in that of the letter S. We are unacquainted with the differences that might exist in the curvature of the tusks of the mammoth occasioned by difference of sex or other causes. Many of the tusks have the common degree of curvature, but others have much more curvature than occurs in any living elephants, approaching to a semi-circle or half an ellipse divided through its transverse axis. Some tusks of the mammoth are formed spiral, like what sometimes occur among living elephants. The height of the mammoth did not greatly exceed that which the Indian elephants can attain. It is however certain from its remains, that the mammoth differed as much from the Indian elephant as the as differs from the horse.

The bones of the mammoth, or fossil elephant, are generally found in alluvial soil, near the surface of the ground. They are seldom isolated, but generally mixed with bones of other quadrupeds of known genera; as the rhinoceros, the ox, the horse, and the antelope; and are often accompanied with the remains of marine animals, such as shells, parts of which are attached to the bones. Cuvier states that he has in his possession a jaw-bone covered with millepores and oysters.

The beds which cover the bones of the fossil elephant have seldom any great depth, and are scarcely ever composed of stone. They are rarely petrified, and only one or two inclusions are quoted where they were incrusted with a silicious stone. Often they are only accompanied with fresh-water shells. Every thing appears, says Cuvier, to announce that the cause by which they were buried is one of the most recent that has contributed to change the surface of the globe. It was nevertheless a cause general in its operation, for these fossil bones of elephants are too numerous, and occur in countries too remote and uninhabited to allow us to suppose that they have ever been brought there by man.

The beds which contain and cover these remains shew, that the cause by which the animals were destroyed was water, and in many instances the waters were the same as those of the present day, since they contained the same species of shell-fish. These bones are not water-worn, and therefore have not been transplanted from a distance.

The shells and millepores which adhere to them prove that they remained some time covered only with water. The different species of mollusca, the gigantic tapir, and the fossil rhinoceros, lived in the same countries as the fossil elephant, since their bones are found in the same beds and preferred in the same strata. Everything therefore leads us to conclude that the mammoth, or fossil elephant, is an extinct species, though it differs less from existing species than the other remains of quadrupeds that are found in the same situations. In a former part of this work, under the article Megatherium, the discovery of the fossil elephant described by Mr. Adams is more particularly given; but the animal is erroneously supposed to belong to another species.
species than the elephant, and the tusks are called horns. (See Mastodon, Megalodon, and Megatherium, Addenda.) According to Pallas, there is a scarcely a river from the Don or the Tanais to Tchutskinof in the banks of which the bones of the mammoth are not abundant, and two islands of great size near the mouth of the Indigirka seem entirely composed of these bones mingled with ice, sand, and the bones of the elk, rhinoceros, and other large quadrupeds.

Similar bones are found in Poland, Germany, France, Holland, and Hungary. We have before mentioned that they are found in various parts of England, and no where more abundantly than in the vale of Thames, particularly near Brentford. The teeth and bones have generally been found in alluvial soil over the chalk formation; but in Mr. Bakewell’s Introduction to Geology, an instance is given of an entire skeleton having been found in a cavern in the mountain lime-dome near Wirksworth, in Derbyshire, in 1663. Its skull was so large that it is flated to have held four bushels of corn.

MANCHA, LA., l. 1 and 2, r. bounded on the N. by New Caftle; deb north of.

MANCHESTER, l. 10, add.—In 1811, the number of houses inManchester and Salford was 16,535, and that of the inhabitants 98,573; 44,332 being males, and 54,241 females: of whom 19,659 families were employed in trade and manufactures, and 47 in agriculture.—l. 15, r. the whole population of which, including Manchester, was 138,349.

MANCHESTER, in America, l. 4, r. 1137; l. 7, r. 1502; l. 9, r. 1579; l. 10, r. 978; add—Alfo, a town ofHillsborough, in New Hampshire, containing 615 inhabitants.

MANEGE, or MENAGE, denotes an academy, riding-school, or other place for learning to ride, and for breaking horses to their various motions and actions. Alfo, the exercife itself, or the art of riding, which teaches at the fame time to form the horfeman and the horfe.

MANE-SHEET, in theManage, a covering for the upper part of a horfe’s head, extending round his neck, with holes for the ears to pass through, and joining to the halter upon the fore-part of the head, and likewise to the surcingle, or long girth, upon the horfe’s back.

MANGANESE, in Chemistry. The specific gravity of manganese, according to Dr. John, is 8.013. A good deal of common flaw exifts refpeeting the oxides of this metal.

According to Dr. John, there are three oxides; the green, the brown, and the black. According to Berzelius, there are no lefs than fve. Sir H. Davy could only obtain two, and Dr. Thomson agrees with him in concluding there are but two; namely, the olive or protoxyd, which combines with acids, and forms the common falks of manganese; and the black or peroxyd, which is found native. From the experiments of Dr. John and Berzelius, Dr. Thomson fixes the weight of the atom of manganese at 35, and of course that of its protoxyd at 45; from which data, if correct, the composition of its falks may be efimated. The following erratum exifts in this article in the Cyclopedia. Col. 3, l. 16, for malts r. metals; also in the fame col. paragraph 9, at the end of the fentence refpeeting iron, add—Berzelius has lately fhewn, that manganese is a con- tinent ofonne iron.

MANGE, a cutaneous difeafe, incident to many domestic quadrupeds, and attended with an eruption and loss of hair. Its caufes, according to Mr. Ryding, are, sudden changes of temperature, hot ftable, bad diet, and want of cleanliness. It is alfo communicated by infection, as when a found horfe rubs himfelf againft a f tall, in which a mangy horfe had been kept. Its symptoms are, a loss of flesh, without any apparent caufe, a forwarding of the coat, and afterwards eruptions, difcharging a thick yellowish matter, which forms a kind of fcurf that peels off, and a falling off of the hair. The difierer, though partial at first, soon penetrates all over the body, and is attended with an itching, which causes the horfe to rub againft every thing that comes in his way. It is faid, that with attention to cleanliness, an ointment composed of 1 lb. of prepared hog’s-lard, ½ lb. of fulphur, 3 oz. of white helbelle in fine powder, and olive-oil in fufficient quantity, rubbed over the affected parts, and repeated after an interval of three days, will after two or three applications complete a cure. Some fay, that if the animal’s strength will allow it, the cure should be commenced with bleedings, and a ball formed of powdered nitre, powdered rofin, and caftile foup, of each 1 oz., 1 drachm of camphor in powder, and honey q. s. should be given in the evening. Attention fould be paid to diet, exercise, and good grooming; the bowls fould be kept in a proper state with mashes, in which 1 oz. of nitre is dissolved; the affected part fould be well washed with a strong folution of fof-loaf, and afterwards rubbed morning and evening with an ointment composed of 4 oz. of flowers of fulphur, 3 oz. of hog’s-lard, and 2 oz. of quickfliver ointment. The ointment may be continued every other day, until the difeafe is removed. Two or three doses of mild physic are recommended, and then a ball made of Ethiopia’s mineral, crude antimony in powder, and cream of tartar, of each ½ oz., and honey q. s. fould be given every night for a month.

In a flight cafe, ftrong tobacco infufion with one-third part of fial urine, used for fwalling the affected parts, will be fufficient; but as an efficacious unguent, the following is recommended; viz. ½ lb. of quickfliver ointment, 4 oz. of finely powdered bromifhone, 2 oz. of black fop, ½ oz. of crude fal ammoniac, and oil of bays and tumentine, q. s., or tar, gun-powder finely pulverized, black fop, and oil of turpentine, of each about equal quantities. Fhe foles may be washed twice a day with a lotion compounded of ½ oz. of muriated mercury (fublimate) in powder, diluted in 1 pint of boiling water; 1 oz. muriated mercury, muriated zinmonia (crude fal ammoniac), of each from two to three drachms, and three half pints of boiling water.

MANTHEIM, l. 3, r. 1282; l. 5, r. 2207; add—Alfo, a township in Berks county, having 1354 inhabitants.

MANINGTREE, l. 18, r. 1811; l. 19, r. 1735—217.

MANNA, Chemical Properties of. Manna differs from sugar in feveral remarkable particulars. It difolves very readily and abundantly in alcohol, and crystallizes on cooling. Nitric acid converts it partly into oxalic, and partly into faclatic acid. It does not ferment like sugar, and of course yields no alcohol. The common manna of the fhips, according to Fourcroy and Vauquelin, confifts of four different ingredients. Pure manna conftituting about three-fourths of the whole—a little common fugar—a yellow matter with a wafeful odour, to which 18 of purgative qualities of manna are chiefly owing—and a little mucilage, convertible into faclatic acid. Manna feems to be formed during the fermentation of many juices, fuch as the juices of the onion, melon, &c.

MANNINGTON. Add—containing, in 1810, 1664 inhabitants.

MANOR, l. 2, r. 2642.

MANTUA, a township of Ohio, in Portage county, containing 243 inhabitants.

MARAZION, l. 15 and 13 from bottom, r. 1811—

MARBLEHEAD, l. 4, r. 5900.

MARECHAUSSES, denoted, under the French monarchy, several small bodies of troops, composed of officers and soldiers who had been in service, that continued stationery in the principal towns, for the purpose of aiding the civil magistrate. That in Paris consisted of three companies; viz. the company belonging to the "Lieutenant criminal de Robe au Coûte," or to that particular court of judicature which was superseded by the provost de la Marechaussée, and which Charles IX. attached to the gendarmerie; the independent company of mounted police, called "Guet à Cheval," and the company of the police or foot patrol, called "Guet à Pied," which was again subdivided into two companies, in order that one might do the duty of the quays. These companies were under the immediate direction of the secretary of state for the interior department of Paris.

MARGARIC ACID, in Chemistry. This acid exists in the form of pearly scales; hence the name. It was first described by Chevreul, who obtained it by digesting a fap made of hog's-lard and potash in water. Part of the margaric of potash was dissolved, while another part was depoited in the form of pearl-coloured scales. The potash was afterwards removed by muriatic acid, and thus the margaric acid obtained in a state of purity. Margaric acid is pearl-white. It is talc-like, and emits a smell something like white wax. It melts at a temperature of 134°, and crystallizes on cooling into beautiful brilliant white needles. It is insoluble in water, but very soluble in alcohol. It reddens vegetable blues very readily, and combines with all the baxes, especially with the alkalies and alkaline earths, forming salts, or rather faptes. Dr. Thomson, from the experiments of Chevreul, fixes the weight of the atom of this acid at 330.

MARGATE, col. 3, l. 9, r. 1811; l. 10, r. 612—

MARION, l. 2, r. 88—

MARK ISLAND, a township of Hancock county, in the district of Maine, with few inhabitants.

MARBOROUGH, col. 1, l. 8 from the bottom, r. 1811—2579; l. 7, r. 445. Col. 3, l. 24, after lady Jane, dele unhappily for herself; l. 27, after favourite, r. who died in childbirth. After Edward VI.; deo who was defined to suffer the fate of her predecessor.

MARBOROUGH, in America, l. 4, add—containing 4906 inhabitants, of whom 1709 were slaves in 1810; l. 7, r. 1674; l. 12, r. 1806—1245; l. 14, r. 1112. Col. 2, l. 1, r. three; l. 2, after Pennsylvania, r. one in Montgomery county, having 672 inhabitants; and E. and W. Marlborough, in Chelster county; the former having 1046, and the latter 917 inhabitants.—Also, a town of Hartford county, in Connecticut, having 720 inhabitants. —Also, a township of Delaware county, in Ohio, containing 177 inhabitants:—l. 5, r. 1832.

MARLOW, Great, col. 2, l. 16 and 17, r. 1811—25—1166 persons; add—and its borough to contain 468 houses, and 2799 inhabitants; l. 20, add—in a parish of the same name, which contains 140 houses, and 730 inhabitants.

MARLOW, in America, l. 2, r. 564.

MARPLE, a township of Delaware county, in Pennsylvania, having 649 inhabitants.

MARSELLOIS, The, or Marselles Hymn, a national march, adopted by the French during the course of the Revolution, and regularly played in their armies when they went to battle. It was frequently accompanied, or rather succeeded by the "ca ira," a lively tune; the former being calculated for slow or ordinary time, and the latter for quick movements. Both are now proscribed.

MARSHFIELD, l. 25, r. 1811—272; l. 26, r. 1415.

MARSHFIELD, in America, l. 4, r. 1364; l. 6, r. 513.

MARSEPEE, l. 3, r. 139.

MARTELLO, or Morteullo, Towers, denoting small cisterns erected for the defence of a coast; such are those of Romny Marsh, of the island of Jersey, Halifax in Nova Scotia, &c. Grofe derives the term martello, from morta, whence moto or moat, which formerly signified a cistern. Others derive it from the Italian "fonare in campagna a martello," to sound the alarm bell, which, in some parts of Italy, is struck by hammers. In old French, the word signifying the same thing, (now martel,) was martel, and martel en fable was the adage for the rumour of annoyance or alarm.

MARTOCK, l. 2, r. 1823.

MARIU. Add—This was the ancient capital of the province of Margiana, founded by Alexander the Great, and afterwards embellished by Antiochus Nicator, who called it Antiochia. It was one of the four imperial cities of Khorassan; its fruits were finer than those of any other place, and the walls were on all sides surrounded with magnificently-paved palaces, groves, and gardens. It was taken and pillaged by the Tubex about 25 years ago; since which time, it has gradually declined, and the population is now reduced to 3000 souls, under the government of Hyder Shah of Bokhara. The revenues of the king are 200000 rupees annually. It is 80 furlongs hence to Herat. Del the next article.

MARY, queen of Scotland, l. 2, first (or 7th). Col. 2, l. 29, after their own, add—This article, says Mr. Chalmers, (ubi infra) denounced the Scottish queen, who was heir-presumptive to the crown of England, of all future pretensions to the crown. The flpulation, he says, ought to have been, not in all times coming, as expressed in the article, but during the life of Elizabeth. Considering, moreover, the defective powers of the French negotiators to treat upon the matter of that importance, in addition to the wordings of the clause, these circumstances created an insuperable objection to the ratification of such a treaty; which treaty was never ratified by the Scottish queen, or by any person under her authority. Col. 4, l. 8, for He r. Darnley; l. 20.—We know for certain, says Mr. Chalmers, that the king was murdered by Murray's faction, and that Morton, Bothwell, and Maitland, were the eminent characters who were attained by parliament for the deed, though many inferior persons, and some of the innocent, were tried and punished for the same crime. But the queen, he says, as she was not one of that faction, was not guilty; and every attempt of Robertson and Laing to establish her privy to this transgression has failed. Col. 6, l. 28, after employers, add—Queen Elizabeth, it has been said, wished to have had Mary put to death privately by poison or by affimation, and actually suggested and expressed her wishes to this purpose, and she thus acted suitably to the declaration made by her on Palm-sunday 1572, viz., "that the queen of Scots' head should never be quit." At length, when she dark hints or more explicit instructions, communicated to Paulet and Drury her keepers, had failed of producing effect, preparations, &c.; l. 29, after publicly, add—but the privy-counsellors differed in their opinion
opinion concerning the law by which he should be tried, whether it should be the statute of treasons, (25 Edw. III.) or a late act of the 27th of Elizabeth, which had been made for this special occasion. However, the last opinion prevailed. At the close, add—Chalmers's Life of Mary, Queen of Scots, vol. i. 4to. 1818.

Mary, St. col. 2. 1. 8. 12. 794; l. 9. 6000; l. 13. add—in the county of Camden, which fee.

MARYLAND. Add—See United States.

MARYPORT, col. 2. 1. 5 and 6. l. 1811—322—

MASHAM, l. 7. r. 1811—213—1014.

MASOLES, the name of a militia in Croatia, which is bound to march to the frontiers whenever there appears the least symptom of hostile disposition on the part of the Turks. The private soldiers have lands allotted to them, which they cultivate for their own use, but receive no pay from the public. The officers are paid.

MASON, l. 7. r. 1077.

MASSACHUSETTS. Add—See United States.

MASTODON, in Natural History, a large quadruped, whose bones are found in a fossil slate. It was for a long time confounded by naturalists with the mammoth or fossil elephant. (See Mammoth, Addenda.) Cuvier has ascertained, that the mastodon is not only a distinct animal from the mammoth and the living species of elephants, but that it must be classed as a new genus. Five species of this genus have been at present discovered.

The great mastodon, or the animal of the Ohio, the bones of which have been found in the greatest abundance near the Ohio river, in the province of Kentucky, in North America, bears a considerable degree of resemblance to the elephant in its tufs and general ooleogy, the form of the grinders excepted. It had probably a trunk, but this part being more perishable than the bones has not been discovered. Cuvier concludes from its general structure, that it could not have fed itself without the aid of a trunk. Its height did not surpass that of the largest elephant, but its body was longer, and its members were somewhat thicker; its belly was less extended than that of the elephant. Notwithstanding the general resemblance, the structure of the grinders is so different, as to entitle us to class it as a different genus. It fed itself nearly in the same way as the hippopotamus and the wild boar, on the roots and pulpy parts of vegetables; and this kind of food would naturally lead it to moil and marshy ground; but it was not made for swimming, or living under water, like the hippopotamus, but was really a land animal. Its bones are more common in North America than elsewhere, and are more fresh and better preserved than any other known fossil bones. Yet there is not the least reason to believe, according to Cuvier, that there are any living mammals either in America or elsewhere. The most celebrated place where the remains of the mastodon occur is called Big-bone Lick, on the south-east of the Ohio, five miles from the river, and thirty-six miles below the entrance of the Kentucky river, and nearly opposite the great Miami. The place where they occur is a fall marsh surrounded by hills. The bottom of the marsh is a black and fetid mud. The bones are found in the mud and on the borders of the marsh at about four feet below the surface, but they occur also in various parts of North America in marshy situations. In 1805, many bones of these animals were found in the county of Wythe, in Virginia, about five feet under the earth, upon a bed of lime-stone. One of the teeth weighed seventeen pounds. But what renders this discovery the more remarkable is, that a mafs of half-ground branches, roots, and leaves, included in a kind of hum, supposed to be the foimach, was found in the midst of these bones, so as to leave no doubt that these were substances that the animal had devoured. Among the vegetable matter in this hum were distinguished the remains of some plants known in Virginia. The bones of the great mastodon may be said to be common in North America; two nearly entire skeletons were collected by Mr. Peale; one of the largest is preserved in the Museum of Natural History at Philadelphia, the smaller was exhibited in London a few years since. These bones are scarce in other parts of the world; but wherever they have been found, it is at no great depth under the soil, and yet they are but little decomposed. They are not rounded by attrition, and offer proofs that they have not been removed from the places where the animals died. The skeletons found near the river called the great Ofages were nearly in a vertical position, as if the animals had simply sunk into the mud and been buried there. According to a letter from Mr. Smith Barton, professor at the university of Pennsylvania, to M. Cuvier, "An intelligent traveller had seen near that river thousands of these bones, and had collected seventeen tufks, some of which were fix feet in length, and a foot in diameter; but the greater part of these bones was much decomposed." Mr. Barton sent a grinder to M. Cuvier, so that no doubt can be entertained that the bones belonged to the mastodon. No remains of marine shells have been discovered with the bones of the mastodon, as is the case with those of the mammoth. Mr. Barton thinks, that the salt water of the marshes where they are found has contributed to the preservation of the bones. He states also two instances which appear to prove that from time to time the soft part or flesh of these animals has been dug up; a circumstance which, from the heat of the climate, is much more astonishing than what is stated of the flesh of the mammoth and rhinoceroses being found in Siberia. (See Mammoth.) The Indians, who discovered five skeletons in 1762, relate, that one of the heads had a long nose above the mouth; Mr. Barton supposes that this was in fact the trunk. Kalm, in speaking of a great skeleton discovered by the savages in a marsh in the Illinois country, says, that the form of its beak was still discoverable, though half decomposed; it is probable that this was the root of the trunk.

Some doubts exist whether the mastodon be really an extinct genus, and whether it may not be found living well of the Missouris. The Indians of Virginia, according to Mr. Jefferson, say, that a troop of these formidable beasts destroyed the deer, buffaloes, and other animals created for their use; when the great man above destroyed them all with his thunder, except the largest male, which presenting its head to the thunder-bolts threw them off as they fell, but being at last wounded in the side, it fled towards the lakes, where it lived to this day.

The skeleton of the great mastodon exhibited in England was near eleven feet high. From the size of detached bones, Cuvier conjectures that the animal never exceeded twelve French feet, but its body was much longer in proportion than that of the elephant.

The form of the crown of the molares or grinders is nearly rectangular. The substance of the teeth is of two kinds only, the inner or ooleous part, and the outer or enamel, which is very thick, and has no kind of cement or cortical. This very important difference joins with the form brings this animal nearer to the hippopotamus and the pig, than to the purely herbaceous animals like the elephant.

The crown of the grinders is divided by deep open furrows into a certain number of transversal ridges, and these ridges
ridges are again divided into two large irregular pyramidal oblique points, a little rounded. The crown therefore is fluted with these pyramidal points disposed in pairs; it is however very different from the teeth of carnivorous animals, which have only one principal longitudinal furrow divided into lesser indentations, like a saw. The teeth of the elephant have on the crown several little transverse walls, divided into a number of small tubercles, and these grow flat early, whereas the tubercles or cones on the tooth of the mastodon being much larger, the crown remains long mantled. It was this circumstance of the grinders being fluted with points that gave rise to the opinion of the mastodon being carnivorous.

The number of grinders, according to Cuvier, are fix on each side, three above and three below.

The structure of the jaws indicates that the mastodon had tusks like the elephant or more. The number of tusks which occur with the teeth further confirms this opinion. A skull was found by Mr. Peale which proves this fact, being furnished with alveoles. The curvature of the different tusks varies as much as in the elephant; but M. Cuvier thinks there is no ground for believing with Mr. Peale, that the tusks turned downwards.

The head of the mastodon being of vast size, and rendered exceedingly heavy by the teeth and tusks, which carried the centre of gravity far from the point of support, the neck was therefore necessarily short, like that of the elephant; so that without a trunk it could not have reached the ground with its mouth. Its tusks would also have deprived it of the power of eating on the ground; it is therefore certain that it must have had a trunk like that of an elephant.

From the remains of the mastodon, it appears there were five species, all of which are believed to be extinct.

1. The great mastodon that we have been describing.
2. The mastodon with narrow grinders. The remains of this species have been dug up at Semorea, and many other places in Europe, and also在美国.
3. The small mastodon with small grinders. This species is much less than the preceding, and was found in Saxony.
4. Mastodon of the Cordillera. This species was discovered in South America by Humboldt. Its grinders are square, and it appears to have been equal in size to the great mastodon.
5. Humboldtian mastodon. This, which is the smallest species of the genus, was found in America by Humboldt. These five species may be considered as forming a distinct and hitherto unknown genus.

The following are the dimensions of the skeleton of the great mastodon found by Mr. Peale, and placed in the Museum of Natural History in Philadelphia.

MATTHEWS, in Geography, a county of Virginia, containing 4227 inhabitants, of whom 2908 were slaves in 1810.

MATTHIOLA, or rather Matthiola, in Botany, Brown in Ait. Hort. Kew, v. 4. 119. See our former article. Mr. Brown has restored this meritorious name, to designate a new genus of his own, extracted from the more hoary kinds of Cheiranthus, (see that article,) n. 16, 17, 20, 24, 31, 28, and 15. We allow a difference of habit, but scarcely perceive a sufficient character.

MATLOCK, l. 14, r. 1811—525—2496.

Vol. XXIII.

MAURICE, l. 4, add—The town contains 2085 inhabitants.

MAURY, a county of West Tennessee, containing 16,335 inhabitants, of whom 2626 were slaves in 1810.

MAWS, St. In 1811, the parish of St. Juft contained 272 houses, and 1639 persons; viz. 751 males, and 888 females; 72 families being employed in agriculture, and 59 in trade, manufactures, and handicraft.

MAYOMBA, or MAJUMBA, Cape, a cape on the coast of Africa, in S. lat. 3° 34'. E. long. 11° 13' 30'.

MEADS, a township of Crawford county, in Pennsylvania, containing 736 inhabitants.

MEADVILLE, l. 5, after houses, add—457 inhabitants.

MECKLENBURG, l. 2, r. 18,453 inhabitants, of whom 16,264 were slaves in 1810; l. 6 and 7, r. 14,272—3494.

MECONIC Acid, in Chemisty. See MORPHIA, and OPIUM.

MECRAN, or Mekran. At the end, Kidge or Kej, add—The population of Mekran is formed of many different tribes and independent chiefs, of which the Balouches are the most numerous; a middle-sized race of men, spare, muscular, and active, and armed with a match-lock, sword, shield, and dagger. The common language of the country is a corrupt Persian, mixed with Scindi, and the Balouches in general are of the Soonee persuasion. Thos. of the central territories reside mostly in towns; those of the lower countries scattered over the plains, in hamlets of eight or ten huts, built of branches of palm, and covered with mats. The Balouches take, in general, but one wife, and their chiefs four; they are said to have great influence in the disputes of their tribes. The women of Mekran are allowed to appear indifferently in public. Mekran was formerly under the dominion of Naffir Khan, the chief of Kelat; but since his death, in 1795, the authority of his son has ceased, and of the dominions of his father he only retains possession of the fort of Kej. The whole force of the country, it is thought, may amount to about 25,000 men, whom it would be impossible to collect or to induce to concur in action. The revenues of this country are trifling.

MEDFIELD, l. 3, r. 786.

MEDFORD, l. 6, r. 1443.

MEDICAL ELECTRICITY. Since our remarks on medical electricity (see Medical Electricity) were written, a method has been announced, in some degree new, of exhibiting this remedy, which we shall very briefly notice here. This consists in employing a jar coated on the outside with paper tinfoil, and instead of a coating on the inside, having only a spiral coil of wire in contact with its surface. On making the experiment, we find the shock is modified and softened by this contrivance. It appears, therefore, much better adapted for administering what is commonly called vibratory shocks, (that is to say, small shocks in very quick succession,) than the jar commonly used for the purpose. We omitted to mention that this method of exhibiting electricity (called vibratory) is commonly practised by electricians, chiefly from its requiring
requiring a very small apparatus, and from its being at the same time equal, or nearly so, in effect to a large current of fluid produced from a very powerful machine.

MEDOMAN, in Geography, a town of America, in Maine, and county of Lincoln, having 121 inhabitants.

MEDULLIN, in Chemistry, a name given by Dr. John to the pith of the sunflower, the *safranga vulgaris*, &c. and which, according to him, is distinguished by the following properties: It is soluble in water, alcohol, ether, and oils. It has neither taste nor smell. It is soluble in nitric acid; but instead of forming fuferic acid, furnishes a quantity of oxalic acid. Its structure is peculiar, and when burnt it leaves a charcoal having a metallic bronze-like appearance.

MEDOWAY, in America, l. 4. r. 1713.

MEERSCHAUM, See Meerschaum, and Mineralogy, Addenda.

MEGALONIX, in Natural History, an extinct species of quadruped, about the size of an ox, whose remains were first discovered in Virginia. It was supposed by Mr. Jefferson to be allied to the lion, and hence received its name. According to Cuvier, however, the megalonix and megatherium are nearly allied, and may be considered as belonging to the same genus, which may be placed between the floth and the ant-eaters, but nearer to the former than the latter. The remains of these animals have hitherto been found only in America, where floths and ant-eaters are present exit. See Megatherium, Addenda. Semegatherium. (See Megatherium.) The animal described in the former part of that article, whose remains were found in Siberia, and noticed by Mr. Adams, was not the megatherium of Cuvier, but the fossil or extinct elephant. (See Mammoth, Addenda.) The megalonix was of the size of the rhinoceros; its fossil remains have hitherto been found only in South America. The first and most complete skeleton was sent from Buenos Ayres in the year 1789. It was found in digging in alluvial soil, on the banks of the river Lusitania, a league S.E. of the village of that name, and three leagues W.S.W. of Buenos Ayres. A second skeleton was sent from Lima to Madrid in the year 1795; and a third was found in Paraguay. This animal differs from the megalonix chiefly in magnitude, being much larger. See Cuvier's description in the latter part of the article Megatherium.

MEGIDDO, or Megede, in Scripture Geography, a city of Mansiel (Joh. xvii. 11. Judg. i. 27.), famous for the defeat of king Josiah. (1 Kings, xxix. 29, 30.) Herodotus, speaking of this victory, says, Nehoch obtained it at Megador, lib. ii. cap. 159.

MEIGS, in Geography, a township of Adams' county, in Ohio, having 835 inhabitants.

MEKAN. See Mekan.

MELDUM. In 1811, the parish of Old Meldrum contained 411 houses, and 1635 persons; viz. 736 males, and 919 females: 335 families employed in agriculture, and 86 in trade, manufactories, and handicraft.

MELFORD, Long, l. 5 and 6, r. 1811—415—2668—951—1117.

MELLIT, in Farriery, a dry scab growing upon the heels of the foot of a horse, which is cured by a mixture of half a pound of common honey, and a quarter of a pound of black soap, with four or five spoonsful of vinegar, half an ounce of finely powdered alum, and two spoonsful of fine flour, applied to the affected part, after removing the hair, like a plaster, and suffered to remain five days. If the cure be not completed, the leg, foot, and toe, should be washed, and the same application repeated.

MELMOTH, col. 2, l. 20 and 21, r. thus—The author of 'The Pursuits of Literature' says, 'Mr. Melmoth is a happy, &c."

MELROSE, l. 12. In 1811, this parish contained 538 houses, and 1832 persons; viz. 1531 males, and 161 females: 239 families employed in agriculture, and 251 in trade, &c.

MELTON-MOWBRAY, l. 24 and 25, r. 1811—451—275.

MENALLENG, a township of Fayette county, in Pennsylvania, having 1288 inhabitants.

MENANGEEBOW, for Menangeebow.

MENDHAM. Add—containing 1277 inhabitants.

MERA, l. 14 from bottom, after Lingo, add a comma.

MERCER, after acres, add—16 townships, 8277 inhabitants; l. 6, 11, 587 inhabitants, of whom 3500 were slaves in 1810.—Also, a township of Mercer county, having 692 inhabitants.—Also, a township of Butler county, in Pennsylvania, having 588 inhabitants.—Also, a township of Maine, in Somerset county, having 562 inhabitants.

MERCURY, p. 12, col. 2, l. 12 from bottom, for Todd r. Thomson.

Mercury: This metal boils, according to Crichton, at 65°; according to Heirich at 65°. These differences respecting the boiling point of this metal, as well as those mentioned in the original article, probably arose in part from the mode in which the thermometers employed were graduated. See further on this subject under Heat. There are but two oxyds of mercury known, and not three, as stated in the Cyclopaedia, the black or protosyd, and the red or persyed: the former of which, according to Dr. Thomson's recent determinations, is a compound of 100 mercury + 4 oxygen; and the second, 100 mercury + 8 oxygen. Hence the weight of an atom of this metal will be 250, and from this the composition of its salts may be deduced. (See Atomic Theory.) What has been said in our original article respecting calomel and corrosive sublimate, formerly termed submuriate and oxymuriate of mercury, is now to be understood, according to the present views of their composition, as applicable to the protechloride and perchloride of mercury. See further on this part of the subject under Chlorine.

MERDIN, l. 7. Its inhabitants amount to nearly 11,000 souls; l. 9, add—their number is supposed to be 1500, having several churches, and a parochial, and besides here are 200 Jews, and also Turks, Arabs, and Kurds. At the end, add—it is 45 furlongs from Diarbekr. It is the frontier of the pachalic of Bagdad, towards Constaninople, and under the government of a Mussaleem, appointed by the pacha.

MERIDEN, a town of New Haven county, in Connecticut, having 1249 inhabitants.

MERION, l. 3. r. 1156—1835.

MERIONETSHIRE, col. 5, l. 37 and 38, r. 1811—6022—30, 924—14, 089—16, 616—3619—1720.

MERRICK, l. 3, r. 1048.

MERTHYR-TFYDVI, col. 2, l. 30, add—in its five hamlets, by the parliamentary returns of 1811, it is rated to amount to 11, 104 persons, occupying 2264 houses.

MERTON, l. 4, r. 1811; l. 5, r. 135—905.

MERU-SHAH-JEHAN, See Mearu.

MESCHID, Maschid, or Meched, l. 1, infer—The capital of the Persian division of the province of Khorasan, situated about two furlongs from the ruins of the ancient city of Tous, and celebrated for a very superb sepulchre, containing the relics of Imam Reza, and those of the caliph Haroun ul Ruchid. This city, though a great part of it
it is in ruins, has a population of 50,000 souls. The bazaar is well supplied with fruits and provisions, from the fertile plain on which the city stands. It is surrounded by a strong wall, three furlongs in circumference, and the great bazaar is three miles in length. The city is governed by one of the king's sons, and with the districts belonging to it yields a revenue of 99,000 tomans. It carries on a considerable trade with Bokhara, Bukh, Candahar, Yezd, and Herat. Velvets of the finest quality are manufactured here, and its fur pelisses are much esteemed.

MESHED. See MESHID.

MESHED. Ali. See NEJAF.

METAL, in Geography, a township of Franklin county, in Pennsylvania, having 1236 inhabitants.

METALS, in the Materia Medica, vol. 2, l. 24, for Todd r. Thomson.

METEORIC IRON. See Mineralogy, Addenda.

METHERVAN, in Geography, a town of Essex county, in Massachusetts, containing 1181 inhabitants.

METWOLD, col. 9, r. l. 4, 1. 1981-94—174.

METROXYLON, in Botany, a name given by Rotboll, in the Copenhagen Translations, to the true Saga Palm, described from Dr. Konig's manuscripts, by Mr. Charles Konig, in Ann. of Bot., v. 1. 195, l. 4. This genus appears to differ from Gertner's Sago, (see that article,) in having a corolla; which is monopetalous and three-cleft. See Saga.

MEXICO, col. 15, l. 21 from bottom, add—The industrious researches of the ingenuous and philosophical traveller M. Humboldt have established the remarkable fact, that in the whole of the New Continent, there is nothing which indicates the existence of alphabetical writing, nor any very near approach to it. Although the use of hieroglyphic paintings was common among the Toltecks, Aztecks, and other tribes, which, since the sixteenth century, have appeared successively on the elevated plain of Anchau, Humboldt suggests, that the progressive perfection of Symbolical writing, and the facility with which objects were painted, prevented the introduction of letters. It is alleged, that they have done so for a much longer time with the Chinese.

MIAMI, a township of Clermont county, in Ohio, containing 1670 inhabitants.—Also, a township of Greene county, in Ohio, containing 704 inhabitants.—Also, a township of Hamilton county, in Ohio, containing 495 inhabitants.—Also, a county of Ohio, containing 6 townships, and 3941 inhabitants.

MICHIGAN. Add—The territory of Michigan includes four districts, viz. Detroit, Erie, Huron, and Michilimackin, and by the census of 1810, 4702 inhabitants, of whom 24 were of foreign birth.

MICKLEHAM, col. 2, l. 1, r. 1811; l. 2, 416 persons, occupying 34 houses; l. 3, 190—226.

Eff. Ch. Calyx of five spreading leaves. Petals five, minute, undivided; or wanting. Stigmas four, sessile. Capsule ovate, longer than the calyx, of four valves.

Mr. Pursh speaks of Arenaria foetidissima as probably belonging to this genus, but we know not whether he intends the plant of Linnaeus, or of Jacqu. "t. 182; see Al. Bot. t. 1744.

After the observations on curd, add—Curd has many of the properties of coagulated albumen. It is white and solid, and when all the moisture is squeezed out, it has a good deal of brittleness. It is precipitated by acids, and the precipitate consists of the curd combined with the acid employed. If this precipitate be digested with carbonate of lime or barytes in water, the acid combines with the earth, remains undiffolved, (supposing the sulphuric acid employed,) and leaves the curd in solution. The aqueous solution of curd thus obtained is yellowish, and resembles a solution of gum. When the solution is boiled in an open vessel, it becomes covered with a white pellicle, precisely as milk does, and acquires the smell of boiled milk. The membrane is almost insoluble in water, and appears to be produced by the action of the air on the diffused curd. With the mineral acids, curd forms the same compounds as albumen and fibrin do; but the neutral compounds are less soluble. A great excess of acetic acid is required to dissolve curd, and the neutral compound of curd and this acid appear insoluble. According to the analysis of Gay Lussac and Thenard, curd is composed of

MINERAL CAOUTCHOUC. See MINERALOGY, Addenda.

MINERALOGY, according to the most eminent mineralogists of the French school, comprises the study of all inorganic substances that exist naturally in the earth, or on its surface. According to this comprehensive definition, water, air, and all ponderable elementary matter, may be clasped with minerals. The German mineralogists use the term mineral in a more restricted sense. See MINERALOGY, where is given a history of the progress of this science, and an outline of the systems of Werner and Haüy. For a more full account of the external characters of minerals, and of the systems of classification introduced by Werner, see OBYECTOGRAPHY; and for the leading principles of crystallography, on which the system of Haüy is formed, see CRYSTALLOGRAPHY, Addenda. Under the article SYSTEMS OF MINERALOGY, we have given a summary view of the chemical systems of mineralogy recently attempted to be introduced by the distinguished Swedifh philospher Berzelius.

Mineralogy has scarcely been cultivated as a regular science in Europe longer than fifty years, and in England it has not excited much attention until the present century; since which time our acquaintance with the mineral kingdom has been rapidly extending. We propose in the present article to describe those minerals which have been recently discovered, or whose characters have been more accurately known since the articles were written in which they were described. Many minerals having received several different names, we have also deemed it expedient to give an alphabetical list of all the known species of minerals, with references to the particular name under which each is described. This will, we trust, in a considerable degree, remedy the inconvenience resulting from the ulelefs multiplicity of names; an evil which, in this department of science, tends greatly to retard the progress of useful knowledge. To Werner, we are indebted for the first precise definition of the external characters of minerals; but unfortunately both he and the mineralogists of the Freyberg school have introduced such a multiplicity of divisions, subdivisions, and minute distinctions into the science, with so many quaint terms to express what was before perfectly definite in the language of common life, that the description of the most intelligible properties is often rendered harsh and obscure to the student. This is greatly to be regretted, as it prevents many from cultivating mineralogy, deterred by a parade of frivolous distinctions which affail them in limine.

The
The characters of minerals, arranged according to the Wernerian method, are enumerated under the article **Oryctognosy**; but a selection of the most important ones, with a further definition of some of them, appears necessary to render more complete this department of our work, and to enable the general reader to understand the descriptive language used by mineralogists. The characters of minerals are either **physical** or **chemical**. Physical characters are those properties which can be discovered without decomposing or changing the nature of minerals; under this term we comprehend the external characters of Werner, and also some of those properties which are elicited by the action of other bodies on the mineral examined, such as magnetism and electricity.

Chemical characters in mineralogy are those properties which are most easily discovered by the action of heat, of acids, and of various re-agents. It is in this limited sense that these characters are understood by the mineralogist. A complete analysis of minerals belongs to chemistry.

In our enumeration of physical characters, we shall commence with those which depend on the action of light; namely, colour, transparency, lustre, and refraction.

Colour is regarded by the German mineralogists as an important character, and it is that which first arrests the attention of the observer; but in earthy minerals, the colours of the same species are often so various, that this character loses much of its value as applied to them. The colours of minerals, as far as they have been chemically examined, are principally owing to metallic oxides and inflammable matter: the earths, the acids, and the alkalies, in a state of purity, are white or colourless. The colour of earthy minerals may, therefore, be regarded for the most part as arising from accidental admixtures with unimportant ingredients. But in the inflammable minerals and metallic ores, and in a few of the earthy minerals, the colouring matter is as important as the other parts, and generally more so; hence in the latter, the colour varies but little in each species, and is a character of importance precisely in proportion to its simplicity. For an enumeration of the different varieties of each colour, and the minerals in which they are most characteristic, and for change of colour, see **Oryctognosy**.

Transparency, in its different degrees, from perfect transparency, semi-transparency, translucency, and opacity, are terms perfectly intelligible to every reader. When the cloudiness in semi-transparent minerals increases, so that the outline of objects can fearfully be seen, translucency commences, as in common chalcedony.

Double Refraction, or Duplicating, is the property which some transparent minerals possess of presenting a double image of an object when seen through them in particular directions, of which calcareous spar, an Iceland crystal, offers a remarkable example. See **Crystal of Iceland**.

Opalescence, a term not unfrequently applied to some minerals, is thus defined by Mr. Jamefon: "Some minerals, when held in a particular direction, reflect from some fingle spots in their interior a coloured glancing lustre; this is what is understood by opalescence: it is distinguished into simple and fiddler; in the latter, the lustre diverges in fix rays in the form of a star, as in the flar-sapphire."

Lustre.—The lustre of a mineral produced by the reflection of light is of different kinds, and is called metallic, semi-metallic, adamantine, pearly, resinous, and vitreous. Perfectly opaque minerals, as the metals, and most of the metallic sulphures, reflect the light wholly from the surface without undergoing any refraction, and exhibit the metallic lustre of various degrees of intensity; and the lustre is increased, and the colour is unchanged, when a scratch is made in them with a knife or file. Minerals having a metallic lustre yield a lighter colour, or have their lustre destroyed when scratched. The adamantine lustre is exhibited by minerals which are translucent, and possefs great refractive power; the lustre is reflected from the interior of the mass with great vivacity, and is produced both by reflected and refracted light. Examples, the diamond, sulphur, and the native salts of lead. In these minerals, though the lustre is increased by polishing, yet its particular character is lost distinct, owing to the increased reflection of unrefracted light from the surface.

The pearly or nacreous lustre is well exhibited in some kinds of zeolite, and in kyanite. When it proceeds from fibrous minerals, as in satin spar and fibrous gypseum, it is sometimes called a silky or faty lustre.

The resinous lustre is well represented by that of pitch: it exists in pitch-foncé and resinous flints.

The vitreous lustre is perfectly represented in rock-crysal.

Each of these kinds of lustre may vary in degree from the most splendid, which can be seen at a great distance, to shining, glinting, or glimmering. When entirely deficient, a mineral is called dull.

The streak implies the colour or lustre which a mineral exhibits when scratched with a knife or file; the colour is the same as that of the mineral when pulverized.

Soiling is a character that occurs in some soft minerals, which leave a mark when drawn on the surface of other bodies, or on the fingers, as plumbago, chalk, and redde.

The above are the principal characters depending on the action of light.

**Phosphorescence**.—Certain minerals give out light when rubbed against each other, as quartz; or when scratched with a knife, as dolomite. Other minerals give out light when heated on hot coals, or heated iron, as fluor spar; and certain minerals emit light when exposed to the action of the blow-pipe.

**Hardness and Solidity**.—Solids are the only bodies to which the terms hard or soft can properly be applied. In common language, hardnefs and frangibility are often confounded. A stone that endures many heavy blows before it breaks, is considered as harder than another which requires fewer blows for its fracture; but the property which different minerals have of resisting the point of a knife or file of hardened steel, or the effect produced when a mineral is rubbed on other minerals, or scratched by them, is the most exceptionable test of their hardnefs. Thus some minerals, as the crystal, quartz, a stone easily recognized, and whose hardnefs in that state is always the same; other minerals scratch steel, glass, steel, &c.; and soft minerals do not unfrequently contain minute grains of harder ones, which will give sparks with steel.

As a knife is the most convenient and portable instrument for determining the hardnefs of most minerals, except gems, the following judicious observations on the use of it, by Mr. Aikin, are deserving the attention of the student. In fibrous minerals, a scratch directed across the fibres will always indicate a lower degree of hardnefs than the true one; for the fibrous structure presenting an alternation of ridges and furrows, the knife glances across the intervals, thus interrupting the uniformity of the stroke, and producing a succession of small blows, which rather break down than divide the

---

Vol. XXXIX.
fummits of the ridges. The hardness of, therefore, be tried by a scratch parallel to the direction of the fibres, or, still better, on the surface of the transverse fracture. Another precaution is always to select a second undeformed or blemish of a specimen to make a trial of the hardness, this character being affected sooner than any other by the spontaneous alteration of a mineral. In examining the relative degree of hardness of two minerals, by trying which will scratch the other, it is necessary to be aware that the solid angles and edges of the primitive forms are very sensibly harder than those of the derivative forms, or than the angles and edges produced by casual fracture, either of crystals or malleable varieties of the same species. This fact has been long known to diamond-cutters, who always distinguish between the hard and soft points of the gem, that is, between the solid angles belonging to the primitive octahedron, and those belonging to any of its modifications, the latter being easily worn down by cutting or rubbing them with the former.

The whole range of hardness of minerals is thereby classified. When a mineral does not yield to the point of a knife, it may be called very hard, as quartz and feldspar. If it yields with great difficulty, it may be called hard, as feldspar. When a mineral yields more readily than the former, it may be called semi-hard, as hornblende and fluorspar. When it is easily scratched with a knife, it is called soft, as calcareous felspar and barytes. And when it yields to the nail, very soft, as gypsum and chalk.

Tenacity.—By this property is understood the relative mobility of the particles of minerals, and the different degrees of cohesion. In some metallic minerals, particularly native gold and silver, the particles, though they cohere with great force, are capable of a considerable degree of motion, and may be cut with a knife or extended with a hammer. Such minerals are called malleable. When a mineral may be cut into fragile shavings, or coarse grains, adhering to the knife, it is called brittle, as in plumbago and soapstone. When on cutting a mineral with a knife, the particles do not fall off with a grating noise, it is said to be brittle. All hard minerals, and the greater number of semi-hard minerals, are brittle, as quartz and fluorspar.

Frangibility.—By this property is understood the resistance which minerals oppose to the stroke of a hammer before they are broken into fragments. The degrees of frangibility depend partly on the cohesion of the particles; partly on the structure of the mineral. Frangibility must not be confounded with hardness; for soft minerals are more infrangible than hard ones. Quartz is much harder than hornblende, but may be broken with greater facility. The brittle minerals are the most frangible, whilst those which yield to the knife and are brittle are generally very tough; and the malleable minerals, such as native gold, can scarcely be said to be frangible.

A mineral is more easily frangible by a sharp blow from a small hammer, than by a heavier blow from a large hammer; hence this property appears to depend much on elasticity. Some earthly minerals, as beryl, felspar, and topaz, are more frangible when first obtained from their native beds, than when they have been exposed for some time to the atmosphere, owing to their containing a number of moistures which is afterwards evaporated. The degrees of frangibility, from very difficultly frangible to very easily frangible, are enumerated under Onyxography.

Some earthly minerals, and all malleable minerals, bend without breaking, or are flexible; and some minerals are both flexible and clastic, as mica.

Structure of Minerals.—This is the internal arrangement of the particles of a mineral. The three great divisions of structure are, the perfectly crystalline, imperfectly crystalline, and the promiscuous structure. The perfectly crystalline structure is described under the article Crystal; and the Wernerian description of crystalline forms will be treated of in the following section. For the imperfectly crystalline and promiscuous structure, see Structure of Minerals, where these important characters are described. The structure of minerals is ascertained by the number of joints, or determinate directions in which a mineral can be split, or exhibits distinct laminae. This is called the cleavage by the German mineralogists.

When a mineral splits in one direction, it is said to have a single cleavage, as in mica. The cleavage may be double, as in felspar; triple, as in calcareous felspar; quadruple, as in fluorspar; or six-fold, as in blende and rock-crystal.

The Wernerian system takes no account of the angles under which the planes or laminae of a mineral meet, except as being rectangular, equiangular, or oblique. But the angular measurement of the inclination of the planes forms the basis of Hauy's system of crystallography. (See Crystal and Goniometer.) According to Werner, the two-fold cleavage is described either as rectangular, (examples, felspar and hyacinth,) or oblique, as in hornblende.

The four-fold cleavage may either be equiangular and oblique, as in fluorspar and the diamond, or three of the cleavages may be equiangular and oblique in the common axis of the crystal, and intersected by a fourth, which is at right angles with the axis, as in beryl.

In the six-fold cleavage, all the laminae may meet under equal oblique angles, as in rock-crystal, or three of the cleavages may form equal and oblique angles in a common axis, and be obliquely intersected by three others, which also intersect the axis in an oblique direction.

Fracture.—This property is carefully distinguished from the fracture by Hauy. The fracture is the casual division of the whole into fragments, and depends much on the kind of fracture. In this sense, a mineral is said to be glassy, conchoidal, or tenaciously fragile. Glassy fracture denotes a smooth, adhering, conchoidal fracture. A mineral is said to be tenaciously fragile, when the fragments are very adherent, and will not part, even at unequal angles, as in quartz. Glassy fracture is more frequent in metallic minerals, and in opaque minerals which have some degree of lustre and transparency. The uneven fracture denotes elevations which are commonly irregular, and angular. This fracture is most frequent in metallic minerals, and in opaque minerals which have some lustre; it passes into flat and imperfect conchoidal, and finally into earthy. The even fracture is that kind of surface which leaves the fewest inequalities, and these inequalities are flat and never sharply defined. It passes into large conchoidal and splintery. The splintery fracture, improperly so called, denotes a nearly flat surface, on which are numerous small wedge-shaped scales, adhering by their thick ends.

The earthy fracture is peculiar to opaque earthy minerals.
The surface has a number of minute elevations and depreffions, which makes it appear rough.

The backly fracture is peculiar to the malleable metals, and consists of short sharp-pointed protruding fibres, which are sometimes only discoverable by the feel.

These different kinds of fracture often pass into each other, and occur together: the most prevalent one must be taken as the characteristic fracture. In minerals which have a crystalline structure, the true or proper fracture is that which is across the direction of the planes. When crystalline minerals are broken, the division taking place more readily in the direction of the planes, the fragments have generally a tendency to a regular form, as cubic, rhomboidal, &c. according to the structure of the mineral from which they are broken.

Imperfectly crystalline minerals break into fragments, which are more or less regular, and contain the following varieties: the wedge-shaped, splintery, specular, and tabular.

Indeterminate fragments, from hard and brittle minerals, which possess no crystalline structure, have sharp edges and angles. In other minerals, the angles and edges are more or less blunt in proportion to their softness and toughness.

External form or shape of minerals is either indefinite, definite, or crystalline.

The indefinite or amorphous, called by Mr. Jamefon the common external shape of a mineral. This character is applied when a mineral exhibits no appearance of regular planes or laminae, nor any resemblance to well-known natural or artificial bodies. When the mineral forms a thin coat or crust on other minerals, it is called superficial or investing, which is common to friable or pulverulent minerals.

Another variety is called plated or membranaceous, where the mineral forms thin membranes or flakes not exceeding in thickness common paper. When the three dimensions are not very different from each other, if the bulk is not considerable, the mineral is said to be in pieces, which may be either angular or rounded. If the bulk of an amorphous mineral be considerable, it is called sphenose. An enumeration of Werner's common external forms is given under Oryctognosy; which fee.

The definite form, or particular external shape, appears in many instances to be derived from crystallization modified or disturbed by other causes. According to Mr. Aikin, many of the definite forms have evidently been occasioned by matter in a semi-fluid state having been exposed to the simultaneous action of crystallization, concentric attraction, and gravitation. To crystallization is owing the minute structure in short prisms or fibres laterally aggregated; to the concentric attraction it is owing that each of these fibres converges towards a real or imaginary centre, forming a curved thick plate of the whole, or several plates in succefsive coats, like the structure of the onion; and lastly, it is owing to gravitation that these concretions do not form perfect spheres, but are more or less elongated into the mamillary, the reniform, the botryoidal, and the alabastrine varieties. Of particular external forms, a great variety are enumerated. (See Oryctognosy.) The definite form that approaches nearest to the regular crystalline, is the arborensent or dendritic: it bears a near resemblance to a vegetable spray; hence its name. On minute examination, it will, however, be found to consist of crystallals occasionally very perfect, implanted one into another, and branching in different directions. Certain varieties have obtained particular names, as rictulated or reniform, when the branches interlace like the meshes of a net; and peltinated, when a number of short branches rise parallel to each other, at nearly equal distances, on the same side or on opposite sides of a main branch, as in a comb.

The crystalline form of minerals is called by Mr. Jamefon the regular external shape. When a mineral occurs crystallized in a simple form which has received a name in geometry, as the cube, the rhomboid, the octahedron, &c. it is easy to give an idea of it by referring it to that form: but when a crystall presents a great number of unequal planes, or is very complicated, the description becomes difficult without a drawing or model. Mr. Werner has, however, confiderably facilitated the mode of describing crystals by considering them as modifications of certain simple forms; and this mode, though not strictly scientific, is found most convenient in practice.

The simple forms, or what he calls the fundamental forms, are, the cube (fig. 1); the rhomboid (fig. 2); the prism, which may have three, four, or a greater number of sides (figs. 3, 4, 5, &c.); the pyramid, which may have three, four, five, or six triangular planes (fig. 6); the table, which has two equal and parallel planes, which are very large compared with the thickenss of the table, and is bounded by an indeterminate number of sides (figs. 7 and 8.). The three following forms are very rare. The isoscadron, having twenty equilateral planes (fig. 9.); the dodacahedron, having twelve pentagonal faces (fig. 10.); and the lens, which has two curved faces (fig. 11.)

Mr. Aikin is of opinion, that the number of simple forms, or models, to which almost all crystals can be referred, may be reduced to four. The prism, the rhomboidal dodecahedron (fig. 12.); the regular tetrahedron (fig. 13.); and the double pyramid formed by two equal and similar pyramids joined together by a common base. The pyramid, like the prism, may have a greater or smaller number of sides, and the edges of the base of each pyramid may be in the same plane, as in fig. 14., or so on obliquely, as in fig. 31.

These forms, or models, must be carefully noticed, have no connection with the true primitive forms of crystals (fee (Cristallography, Addition), but are merely adopted as convenient types for the description of crystals. The changes which these forms are supposed to undergo by truncation and bevelling may take place either on the edges or fold angles of the crystal. As the prism and the cube are the most common forms of crystals, we shall proceed to describe them modified by these changes. The prism, as we have before observed, may have several sides, and may be triangular, or rectangular, or as in fig. 3; oblique, as in fig. 4.; or polygonal and equiangular, as in fig. 5. The sides are technically called the lateral planes, they are parallel to and surrounding an imaginary axis. The bafes at each extremity of the prism are called the terminal planes. The lateral edges are formed by the junction of two contiguous sides or planes, and the terminal edges are formed by the junction of the lateral planes with the base or terminal planes, and the fold angles are formed at the point of junction of the terminal planes with the lateral planes. The cube may also be described as a short rectangular four-sided prism. When a solid angle is removed and one plane is formed in its place, as in Plate VII. fig. 16., the crystal is said to be truncated on the angles. When planes are formed on the edges of a crystal, as in fig. 17., it is described as truncated on the edges; and when two planes are formed on an edge of the crystal, as in fig. 18., it is said to be bevelled on the edges. Fig. 19. is a three-sided prism bevelled on its lateral edges. When the fold angles of a crystal, or the terminal planes, appear cut off by three or more planes converging to a point, the crystal is said to be acuminate; in fig. 20., each angle of the crystal is acuminate by three small planes set on the lateral planes; and in fig. 21., each angle is acuminate by planes set on the lateral edges. Fig. 22, according
to the Wernerian method, is a four-sided prism, acuminate at each extremity by four planes set on the lateral planes. 

**Fig. 23.** is a four-sided prism acuminate by four planes set on the lateral edges. 

In the second instance, the acuminating planes are rhomboidal; in the first instance, triangular. 

**Fig. 24.** is the equiangular fix-sided prism, acuminated at each extremity by fix planes set on the lateral planes. 

**Fig. 25.** is a similar prism acuminated by three planes at each extremity set on the alternate lateral planes; and 

**Fig. 26.** is also a similar fix-sided prism acuminated by three planes at each extremity, set on the alternate lateral edges. 

The planes at the opposite extremities in **figs. 25 and 26.** are set in different planes or edges, and are what the Germans call unconfomable. 

The octahedron, or double four-sided pyramid (**fig. 27.**), is a common form of crysftals: it is frequently truncated or bevelled. 

**Fig. 28.** represents the octahedron bevelled at each of the angles. 

**Fig. 29.** is a double eight-sided pyramid acuminated by four planes at each extremity, set on the alternate lateral edges of the pyramid, thus forming a crystal with twenty-four faces, a form common in the leucite. 

The table may be bevelled on the surrounding edges, as in **fig. 30;** but in this figure, the Wernerian mineralogists call the surrounding sides the terminal planes, and the larger sides the lateral planes, a deviation for which there does not appear any sufficient reason, and which is liable to introduce confusion into the description of crysftals. Some of the forms here referred to, particularly **figs. 22 and 24.,** may be more simply described as four-sided and fix-sided prisms, truncated at each extremity by four-sided or fix-sided pyramids. The edges of a crystal may sometimes be doubly bevelled, or may be bevelled, and the edge of the bevelment truncated. Such modifications are better described as replacements of the edges by three, four, or more small planes or secondary faces. 

A very long prism is called a capillary crystal, if the diameter be too small to render the faces distinct. A very short prism, in which the length is very small in proportion to the thickness, may be regarded as a tabular crystal. Most crysftals may be very intelligibly described by alluming the fundamental forms of Werner variomomly modified. We are not, however, to suppose, that Werner himself intended to convey the idea that nature first made crystals complete, and then cut away the angles and edges: he only expresses, by the terms truncation and bevelment, the appearance the crystal presents to the eye. 

The primitive forms, or the true fundamental forms of crysftals, as given by Haüy, are enumerated under the article Crystai; but **Plate VI.** Crystallization, comprises those forms, and also those of the integnet molecule. The primitive forms are, the paralleloiped, including the cube and rhomb (**fig. 1 and 2.**), and the rectangular-table (**fig. 7 and 8.**), the octahedron (**fig. 27.**), the tetrahedron (**fig. 13.**), the hexagonal prism (**fig. 5.**), the rhomboidal dodecahedron (**fig. 12.**), and the dodecahedron with triangular faces (**fig. 14.**). The integrnet molecules are, the tetrahedron (**fig. 13.**), the three-sided prism, and the cube (**fig. 1.**) 

In nature, we rarely find crystals entirely perfect and symmetrical. If, says Mr. Aikin, the student should imagine that the real crysftals of minerals, such as nature presents them, are formed with the precision that characterises the models of the crysftallographer, he will in general find himself much mistaken. By far the greater number of crysftals are either imbedded in other substances, from which it is difficult to disengage them without much injury, or inhere by one extremity in amorphous or uncrystallized matter of the same nature with themselves. Hence it is, that few prisms occur both terminations of which are entire. Not unfrequently also crysftals, by being formed in narrow clefts, are compressed, or in other ways variously mutilated, and thus perplex even the most skilful mineralogist. Their minutencies too, when the parts are much complicated, is frequently such as to elude the keenest eye and the most adroit use of the goniometer. 

It is often by no means easy to distinguish genuine from spurious crysftals. The latter are generally supposed to have been formed in cavities occasioned by the decomposition of real crysftals. These are called casts. Spurious or suppositious crysftals are either casts or imitations; the latter occurs when a mineral is deposited over a pre-existing crystal and assumes its figure. The crystal either remains forming a nucleus, or it disappears, and the suppositious crystal is hollow. 

In the Wernerian crysftagnosty, the magnitude of crysftals and their mode of aggregation are minutely enumerated. (See Orvslctognosy.) In the last edition of Mr. Jameson's external characters, he defines the scopiform or fascicular aggregation as "formed of a number of thin prismatic crysftals, diverging from their point of attachment, and forming a kind of fasciculus or bundle; example, zeolite." The manipulator, or file-like, consists of a number of crysftals that diverge towards both ends and are narrower in the middle, thus resembling a file; examples, zeolite and prehnite. 

Scalawgife is when many cubical crysftals are arranged like the lips of a srair; example, cubes of conoic silver. 

The surface of crysftals is either smooth or streaked, the streaks sometimes cross longitudinally and sometimes transversely. These streaks are deferving of notice, as they frequently serve to indicate the structure of crysftals. See Crystallography, Addenda. 

**Electricity** is a character peculiar to a small number of crysftallized minerals, that exhibit the positive and negative electricity at their extremities on being heated. This property was first discovered in the tourmaline. (See Triple.) The points which exhibit electricity are called the electric poles. In order to distinguish these poles from each other, the following simple apparatus is employed. (See Crystallography, Plate IV. fig. 92. A.) It consists of a needle of copper or silver, having at each end two small balls a, b; this needle, like the common compass-needle, is moveable upon a pivot, having a very fine point, and at the bottom a frind or foot. The needle and item are insulated by placing the foot on a plate of wax or resin. To use the apparatus, we place one finger on the item, and present near to the needle a flick of sealing-wax, made electrical by rubbing, then withdraw the finger, and afterwards the flick of sealing-wax, and the needle will be positively electrified; and when a crystal electrified by heat, and held by a pair of small pincers in an insulated handle, as at B, is brought so that the positive or negative pole may approach one of the balls a, a, b, it will be attracted or repelled. The electricity of the needle will be perceived a quarter of an hour, or longer, and may be rendered more or less strong by varying the distance at which the flick of sealing-wax is held. It may be proper to observe that many minerals become electric by friction. 

**Magnetism** is a character which occurs principally in ores of iron, or in minerals that contain a portion of iron, or iron in a state of black oxyd. 

The above are the most important physical characters, comprising those which are called the external characters by Werner, and those to which he restricts the term physical. 

**Specific Gravity**, or weight, is one of the most impor
MINERALOGY.

The continued rendering of a minerologist is sufficiently accurate. The mineral may first be weighed, and the weight be noted, and then it must be suppended by a fine thread, and weighed again in rain or river water, about the temperature of 60°. The original weight of the mineral divided by the difference of the weight will give its specific gravity, or the weight compared with that of water. The heaviest bodies are the metallic, and the metallic ores, which range from about five times the weight of water to seventeen; the latter is the specific gravity of native platinum. The heaviest earthy minerals are the barytic and frontitic earths, and the gems; these range from 2.5 to 4.5. The other solid earthy minerals range from 2. to 3.5: and some few solid minerals are lighter than water, as rock-cork.

The feel, whether unctuous, or smooth or dry, meagre or harsh, is a character which serves to distinguish particular minerals. The odour and taste are also characters of particular minerals; some yielding a peculiar odour naturally, as petroleum, or when rubbed, as sanguine-red; and others, as the saline, affect the taste. Adhesion to the tongue is also a character possessed by minerals which absorb water. The coldness and found of minerals are also given as characters by Werner, but they are of little practical value.

Friable minerals are either loose, as when the particles have no perceptible cohesion, or are slightly cohering. The particles are in some instances scarcely discernible, and are called duluy particles, as in cobalt-crust; in other instances, the particles are large and incly.

The fluid minerals are few in number, and are characterised by their fluidity, transparence, and lustre.

The remaining characters are purely chemical, except the action of water, and of the atmosphere, which is in some instances chemical, and in others mechanical. Water unites with many of the clays, and renders them plastic; other minerals, as fuller's-earth, fall to pieces in water, without being disintoeled, or even rendered plastic. In some cases, minerals absorb water, which alters their transparence and colour. Saline minerals chemically combine with water, and are dissolved. To the absorption of water, is owing the property of adhering, when applied to the tongue before noticed. The action of the atmosphere on minerals is principally effected either by the abstraction or absorption of moisture, and the oxidation of minerals when exposed to the air is for the most part owing to the moisture which it contains.

The chemical characters of minerals are those which the mineralogist can ascertain by the action of acids, or of heat as applied by the blow-pipe, either simply or aided by reagents. The action of acids is of great use in ascertaining many essential characters of minerals. For this purpose, the muriatic or the nitric acids of moderate strength are most convenient. A minute fragment of the mineral may be placed in a watch-glass, and a few drops of acid poured upon it. The native carbonates effervescence, and are dissolved. Some minerals require to be reduced to a state of powder to shew the action of acids, and are thereby reduced to the form of jelly in a few hours, as zeolite. Other minerals only require to be touched with a glass rod dipped in acid to ascertain their nature.

The blow-pipe is an instrument of very great use to the mineralogist; it has been already described. (See Blow-pipe.) A blow-pipe which can be carried in the pocket, to be worked when required by the mouth, is by far the most convenient; but it requires some precautions in the management to render it efficient. The bell and clearest directions for this purpose which we have are those given by Mr. Aikin.

"Few persons," he says, "are able at first to produce a continued stream of air through the blow-pipe, and the attempt often occasions a good deal of fatigue. I shall make no apology, therefore, for treating this matter somewhat in detail. The first thing to be done is to acquire the habit of breathing easily and without fatigue through the nostrils alone; then to do the same while the mouth is filled and the cheeks inflated with air, the tongue being at the same time slightly raised to the roof of the mouth, in order to obstruct the communication between the mouth and the throat. When this has been acquired, the blow-pipe may be put into the mouth, and the confined air expelled through the pipe by means of the muscles of the cheeks. As soon as the air is nearly exhausted, the expiration from the lungs, instead of being made through the nostrils, is to be forced into the cavity of the mouth; the communication is then instantly to be shut again by the tongue, and the remainder of the expiration is to be expelled through the nostrils. The second, and all subsequent supplies of air to the blow-pipe, are to be introduced in the former manner as the first. Thus, with a little practice, the power may be obtained of keeping up a continued blast for a quarter of an hour, or longer, without inconvenience.

"Much depends on the size of the external aperture of the blow-pipe. If too large that the mouth requires very frequent replenishing, the flame will be wavering, and the operator will soon be out of breath; if, on the other hand, the aperture be too small, the muscles of the cheeks must be strongly contracted, in order to produce a sufficient current, and pain and great fatigue of the part will soon be the consequence. An aperture about the size of the smallest pin-hole will generally be found the most convenient, though for particular purposes one somewhat larger or a little smaller may be required.

"Several varieties of form have been recommended for the blow-pipe; they all have their advantages and disadvantages. Upon the whole, it appears desirable that there should be an expansion of the tube somewhere between the two extremities, both for the sake of collecting and retaining the condensed moisture of the breath, and for producing a regulated pressure, and therefore a regular blast. The nozzle also should be tipped with a moveable piece for the convenience of giving at least three different sizes of aperture. These conditions being obtained, other circumstances are of small importance, provided neither the bulk nor weight of the instrument be troublesome.

"The fuel for this little reverberatory furnace (as the blow-pipe apparatus may, without impropriety, be denominated) is oil, tallow, or wax, kept in combustion by means of a wick. The oil is the wick, the tallow is better, and the wax is best, not only as being cleaner, and free from any offensive smell, but also as affording a greater heat. The management of the wick too is a matter of some nicety. It should neither be too high nor inundated too low, and should be a little bent at its summit from the blast of the pipe. All casual currents and drafts of wind ought to be carefully avoided, as rendering the flame unsteady, and very materially impairing its strength. The above conditions being duly complied with, the flame, while acted on by the pipe, will evidently confine to two parts, an outer and inner; the latter will be of a light-blue colour, converging to a point at the distance of about an inch from the nozzle; the former will be of a yellowish-white colour, and will converge into a shining point.
lefs perfectly. The most intense heat is just at the point of the blue flame. The white flame consists of matter in a state of full combustion, and calcines or oxygenates the substances immersed in it; the blue flame consists of matter in a state of imperfect combustion, and therefore partly deoxygenates metallic oxides which are placed in contact with it.

"The supports of the various substances while undergoing the action of the blow-pipe come next to be considered. Of supports there are two kinds, combustible and incombustible. The combustible support (used chiefly for metallic ores) is charcoal. The clove-grained and soundest pieces are to be selected for this purpose; and even the best often split and become rifty after being used for a short time. This will not oftentimes happen in the middle of an experiment, when the melted globule sinks into the cracks, is lost, and the experiment must be begun again. Instead of flocks of charcoal, some persons recommend that the charcoal, after being finely pulverised, should be moistened with a solution of gum tragacanth, and moulded into a convenient form; a plan that will defer its being tried. Perhaps simply moistening the charcoal-powder, and then submitting it to the action of a very strong screw-prest, might be still better. The incombustible supports are, metal, glass, and earth, in the use of all which one general caution may be given,—to make them as little bulky as possible. The support always absorbs more or less of the heat, and in many cases, especially when metallic spoons are employed, entirely prevents the flame from producing its due effect. The best metallic support is platinum, because it is insensible, and transmits heat to a less distance and more slowly than other metals. A pair of slender forceps of brass, pointed with platinum, is the best possible support for non-metallic minerals that are not very fusible. For the fusible earthy minerals, and for the fusible ones when fusives are used, leaf-platina will be found the most convenient; it may be folded like paper into any deformable form, and the result of the experiment may be obtained simply by unfolding the leaf in which it was wrapped up. Glass supports are slender tubes or rods of this substance. If the mineral to be examined is of a longish or fibrous shape, one end may be cemented to the top of the glass rod by heating it, and in this state it may be further examined with great convenience. Earthen supports are used only for extemporaneous cupellation; they are best made of bone ash, and must of necessity be of a certain bulk, in order to absorb the litharge, and other impurities, which it is the object of this process to separate from the fine metal. With regard to the magnitude of the specimens required for examination, no very precise rule can be given; the most fusible, such as some of the metallic ores, may be as large as a small pea, while the more refractory of the earthy minerals should scarcely exceed the bulk of a pin's head.

"The heat that is first applied to investigate the properties of mineral substances should be very slow, not exceeding that which exists on the outside, even of the yellow flame; at this temperature, the phosphorescence is best elicited, and decrepitation for the most part takes place, the fusible inflammables begin to melt, and the metallic and most other mineral salts lose their water of crystallization. The yellow flame will raise a substance to a tolerably full red heat, by which the following effects are produced. Many changes of colour take place, all the yellow ores of iron become red, and the peach-bloom tinge of flowers of cobalt becomes blue; certain earthy minerals lose their water of crystallization or of composition, and exfoliate, as gypsum, or throw up coarse and irregular ramifications, as prehnite and metate. At this temperature, also, carbonate of thomont begins to tinge the flame with its peculiar crimson colour, and malate of copper with its bright green colour. The roasting of all the metallic ores is best carried on at this heat; sulphur and arsenic are drawn off, and exhibit their characteristic odours; grey antimony melts; native bismuth runs out from the matrix, through which it is disseminated; and pearlspur and spathole iron blacken and become magnetic. In the still higher degree of heat produced at the point of the interior blue flame, although some minerals still continue perfectly refractory, and undergo but little change of any kind, yet the greater part is very sensibly altered. Some, as pearlstone, enlarge very considerably in bulk at the first impression of the heat, but are with difficulty afterwards brought to a state of fusion. Others become covered with a superficial glazing, and the sharp edges and angles become glossy and rounded off. Others, confining really, though not visibly, of an intermixture of two substances differing in fusibility, undergo the process of fritting, in which refractory grains are dispersed through a vitreous mass. In others, a complete fusion takes place, and produces a ppyogic opaque fuscireous mass called a flag, or an opaque glas called a enamel, or a more or less transparent or true glas, which latter may vary in texture from compact to porous and opaque or intersetent.

"In examining the habits of the earthy minerals with the blow-pipe, no fruses are required; whereas to most of the metallic ores,fluxes will be found at almost all times a very useful and often a necessary addition. The ores of the difficultly reducible metals, such as manganese, cobalt, chrome, and titanium, are characterised by the colour which their oxides give to glasses; in all these classes, therefore, vitreous fluxes must be largely made use of, both to diffuse the earthy matter with which the oxides are generally mixed very intimately, and to furnish a body with little or no colour of its own, which may receive and sufficiently diffuse the inherent colour of the oxide. I say sufficiently dilute, because the colour of most oxides is excessively intense, and most persons in their first experiments of this kind, are very apt to obtain ambiguous results in consequence of using too large a proportion of oxide, that the glass, whether blue, red, or green, appears quite black. With regard to fluxes, the following will, I believe, be found amply sufficient. Where the object is not only to diffuise the oxide, but at the same time to retain it at a high state of oxidation, the flux employed should be either nitre or a mixture of this with a glas of borax, or, still better, nitrous borax formed by dissolving common borax in hot water, neutralizing its excess of alkali by nitric acid, then evaporating the whole to dryness, and lastly half-melting it in a platina crucible. For an active, and at the same time non-alcaline flux, boracic acid may be used, or neutral borate of soda; and where a slight excess of alkali is required, or at least does no harm, common borax by itself, or mixed with a little cream of tartar, when a strong reducing flux is wanted, may be had recourse to. For coloured glasses, the proper support is leaf-platina; but for reductions, charcoal. In the latter case, the ore previously roasted, if it contain either sulphur or arsenic, is to be pulverised and accurately mixed with the flux; a drop of water being then added to make it cohere, it is to be formed into a ball, and deposited in a shallow hole in the charcoal, being also covered by a piece of charcoal, if a high degree of heat is wanted. The easily reducible metals, however, may be treated with less ceremony; a bit of the ore being placed on the charcoal, and covered with glasses of borax, will, in a space of a few seconds, be melted by the blow-pipe, and converted
converted into a metallic globule, imbedded in a vitreous fcoria.

"In all cases where a metallic globule is obtained, it should be separated from the adhering fcoria, and examined as to its malleability and other external characters; being then placed a second time on the charcoal, but without flux, it is to be brought to a state of gentle ebullition, during which the surface being oxygenated, will exhale a heavy vapour that condenes on the blow-pipe, or falls down on the charcoal in form of a powder, or of piccular crystals, from the colour and other characters of which the nature of the metal may probably be ascertained. If any fulpicion is entertained of a portion of silver or of gold being mixed with the oxidable metal, the button must be placed on an earthen support, and there brought to a full melting heat; by degrees the oxidable metal will become怂erified, and will entirely sink into the support, leaving on the surface a bright head of fine metal, if such was contained in the alloy; but the proportion of this last being generally very small, and the entire mass of the alloy often not exceeding a large shot, it is not unfrequently necessary to have recourse to the magnifying glafs, to be fully convinced of the presence or absence of fine metal." Aikin's Manual of Mineralogy.

The above directions will be found of the greatest use, and are sufficiently ample to make any additional remarks unnecessary. Some German mineralogists have, indeed, arranged under nearly one hundred heads, the different changes produced on minerals by the action of the blow-pipe, and have given elaborate explanations of words known with sufficient accuracy by almost every child of seven years of age. This we regard not as smoothing the paths of science, but as blocking them up with rubbish to impede the progress of the student.

In the mineralogy of Haiiy, he has introduced very judiciously what he denominates the distinctive characters of minerals, noting the particular characters which serve to distinguish one mineral species from another, to which it has the greatest general resemblance.

New species of minerals have been discovered almost every year since the commencement of the present century, the greatest number of these discoveries have been made in the mines of Sweden. Few, however, of the newly discovered minerals possess properties that entitle them to much notice, and it is highly probable, that as the science of mineralogy advances to perfection, many of these supposed new species will be discovered to be only varieties of species that have been long known.

Acinolite, or Alcyonite. Fr. altinate. See Strahlstein.

Acinote, Amphibole. See Strahlstein.

Adamantine Spar, or Common Corundum; Corindon harzophane, Haiiy. See Adamantine Spar.

Adhesive Slate, a species of polishing slate, or polier schifte. See Polishing Slate, Addenda.

Adularia. (See Felspar, Addenda.) This variety of felspar was formerly confounded with glaffy felspar. (See Glassy Felspar, Addenda.) Adularia occurs in veins of granite in Barmahire, in the Ife of Arran, and other parts of Scotland. Rolled pieces of adularia having a most beautiful pearly light are found in the island of Ceylon.

Agalmatolite, or Figure-Stone; Beldjlein, Werner; Tule graphique, Haiiy. A mineral which may be regarded as an indurated flintecite, or rather, according to Jameson, as intermediate between flintecite and nephrite or jade. It occurs maslive; the fracture is splintery, or imperfectly flat; the colours are greenish-grey, apple-green, or yellowish-brown, and sometimes flesh-red and rose-red. It is translucent, unctuous to the touch, and yields with ease to the knife, owing to which property it is carved with facility into different figures by the Chinese, and into pagodas, cups, and snuff-boxes. The specific gravity is from 2.6 to 2.8. According to Klaproth, the confluent parts of agalmatolite are:

According to Aikin, this mineral occurs at Glyder Bach, Caernarvonshire.

Agaric Mineral, or Rock Milk; Chaux carbonatée spongeus, Haiiy. See Agaric Mineral.

Agate. (See Agate.) The agate is not a single mineral, but is composed of various siliceous substances arranged in concentric lamellae, exhibiting, when cut and polished, zones and angular lines, like fortifications. There is also a kind of agate-breccia, in which angular fragments are cemented by quartz or chalcedony. Agates appear to be formed by siliceous infiltration in the cavities of basaltic rocks, the formation commencing from the surface, and the cavity gradually filling by successive depositions on the fides, until the whole forms one solid nodule. According to the direction of the lines or the structure of agates, they are denominated ribbon or striped agate, fortification agate, landscape agate, brecciated agate, tubular agate, Jasper agate, spotted agate, banded agate, flar agate, marked with radiated spots; petrification agate, flossil-shells and zoophytes are sometimes penetrated or filled with agate. In the variety called moss agate, nodules of chalcedony inclose minute arborizations resembling moss, some of which are tupposed by mineralogists to be branches of moss suddenly inclined and preferred in siliceous matter.

Alabaster, Calcaceous, or Cale finter Alabaster, Gypsiferous Alabaster. See Alabaster and Gypsum.

Albite, Diopside, and Muffite, a mineral allied to augit; first found in the Alp of La Muffa, near the town of Aia, from whence the names albite and muffite are derived. See Diopside, Addenda.

Albanite, Cerium amalgame, Fr. an ore of the newly-discovered metal cerium, first analyzed by Mr. Allan, and hence called albanite. Its colour is a brownish-black; it occurs disseminated and crystallized in rhomboidal prisms, the angles of which measure 115° and 65°. The internal lustre is shining, and refino-metallie. It is opaque, and yields a greenish-grey streak. It scratches glass, is brittle and easily frangible. Before the blow-pipe it froths, and melts into a brown liquid. It gelatinizes in nitric acid. The specific gravity is from 3.5 to 4. The confluence of parts are:

It occurs in granite in West Greenland.

Allochroite,
MINERALOGY.

**Allochroite, idem, Haüy; splintery garnet of Karff.** It is classed with the garnet family by Werner, but is regarded as a distinct species. It occurs massive; the fracture is uneven, passing into conchoidal. Its colours are greenish and yellowish-grey: it is translucent on the edges; internally it has a bluish tincture. It gives sparks with fleecy. The specific gravity is 3.5. It has hitherto been found only in an iron-mine at Dramman, in Norway. It is less hard and lighter than common garnet. According to Vauquelin, the constituent parts are,

**Almandine, regarded as a variety of garnet.** See Almandin; but for garnet r. garnet.

**Alum-Earth, Alum-Slate, Common and Glossy, Alum-Stone.** See Alum, Ores of.

**Aluminate, Subulphate of Alumine; Reine thonerde, Werner; Alumine pure, Haüy.** This mineral is of a snow-white colour, verging on yellowish-white. It occurs in reniform pieces, it has no fracture, the fracture is earthy, and the confluence between friable and solid. It is opaque, foils slightly, affords a glintening streak, and adheres feebly to the tongue. It feels fine, but meagre. The specific gravity is 1.66. A variety of the same mineral substance occurs at Newhaven in Sussex, filling up fissures in chalk. This variety is white, yields to the nail, and adheres strongly to the tongue. The constituent parts of the foreign aluminate are,

**Amalgam, Native, semi-fluid and solid.** See Mercury, Ores of.

**Amathoidite, Capillary, and Amathoidite, Byssolite; the latter so called by Saussure.** The former appears to be a variety of amathusite; the latter resembles it, but differs from it in chemical composition, if the analysis of Saussure be correct. It is supposed to be hornblende in a capillary form. Haüy.

**Amazon-Brine, green felspar from South America, which is cut and polished, and sold under that name, because it is found in rolled pieces on the banks of the river of the Amazons.**

**Amber, White and Yellow.** The white amber is of a straw-yellow or yellowish-white colour. It occurs massive, and sometimes inclosed in the yellow amber; it is less transparent than yellow amber. See Amber.

**Amethyst, a variety of crystallized quartz.** See Quartz, and Amethyst. Werner divides amethysts into two sub-species, common and fibrous. The prevailing colour of the amethyst is violet-blue of different degrees of intensity; but it is sometimes plum-blue and brownish-black; also grey, olive-green, and piftachio-green, which last colour is very rare. In massive varieties of amethyst, several colours occur together. In crystallization and other properties, the amethyst does not differ from quartz. It contains 97.50 of silex, with a minute trace of alumine, oxides of iron, and manganese; to these oxides, no doubt, its colours are owing. Amethysts occur in agate boulders in basaltic rocks. Thick fibrous amethyst occurs in massive and in rolled pieces; it occurs in agate veins, in the same rocks as common amethyst. A red colour is given to amethysts by the jewellers, by inclosing them in charcoal, which is ignited, and allowed to consume gradually. When the colour is not uniformly diffused, it is exposed in a mixture of sand and iron to a moderate heat, by which it is rendered more uniform.

**Amianthus, Flexible aequalis; Amiant, Werner; Athesan amiantus, Fr.** (See Amianthus, and Asbestos.) It is found in serpentine in the Isle of Anglesea, and in the same rock at Portlow in Scotland.

**Amelolite is a bituminous slate, or shale, of which drawing-flake, alun-flake, and slate-clay, are varieties.** See Slate.

**Amphibole, hornblende.** See Hornblende, Adenda.

**Amphibole Lamellaire, common hornblende.**

**Amphibole Crystallide, basaltic hornblende.**

**Amphibole Actinolite.** See Strahlstein.

**Amphibole Fibreux, glassey actinolite.** See Strahlstein.

**Amphibole Actinolite, asbestos actinolite.** See Strahlstein.

**Amphibole Garnematite, common tremolite and glassey tremolite.**

**Amphigene.** See Leucite.

**Analine.** See Zolite.

**Anatase, of Oolithedrite, Titane natare, Haüy.** See Titanium.

**Andalusite, Feldspath-aphyre, Haüy, is of a chestnut-red colour, sometimes inclining to pearl grey; it occurs massive or crystallized in rectangular four-sided prisms, with the terminal edges and angles sometimes truncated. The structure is imperfect lamellar, with a double rectangular cleavage, parallel with the lateral planes of the prism. It is translucent; it fractures with ease, but is rather easily fragmentable. The specific gravity is 3.16. Before the blow-pipe it becomes white, but is insubflible. According to Vauquelin, the constituent parts are,

It occurs in veins in granite, gneis, and mica-flake, along with felspar, quartz, mica, and schorl. It was first found in the province of Andalusia. It has since been found in Aberdeen. The crystals are generally middle-sized or small, and occur imbedded. It is distinguished from felspar by its greater hardness, weight, and insubflibility; and from corundum by its double rectangular cleavage, and its inferior specific gravity.

**Anhydrite, or Anhydrous Gypsum, a species of gypsum which contains scarcely a trace of water in its composition, and is much harder than common gypsum; the latter (see...)}
MINERALOGY.

(see Gypsum) contains 22 per cent. of water, and some varieties 38 per cent. There are five varieties of anhydrite: compact, fibrous, radiated, sparry, and feebly crystalline. It is a peculiar stone, being a member of the class of earthy substances, but it is not a mineral in the strict sense of the word. It is a natural analog of the mineral gypsum, and is often found in association with it. It is a white, soft, and friable substance, and is often found in the form of crystals, which are usually elongated and prismatic. It is often found in the form of stalactites, and is often found in the form of stalagmites.

Compact Anhydrite.—Its colours are various shades of white, inclining to greyish-blue, and is also red and brownish-red. It occurs massive, contorted, and reniform. The compact variety, from its resemblance to the convolutions of the intellines, was called triphe-lone, or pierre de triphe. Compact anhydrite is more or less translucent, and is feebly glimmering, with a small splintery fracture, passing or in conchoidal. The fragments are sharp-edged; it is difficultly frangible. Specific gravity from 2.8 to 2.9. According to Klaproth, the constituent parts are,

\[ \text{Lime} \quad 41.48 \\
\text{Sulphuric acid} \quad 56.28 \\
\text{Water} \quad 1.75 \\
\hline
\text{99.51} \\
\]

Fibrous Anhydrite is of a red colour: it occurs massive, and has a delicately fine and parallel fibrous structure. Radiated anhydrite has a blue or greyish-colour, and is sometimes spotted with red: it occurs massive. The structure is radiated, the surface splintered and pearly: it is translucent and rather hard. Its specific gravity and constituent parts are the same as the former variety.

Sparry Anhydrite, or Cube-Spar; Chaus sulphaté laminaire, Haüy.—The prevailing colour is white, inclining to blue-grey, pale yellow, and red. It is more or less transparent, the lustre splintered and pearly; it refracts doubly. It is crystallized in rectangular four-sided prisms, and in fix or eight-sided prisms. It also occurs massive. It has a foliated structure, with a cleavage parallel with the sides of a rectangular prism, which is its primitive form. It fractures calcareous spar, but is easily frangible. The specific gravity is 2.9. Before the blow-pipe, it becomes glazed over with a white friable enamel, but does not melt and exfoliate like gypsum. It is met with in the salt-mines of the Tyrol, and in Switzerland, and also in the gypsiferous of Nottinghamshire. Scaly anhydrite is generally white, inclining to blue or grey: it occurs massive, has a confused foliated structure, and a splintered and pearly lustre. It is translucent on the edges, is easily frangible, and is soft. Specific gravity 2.9. According to Klaproth, the constituent parts are,

\[ \text{Lime} \quad 41.75 \\
\text{Sulphuric acid} \quad 55. \\
\text{Muriate of soda} \quad 1. \\
\hline
\text{97.75} \\
\]

It occurs in the salt-mines of Hall in the Tyrol.

Asbestos. Its colour is between dark yellowish-grey and olive-brown: it occurs massive and crystallized in red-banded crystalline, which appear to be four-sided prisms longitudinally streaked. The lustre is shining and pearly, approaching to metallic. The structure is radiated. It has a two-fold cleavage parallel with the sides of a rectangular prism. It is more or less translucent, yields to the knife, but fractures glads with difficulty. It is infusible before the blow-pipe. Its specific gravity is 3.2. The constituent parts are,

This mineral is allied to hornblende; it occurs at Konigberg in Norway.

Asbestos, or Anthracelite, is a greyish-colour and columnar, and is allied to hornblende. Anthracelite is that species of coal which has a shining lustre approaching to metallic, and burns without smoke. Kilkeen coal and Welsh coal are varieties of anthracite. See Coal.

Antimony, Native, and Ores of. See Antimony-Ores, and Red Antimony, Addenda.

Apatite. (See Apatite.) Chaus phosphate, Haüy. Werner makes two sub-species of apatite, the common and conchoidal. The latter, or conchoidal apatite, has a conchoidal fracture; it has been called asperagus stone. Apatite has been discovered in Cornwall, and recently near Bovey in Devonshire. Massive apatite and earthy apatite have received from Werner the names of common phosphorite and earthy phosphorite. Phosphorite has nearly the same constituent parts as apatite, with an addition of a small portion of fluorite acid, about 2.50 per cent.

Aphrite. (See Scholum-Earth.) Aphrite is divided into feebly apatite, flatly apatite, and sparry apatite.

Aplonite, a mineral closely allied to garnet, but is supposed to have a different primitive form of the crystal or that of a cube. (See Garnet.) Aplonite is considered by Jansen as crystallized common garnet.

Aphrylite. See Zeolite.

Arietin, a name given by Werner to the mineral since called Wernerite. See Wernerite.

Aragonite. (See Aragonite.) Since that article was written, the remarkable anomaly in the crystallization of this mineral has been partly explained by the discovery that it contains a portion of the carbonate of iron, which is supposed to give a different form to its primitive crystal.

The constituent parts, as given by Stromeyer, are,

Werner divides aragonite into common, columnar, and acicular. Aragonite occurs in trap rocks in various parts of Scotland, and we have acicular crystals of aragonite in lava from Vesuvius.

Arseniate of Copper. See Copper-Ores.

Arseniate of Lead. See Lead, Ores of.

Arsenic, Native. See Arsenic, Ores of.

Arsenic Bloom. See Phosphorite, Addenda.

Arsenic Oxide, and Arsenical Pyrites, or Marcasite. See Arsenic, Ores of.

Asbestos, Common and Flexible, (see Amiantus and Asbestos,) Asbestos ligniform, or wood asbestos. Its colour is
It occurs in common basalt, in wacke, and in lava; also in some kinds of porphyry. It decomposes more slowly than basalt; hence, according to professor Jameson, we frequently find crystals of basaltic hornblende dispersed through clay formed by the decomposition of basaltic rocks. See Hornblende, Addenda.

BASANITE, black flinty slate. See Slate.

BERGMANNITE, a mineral which occurs massive with grey and red quartz at Freidichswarn, in Norway, and is classed with scapolite in the felspar family in Jameson's Mineralogy. Its colours are greenish and greyish-white, or yellowish-grey and muddy flesh-red. It is extremely glissening, with a lustrum between pearly and resinous. The structure is delicately fibrous, curved, or diverging. It is faintly translucent on the edges, and scratches felspar. It melts before the blow-pipe without intumescing into a white enamel.

BERYL. (See BERYL and EMERALD.) In Weisse's collection at Vienna, there are two crystals of beryl in a group crossing each other, which are a foot and a half in length, and one foot in diameter. It has been found in alluvial soil, in the upper part of Aberdeenshire, and in the county of Wicklow, in Ireland, imbedded in granite.

BILDSTONE, See AGAMMATOLITE.

BISMUTH, Native. See BISMUTH-ORE.

BISMUTH, Glance, or Sulphuretted Bismuth. See BISMUTH-ORE.

BISMUTH-ORE, Plumbum cupriferum, has a steel-grey colour, with a pale copper-red tarnish. It occurs disseminated and crystallized in oblique four or six-sided acicular prisms, longitudinally streaked. The crystals are frequently adhering together, and are sometimes curved, and divided by cross rents. The lustrum is metallic. The cross fracture is fine-grained and uneven. It yields easily to the knife. The specific gravity is 6.2. Before the blow-pipe, it melts into a steel-grey globule; by continued the heat, it is partly volatilized, and deposits in the charcoal a yellow powder, after which there remains a red globule, containing a grain of cupriforous metallic lead, which communicates a bluish-green colour to borax. According to John, the constituent parts are,

It occurs near Berezof, in the district of Catharinenburg, in Siberia.

BISMUTH-ORE, Cupreous, or Cupriferos sulphuretted Bismuth-Ore, has a light lead-grey colour, sometimes steel-grey and tin-white. It occurs massive, disseminated, and in diverging prisms. The lustrum is metallic; it is feticile. According to Klaproth, the constituent parts are,

This is a very scarce ore of bismuth.

BISMUTHIC Silver-ORE. See SILVER-ORE.
MINERALOGY.

BITUMEN, Liquid, Tenacious, Solid, Compact, and Elastic. See Bitumen.

BITUMINOUS MARLE-SLATE occurs in beds in the lower stratified lime-stone in various parts of Europe. It has a dark-brown or blackish-grey colour, a glimmering or glinting fault, a flaty fracture, and is soft, meagre, opaque, and feetile. It frequently contains ores of copper. It is remarkable for the number of petrified fish which occur in it. It also contains fossil remains of shells, corals, and of cryptogamous fresh-water plants. In many of its characters, it appears to resemble the alun-halite of Whitby. It is a frequent mineral in Saxony, Thuringia, Franconia, Bohemia, Bavaria, and in Switzerland.

BITUMINOUS WOOD, a variety of brown-coal or wood-coal, in which the fibres of the wood are distinguishable. See Coal and Wood-Coal.

BLACK COAL. See Coal.

BLACK CHALK, or Drawing-Slate, Ampellite graphique, Fr. occurs in beds, in rocks of the slate formation. It has a blueish or greyish-black colour, a flaty fracture, an earthy crofs fracture, is dull, meagre to the touch, and leaves a distinct mark on paper. It is feather, and becomes glintening in the streak. The specific gravity is 2.11. According to Wregleb, its constituent parts are,

<p>| | | | | |</p>

It is found at Morilla in Spain, in Brittany, in Germany, and in Italy. It is cut into square pencils, and used for drawing; it is also ground and used in painting. Those varieties which have the darkest colour and the finest earthy texture are to be preferred. The pencils become hard, unless kept in a moist place.

BLACK-JACK, a provincial name for blende.

BLENDX, Black, Brown, and Yellow, various sulphures of zinc. See Zinc-Ores.

Bog Iron-Ore. (See Iron-Ores.) Werner supposes bog-iron, whether in meadows, swamps, or marshes, to be formed by water impregnated with vegetable acid, dissolving part of the iron in the rocks over which it flows, which, being poured into hollows, becomes flagrant, and evaporates. Thus succeffive depoitions are formed, which are at first yellowish earthy, and of little confection. This is moras-or-e. In course of time, it becomes harder, and the colour palaces to brown, forming famp-ore. After the swamp is dried up, the ore becomes much harder, and palaces into meadow-ore, which is covered with soil and vegetation.

BOLE. See BOLE.

BOLOGNESE SPAR, or Radiated Heavy SPAR. See Heavy SPAR, Aldenda.

BORACIC Acid, Native or Saffoline, is found in salie incrustations on the borders of hot springs, near Saffo, in the territory of Florence. It has a greyish or yellowish-white colour; it occurs in thin crusts or minute pearly fale; it is soft and friable, and is feebly translucent. To the taste, it is slightly bitter and acidulous. It melts easily before the blow-pipe into a transparent globule. According to Klaproth, the constituent parts are,

Boracic acid - - - - 86
Ferruginous sulphate of magnesia - - 11
Sulphate of lime - - - - 3

BORACITE, Magnesie boras, Haüy. (See Boracite.) Vaquetin found no lime in this mineral, and supposes it to be a simple boras of magnesia. Boracite is remarkable for its electric properties when heated. The form is generally that of the cube, and those angles which are diagonally opposite are, one positive, and the other negative, forming eight electric poles.

BOTRYOLITE occurs in mammillary or botryoidal concrections, in a bed of gneifs, near Arendal in Norway, associated with quartz, fchol, calcareous spars, and iron pyrites. Its colours are, pearl-grey, greyish or reddish-white, and pale rose-red. The colours are concentric stripes. It has a delicately fibrous flatter structure, and sometimes a sphericl fracture. It has a pearly glintening lufure internally, is translucent on the edges. According to Klaproth, the specific gravity is 2.88; and the constituent parts are,

<p>| | | |</p>

Earthly botryolite occurs with the above, which has a snowy white colour, and an earthy fracture.

BOVEY COAL. Bituminous wood coal, found at Bovey Heathfield, Devonshire. See Coal.

BROXITE, Diatolage metalloid, Haüy. A mineral nearly allied to Labrador hornblende or hyperthine. It has a yellowish-brown or pincheck-yellow colour, and a ferrimetallic lustre; it occurs massive, and coarfly disintegrated; it has a foliated and fibrous structure, with a distinct angle cleavage. It is opaque. The specific gravity is 3.2. According to Klaproth, the constituent parts are,

BROXITE. See Broxite.

BURRSPAR, or Dolomite SPAR; Chalk carbonaté ferro manganosferi, Haüy; Bitter Spar, Werner. Its prevailing colours are, milk-white, greyish-white, yellowish-grey, and pearl-grey; it also occurs red, brown, yellow, and black. It occurs both massive and crystallized in oblique rhomboids, and in compressed hexahedrons. The joint are parallel to the faces of an oblique rhomboid, the alternate angles of which measure 106° 18' and 73° 45'. The faces of the rhomb are sometimes convex or concave; it occurs also in lenticular forms. The lustre is shining, and between vitreous and pearly; it is more or less translucent. It yields to the knife, but is harder than calcareous spar. Its specific gravity is from 2.18 to 2.88. It hardens and becomes an opaque brownish-black before the blow-pipe. It diffuses slowly in cold muriatic acid, but with considerable effervescence in hot acid. According to Klaproth, the constituent parts are,

<p>| | |</p>

MINERALOGY.

The proportion of manganese and iron is sometimes much greater, and there are several intermediate varieties, which it is difficult to determine whether they are to be classified with brown spar or sparry iron-ore. Brown spar occurs in veins along with galena and other ores of lead, in the mines of Cumberland and Northumberland. Fibrous brown spar, both massive and in balls, occurs in veins in Lower Hungary. Columnar brown spar has a splendent lustre and a foliated structure, but no distinct cleavage can be observed in it. The fragments are wedge-shaped. It has been found at Gersdorf in Saxony, and Guanaxto in Mexico. The name brown spar was given to this species because it changes its colour, on exposure to the air, from a light to a dark brown, becoming oxidized on exposure.

BUTTERMILK, Silver. See Silver-Ores.

BYSSOLITE, a name given by Sauvage to a variety of asbestous actinolite, which occurs in minute acicular diverging crystals, which are elastic. See Actinolite.

CACHOLONG, Quarz agate cacholong, Häi'y, is by some mineralogists considered as a variety of milk-white chalcedony, by others as a kind of common opal. Cacholong is distinguished by its milk-white colour, its refulgent lustre, its even fracture, and its want of translucency, except at the edges. It sometimes adheres when applied to the tongue. This mineral accompanies flints and chalcedony, and, according to Brongniart, even pitch-flons is sometimes coated with it; hence it is supposed to be the result of alteration in those minerals, produced by an unknown cause, as it is observed passing into them by almost imperceptible gradations. The true cacholongs, which have given the name to this variety, are found near the banks of the river Cach, in Bucharis; they are spread over the fields, but are not rounded; on the contrary, they form tables composed of alternate layers of cacholong and chalcedony. Cacholongs are sometimes cut and employed in jewellery.

CALAMINE. See Zinc-Ores.

CALCAREOUS Spar, - crytallized carbonate of lime. See Lime-stone.

CALC SINTER. See Statistical fibrous Lime-flon, in the article Lime-stone.

CALC TAFF, or Taffaceous Lime-flone, a light porous lime-flone, formed by the deposition of calcareous matter, in calcareous springs, or near lakes or rivers. It frequently encloses the remains of animals or vegetables which have been encased and imbedded in it by successive deposits. See Taff.

CALF, a name given by Kirwan to a dark ferruginous lime-flone, agreeing in many of its characters with the English lias. See Lias, Addenda.

CANDLE Coal. Bituminous coal, so called on account of the great light which it affords in burning. See Coal.

CAT'S-EYE, Quarz agate chatoyant, Häi'y; by some mineralogists called false opal. It appears to be a variety of agate occurring like the latter mineral in trap rocks, but remarkable for reflecting a peculiar play of colour, resembling that of the eye of a cat, whence its name; it is used in jewellery, and is generally cut into ring flons. Cat's-eye occurs massive and in loose angular and rounded pieces; its colours are various, inclining most frequently to yellowish and greenish-grey, and sometimes to brown-red and greyish-black. It exhibits a beautiful opalescence when cut in a spherical form, which proceeds from the fibrous structure, and sometimes from the mixture of amianthus. It is translucent in different degrees; it has a shining vitreous-refinonous lustre, a small conchoidal fracture; it scratches quartz. Cat's-eye becomes opaque and spotted by exposure to the blow-pipe. Its specific gravity is 2.64. According to Klaproth, its constituent parts are,

<table>

Cat's-eye occurs in the Hartz, in Hanover, in trap, with amianthus, aegius, azinite, and calcareous spar. It is obtained from Ceylon, Malabar, Sumatra, Peru, and Arabia.

CELESTINE, sulphate of Strontian. See Strontian.

CEMER, or Cerite, Cerium oxyd filifere, Häi'y, an ore of the newly-discovered metal cerium. (See Cerium.) The colour is between rofe-red and flesh-red, and also reddish-brown; when pulverized it is grey; it occurs both massive and disseminated. The fracture is splintery, the lustre glimmering and refringent. Opake (Jame'son), transparent (Aikin). It scratches glas with difficulty; it is brittle and easily friable. Specific gravity 4.6 to 4.9. Infusible before the blow-pipe, but changes from grey to yellow. According to Klaproth, the constituent parts are,

<table>

Cerium occurs in a bed of copper pyrites, situated in graves, near Riddarhyttta, in Westermanland, Sweden.

CEYLANITE, Phenagite, Häi'y, is claffed with the ruby family by Werner; its colours are a muddy dark-blue and greyish-black, which approaches to iron-black; it occurs in grains and in small crystallites, either perfect octahedrons or truncated on the edges, or with the angles acuminated by four planes, which are set on the lateral planes, also in rhombo-dodecahedrons. The crystals are smooth and splendent; it is translucent on the edges. The fracture is flat conchoidal; it scratches quartz. Before the blow-pipe, it is infusible. The specific gravity of ceylanite is 3.8. According to Berzelius, the constituent parts are,

<table>

This mineral was first found in the island of Ceylon, where it occurs in the sands of rivers with tourmaline, zircon, sapphire, and iron-fund. It occurs in lava from Verfuria, with olivine, augit, and mica. It occurs also in bafalt, near Andenach, on the Rhine.

CHALCEDONY. See Chalcedony and Quartz.

CHALK. See Chalk, and Geology, Addenda.

CHERT, a variety of horn-flone; it differs from flint principally by being more opaque, and having less lustre; it occurs in nodules and masses in the sand under the chalk formation, and in beds in some mountain lime-flone.

CHLAMYTOLITE, or Hollow Spar, occurs crystallized in slender rhomboidal prisms, the edges of which are sometimes rounded,
MINERALOGY.

rounded; sometimes four prisms are arranged in the form of a cross. The prisms appear composed of two distinct substances, as if they had once been hollow, and these hollows filled up with clay-flake, nearly similar to what the crystals are imbedded in. The exterior part of the prism is of a greyish-white or reddish colour, and varies in thickness, in some specimens being a mere shell; within this, is a dark-blue or black prism, exactly parallel to that by which it is inclosed. Frequently from each angle of the interior prism a black line or thread proceeds, bifurcating the corresponding angle of the white prism, and often terminated by a small black prism. The white part exhibits a lamellar structure, parallel with the lateral planes of the prism; it has a slight glimmering lustre, is translucent, and feraches glafs. The specific gravity is 2.6. Before the blow-pipe, it fufes into a whitish scoria; the black part affords a black glafs. This mineral occurs in scicular crystals in some beds of dark flake in the mountain Skiddaw, Cumberland. The largest crystals are found in clay-flake, near St. Brieux, in Brittany. Some mineralogists consider chalcedony as the same substance as andalusite; others clas it with common felfspar, and some regard it as a distinct species.

Chlorite, Talc chlorite, Haüy. This mineral is nearly allied to tale and mica. The prevailing colour is various shades of green; hence it derives its name from the Greek ἰχνένης, green. It is divided by professor Jameson into four sub-species: earthy chlorite, common chlorite, fatty chlorite, and falked chlorite.

Earthly Chlorite occurs massive and disseminated, and in- cruating other minerals, and inclosed in dendritical forms in adularia and rock-crystal. It contains fine scaly particles closely adhering, and has a glimmering or glittening pearly lustre, and feels rather greasy. The green colour becomes lighter in the flake. The specific gravity is 2.6. Before the blow-pipe, it melts into a blackish flak. According to Vanuelpin, the constituent parts are,

According to Haüy, the scaly particles are regular hexagonal prisms when viewed with the microscope.

Common Chlorite is a leek or dark-green colour, inter- mixed with black. It occurs in rocks of various kinds, in beds and veins, either alone, or with quartz, magnetic iron-flone, iron-pyrites, hornblende, actinolite, and other minerals. It is amorphous, has a glimmering lustre, an earthy fracture, and a fine granular, laminated, or scaly structure. Common chlorite is soft, opaque, and greasy. Its specific gravity is 2.8. It occurs in various parts of Scotland, and in Cornwall, Cumberland, and all alpine parts of England.

Foliated Chlorite: Tale chlorite, Haüy.—Its colour is leek-green; it occurs crystallized in six-sided tables, curiously aggregated in cylindrical or conical forms. The crystals are longitudinally streaked. The lustre is resinous, either glittening or fibbing. The structure is curvedly lamellar, with a single cleavage. It is opaque or translufcent at the edges; it is soft, felcile, and rather greasy. The specific gravity is 2.8. According to Lampadius, the constituent parts are,

Foliated Chlorite is found in various parts of the continent of Europe, and on the island of Jena, one of the Hebrides.

Chlorite Slate has a greyish or darkish-green colour; it occurs in beds in clay-flake, sometimes associated with talc-flake, into which it passes. It has a glitinning resinous lustre, a flaky structure, inclining to scaly. On minute examination, it appears composed of small scales of chlorite closely adhering. Chlorite-flake forms beds in mountains of clay-flake in various parts of the Grampian-hills. It passes into hornblende-flake and clay-flake. The specific gravity is 3.03.

Chlorophane, a variety of flour spar from Siberia, which gives out a beautiful apple-green light when placed on a heated iron. Pallas mentions a pale-violet blue variety spotted with green, which becomes phophorescent when held in the hand, and gives out a pale-whitiff light; in boiling water, it emits a green light, and at a higher temperature a blue light. See FLUOR SPAR.

Chromate of Iron, Fer chromate, Fr. has a pitch-black colour, with somewhat of an olive tinge superficially. It occurs massive and disseminated, and also crystallized in octahedrons. It has a shining lustre, between refringent and metallic. The fracture is uneven, or imperfectly small conchoidal, and sometimes imperfectly lamellar. It feraches glafs, is opaque. The colour of the flake is ash-grey or brownf. The specific gravity is 4.03. It is rarely magnetic, is infufible, but tinges borax of a beautiful green colour. According to Vanuelpin, the constituent parts are,

Chromate of iron occurs in beds and veins, and in im- bedded mafles, in ferpentine and tale-flate. It has been found at Portfuy, in Bamfshire, and is said to occur in considerable quantities in the Shetland islands. It occurs in the vicinity of Nautes, and in the department of Van. The greatest quantity has hitherto been found in fer- pentine, in the Bare hills near Baltimore. The chromic acid
MINERALOGY.

acid obtained from this mineral when combined with lead forms a beautiful yellow pigment, and is now an article of commerce.

Chromate of Lead, red lead-ore. See Lead-Ores.

Chrysolite, Earthy Malachite, Cinnor malachite cry-

socolla. Fr. See Copper-Ore.

Chrysolite, Peridot chrysolites, Fr. (See Chrysolite.)

This gem is the softer of the precious stones; its colours change by heat. It is brought to Europe from the shores of the red sea. Jamefon.

Chryzo-Prase. Apple-green chalcedony coloured by the oxyd of nickel. (See Chryzo-Prase.) It has hitherto been found only in the vicinity of the towns of Glaffendorf, Grochau, and Kofenunitz, in Lower Silelia. It is softer than common chalcedony. It is used in jewellery.

Ciomolite. See Ciromolite.

Cinnabar, Mercurius sulphur, Haüy. (See Mercury-

Ores.) Besides the localities of cinnabar there enumerated, various mines of cinnabar occur in New Spain. In the kingdom of New Granada, cinnabar is found in three different places in veins, and also in alluvial soil, mixed with gold. In Peru, cinnabar occurs in various parts, particularly near the town of Huancavelica, at the height of twelve thousand feet above the level of the sea. Cinnabar is found in veins near to Silacara, interflecting alpine lime-stone; these veins, according to Humboldt, at present furnish all the mercury of Peru.

Cinnamon-stone. This gem was originally found in the sands of rivers in Ceylon. It has been classed with hyacinth, but it is a variety of garnet. Its colours are, hyacinth-red inclining to oranges-yellow. It is found in blunted-angular or in roundish pieces. It has a shining vitreous lustre approaching to splendent. The fracture is flat and small conchoidal. It is transparent or semi-transparent, but generally full of cracks. It scratches quartz with difficulty. When cut it feels rather greasy. The specific gravity is 3.6. According to Klaproth, the crystalline parts are,

Before the blow-pipe, it fuses into a blackish enamel. When free from flaws it is of considerable value.

Clay Iron-flone, Argillaceous Iron-flone; Fer oxyd maf-

fi, Haüy. (See Iron-ores.) The name has been inappropriately given to this species of iron-ore, as it frequently contains scarcely any alumine or clay in its composition. The following analysis of Defcots, given in the Ann. de Chemie for 1812, No 251, will shew how greatly this species of ore varies in its composition.

In these specimens, the iron was in the flate of carbonate; in others, it exits in the flate of oxyd. According to Mr. Jamefon, it would appear that the carbonated iron-flones by decomposition lose their carbonic acid, and are in time converted into the oxydized varieties. In those common clay iron-flones which have a yellow or brown streak, the iron is in the flate of hydrate; in those having a red streak in the oxydized flate, and in most of the varieties having a grey streak, the iron is carbonated. When the carbonated varieties begin to decay they become soft, and assume a liver or reddish-brown colour. This species of iron-flone, besides occurring in numerous thin flata alternating with coal-flake and sand-flone in the coal formation, occurs in kidney-shaped and rounded nodules. The greatest repository of this ore in Great Britain is in the coal basin extending from Pembroke-on-Gower to Camborne, on the borders of the Brill Channel.

Clay-slate, Argilaceous Schistus. See Slate.

Clay-stone is nearly connected with basaltic and porphyritic rocks of the trap formation. It forms the basis of clay porphyries. The colours of clay-flone are bluish and yellowish-grey or yellowish-white, lavender-blue and brownish-red. It is sometimes spotted and striped. It has a line earthy fracture, sometimes inclining to flat or conchoidal. The fragments are angular and rather blunt-edged. It is opaque, yields to the knife, and is rather easily frangible. The specific gravity is 2.2. It occurs in various parts of Scotland, in North Wales, and in Shropshire.

Clint-stone, Phonolite, Porphyry-flone, Felspath compacte flone, Fr. has mol closely a greenish-grey colour. It occurs in beds of considerable magnitude in rocks of the trap formation. (See Trap.) The principal fracture is flaky, with a fcale aspect and a glinting pearly lustre. The crofs fracture is splanhry and faintly glimmering. It occurs columnar and tabular, is translucent on the edges, and easily frangible. The thin tables yield a metallic found when struck. The specific gravity is 2.8. It melts before the blow-pipe into a grey-coloured glass. According to Klaproth, the crystalline parts are,

Cornelian. See Chalcedony and Agate.

Corundum, Corinden, Fr. The French mineralogists class as varieties of corundum the oriental ruby, the sapphire, and emery. (See these articles.) Though they are principally composed of alumine, they are, excepting the diamond, the hardest of mineral substances, and nearly the heaviest of earthy minerals, the specific gravity being from 3·87 to 4·28. Common corundum, or adamantine spar, has a greenish-white colour: it is sometimes pearl-grey, brown, or red. It is translucent and sometimes nearly transparent, and is doubly refracting. It has a distinct lamellar structure, and splits into rhomboids, the angles of which are 86° 38' and 93° 22'. (See Adamantine Spar.) This mineral is found imbedded in granite, like felspar, in various parts of India, and also in North America, and imbedded in micaceous schist in Italy.

Cross-stone, Harmotome, Haiy. See Zolite.

Cryolite, Alumine fluétée, Fr. This mineral has hitherto been found only in West Greenland. It occurs in two thin layers in gneiss. Its name is derived from the Greek word denoting ice, because this mineral melts almost like ice at a low heat. Its colours are pale greyish-white, snow-white, and yellowish-brown. It occurs massive and disseminated. It has a thinning or glinting vitreous lustre, inclining to pearly, and is translucent. The fracture is imperfectly lamellar, with joints in three directions parallel to the faces of a rectangular parallelopiped. It is softer than fluor spars, and is easily fragile. The specific gravity is 2.9. It becomes more translucent in water, but does not melt. Before the blow-pipe it first melts, then hardens, and assumes the appearance of a flag. According to Klaproth, the constituent parts are,

Cryosberyl, Gymophane, Haiy. See Cryosberyl.

Cuprous Arseniate of Iron, Martial Arseniate of Copper. See Copper-ores.

Cyanite, or Kyanite; Sappin, Saufrine; Dortheen, Haiy. See Kyanite, Addenda.

Datolite. See Datolite. This mineral is composed of boracic acid, united with lime and fels. It occurs massive and crystallized in oblique four-sided prisms, generally truncated on the edges and angles. The primitive form of the crystal is fluted by Hamsmann to be an oblique four-sided prism, with angles of 77° 30' and 103° 30'. It gelatinizes with acids. In the flame of a candle it becomes opaque and friable. Before the blow-pipe it intumesces, and then melts into a globule of a pale rose-colour.

Diallage, Smaragdit de Saufrine; Diallage verte, Haiy. Its colours are greenish-yellow, and yellow. It occurs massive and disseminated. It has a fibrous growth, or a two-fold nearly rectangular cleavage, one of which is distinct. It is rarely so hard as glass. The specific gravity is 3. Before the blow-pipe, it melts into a grey or greenish enamel. According to Vauquelin, the constituent parts are,

Diallage is found in Corfica with saufrite, and on Mont Blanc in Switzerland; also in Carinthia and Transylvania. The mixture of diallage and saufrite is named Gabbro by the Italians, Euphotide by the French, and Verde de Corfica duro by artists. When cut and polished it has a beautiful appearance, and is made into various articles of ornament.

Diallage Metalloïde. See Bronzite, Hyperstene, and Schiller Spar, Addenda.

Diamond, Diamant. (See Diamond.) In addition to the characters of the diamond given under that article, it may be proper to state, that besides the colours there enumerated, the diamond occurs sometimes blue, red, brown, yellow, and green, with the following transitions. The only variety of blue is indigo-blue, which appears to pass into red. Of red, the varieties are rose-red and cherry-red. From the latter colour it passes into olive-brown, and yellowish-brown, ochre-yellow, orange-yellow, wine-yellow, and
MINERALOGY.

and fulplur-yellow; further into fiskin-green, afparagus-green, pitachios-green, keek-green, and mountain-green, which latter passes into greenish-grey and greenish-white.

The olive-brown phases into blackih-brown, pitch-black, and greyih-black.

Besides occurring crystallized, the diamond is also found in rolled pieces and grains. The crystallizations of the diamond, besides the octahedron and its varieties, are, the perfect tetrahedron; the tetrahedron with truncated angles, or with the angles acuminated by three planes, fet on the lateral planes; segments of the tetrahedron, either detached or united, forming twin crystals; the rhombohedral dodecahedron, with convex planes or faces; the same figure somewhat elongated; the dodecahedron, with the planes divided diagonally; an acute double fix-fided pyramid, with the lateral planes fet on each other, and the apex acuminated by fix planes fet on the lateral planes; a flat double threfiided pyramid, with convex planes fet laterally on each other, and the angles of the common bafe acuminated by four planes fet on the lateral planes; a flat double threfiided pyramid, on which the lateral planes of the other are fet on the lateral edges of the other, and the angles of the common bafe truncated; a fix-fided table, with oblique terminal planes; and lastly, the diamond has been found in a cubic form, either perfect or with the edges truncated, or variously modified.

The surface of the octahedron is either smooth or flecked; the external luftre of the natural diamond is adamantine, and alternates from fplendent to glimmering; internally it is highly fplendent. It is seldom completely transparent. The black diamonds are nearly opaque. The diamond has a four-fold equiangulear cleavage parallel with the planes of the octahedron in this direction; it is rather easily frangible. The diamond scratches all other minerals. Its specific gravity is fixed by Mr. Lowry at 3.488.

The diamond, besides its other localities, is found in the district of Serro Dofria, in Brazil; it was first discovered there about the middle of the last century, in gullies of torrents, and at the beds of rivers, where gold is also obtained, but for a very considerable time the diamonds being unknown, were disregarded and thrown away. Diamonds occur also in other parts of Brazil, in the rivers Giquitig-nagoa, Riais Fundon, and Rio de Peixo. See Gem.

Diaspore is regarded as a variety of wavellite. (See Wavellite.) It occurs in curved lamellar concretions easily separable from each other; it has a grey colour, a shining pearly luftre, the angular pieces cut glaft. It flies before the blow-pipe, but is infufible. Its specific gravity is 3.43. According to Vaquelin, the con黉ent parts are,

A very small specimen analyzed by Vaquelin gave fortytwo per cent. of lime. This mineral is found, according to Hermann, in the land of Konguir, 125 leagues from the Russian frontier, where it is associated with malachite and calcareous spar.

Dipyre. See Zeolite.
Disthene, or Kyanite. Sappare, Saffare. See Kyanite, Addenda.

Dolomite, a species of magnesian lime-flone, to which the name was given in honour of Dolomieu, the celebrated French Geologist. Mr. Jamelon has claffed the different kinds of magnesian lime-flone into one order, which he calls the dolomite family: it contains four species, dolomite, brown flspar, mienite, and gyrotile. The dolomite species he has divided into four sub-species, common dolomite, dolomite spar or rhomb spar, columnar dolomite, and compact dolomite or maghnian lime-flone.

Common dolomite occurs in beds in primitive mountains, and frequently contains tremolite. It nearly resembles primitive lime-flone or flatusy marble, the chaux carbonate faceroid of the French, but may be distinguished from it by the little effervescence which it yields on the application of mineral acids compared with the former. The grains of dolomite are also more loosely adhering than in white primitive lime-flone. The mineralogical characters of common dolomite are given under the article Dolomite. Dolomite generally phosphorizes when rubbed in the dark or heated. The con黉ent parts of different dolomites are given by Klaproth as under:

Oxyd of iron - - - 4.00

98.50

98.62

This mineral has hitherto been found only in the rock named zircon fineite. (See Zircon Fineite.) It is classed by Mr. Jameson in the felspar family; but is placed by Werner between jasper and cat's-eye.

ELECT, an argentiourous gold-ore, or native alloy. Its colour is a pale braun-yellow. It is not soluble either in nitrous or nitro-muriatic acid. It contains, according to Klaproth,

Gold - - - 64
Silver - - - 36

100

It occurs at Schlagenberg, in Siberia.

EMERALD, Emeraude verte, Haüy. See Emerald.

Faffe emeralds are sometimes offered for sale, which are either green fluor spar, green quartz, or prase. The emerald of Brazil is sometimes the green tourmaline. The true emerald is harder than quartz. The beryl and the emerald have both the same primitive form of the crytal or the hexahedral prism. The terminal planes of the emerald are rough, those of the beryl smooth. The emerald agrees in chemical composition with the beryl, both containing from thirteen to fourteen parts of the newly-discovered earth galicium; but the colouring matter of the emerald chrome is wanting in the beryl. See Gem.

EMERY, Corindon granulaires, Haüy. (See Emery.)

This mineral owes its hardness to an intermixture of blue corundum. See Adamantine Spar, and CORUNDUM, Addenda.

EPIDOTE. (See Pistazite, and Thallite.) Under the latter article, for Arundel in Norway r. Aredal.) Epidote occurs at the Malvern-hills in Worcestershire, at Wallow Crag near Kewick in Cumberland, and near Marazzion in Cornwall.

EPSON Salt, Natron, or sulphate of magnesia, occurs as an efflorescence at Hurlet near Pailey, and sometimes is found efflorescent on old walls, and on the surface of different rocks, particularly gypsum, sand-stone, clay, and compact lime-stone.

EUCLARE. See Euclaire.

FAHLLERZ, Werner; grey copper ore. See Copper-ores.

FELSPAR. (See Felspar. The name of this mineral appears to be derived from the Saxon term fell, a mountain, still used in the northern counties of England; hence felspar, in its original signification, denoted mountain spar. In the mineralogical systems of Werner and Mr. Jameson, the felspar family comprises various species of minerals, which are supposed to be nearly allied to felspar. The felspar species is also divided into adularia, gluffy felspar, Labrador felspar, common felspar, disintegrated felspar, and compact felspar.

Adularia. (See Felspar.)—The forms of crytahls of adularia are the same as those of common felspar. It polishes double refraction. It melts before the blow-pipe into a transparent white gale. Adularia occurs in veins in granite and gneiss, in various parts of Aberdeenshire and Banffshire, in the Isle of Arran, and in the granite of Switzerland, France, and Germany. The largest and most beautiful crystals are found in the mountains of Stelis, a part of St. Gothard. Rolled pieces having a beautiful pearly light are collected in the island of Ceylon. The variety which exhibits a strong pearly light is cut in a semi-globular form, and is sold under the name of mornilone, and is usually worn as a ring-stone.

Gluffy Felspar occurs always crystallized in broad rectangular four-sided prisms, bevelled on the extremities. These crystals are very much cracked, and always imbedded. It is transparent, and has a splendid vitreous lustre internally. Its other characters agree with adularia. It occurs in pitch-ftone and trap in various parts of Scotland.

Labrador Felspar. See Felspar.

Common Felspar occurs variously crystallized. Haüy enumerates more than twenty of its secondary forms; several of these are represented Plate I. figs. 8, 9, 10, 11, 12, &c. Crystallography. The primitive form is an oblique-angled paralleloipipedi. The structure is perfectly lamellar, with a double, very distinct, rectangular cleavage, and an oblique indistinct cleavage intersecting the two former. The four rectangular planes have splendent faces; the faces of the oblique cleavage are dull. This remarkable character is peculiar to felspar, and may very frequently be observed in the rhomboidal fragments of this mineral. Felspar has been frequently analyzed with different results. According to Berzelius, the most probable composition of common felspar, so far as we can calculate it from the many analyses of which we are in possession, is, that the alumine bears the same proportion to the potash as in alum, and that the silica contains three times the oxygen of the base. The following is therefore a comparison between the calculated and experimental results, according to the principles of Berzelius's new system of Mineralogy. See Systems of Mineralogy.

The lime and protoxyd of iron are regarded as accidental admixtures. Felspar is one of the principal constituents of many of the rocks called primary, formed from the trap rocks, and many of the lighter-coloured lavas. It forms an essential constituent part of granites, gneiss, sienite, greenstone, and forms the basis of many porphyries, and the rock called sublite-flone. (See White-Flone.) In green-flone, the felspar is often tinged of a green colour, from the admixture of hornblends or augit. In many of the porphyries, it exists in a compact flake, or as compact felspar. The colours of compact felspar are various shades of white, grey, green, or red. The
MINERALOGY.

Flamellar structure is nearly lost in many of the compact felspars, particularly in those varieties which have little lustre. When it contains crystals of quartz or felspar, it constitutes a felspar porphyry. It forms extensive beds in many alpine districts. It is distinguished from hornstone by its inferior hardness, fusibility, and its frequent intermixture with hornblende or mica.

Disintegrated Felspar has generally a greyish-white colour. It occurs massive and in imbedded crystals which have the same form as common felspar. It is glitthening, glimmering, or dull, and soft and feétile. In fome instances, it appears to be felspar in a decomposing state; in others, to be a softer kind of felspar in an unaltered state.

Fibrolite, a mineral which occurs with corundum; it has a white or grey colour, is crystallized in rhomboidal prisms, the angle of whose planes are 80° and 100°. It has a fibrous fracture, and an uneven cross fracture. Internally it is glitthening. Fibrolite is harder than quartz. Its specific gravity is 3.21. According to Chenevix, the constituent parts are:

It is found at St. Ouen, in the vicinity of Paris, along with flint, and sometimes contains the same petrifactions as those found in flint. Flint is sometimes found in the centre of float-stone, and passes into it by gradation. Float-stone may therefore be considered as a porous flate of flint.

Flos Ferri, Coralloidal Argonite, occurs in snow-white dendritical branches, either smooth or incrusted with points. It is found in the mines at Duaston Fell, Weilmorland; it is supposed by count Bournon to be formed by sublimation.

Fluor Spar, Fluss, Werner; Chaux fluantées, Fr. See Fluor Spar.

Foliated Granular Lime-flone. The name given by Mr. Jemlon to cryalline primitive lime-flone, called by the French chaux carbonaté fauvarole. See Lime-stone, and Lime-stone, Addenda.

Fossil-Copal, or Highgate Resin, a reinosus substance found in perforating the bed of London clay at Highgate. It appears to be a true vegetable gum or resin, partly changed by remaining in the earth. It gives out a reinosus aromatic odour when heated, and melts into a limpid fluid. It takes fire when applied to the flame of a candle, and burns away entirely before the blow-pipe. The colour of fossil-copal is a yellowish-brown; it has a reinosus lustre, is brittle, and yields easily to the knife. The specific gravity is 1.048.

Fuller’s-Earth, Argile froide; French. See Fuller’s-Earth.

Gadolinite. See Gadolinite.

Galeena, or Sulphuret of Lead, Lead Glance; Plomb sulphure, Hayt. See Lead.

Garnet, Grenat, French. (See Garnet, Precious, and Garnet, Common.) The garnet family of Werner and professor Jemlon, in their mineralogical systems, comprises the following minerals, supposed to have an alliance with garnet: lenite, vesuvian, grossular, melilith, alaquoi, garnet, grenate, pyrope, and cinnamon-flone. (See these articles in the preceding volumes, and in the Addenda.) In the British Museum, these minerals are claffed together under the name of gneumatic substances, whereby the confusion of making the name word represent both the genus and species is avoided.

Glance-Coal, Ambraicite. The coal which has a splendid lustre, and burns without flame. (See Coal.) It is principally composed of carbon, and passes into graphite, or black-lead. Werner divides glance-coal into three sub-species: conchoidal glance-coal, flaky glance-coal, and columnar glance-coal. See Coal.

Glauber Salt, Native Glauberite; Salze sulphatarum, Fr. occurs as a mealy efflorescence in the neighbourhood of some salt lakes, and occasionally encrusting sand-flone and marle-flone. It is sometimes fialatitic, botryoidal, or crystallized in acicular crystals. According to Reufs, the glauber salt of Eger, in Bohemia, contains

Glassy Felspar. See Felspar, Addenda.

Glassy Tremolite. See Tremolite.

Gold. (See Gold.) In addition to the localities of gold given under that article, we may state that native gold is found in some of the stream works of Cornwall, and, like the stream tin which accompanies it, was doubtless once a part of the metallic veins that have been defroyed by the natural disintegration of the rocks which these once interfected. We have seen globules of native gold the size of a pea in a matrix of quartz, in the potholes of the Rev. Mr. Hennor, of Plymouth.

Native gold was found in alluvial soil in various parts of Scotland, and was once extensively worked at the leadhills. In the time of queen Elizabeth, it is said that three hundred men were employed in searching for it, and that in the course of a few summers a quantity was collected equal to 100,000l. sterling. Gold was obtained a few years since in a ferruginous sand in Ireland, near Arklow, in the county of Wicklow. One mass of pure gold weighing twenty-two ounces was found, which was the largest piece hitherto discovered in Europe. The total amount of gold exported to Europe annually from the Spanish and Portugueee colonies in America is stated by Humboldt at 455,800 pounds troy, of which 25,000 pounds weight comes from the Spanish colonies; the remainder comes from the Portugueee, principally from the Brazil, where it is collected by washing the sands of rivers and alluvial deposits. Gold is found almost every where along the feet of these immense mountains which run in a chain nearly parallel with the coast, from 5° to 30° of south latitude. Many of the silver-ores in America are also rich in gold. (See Silver.)
MINERALOGY.

SILVER.) For a more particular account of the various travels of M. Humboldt, to whom we are indebted for most of the correct information we have respecting the European colonies in South America. The quantity of gold and silver imported from these colonies between the years 1492 and 1803, it states at eleven hundred and sixty-six millions in pounds sterling; an amount somewhat exceeding that of the present national debt of England! 

GRAMMATITE, Tremolite. See Tremolite. 

Granular Lime-flone, flatyary marble; Chaux carbonatée fauricidiat. Fr. See Limestone, and Limestone, Addenda. 

Graphic Gold and Graphic Tellurium. See Tellurium. 

Graphic Plumbago or blackLead, (see Plumbago,) has an iron-grey colour, and a glimmering or glintening metallic lustre. It is greasy and, when fresh cut has a lead-grey colour: it is unctuous to the touch, and leaves a distinct lead-grey mark on paper. Before the blow-pipe it gradually burns away, leaving a portion of red oxide of iron. According to Berthollet, the constituent parts are, 

\[
\begin{align*}
\text{Carbon} & \quad \ldots \quad 92.9 \\
\text{Iron} & \quad \ldots \quad 7.1
\end{align*}
\]

The graphite of Borrowdale occurs with ochreous and unctuous clay; it is found in nodules and masses of various sizes. The bed in which it is found lies in a rock of grey porphyrite felspar, which has been improperly called grey wacke. 

Green Earth, Chlorite zographique, French. This mineral, though made a distinct species by Werner, appears to be soft earthy chlorite (see CHLORITE;) it generally occurs in cavities or incrusting agates in amygdaloid. It is of various shades of green, is soft and felicitus, and adheres lightly to the tongue. The specific gravity is 2.5. Before the blow-pipe, it is converted into a black flake. It is used as a green colour in water-painting. When slightly burned, it affords a beautiful and durable brown.

Grenatite, Staurolide, Haüy; the staurolide of some mineralogists. (See Staurolite.) This mineral is classed in the garnet family by Werner; but it varies from garnet in the form of its crystal, which is an oblique four-sided prism, truncated on the acute lateral edges. Sometimes it is bevelled on the extremities by two planes set on the lateral edges, and the edge of the bevelment is truncated. The crystals sometimes intersect each other, forming a cross; hence it has been called cross-flone by some mineralogists; but it is a very distinct species from the barnstonite, or cross-flone, which is a member of the zoelite family. (See Zeolite.) The colour of grenatite is dark reddish-brown. It is infusible before the blow-pipe. The above characters distinguish it from precious garnet. It occurs imbedded in mica-flone, and in talc, generally accompanied with kyanite and precious garnet.

Grey Antimony-Ore. (See Antimony-Ores.) Grey antimony occurs in some of the mines in Cornwall in considerable quantities, particularly at St. Stephen’s, Padstow, and Huel bays. It is found also at Glendening, in Dumfriesshire.

Grey Cobalt-Ore. (See Cobalt-Ore.) This mineral is found at Herland and Dolgoth mines, and in some other veins, in Cornwall.

Grey Manganese-Ore. See Manganese. 

Gypsum, Telenite; Chaux fulvata, Haüy. See Gypsum.

Harmonite, Groffflone. See Zeolite.

Haüyne, Latitale, Haüy. A mineral classed by the German mineralogists with the azure-stone, or lapis lazuli family. It was first discovered in the volcanic rocks of Albano and Praetoria, and called latitale, from ancient Latium, and was afterwards discovered in the basaltic rock of Andenmond, and has been called Haüyne, in honour of the celebrated mineralogist Haüy. Haüyne has a sky-blue colour, passing into pale Berlin-blue and blue-green. It occurs in imbedded grains, and crystallized in minute splinters of rhomboidal dodecahedrons. The fracture is conchoideal, pouting into uneven; it has a vitreous lustre, is transparent, or semi-transparent, scratches glass, and is fusible before the blow-pipe. When pulverized, it gelatinises with nitric acid, giving out an odour of sulphured hydrogen. The specific gravity is from 3.1 to 3.3. According to Vauquelin, the constituent parts are:

- Silex : 
- Alumine : 
- Sulphate of lime : 
- Potash : 
- Iron : 
- Water : 

\[
\begin{align*}
\text{Sum} & \quad 95.0
\end{align*}
\]

It has by some mineralogists been classed with sapphire, and described under the name of saphirin. It was arranged by Cordier with spinel.

Heavy Spar, Sulphate of Barites, Baro-Selenite. This mineral exceeds in weight all other purely earthy minerals, its specific gravity being from 4.3 to 4.49. It occurs both massive and crystallized in many metallic veins. Its colours are various shades of white, yellow, red, greenish-grey, and blue. Crystallized heavy spar is transparent or translucent, and refracts doubly; it has a distinct lamellar structure, and splits into a right-rhombohedral prism, which is its primitive form; the angles of the rhomb are 104° and 78°. The joint parallel to the base of the rhomb is the most distinct. The lustre is shining between vitreous and resinous; it yields readily to the knife. Before the blow-pipe it decomposes violently, and then melts into a hard white enamel. A piece exposed to the blow-pipe, and laid on the tongue, gives the flavour of sulphured hydrogen. The powder of some varieties of heavy spar, when calcined, absorbs light, and emits it again in the dark. Sulphate of froutian (see STROXINT) is the only earthy mineral with which heavy spar can probably be confounded. White lead-ore may be distinguished from heavy spar, as it is softer, and yields a metallic globule before the blow-pipe. Pure heavy spar consists of

- Barite : 67
- Sulphuric acid : 33

\[
\begin{align*}
\text{Sum} & \quad 100
\end{align*}
\]

Mr. Jameson makes the following varieties of heavy spar, which he classifies as sub-species: earthy heavy spar, compact heavy spar, granular heavy spar, lamellar heavy spar, radiated heavy spar, fibrous heavy spar, and prismatic heavy spar; and he divides lamellar heavy spar into three kinds, straight lamellar, heavy spar, curved lamellar heavy spar, and disintegrated lamellar heavy spar.
MINERALOGY.

Earthly Heavy Spar occurs sometimes loose, and sometimes cohering in the drusy cavities in veins: it is composed of dull or glimmering dully particles, which feel meagre.

Compact Heavy Spar occurs massive, diffedimented, reniform, semi-globular; it has a coarse earthy fracture, and is sometimes imperfectly foliated; it has a glistening lustre, is slightly transient, soft, and easily frangible. It is often marked with dendritic delineations. According to Well-rumb, it contains

| Sulphate of barytes | 83 |
| Silex | 6 |
| Alumine | 1 |
| Water | 2 |
| Oxyd of iron | 4 |

In Derbyshire, this mineral is called cowk by the miners.

Granular Heavy Spar occurs massive: the structure is finely granular; the structure of the grains is lamellar. This mineral nearly resembles granular line-lime, but is much heavier, and does not effervesce with acids.

Lamellar, or Crystallicised Heavy Spar, occurs in the following secondary forms. 1. A rectangular four-sided table, either perfect, or with the terminal planes bevelled, and sometimes the angles of the bevelment are truncated. 2. An oblique four-sided table, perfect, or with the angles or edges truncated. 3. A longish six-sided table, either perfect or variously bevelled. 4. Eight-sided tables, either perfect, bevelled, or truncated. Curved lamellar heavy spar occurs in distinct concretions, which have a curved lamellar structure.

Fibrous Heavy Spar has a chestnut-brown colour. It occurs in reniform or botryoidal masses, and has a plumose or diverging fibrous structure.

Radiated Heavy Spar, or Bolognese Spar.—Its colours are, smoke-grey, ash-grey, or yellowish-white. It occurs in roundish compacted pieces, which are always covered with marble or clay. The structure is lamellar in one direction, and in the longitudinal fracture radiated; it is translucent. It is remarkably phosphorescent after being heated and exposed when cool to the light, and carried into a dark room. It was first found at Monte Paterno, near Bologna. Its constituent parts are,

| Sulphate of barytes | - | 62 |
| Lime | - | 2 |
| Silex | - | 16 |
| Alumine | - | 14.75 |
| Oxyd of iron | - | 0.25 |
| Water | - | 2 |

in diameter; these masses have a curved lamellar structure. According to John, the constituent parts are,

| Sulphate of barytes, with | 93.58 |
| Trace of frontian | - |
| Sulphate of lime | 3.58 |
| Oxyd of lime | - | 0.87 |
| Water, carbonaceous matter, | - | 2.00 |

According to Klaproth,

| Sulphate of barytes, with | 85.25 |
| Trace of frontian | - |
| Carbon | - | 0.50 |
| Sulphate of lime | - | 6.00 |
| Oxyd of iron | - | 5.00 |
| Alumine | - | 1.00 |
| Lof, including water and | 2.25 |

Hepatite occurs at Buxton, in Derbyshire.

Heliotrope, Quarz agate ponizé, Haüy.

Hematite, Black and Brown; For oxydé hematite, Haüy.

Hemátite, Red; For oligiste concretion, Haüy. See Iron-Ores.

Hepatic Pyrites, or Lower Pyrites. See Pyrites.

Hematite. See Heavy Spar, Addenda.

Highgate-Resin. See Fossil-Copol, Addenda.

Hollow Spar. See Chalcolith, Addenda.

Honey-Stone. See Mellite.

Horn-stone, a mineral nearly allied in composition to flint, but has a more earthy texture; it received its name from the supposed resemblance to horn. A more opaque variety of flint, which occurs along with flint and chalcedonic flint in the sand flata below chalk, is called chert. (See Chert, Addenda.) This is a kind of horn-flint. Horn-flint is the petro-flake of some mineralogists, and under that name is often confounded with compact felspar. Indurated flake, which contains a large portion of silex in its composition, is sometimes called horn-flint flake. Sanstone, under the names of palaeopter and neopter, appears to include both the splintery horn-flint and flinty flate of Werner. Werner divides horn-flint into three sub-species, splintery horn-flint, conchoideal horn-flint, and wood-flint.

Splintery Horn-flint occurs of various shades of grey, red, and green. It is generally massive, but sometimes is found in large balls, and sometimes lenticular, or in the form of crstals, in the cavities where crsytals have once occurred, and hence called suppositious crsytals. The flate is dull, the fracture splintery; it is more or less translucent, is somewhat less hard than quartz. It is infusible before the blow-pipe, which distinguishes it from compact felspar. The latter mineral is not so hard as horn-flint, and has more flurate. Horn-flint passes into compact felspar, quartz, common jasper, and chalcedonic flint. In these transitions, it is frequently difficult to determine among which of these it should be placed. It forms the basis of horn-flint porphyry.

Conchoideal Horn-flint is glimmering or glintening, with a vitreous flute; it has a more or less perfect and flat conchoideal fracture. It is harder and less translucent than splintery horn-flint. It occurs massive, globular, and sometimes forms suppositious crsytals. It is found in veins and beds. Chert appears to belong to this sub-species.
MINERALOGY.

Wood-(optionally Quarz agate xylloid, Hayny, is generally various shades of grey, frequently striped or clouded. It occurs rounded, in the shape of the trunks, branches, or roots of trees: it is generally translucent at the edges, with little or no lustre. The crofs fracture is imperfectly conjoint, the longitudinal splinter and fibrous. Wood-robe is properly wood filifere, in which the greater part of the vegetable matter has disappeared, and fibrous matter has occupied the place, preserving the form and texture of wood. Some wood is petrified with opal, forming wood opal; and sometimes the mineral matter of petrifed wood is quartz, or calcareous earth.

Hornblende, Amphibole, Hayny. The description of this mineral, so important in geology, was omitted in the proper place, and is given here. Hornblende may be divided into common hornblende, bafaltic hornblende, and hornblende slate. Hayny, under the term amphibole, classifies actinolite with hornblende. (See Actinolite.) Hornblende generally occurs of various shades of dark green passing into black; sometimes common hornblende occurs of various shades of brown. Hornblende has a lamellar structure longitudinally, with a two-fold oblique angular cleavage, parallel to the planes of a rhombohedral prism, the alternate angles of which are 124° and 56°. This is the form of the primitive crystal, and distinguishes it from epidote, which cleaves at an angle of 111° and 69°; and augite or pyroxene, which cleaves at an angle of 92° and 88°. The crofs fracture of hornblende is coarser-grained, uneven; it melts easily before the blow-pipe into a greyish-black coloured glaze. These characters, together with the cleavage, serve to distinguish hornblende from augite or epidote; its inferior hardness distinguishes it from felspar.

Common Hornblende occurs both massive, disseminated, and crystallized; the crystals are oblique four-sided prisms, aggregated or long flatish prisms, intersecting each other, or confusely radiated. The structure is lamellar or bladed. The crystals are long and deeply streaked longitudinally. The lustre is shiny and pearly. The black-coloured varieties are opaque; the green generally translucent at the edges. It yields pretty easily to the knife, leaving a greenish-grey streak. It is very tough, and becomes indented by the stroke of a hammer. The specific gravity is from 3.20 to 3.28. According to Klaproth, the constituent parts are,

This mineral occurs forming beds in mountains, or is disseminated, as a constituent part of many compound rocks. It occurs occasionally in granite, gneifs, mica-flate, and flate, and is an essential part of fiente and green-flone. It forms a constituent part of many bafaltic and volcanic rocks, but has frequently been confounded with augit. (See Volcanic Products.) Hornblende occurs abundantly in various parts of Scotland and in England, particularly at the Malvern-hills in Worcestershire, and at Charlwood forest in Leicestershire, and in Devonshire, Cornwall, and Cumberland.

Bafaltic Hornblende, Amphibole felifique bafaltique, Fr. is distinguished from common hornblende by its velvet-black colour, and more perfect crystallization. It occurs crystallized in unequangular six-sided prisms, terminated at each extremity by a trihedral pyramid, with rhombic faces. It is sometimes terminated diffusely at each extremity, and sometimes acuminated by four or more planes. The angles of the cleavage have already been described. Bafaltic hornblende has a splendid vitreous lustre. The fracture is fine-grained, uneven, and glinting. It is black, opaque, and builds glaft. It is more iridescent than common hornblende, and melts with greater difficulty. The specific gravity is from 3.15 to 3.19. According to Klaproth, the constituent parts are,

It occurs imbedded in bafalt, as at Arthur's seat, near Edinburgh, and in various parts of Scotland. It is frequently found in lava, particularly in the lava of Vefuvius. It was formerly confounded with felspar, until Werner pointed out its characters.

Hornblende-Slate occurs in beds in granite, gneifs, and mica-flate; in the latter rocks, it is often much intermixed with mica, and sometimes contains garnets, as is the case near Tyrnodr in Prescott. Its colour is greenish-black. It has in the mafs a flaty structure, and is internally laminar or fibrous, and has a glinting or velvet-like lustre. No very well characterised beds of hornblende-flate occur in England.

Horn-Mercury, Mercure muriatis, Hayny. See Mercury-Ores.

Horn-Silver, Argent muriatis, Hayny. See Silver-Ores.

Hunite occurs at Mount Somina near Naples, in a granular topaz rock, intermixed with brown and olive-green mica and white Haynye. Its colour is reddish-brown; it occurs crystallized in oofathrous, which are always more or less truncated and bevelled; the planes are frequently transversely streaked; it has a shiny lustre, and is transparent; it scratches quartz with difficulty. This mineral was named humite in honour of Sir Abraham Hume, by the count de Bourbon, who has given the preceding characters of it in his Catalogue Mineralogique.

Hyacinth, Zircon hyacinth. See Zircon.

Hyalite, Muller glaft, Werner; Quarz concretion, Hayny. (See Hyalite.) The specific gravity of this mineral is given in the last edition of professor Jamefon's Mineralogy at 2.47, from Karsten. Its constituent parts are given by Bucholz as under:

**Hydroplane.** See Opal, Addenda.

**Hyperstene.** Labrador Hornblende; Diallage metallic, Haüy. Its colours are, dark-greyish, brownish, or greenish-black, with generally a pseudo-metallic lustre, reflecting a copper-red, a pinchbeck-brown, or a gold-yellow light. It occurs both massive and disseminated; it has a lamellar structure and a two-fold cleavage, the planes forming angles of 100° and 80°. It is opaque, and yields a greenish-white streak. It is harder than common hornblende. Its specific gravity is 5.38. Before the blow-pipe it blackens, but is insoluble. According to Klaproth, the constituent parts are,

**Iridium, Native.** has a pale lead-grey colour; it occurs in flat small irregular grains in alluvial soil in South America. It has a shining metallic lustre, a lamellar structure, is brittle and harder than platinum. The specific gravity is 19.5. It is proved by Dr. Wollaston to be an alloy of Iridium and Osmium; which see.

**Iron-Clay.** is of a reddish or brownish-red; it occurs massive and vesicular, as the bases of some mygaloides which form beds in basaltic rocks. It is intermediate between basalt and wacke, having less hardness than the former, and more than the latter. It is also more easily frangible than either basalt or wacke.

**Iron-Flint** is generally of a brown or brownish-red colour; it is opaque and hard, and has an imperfect conchoidal fracture. It occurs massive in rounded pieces, and crystallized in small equiangular fix-sided prisms. Its specific gravity is from 2.5 to 2.8. It is insoluble. This mineral appears to be quartz rendered opaque by a chemical combination with iron. According to Bucholz, the constituent parts are,

Pebbles of iron-flint are used at Worcester for burnishing the gilding in china. They have sometimes been found in considerable quantities in the ploughed fields near Ashby-de-la-Zouch in Leicestershire.

**Iron-Mica.** Micaceous iron glance, or iron-ore. See Iron-ores.

**Iridium, Native.** See Iron-ores.

**Iron, Native and Meteoric, For native metorique, Haüy.** is the iron which has been observed in various places to fall from the atmosphere. See Stone, Meteoric, Falling Stone, and Meteoric Iron, Addenda.

**Iron-Orfe and Iron-Stones. (See Iron.)** We shall here enumerate the different species of iron-ore, with the names given to them by the French and German mineralogists.

**Iron Pyrites, Common; For sulphure, Haüy; Gmelin scheufelkies, Werner.** Chalcopyrite Pyrites, For sulphure capillaire, Haüy; Haarkies, Werner. Cellular Pyrites, Zellkies, Werner. Radiated Pyrites, For sulphure radiate, Haüy; Strebbkies, Werner. Hematite, or Liver Pyrites, La pyrite hepaitique, Brochant; Laberkies, Werner. Magnetic Pyrites, For sulphure ferrufere, or magnetique, Haüy; Magnetkies, Werner. Polished Magnetic Pyrites, Blatbichier magnetikies, Werner. For an account of these species, see Pyrites, and Iron-ore.

**Iron-Stone, Magnetic, Common, For oxyde, Haüy; Gmelin.**
MINERALOGY.

Geimer magnetfein, Werner. This ore is highly magnetic with polarity. According to Berzelius, it contains

Peroxid of iron - - 71.86
Protoxid of iron - - 28.14

---

It occurs in various parts of the world, chiefly in primitive mountains; it is found at St. Juft in Cornwall, and Tavistock in Devonshire.

Iron-sand, or Sandy Magnetic Iron-flone, Fer oxydul titanifer, Haüy, (see Iron-ore,) occurs in volcanic and basaltic rocks, forming a component part of many black lavas, and in the sands of rivers. According to Cordier, its constituent parts are,

Iron-sand, Teneriffe.

Oxyd of iron - - 79.2
Oxyd of titanium - - 14.8
Oxyd of chrome, a trace - -
Oxyd of manganese - - 1.6
Silex and alumine - - 0.8

---

According to Thompson,

River Dee, Aberdeenshire.

Oxyd of iron - - 85.3
Oxyd of titanium - - 9.5
Arsenic - - 1.0
Silex and alumine - - 1.5

---

Earthy Magnetic Iron-flone; Fer oxydul fulgineux, Haüy; Ööhriger magnetfeinstei, Werner.—The colour is blueish-black; it is opaque, soft, sectile, and easily frangible. It appears to be common magnetic iron-flone in a state of decomposition. Common magnetic iron-flone and iron-sand are distinguished from iron-glance by the colour of the streak, which is black; but that of iron-glance is red. According to Mr. Jameson, Werner was the first who observed that magnetic iron-flone does not pollute the magnetic property when that at a depth in the earth's surface; but acquires it after exposure to the atmosphere.

Specular Iron-ore, Fer Common Iron Glance; Haüy; Eifenhans, Werner.—This ore, according to different analyses, appears to contain about 90 per cent. of oxyd of iron. See Iron-ores.

Scaly Red Iron-ore, or Iron Frath; Fer oxydul rouge luifant, Haüy; Rother eisenraum, Ööhr Red Iron-flone; Fer oxydul rouge graffier; Ööhriger rathfeinstei, Werner.

Compáet Red Iron-flone; Fer oxydul compacte, Haüy; Dichter rathfeinstei, Werner.

Red Hematite, or Fibrous Red Iron-flone; Fer oxydul concretion, Haüy; Rother glasflöste, Werner. See Iron-ores.

—Brown iron-flone is distinguished from red iron-flone by its red streak and inferior specific gravity; it also contains more water, the brown iron-flone being an hydrate. This ore, according to professor Janson, makes but indifferent cast-iron, but affords good malleable iron and excellent steel.

See Iron-ore.

Compáet Black Iron-flone; Dichter saurezeisenstei, Black bematite; Mine de fer noire compacte, Fr.; Schwarzer glasflöste, Werner.—When melted with borax before the blow-pipe, it yields a violet-blue glas; hence it is conjectured to contain much manganese.

Sparry Iron-flone; Chaux carbonaté ferrifere over manganace, Haüy.

Reddle; Argile acaufe rouge graphique, Haüy; Rotfei, Werner.

Columnar Clay Iron-flone; Fer argileux baillé, Fr.; Lenticular Clay Iron-flone; Fer oxydul brun granuleux ou lenticleulaire, Fr. (See Iron-ore.)—The following analysis of this ore is given by Daubuisson, Journal des Mines, 1810.

Peroxid of iron - - 73
Water - - 14
Silex - - 9
Peroxid of manganese - - 1
Lofs - - 3

---

Renniform Clay Iron-flone; Fer oxydul geodique, Haüy.—The constituent parts of this ore are stated by Daubuisson.

Peroxid of iron - - 76
Water - - 14
Silex - - 8
Oxyd of manganese - - 3
Alumine - - 1

---

See Iron-ore.

Pea-ore, or Pfisform Iron-ore; Fer oxydul globuliforme, Haüy; Bobners, Werner. See Iron-ore.

Pitchy Iron-ore; Fer oxydul refusite.—The pitchy iron described under the article Iron-ores appears to be a phosphate of iron; later mineralogists describe it as an oxyd and sulphate of iron. It is a rare ore, having been found only in one mine near Freyberg, and in the district of Pfis in Upper Sileia. Its colour is greyish-black, passing into dark liver-brown. It is said to occur forming crusts. It has a splendid or shining resinous luster. The fracture is imperfectly conchoidal: it is composed of granular distinct concretions: it is translucent on the edges; the streak is lemon-yellow: it is soft. When placed in water, it becomes semitransparent and vitreous. According to Klaproth, its constituent parts are,

Oxyd of iron - - 67
Sulphuric acid - - 8
Water - - 20

---

Blue Iron-ore; Blue Iron Earth; Fer phosphaté terreux, Haüy.
MINERALOGY.

Klaprotli, (See Iron-ore.) According to Klaprotli, this ore contains,

Chrome of Iron. See Chrome, and Chromate of Iron.

Cubé Ores. See Ores of Iron.

Muriate of Iron, Native, or Pyroslonite, Fer muriaté, Fr. has a liver-brown colour, inclining to pittachio-green. It occurs crystallized in short six-sided prisms. The terminal planes of the crystals are shining and pearly, the lateral planes, when clear, are shining and vitreous. It has a foliated structure and four-fold cleavage, the last distinct of which is parallel with the terminal planes. It is translucent on the edges, and yields a brownish-white streak. Its specific gravity is 3.08. It is insoluble in water, but soluble in muriatic acid, except a small residuum of silicious earth. Before the blow-pipe, it gives out copious fumes of oxy-muriatic acid. This is a very rare ore of iron.

The following table of the annual quantity of iron raised and smelted in different parts of Europe, is extracted from the second edition of Jameson’s Mineralogy, vol. ii. p. 314.

The United States of America, without including Louisiana and the Indiana territory, are said to yield 480,000 quintals, and, according to Dr. Bruce, the value of the iron and manufactured articles of iron in the United States is from twelve to fifteen millions of dollars. The annual importation, including bar-iron and every article of iron or steel, is estimated at four millions.

Iridium, an alloy of iridium with osmium. See Osmium, Addenda.

Isingale. See Titanium.

Jade, Jade-Nephrite, Fr. See Nephrite, Addenda.

Jasper. (See Jasper.) In that article it is stated, that common jasper is exclusively found in veins; this is not strictly correct, for jasper occurs in irregular beds and masses in the argillaceous schists, which cover the granite of the Grampian-hills in Kincardineshire. Jasper occurs in some of the beds of manganite near Exeter.

Jenite. See Jenite.

Jet Pitch-coal. Jetl, Fr., has a black colour, and yields a brownish-black streak. It occurs massive, and in the shape of branches. Jet has a ligneous structure. The fracture is large and perfect conchoidal, with a shining lustrous lustre. It becomes electric by friction, and burns with a greenish flame and bituminous odour. Jet, according to the experiments of Dr. Macculloch, contains vegetable extract on dilillation; but when heated under compression, it is converted into true mineral coal. For some account of the localities of jet, see Jet.

Kaolin. See Porcelain Earth, Addenda.

Kyanite, or Cyanite; Diffrène, Haiy; Suporre, Sauffure. Its colours are blueish, or grey sky-blue, and pale blueish-green. The white varieties are partially shaded with blue. It occurs crystallized and massive. The form of the crystals are an oblique four-sided prism, with two opposite broad, and two opposite narrow planes. This is the primitive crystal. It occurs also truncated on the two opposite acute lateral edges, forming an hexaehedral prism; sometimes all the lateral edges are truncated; and sometimes two prisms are joined by their broader lateral planes, forming a twin crystal. The narrow lateral planes are longitudinal streaked. The lustre is shining and pearly, and that of the broad planes is sometimes pellucid. Kyanite has a lamellar structure, with a cleavage parallel to the planes of an oblique tetrahedral prism; that parallel with the broad lateral planes is the most distinct. The structure of amorphous kyanite is more or less curvedly lamellar, passing into bladed. It is translucent or transparent; it fractures silky, and is easily fragile. The specific gravity is 3.47 to 3.51. Some of the crystals become positively electric, others negative; hence the name diffrène was given to it by Haiy, on account of its double electrical powers. It is insufible before the blow-pipe. According to Klaprotli, its constituent parts are,

It occurs in primitive mountains, in micro-flate, talc-flate, and white-flone. It has been found at Bohorn, in Banffshire, and Banbury, Aberdeenshire. In India it is cut and polished, and sold as an inferior kind of fapphire. Sometimes crystals of kyanite may be seen joined and intermixed with garnetite, (see Grivetite,) which forms the near alliance of these minerals, which have also nearly the same chemical composition.

Labrador Felspar. See Felspar.

Labrador Hornblende. See Hyperstene, Addenda.

Lapis-Lazuli. See Lazuli.

Lattialite. See Haüyne, Addenda.

Laumontite. See Zedolite.

Lazemestone. See Lazuli.

Lazulite. See Lazulite.

Lead-ores. (See Lead, where eleven species of lead-ore are described.) The ammonial lead-ore is called the triple sulphuret of lead. Four other species of lead-ores have since been described; cobaltic lead-ore, native minium, arseniate of lead, and muriate of lead.

Cobaltic Lead-ore has a fresh lead-grey colour, and a shining metallic lustre. It occurs minutely disseminated, and
and in extremely minute crystals, aggregated like moss; it is opaque, soft, and seifile. Before the blow-pipe it splits into small pieces, and communicates a small blue colour to borax.

Native Minium; Plumb oxydé rouge, Haiy.—It has a scarlet-red colour. It occurs massive and pulverulent; when examined with a lens, it exhibits a crystalline structure, like galena, in which it is generally found. Before the blow-pipe, on charcoal it is first converted into litharge, and then into metallic lead. This mineral is probably produced by the decomposition of galena, which it incrusts. It has been found at Graffington, and other parts of Craven, in Yorkshire.

Muriate of Lead, or Cornoc Lead-Ore.—Its colours are greyish or yellowish-white, passing into wine-yellow. It occurs crystallized in cuboidal prisms, either simple, or terminated by tetrahedral pyramids, or bevelled on the edges. It exhibits a lamellar structure, with joints in three directions parallel to the faces of a cuboidal prism; the core fracture is conchoidal; it has a splendent adamantine lustre; is more or less transparent. It is very soft and fragile. On exposure to the blow-pipe, on charcoal it melts into an orange-coloured globule, and appears reticular externally, and of a white colour when solid; if melted again, it becomes white; and on increase of the heat the acid flies off, and minute globules of lead remain. According to Klaproth, its constituent parts are,

\[
\begin{align*}
\text{Oxyd of lead} & \quad - \quad - \quad 85.5 \\
\text{Muriatic acid} & \quad - \quad - \quad 8.5 \\
\text{Carbonic acid and water} & \quad - \quad - \quad 6 \\
\end{align*}
\]

According to Langier, its constituent parts are,

\[
\begin{align*}
\text{Oxyd of lead} & \quad - \quad - \quad 76.8 \\
\text{Phosphoric acid} & \quad - \quad - \quad 2 \\
\text{Arfenic acid} & \quad - \quad - \quad 4 \\
\text{Muriatic acid} & \quad - \quad - \quad 7 \\
\text{Water} & \quad - \quad - \quad 1.5 \\
\end{align*}
\]

Arfénite of Lead, or Reniform Arfénite of Lead; Plomb arfénic compaît, Haiy.—Its colours in the fresh fracture are reddish-brown and brownish-red; externally ochre-yellow and straw-yellow; internally the lustre is shining and refrinous; the fracture is conchoidal, inclining to uneven; it is opaque, soft, and brittle. The specific gravity is 3.93. This ore has hitherto been found only in one mine near Nertchenk, in Siberia. It occurs in reniform and tuberous masses; it is fusible in water. Before the blow-pipe, on charcoal it gives out arfénical vapours, and is more or less perfectly reduced. Its constituent parts are,

\[
\begin{align*}
\text{Oxyd of lead} & \quad - \quad - \quad 35 \\
\text{Arfenic acid} & \quad - \quad - \quad 25 \\
\text{Water} & \quad - \quad - \quad 10 \\
\text{Oxyd of iron} & \quad - \quad - \quad 14 \\
\text{Silver} & \quad - \quad - \quad 2.5 \\
\text{Silex} & \quad - \quad - \quad 2.5 \\
\text{Alumine} & \quad - \quad - \quad 2 \\
\end{align*}
\]

Filamentous Arfénite of Lead, Plomb arfénic filamen-
tena, Haiy, occurs crystallized in small acicular prisms, or in delicate silky filaments, at St. Poix, in the department of Saône and Loire, in France.

Earthly Arfénite of Lead occurs in crusts, in the same mine with the filamentous. Its colour is yellow; it has an earthy fracture; it is soft and friable. This ore has also been found associated with white lead-ore, copper-ores, and quartz, in the hill of Horpie, in Oisans.

Vol. XXXIX.

Indurated Earthy Lead-Ore, Plomb carbonatis teneus, Fr. described as lead-earth under the article Lead-Ores, has been analyzed by John. Its constituent parts are,

\[
\begin{align*}
\text{Oxyd of lead} & \quad - \quad - \quad 66 \\
\text{Carbonic acid} & \quad - \quad - \quad 12 \\
\text{Water} & \quad - \quad - \quad 2.25 \\
\text{Silex} & \quad - \quad - \quad 10.50 \\
\text{Alumine} & \quad - \quad - \quad 4.75 \\
\text{Iron and oxyd of manganete} & \quad - \quad - \quad 2.25 \\
\end{align*}
\]

This ore occurs in considerable quantities in some of the mines in Craven, in Yorkshire, and is smelted as a rich ore of lead.

Conchoidal Phosphate of Lead contains a small portion of arfénic and muriatic acid. It differs from green lead-ore, described under the article Lead-Ore. When crystallized, the planes of the crystals are generally convex. It occurs also fibrous, reniform, and botryoidal. The colour is orange-yellow, passing into lemon-yellow and red; the fracture is conchoidal; it is translucent; internally the lustre is shining and refrious. Its specific gravity is 7.26. According to Langier, its constituent parts are,

\[
\begin{align*}
\text{Oxyd of lead} & \quad - \quad - \quad 76.8 \\
\text{Phosphoric acid} & \quad - \quad - \quad 7 \\
\text{Arfenic acid} & \quad - \quad - \quad 12.5 \\
\text{Muriatic acid} & \quad - \quad - \quad 1.5 \\
\end{align*}
\]

According to Rose,

\[
\begin{align*}
\text{Oxyd of lead} & \quad - \quad - \quad 77.5 \\
\text{Phosphoric acid} & \quad - \quad - \quad 7.5 \\
\text{Arfenic acid} & \quad - \quad - \quad 12.5 \\
\text{Muriatic acid} & \quad - \quad - \quad 1.5 \\
\end{align*}
\]

This ore has been found in Huel Unity mine, Cornwall.

The greatest quantity of lead is raised in England of any country in Europe. The following table contains the annual amount of lead in quintals from the following countries:

Lelleite, a mineral very recently discovered at Gryphyla, in Sweden, of which we have only the following description. It has a red colour, the lustre and trans-

4 C
The specific gravity is 2.71. Its constituent parts are,

Silex - - - - 75
Alumine - - - - 22
Manganese - - - 2.50
Water - - - - 5.00

100

Lepidolite. (See Lepidolite.) When that article was written, it was supposed that this mineral was exclusively found on Mount Hradîfo, in Moravia. Lepidolite has since been discovered in Saxony, Sweden, Norway, France, the Island of Elba, and in several parts of Scotland, particularly in lime-stone, near Dalmally, in a slate-quarry at Ballachulish, at the head of Loch Fyne, and at Glenilt in Perthshire.

Leucite, Amphibole, Häüy. See Leucite.

Leucite, or Yenite. See Yenite.

Lime-stone. See Lime-stone and Geology, Addenda.

Lithomarge, Friable. (See Lithomarge.) This variety is characterised by its scaly particles foiling, and low degree of coherence. According to Klaproth, it contains

Silex - - - - 32
Alumine - - - - 26.50
Iron - - - - 21
Muriate of soda - - 1.50
Water - - - - 17

98

Lithomarge, Indurated; Argil lithomarge, Häüy. (See Lithomarge.) This variety occurs in veins in porphyry, gneifs, grey wacke, and serpentine, and in drusy cavities in bafaltic rocks. It is intermediate between felsite and variegated clay, and appears sometimes to pass into meerschaum.

Lydián-stone. See Flinty Slate, and Horn-stone, Addenda.

Lythores, a mineral discovered in Norway, which appears allied to chaoîite, and was called lythores by Kärlén, because when first broken it appears as if spotted with coagulated blood. Its colour is aurora-red, passing into brownish-red or brown; it is occasionally marked with cream-yellow and greenish spots. It occurs mafive and disseminated; it has an imperfect foliated structure. The luster of the surface is resinous and glimmering. The cross fracture is splintery and dull; it is feebly translucent on the edges; it is hard. The specific gravity is 2.5. According to John, the constituent parts are,

Silex - - - - 44.62
Alumine - - - - 37.36
Lime - - - - 2.75
Soda - - - - 8.00
Water - - - - 6
Oxyd of iron - - - - 1.

99.73

Macle, a name given by the French mineralogists to chaoîite or Hollow spar; which fee.

Madreporeite, a variety of black lime-stone, so called on account of its occurring in radiated or diverging prismatic concretions, which are supposed to resemble the stars of madrepores: it has a minute and indistinctly curved lamellar structure. When rubbed, it emits a strong smell of sulphuretted hydrogen gas. Patron suspects that this mineral is faciculated aragonite. According to Klaproth, it consists of

Carbonate of lime - - 93
Carbonate of magnesia - - 0.50
Carbonate of iron - - 1.25
Carbon - - - - 0.50
Silicious sand - - 4.50

99.75

Other analyses give a small portion of sulphur and manganese.

Magnesian Lime-stone, or Compact Dolomite, has generally a yellowish-brown or yellowish-grey colour, a granular structure, a glimmering or glitthening lustre, and diffuses flowly in acids; these characters distinguish it from common lime-stone. The specific gravity is about 2.8. It contains fewer petrifactions than most common lime-stones. It occurs in regular strata on the eastern side of England from Nottinghamshire to Sunderland. It occurs also in amorphous masses, and variously contorted beds, and also forming a kind of lime-stone breccia in the red marls. According to Tennant, its constituent parts are,

Yorkshire.
Lime - - - - 30
Magnesia - - - - 20
Carbonic acid - - - - 47
Alumine - - - - 4

98

According to Thomson,

Near Sunderland.
Carbonate of lime - - 56.80
Carbonate of magnesia - - 40.84
Carbonate of iron - - 0.36
Insoluble matter - - 2.

100

Magnesite, Magnesia carbonatè, Häüy. It occurs in amorphous masses and tuberous spongiform. The fracture is splintery and large; and flat conchoïdal. It is opaque, earthy. The colour is yellowish-grey or white, with spots and dendritic delineations of blackish-brown. Magnesite yields to the nail externally, but internally it is harder than calcareous spar; it feels somewhat meagre, adheres to the tongue, and absorbs from nine to ten per cent. of water when immered in it, and becomes semi-transparent on the edges. It is flowly soluble with effervescence in concentrated muriatic acid. Before the blow-pipe it is inffuable, but becomes sufficiently hard to scratch glass. Its specific gravity is 2.88. According to Bucholz, the constituent parts are,

Magnesia - - 45.52 to 48
Carbonic acid - - 47.00 to 52
Silex - - 4.50
Alumine - - 0.50 a trace
Manganese - - 0.50 a trace
Lime - - 0.08 a trace
Water - - 2

100.10 100
MAGNETIC Iron-Stone, and Magnetic Pyrites. See Iron-
Stone, and Pyrites.

MOLYBDENA, or Sulphuret of Molybdena; Molybdenum Sul-
phur, Haüy; is of a bright lead-grey colour. It occurs
massive, differentiated in plates, and crystallized. The form
of the crystals is a regular six-sided table, or a very short six-

MERCURY-Ores. See Mercury, and CINNABAR, Addenda.

METEORIC, Native Iron; Fer natif meteorique, Haüy.
The colour is pale steel-grey, which inclines to silver-white,
like platinum; it is generally covered with a thin brown crust
of oxyd of iron; it occurs in racemose or globular maf-ces,
and also minutely disseminated in meteoric tones. (See
Stone, Meteoric.) The external surface is smooth and
polifhed; the internal glimmering or glintening with a
metallic lustre: it yields a splendent streak, and is malleable
and flexible, but not elastic. The specific gravity of
meteoric iron is from 6.48 to 7.57; it is magnetic. Accord-
ing to Mr. Howard, the conftituent parts are,

| All the meteoric iron which has yet been examined |
| contains a portion of nickel; the latter metal is also found in |
| molten of the meteorite tones. The phenomena attending the |
| defent of meteoric iron are precisely similar to thoce which |
| accompany the fall of meteorite tones. In molten inclufes, |
| loud detonations and brillant light or fire-balls have pre-
| ced the fall. These fire-balls appear to be the metallic |
| or mineral matter in a flate of vivid ignifcation. Pliny |
| mentions the fall of a mass of fpozy iron from the atmosphere |
| in Lucania fifty-six years before the Christian era. |
| Avicenna mentions a mass of iron weighing fifty pounds, |
| which fell from the air near Lurgea; and Averroes fays, a |
| mass of iron weighing one hundred pounds fell at Cordova |
| in Xpain. In the year 1164, a flower of iron fell in |
| Xfinicia. (Georg. Fabri. Rer. Xfinicia, lib. i. p. 32.) In |
| the year 1552 fire-tons or mafces of iron fell near Milkos, |
| in Tranflyavia. And among numerous other inflances in the |
| year 1751, a fire-ball built with a loud explofion in the |
| biffopic of Agram, in Croatia; two mafces of iron fell |
| from it; the one, which weighed seventy-two pounds, sunk |
| a confiderable depth into the earth; and the other, which was |
| sixteen pounds, fell on the surface of a meadow, at the dif-

| tance of 2000 paces from the former; the larger is still pre-
| served in the Imperial cabinet of Vienna.

Numerous mafces of native iron occur in various parts of |
the world, which agree in external appearance and chemical |
compoftion with those whose defent from the air is well |
attested. Professor Pallas discovered a mass of native iron, |
weighing about 1600 pounds, on the surface of a hill |
between Krainojark and Abakanufk, in Siberia. It is con-

Several mafces of native iron have been met with in |
Mexico; and many years since, a mass of native iron, cal-
culated to weigh about thirty tons, was discovered in the |
district of St. Jago de Eftro, in South America. It lies in |
the middle of a great plain, where no rock or mountain is |
within an hundred miles of it. According to Howard, it |
confids of go parts of iron, and 10 of nickel. Similar mafces |
have been found in Africa, North America, and the |
East Indies.

MICHA. See MICA.

MIEIMITE, Granular, is a variety of cafnfian lime-tons |
first found at Micen in Tucfany: it has a light green or |
greenish-white colour; it occurs massive and crystallized, |
in small flat double three-sided pyramids, in which the lateral |
planes of one pyramid are fat on the lateral edges of the |
other; the cryftals are often joined by the edges, or interfecl |
each other. It is transftuent, and has internally a fpidenten |
and pearly lustre. The ftucture is curvedly lamellar. Its |
specific gravity is 2.88; it diffolves slowly in acids. The |
conftituent parts are,

| Carbonate of lime - - - 53 |
| Carbonate of magnesia - - - 42 |
| Carbonate of iron and magnesia - - 3 |
| - - - 98 |

Prismatic Mieinite occurs in low, small, three-sided |
pyramids, deeply truncated on the edges; it appears to |
contain lefs magnesia than the preceding.

Milk Quartz, or Rose Quartz. See Quartz.

MINERAL CAOUTCHOUC, or Elaffite Bitumen. (See Bitu-
men.) This singular mineral has been hitherto only found |
in the Odin mine, near Caftleton in Derbyshire. Accord-
ging to the analysis of Klaproth, it contains in 100 grains,

| Carbonated hydrogen 38 |
| Carbonic acid - - 4 |

| Bituminous oil - - 73 |
| Acid water - - 1.50 |
| Carbon - - 6.23 |
| Lime - - 1.50 |
| Silex - - 75 |
| Sulphate of lime - - 50 |
| Alumine - - 25 |

MOLYBDENA, or Sulphuret of Molybdena; Molybdene Sul-
phur, Haüy; is of a bright lead-grey colour. It occurs |
massive, differentiated in plates, and crystallized. The form |
of the cryftals is a regular fix-sided table, or a very short six-

+ C 2
fied prism, terminated by two low, six-sided pyramids. The latter is metallic and shining. The structure is familiar, with a single cleavage parallel with the lateral planes of the table. It is feeble and somewhat flexible, but not elastic. Molybdenum is translucent to the touch, and leaves a mark on the paper like plumago, but on white porcelain it makes a greenish mark. Its specific gravity is from 3.5 to 4.7. Before the blow-pipe it gives out a fulgurite odour, and when urged by the ushotmail force, it yields a white vapour, and a pale blue flame; in carbonate of soda, it is soluble with violent effervescence. The characters here given, particularly its mark on china, serve to distinguish molybdena from graphite and plumago. (See MOLYBDENUM, and SULPHUR.) According to Bucholz, its constituent parts are,

Molybdenum - - 60
Sulphur - - 40

This mineral occurs in some parts of Scotland, and in granite at Coldbeck-fell in Cumberland. It is found also at Huel-Gorland, Cornwall.

MOLYBDENA Ochre is a yellow colour, passing into yellowish-green; it is friable and dull, and occurs incrusting molybdena, on which it is doubtless formed by the decomposition of the latter mineral.

MOONSTONE, a variety of adularia. See ADULARIA, and FELSPAR.

MORANO. Ore. See Bog Iron-Ore.

Mountain, or Rock Wood, or Lignum Affusus; Affusae ligniforme, Haüy; has a wood-brown colour, and a curved and fibrous structure resembling wood. It is soft, opaque, and feeble; it is slightly flexible; it feels meagre. According to Jamefon, it is insufiible; it is classified by him in the talc family.

MULLER GLASS. See HYALITE.

MURicate of Ammonia, Native, is a frequent product of volcanoes. See AMMONIA.

MURicate of Copper. See COPPER-Ores.

MURicate of Lead, or Cornue Lead-Ore. See LEAD-Ores.

MURicate of Soda. See ROCK-SALT and SALT.

Muscovy Glass, the large plates of mica, which are generally brought from Siberia. (See MICA.) These plates are erroneously called talc.

MUSITE, a variety of DIOPSIDE; which fee.

NAPHTHA, Bitume liquide blancatre, Haüy. See BITUMEN.

NATROLITE. See NATROLITE, and ZEOLITE.

NATRON, Soude carbonataé, Fr. Native carbonate of soda is deposited on the sides of lakes, or on the surface of the ground, and generally containing muriate and sulphate of soda. See SODA.

Radiated Natron, Soude carbonataé acuticulairae, Fr. occurs in Africa, and forms a considerable article of commerce. This variety is nearly pure carbonate of soda, containing, according to Klaproth,

Nepheline, or Sommee. (See SOMMITE.) This mineral occurs in the lava of Vefvius, and bears a near resemblance to MECONITE (which see). Nepheline is cryzzallized in six-sided prisms or tables, but the crystals of meconite are four-sided prisms. The latter mineral is easily fusible, but nepheline melts with difficulty. Nepheline has a four-fold cleavage, three of which are parallel with the lateral planes, and one to the terminal planes of the prism. Transparent pieces of nepheline become cloudy in nitric acid; hence it was named by Haüy from the Greek word πέραν, a cloud.

Nephrite, or Jade; Jade nephritique, Haüy. The colour is leek-green, paffing to greyish-green; it occurs mafive. The fracture is uneven and splinterly, with a glimmering and somewhat greasy luster; it is translucent. Nephrite yields to the knife, but fractures glass; it has a greasy feel, is very tough. The specific gravity is from 2.9 to 3. Before the blow-pipe, it melts into a white enamel. According to Kautner, its constituent parts are,

99.30

Nephrite occurs in granite veins in the Hartz in Saxony; the most beautiful varieties are from Peria and Egypt. In Turkey it is cut into handles for fabrics and daggers. It was formerly believed that this stone had the property of relieving nephritic complaints; hence it has been called nephritic stone. A flaty kind of nephrite is used by the inhabitants of New Zealand for hatchets, and hence it has been called axe-stone. Nephrite is nearly allied to serpentine and felsite; there is also a kind of nephrite which is more nearly allied to felspar, and is classified by Mr. Jamison with the felspar family; it is called faussurite, after the celebrated geologist Saussure, by whom it was first discovered. See SAUSSURITE, Addenda.

Nickel-Ores are, native nickel, copper nickel, and nickel ore.

Native Nickel has only been found hitherto in the Adolphus mine at Johanngeorgenstadt in Saxony, and at Joachimsthal in Bohemia. Its colour is bronze-yellow, but is frequently tarnished greenish-grey, or fleed or lead-grey, and occasionally invested with a crust of brown iron-flone. It occurs in capillary crystals, which are either promiscuously or scopiformly aggregated. Internally the luster is splendent and metallic, externally shining or splendent when untarnished.
unartificial. The cleft fracture is even passing into flat conchoideal; it is easily flangeable, and rather hard; it is more or less flexible and elastic. Before the blow-pipe, on charcoal it melts into a metallic globule, without any smell of arsenic or sulphur, which serves to distinguish it from capillary pyrites. Native nickel contains the metal nickel with a minute portion of cobalt. See Nickel.

Copper Nickel, Nickel arsenical, Haïy, has a copper or crimson colour, of different degrees of intensity, and often tarnished grey or black. It occurs massive and disintegrated, and sometimes reticulated, botryoidal, or dendritical, and very rarely crystallized in six-sided tables; it has shining metallic lustre. The fracture is imperfectly conchoideal, passing into granular and uneven. It is usually compact, but sometimes occurs in granular distinct concretions. It yields with difficulty to the knife, and is difficultly flangeable. Its specific gravity is from 6.5 to 7.5. Before the blow-pipe it gives out an arsenical vapour, and then fumes with difficulty into a dark secon, mixed with metallic grains; it is soluble in nitric acid, forming a dark green liquor, from which calcium alkali throws down a pale green precipitate, which distinguishes it from copper; the precipitate of the latter is a dark brown. This ore is a compound of nickel and arsenic; it occurs in small quantities in the lead-mines of Lead-hills and Wanlockhead, in Scotland, and in various parts of the continent of Europe, generally in veins in primitive mountains; it nearly resembles native copper, but may be distinguished by its brittleness.

Black Nickel-Ore has a greyish or brownish-black colour; it occurs massive, disintegrated, and in clints; it is dull, has an earthy fracture, but becomes resinous and shining in the fissure; it, as a grey, in nitric acid it forms an apple-green solution, which lets fall a precipitate of white arsenic. It is rather a rare mineral, and is found in veins with other ores of nickel, and is supposed to be formed by the decomposition of copper nickel.

Nickel Ochre, Nickel oxide, Haïy, has an apple-green colour, but on exposure to the air becomes greenish-white; it is generally found as a thin coat or crust, and seldom massive or disintegrated; it is in loose powder or friable, meagre to the touch, and light. It is infusible before the blow-pipe, but with borax it forms a red colour; in cold nitric acid it remains infusible. This ore occurs at Lead-hills and Wanlockhead, in Scotland, and in Saxony and France.

Nigrite. See Titanium.

Nitre, Nitrate, Potasse nitratté, Fr. occurs in flakes, clints, and capillary crystals on the surface of the ground. In many countries, it appears to form at certain feasons of the year. It abounds in many of the plains of Spain, Hungary, the Ukraine and Podalia, and on the walls and floors of chalk caves in France. It is very abundant in India, Egypt, and in some parts of North and South America. See Potash, Nitrates of.

Obsidian, or Volcanic Glass; Lava vitrée obsidienne, Haïy. (See Obsidianus LAPIS.) This mineral bears so close a resemblance to dark-green bottle-glass as scarcely to be distinguished from it. Its most common colours are dark-grey or greenish, or brownish-black; it has a vitreous and shining or splendent lustre; the fracture is large and perfectly conchoideal. It passes from transparent to nearly opaque, according to the intensity of the colour; it scratches glass, but is easily flangeable. The specific gravity varies from 2.34 to 2.38. The black obsidian of Iceland is said to melt into a pale agh-grey vetricular glass on charcoal; that of Spanish America too its black colour when exposed to heat, became white, pnsy, and fibrous, and increased to seven or eight times its original bulk; hence it appears that some gaseous substance escapes. Humboldt conjectures, that the gas evolved during the volcanic fusion of obsidian in the interior of the earth, may give rise to the earthquakes that agitate the Cordilleras. According to Abligard, the constituent parts of obsidian are given as under:

<table>
<thead>
<tr>
<th>Mineral</th>
<th>Silica</th>
<th>Alumina</th>
<th>Oxyd of iron</th>
<th>Lofs, supposed to be potash or soda</th>

<td>2.0</td>
<td>10.0</td>
</tr>
</tbody>
</table>

Some analyses give 1.6 lime, and only 5 of potash and soda.

Obsidian is found in a great many volcanic countries, and also in various parts of the world, where no volcanic fires have existed since the history of man. For a long period it was contended by Werner and his followers, that this mineral was of aqueous origin, but the appearance of obsidian, and the situations in which it occurs, offer decisive proofs of its formation by fire. The Mount of de Calagna, in Lipari, according to Spallanzani, is wholly composed of it, which appears to have flowed in succeffive currents, like streams of water falling with a rapid descent and suddenly frozen. The obsidian is sometimes compact and sometimes porous and psony. On the south side of the Peak of Tenerife, there is a stream of obsidian several miles in length. In the island of Felicida, a current of lava intermixed with obsidian may be traced to the very crater of a volcano. Obsidian appears to be lava toodnently cooled, as it is well known, since the experiments of Mr. Keir, Mr. Watt, and Sir James Hall, that lava or baltol cooled suddenly forms black glass; and we have a specimen of lava from Vesuvius, which flowed in the year 1718, one part of which is compact black lava, the other is a vitreous substance passing from pitch-lobe to obsidian. See Volcanic Products.

Octahedrite, Anatase. See Titanium.

Olivine. (See Olivine.) This mineral forms a constituent part of many lavas, and is of frequent occurrence in basaltic rocks. When crystallized, it is in broad rectangular four-sided prisms, which are imbedded, and so easily broken, that it is difficult to ascertain their form; the structure of the crystals is imperfectly lamellar, in a direction parallel with the planes of the prism. Werner considers olivine as a distinct species from chrysolite (see Chrysolite), with which it is classed by many mineralogists. The colour, lustre, and fracture of olivine and chrysolite, are not precisely the same; olivine is also softer and more flangeable than chrysolite. Chrysolite is more transparent, and has a greater specific gravity, being from 3.4 to 3.34; that of olivine is 3.22 to 3.26. Olivine is often much intermixed with augite; it has generally a paler colour and greater transparency than the latter mineral. Olivine is subject to decomposition, and when this commences it exhibits on the surface iridescent colours, but afterwards falls into an earth resembling iron ochre.

Olivine.
MINERALOGY.

Oliven-Ore, or Olive Copper-Ore, arseniate of copper. See Copper-Ores.

Onyx, a variety of chalcedony with white and grey stripes. See Chalcedony.

Opal. Quartz resinite opalin, Huhny. (See Gem.) This mineral is divided into seven sub-species by Mr. Jameson.

Precious Opal has frequently a milk-white colour inclining to blue, and displays brilliant and changeable reflections of green, blue, yellow, and red. It is translucent or semi-transparent, and when placed between the eye and the light exhibits a beautiful yellow or blue colour. It occurs in veins in clay-porphyry, either massive, disseminated, or in plates: it has a shining or splendent vitreous luflre, a perfect conchoideal fracture, feratches glassy, and is easily friable. Some varieties adhere to the tongue. Precious opal becomes white and opaque when brought through the blow-pipe, but is infusible. The specific gravity is 2.110. According to Klaproth, the constituent parts are,

<table>
<thead>
<tr>
<th>Silex</th>
<th>Water</th>

<td>5</td>
<td>1.25</td>
</tr>
</tbody>
</table>

Hence it appears, that the precious opal is properly a hydrate of pure siliceous earth. This mineral, on account of its beauty, is employed in jewellery, and is held in great estimation. Jewels of opal must be kept with care, as they are easily scratched, and are apt to crack on sudden changes of temperature. Precious opal is found more abundantly at Caferher Wenitz, near Kaffehau, in Upper Hungary, than in any other known situation. It occurs there in clay-porphyry, and mines of it have been worked for a long period; towards the end of the fourteenth century, about 300 men were employed in these mines. Precious opal is sometimes sparingly found in the basaltic rocks, in the north of Ireland, and in the Faroe islands. The finer varieties of opal are named oriental opal. Taverner, however, informs us, that no precious opal is found in the east, and those which are sold as oriental are brought from Hungary. Those varieties of opal that adhere to the tongue are less translucent than the others, and more dull; but when immersed in water, they become nearly transparent, and acquire a beautiful play of colours. These opals have received various names, as the oculus mundi, hydrophone or changeable opal. They are much prized by collectors. To preserve their beauty, the water in which they are immersed should be perfectly pure, and they should be taken out as soon as they have acquired their full transparency. If these precautions are neglected, the pores become filled with earthy particles deposited from the water, and the hydrophone will remain more or less opaque.

Common Opal differs from precious opal, principally by its inferior luster and transparency, and the greater variety of its colours, which are either milk-white, grey, yellowish-white, yellow, red, or green. The same specimens never shews more than one colour by reflected light, but the milk-white variety, when held opposite the light, transmits a wine-yellow colour. Common opal occurs massive, disseminated, and in sharp angular pieces. Internally the luster is shining, splendent, and vitreous; the fracture is conchoideal; it scratches glass, and is easily friable. Before the blow-pipe it is infusible. The specific gravity is 2.01 to 2.14. According to Klaproth, its constituent parts are,

<table>
<thead>
<tr>

<td>7.5</td>
</tr>
</tbody>
</table>

Semi-opal.—Its colours are generally darker and more muddy than those of common opal; sometimes several colours occur together. Semi-opal is massive, disseminated, resplendent, and botryoidal; it has a glitrering luster, is more or less translucent, and is hard and easily friable. The fracture is large and flat, is conchoideal; it adheres to the tongue. The specific gravity is from 2.0 to 2.18; it is infusible. According to Klaproth, the constituent parts are,

<table>

Mother-of-Pearl Opal, or Casbolong, is a milk-white variety of opal, not unlike mother-of-pearl.

Semi-opal.—Its colours are generally darker and more muddy than those of common opal; sometimes several colours occur together. Semi-opal is massive, disseminated, resplendent, and botryoidal; it has a glitrering luster, is more or less translucent, and is hard and easily friable. The fracture is large and flat, is conchoideal; it adheres to the tongue. The specific gravity is from 2.0 to 2.18; it is infusible. According to Klaproth, the constituent parts are,

Common opal occurs in veins of porphyry and serpentine, and with chalcedony in basaltic amygdaloid; it is found in some metallic veins in Cornwall. Green common opal is sometimes cut into ring-stones. The yellow variety is also used for jewellery; it has been called wax opal and pitch opal.

Fire Opal, so called on account of its brilliant red colours and transparency, is properly a variety of precious opal; it has hitherto been found only in Zimapan in Mexico. According to Klaproth, its constituent parts are,

<table>

Wood Opal, Quartz resinite xyloide, Fr. is petrified wood, penetrated with opal, and is intermediate between common opal and semi-opal. It has a ligneous structure, and is distinguished from wood-stone by its lighter colours, higher luster, perfect conchoideal fracture, greater transparency, and inferior hardness. Wood-opal is cut into plates, and used for snuff-boxes and ornaments.

Jasper Opal is of various shades of reddish-yellow or reddish-brown; it is sometimes veined and spotted; it has a shining luster, between vitreous and resplendent, and is opaque or feebly translucent at the edges. It is hard, and easily friable; it occurs massive in large and small pieces, in porphyry and in veins. The specific gravity is from 2.86 to 2.07; it is infusible. According to Klaproth, its constituent parts are,
MINERALOGY.

It appears to be common or semi-opal rendered opaque by the great intermixture of oxyd of iron. Oriental Amethyst, Sapphire, Ruby, Topaz, and Emerald, names given by jewellers to varieties of the fapphire. The blue sapphire is the true or oriental sapphire; the violet-blue is the oriental amethyst; the red sapphire, the oriental ruby; the yellow sapphire, the oriental topaz; and the green sapphire, the oriental emerald. See SAPPHIRE, &c.

OrePIMENT, Red, or Realgar, Sulphuret of Arsenic; Arsenic sulphure rouge, Fr. (See ARSenic.) According to Klaproth, the composition of this ore is,

<p>| | | | |</p>

Osmium occurs as a native alloy of the metal so called with iridium; it is found in grains along with platina in alluvial foil in South America. The greens have a pale steel-grey colour, a metallic lustre, and lamellar structure; it is harder than platina, and brittle. The specific gravity is 19.5. By fusion with nitre, it acquires a dark-black colour, but regains its lustre and colour by heating with charcoal.

Palladium is a native alloy of the metal palladium, with a minute portion of platina and iridium; it occurs in grains along with grains of platina in the alluvial gold districts in Brazil. Its colour is pale steel-grey, falling into silver-white; the fracture of the grains is divergingly fibrous, the lustre metallic. The specific gravity is 12.148. It is fusible; but on the addition of sulphur, it melts with ease by continuance of the heat, the sulphur is disseminated, and a globule of metallic palladium remains. With nitric acid, it forms a deep-red solution.

Paranthine. See SCAPOLITE.

Pearl-Spar. (See BROWN SPAR, Addenda.) The name pearl-spar has been given to those varieties of this mineral which in colour and lustre have a strong resemblance to pearl, but it often occurs brown, black, and of various colours.

Pearl-Stone, Lave vitreuse perlée, Hauy. (See Pearl-Stone.) This mineral is regarded by many mineralogists as a volcanic production; it is frequently intermixed with obdidian, and hence is classed by them as a variety of the latter mineral. It occurs in basaltic and porphyritic rocks, in large and somewhat angular concretions, which are composed of smaller roundish concretions, and those of others still smaller. The surface of the concretions is smooth, shining, and pearly. The colour is grey, passing into pearl-grey and greyish-black. It is translucent on the edges; it scarcely scratches glass, is easily frangible, and is fusible with intumescence before the blow-pipe into a white spongy glassy film. This mineral has been found near Sandy Brae, in Ireland, in the island of Iceland, and in Mexico; it was first discovered in Hungary, where it occurs in large beds. It is classed by Mr. Jameson and Werner with obdidian, pitch-flone, and pumice, as forming a member of the pitch-flone family.

Pea-Stone, Pifolite, Fr. This mineral is composed of carbonate of lime, slightly coloured yellowish-white or brown by the oxyd of iron; it is properly a calcareous tuft, containing round globules, varying in size, from a pea to a hazel-nut; these conch of concentric lamellae, and often contain in the centre a minute fragment of quartz, felspar, or granite, and sometimes, but rarely, a double six-sided pyramid of rock-crystal; but in some infusions, the centre of the globule is hollow. Pea-flone occurs in great masses in the vicinity of the hot springs at Caribbad, in Bohemia; its formation we conceive to be analogous to that of roe-flone, and to be the result of crystallization; the particles included having disposed the calcareous matter to crystallize round them, in the same manner as a thread or fragment of a stone in a saline solution, generally disposes the crystals to shoot round them.

Peridite Chrysolite. See CRYSTOLITE and OLIVINE.

Petalite, a mineral recently discovered in Sweden; externally, it nearly resembles some varieties of quartz, but the cleavage is two-fold, parallel to the sides of a rhomboidal prism; two of the planes are fplendent, and two dull. The planes meet at angles of 100° and 85°, forming a four-sided prism with a rhomboidal base. Its colour is white with a slight tint of pink; it scratches glass, but yields with difficulty to the knife. When exposed to the flame of a blow-pipe it remains for some time insubflible, but by continued heat it exhibits a glazed surface, which, on examination with a lens, appears full of minute bubbles. When triturated, the powder has the whiteness of snow. It is partially soluble in highly concentrated nitric acid, losing its colour, and changing to a dingy hue; the acid at the same time becomes clouded. The prufilated alkali throw down a green precipitate, and the solution assumed an amethystine colour, which afterwards changed to brown. The constituent parts of this mineral are stated to be,

<p>| | | | |</p>

100.09

This alkali proves to be the oxyd of a new metal. The new alkali has been called lithia and lithion; it has a greater capacity of saturating acids than any other alkali, and forms a class of faults that are remarkably delicate. With alcohol, lithion yields a rofe-coloured flame, like that communicated by florelastic. The metal of lithion bears a strong resemblance to fiodium. The alkali found in petalite contains 44.84 oxygen, united to a metallic base.

Petroleum, Liquid Bitumen, or Mineral Oil. (See BITUMEN.)
MINERALOGY.

Bitumen.) It is essentially composed of carbon and hydrogen, containing less carbon than the fold bitumens, or than any kind of mineral coal. In Piedmont, Peria, Japan, and other countries, it is used in lamps, in place of oil, for lighting streets and public buildings; it is also mixed with earth, and burned for warming rooms. In Asia, numerous mines are worked for mineral oil or petroleum, the shafts are sunk through coal strata to the coal from whence the oil issues; it is intermixed with water, and is separated by decantation.

Pharmacolite, Arseniate of Lime, Chaux arsénicate, Haüy. Its colours are snow-white and milk-white, sometimes inclining to reddish or yellowish-white. It occurs in small reniform botryoidal and globular masses; sometimes it infects other minerals, or is crystallized in small diverging capillary crystals. It occurs in small reniform botryoidal and globular masses; sometimes it infects other minerals, or is crystallized in small diverging capillary crystals. Externally, it has a silky glimmering lustre; internally, it is shining or glinting. The structure is delicately radiated, either straight, diverging, or spheruliform, and sometimes fibrous. It yields to the nail, and is easily frangible. The specific gravity is 2.5. According to Klaproth, the constituent parts are,

There is an earthy variety of pharmacolite, which occurs in thin crusts, and is dull and opaque. Pharmacolite is found in veins in granite, with ores of cobalt and native arsenic.

Phosphate of Copper, Cuivre phosphaté, Haüy. Under the ores of copper, one species of this mineral is described, which was the only one then known. Mr. Jamefon makes three sub-species of phosphate of copper: foliated phosphate of copper, fibrous phosphate of copper, and compact phosphate of copper.

Foliated Phosphate of Copper, Cuivre phosphaté rhomboïdal, Haüy, has a greyish-black colour externally, but internally is emerald-green, verdigris-green, and leek and olive-green. It occurs crystallized in octahedrons, which are sometimes lengthened or cubic form; also in rhombohinds with small curvilinear faces; the edges and angles are sometimes truncated. The structure is lamellar, the lustre shining, between vitreous and pearly; it is translucent. This ore is insoluble in water, but dissolves without effervescence in nitric acid. Before the blow-pipe, it fuses into a brownish globule, which spreads on the surface of the charcoal by a continuance of the heat, and acquires a reddish-grey metallic lustre. The globule on cooling crystallizes into three-sided and six-sided faces. According to Bucholz, it is a compound of copper and phosphoric acid. It has been found in the neighbourhood of Neufchat, in Hungary, and at Wirneberg, near Rheinbreitenbach, on the Rhine; at the latter place it occurs with fibrous phosphate of copper; the latter mineral is found massive, botryoidal, and in crusts; it has a divergingly fibrous or radiated structure.

Compact Phosphate of Copper, Cuivre phosphaté compacta, Haüy, has the same localities as the foliated sub-species; it occurs massive, reniform, botryoidal, and incrusting; it has a flat conchoidal fracture, a fibrous structure may sometimes be observed. It contains near 3.5 parts of phosphoric acid united with 68 of copper.

Phosphate of Manganese. See Manganese-Ore.

Phosphorite, Common, and Phosphorite, Earthy. These minerals have been called by mineralogists as varieties of apatite; but Mr. Jamefon makes phosphorite a distinct species, which he divides into two sub-species.

Common Phosphorite, Maffive Apatite, Atkin; Chaux phosphaté terreuse, Haüy; has generally a yellowish, greenish, or reddish-white colour; it occurs massive, fibrous, reniform, and incrusting, also crystallized in six-sided tables; it is opaque, soft, and easily frangible. The specific gravity is 2.81. When rubbed in an iron mortar, or laid on hot coals, it emits a greenish light. According to Pelletier, its constituent parts are,

In part of Etruramuris in Spain near Lagrofain, it forms whole beds that alternate with lime-stone and quartz.

Earthy Phosphorite consists of dull earthy particles, loosely cohering, and appears to be the preceding mineral in a decomposing state, intermixed with earthy matter. We think the characters and constituent parts of these minerals entitle them to be classed merely as varieties of apatite. The multiplication of species, where no sufficient specific difference exists, tends to retard the progress of useful knowledge, and ought not to be unnecessarily introduced.

Phosphormangan. Phosphate of manganese. See Manganese.

Pharmacolite, a mineral described by Hanffmann. It is principally composed of the carbonate of magnesium. According to the description of Mr. Jamefon, (Mineralogy, vol. ii. p. 537.) its colours are leek-green, mountain-green, or straw-yellow. It occurs massive; internally it is dull or glimmering and pearly. The fracture is long, splintery, which falls by gradation to flat conchoidal. In some instances, it shows a delicate concentric fibrous structure. It sometimes occurs in concretions which are either concealed or have undulating lamellae. It is translucent on the edges, and is rather hard, and difficultly frangible. It feels meagre, and is infusible. The specific gravity is 2.53. It appears to be allied to serpentine and talc.

Pitchite. This mineral is nearly allied to mica. It occurs crystallized in regular six-sided prisms, which, according to Haüy, is the primitive form. The prisms are sometimes truncated on the edges and angles. Massive varieties of pinite also occur in thick and straight lamellar concretions. (See Pitchite.) This mineral is found in the granite veins at St. Michael's Mount, Cornwall, and in some parts of Scotland in porphyry.

Pistacite, or Epidote. See Pistacite, and Epidote, Addenda.

Pitch-coal, or Jet, See Jet.
**MINERALOGY.**

**Pitch-ore, or Pitch-blende,** an ore of Uranium. See Uranium, and Pitch-ore.

**Pitch-stone, Refinite, and Petroflex reffinite, Fr.** This mineral is named from the striking resemblance which some varieties have in colour and lustre to pitch. Its prevailing colours are dark-green, from which it passes into black, grey, and blue, to brown and red. It is feebly translucent, and has a glintening or shining vitreo-refinosus lustre. It occurs massive in veins and beds of considerable magnitude. Pitch-stone is sometimes columnar, and sometimes in thick and wedge-shaped concretions, or in somewhat globular or curved lamellar distinct concretions, and sometimes it has a flaty structure. The fracture is more or less perfectly conchoidal, or passing into splintery. The fragments are angular and sharp-edged. It scratches glasses, is rather easily fragile, and is fusible into a grey fpongy enamel. Some varieties of this mineral, however, fuse with great difficulty by the blow-pipe. The specific gravity of pitch-stone is about 2.3. According to Klaproth, its constituent parts are,

Pitch-stone is found in various parts of Scotland, and in the islands of Rum, Egg, and Arran. It bears a near resemblance to obsidian, or volcanic glasses, into which it appears to pass, and also into pearl-stone. It is regarded by many geologists as a volcanic product. Like basalt, it intersects rocks of different formations, from granite to sand-stone, and is intimately associated with basaltic rocks.

**Plasma** has generally a dullish-green colour, with yellowish or whitish dots, a glintening lustre, a conchoidal fracture, is translucent, and rather harder than quartz. It consists of about ninety-seven parts of fleshy, and appears to be properly a green variety of frit. It was confused by the Romans as a gem, and figures were engraved upon it. Most of the specimens in collections were found in the ruins of Rome.

**Platina.** See Platina.

**Plenaste.** See Ceylanite, Addenda.

**Plumbago.** Graphite or black-lead. See Plumbago, and Graphite.

**Porcelain-clay.** (See Porcelain.) The porcelain-clay of Cornwall occurs in beds of considerable thicknees in the parish of St. Stephen's. According to Wedgwood, it consists of sixty parts alumine, and forty of fleshy. Porcelain-clay originates from the decomposition of granitic rocks, abounding in felspar, and frequently contains portions of quartz and mica. The absence of iron in porcelain-clay is what constitutes one of its most essentiel properties,—that of remaining white after burning. The Kaolin or Chinese porcelain-clay contains a much larger portion of fleshy than of alumine.

**Porcellanite, or Porcelain Jasper, (see Jasper,)** appears to be formed accidentally by fires in coal-mines, which have indurated and semivitrified beds of coal-flake or slate-clay.

**Pot-stone, Lapis aullaris; Tale olivare, Haizy.** (See Vol. XXXIX.) Pot-stone, a spar of calcite, is a material of great importance. It occurs in an aggregate of innumerable thin plates, which are conchoidal in fracture, and sometimes grow together in the form of a shell. The fracture is perfect. It is white, compact, and very durable.

**Pot-stone.** This mineral appears to be indurated, passing into serpentine; with the latter rock, it is frequently associated. It has a curved and undulating-lamellar structure, passing into flaty. It is very soft, brittle, and greyly to the touch, is translucent on the edges, and affords a white-coloured streak. It is infusible before the blow-pipe. The analysis of this mineral given by Tromsdorf is,

Near Inverary there is a quarry of talcous slate, some of which appears to pass into pot-stone, and can be turned in the lathe; of this stone, Inverary Castle is built. Pot-stone was extensively used in Upper Egypt for culinary vessels. They were found to resist the action of fire, and did not communicate any taint to the food boiled in them. Quarries of pot-stone were worked on the banks of the Lake of Como from the beginning of the Christian era to the year 1618, when the mountain fell down on the 25th of August, and destroyed the neighbouring town of Piers. This town had annually raised stone from these quarries to the value of 60,000 ducats. Pot-stone is also used for lining ovens and furnaces, and is remarkably durable.

**Prase, Quarz hyalin vert obscure, Haizy, is transparent green quartz, the green colour being derived from an intimate mixture of quartz and actinolite. See Quartz, and Prasius.**

**Precious Garnet.** See Garnet.

**Prehnite.** (See Prehnite.) This mineral is divided into two sub-species by Mr. Jameson; foliated prehnite and fibrous prehnite. The prevailing colours are green, greenish-white, and yellowish-white. It occurs both massive and crysallized in oblique four-sided tables, or in six or eight-sided tables; also in four-sided and six-sided prisms. The crystals are generally attached by their lateral plains, and form diverging groups. The cleavage is fingle, parallel to the short diagonal of a rhomboidal prism, the planes of which are inclined at angles of 103° and 77°. The lustre is shining and pearly; it is translucent or transparent, scratches glasses with difficulty, and intumesces before the blow-pipe. Prehnite was discovered by Mr. Bakewell in a rock basaltic amygdaloid, near Berkley in Gloucestershire, accompanied with green earth and massive lamellar prehnite, or kenholite. This is the only English locality of these minerals at present known. It was first brought from the Cape of Good Hope.

**Fibrous Prehnite** has a delicate fibrous structure, either straight, diverging, or stellar. According to Langier, its constituent parts are,

Both sub-species of prehnite bear a near resemblance to zeolites, but they do not gelatinize with acids, and they become electric by heating.

**Pumice.** See Pumice-stone, and Volcanic Products.

**Pye-nite Schorlitt, or Schorlaceous Beryl.** (See D Pyrolite.)
PYCNITE. The crystals of this mineral are long hexagonal prisms, and are deeply streaked longitudinally. They have a cleavage at right angles to the axis of the prism. Pycnite is now considered by Hauy as a variety of the topaz.

PYRITES. See Pyrites.

PYROPE. This mineral is now regarded by Hauy as a variety of the precious garnet, with an accidental portion of magnesia derived from the rock in which it is imbedded.

PYROTHERITE. See Pyrophylite.

PYROMALITE. Native muriate of iron. See Iron.

Pyroxene, Augit. See Pyroxene and Augit, Addenda.

Quartz, Ores byldin, Fr. See Quartz.

Common Quartz, Rock Crystal, Amethyst, and Cairngorm Stone, or Clove-brown Quartz, Aventurine Quartz, and Rose or Milk Quartz, are essentially the same mineral substance or pure flux, varying only in transparency or colour, owing probably to a slight admixture of the other earths or metallic oxyds, an admixture which may be regarded as accidental, and which is scarcely appreciable by chemical analysis. According to Bucholz, rock-crystal is composed of 99.5% of flux. It is probable, however, that many minerals, which have hitherto been classed with quartz from bearing in many characters a close resemblance to it, may contain other ingredients besides flux in such proportions as to constitute them distinct species. This opinion is rendered more probable from the recent discovery of a mineral in Sweden, called petalite, which might easily be mistaken for a variety of quartz, but which contains a considerable portion of alumine, and two parts in the hundred of an alkali heretofore unknown. See Petalite, Addenda, and Rock-Crystal.

Quicksilver. See Mercury, Ores of.

Realgar. See Arsenic-Ores, and Realgar.

Red Antimony Ore. (See Antimony-Ores, and Red Antimony.) A variety of red antimony-ore, called tinderry, is described by Mr. Jamefon as occurring in delicate flexible leaves, which are opaque and friable, foil strongly, and swim on water. Tinderry contains a portion of silver.

Red Cobalt-Ore. (See Cobalt-Ores.) This species of ore is divided by Mr. Jamefon into three sub-species, earthy red cobalt-ore or cobalt ochre, flag red cobalt ochre, and radiated red cobalt-ore or cobalt bloom; Cobalt arseniaté acquisium, Hauy. The analysis of this ore by Bucholz gives:

<table>
<thead>
<tr>
<th>Cobalt</th>

This ore has been found at Alva, in Stirlingshire, and at Tyndrum; also in lime-flone in Linlithgowshire, and at the Dolcoath mine in Cornwall. Slaggy red cobalt ochre has a muddy crimson-red colour, or dark hyacinth-red, which passes into chieftain-brown. It occurs in thin crusts, and sometimes reniform. It has a shining and refractive lustre, a conchoidal fracture, and is translucent, soft, and brittle.

Red Lead-ore, or Chromate of Lead. See Lead-Ores.

Red Magnesite-ore. See Manganese.

Red Silver-ore, or Ruby Silver, where read—before the blow-pipe on charcoal.

Reddy, Red Chalk, or Red Ochre. See Reddy.

Retinasphaltum. See Retinasphaltum.

Reussite, the name given to a salt which occurs in the country round Seltitz, and at Plun near Brux. It forms a mealy efflorescence, and is also crystallized in flat six-sided prisms and in acicular crystals. According to Reufs, it consists of:

<table>

Rhom Spar. See Brown Spar, Addenda.

Rock Butter. (See Rock Butter.) This mineral appears to be a sub-sulphate of alumine. It oozes from numerous rocks.

Rock Cork; Aberg Treps, Hauy. See Rock Cork.

Rock-crystal. (See Quartz.) This is the purest variety of quartz. Very large and brilliant rock-cryxals occur in various parts of Scotland. The smoke-grey or clove-brown crystals are called cairngorm, from a place in the upper part of Aberdeenshire, where they occur in alluvial soil along with beryl and topaz. The largest rock-crystals hitherto found come from the island of Madagascar. Faujas St. Fond mentions a crystal imported from thence into France, which weighed upwards of one hundred and fifty pounds. Very brilliant groups of rock-cryystal occur in Dauphiny. Vases of rock-crystal were highly prized by the ancients. A vase, broke by the emperor Nero in a fit of despair, was estimated at 15,000 livres. Different colours may be communicated to rock-crystals artificially, by heating them and plunging them into different-coloured solutions.

Rock-salt. (See Rock-salt.) According to the analysis of Dr. Henry, the rock-salt of Cheshire contains, in 1000 parts,

<table>

1000

Rock-wood, or Ligniform Aberg. See Asbestos.

Roe-stone, or Oolite; Chaux carbonatée globiforme, Hauy. See Roe-stone.

Rose Quartz, or Milk Quartz. See Quartz.

Rubellite, called Red Schorl, a variety of tourmaline. See Rubellite and Tourmaline.

Ruby, Oriental, or Red Sapphire. See Gems, and Saphire.

Ruby Spinelle. (See Gems and Ruby.) The spinel ruby is the common ruby of the jewellers. It differs from the oriental ruby in the form of its crystalization, and contains a portion of magnesia and chromic acid. The former is nearly unmixed alumine. When these two gems are cut, it is, however, difficult to distinguish them. The oriental ruby is harder than spinel. Though the prevailing colour of the common ruby or spinel is red, yet it is sometimes blue-green or yellowish-brown. The carmine-red is called the spinel ruby; the cochineal ruby is called the balais ruby, from Balachan, the Indian name of Pegu, where it is found. The specific gravity varies from 3.50 to 3.70; that of oriental ruby from 3.97 to 4.28. The latter is a true sapphire.

Rutile,
**MINERALOGY.**

Rutile, or Sphene; Titane oxijé, Haiiy. (See Rutile.) This mineral, which appears to be an analysis of a pure oxyd of titanium, (see Titanium,) is of a dark blood-red colour, or light-red and brownish-red. It occurs massive, difteminated, membranous, and in cryftals. The cryftals are rectangular four-fided prisms, oblique four-fided prisms, and also six and eight-fided prisms. The cryftals are small and often capillary. It occurs imbedded in druffy cavities, in granite, baffe, gneifs, mica-flate, chlore-flate and hornblende-flate, and in lime-flone. It has been found in the granite of Cairngorm, the lime-flone of Rannoch, and at Craig Caileach, near Killin, imbedded in quartz, also near Bedgallfe, in Caernarvonne.

Rutile, Titane fliéco calcaine, or Sphene. See Rutile and Sphene.

Sailhite. (See Sailhite.) Pyroxene laminaire gris verdâtre, Haiiy. According to Bournon, the primitive form of fahlite is a rectangular four-fided prism, having rectangular bases, which are inclined on the two opposite sides of the prism, so as to form angles of 109°15', and 73°45': hence he considers it as a distinct fpecies from augit. According to Jamefon, the cleavages of fahlite are five-fold, one parallel with the terminal planes, two with the lateral planes, and two with the diagonals of the prism; the three fides are made with great facility. The crofs fracture of fahlite is uneven and dull; that of augit, though uneven, generally inclines to conchoideal, and has a con siderable degree of lufpre.

Sal Ammoniac, Naive; Ammoniaque muriaté, Haiiy. (See Sal Ammoniac.) This salt is divided into two sub-fpecies by Werner, volca nic fah ammoniaci and conchoideal fah ammoniaci. The former occurs in fiffures, or coating volcanic rocks, and also in the vicinity of burning beds of coal. The latter occurs with sulphur, in indurated clay, or clay-flate, in Buc haria. According to Klaproth, it contains 25°50 of sulphate of ammonia, with 97°50 of the muriate.

Sappace, Kyanite; Dijthene, Haiiy. See Sappace, and Kyanite, Addenda.

Sapphire, Telef, and Corindon hyalin, Haiiy. The common forms of the cryftals of fapphire are the perfect fix-fided pyramid and fix-fided prism, or the double fix-fided pyramid. These forms are frequently variously modified by truncations on the angles and extremities. (See Gems, Sapphire, and Ruby, Addenda.) The red fapphire is the oriental ruby; it differs from the blue fapphire in its con tinuit parts, which, according to Che nevix, are,

| Silex  | -       | -       | 44 |
| Alumine | -       | -       | 30 |
| Lime   | -       | -       | 4  |

| Iron   | -       | -       | 6.50 |

Before the blow-pipe, faiourite melts on the edges and angles; but according to Mr. Jamefon it is not entirely fublie.

Scapolite, Paranthine, Haiiy. (See Scapolite.) This mineral has been divided by Mr. Jamefon into three sub-fpecies; radiated scapolite, foliated scapolite, and compact scapolite. Foliated scapolite has a three-fold and rather oblique-angular cleavage; the crofs fracture is small and fine-grained, uneven or small conchoideal. This mineral, besides occurring with the other sub-fpecies in Scandinavia, is found along with cholor in granitic maffes that are imbedded in compact felfpar, or white-flone, on the north-western ac tivity of the Saxong Erzgebirge. Compact green scapolite is the wenerite of Haiiy. It occurs both massive and cry stallized in rectangular four-fided prisms, acuminate by four planes set on the lateral edges. Compact red scapolite occurs along with the green sub-fpecies, but is of a blood-red colour. All the varieties of scapolite decay very readily on expooure to the air.

Schorl, Tourmaline noir, Haiiy. (See Schorl.) The con tinuit parts of schorl, as itated by Klaproth, vary considerably
MINERALOGY.

considerably from the analysis of Gerhard, which we have given, and are,

The crystals of school are longitudinally streaked, and have externally a shining luster. It occurs in the granite rocks of Cornwall, and intermixed with quartz, when it forms a compound rock, known to Cornish miners by the name of coke. Very magnificent crystals of school have recently been discovered near Bovey Heathfield, in Devonshire. See Tournaline.

SCHILLER-Spar, Diallage metalloidó, Häiyy, occurs most frequently in laminae disseminated in serpentine, and is regarded by some mineralogists as crystallized serpentine. The colours are, olive-green, pinchbeck-brown, and yellowish-brown. The luster of the principal fracture is splendent and pseudo-metallic; the cross fracture is dull and glimmering. The cleavage is distinct in the direction of the laminae. According to Bournon, the primitive form is a rectangular four-sided prism, in which the bases are set on the broadest lateral planes, forming with them angles of 85° and 95°. The prism is divisible both in the direction of the lateral and terminal planes, but most easily parallel with the latter. Schiller-spar is translucent in thin lamina; it yields a greenish-grey streak, is fectile, and softer than hornblende.

SCHORLACEOUS Beryl. See Pycnite.
Selenite, or Crystallized Gypsum. See Gypsum.
Serpentine, Noble and Common. See Serpentine.
Shale, Coal-Clay and Bituminous Shale, a name given to the argillaceous strata which accompany coal. These consist of clay more or less indurated and fatty, and intermixed with a portion of carbonaceous or bituminous matter.
Siderite, a name given by some mineralogists to Rubellite; which fee.

SILVER-ORES. (See Silver.) A species of native silver occurs in Norway, which contains 28 parts in the 100 of gold, and is called aquiferous native silver. On account of the gold, its specific gravity is greater than native silver. Its other characters, except the colour, (which inclines to brays-yellow,) agree with native silver; which fee, under Silver-Ores.

An ore of silver containing bismuth has been found in one mine on the Schapbach, in the Black Forest. It is called bismuthic silver. It is a pale lead-grey, is soft, fectile, and easily frangible. Before the blow-pipe metallic globules ooze out, which, on the addition of borax, unite in one metallic button, which is brittle, and of a tin-white colour. It contains 27 parts of lead, 35 of bismuth, and 15 of sulphur, combined with a portion of iron and sulphur, and one part copper.

Cornous Silver-Ore, or Horn Silver, is divided by Mr. Jameson, in the last edition of his Mineralogy, into four sub-species; concoidal, radiated, common, and earthy cornous silver-ores.

Concoidal cornous Silver-Ore.—Its colours are greenish or greenish-white. It occurs massive in compact line-fone, at Guantahoygo in Peru; it has an adamantine luster, and is the purest kind of cornous silver known, containing

The radiated cornous Silver-Ore has a dark-green colour, and, like the preceding, has hitherto been found only in South America.

Common cornous Silver-Ore, (see Silver-Ores,) has been found in some of the mines in Cornwall, particularly at Huel-Mexico, and in a mine near Peranzabula, on the north-east of Cornwall. In the analysis of this ore, we have stated the constituent parts at 68 of silver, and 28 of muriatic acid; but 6 parts of the latter are oxygen.

Earthy cornous Silver-Ore is very soft, and almost friable. This mineral is an intermixture of cornous silver-ore and alumine.

Earthy Silver-Glance appears to be a decomposing sulphuret of silver. It has a blue-black colour, and varies from friable to solid; it is dull or glimmering, but yields a metallic streak; it occurs with other ores of silver in veins.

Under the localities of silver in England, in the article Silver-Ores, for Benallith r. Beerralten, Devonshire. One of the richest repositories of silver is the West Duche Mine, on the banks of the Tamor, above Plymouth. Silver-ores occur there in regular veins, but are also disseminated in nodules, through the rock itself, which is killed or clay-flake. The ores are, native capillary silver in considerable branches, vitreous silver-ore, black silver, and ruby silver-ore. Under the article Silver, we have given the annual quantity of gold and silver obtained in Europe, South America, and part of Asia, as given by Humboldt, in killogrammes, which reduced to the value of the pound sterling is as under:

£2,695,436 £7,733,973

Total annual value 10,368,109l.; a sum not equal to the payment of one-half of the interest of the national debt of Great Britain!

SLATE, or Slate-Clay, Werner. See Slate.
Slate-Spar, Chaux carbonate nature, Fr. (See Slate-Spar.) Though this is made a distinct species of the limestone family by some mineralogists, it is composed of carbonate of lime with an admixture of about three or four parts in the hundred of manganese or iron with water, to which probably its nacre luster may be owing. It occurs in some parts of Cornwall, and in Scotland.

SILKENSIDES, a name given by the Derbyshire miners to galena or lead-glance, when it forms a smooth polished surface or lining to veins.

SMARAGDITE, green diallage; Diallage verte, Häiyy. See Diallage.

SCAF-STONE, a variety of fletite, is found in Cornwall, and
and extensively used in the porcelain manufacture at Wor
certer. It has a milk-white or greenish-grey colour, mot-
ted with a muddy-purple; it is very susceptible to the touch,
yields to the nail, and falls to pieces in hot water. Before the
blow-pipe, it is friable into a somewhat translucent enamel.
According to the analysis of Klaproth, it contains

Under the article Steatite, it is stated to differ from com-
mon flint by the absence of alumine; it should have been
by the excess of alumine. Some varieties of flintite scarcely
contain a trace of the latter earth.

Soda, Natron, or Natron. See Natron, Addenda.

Sodalite. (See Sodalite.) This mineral is classified by
Mr. Jamefon with the felspar family, on account of its ex-
ternal characters; it differs from felspar in the proportions
of its constituent parts, and soda supplies the place of potash,
which is a constituent of most felspars.

Sommite, or Nepheline. See Sommite and Nepheline,
Addenda.

Sphene. See Sphene, Rutile, and Titanum.

Spinel. See Gem, Ruby, and Spinel.

Spodumene. (See Spodumene.) According to D’An-
drada, this mineral before the blow-pipe事实 separates into
gold-coloured scales, and then into a kind of powder or ash.
It is recently found to contain 8 per cent. of the new
alkali lithia.

Staurolite, or Grenatite. See Staurolite and Grena-
tite, Addenda.

Streptolite, the name given by Haiiyto staurolite.

Steatite. See Steatite and Soap-stone, Addenda.

Stilbite. See Zeolite.

Striped Jaffier. See Jasper.

Strotianite, or Strotius; Strontian carbonatre. See Strotianite.

Surfat, or Cobalt, of Copper, of Iron, of Lead, of Manganese, of Zinc. See the ores of each of these metals, where the native metallic are described.

Sulphur of Soda, Natron. See Soda.

Sulphur, Common and Volcanic. See Sulphur.

Sulphures, Natron, are combinations of the different
metals with sulphur. See Pyrites and the different metals.

Surfur, or Fibrous Brown Coal, or Bituminous Wood, Fibres, Fr. See Coal and Wood-Coal.

Swine-stone, or Flattet Lime-stone. See Swine-stone.

Tabular Spar. Spath en Tables, Haiiy. See Tabu-
lar Spar.

Talc. See Talc.

Tantalite. See Tantalite.

Telesia, the name given by Haiiy to the sapphire.

Tellurium Ores, and Tellurium. See Tellurium.

Thallite, or Epidote. See Thallite.

Thummerstone, or Axinite. See Thummerstone.

Tile-Ore, Earthy and Indurated, an ore of copper (see Copper); the latter is considered by Werner an intimate combination of red copper-ore and brown iron ochre, con-

aining from 10 to 50 per cent. of copper; the red varieties
contain the greatest quantity of copper. The dark-brown
variety, on account of the resemblance of its fracture to
pitch, has been called pitch-ore (Faberis, Werner.)

Tin-stone. See Tin.

Tin Pyrites, or Bell-Metal Ore. See Tin.

Titanium. See Titanium.

Topaz, Topaz, Fr. See Topaz and Gem.

Tourmaline, Tourmaline, and Le fibro electrifique, Fr. See Tourmaline.

Tremolite, Grammatite, Haiiy. See Tremolite.

Triphol, or Rotting-stone. See Triphol.

Tufa. See Tufa.

Tungsten. See Tungsten.

Variegated Copper-Ore, Cuivre purieux etpavique, Haiiy, a native sulphurifer of copper, which has a variegated or iridescent tarnish. See Copper-Ores.

Vesuvian, Idocrase, Haiiy. (See Vesuvian.) The primit-
ive form of the crystals of Vesuvian is a right prism with
square bases, differing little from the cube. Vesuvian is cut
for ornamental purposes by the lapidaries at Naples, and is
called the chrystalolite of Vesuvius.

Umbare, Argile occufa buen, Fr. See Umbare.

Uran Mica, or Uranite, and Uran Ochre. See Ur-

IUM, Ores of.

Wacke, or Wacken. See Wacke.

Wad. See Wad and Manganese.

Wavellite, or Hydargillite, Diaspare, Haiiy. See Wavellite.

Whet-Slate, or Wheatslate, Neverculrite, Fr. See Slate and Wheat-slate.

White Antimony-Ore, White Copper-Ore, White Mangan-
"eke-Ore, White Silver-Ore, and White Vitriol or Sulphate of
Zinc. See each of these metals, and Ores of.

Witherite, or Carbonate of Barytes. See Witherite
and Barytes.

Wolfman, Schelol Ferrugine, Haiiy. (See Wolfram.)
This mineral occurs most abundantly in many of the mines
of Cornwall, but has not yet been applied to any use.

Yenate, Liegerät, Werner. See Yenate.

Yttero-Tantalite. See Tantalite and Yttero-Tan-

talite.

Zeolite. See Zeolite.

Zinc. See Zinc, Ores of.

Zircone and Zirconite. See Zircone.

Zoisite. See Zoisite.

MINGRELLA, l. 12, after gom, add—a kind of paife
made of. At the close, add—According to Reineggies, it
contains four millions of souls, and annually exports 12,000
flaves.

MINKALLI, an African term, denoting a quantity of
gold, nearly equal to 10,000 florins.

MINOT, in Geography, a town of America, in the dis-
trict of Maine, and county of Cumberland, having 2020
inhabitants.

MIRZIN, r. Wolfein.

MODBURY, l. 33, r. 1811—1890—863 males; l. 34,
1027 females, 190 families, and 156.

MOFFAT, col. 2, l. 13, r. 1811; l. 14, r. 1824
persons, occupying 334 houses; 850 being males, and 974
females.

MODOCKS, a denomination given to a mob of dis-
orderly people, who traversed the streets of London at
night,
night, and amused themselves with wounding and disfiguring the men, and indecently exposing the women, in the year 1711. A reward of 100 d. was offered by royal proclamation for apprehending any one of them.

MOLD, l. 6, r. 181, the parish, &c. 5083 persons, occupying 1026 houses; 2495 being males, and 2618 females: of whom 217 families are employed in trade and manufactures, and 180 in agriculture.

MOLE. See N. E. Vol.

POLYCARPA and HAGAEA.

MOLTON, South, col. i. 15, r. 1811-520-2739.

Molton, North, an adjoining parish, containing 329 houses, and 1526 inhabitants.

MOLYBDENA. See Mineralogy, Addenda.

MOLYBDENUM, in Chemistry. The specific gravity of this metal, according to Hjelm, is 7.400; but according to Bucholz, who, from the greater heat he employed, obtained it in a more compact state, it is as high as 8.611. According to the experiments of this latter chemist, there are three oxides of this metal, the brown protoxide, the blue or molybdous acid, and the white or molybdic acid. Dr. Thomson, from the experiments of Bucholz, deduces the weight of the atom of this metal to be 60.

MONAHAN, or Monaghan. Add—containing 725 inhabitants.

MONEY. See Political Economy.

MONFALOUT, r. See Manfalout.

MONKTON, l. 2, r. 1248.

MONMOUTH, l. 5, r. even for fix; l. 4, r. 22,150—1501.—Alfo, a town of the district of Maine, in the county of Kennebec, containing 1262 inhabitants.

Monmouth, col. 3, l. 37, r. 1811; l. 38, r. 3393. Add—The number of houses is 661; of which 1630, and of females 1873, of whom 375 families are employed in trade and manufactures, and 146 in agriculture.

MONMOUTHSHIRE, l. 10.—In 1811, the county was returned as containing 11,766 houses, and 62,147 persons; 30,987 males, and 31,140 females: 5815 employed in agriculture, and 4812 in trade, manufactures, and handicraft.

MONONGALIA, l. 2, r. 12,793 persons, of whom 351 were slaves in 1810.

MONOPTERUS, in Ichthyology, a genus of fishes of the order Apodes; the characters of which are, that the body is anguilliform, the nostrils placed between the eyes, and the tail caudal. The only animal of this genus hitherto discovered is the M. Javanicus, blackish, with a very sharp-pointed tail. It is a native of the Indian seas, and is very common about the coasts of Java, where it is considered as excellent food.

MONROE. Add—containing 5444 inhabitants, of whom 376 were slaves in 1810.

MONSON. Add—containing 1674 inhabitants.

Vol. XXIV.

MONTAGUE, Edward, col. 2, l. 8, for fine ships.

Montague, l. 4, r. 934.

Montague. See Montague.

MONTENEGRIN, or called from the Monte Negro, or Black mountain, near Cantaro, have been reckoned amongst the most daring inhabitants of Dalmatia; which fece. The whole number of these, who are scattered over mountains, has been estimated at about 60,000. All profess the Greek religion, but with few remains of superstitious. The Morlacs, and other inland tribes of Dalmatia, are honell and sincere barbarians, and the drels of their vaivodes somewhat resembles the Hungarian. The general peace of Europe has restored tranquility and present security to them.

MONTGOMERY, in America, l. 3, r. 2954, of whom 747 were slaves in 1810; l. 6, r. 41,214, of whom 712 were slaves; l. 10, r. 237; l. 12, r. 595; l. 14, r. 39; l. 15, r. 29,793; l. 16, add—containing 580 inhabitants; l. 17, having 2603 inhabitants; l. 18, r. 8430; l. 19, r. 1666 houses; l. 21, r. 8490 inhabitants, of whom 1099 were slaves; l. 22, r. 15,768; l. 27, r. 28, r. 8026 inhabitants, of whom 662 are slaves; l. 29, r. 12,650 inhabitants, of whom 1691 are slaves. Add—Alfo, a town of Somerset county, in New Jersey, having 2282 inhabitants.—Alfo, a township of Franklin county, in Ohio, having 556 inhabitants.—Alfo, a county of Ohio, containing 7 townships, and 7722 inhabitants.

Montgomery, in Wales, col. 2, l. 35, r. 1811; l. 36, the borough and 322,442 males, and 430 females.

MONTGOMERYSHIRE, col. 6, l. ult. r. 1811—51931—25,375—26,558. Col. 7, l. 1, r. 3164 families; l. 3, r. 6360.

MONTICELLO, a town of Georgia, in Randolph county, having 89 inhabitants.

MONIQUE, a town of Suffolk county, in New Jersey, containing 661 inhabitants.

MONTROSE. In 1811 the burghe and parish contained 1064 houses, and 8955 persons; viz. 3857 males, and 5118 females: 170 families were employed in agriculture, and 1529 in trade, manufactures, and handicraft.

MONTVILLE, l. 5, r. 2187.—Alfo, a town in Maine, in Lincoln county, with 864 inhabitants.

Montville Plantation, a township of the same, having 130 inhabitants.

MOON, a town of Alleghany county, in Pennsylvania, having 1622 inhabitants.

Moon, Half, a township in Centre county, in Pennsylvania, having 560 inhabitants.

Moon, Ferry and Second, two townships of Beaver county, in the same state, the former having 1035, and the latter 1245 inhabitants.

MOONSHEE, an Indian term signifying a letter-writer or secretary, and applied by Europeans to the native who instructs them in the Persian language.

MONSSTERLING, in Geography, a township of Kentucky, in Montgomery county, with 325 persons, of whom 222 were slaves in 1810.

MOORE, a township of Northampton county, in Pennsylvania, having 1108 inhabitants.

MOOSH, the ancient Moxoene, called also Daran, a town of Armenia, occupying a small eminence, washed by the Euphrates, on which is a bridge of fifteen arches: badly built and thinly inhabited; but the adjoining country is fertile and populous. The natives of this district, which is one of the Turkifh pachalics of Armenia, are a degenerate race, and paid to amount to 80,000 souls; 12,000 of whom are Yezedii. Considerable quantities of tobacco and manna are exported from hence.

MORAYSHIRE, col. 4, l. 32, r. 1811—6268—28,108; viz. 12,015 males, and 15,093 females: l. 32, r. 2633 families; l. 34, r. 1896.

MORELAND, l. 2, having 400—other having 1092 inhabitants.

MORETON-HAMPSTEAD. In 1811 this parish contained 357 houses, and 1653 persons; viz. 770 males, and
883 females: 253 families being employed in agriculture, and 43 in trade, manufactures, &c.

Moreton in the Marsh. In 1811 this parish contained 194 houses, and 528 persons; viz. 457 males, and 471 females: 60 families being employed in agriculture, and 91 in trade, manufactures, &c.

MORRISTOWN, a town of Chittenden county, in Vermont, having 405 inhabitants.

MORGAN, a town of Orleans county, in Vermont, having 135 inhabitants.—Also, a township of Greene county, in Pennsylvania, having 1621 inhabitants.—Also, a township of Knox county, in Ohio, having 388 inhabitants.—Also, a county of Georgia, having 2294 inhabitants.

MORIEVILLE PLANTATION, a township of Maine, in the county of Hancock, having 224 inhabitants.

MOROKINNE, r. MOROKINNE or MOROTINNE.

MOROXYLIC Acid, in Chemiftry, a name given by Klaproth to an acid principle obtained from a saline exudation from the morus alba, collected by Dr. Thompson in Sicily. This exudation contained the acid in question in combination with lime. When separated, it was found to possess the following properties:—It exists in the form of needle-like crystals, having the taste of fucinic acid. It is not altered by exposure to the air. It dissolves readily in water and alcohol, and does not, like the moroxylate of lime, precipitate the metallic solutions. It is volatile, and may be sublimed without change; hence this is probably the best mode of obtaining it in a state of purity. The moroxylates are little known, and do not appear to possess remarkable properties.

MORPETH. In 1811 the borough contained 464 houses, and 3244 persons; viz. 1470 males, and 1774 females: 77 families being employed in agriculture, and 529 in trade, manufactures, or handicraft.

MORPHIA, the name which has been given to an alkaline principle exuding in opium; the descripion of which, and of the other principles exuding with it, will be found under opium. See Opium.

MORRIS, l. 3, for five r. ten. Col. 2, l. 6, r. 21, 828—856 were slaves in 1810.—Also, a township of Washington county, in Pennsylvania, having 1759 inhabitants.—Also, a township of Greene county, having 944 inhabitants.

MORRISTOWN, l. 4, r. and in 1810, 3753 inhabitants, 214 being slaves.—Also, a town of Orleans county, in Vermont, having 550 inhabitants.

MORRISVILLE, l. 2, r. Bucks; add; having 961 inhabitants.

MOLLACE. In 1811 the parish contained 346 houses, and 2021 persons; viz. 832 males, and 1189 females.

MOSSE, l. 2, after Nineveh, add—though others think that the village of Nuna, on the opposite bank of the Tigris, pretends the position of this ancient city. It is situated in the pachalic of Bagdad; dele in the province of Dibar-kir, situated:—l. 12, r. 7,—The inhabitants are said to amount to 35,000 souls.

MOTACILLA, r. RUBECULA.

MOTHER-KILL. Add—containing 7445 inhabitants.

MOUTONBOROUGH. Add.—It contained, by the census of 1810, 994 persons.

MOUNT HOLLY, l. 3, r. 922.

MOUNT JEFF, after Lancaster r. county, having 1551; at the close, add:—having 636 inhabitants.

MOUNT PLEASANT, l. 4, add:—having 1105 persons.—Also, a township of Wayne county, with 522 persons.—Also, a township of Washington county, having 1165 inhabitants.—Also, a township of the same state, in Westmoreland county, having 1788 inhabitants.—Also, a township of Jefferson county, in Ohio, with 846 persons.

MOUNT Tabor, a town of Rutland county, in Vermont, with 209 inhabitants.

MOUNT VERNON. Add—containing 1098 inhabitants.—Also, a town of Hillborough county, in New Hampshire, containing 762 persons.

MOULTAGU. Add—See Montague.

MOUNTAIN CORK. See Mineralogy, Aidenda.

MOUNTAINS, col. 7, under Ireland, instead of l. 3, infer.—Siebe, Donard, a mountain in the county of Down—2500. Col. 13, l. 10, r. Varemus.

MUCILAGE. Chemical Properties of. See Gum.

MUCOUS Acid, in Chemiftry. See Salalptic Acid.

MUCOUS Membrane, &c. See Membrane.

MUMBO-JUMBO, a kind of bugbear dressed in a masquerade habit, formed of the bark of trees, and suspended upon a tree at the entrance of the Mandingo towns in Africa. It is much employed by the Pagan natives in keeping their women in subjection; for as the Khairs, or infidels, are not restricted in the number of their wives, every one marries as many as he can conveniently maintain; and as it frequently happens that the ladies disagree, family quarrels sometimes rise to such a height, that the authority of a husband can no longer preserve peace in his household. In such cafes, the interposition of Mumbo-Jumbo is called for, and is always devoured. This strange minister of justice, who is supposed to be either the husband himself, or some person instructed by him, disguised in the above-mentioned dress, and armed with the rod of public authority, announces his coming, when called for, by loud and dismal screams in the woods near the town. He begins the pantomime at the approach of night, and as soon as it is dark enters the town, and proceeds to the bentang (a kind of flag erected in every town, answering the purpose of a town-hall), at which all the inhabitants immediately assemble. Every married female, not knowing for whom the viisit is intended, is alarmed, but when summoned must appear; and the ceremony commences with fongs and dances, which continue till midnight, about which time Mumbo fixes on the offender. This unfortunate victim being thereupon immediately seized, is stripped naked, tied to a poll, and feverly scourged with Mumbo’s rod, amidst the shouts and derision of the whole assembly; and it is remarkable, that the rest of the women are the loudest in their exclamations on this occasion against their unhappy sifter. Day-light terminates this indecent and unmauly revel.

MUN, col. 2, l. 3 from bottom, for many-mothered, for r. many-mothered fon.

MURANA, col. 3, r. Myrus.

MURIMATE of ammonia. See Sal Ammoniac.

MURIATIC Acid, Muriates, in Chemiftry. See Chlorine.

MUSCI, col. 8, l. 18, r. Shrinks; l. 7 from bottom, r. exfus.

MUSHROOMS, Chemical Properties of. See Fungi.

MUSKINGUM, l. 5, add.—This county has 11 townships, and 10030 inhabitants.

MUSOPHAGA, PLANTAIN-EATER, in Ornithology, a genus of birds of the Pice order; the characters of which are, bill stout, triangular; the upper mandible elevated at the base, above the front; both mandibles dentated at the edges; nokrls in the middle of the bill; tongue entire, thickish; feet with three toes before and one behind. This genus is constituted by the blackish-violet plantain-eater, with crimson crown and quill-feathers, and at white stripe beneath the eyes. The bird, which is highly elegant, is
MYL

of African origin, and is found in the province of Acre in Guinea, and is said to live principally on the fruit of the mufa or plantain-tree. Dr. Shaw, in the Museum Leverianum, has described this bird as a species of cuckoo, under the name of Cuculus regius; but in his Zoology it is a distinct genus.

MUSTELA, col. 3, under B. r. BARBARA, Guiana weafel; l. 3, r. Guiana.

MUSTELA, in Bones, in memory of Mr. Muifol, who wrote, in Phil. Tran. v. 63, one " New Observations upon Vegetation."—Sprengel Tr. of Linn. Soc. v. 6. 152. t. 13.—This plant is said to differ from Eupatorium, (fee that article,) in having five minute scales accompanying the brilfly feed-crown. How far such exit in any Eupatorium, or not, and whether they ought to make a generic distinction, merits inquiry.

MYLOCARYUM, from μυλος, a mill, and καρυων, a nut, alluding to the four spreading wings of the feed.—Wild. Enum. 454. Pursh 303. (Walteriana; Frazer's Cat.)—Clafs and order, Decandria Monogynia. Nat. Ord. Erice, Jiff.

MYT

MYOXUS. At the close, add—Dr. Shaw enumerates some other fpecies, such as the Chryfurus, or gilt-tailed D, the M. guerlingus, or guerlinguet, and the African, or earlfs Dormont.

MYRIANDRUS. Add—According to Xenophon, it was a Phocian city, a mart-town, and many merchant-flips lay at anchor before it.

MYRICIN, in Chemifry, a name given by Dr. John to the infusion which remains after bees-wax, or the wax of the myricia cordifolia, has been heated with alcohol. This infusion is soluble in water, ether, and alcohol, both hot and cold. It is soluble in the fixed and volatile oils, and does not precipitate from the former of thee. It melts between 100° and 140°, and is somewhat glutinous, but of the conftence of wax. Its fp. gr. is 0.900.

MYTHOLOGY of the Hindoos, l. 26 from bottom, for flowers r. flores.

N.

NACHITOCHES, l. 2, after Orleans, add—and in the territory of Orleans; its inhabitants in 1810 being 2870.

NACOGDOCHES, a small town of Louisiana, situated in N. lat. 31° 27', W. long. 24° 17', on the Arroyo de la Nana, in a beautiful, healthy, well-watered country. This small town, and a few farms in the vicinity, are hitherto the only improvement made by the Spanish emigrants after the revolution of 98 years. A tribe of Indians, called Nacadoes, resides about 30 miles N. of Nacogdoches, upon the head-waters of the Angelina, where they were found near a century ago by the French and Spaniards. The Nacadoes are a poor inoffentive race, in peace with all their neighbours, both white and black.

NAGA, a name of the Hindoo mythological serpent, otherwise called Sija; which fee.

NAGANTEKA, in Hindoo Mythology, is a name of the hypogrii Garuda, the vehicle of the god Vishnu. It means the destroyer of ferpents. Another of its names is Sufervas, which fee.

NAIRIT, is one of the eight regents of the winds, or points of the heavens. He rules the fourth, west quarter, and is subordinate to Indra, regent of the firmament. (See Indra.) These rulers of the cardinal and intermediate points are sometimes called Maru (which fee). See also Virupaksha, meaning a difagreeable countenance.

Another of his names is Karbara. He has a sakti or conflfort affigned him, usually named Nirriti; which fee.

NAIRN, l. ult. for 632 r. 613.

NAIRNSHIRE, col. 2, l. 46, number of houses was 1746, and the inhabitants, &c.

NAKAL, one of the champions of the Hindoo heroic poem, entitled the Mahabharat (which fee). As that poem is supposed to be allegorical, and to reprefent the conflicts between man's virtues and vices, Nakal, one of the five sons of Pandu, is said to be a perfonification of temperance, and is made the twin-brother of Sahadeo, or chaflty. Other commentators make them to repreffent beauty and wisdom. Their mother was Maderi, a wife of Pandu; which fee.

NAKSHATRA, in Astronomy, is the name given by the Hindoos to the manifons which they affign to the moon. They seem to be the same, though not exactly coinciding, with the lunar ratures of the Arabians, which they call marzil. The " Nakshatras, or alteriims, marking the moon's path," are twenty-seven or twenty-eight in number. A table of them is given in the ninth volume of the Asiatic Reaches, by Mr. Colebrooke, the president of the Asiatic Society. See also the second volume of the fame work, together with the Indian zodiac, accompanied by an effay on its antiquity, by fr W. Jones.

The Hindoos affcribe the invention of their solar and lunar
NAR

Lunar zodiacs to Daksha, who is mythologically represented as a son of Brahma, and they then give a free rein to their poetical imaginations, representing the Nakhathras as the daughters of Daksha.

NALA, in Hindo Romance, is a periphrase of considerable import, though described as an ape. Others begat by the divine architect Vīsnučarma (which see); and he is said in the Ramayana to have been the builder of Rama's bridge, usually called Adam's bridge, from the continent to the island of Ceylon, or Lanka. See Ceylon and Lanka.

NAMUKI, is the name of a friend and companion of Indra, the regent of the firmament.

NANCEmond. See NANCEMOND.

NANDANA, the name of the garden, or city, assigned by Hindoo fabulists for the delightful residence of their demigod Indra, the regent of the firmament. (See Indra.) There are four cities or gardens of this name, and three of them are said to belong to Gandeh, or Pattear. One of them is called Sva-nandana-puri, the self-delighting city; nandana meaning delightful or happy.

NANDI, in Hindoo Mythology, is the name of the bull on which the god Siva rides. The bull, with the Hindoos, is the symbol of divine justice, as it is able of generation or production. See Siva.

NANCEMOND, l. 4, r. 10; 324—4462.

NANTICOKE, l. 2, r. 2843 inhabitants, including 192 slaves in 1810.

NANTMILL for NANTRILL, l. 2, add—the former contains 1544, and the latter 1188 inhabitants.

NANTUCKET, l. 13, r. 6807.

NARAKA, one of the receptacles for sinners, or hells of the Hindoos. Of these, they have at least seventy-one; and their names are given in the Inf. of Menu, c. iv. v. 88, 89, 90.

Naramedha, a term in the Sanskrit language signifying the facrice of a man. It cannot be doubted that human sacrifices were formerly offered by some tribes of Hindoos, although it is said, and may be reasonably believed, that in these days the practice is wholly discontinued. (See Ruman.)

Tour goddes Parvati, or Bhavani, the consort of Siva, under her name of kali, or black goddes, these offerings, it would appear, were usually, if not always, made. The rules and regulations for this horrid facrice are laid down in a chapter, emphatically called the fanuginary chapter of the Kalika-Purana, which has been translated by Mr. Blaquiere, and published in the fifth volume of the Asiatic Recherches, art. xxiii. No religious rite can be more minutely ordained and detailed.

Although it must appear evident, that human sacrifices were formerly legal and practised among Hindoos, they are most pointedly prohibited in very ancient, as well as in more modern books; such prohibition is, indeed, a farther, and of itself sufficient proof of the existence of the practice. In the Brahma Purana, (see Purana) every Naramedha, or manfacrice, is expressly forbidden; and in the fifth book of the Sri-Bheegasut, (see that article) Sir W. Jones has pointed out the following emphatical words: "Whatever men in this world facrice human victims, and whatever women eat the flesh of male cattle, those men and those women shall the animals hereafter torment in the mansions of Yama, (see Yama,) and, like slaughtering giants, having cleaved their limbs with axes, shall quaff their blood." (See Asiat. Recherches, vol. iii.)

In the first Veda an emblematical or vicarial facrice is ordained, in which men and animals are the victims, but are releaved after certain ceremonies.

Vol. XXXIX.

NARASINGHA, in Mythology, is the designation of the fourth avatar or incarnation of the Hindoo deity Vishnu. It means literally man-lion, such being the form in which this dect is related to have taken place.

Sir W. Jones furnishes that this avatar, and the following of Vamanara, (see Vamanavatar) were allegorical references to the two prehuman monarchs Namrod and Belus, under the names of Hiranayasakipu and Beli, the former name meaning with a golden axe; or, according to other authorities, clad in gold. Hind. Panth. Af. Ref.

The three avatars, or dect of Vishnu on earth, preceded that which is the subject of this article, were the Matya or fish, the Kuru or tortoise, and the Varaha or the boar; under each of which words, having the common denomination of avata or pell, some account of them will be respectively found. A list of the ten grand dect, or dasavatara, will be found under the article VishnU. This is sometimes written Nri Sinha.

Narasinh, Narasimha, or Nrsinbhi, is the name given to the Hindoo goddes Lakshmi, who became thus incarnated to accompany her lord Vishnu in his avatar or dect of Narasinha, as sufficiently explained under that article, and the others thence referred to.

Narayana, a periphrastic of rather a bold and apparently reprehensible nature. "The waters are called nar, because they were the first production of Nara, or the Spirit of God; and since they were his first ayens, or place of motion, he is thence named Narayana, or moving on the waters." (See Menu.)

On the whole, Narayana seems to refer in character more to Vishnu than to any other of the Hindoo deities.

Narayan, a name and form of the Hindoo goddes Lakshmi. In this character, she is considered as the Sakti or confort of Narayana; which see, and Matth.

NARBETH, l. 9, r. 388.

Nareda, or Narada, in Hindoo Mythology, a periphrase among the Hindoos, deemed the mythological offspring of Brahma and Sarawati. In the popular histories of Krishna, Narada is represented as his humble friend, on whom hepalads many practical and whimsical jokes, metamorphosing him into a woman, &c. But in more serious books, his character is more corresponding with the magnificence of his origin. He is represented as a wife legislator, great in arms, arts, and eloquence; and, indeed, of such historical celebrity, that his actions are the subject of a Purana, named after him; some account of which is given under Purana. He was also an astronomer, and an exquisite musician. Hence Sarawati, the patrons of science and harmony, is said to have been his mother. He farther invented the vina, a sort of lute, which sir W. Jones remarks as a singular fact, otherwise called katepni, having the name meaning ejoyd; and Narada being also a frequent messenger of the gods, to one another, or to favoured mortals. His character, in these and other points, resembles that of Hermes, or Mercury.

NASH, l. 2, r. 7268—2897.

Nastick, in Phillips, the name of a sceptical sect of Hindoos. The word in the Sanskrit tongue means negative, and is intended to designate those who do not believe the Veda. Individuals of more orthodox sects call the Nasticks, materialists and atheists.

Nasturtium, in Botany, (see our former article) is now adopted to designate the Water-cres and its allies, separated by Mr. Brown from Sismbrum, (see that article;) sect. 1.—Br. in Ait. Hort. Kew. v. 4. 169.—Clafs 4 E.

Eff. Ch. Ped. nearly cylindrical; valves concave, without rib or keel.

*N. officinalis*, (Sisyfr. Naturtium; Linn. &c.), with *fleshyfr., terryfr., amphibus, pyrenicum*, and *faggittare*, are the species mentioned in Hort. Kew. We have already described all but *pyrenicum*, which is a well-known species.

NATICK, 1. * adv. r. in 1810, contained 766.

NATRON. See *Mineralogy, Addenda*.

NATUNZ, in a town of Peria, in the province of Irak, 63 miles from Iphshon, and 43 from Cuthan, situated on a very delightful spot, in a valley surrounded by high and rugged mountains, and famous for the salubrity of its climate. It is inhabited by Jews and handfome females. It has a fort in the centre of the valley, an excellent warm bath, and an old mosque, with a very handsome mineral, said to have been built 300 years ago.

NAVY. Add—having 56 inhabitants.

NAXIA, 1. from bottom, after villages, add—Dr. Clarke (in vol. vi. of his Travels) states the whole population of the island, including women, at 18,000 persons, about 3000 of whom are Latins, and the rest Greeks.

NAZARETH, 2. at the close, 1. 34. add—Lower Nazareth is a township containing 475, and Upper Nazareth is a township in the same county and state, containing 535 inhabitants.

NEATH, col. 2, 1. 5. r. Saturday for Thursday; 1. 6. add—It has three fairs; 1. 12. r. was for is.

NECYDALIS, Minor, add—in fields and about hedges in the summer months. *Cruella*, add—in woods during the summer months.

NEEDHAM, 1. 7. r. 1897.

NEJIFF, or Meshed Ali, a holy city, being the supposed burying-place of the caliph Ali, a town of the pachalic of Bagdad, nine furlongs from Hilleh, and four miles from Kufa, situated on a hill, at the bottom of which is an artificial lake. It was founded by Alexander the Great, and bore the name of Alexandria, which was afterwards changed into that of Hira, when it became the residence of a dynasty of Arabian princes, who fought under the Parthian banners against the emperors of Rome. Nejiff is not so large as Kerbela, but better built, and defended by a good wall, deep ditch, and lofty towers, lately renewed, under the apprehension of an attack from the Wahabees, who extend their ravages to the gates of the town. The tomb and mosque of Ali occupy an ample space in the middle of the city, and form a handsome structure, within a high wall, which an infidel subjects himself to death for attempting to pass. The governor of Meshed Ali is a Turk, but the population, not easily estimated on account of the confiding influx of pilgrims, is like that of Kerbela, chiefly composed of Persian fanatics. The relics of almost all persons of rank are transported from the most remote parts of Persia to be interred either here, or at Kerbela, Kazameen, Koom, or Meshed in Khorasan.

NELSON, 1. 2. r. 184, 579 —2908. Add—Alf, a county of Virginia, containing 968 inhabitants, of whom 467 were slaves in 1810.

Eff. Ch. Calyx in five deep segments. Corolla spurred at the base; throat closed by the palate. Capsule compressed, of two cells, and two boat-like valves; partition linear, covered with seeds.

2. *N. bicornis*. Horned Nemedia. Ait. n. 2. See Antirrhinum, n. 24. (Linaria; Burm. Ait. vol. vi. t. 75, f. 3.)—Leaves lanceolate, with tooth-like serratures. Clutfer terminal, rather lax.—From the same country. Annual. The specific name applies to the capsule.

NEPANESE, in Geography, a townhip of Lycoming county, in Pennsylvania, having 298 inhabitants.

NEPER, 1. 1. 2. 22 from bottom, for Nepé's rods r. Nepé's bones.

NEPHELINE, or Somerite. See Mineralogy, Addenda.

NEPHRITE. See Mineralogy, Addenda.

NERANTEK, in Hindoo Mythology, is the name of a malignant demon, mentioned often in their heroic poems, slain by Kriyuna, and by other divine warriors. The name generally means destroyer of men.

NERKA, one of the many hells of the Hindoos. See Naraka.

NEROS, in Chronology, an ancient Chaldean period of 600 years, and equal to the Sosos of 60 years multiplied by 10.

NESENPACK, in Geography, a township of Luzerne county, containing 460 inhabitants.

NESEHNACK, a township of Mercer county, in Pennsylvania, having 700 inhabitants.

NETCHEZ, or western branch of the Sabine, a river of Louisiana, formed from the united streams of the Ange- linia, Attoquaque, Nena, and the Attacocit. The Netchez, though not so long as the Sabine, exceeds it as to quantity of water. The lands watered by this river, and its tributaries, are of superior quality to the country on the Sabine; but barren compared with those on the margin of many rivers in Louisiana.

NETTING. Add—The netting is used in different parts of a ship; thus, the *boarding-netting* is thrown over the hatches to prevent the enemies boarding. *Bowsprit-netting* is fastened near the outer end of the bowsprit, to the man-ropes or hores, to flow away the fore-topmasts, jib and jib. *Bowsprit quarter and waist nettings* are used to keep the hammers in the flanks. *Head-netting* is fastened to the horset and upper rail, to prevent the men from falling overboard. *Quarter-deck netting* is suspended over the officers' heads, to prevent any thing falling thereon. *Top-netting* is fastened to the rail, throuws, and top, to prevent the men from falling.

NEWARK, in America, 1. 2. add—having 88 inhabitants; 1. 12. add—and in 1810 contained 8000 inhabitants, of whom 360 were slaves.

NEW BRAINTREE, 1. 2, after Worcester, infelt—Massachu-
NEWBURY, or NEWBURY, l. 2, add.—It contained, in 1810, 13,604 persons, of whom 4006 were males; l. 3, r. 1706; l. 10, r. 1365; l. 13, r. 5176.

NEW CANAAN, a town of Fairfield county, in Connecticut, containing 1599 persons.

NEWCASTLE, l. 5, r. 9 hundred, and 24,429; l. 6, r. 1087; l. 16, add.—It contained 2340 inhabitants, including 1748 males; l. 19, r. 592; l. 26, r. 1232. At the close, add.—Alfo, a township of Muskingum county, in Ohio, containing 370 persons.

NEWCASTLE-in-EMLYN, col. 2, l. 2, for Saturday r. Friday. Add.—A few miles below the town is a beautiful salmon- leap.

NEW CHESTER. Add.—containing 895 inhabitants.

NEW DURHAM, a town of Strafford county, in New Hampshire, having 888 inhabitants.

NEW FAIRFIELD, a town of Connecticut, in the county of Fairfield, having 772 inhabitants.

NEW-FANE, l. 3, r. 1276.

NEWFIELD, a town in Maine, in the county of York, with 815 inhabitants.

NEW GRANTHAM. Add.—containing 864 inhabitants.

NEW HAMPSHIRE. Add.—See United States.

NEW HAMPTON, l. 4, add.—and contains 1293 inhabitants.

NEW HARTFORD. Add.—containing 1507 inhabitants.

NEW HAVEN, in America, l. 4, r. 18; l. 5, r. 1810; containing 37,064 persons. For other particulars, besides those which have been mentioned, see New Haven, and United States.

NEWINGTON, l. 3, r. 508.

NEWINGTON, Stoke, a village of the county of Middlesex, in the Finchbury division of Essex hundred, and parish of St. Mary’s. In 1811 the parish contained 342 houses, and 2149 persons; viz. 990 males, and 1159 females.

NEW KENT, l. 3, r. 6478 inhabitants, of whom 3725 were males in 1810.

NEWLIN. Add.—containing 780 inhabitants.

NEW LONDON, l. 4, r. 14; l. 6, r. 1810—34,707—77; l. 14, r. 3238; l. 26, r. 692. At the close, add.—Alfo, a township of Pennsylvania, in Chester county, containing 1018 persons.

NEW MARKET, in America, l. 3, r. 1651. Col. 2, l. 1, add.—Alfo, a township of Highland county, in Ohio, containing 978 inhabitants.

NEW MILFORD, l. 7, add.—In 1810, the inhabitants were 5573. At the close, add—It has 797 inhabitants.

NEWPORT, in Cornwall. In 1811, the parish of St. Stephen’s contained 159 houses, and 856 persons; viz. 433 males, and 423 females.

NEWPORT, col. 1, l. 4, r. 1427; l. 7, r. 16,294; l. 19, r. 7907. Col. 2, l. 9, add.—containing 566 inhabitants. Add.—Alfo, a township of Washington county, in Ohio, having 323 inhabitants.

NEWRY, a township of the district of Maine, in the county of Oxford, having 202 inhabitants.

NEWTON, l. 3, r. 1709; l. 5, add.—Alfo, a township in Bucks county, having 902 inhabitants:—l. 8, r. 454; add.—Alfo, a township of Delaware county, in Pennsylvania, containing 601 inhabitants.—Alfo, a township of Cumberland county, in the same state, having 1312 inhabitants.—Alfo, a township of Miami county, in Ohio, having 556 inhabitants.—Alfo, a township of Muskingum county, in Ohio, having 802 inhabitants.—Alfo, a township of Trumbull county, in Ohio, having 490 inhabitants.

NEWTON-NOTTAGE, a parish formed by the hamlets of Newton and Nottage, situated in the county of Glamorgan, near the Bristol Channel. In 1811, the former hamlet, at a small distance from Pyle, that lies in the road between Cowbridge and Neath, contained 55 houses, and 254 persons; viz. 117 males, and 137 females: and the latter contained 43 houses, and 217 persons; viz. 107 males, and 110 females.

NEWTOWN, l. 3, containing 2834 persons; l. 14, having 1951 inhabitants; l. 17, and 2082 persons; l. 25, add.—See Newton; l. 27, add.—See also Newton.

NEW VINEYARD, l. 1, for Kennebec r. Someret. Add.—containing 484 inhabitants.

NEW YORK. See New York.

NIAGARA, l. 1, infert—a county, &c. l. 2, add.—the county including 8971 inhabitants.

NIBBED-HOOKS, in Rope-making, are iron winches used to hang the yarn on to harden, and to lay small ropes on.

NICHOLAS, l. 2, r. 4338 inhabitants, 569 being males.

NICKEL, in Chemistry. The weight of an atom of this metal, according to the recent determinations of Dr. Thomson, is 33.75, from which datum the composition of its falls may be easily ascertained. See Atomic Theory.

At the end of the article in the Cyclopaedia, add.—From the experiments of Tapperti, it appears that preparations of nickel poiffes poisonous properties.

NICKEL-ORE. See Mineralogy, Addenda.

NICOTIN, in Chemistry, the name which has been given to a peculiar principle in the leaves of the Nicotiana Latifolia, or Tobacco, and to which that plant owes its peculiar properties. This substance was obtained by Vauquelin from the juice, by a process sufficiently complicated. When pure it is colourless. It has an acrid taste, and the peculiar smell which distinguishes tobacco. It occasiona violent freezing. It is soluble both in alcohol and water; the solutions are colourless, and distinguished by the peculiar taste and smell of nicotine. It is precipitated from its solutions by tincture of nut-galls. It is volatile, and somewhat resembles in short the volatile oils in its properties. It poiffises poisonous properties. See further in the Annales de Chemie, lxxxi. 139.

NIGER. Add.—It has been supposed that the Niger terminates in the Nile; but this hypothesis, though maintained by several modern travellers, viz. Hornemann, Jackson, &c. is the most unfounded of any, and the least conformant with acknowledged facts. The supposition adopted by Mr. Park is, that the Niger terminates in the river Congo, or, as it is sometimes called, the Zaire; which see. Another supposition, respecting the termination of the Niger, is that of a German geographer, Mr. Reichard, published in the “Ephemerides Geographiques,” in August 1808, who represents the Niger, after reaching Wangara, as seeking a direction towards the south, and being joined by other rivers from that part of Africa, taking a great turn from thence towards the south-west, and pursuiving its course until it approaches the north-eastern extremity of the gulf of Guinea, whence it divides and discharges itself by different channels into the Atlantic; after having formed a great Delta, of which the Rio del Rey constitutes the estuary of the Rio Formoso, and Benin river the western branch.

N'LA, in Mythology, is one of the many names of the Hindu goddes Parvati. The word means blue or dark-azure, and is one of the Sanscrit names for the Nile, as is also Kali.

NILAKANTHA, a name of the god Siva, meaning blue-throated, similar to Shitakantha, or Shitakoontha, under which word some account is given of the origin, &c. of the apellation.

NILE, in Geography, a town of Ohio, in the county of Scioto, having 3,360 inhabitants.

NIMMISHITAN, a township of Ohio, in Stark county, having 385 inhabitants.

NIODER, in Ancient Mythology, was, according to the historians who acquire in the authority of Diodorus Siculus and Apollodorus, the daughter of Tantalus, and sister of Pelops. Pelops, removing from Phrygia, carried his sifter with him to that part of Greece which afterwards took his name; and for the security of his new dominions, married her to Amphion, a prince eminently powerful and eloquent, who fortified Thebes with walls. Niobe became, in consequence of that marriage, the mother of a numerous progeny; and was thus led to despise Latona, who in revenge induced Apollo and Diana to put all her children to death, in the manner related by Ovid and Phytarch. This epistle, as it is said by some writers, contains a history no less true than tragic. The city of Thebes was defolated by a pestilence, which destroyed all Niobe's children; and as contagious distempers have been attributed to the immediate heat of the sun, it was reported that Apollo flew them with his darts. Niobe, after the death of her children, and husband, who, overpowered with grief, destroyed himself, returned to Lydia, and ended her days near mount Sipylos, upon which was seen, according to Pauflanias, a rock that, viewed at a distance, resembled a woman in deep melancholy and distress. Sophocles, in his Antigone, says, that this princess was not at first transformed into a stone; but that the gods, at her request, granted her that favour afterwards. The fame poet, in his Electra, says, that Niobe sheds tears in a tomb of stone.

NIPPER, in Rope-making, is formed of two flat plates, through which the yarn passes from the tar-kettle, which are so adjusted by weights and a lever, that the yarn receives no more tar than is required, and what is squeezed out drops into a trough and returns into the kettle.

NIRRITI, is the name of a Hindu deity, comfort or father of Nirit or Nairit. (See the latter article.) She shares with her husband the regency of the south-west quarter of the heavens.

NISHAPOUR, anciently the greatest and richest city of Khorasan in Persia, and one of the four royal cities of the province, is seated on a plain, formerly irrigated by about 12,000 aqueducts, which have fallen into decay. It is said to have been founded by Taimuras, and destroyed by Alexander the Great. After the lapse of many years, it was rebuilt by Sapor I., and its statue was seen in it till the Arabs destroyed it. This city was taken in the 548th year of the Hegira by the Tartars, who completely ruined it, that when the original inhabitants returned to the possession of it, they could not distinguish their own houses. After having regained its former splendour, it was again taken and pillaged by the Tartars under Gengis Khan; so that the present inhabitants do not exceed the number of 15,000. The ruins of the city are nearly ten furlongs in circumference. It is at present subject to the dominion of the king of Persia, and has nine districts dependent upon it, each of which has about ten walled villages. The fruits are abundant and delicious.

NITRE, Native. See Mineralogy, Addenda.

NITRIC ACID, NITRATES, &c. in Chemistry. The correct proportions in which azote and oxygen combine, will be found in the tables appended to ATOMIC THEORY, to which therefore we refer our readers. We shall only state here the composition of nitric acid, which is azote oxygen + 1 atom azote: hence the weight of its azote is 67-5, from which datum the composition of the nitrates can be accurately determined.

Ten species are described, all shrubs, natives of hills at the Cape of Good Hope. Leaves scattered, doubly pinnatifid, thread-shaped; the upper ones, in fix of the species, undivided and flat. Flowers (piket, capitate, bracteated, purplish.—Four species are mentioned in Hort. Kew.

3. N. spicata, and N. crithmifolia, the latter P. Lagos; Andr. Repof. t. 243, have all the leaves doubly pinnatifid.

NOBLEBOROUGH, l. 3, r. 1206.

NOCK, the foemft upper corner of boomsails, and of stayfoils cut with a square tare.

NOCKAMIXON, l. 2, r. 1290.

NOCTURN, LITURGIC, the divine office of the night, as distinguished from that of the day. The latter consists of the seven canonical hours, the former of three noontimes, each consisting of several psalms, lefions, &c.; and it was heretofore customary to interrupt the sleep three different times for the performance of them.

NOOTH'S Apparatus. See Laboratory.

NORFOLK, col. 2, l. 15, add.—By the parliamentary returns in 1811, this county contained 33,000 square miles, 3 foothills, viz. king's Lynn, Titchford, and Great Yarmouth, and one city, viz. Norwich; 6,774 houses, occupied by 3,999 persons; 138,089 being males, and 153,910 females; of whom 31,454 families are employed in agriculture, and 25,082 in trade and manufactures.

NORFOLK, in America, l. 4, r. 22; l. 6, r. 31,245; l. 8, r. 18,579-567; l. 4 from bottom, r. 1441.

NORMAN. Add.—Allo, a square or of oak, or short carving, fixed through the head of the rudder of East India ships, to prevent the loss of the rudder, in case of its being unhitched. Allo, a short wooden bar with a head, used in one of the holes of the windlass when there is little strain on the cable.

NORRIDGEWOCK, l. 2, add—and county of Somerset; l. 3, r. 880.

NORTH BEAVER. See BEAVER.
NOR

NORTH-WEST Fort, a hundred of Suffolk county, in the state of Delaware, containing 3293 persons, of whom 38 were slaves in 1810.

NORTH-WEST Passage, l. 15; after Labrador coast, add—nor of the Corteles of Portugal in 1500, nor of the Cartiers and others from France in 1568 and 1534; nor of Gomez, &c. from Spain in 1524, &c. nor of Sir Hugh Willoughby in 1533, of Richard Chancellor and Steven Burrough in 1555 and 1556—l. 19, such as Edward Fen ton in 1577, Arthur Pet and Charles Jenkinson in 1580, sir Humphry Gilbert in 1583, John Davis in 1585, 1586, and 1587, Cornelis Cornelison, Brands Vibrants, and William Barentz in the United Provinces, in 1595 and 1596, William Adams in 1596, George Wy emouth in 1602; James Hall in 1605—7, John Knight in 1606, Henry Hudson in 1607—9—10, sir Thomas Batlon in 1612, James Hall in 1612, Gibbons in 1614, Robert Bylot in 1615, Bylot and William Baffin in 1616, Jens Mank, a Dane, in 1619—20, and, after the failure of Samuel Hearne in 1760, 1770, Conflation John Philp (lord Mulgrave) in 1775, captain Cook, &c. Col. 2, l. 59; add—our limits will not allow our detailing the voyages of captain (now admiral) Lovewen, lieutenant Egede, and lieutenant Rothé, Danes, in 1786 and 1787, nor the travels of Alexander Mackenzie in 1789, nor the travels of Charles Duncan in 1790 and 1791, nor the discoveries made by the Ruffians on the northern coast of Siberia during the 18th century, nor the voyages for further discovery, undertaken in the early part of the 19th century by lieutenant Kotzebue in 1815 to 1818, of John Ross, David Buchan, William Edward Perry, and John Franklin in 1818. Add to the references—Barrow's Chronological History of Voyages into the Arctic Regions, &c. 8vo, London, 1818.

NORTHAMPTON, col. 9, l. 7, for 1623 r. 1756.

NORTHAMPTON, in America, l. 4, r. 32—38,415; l. 5, r. 1756; l. 6, r. 710; l. 10, r. 13082; l. 11, r. 7258; l. 17, r. 7454; l. 18, r. 3350. Col. 2, l. 2, r. 2631. Add at the close—In 1810 it contained 4717 inhabitants.

NORTHAMPTONSHIRE, l. 24, r. 28,318. Add—68,279 being males, and 73,074 females, of whom 14,100 families were employed in trade and manufactures, and 15,235 in agriculture.

NORTHBOURGH, l. 3, r. 794.

NUX VOMICA, Chemical Properties of. MM. Pelletier and Caventon, in analyzing the nux vomica and St. Ignatius's bean, observed a new vegetable alkaline substance, having the following properties.

It is slightly soluble in water, very soluble in alcohol, reffores the colour of turnifole after it has been reddened with an acid, does not redden turmeric, combines with acids which it furatates, and forms with them cryflalizable salts. The discoverers have suggested the name: Vauqueline for this substance, in honour of the celebrated chemist Vau quelin, who is laid to have first discovered the alkaline properties of a substance obtained by him from the dophine alpina.

NYCTERIUM, in Botany, a genus entirely artificial, made by Ventenat in Hort. Malmaign. 85; out of such species of SOLANUM, (fee that article,) as have irregular flowers.—Sims in Curt. Mag. 1801.—M. Dunal has very judiciously, as we presume to think, kept Solanum entire.

OLEFIANT GAS, Chemical Composition of. See Atomic Theory and Carbon.

OLEIC ACID, in Chemistry, obtained by Chevreul from a soap made by digesting hog's-lard in potash ley. When this soap is put into water, a portion was deposited in pearl-coloured scales, which was the margarate of potash. (See Margaric Acid.) Another portion, consisting of the oleate of potash, mixed with some margarate of potash, remained in solution. These two were then separated, and the oleic acid obtained in a flake of purity. Oleic acid when pure is an oily fluid, without taste or smell. But most commonly it has a rancid odour, and a yellow or brown colour, somewhat resembling olive-oil. Its specific gravity is .899. Sometimes it remains liquid at 35°, though other varieties of it congeal at 45°, or even higher. When congealed it crystallizes in needles. It reddens litmus with great energy. It is insoluble in water, but very soluble in alcohol. It combines readily with the alkalis and earths, forming farts, or rather foaps, none of which possess very remarkable properties. Dr. Thomson, from Chevreul's experiments, estimates the weight of its atom at 356. It may be obtained from most other animal fats as well as hog's-lard.

OLEY, in Geography, a township of Berks county, in Pennsylvania, having 1284 inhabitants.

OLIVINE. See Olivine, and Mineralogy, Addenda.

ONSLOW, l. 3, r. 669—2299.

ONTARIO, l. 3, l. number of inhabitants in 1810 was 43,032, of whom 212 were slaves.

OPÆTHUS, Touraco, in Ornithology, a genus of birds of the order of Picae; the characters of which are, beak short, convex above, rather bent, compressed laterally, and denticulated from the middle to the tip; nostrils covered with short silky feathers; feet simple, with two toes before and two behind. One species of this genus is known, which is a native of Africa, and one of the most beautiful of the birds that are found in that quarter of the globe. It feeds on fruits, is easily tamed, and capable, as it is said, of turning its exterior hinder toe either backwards or forwards. This is the Cuculus Varus of the Linnean sytem. Shaw.

OPAL. See Mineralogy, Addenda.
OPELOUSAS, in Geography, a county and parish of the territory of Orleans, containing, in 1810, 50,48 inhabitants. This territory presents a great variety of soil, or, if we except the cactus tree and orange tree, the cultivation of most valuable vegetables has succeeded. Cotton, indigo, and tobacco, have been and now is the staple commodity of the country; to which we may add, cattle, hides, leather, cheese, and pork.

OPHIDIIU, l. 25, add—See Dr. Broussonet's description of this fish in the Phil. Trans. vol. lxxi.

OPium, Chemical Properties of. M. Deroine, in 1803, published an analysis of opium, in which he announced the existence of a peculiar crystalizable substance to which that drug owes its narcotic properties, whence it was named the Narcotic Principle (which see). Soon afterwards, M. Sertuirner published an analysis of the same substance, but the results of the two chemists were so different, as to render both doubtful. This latter chemist, however, pursued the subject, and at length succeeded in separating a peculiar substance from opium, which he denominated morphia. It is to this principle that opium owes its narcotic properties; and the narcotics principle of Deroine, according to Sertuirner, is a compound of morphia, and a peculiar acid called the meconic, which opium contains. This latter circumstance, however, has since been called in question by Robiquet.

According to Sertuirner, morphia occurs in opium combined with meconic acid. There are different methods of separating morphia from opium. Sertuirner effected it by adding acetic acid, and thus forming an impure acetate of morphia. The acetic acid was then separated by ammonia, and the morphia thus obtained purified by means of alcohol. Others, after separating the extraneous matter as much as possible, add at once to the watery solution of opium pure ammonia, to precipitate the morphia, which is to be purified as before.

Morphia thus obtained is crystallized in the form of double four-sided pyramids, whose faces are squares or rectangles, and sometimes of four-sided prisms with trapezoidal bases. It diffuses in eighty-two times its weight of boiling water, and the solution on cooling deposits regular colourless transparent crystals. It is soluble in thirty-six times its weight of boiling alcohol, in forty-two times its weight of cold alcohol, and in eight times its weight of sulphuric ether. All these solutions change the infusion of Brazil wood to violet, and the tincture of rhubarb to brown, thus denoting distinct alkaline properties. They have a bitter and peculiar astrignent taste; and the saturated solutions, when rubbed upon the skin, leave a red mark. It acts with great energy on the animal economy. Half a grain being swallowed by a young man of seventeen, produced a flushing in the face and an augmentation of the mucular energy; another half grain being swallowed half an hour afterwards, occasioned a dull pain in the head, giddiness, stupor, and nausea. A third half grain aggravated the symptoms so much, that Sertuirner became alarmed, and made his patient swallow a quantity of vinegar. But the symptoms were rather aggravated and continued all night, though they were removed the next morning by the use of magnesia.

Morphia readily combines with the different acids, neutralizes them, and thus forms salts, of the properties of which the following is a brief summary. The carbonate of morphia crystallizes in short prisms. The acetate of morphia crystallizes, but is very soluble in water. The sulphate of morphia is likewise very soluble. The muriate of morphia affhnes a plume appearance, and is much less soluble than any of the other salts of morphia. The nitrate of morphia crystallizes in prisms.

Dr. Thomson estimates the weight of the atom of morphia, from the experiments of Choulant, at 58.5; but this probably differs considerably from the truth.

Meconic Acid.—This acid may be obtained from the infusion of the plant after the morphia has been separated by ammonia as above-mentioned, by adding muriate of barytes as long as any precipitate falls, which is moneionate of barytes. To obtain the meconic acid from this salt, M. Choulant triturated it in a mortar with its own weight of glaffy boric acid. This mixture being put into a small glass flask exposed gradually to heat in a sand-bath, the meconic acid sublimed in the flates of fine white flakes or plates.

Meconic acid thus obtained has a strong four taste, which leaves behind it an impression of bitterness. It is readily soluble in water, alcohol, and ether. It reddens the greater number of vegetable blues, and changes the solution of iron to a cherry-red colour; when these solutions are heated, the iron is precipitated in the flate of protosyoxy. This acid unites with the different bases forming meconiates. The meconiate of potash crystallizes in four-sided tables, and is soluble in twice its weight of water. The meconiate of soda crystallizes in soft prisms, and is soluble in five times its weight of water. It seems to effloresce. The meconiate of ammonia crystallizes in star-form needles, which when sublimed lose their water of crystallization, and assume the form of scales. The meconiate of lime crystallizes in prisms, and is soluble in eight times its weight of water. Dr. Thomson estimates the weight of the atoms of this acid, from the experiments of Choulant, at 27.5; but this can only be considered as an approximation.

Such is a brief account of the principles which chemists have lately detected in opium, and which, from the importance of the subject, we have thought proper to insert here.

ORES, Chemical Analyses of. See Analysis.

ORFA, in Geography, the present name of the ancient Edessa (which see), from which the pachalic of Orfa derives its appellation. This pachalic is almost entirely encircled by the windings of the Euphrates and the river Khabour, and occupies a considerable portion of the most barren part of Melopotamia. In the early ages of the Roman empire, this division of Melopotamia bore the name of Otbohne. It had fulfilled 843 years as an independent kingdom, when it was reduced under the form of a province by the Caracalla, who led Abgarus, the last of its kings, in chains...
chains to Rome. The city of this name, after the expulsion of the princes of Orhoene, became a Roman colony, and was regarded as one of the bulwarks of Mepopotamia against the Parthians and Persians. It was the residence of the Courtneys, counts of Edessa; and fell, together with the adjoining territory, into the hands of Zangi and Salllahadene. In the thirteenth century it was sacked by the Moguls, and by Timur in the 84th year of the Hegira. It is now subject to the grand feignor, and the residence of a pacha of two tails. It is situated in a barren country, 232 miles from Diarbekr, surrounded by a stone-wall, defended by a citadel, and a broad deep ditch. The houses are well built, and the inhabitants, composed of Turks, Arabs, Armenians, Jews, and Neflians, amount to about 20,000 souls. The chief ornaments of the city are, a magnificent mosque, consecrated to Abraham, and the cathedral of the Armenians, now fallen to decay. On an adjoining mountain are the ruins of a building, called the palace of Ninrood, and several extraordinary subterraneous apartments, apparently very ancient. McKimine's Peria.

**ORFORD.** Add—It contains 860 inhabitants.

**ORLANDO.** See **LASSUS.**

**ORLEANS.** L. 4r. 23; l. 10, r. 5820; l. ult. and in 1810 of 12148 persons.

**ORLEANS.** New, l. 3, enter 105 miles, &c.; l. 3, add— or, by the statement of Mr. Darby, N. Lat. 28° 37'. W. long. 9° 8'. At the close, add—By the census of 1810, it is stated as comprising the following counties: viz. Orleans, German Coafi, Acadia, La Fourche, Iberville, Point Coupee, Concordia, Ouachita, Rapides, Natchitoches, Opelousas, and Arkansas, which include a number of parishes, and a population of 57,656 souls. The city and suburbs of New Orleans contained 17,242, and its precincts 7310: the number of slaves in the former is stated at 5901, in the latter at 4863. Since the census of 1810, there has been a rapid increase of population. Mr. Darby, in his "Description of Louisiana," published in 1816, states, that 1000 may be added for the annual increase, so that the present population may be estimated at more than 23,242 persons. No city perhaps on the globe, he says, presents a greater contrast of national manners, languages, and complexion, than New Orleans. The proportion between the whites and men of mixed cast or black is nearly equal. Among the whites, the French are hitherto most numerous and wealthy; next to these are the Anglo-Americans; and lastly, the natives of the British islands. Here are but few Spaniards and Portuguese, face Indians, and dispersed individuals of all the nations of Europe. For a further account, see **UNITED STATES.**

**OTAHITE, l. 6 from the end, add—From a survey made by captain Wilfon in this voyage, he estimates the whole number as not exceeding 16,050 persons; and Turnbull, in his "Voyage round the World," performed from 1790 to 1804, says, that they cannot now be estimated at more than 5000.**

**OTALGIA, derived from Gr. oTive, the ear, and paxv, pain, signifies the disorder, which, in plain English, is generally called the ear-ache.** The pain may be confined to one ear, or affect both these organs with different degrees of severity. It may be either of a burning, shooting, pricking, piercing, throbbing, or gnawing description; or it may consist of an unpleasant sensation of whistling in the ear, of a ringing of bells (see Tinnitus Aurium), a continual humming noise, &c.; the complaint in such instances usually depending upon irritation of the nerves of the ear.

According to the nature and situation of the disease, the pain may affect either the outer part of the ear, the meatus auditorius externus, the cheeks and temples, or the internal parts of the organ, the cavity of the tympanum, the labyrinth, and the auditory nerve itself. Otalgia is divided into several species, which are determined by the nature of their particular causes. Califon mentions five varieties of the disorder; viz. the otalgia inflammatoria, catarrhalis, purulenta, metastatica, (a cafe which the modern doctrines in pathology hardly allow us to admit,) and the otalgia a corporis alinis intrusus.

The inflammatory form of the complaint, when seated in the external parts, is indicated by the common symptoms of inflammation, as heat, swelling, and redness, extending over the lobe of the ear, and the adjoining part of the cheek, attended with a diminution in the diameter of the meatus auditorius, and a consequent dulness in the power of hearing. But when the inflammation is seated in the internal ear, it is accompanied with acute fever, exacerbating pain in the deeper part of the organ, exquisite sensibility to the slightest noise, intolerance of sounds, refulfections, sometimes a great deal of delirium, convulsions, and coldness of the extremities, and, according to the accounts of several respectable writers, the diseased may even have a fatal termination.

The otalgia catarrhalis is preceded by the usual symptoms of a cold, which is very frequently the consequence of an exposure of the head to a current of wind, or of the feet to damp, at a period when they are much heated. This ear-ache is commonly characterized by much milder symptoms than other varieties of the complaint; the swelling of the parts about the ear is not considerable; the nose discharges a vast quantity of mucus; the patient is troubled with cough and tooth-ache; and not unfrequently an enlargement
enlargement of the neighbouring glands is conjoined with the catarrhal swelling of the fauces.

The inflammatory otalgia sometimes terminates in the formation of an abscess, which may be superficial, being then sufficiently manifest from the presence of the ordinary symptoms of a cutaneous collection of matter. In this case, the fever and pain abate as soon as the abscess is opened, or has spontaneously burst, and the pus has been discharged. In other examples, the matter forms more deeply in the cavity of the tympanum, and it either makes its way outward by ulceration of the membrane tympani, or, in a more favourable way, through the Eustachian tube. When the abscess occupies a still deeper situation, that is to say, when the matter collects in the labyrinth, a necrosis of the bones often follows, the abscess either discharging itself into the cavity of the tympanum, or becoming diffused under the pericranium.

The otalgia curvis may originate from a caries, or rather a necrosis of the temporal bone, or, sympathetically, from a caries of one of the teeth. As the communicating branches of the facial nerve are affected, we see why paralysis of the muscles of the face is a frequent concomitant of this species of otalgia.

The otalgia from extraneous substances in the ear, as maizes of hardened cerumen, infects, the lodgment of any small body, like a pea, &c. may be suspected from the account which the patient will give of his case; but it may be clearly ascertained by examining the state of the meatus auditorius in a strong light, and by the use of a probe. An obstruction or compaction of the Eustachian tube may also become a cause of otalgia, as Callien afferted, by confining fluids in the tympanum.

From what has been stated, it is obvious that although otalgia may indeed at times be an idiopathic disorder, it is more commonly only symptomatic, in which last circumstance it necessarily requires for its relief the same means which are proper for the cure of the primary disease, of which it is merely the effect.

In otalgia, the prognosis generally differs according to the seat of the disease, its nature and violence, and the ease or difficulty of removing the cause. The following circumstances are more or less favorable to the prognosis, according to the case.

Young persons usually suffer more severely from ear-ache than older subjects, and experience more serious degrees of indisposition from the complaint. The internal inflammatory otalgia which produces suppuration affects the trunk of the auditory nerve itself, and discharges its matter within the cranium, may destroy the patient in a few days, if we are to credit the observations of Callien. A subsidence of the inflammation, as indicated by a remission of the fever and pain, and a speedy evacuation of the matter by the rupture of the abscesses, are events which augur a favourable termination of the disorder. When suppuration has occurred in the cavity of the ear, and the abscess uncomplicated with any carious affection has burst and discharged itself through the meatus auditory externus, the disorder may prove no more dangerous than any other simple abscesses. For the most part, after every severe attack of otalgia a degree of deafness remains, and this happens with still greater certainty when the case has been attended with suppuration.

The treatment of the various forms of ear-ache must of course depend upon the nature of the causes of the disorder. In general, however, if inflammation exist in the organ, it is to be opposed by the active employment of antiphlogistic remedies, especially topical bleeding with leeches, venesection, gentle purgatives, and anodyne fomentations. When matter is collected, the bursting of the abscesses should be accelerated with emollient applications, or an opening should be made with a lancet. In such circumstances, the ear should be frequently cleansed by means of injections, which, generally speaking, ought to be of a simple unirritating kind. Foreign bodies must be extracted. A morbid sensitiveness in the nerves of the ear must be lessened by suitable internal and external remedies, the use of opium, anodyne fomentations, the exhibition of conium or fras/minum, the introduction of a drost of soft cotton into the meatus auditorius, dipt in a mixture of olive-oil and laudanum, or the tinctura camphora, a perpetual blister in the vicinity of the ear, &c.

OTIS, in Geography, a town of Berkshire county, in Massachusetts, containing 1,111 inhabitants.

OTSEGO, l. 6, r. 38,802 inhabitants, of whom 74 are slaves.

OUACHITTA, a county and parish of the territory of Orleans, which, in 1810, contained 1,077 inhabitants. The lakes of this territory are, cotton, tobacco, lumber, and peltries. Ouachita river is not navigable in autumn, when the waters are low, for any vessels above the size of canoes.

OVERTON. Add—Allo, a county of West Tennesse, containing 564,3 inhabitants, of whom 355 are slaves.

OUGEN, col. 6, l. 39, for here r. yest.

OUNDLE. In 1811, the parish of Oundle contained 362 houses, and 1,833 persons; 821 males, and 1,012 females: 62 families being employed in agriculture, and 302 in trade, manufactures, and handicraft.

OWNHEY, col. 2, l. 18. Its height is estimated at no less than 18,400 feet.

OXALIC Acid, in Chemistry. The last analysis of this acid is by Berzelius. According to him, it is compos'd of

<table>

OXYGEN Gas, in Chemistry. According to the most recent determinations, the specific gravity of this gas is 1.111; and 100 cubic inches of it, at a mean temperature of 150 degrees, and 760 mm. pressure, will weigh 38,883 grains. See Aromat Theory.

OXYGENIZED Acids. M. Thenard has recently been enabled to combine oxygen with acids almost to an unlimited extent, chiefly by means of the peroxide of barium. His general method was, to dissolve the peroxide of the acid intended to be oxygenized, and afterward to separate the barytes by means of sulphuric acid; the oxygen was thus transferred from the peroxide of barium to the acid, and by repeating the operation he found that additional doses could be added. In this way, he oxygenized the nitric, muriatic, phosphoric, and other acids, and by taking advantage of its other properties, the muriatic acid in particular was oxygenized, even so far as to contain 64 atoms of
OXY

of oxygen to 1 of muriatic acid. These oxygenized acids combine with the different bases, and neutralize them; but they are by no means permanent, readily giving off their superfluous oxygen upon the application of heat, &c. The oxygenized muriatic acid also is decomposed by the oxyd of silver, chloride of silver is formed, and the oxygen is set at liberty.

By similar methods, M. Thenard has been able to combine additional doses of oxygen with many of the metallic oxys. See Annales de Chimie et Physique, vols. viii. and ix.

OXYMURIATIC Acid. See Chlorine.

OXYPRUSSIC Acid. See Cyanogen and Prussic Acid.

Vol. XXVI.

PACKERSFIELD, 1. 3, r. 1076.

PACOLET. Add—Also, a town of Rutland county, in Vermont, containing 2233 inhabitants.

PADMA, l. 2, del of.

PAINT, in Geography, a township of Fayette county, in Ohio, having 334 persons.—Also, a township of High- land county, in Ohio, with 775 inhabitants.

PAINTING in Enamel. Of all the various mediums of painting none is so durable as enamel, since time, which destroys all other things, alters neither its beauty nor its brilliancy; and that this great advantage may not be too easily attained, it may be laid, also, that no other method of painting unites in itself so many difficulties in the execution.

Enamel painting differs from every other kind of painting, in employing, as a vehicle for the colours, glafs or some vitreous body, to hold the parts together, and fix them to the ground on which they are laid. This being mixed with the colours, and fused or melted by means of heat, becomes fluid; and having incorporated with the colours, forms together with them a hard shining mass. This vitreous body, called flux, is to an enamel picture what oil, gum, or varnish, is in the other modes of painting, as by its means the work acquires its full degree of brilliancy and depth. See Flux.

The quality of the flux is an object of the greatest consideration to the enamel painter; when it is easily fusible, it is called soft; and when it requires a greater degree of heat, it is called hard; these terms are applied as well to the enamel grounds, and the other vitreous substanstes employed, as to the fluxes. It is essential that the fluxes compounded with the different colours should be of the same degree of hardness, or nearly so: as otherwise none, from being too soft, would be destroyed by the fire; while others, from having the contrary defect, would not be fixed to the plate, nor acquire their proper colour. It is necessary too, that the plate or enamel ground on which the picture is painted should be harder than the colours; for if they both melted with the same degree of heat, they would necessarily run together, and render the work indistinguishable.

The ground-work of the enamel plate is metal. Gold and copper are those chiefly employed. For small plates, where great neatness and delicacy are necessary, gold is preferable, on account of its not blistering round the edges in the fire, as is the case with copper: for large plates, copper is preferred, not only on account of the difference of expense between it and gold, but because it is found from experience to be better: gold being a much softer metal than copper, the plate, if of any size, is not found to retain its original form, in passing through the fire, so well, when made of it, as when it has copper for its bases.

The form of the enamel plate is slightly convex; if it were made quite flat, in passing through the fire repeatedly it would become concave. It is on this account that gold is not proper for large plates, being heavier as well as softer than copper: its own weight added to that of the enamel would naturally tend, while in a state of fusion, to sink them in the middle, and render the surface warped and uneven, unless they experienced resistance from the back, which would most probably occasion the destruction of the whole.

When platina was first discovered, it was imagined, from its great difficulty of fusion, that it would be of essential service in the making of enamel plates, but it was found to be useless for that purpose: as, although a plate made of it passed through the fire with its form unaltered in the highest degree, there was found wanting that union between the enamels and the metal on which it is laid, that is so necessary to ensure its safety, since a slight shock was sufficient to separate them and leave the platina quite free from the enamel. With gold and copper it is quite different, it is hardly possible to free the gold entirely from the enamel, and so strict is its adhesion to the copper, that if broken it invariably brings a lamen of the copper with it. The mode of preparing the enamel plate for painting is exactly similar to that for watch and clock dialing (see Enamelling), with this exception, that over the enamel is passed a softer body, a flux for the purpose of incorporating with the colours laid on: this flux should agree with every colour used.

The colours used in enamel painting are all prepared from metals, earths, or other mineral bodies, mixed and melted with certain proportions of flux, which, when fused, discover the colours, and fix them to the plate. The colours of the enamel painter are few, and his palette, when compared to that of other artists, of the most discouraging description, many of them appearing very different before and after passing the fire. This is indeed one of his greatest difficulties, and one which requires the greatest practice to overcome.
The colours used in enamel are few and simple, and from them the different tints should be made by the artist himself, (and not by the colour-maker, as used to be the case,) in the same manner as in any other way of painting. They are, white, yellows, rose-colours or reds, browns, blues, and blacks. The white is prepared from tin; the yellows from silver, antimony, and from some ochres; the rose-colours from good; the blues from cobalt; and the browns and blacks from iron. A red may be prepared from iron, and a green from copper, but these will not agree with the other colours. A green cobalt has been lately found in some parts of Germany, from which a green may be made, as also one from the chrome; but neither is found to be in any respect better than that which may be made from blue and yellow, and it is therefore unnecessary to encumber the palette with them. No colour should be admitted till, from repeated experiment, it has been found to agree with every other in every possible combination.

The oils employed are essentiai, and they are such as on application to the fire evaporate with a flight degree of heat; for this purpose, the oil of spike lavender is the best. The oil of amber is used to keep the colours moist for the day's use, as it does not evaporate before exposure to heat. A thick oil of turpentine is likewise used for the purpose of binding the colours together, and making them work more pleasantly; this however must be done with the greatest caution, as if used too freely it will not escape in the fire, and will occasion corrosion.

The last proceeds which the enamel picture undergoes is that of passing the fire: this is done after every painting, and is very often necessary; as without it the artist cannot tell the real state of his work. The fire for this purpose is of the same utility to the enamel painter, as a proof of his plate is to the engraver; it tells him what he has accomplished, and points out to him what remains to be done. The last time of passing through the fire is, as may naturally be supposed, a moment of great anxiety to the artist, as he may, in an instant, witness the destruction of his picture, and fee the labour of months rendered unavailing, by the enamel ground opening and throwing a crack across his work. This accident may sometimes be repaired, but never without great labour. The mode of firing the picture is exactly similar to that used in the making of the clock plates. See Enamelling.

The history of enamel painting is involved in the greatest obscurity; of its antiquity, we have ample testimony in the account which Diodorus Siculus gives of the painted walls executed by the command of Semiramis, in her city of Babylon. At this time, enamel painting had attained the highest eminence to which any art can aspire; when it was made the engine of policy, and the instrument of religion; when it was employed to commemorate the heroic deeds of the living, and celebrate the virtues of the dead. How long it retained this elevation we know not, but it is probable it was extemned while Babylon remained, and, like that majestic city, was overwhelmed with such entire ruin, as feecely to leave a wreck behind.

The coloured beads which envelope the mummies, and the painted idols of the Egyptians, prove that this art was not unknown to that extraordinary people; although nothing which exactly deferves the name of painting has descended to us.

To the Greeks it was known, as is evident from their painted vases, which although generally executed in one or two colours, yet furnished some instances in which, departing from this simplicity, they have displayed a variety of colours with great successe.
By the Romans, if this art were not unknown to them, which, considering their intimate knowledge of the acquirements of the Greeks, is not probable, it was at least unpractised: sculpture with them seems to have superseded painting in the decoration of their vases, the embellishing of their sarcophagi, and for all ornamental purposes.

Some ornaments which have reached our time indicate that the Saxons were not unacquainted with the art of enamel; and in the tomb of Edward the Confessor are many specimens of coloured glass. Other monuments of a subsequent period prove that the art regularly declined, although with varied successes, at different intervals; but in the tomb of Edward III. John of Eltham, and some others of that period in Westminster Abbey, are striking instances of the art of enamelling. On the monument of the king, the coats of arms are enamelled in their proper colours on thick plates of copper; and the armour of the warrior is curiously ornamented with an enamelled pattern of blue, white, and gold.

These remarks may be said more properly to relate to the practice of enamelling than to the art of enamel painting, and are only mentioned here to prove that it was never entirely lost fight of; although it was long after that it became enamel painting, as that term is now understood.

In the sixteenth century, ornamental works of considerable dimensions were executed: every one conversant with the arts must be acquainted with the painted dials called Raffaelle ware, copied from the designs of that immortal painter and his disciple Jusep Romano: these are, strictly speaking, legitimate enamel pictures, executed on a ground prepared as it is at present, and differing only in the shape. They are generally painted in two colours.

Enamel painting seems long to have remained in this state, and there are but few examples where a variety of colours was used until the time of Petitot, who died in the latter end of the seventeenth century. He is the first painter in enamel of whom any particular mention is made: he was in this country in the reign of Charles I. His pictures are of a small size, not exceeding two or three inches; they are very highly and beautifully finished, but certainly not deserving the distinguishing commendation bestowed on them by Pilkington, who says, that if they were magnified to the size of life, the pictures of Vandyck would suffer by the comparison. His best pictures were copied from that master, and are of a small size: his portrait of lady Southampton, a whole length after Vandyck, in the duke of Devonshire’s collection, the largest picture he ever painted, is certainly not among his best. His works have too much that particoloured appearance, for which enamel painting has by persons of true taste been so justly censured. The reputation of Petitot was no doubt owing to the novelty of his pursuit, as he has since been much surpassed. His son practised the same art when his father quitted this country, and his pictures are now generally taken for those of his father.

No farther mention is made of enamel painting until the reign of queen Anne, when Boit, who polished very little ability, appeared: he did not practise long in this country. He had the honour, however, of instructing Zincke, who far surpassed not only his master but Petitot. Although his pictures are not so highly finished, his work has the least of that parti-coloured effect, and consequently more the appearance of nature, than those of his great predecessor. Petitot’s best works were copied from Vandyck, those of Zincke from Kneller. Meyer, who chiefly painted in water-colours, commenced enamel painting on the decline of Zincke; as he applied but little to this branch of art, he could not be expected greatly to excel: his principal work, the portrait of the marquis of Granby, in the king’s collection, though polished of considerable ability and sweetness in the execution, has too much of the defects of early enamels, and by no means conveys an idea of the fyle of the great original from whom it is copied, sir Joshua Reynolds. The best pictures of Meyer are inferior to those of Zincke. Spencer’s pictures, as far as they go, are very beautiful both in colour and execution; but he, as well as all other enamel painters, confined his efforts to a very small scale, and either did not with or thought it impossible to obtain depth and richness; his pictures, therefore, are little more than beginnings. The other professed of this art, of this period, were Hole, who afterwards became a portrait-painter in oil, Spicer, Burch, and Craft. Craft is only mentioned here to caution future enamel painters against an error into which he fell,—of painting on an enamel ground without the addition of a flux. The flux being hotter than the enamel incorporates more readily with the colours, and gives that melting softness to the tints so peculiar to enamel painting. By omitting this, he deprived himself of one of his greatest advantages; and the consequence is, that instead of great delicacy and finishing, his pictures appear hard, crude, and inharmonious.

Stubbs, an animal painter in oil, a comparative anatomist, and eminent as either, was also a painter in enamel. Unfortunately he took up this branch of art on too confined a principle, considering rather its durability than that excellence which alone can render durability truly estimable. His pictures are painted on plates made of Wedgwood’s ware, and he prided himself on being the maker of his colours, which are, however, of the most ordinary kind. Now, although it is defirable that the artist should know how to make his own colours, it is equally certain, that if he can get them made for him, it is much better to do so than to employ his own time in preparing the means, when it should be directed to the accomplishment of the end. Neither the material on which he worked, nor the colours with which he painted, were calculated to bear more than two or three fires, consequently great perfection could not be expected; and although they might tolerably well answer his purpose for the painting of animals, it is certain that his pictures in oil are in every respect inferior to those he executed in enamel.

We have now brought enamel painting down to our own time, when such great improvements have been made by the exertions of a living artist, Bone, as to render it an era in the art; that he is living, must be our apology for not entering into a full discussion of his merits: but it must be said, that by his endeavours, aided by the liberal encouragement of that true lover and magnificent patron of the arts of his country, the Prince Regent, from a mere mechanical labour, enamel painting has become a highly useful branch of a liberal art; no longer confined to things merely ornamental, no longer differing from every other mode of painting, as much in its effect as process, it now assumes the appearance of highly-finished oil-painting, with the advantage of perpetual durability. As enamel painting from its nature must be always copied, the style of the original should be perfectly observed, as to convey an instantaneous recollection of the painter. In this respect, the works of Bone are pre-eminent; whether the severity of Leonardo, the purity of Raffaelle, the glow of Titian, or the splendour of Rubens, is enframed to his pencil, each is alike successfully portrayed. To the admirers of that ornament of our country and of the arts, Reynolds, this must appear in its full force; and it must afford them great pleasure.
pleasure to find, that such close imperishable copies of the
rare and justly valued pictures of this great master can thus
be transmitted to posterity.

Of the advantages of the science of painting, it will be super-
fuous to speak, they are so obvious as to occur to the
most superficial observer. Its unalterable durability is
alone sufficient to counterbalance every disadvantage to
which it is subject: to point for eternity is the peculiar
province of the painter. To him the hyperbolical
compliment which Pope paid to Jarvis is justly due:

"Beauty, frail flower, which every season fears,
Bloom in his colours for a thousand years."

How often have we mingled pity with our admiration of
the fine works of the great masters, coloured in particular,
when we have observed the dreadful ravages of time on
their pictures. By enamel painting this disadvantage is
removed; by means of this art, posterity will become
acquainted with the real merits of their predecessors; and
those works which must of necessity decay, will be preferred
in all their original splendour. How invaluable at present
would the portraits of the illustrious characters of Greece
and Rome appear! Had enamel painting been known as
it is practiced at present, we should not now have to seek
their imperfect remembrances in buffs and gems.

Thus has this art, sometimes shining forth in full
splendour, sometimes nearly merged in obscurity, sur-
vised the lapse of ages, and descended to the nineteenth
century, whose enlightened policy and liberal patronage
will never allow it to be again disregarded; but will employ
the talents of the enamel painter in the way which they can be
best employed, by preferring for futurity the portraits of
our illustrious ancestors, whose deeds have conferred an
honour on their country; and in handing down to posterity
the remembrances of our great contemporaries, and in per-
petuating the best efforts of native genius. See Enamel-
ing.

Painting of Clocks and Watches. See the preceding
article, and EnameUing.

Maine, and county of Lincoln, having 761 inhabitants.

PALLADIUM, in Chymistry. According to the recent
determinations of Dr. Thomson, the weight of the atom of
this metal is 79, oxygen being 16; though this, perhaps, is
not to be depended on, but as an approximation.

Palladium. See Mineralogy, Addenda.

PALMA, Giacopo, in Biography, called the Younger,
to distinguish him from his great uncle, has been styled by
Lanzi, "the last painter of the good and the first of the
bad epochs of the art of Venice." He was born in 1544,
the son of Antonio Palma, an obscure painter, who first
taught him the little he knew, and encouraged him to study
the works of others, particularly those of Tintoretto and
Titian. At the age of fifteen, he obtained the patronage of
the duke of Urbino, who sent him to Rome, and maintained
him there for eight years, during which time he employed
himself in copying the works of M. Angelo, of Raphael,
and above all, of Polidoro, and was employed by the pope
to adorn one of the rooms of the Vatican.

On his return to Venice he found but little employment,
Tintoretto and Paolo Veronese occupying the places of
renew, and being engaged in all the public works. Their
disagreement with a celebrated architect and sculptor,
named Vittoria, furnished Palma with a patron, who endeav-
ouring to lower the esteem of his enemies, used his utmost
efforts to establish the rival painter, afforded him with his
advice, and found him employment. Their united en-
daevours failed however of success, and Palma was obliged
to be contented to hold the third rank in the art till their
deaths left him without a rival. He had, in the mean time,
painted in competition with them both, and produced very
excellent works.

When he was left alone and was much employed, he
relaxed from the care and diligence he had formerly used,
and his works became light in execution, so much so that
Cefare d'Apina, remarking upon the lightness of the
style in which he painted, observed, that he meant to make
some stay at Venice, to learn of him to make such admirable
sketches. When price and time, however, were left to his
own discretion, in which he did not abound, he produced
some works worthy of his former fame; such as the altar-
piece at the church of S. Cosmo and Damiano; the cele-
brated naval battle of Francisco Bembo, in the public
palace; the Saint Apollonia at Cremona, &c. The com-
positions of the younger Palma are more disinguishable for
their copiousness than the judgment with which they are
conducted, and his design is more bold than correct. His
colouring is more vivid than true, but is deservedly admired
for its richness, fineness, and freshness.

PALMER, in Geography, l. 4, r. 1114.

PALMYRA, a township of Maine, in the county of
tomfort, having 117 inhabitants.—Allo, a township of
Wayne county, in Pennsylvania, having 336 inhabitants.—
Allo, a township of Knox county, in the Indiana territory.

PALOMINO Y VELASCO, Don Antonio, in Bio-
ography, a Spanish painter, born in Valencia, in 1653.
He studied at Cordova in grammar, philosophy, theology, and
jurisdiction; the elements of his art he acquired of Don
Juan de Valdes Seal, and to acquaint himself with the
styles of the different schools, he went to Madrid in 1678.
Here he painted the gallery del Cierzo, and pleased the
king and the minister, and in 1688 he was made painter
to the king. He was overwhelmed with commissions, for
many of which he made only the designs; but whatever
was begun and terminated by himself in fresco, or in oil,
polettes invention, design, and colour, in the effential,
and taille and science in the ornamental parts. His style
was certainly more adapted to the demands of the epoch in
which he lived, than to those of the preceding one, and
probably would not have obtained from Murillo the praises
lavished on it by Luca Jordan.

Palomino may be considered as the Vafari of Spain,
as copious, as credulous, and as negligent of dates, too
garrulous for energy, and too indefinite for the delineation
of character, but eminently useful with the emendations of
modern and more accurate biographers.

His literary work is divided into three parts, theoretical,
practical, and biographical. The first part bear one title,
viz. "El Parnaso Espanol Pittresco y escala optica." The third
part, distinguished by that of "El Parnaso Espanol Pittresco
laureada, &c." Madrid, 1724, though perhaps only intended
as an appendix to the two former, is by far the
most important and interrelling.

PALOU, or PALO, l. ult. add—palacial of Erzerom,
 situated on the edge of a mountain and the banks of the
Euphrates: the population amounts to about 8000 souls,
Turks, Armenians, and Kurds: the river here is very rapid,
and from the bad construction of the bridges made of wood,
whole caravans have been swept away after the melting of
the snow. The district of Palo is four days' journey in
length and two in breadth.

PANDEANS,
PANDEANS, a title given to itinerant companies of Italian musicians, who perform on the Syrinx or Pan's pipes of different pitches with their mouths, and accompany themselves on different instruments with their hands and feet.

The lowest set of reeds (the septem discrimina vocum of Virgil) is called the contra basset, or double-bass; the next fogato, or bassoon; the third, feuienty, is the tenor or second treble; and the fourth, or highest range of pipes, the first treble: so that in the aggregate there is a complete scale of four octaves, and they never play in less than three or four parts. The instrumens with which they accompany themselves with their hands are the cymbals, the triangui, the double drum beat at both ends, the mezza luna, a Turkish instrumemt, and the tambour de barque.

The reeds or pipes are fastened under the chin of the performer, and the lip of the player runs from one to the other with seening facility, without moving the instrument by manual assistance. (El supr talamus unce percurrere liber, Lucr. Tu.) The music which these people perform is very gay and pleasing. One of the company with whom we conversed told us that they were Milanese peasants and villagers, not allowed to stroll into great cities: which accounts for our never having heard them in their own country, nor any of our friends who have made the tour of Italy, and remained there some years.

The ufe which these ingenious people have made of Pan's pipes, by playing in troops and in different parts, is beating the ancients at their own weapons. The Grecian shepherds of Theocritus, and the Roman of Virgil, contend in dialogue, but never perform in parts.

It will be observed, that some of the performers, particularly the first treble, have more than seven pipes, which enables them to extend the melody beyond the feventy. PANIS. Add—See TOWIACHES.

PANTING, in Physiology. See LUNGs.

PANTON. Add—containing 520 inhabitants.

PARK, Mungo, in Biography, a celebrated traveller, was the son of a farmer on the banks of the Yarrow, near the town of Selkirk, in Scotland, and born on the 10th of September 1771. After having received the first rudiments of education in his father's family, he was removed to a grammar-school at Selkirk, where he remained for a considerable number of years, and where he was distingished by his application and improvement. At this early period, though he was sedate, studious, and thoughtful, he manifested traces of that ardent and adventurous disposition which formed his distinguishing character in future life. Preferring the medical to the ecclesiastical profession, for which he was originally designed, he was bound apprentice, at the age of 15, to Mr. Anderson, a respectable surgeon at Selkirk; and after residing with him for three years, he removed in 1789 to Edinburgh, where he attended the usual medical lectures during three successive sessions. In this situation he distinguished himself among his fellow-students, by ardour and fidelity in the prosecution of his studies, and by particular attention, during his summer vacations, to botanical pursuits, in which he was assisted by his brother-in-law, Mr. James Dickson. Upon his removal to London, this eminent botanist introduced him to Sir Joseph Banks, by whose recommendation he was appointed assistant-surgeon to the Worcesters. East Indians. In 1792 he failed for Benecoola, and having availed himself of the opportunities for scientific researches, which this voyage afforded him, the result of his inquiries and observations was communicated, after his return, to the Linnean Society, and published in the third volume of their Transactions. Some years prior to this period, a society had been formed with a view of promoting discoveries in the interior parts of Africa, of which we have already given a brief account under the article AFRICAN ASSOCIATION; and several persons had been employed in accomplishing the laudable purposes for which this society was established. Among these, we may reckon Meffrs. Ledyard and Lucas, major Houghton, and Mr. Hornemann, who fell sacrifices either to the severity of the climate, the fatigue of the service, or the violence of the natives. The Society, though disposed to afford liberal encouragement to any person who was qualified for this undertaking, and who had at the same time resolution sufficient to engage in it, with the prospects which that experience presented to view, found themselves at a loss for a person in every respect fit for this hazardous mission. At this interesting period Mr. Park returned from India, and no person could have been found better qualified for such an adventurous office. Sir Joseph Banks, the distinguished patron of genius and science, had been his friend, and with him Mr. Park was in habits of frequent and intimate intercourse. Thus circumstanced he offered his services, and they were accepted. Having received his final instructions from the Society, he set sail from Portsmouth on the 22d of May 1795, and on the 21st of June landed at Jullifree, a small town near the mouth of the river Gambia, whence he proceeded to Pifania, where he was hospitably received by Dr. Laidley, to whom he had letters of recommendation. For an account of his progress, see the articles AFRICA and AFRICAN ASSOCIATION. Upon his return, he was received with cordial congratulation, both by his friends and the gentlemen of the African Association; and he was allowed to publish an account of his travels for his own benefit. In the mean while, Mr. Bryan Edwards, secretary of the Association, printed and distributed among the subscribers an abstract of the Travels from Mr. Park's papers. To this attraéct was annexed an important Memoir by major Rennell, containing geographical illustrations of Park's journey; and this, by Mr. R.'s permission, formed a valuable appendage to the fourth edition of the Travels. In the spring of 1798, government having it in contemplation to obtain a complete survey of New Holland, applied to Mr. Park for this purpose; but the proposed plan was never executed. The remainder of this year was spent by Mr. Park in visiting his friends in Scotland, and arranging the materials of his Travels. Towards the close of this year he returned to London, and devoted the principal part of his time to the correction of his MSS., which he committed to the press in the spring of the year 1799. The work, as soon as it was published, commanded an extensive and rapid sale, both on account of the interesting information which it contained, and the general elegance of its composition. An abstract of Mr. Park's discoveries, with
with regard to the easterly course and magnitude of the Niger, the large and populous towns and villages that occupy the interior parts of Africa, the discriminating character of the negroes, contrasted against that of the Moors, and the civilization of the inhabitants of the interior, beyond the influence of the slave-trade, compared with that of those who are situated near the coast, and a variety of other particulars relating to the soil and productions of the country, and the manners and habits of its inhabitants, has been already given under the articles AFRICA, MOROCCO, NIGER, &c. so that we need not here enlarge. The curiosity of the public was amply gratified, and the name and work of Mr. Park became singularly popular, though neither the one nor the other altogether escaped censure. The slave-trade was at this time a subject of general reprobaton, and attempts were repeatedly renewed for the abolition of it. It was, therefore, natural to imagine, that in a work of this kind, the author would have availed himself of the opportunities which his narrative afforded him, of expressing his decided disapprobation of this nefarious species of commerce: more especially as it was well known to many of Mr. Park's intimate and confidential friends, that in conversation he had frequently declared his abhorrence of slavery and the slave-trade. Nor was it sufficient to allege, as some of his advocates have done, that he considered the abolition of the slave-trade as a measure of state policy; and that it would be improper for him to give an opinion on a subject which was at this time under the deliberation of the legislature. This neutrality on his part, to say the least of it, led persons, who did not know his real sentiments, to reckon him among those who were hostile to the abolition; and his authority was triumphantly appealed to by the advocates of the slave-trade. Whilft he seems to have studiously avoided giving an opinion on the pernicious influence of this trade, he states facts which have been cited and strongly urged in favour of its abolition. In order to account for this kind of inconsistency without impeaching his integrity, we should recollect how he was circumstanced whilft he was preparing and publishing his narrative. "He was then," says a candid biographer, "a young man, inexperienced in literary composition, and in a great measure dependent, as to the prospects of his future life, upon the success of his intended publication. His friend and adviser, Mr. Bryan Edwards," (a Weit India planter, and a systematic advocate of the slave-trade in the House of Commons,) "was a man of letters and of the world, who held a distinguished place in society, and was besides a leading member of the African Association, to which Park owed every thing, and with which his fate and fortunes were still intimately connected. It is difficult to estimate the degree of authority which a peron possessing these advantages, and of a strong and decisive character, must necessarily have had over the mind of a young man, in the situation which has now been described. Suggestions coming from such a quarter must have been almost equivalent to commands; and instead of severally animadverting on the extent of Park's compliances, we ought, perhaps, rather to be surprized, that more was not yielded to an influence which must have been nearly unlimited." Mr. Park is known to have regretted that some parts of his publication, relating to the slave-trade, had been misunderstood, and applied in a sense which it was not intended they should have been. The writer of this sketch of his life knew, from personal intercourse, that he lamented any fulfilment of his integrity should attach to this part of his publication; and we can well imagine, that he did not perceive the bias of his mind, or the causes that produced it, which were apparent to every one besides himself. Such a bias would naturally result from the assistance afforded by Mr. Edwards in the composition of Mr. Park's work, and from the influence attending the connection that subsisted between them. How far Mr. Edwards's assistance might extend, it is difficult to say: but of this we are certain, that it was not such as to affect the authenticity of the work itself, or the literary reputation of Mr. Park; we regret, however, that in deference to Mr. Edwards's judgment or authority, Mr. Park should admit into his narrative some reflections pertaining to the slave-trade, which should have given occasion for concluding that he was friendly to its continuance, or that he should have omitted any favourable opportunity that occurred for expressing in an explicit manner his real sentiments concerning it. But it is now needless to pursue this kind of diffusion. The narration of Mr. Park, written as we have reason to believe by himself, entitles him to respect as an author; but he has other more unequivocal claims to grateful and honourable remembrance, as a person who hazarded much in making geographical discoveries, and who maintained in traversing unknown countries, and in very trying situations, a degree of firmness and self-possession that has seldom or ever been surpassed.

After the publication of his Travels, he returned to Scotland in the summer of 1799; and on the 2d of August in that year, he married a daughter of Mr. Anderdon of Selkirk, with whom he had served his apprenticeship. In the month of October 1801, he settled at Peebles, with a full purpose of pursuing his medical profession; but as he devoted much of his time and attention to the poor, the profits of his labours were inconsiderable; nor could he far bear wishing for a change of situation that would be more advantageous. His views, however, were directed towards a second African mission. A prospect of this kind was presented to him by a letter from Sir Joseph Banks, soon after the signature of the preliminaries of peace with France, in October 1801; but it was not till the autumn of the year 1803, that a specific proposal was made to him for this purpose. Previously disposed to accept it, he did not long hesitate in announcing his purpose; and, accordingly, he took leave of his friends, and left Scotland in December 1803, confidently expecting that he should soon embark for the coast of Africa. A variety of circumstances occurred which threatened the total failure of the expedition; however, in a course of time all difficulties were obviated; the objects and plan of the undertaking were settled to the satisfaction of Mr. Park, and he received a commission from government in January 1805, for conducting and executing it. To himself was granted a brevet commission of a captain in the navy, and to his friend Mr. Alexander Anderdon a similar commission of lieutenant; and Mr. Scott was appointed to attend him as a draughtsman. He was empowered to enlist at Goree any number of the garrison that would be necessary for his purpose, not exceeding 45, with such fortunes as would induce them cheerfully to accompany him. From Goree he was directed to proceed up the river Gambia, and thence, croosing over to the Senegal, to march by such routes as he should find most eligible to the banks of the Niger. The great object of his journey was to pursue the course of this river as far as it could be traced; to establish a communication and intercourse with the different nations on the banks; to obtain all the knowledge in his power respecting them; and to ascertain various points which he had stated in his Memoir. Mr. Park was empowered to draw for any sum which he might want, not exceeding 5000.

When the preparations for the expedition were completed, Messrs. Park, Anderdon, and Scott, proceeded to Portsmouth,
mouth, and being there joined by four or five artificers from the dock-yards appointed for the service, they set sail on the 30th of January 1805, and on the 28th of March arrived at Goree. On the 27th of April 1805, Mr. Park took his departure from Kaye, a small town on the Gambia, a little below Piania, having previously engaged a Mandingo prieft, named Ifaco, who was also a travelling merchant, and much accustomed to long inland journeys to serve as a guide to his caravan. On the 11th of May, he arrived at Madina, the capital of the kingdom of Woolli, and on the 14th he reached Kuffa, on the banks of the Gambia, where the river is about 100 yards broad, and has a regular tide. On the 18th, he crossed the river Nirkoo, 60 feet broad four feet deep, flowing at the rate of two miles an hour, and with a heat at two o'clock of 94° Fahrenheit, and arrived at Jallacotta, the first town of Tendico, at sun-fet. On the 20th reached Tendico or Tamibco, a village belonging to Jallacotta, lat. 13° 53', half a mile from which is a pretty large town, called Bady. May 21st at eight, halted at Jeningalla, near Buffa or Kabatenda. On the 24th, floated at Manifara, which consists of three towns, contiguous to each other, and distant from the village of Nittakaara, on the north bank of the Gambia, a mile and a half due south. Next day entered the Tenda or Samakara wildermefs, and halted at Sooteetaba, lat. 13° 33' 33", after leaving this place, crossed the first range of hills, which afforded a beautiful route and prospect. On the 26th reached Bee creek, lat. 13° 32' 45", W. long. 10° 59', where men and beasts were attacked by an immense number of bees, who seemed for a time to have completely terminated their journey. Arrived at Sibilkillin, after travelling four miles, on the 27th; and on the 28th, arrived at Badoo, a small town, consisting of about 500 huts, near which is another town of the same name; but the two towns are distinguished by the names of Samanding and Sanfuna, at each of which customs are demanded of all carriages or caravans, lat. 13° 32'. From Badoo proceeded to Tambahunda, about four miles east of it, and about four miles distant from the river Gambia, south of Badoo: leaving Tambahunda on the 30th, entered the woods, and at dark arrived at Tabba Gee, which was left at day-break the 31st of May, and halted during the heat of the day at a small village, called Mambiri. On the 1st of June, arrived at Jilfundu, a considerable trading town, containing about 2000 persons, who trade on credit, and are called "Juli," by way of distinction from the Slates, who trades with his own capital. At this place, lat. 13° 33', they are extortionately taxed by Mina Kuffa, who is reckoned one of the most avaricious chiefs on the road. On the 4th of June, arrived at Banierle, a Mahometan town, whose chief, Fodi Brisha, was one of the most friendly men they met with, lat. 13° 35'. The kingdom of Dentila is famous for its iron; and the flux used for smelting it is the ashes of the bark of the kingfisher. On the 7th of June, in progression of their journey, crossed the bed of a stream that runs towards the Falame river, called Samako, on account of the vast herds of elephants which wander themselves in it during the rains. At noon of the 8th, reached Madina, and halted by the side of Falame river; in the evening went to Satado, on the middle east of the river. On the 10th reached a small town called Shondo at sun-fet; here they were alarmed by a tornado, which was the commencement of the rainy season, and extremely pernicious to the attendants on the expedition.

In the vicinity of this town are four gold-mines, which were inspected, and which afforded occasion for witnessing the expeditionsmode practised by the female natives, for separating the particles of gold from the sand. Leaving Shondo on the 12th, they travelled along the bottom of the Konkodoo mountains, which are very steep precipices of rock, from 80 to 200 or 300 feet high, and at noon reached Dindikoo, near which are gold-pits. On the 13th, they arrived at a small village called Fanka, four miles N.W. from Binlingalla, lat. 13° 22' 30".

On the 15th, they proceeded from Fanka to the delightful village of Toombin, and on the 17th travelled from Serimana to Fajemmla, a small village, fortified with a high wall, the chief of which is the most powerful in Konkodoo, and has in subjection the whole country from Toombin to the Ba Bing. At Fajemmla, N. lat. 13° 35', the customs paid to the chief are very high. On the 20th, they arrived at an almost deserted village, called Necakalla, close to the Ba Lee or Honey river, where they saw two crocodiles and an incredible number of large fish. On the 21st, they passed the village of Boo tormentooran, and halted for the night at the village of Doggkotta; and the next day they observed many very picturesque and rocky hills during their march, and in the evening halted at the village of Talting, situated on the summit of the ascent which separates the Ba Lee from the Ba Bing. On the 23d, they arrived at the village of Gimba, or Kimba; and about noon reached Sullo, an unvallewed village, at the bottom of a rocky hill, at which place horse-flesh is much valued as food, and where they observed on the adjacent rocks numbers of large monkeys. On the next day, they arrived at Seocoa, lat. 13° 27' 26", and here they halted on the 25th. On the following day, they arrived at the village of Konkrom, about seven miles east of Seocoa, W. long. 8° 0', near the river Ba Bing, a large river quite navigable, and which they crossed in canoes on the 27th; and on the next day, they passed by several heaps of stone, precisely the same with those that are called in Scotland cairns. In pursuing their march, they were alarmed by herds of lions and wolves, and on the 30th, reached a small town, called Kandy. On the 2d of July, they arrived at Koeena, a village encompassed by a wall, and where they were terrified by the roaring and affright of several young lions. On the 3d, they arrived, after a march of six miles, at Koombandi; and at sun-fet reached Fonilla, a small walled village, on the banks of the Wonda, which they crossed on the 4th in canoes, Ifaco having had a surprizing escape from the jaws of a crocodile. On the 5th, they arrived at a village called Boodlinkoombo, sometimes Moaiaharra; and on the 10th, left this village; and eight miles N.E. passed the village of Serrabobo, and a little before sun-fet reached Sabooloo, (Dooty Matta,) a scattered unvallewed village, lat. 13° 50'. From Sabooloo, or Mallahoo, they purfued their march on the 11th to Keminoom, or Maniakorro, a walled town, strongly fortified, lat. 14°; near which the river Ba Lee runs with great velocity, and breaks into small cataracts. This place is notorious for theft and impudence, and they were glad to leave it on the 13th, and to pursue their march by a walled village, called Numbaoo, to the banks of the Ba Woolimma, where they arrived on the 19th; and having crossed the river by means of a wooden bridge of singular construction, they reached Mareena on the 21st, where they suffered depredation; and on the 22d, they arrived at Bangaff, six miles from Mareena, a large town, four or five times larger than Maniakorro, and fortified in a similar manner. On the 27th, they arrived at Nummafooloo, a large but much ruined town, and which they left on the 30th.
31st, they halted at Sobee, a town, the walled part of which serves as a citadel. On the 2d of August, they halted at Bandalung; and on the 3d, at Bandaloo; and on the 4th reached Koolhori, a town partly walled, but having the greater part of its huts without the walls. On the 6th, they reached Ganifarra, a small beggarly village. On the 9th, they crossed the Ba Woolli, a very deep river, flowing at the rate of four or five miles per hour. They pursued their route, until on the 13th, those of them who survived reached Koomikoomi, where they halted; lat. 13° 16' 26". On the 15th, they reached Doombilla, where Mr. Park met with an old friend, Karfa Taura, a worthy negro whom he had known, and whose kindnotes he had experienced in his former travels. From Doombilla, they proceeded on the 18th to Toniba, and from thence they ascended the mountains south of it, till having attained the summit of the ridge which separates the Niger from the remote branches of the Senegal, Mr. Park had the satisfaction of once more seeing the Niger rolling its immense stream along the plains. But this satisfaction was accompanied by the mortifying reflection, that three-fourths of the soldiers had died on their march, and that in their weakly state, they had no carpenters to build the boats in which they proposed to prosecute their discoveries. It was, however, a pleasing consideration, that in conducting a party of Europeans, with immense baggage, through an extent of more than 500 miles, he had always been able to preserve the most friendly terms with the natives; and hence he was warranted to infer, that with common prudence, any quantity of merchandise may be transported from the Gambia to the Niger, without danger of being robbed by the natives; and that this journey may be performed in the dry season, with a probability of not loosing more than three or at most four out of fifty. But Mr. Park was unfortunate in undertaking such a journey with the prospect of the rainy season, and the event proved, that this feafoo fort in before his journey to the Niger was more than half completed. The effect produced on the health of the soldiers by a violent rain, preceded and accompanied by tornadoes, on the 15th of June, was almost incalculable; twelve of them at once were dangerously ill, and from this time, the great mortality commenced, which was ultimately fatal to the expedition. When he reached the Niger at Bambakoo, where the river begins to be navigable, on the 19th of August, there remained out of thirty-four soldiers and four carpenters, who left the Gambia, only six soldiers and one carpenter, and the principal persons who composed the expedition, besides Mr. Park himself, were three, viz. Mr. Anderson, Mr. Scott, and lieutenant Martyn, who were more or less affected by the disease of the climate; the two former very seriously, so that Mr. Scott was left behind at Koomikoomi, and died without reaching the Niger. Mr. Park had been slightly affected, and it is wonderful, that the anxiety and fatigue which he must have experienced did not break down both his spirits and his strength.

Having arrived at the Niger, Mr. Park, and the few companions that remained, embarked in a canoe on the 22d of August, and were borne away by the current at the rate of about five knots per hour. The river is at the point of embarkation an English mile broad, and at the rapids, of which there are three principal ones, it spreads out to nearly twice that breadth. On the 23d, they arrived at Marraboo, where they were joined by those who came by land. Isaaco was immediately dispatched to Sego, the capital of Bambara, to negotiate with Manfong, the sovereign, for a free passage through his dominions, and whilst Mr. Park waited for his return, he was feized with the dysentery, that threatened the termination of all his projects. But by the aid of medicine and the advantage of a good constitution, he was soon restored to health. Many difficulties and delays occurred in the negotiation, which was conducted on the part of Mr. Park with singular judgment and address; but at length, after many unfavourable rumours, which kept his mind in a state of diffuelling suspense, Manfong deputed a messenger to conduct him towards Sego. Under his escort, he left Koolkoro (N. lat. 12° 52') on the 13th of September, and enjoyed the beautiful views which his voyage afforded him; "the river," as he says, "being sometimes so smooth as a mirror, at other times ruffled with a gentle breeze, but at all times sweeping us along at the rate of six or seven miles per hour." On the 14th, they departed from Deena, where they had lodged, and arrived at Yamina, (lat. 13° 15') where they halted on the 15th; and on the 16th reached Samee (lat. 13° 17'). A deputation of Manfong's friends visited Mr. Park, in order to hear from himself a statement of his views and purports in the voyage he was undertaking. His statement was satisfactory to the grandees that had executed this commission, and Mr. Park was assured of permission to pursue his voyage, and of protection from Manfong as far as his power extended. The king and his courtiers were much gratified by the presents which they received on the occasion. Accordingly, on the 26th of September, Mr. Park proceeded from Samee to Sanfandung; which fee. Here he intended to provide a proper relief for his further navigation down the Niger; but it was with difficulty that he procured from Manfong and his son, in return for the presents he had given them, two decayed canoes, which merely afforded him materials for constructing with his own hands, and some assistance from one of the surviving soldiers, a flat-bottomed boat, to which he gave the foundling title of His Majesty's Schooner, the Joliba. In the meanwhile, Mr. Park was informed of the death of Mr. Scott, and he had now occasion to lament the loss of his friend Mr. Anderson, who died, after a lingering attack of four months, on the 26th of October. The sensibility he expressed on this occasion did honour to his feelings, and yet considering his present perilous situation, and the dreary and discouraging prospects which presented themselves with regard to the projects of his undertaking, he must polls a very high degree of equanimity,自制力, and self-possession. On the 16th of November, the schooner having been completed, and every thing in Mr. Park's power to command being ready for the voyage, he clofes his journal; and in the course of the succeeding days previous to his embarkation, which was on the 19th, he wrote several letters to his friends and kindred in England and Scotland. In these letters, we discover traces of that deliberate and inflexible resolution, without effort or ostentation, which proved a distinguishing feature of his character. From this period, we have no strictly authentic information concerning Mr. Park, or the progress and termination of his expedition. In the course of the year 1866, conjectures and reports agitated the public mind; and the agitation was aggravated, by intelligence communicated by the native traders from the interior of Africa to the British settlements on the coast; whence it was concluded, that Mr. Park and his companions were killed. In consequence of these unsatisfactory and alarming rumours, lieutenant colonel Maxwell, then governor of Senegal, obtained permission from government to engage a proper person to investigate and ascertain the truth of these
rumours. Accordingly, he engaged Iiacao, Mr. Park's
guide, to conduct this business. In January 1810,
Iiacao left Senegal, and returned on the 1st of September,
1811, fully confirming the reports of Mr. Park's death.
His journal, including another from Amadi Fatouma, the
guide who had accompanied Park from Sanfanding down
the Niger, was delivered to the governor, and transmitted
by him, after having been translated from Arabic to
English, to the secretary of state for the colonial depart-
ment. From Amadi Fatouma's journal we learn, that
the conductors of the expedition went from Sanfanding to
Silla, where Mr. Park had ended his first voyage; and
that from thence, Mr. Park, Martyn, three other white
men, three slaves, and Amadi, as guide and interpreter,
were in number, proceeded in a canoe to Gima; and as
they passed Sibby, or Dibbie, they were attacked by an
armed force in three canoes, which they repulsed. Again
at Rakbara, or Kabra, they repelled another assault; and in
passing Tombuctoo, they refilled another familiar attack,
escaping by force and by the slaughter of many of the natives.
As they advanced, the number of hostile canoes increased,
until at length it amounted to 60, and in self-defence they
killed a very considerable number of persons; their
own number being now reduced by the death of one of
the white men to eight. At length having passed
Kaffo and Gourmou, and having supplied themselves with
provisions, they entered the country of Haouffal.
The king of the country having received information from
the chief of Yaour, a village in this district, that the white men
had departed without giving them any presents, sent an
army to a village called Bouiffa, near the side of the river,
which was posted on the top of a rock that traversed the
river, in which rock there was a large cleft or opening,
that admitted the water to pass in a strong current; and
when Mr. Park arrived at this opening and attempted to
pass, he was attacked with lances, pikes, arrows, and stones;
again which he for some time resolutely defended himself,
till at length, overpowered by numbers and fatigue,
and unable to keep up the canoe against the current, Mr. Park
laid hold of one of the white men and jumped into the
water; Mr. Martyn did the same, and they were drowned in
the stream in attempting to escape. One canoe was
left, and they took him and the canoe, and carried them to the
king. Amadi, after having been kept in prison for three
months, was released; and obtained information from the
surviving slave, concerning the manner in which Mr. Park
and his companions had died. Nothing was left in the canoe
but a sword-belt, of which the king had made a girdle for
his horse; and this belt Iiacao afterwards recovered.
Amadi, according to Iiacao's report, was a good upright
man, and delivered the above account to him on oath, nor
could he have any interest in deceiving him. From
circumstances it is concluded that Mr. Park died four
months after his departure from Sanfanding.

On Mr. Park's disposition and character it is needless to
enhance, after the detail of the principal transactions
and events of his life given in this article and the article Africa.
In private life his conduct was exemplary, as a son, a
husband, and a father. As to his perfon, he was about six
feet high, and well proportioned. His whole aspect was
mellifluous and his corporeal frame robust and active; and in
fit for great exertion, and for enduring severe hardships.
His family consist of three sons and one daughter, who
with their mother survived to lament the loss of him. See
the second volume of his Travels, a new edition of which
was published in 1816. Svo. For some other particulars,
we refer to the articles Africa, Niger, and Zaire.
thofe of any other ftringed instrument played with the naked fingers; that it is more touching and proper to express tenderness and grief than other affections of the heart; that the ftrings muff be moderately fluck, otherwise the muflc would be as confufed as on the harpsichord or pianoforte without dampers; and, fubly, the author of the article (the comte de Hoghenfki) fays, that the Irish, of all the people in the world, are thofe reputed to perform the fift on the harps of their country.

**PEDILUVIUM**, in Medicine, from pedes, the feet, and lava, I wash, a bathing or immersion of the feet in warm water.

The older practitioners reftored to the pediluvium in a variety of difeafes upon hyfhopatical principles; conceiving that, by drawing the blood into the veffels of the feet, it relieved dilfant organs, as the head or lungs, which were overcharged by a ftate of inflammation in congestion; hence it was recommended in apoplexy, pleury, and other topical affections of dilfart parts. This doctrine of revulfion, however, as applied to the operation of the pediluvium, is more questionable than under any other application of it; for as, like the general warm-bath, it somewhat accelerates the general circulation, it might be a doubtfuil remedy in cafes where the motion of the heart and arteries is already too great.

The operation of the pediluvium is, in fact, simply that of a partial warm-bath; and with great fpeed limited to thofe disorders in which more general remedy is indicated; being more practicable and easy expedient, though necessarily much less effective in its influence. The most valuable and common application of the pediluvium is at the onft of febrile difeafes, while a certain degree of chillinefs is prefent. Used in this ftate previous to going to bed, it contributes, by moderately exciting the heart and arteries, to equalize the circulation, and determine the blood to the ftomach, whence a flight diaphoresis often follows its use under these circumstances. Thus the attack of a commencing catarrh or rheumatism is often warded off by the ufe of pediluvium, aided by other proper means; and to this kind of treatment its operation is probably to be limited. In the more advanced ftage of febrile difeafes, especially when there is delirium, or a general heat, its advantages are very problematical.

**PENDLETON**, l. 4, r. 439; inhabitants, of whom 202 are felves; l. 6, r. 22,897; l. 23, r. 3485. Col. 2, l. 1, r. 2040; l. 2, r. 346.

**Pendulum**, col. 10, l. 16, add—The latel and most correct experiments that have been made for determining the length of the pendulum vibrating feconds are thofe of captain Kater. Thefe experiments were performed with a pendulum constructed on the following principle: In illustrating this principle he flates, as a known fact, that the centres of fulpenfion and oscillation are reciprocal; or, in other words, that if a body be fo suspended by its centre of oscillation, its former point of fulpenfion becomes the centre of oscillation, and the vibrations in both positions will be performed in equal times. As the diftance of the centre of oscillation from the point of fulpenfion depends on the figure of the body employed, if the arrangement of its particles be changed, the place of the centre of oscillation will also fuffer a change. Suppose then a body to be furnished with a point of fulpenfion, and another point on which it may vibrate, to be fixed as nearly as can be estimated in the centre of oscillation, and in a line with the point of fulpenfion and centre of gravity. If the vibrations in each position should not be equal in equal times, they may be readily made fo, by shifting a moveable weight, with which the body is to be furnished, in a line between the centres of fulpenfion and oscillation; when the diftance between the two points about which the vibrations were performed being measured, the length of a fimple pendulum, and the time of its vibration, will at once be known, uninfuenced by any irregularity of definity or figure. This principle being adopted for the conftuction of the pendulum, the next objed of importance is to felect a mode of fulpenfion equally free from objection. For this purpose a knife-edge was preferred, and the grounds of preference are hereby stated. The pendulum is formed of a bar of plate bras, an inch and a half wide and one-eight of an inch thick. Through this bar two triangular holes are made at the diftance of three-quarters of an inch from each other, to admit the knife-edges. Four strong knees of hammered bras, of the fame width as the bar, fix inches long, and three-quarters of an inch thick, are firmly screwed by pairs to each end of the bar, in fuch a manner, that when the knife-edges are paffed through the triangular apertures, their backs may bear readily against the perfectly plane surfaces of the bras knees, which are formed as nearly as poffible at right angles to the bar, which is cut of fuch a length, that its ends may be short of the extremities of the knee-pieces about two inches. Two slips of deal 17 inches long, and of the fame thicknefs as the bar, are inferted in the spaces thus left between the knee-pieces, and are firmly secured there by pins and fcrews. These slips of deal are only half the width of the bar; they are fainted black, and in the extremity of each a small whale-bone point is inferted, for the poffe of indicating the extent of the arc of vibration. A cylindrical weight of bras, in diameter three inches and a half, and an inch and a quarter thick, and weighing about 2 lbs. 7 oz., has a rectangular opening in the direction of its diameter, to admit the knee-piece of one end of the pendulum. This weight being paffed on the pendulum, is fo thoroughly secured there by means of a conical pin fitting an opening made through the weight and knee-pieces, as to render any change of position impossible. A second weight of about seven ounces and a half is made to slide on the bar near the knife-edge at the opposite end; and this weight may be fixed at any diftance on the bar by two fcrews with which it is furnished. A third weight, or slider of four ounces, is moveable along the bar, and is capable of nice adjuftment by means of a fcrew fixed to a clamp, which clamp is included in the weight. This slider is deigned to move near the centre of the bar; and it has an opening, through which may be feen divisions, each equal to one-twentieth of an inch, engraved on the bar; and a line is drawn on the edge of the opening to ferve as an index for determining the diftance of the slider from the middle of the bar. The knife-edges are made of that kind of fteel prepared in India, and called wootz. Their form is triangular, and their length an inch and three-quarters. They were ground on a plane tool, so as to ensure their having a perfectly ftraight edge. They were then carefully finned on a plane green bone.
home, giving them such an inclination as to make the angle on which the vibrations are performed about 120 degrees. Before the knife-edges were hardened, each was tapped half-way through, near the extremities, to receive two screws, which being palled through the knee-pieces, drew the knife-edges into close contact with them; the surfaces of both having been previously ground together to guard against any strain which might injure their figure. For the description of the support and other apparatus of this pendulum, illustrated by drawings, and the method of determining the experiments, and certain other observations, our limits require us to refer to the Phil. Trans. for the year 1818, pt. 1.

From his experiments and observations, Captain Keeler concludes, that the length of the pendulum vibrating seconds in vacuo at the level of the sea, measured at the temperature of 62° of Fahrenheit, appears to be

PERTH, col. 4, l. 23 from bottom, for 4715 r. 4510; and after 16,948 inhabitants, r. viz. 7687 males, and 9261 females.

PERTH-AMBOY, l. 11, r. 815 inhabitants.

PERTHSHIRE. In 1811 this shire contained (ex-
clusive of the town) 21,894 houses, and 116,975 persons;
given every other night for four or five nights, for horses affected with gravel. Mr. White directs a composition of 6 oz. of levigated antimony, 8 oz. of flowers of sulphur, mixed with treacle, to be made into 8 balls;—or, 4 oz. of powdered rosin, 3 oz. of nitre, 1 oz. of tartarified antimony, mixed with treacle, and divided into 8 balls;—or, 3 oz. of unwashed calx of antimony, 2 drs. of calomel, and 4 oz. of powdered aniseeds, mixed with treacle, and divided into 8 doses;—or, ⅜ dr. of calomel, 1 dr. of aloes, 2 drs. of Caliile foap, 30 drops of oil of juniper, and ⅜. oz. of powdered aniseeds, made into a ball with syrup, which serves for one dose, and which Mr. W. calls the “mercurial” alternative.

Mr. Taplin recommends levigated antimony, flowers of sulphur, and nitre, of each 3 oz., 10 oz. of Caliile foap, 3 drs. of oil of juniper, formed into a mafs with honey q.s.; and divided into 12 balls, and one to be given every morning or for three or more weeks, in cafes of gravel, after purging with a common ball;—or, milk of sulphur, prepared antimony, cream of tartar, cinnabar of antimony, of each 5 oz., 4 oz. of Æthiops' mineral, and honey q.s.; and the mafs divided into 12 balls, one of which should be given every morning, for a month, in the farcy.

Purging balls are prepared, according to the directions of Mr. Taplin, of 1 oz. of fococotan aloe, 2 drs. of rhubarb, jalap, and cream of tartar, of each 1 dr., 2 scruples of ginger, oil of cloves and oyl of aniseed, of each 20 drops, and fyrup of buckthorn q.s. Mr. White orders 5 drs. of fococotan aloe, 2 drs. of prepared astron, 1 dr. of aromatic powder, 10 drops of oil of caraway, and fyrup q.s.;—or, 7 drs. of fococotan aloe, ¼ oz. of Caliile foap, 1 dr. of ginger, and 10 drops of oil of caraway, with fyrup q.s.;—or, 1 oz. of fococotan aloe, 2 drs. of prepared astron, 1 dr. of aromatic powder, 10 drops of oil of aniseeds, and fyrup q.s. Mr. White allows us, that the second of his compositions is generally sufficient for strong horses, and that he has never had occasion for a more active purge than the ball. Mr. Ryding directs 6 drs. of Barbadoes aloe, 1 scruple of ginger, and soft-foap q.s.;—or, ⅔ oz. of Barbadoes aloe, 1 dr. of calomel, and mucilage of gum arabic q.s. The first he calls a mild purging ball, and the latter the mercurial purging ball. Mr. J. Lawrence directs 2 or 3 balls to be made of the following ingredients; ⅔ oz. from 12 to 14 drs. of fococotan aloe, from 1 to 2 oz. of cream of tartar, a tea-spoonful of powdered ginger, a table-spoonful of olive-oil, and fyrup of buckthorn or treacle, q.s. Mr. R. Lawrence, for the same purpose, orders 9 drs. of Barbadoes aloe, and 1 dr. of ginger, to be formed into a ball with fyrup or treacle.

Diuretic balls are prepared by Mr. R. Lawrence of ½ oz. of Venice turpentine, 2 drs. of tartarified antimony, and 1 oz. of liquorice-powder, with treacle. By Mr. White, they are made to consist of 4 oz. of Caliile foap, and powdered rosin and nitre, of each 2 oz., ⅓ oz. of oil of juniper, linedine-powder, and fyrup q.s. This mafs for strong horses is divided into 6 balls, but for weak ones into 8:—or, the fame balls may be prepared of 4 oz. of Caliile foap, 2 oz. of Venice turpentine, and powdered aniseeds, and treacle, q.s. fo as to form 6 balls;—or, balls from 1 to 1½ oz. are prepared, according to Mr. Ryding's directions, of yellow rosin, Caliile foap, and Venice turpentine, of each 1 lb. divided slowly over the fire and formed into a mafs. Thefe balls, he fays, are excellent diuretics, and may be given in grippes, in glided legs, gravel, or in difeafes of the eye, &c.

Cordial balls are prepared by the fame of 2 oz. of grains of paradylfe, finely powdered, ginger and canella alba, of each ⅜ oz., aniseeds and caraway-seeds, of each 1 ½ oz., 2 oz. of liquorice-powder, and honey q.s.; to be given occasionally. By Mr. White, thefe balls are prepared by making a mafs with treacle of cummin-seeds, aniseeds, caraway-seeds, of each ½ oz., and 2 oz. of ginger; and they are given in the quantity of about 2 oz.;—or, they may be made of aniseeds, caraway-seeds, moit fennel-seeds, or liquorice-powder, of each 4 oz., ginger and cafea, of each 1 ½ oz., made into a mafs with honey, and given in a dose of about 2 oz.

Affinuent balls are prepared by Mr. Taplin's directions of 6 drs. of diafcorum, gum arabic, prepared chalk, and Armenian bole, of each ½ oz., 1 dr. of ginger, 40 drops of oil of aniseed, with fyrup q.s.; they are given in cafes of lownefs or fcurfing, and repeated every 6, 8, or 12 hours, as the cafe may require. For this purpofe balls may be prepared of rhubarb, and compound powder of gum tragacanth, of each ⅔ oz., colombo and ginger, of each 1 dr., 15 grs. of opium, 6 drs. of orange-peel, and fyrup of poppies; the ball to be repeated in 12, 18, or 24 hours;—or, 1 oz. of mithridate, Armenian bole, gum arabic, and prepared chalk, of each ⅔ oz., 2 drs. of ginger, and fyrup of poppies, may form a ball.

Refractive ball is formed, according to Mr. Ryding, of ½ lb. of Peruvian bark, 2 oz. of grains of paradylfe, gentian, and colombo, of each 3 oz., and honey q.s.; the mafs is to be divided into 16 balls, and one to be given every morning in cafes of indigention or lofs of appetite. Mr. Taplin directs a ball for this purpofe to be made of 4 oz. of Peruvian bark, 2 oz. of mithridate (or diafcorum), canella alba, snake-root, and camomile, of each, in powder, 10 oz., or formed into a mafs with honey q.s.; and divided into 6 balls, one to be given night and morning;—or, ⅔ oz. of Venice treacle, 6 drs. of Peruvian bark, colombo, and camomile, of each 2 drs., 25 drops of oil of caraway, and honey q.s.

Disphoritic balls are formed, according to Mr. White's directions, of 1 dr. of opium, 2 drs. of camphor, 3 drs. of tartarified antimony, ⅔ oz. of powdered aniseeds, and fyrup q.s.

PHASIS, l. 9, infect—it is at the town of Serpasa that it becomes navigable, and after collecting the streams of the plain of Mingrelia, it enters the Black fea. It pursues a course of 500 miles, 40 of which are navigable for large vessels. At its discharge into the fea, it has a small woody ifland in the midit of the channel.

PHASMA, in Entomolog, genus of insects formed from some of the Linnaee Mantes, and differing from that genus in having all the legs equally formed for walking, and without the falcforn joint that diftinguifhes the fore-legs in mantes. The characters are, head large, antena fylforn, eyes small, rounded; stemmas three between the eyes; wings four, membranoufe; the upper pair abbreviated, the lower pleated; and feet formed for walking. They feed entirely on vegetable food. The molt remarkable is the P. gigas or M. gigas of Lineus. It is a native of the ifland of Amboina. Another extraordinary species is the P. dilatatum, defcribed in the 4th volume of the Transactions of the Linnaean Society. Some infects of this genus, as well as thofe of the mantis, have their upper wings reftembling the leaves of trees; nature having thus provided for their fecurity againft the attacks of birds, and as well as for the more ready attainment of their prey. The female of the P. fucifolium has no under wings.

PHILADELPHIA, l. 6, r. 19.; 1. 7, r. contained, in 1810, 57,488 inhabitants. Add—Allo, the metropolis of Pennsylvania, and now a dinct county, containing 14 wards, and, by the census of 1810, 53,722 inhabitants.

PHILADELPHIA Store, l. 3, after city, add—in Asia.

PHILIP S
PHILIPSBURG, a town of York county, in Maine, with 1427 inhabitants.

PHILOSOPHER'S STONE, l. 23 from the end, r. should not be enceraged.

PHLOGISTON, l. 19, r. now said to be separaged.

PHOCA, l. 4, r. fix (or four, Shaw).

PHOSPHATE of Copper, in Mineralogy. See Mineralogy, Addenda.

PHOSPHORE. See Mineralogy, Addenda.

PHOSPHORUS, Phosphoric Acid, Phosphates, &c. in Chemistry. According to the most recent determination of Dr. Thomson, the weight of the atom of phosphorus is 15, that of phosphoric acid 25, and that of phospboric acid 35. A good deal of doubt, however, still hangs over this principle and its compounds. The hypophosphorous acid, discovered by Dulong, and which is formed when phosphuret of barytes is dissolved in water, appears to contain less oxygen than either the phospborous or phosphoric acid, and was formerly considered as the protoxyl or first compound of phosphorus and oxygen. Dr. T., however, is lately disposed to consider the hypophosphorous acid as a compound of 2 atoms phosphorous + 1 atom oxygen; but this is by no means ascertained. We may also observe, that all the ball analyses of the phospberettes shew that the weight of the atom of phospboric acid lies between 40 and 45.

We may mention here, that Dulong observed an acid formed during the slow combustion of phosphorus, composed, as he supposed, of 1 atom phosphoric acid + 1 atom oxygen, and which he has named phospbhoric acid. (Phragm. Minor. l. 6, r. N.W.; l. 20, r. Alexandria, From. Col. 3, 18, r. Podarcis.)

PICA. At the closet, add—See Aves, Classification, and Natural History.

PICROLITE. See Mineralogy, Addenda.

PICROMEL, in Chemistry. See Bile.

PIGMENTS. Add—The results of sir Humphry Davy's late experiments on the colours used by the ancients as pigments are as follow. The red colours which they employed he found to be red-lead, vermilion, and iron ochre. The yellows were yellow ochre, in some cafes mixed with chalk, in others with red-lead. The anciently used umber and masonic as yellow paints. The blues were a pounded glafs, composed of soda, lime, and oxys of copper. Indigo was likewise employed by the ancients, and they coloured blue glafs with cobalt. The greens were compounds containing copper; sometimes the carbonate mixed with chalk; sometimes with blue glafs. In some cafes, they confined of the green-earth of Verona. Verdigris was likewise used by the ancients. The purple colour found in the baths of Titus, was an animal or vegetable matter combined with alumina. The blacks were charcoal; the brown ochres; the white chalk or clay. White-lead was likewise known to the ancient painters.

PILKINGTON, l. 1, r. 18, after Lancashire, add—in the hundred of Salford, and parish of Peelwick, containing 7353 persons, occupying 1196 houses, of whom 1223 are employed in trade and manufactures, and 166 in agriculture.

PILLORY. This kind of punishment is now abolished in England.

PITCH-STONE. See Mineralogy, Addenda.

PITT, in America, l. 2, add—of whom 5589 were slaves in 1810.

PITTSTOWN. Add, at the closet—containing 694 persons.

PIITTSVLANIA, l. 2, add—of whom 6312 were slaves.

PLANE-Tree, for Plantanus v. Platanus.

PLANET, col. 20, l. 6 from bottom, for 365 days, hours and minutes, r. 365 days.

PLANETARIUM, col. 20, l. 3 from bottom, for Jupiter's r. Saturn's. Col. 23, l. 15 from bottom, for 23° 32' 59" r. 23° 59' 59".

PLAQUEMINA, in Geography, a parish of the county of Orleans, in the territory of Orleans, containing 1549 persons. The soil of this parish is well adapted to the cultivation of the sugar-cane, and some of the largest sugar estates yet formed on the Mississippi are within its limits, so that sugar is its staple commodity. The important port of Fort St. Philip is one of the defences of Louisiana.

PLASANIA. See Mineralogy, Addenda.

PLATINUM, in Chemistry. Dr. Thomson concludes, from the few experiments that have been made on this metal and its compounds, that the weight of its atom is 226.25.

PLATYSTACUS, in Ichthyology, a genus of abdominal fishes, imported by Dr. Bloch, and nearly allied to that of Silurus. Its generic characters are, that it has the habit of silurus, mouth beneath, bearded with cirri, body scaleless, depressed, tail long, compressed. Dr. Shaw enumerates and describes the following species, viz. cyathophorus, with fix beards, and ventral acetabula, the Silurus spp. of Linnaeus, a native of the Indian seas and rivers Lancus, with eight beards and smooth abdomen, differing perhaps only in fix from the former; verrucosus, or warted brown P., marked above by longitudinal warty lines, with short anal fin, similar to the last, but smaller and of a beads elongated form; a native of the Indian seas; anguillaris, or eel-shaped brown P., with longitudinal white stripes, and the second dorsal, anal, and caudal fin united, form beads bold in front that of the preceding species, having eight instead of five beards; a native of the Indian seas.

PLEASANT, in Geography, l. 2, r. 1246. Add—Alfo, a township in Franklin county, having 159 inhabitants.

PLEASANT, Mount. Add—a township in Madison county, having 326 inhabitants.

PLUMSTEAD, l. 2, in Bucks county, having 1407 inhabitants.

PLUTONIUM, in Chemistry, a name given by Dr. Clarke to the suppressed metallic balls of barytes. See Barytes and Blow-Fire.

Vol. XXVIII.

POGONIUS, in Ornithology, a genus of birds of the order Pice; the characters of which are, beak large, thick, dilated at the base, with the upper mandible bidentate on both sides; nostrils covered with bristles, feet lineate, with two toes before and two behind. This genus is given three species, all inhabitants of Africa; viz. fulicaris, or groove-beaked, the blue-black P. with throat, neck, belly, and an obscure stripe on the wings, scarlet, fides yellowish, back with a white spot, quills dark-brown, upper mandible with one longitudinal, under with many transverse grooves; inhabits about the coast of Barbary; leucophris, or smooth-beaked black P., with throat, neck, breast, abdomen, and a stripe on the wings, scarlet, back with a white spot, crown of the head variegated with scarlet; beak smooth, not grooved; the buccus dubius B. of Latham; nicollii, or brown P., whitish beneath, head, neck, throat, and spots on the breast, scarlet; interior wing-quills externally margined with pale; beak smooth, not grooved. Shaw.
POINT, in Geography, a township of Northumberland county, in Pennsylvania, having 431 persons.

POINTE COUEPE, a county and parish of New Orleans, containing 4539 persons.

POIRET, See THEOSOPHISTS.

POISON, col. 3, l. 15 from bottom, for verus R. berus.

POLAND, col. 9, l. 31, add—From a flatitical account of Poland, published at Warsaw, it appears, that this kingdom in its present state contains 1291 square miles, (of 15 to a degree,) 481 towns, 22,604 villages, and a population of 5,732,374 persons, of whom 219,442 are Jews.

Poland, in America, col. 2, l. 2, r. 850. Add—Alto, a township of the county of Trumbull, in Ohio, with 827 inhabitants.

POLARITY of Light. See Light.

POLARIZATION, in Optics, a term which has been lately applied to that change which takes place in the direction of rays that pass through certain crystals, and which derives this appellation from its analogy to magnetic phenomena. It was first suggested by the modifications of light discovered by M. Malus (see Light), and has since been investigated with equal ingenuity and diligence by Dr. Brewster. For his numerous communications on this subject to the Royal Society, he was honoured with the Copleyan medal.

POLASKI, in Geography, a county of Georgia, containing 2691 inhabitants, of whom 528 were slaves in 1810.

POLE, l. 2, add—the fourth son of the countes of Salisbury, who was cruelly and unjustly beheaded by Henry VIII., and whose father, the duke of Florence, was drowned in a butt of maltwine by his son.

POLOPHILUS, CoucAL, in Ornithology, a genus of birds of the order Picæ; the characters of which are, beak strong, slightly incurved, nostrils straight, elongated, feet simple, two toes pointing forward, the exterior being the largest, two toes turning backwards, the interior furnished with a very long claw. The Coucals, so first called by Vaillant, form a most beautiful tribe of birds. They divide in woods, feed on insects and fruits, and construct their nests in trees, and (contrary to the manners of cuckscoos) bring up their young, from which circumstance their generic name is derived. Shaw.

POLYPTERUS, in Ichthyology, a genus of the abdominal fishes; the character of which is, that the gill-membrane is single-rayed, and the dorsal fins numerous. This fish constitutes a new and remarkable genus, and was first scientifically described by M. E. Geoffroy, who considered it as forming a connecting link between the oblong and the cartilaginous fishes. It seems most nearly allied to the genus Elox. It is known to the Egyptians by the name of Biche, among whom it is rare, and supposed in general to inhabit the depths of the Nile among the soft mud. Its flesh is white and savoury, though it is hardly possible to open its skin with a knife; and therefore this fish is first boiled, and its skin drawn off whole. It's specific name is Niloticus, and it is characterised as the green P., with the abdomen spotted with black. Shaw.

PONT-VOLANT, delie the description, and let the reference remain.

PORANTHERA, in Botany, from pears, a pure, and anthier, an anther.—Rudge Tr. of Linn. Soc. v. 10. 322.

1. P. cricifolia. Rudge as above, t. 22. f. 2.—Native of New South Wales. Dr. White. A very extraordinary little plant. Stem branched, round, leafy, four to five inches high. Leaves scattered, numerous, linear, glaucous. Flowers coromycose, minute, white. The dried specimens resemble some small kind of Lepidium.

PORCELAIN, col. 24, l. 31, r. in a melted flate.

PORCELAIN Jasper. See Minerology, Addedenda.

PORCILLA, in Botany, so called by Ruiz and Pavon, in honour of Don Antonio Porcela, a Spaniard, whom they celebrate, in the highest terms, as a promoter of botanical pursuits. Our readers for adopting this name, in preference to any other, for the genus we are about to describe, may be found under the article ASIMA. Thus we preface to consider the Affamina and Porcella of De Candolle as one and the same genus, may require a still further apology, and we shall presently give it, as far as we are able.—“Ruiz et Pavon Fl. Peru. v. 1. 144. Prodr. 84. t. 16. Dunal Annonce. 85.” De Cand. Syd. v. 1. 480. “Perf. Syn. v. 2. 95.” Pursh 383. (Affamina; Adans. Farn. v. 2. 365. Dunal Annonce. 81. De Cand. Syd. v. 1. 478. Orchidocarpum; Mich. Bor.-Amer. v. 1. 329. Annexe spec. Linn. Juss. Gen. Willd. Ait. &c.).—Clafs and order, Polyandra Polygynia. Nat. Ord. Conandtes, Linn. Annonce. Juss. Annexes. De Cand.

Gen. Ch. Cal. Perianth inferior, of one leaf, in three deep, equal, ovate, concave, permanent segments. Cor. Petals five, unequal, in two rows, stellate, ovato-oblong, spreading, coriaceous; the three innermost either larger or smaller than the rest. Stam. Filaments scarcely any; anthers very numerous, nearly stellate on the convex receptacle, oblong, bristling at each side. Pfll. Germinis from three to six, ovato-oblong, sessile, fyles none; frigues oblong. Peric. Berries as many as the germines, sessile, crowded, ovato or nearly cylindric, more or less succulent, of one cell. Seeds numerous, elliptic-oblong, ranged transversely in a double row, inferior into the inner margin. Eff. Ch. Calyx inferior, deeply three-cleft. Petals five, ovato-oblong, spreading, in a double row, unequal. Germines oblong. Stigma sessile, obtuse. Berries sessile, of one cell, with many seeds.

A shrubly or arboreous genus, with oblong, undivided, deciduous leaves, and axillary, nearly solitary flowers, either sessile or stalked, in some instances expanded before the foliage. All the species are natives of the cooler parts of America. The able professor De Candolle separates Affamina of Adanson from Porcella of the Fl. Peruv., the latter having its three inner petals rather the largest, the fruit more cylindrical and coriaceous, the seeds in a double row. In Affamina the three outer petals are much the largest, and the fruit more ovate. But the seeds are likewise in a double row in one species at least of this genus, the tribola, as De Candolle, on the authority of Ehret, admits; and the comparative size of the inner and outer petals, different in different species of Affamina, can hardly be much relied on, nor is this admitted by De Candolle among his most essential characters, p. 465. The more or less cylindrical or ovate form of the fruit will not, surely, be infested on; nor can that of the original Porcella differ essentially in substance from the others, being like them succulent and eatable.

tainous woods in Peru. A tall and very handsome tree, forty ells in height, with greyish, rugged, minutely dotted branches. Leaves alternate, on short stalks, oblong-lanceolate, rounded at the base, entire, shiny on both sides, shining above. Stalks axillary, several together, drooping, thickened upwards, each bearing one or more yellowish-white flowers, about an inch in diameter. Berries cylindrical, tumid, rather coriaceous, but juicy and eatable, each marked with a longitudinal seam. Seeds oblong-kidney-shaped, compressed in two rows. The leaves afford a yellow dye.

2. P. parviflora. Small-flowered Porcelain. Pursh n. 2. (Afinima parviflora; De Cand. Syll. v. 1. 478. "Dunal Anon. 82. t. 9." Orchidocarpum parviflorum; Mich. Boreal.-Amer. v. 1. 329.)—Leaves obovate-wedge-shaped, pointed, clothed with rusty down below, as well as the young branches. Flowers small. Outer petals long, scarcely twice the length of the calyx. In shady woods, near rivers and lakes, from Virginia to Georgia, flowering in April and May. A low shrub, sometimes not above two feet high when in full fruit. Flowers small, dark purple. Pursh. Branches smooth, slightly rugose; when young leafy, and covered with reddish pubescence. Leaves on very short stalks; acute at the base; ribbed and downy beneath; smooth and green above. Flowers nearly or quite seife, coming before the leaves, from the axillary scapes of last year's foliage. Their stalks, if any, as well as the outides of the calyx and corolla, are clothed with reddish down. Berries two or three from each flower, aggregate, ovate, smooth, rather seife, "the size of a plum." De Candolle.

3. P. triloba. Three-leaved Porcelain. Pursh n. 1. (Afinima triloba; De Cand. Syll. v. 1. 479. "Dunal Anon. 83." Anons triloba; Linnae. Sp. Pl. 758. Willd. Sp. Pl. v. 2. 1267. Ait. Hort. Kew. v. 3. 335. A. folinis lanceolatis, fructibus trifidis; Mill. Ilc. v. 1. 23. t. 35. A. fructu luteoente lavi, ferotum arietiis referente; Catech. Carol. v. 2. t. 85. Trew Ehret 1. t. 5. Dulham. Arb.v. 1. 60. t. 19. 20. Orchidocarpum arizematicum; Mich. Boreal.-Amer. v. 1. 329.)—Leaves elliptic-oblong, pointed at each end, nearly smooth, as well as the young branches. Flowers small. Outer petals roundish-ovate, four times the length of the calyx. On the overflowed banks of rivers, from Pennsylvania to Florida, flowering in March and April. A small tree. Flowers dark brown. Fruit large, eatable. Pursh. This species, introduced by the celebrated Peter Collinson, is still met with in several curious gardens, like those of Kew, Sion-house, &c., where it produces in the spring large inodorous flowers, an inch and a half broad, with wrinkled dark-brown petals, as represented by Miller. Catech and Ehret make them of a pale yellowish-green. The leaves, which come forth as the flowers begin to fall, are five or six inches long, and an inch and a half or two inches broad, on short stalks. The flowers—flats are solitary and single-flowered, from one to two inches long, downy with purplish hairs. Berries ovate, yellow, two or three inches long, not perfetked in England, eatable, though reported by some persons to have an unpleasant smell. Seeds eight or ten, large, brown, rugose, in a double row, as represented by Ehret. Miller's figure exhibits a single row only. One or two berries only appear to be perfetked from each flower.

4. P. pygmaea. Dwarf Porcelain. Pursh n. 3. (Afinima pygmaea; De Cand. Syll. v. 1. 479. "Dunal Anon. 84. t. 10." Orchidocarpum pygmaeum; Mich. Boreal.-Amer. v. 1. 330. Anons pygmaea; Bartr. Trav. v. 1. 10. Willd. Sp. Pl. v. 2. 1268.)—Leaves oblong-lanceolate, obtuse; wedge-shaped at the base; smooth, as well as the young branches. Outer petals large, obovate-oblong, greatly exceeding the calyx. In the sandy fields of Georgia and Florida. The whole shrub not above a foot high. Flowers the size of Anons squamosa. Pursh. This is smooth in every part, with very long leaves, and short, single-flowered, solitary, bracteate flower-flats. Flowers white; their inner petals small, elliptical and obtuse. De Candolle. Pursh, by a faulty punctuation, makes the inner petals long.

PORTER, in Geography, a small township of the district of Maine, in the county of Oxford, having 292 persons.

PORTLAND, New, a township of Maine, in the county of Somerset, having 421 inhabitants.

PORTSBOROUGH. In 1811, the parish of St. Cathert's contained 1058 houses, and 38,673 persons; viz. 16,873 males, and 21,800 females: 210 families being employed in agriculture, and 3342 in trade, manufactures, or handicraft.

PORTSMOUTH, col. 51. 1. 20. for tons r. cwt.

POTASSIUM, Potash, in Chemistry. The most recent determinations make the weight of the atom of potash to be 50, and that of potash of course to be 60. Potash, when heated in oxygen gas, combines with a larger quantity of oxygen than exists in potash, and thus forms a compound which is, in fact, a peroxide of potash. This peroxide is of a lemon yellow colour; when put into water it effervesces, giving off oxygen gas. Phosphorus, sulphur, and carbon, are acidified when brought in contact with it. Hydrogen, when heated with it, is slowly and without combustion converted into water. It decomposes ammonia, converting it into water and azotic gas.

POTT, Percival, col. 2. 1. 27. for 1726 r. 1736.

POZTZAM. Add.—Potzdam contains (the military not included) 115,426 souls.

POULTICE, in Farriery, is compounded of various ingredients, according to the purposes of its application. Some of the most approved, founded in modern veterinary science, are the following:—The common poultice consists of 3 pecks of bran and water, g. f. boiled for ten minutes, and then thickened with linseed-meal, having the addition of 3 oz. of hog's-lard: or, 5 peck of fine pollard, 2½ lbs. of linseed-meal, and boiling water, g. f. adding 2 oz. of hog's-lard. Fermenting poultice is obtained by boiling a quantity of brewer's wort, and throwing into it as much oatmeal as will thicken it; adding, lastly, a tea-cupful of yeast: this is adapted to putrid ulcers, or mortified parts. Saturine poultice is had by adding to the common poultice 3 drs. or ¾ oz. of extract of lead, and mixing them well together: or, 1 oz. of acetate ceruf, (figur of lead,) 3 quarts of boiling water, with the addition of bran and linseed-meal, g. f. A suppurative poultice may be made by stiring a sufficient quantity of common turpentine into some
Some of the common plant dyes. An anodyne poultice may be prepared in the same way, by adding a sufficient quantity of tincture of opium.

POWATAN, i. 1, r. 8073 inhabitants, of whom 5091 were females in 1816.

POYANG, i. 2, add.—According to a statement in "Ellis's Journal of an Embassy to China," (vol. ii.), this lake is very extensive in extent to the Tung-ting-hoo, in Ho-quaung, the one being 180 miles, and the other 5000 acres; the lake being rather more than one-third of a mile.

POWDER-CHESTS, i. pennii, for fixed r, fired.

PRAIRIE, or MEADOW, a term used in North-West America, to denote a tract of land diversified of timber. In travelling W. from the Alleghanies, such tracts occur more frequently, and are of greater extent as we approach the Mississippi. When we proceed to the distance of 2 or 300 miles to the west of that river, the whole country is of this description, which continues to the rocky mountains westward, and from the head waters of the Mississippi to the gulf of Mexico, an extent of territory which probably equals in area the whole empire of China.

PREBELL, in Geography, a county of Ohio, containing 7 townships, and 8,304 inhabitants.

PRINCESS Anne, i. 4, infant,—of whom 3726 were males in 1816.

PRINTING, Calico, is the art of imparting various colours to plain calicoes, in any form, or according to any pattern that may be desired, by means of certain colourless mordants previously applied to the cloth. This art has sometimes been denominated topical dyeing, and the various branches of it are calculated to afford the those who may have the opportunity of witnessing the different processes, without being acquainted with the nature of chemical mordants, and their several uses in the arts.

The art of calico-printing is of great antiquity. Homer speaks of the variegated cloths of Sidon, as having a very splendid appearance; and Pliny describes the Egyptians as accustomed to prepare parti-coloured linens, and observes that these colours were produced after a manner corresponding with our method of topical dyeing. He says the Egyptians began by painting or drawing on white cloths (doublets, linen or cotton,) with certain drugs, which in themselves poissied no colour, but had the property of attracting or absorbing colouring matters. After which, these cloths were immered in a heated dyeing liquor; and though they were colourles before, and though this dyeing liquor was of one uniform colour, yet when the cloths were taken out of it soon after, they were found to be wonderfully tinged of different colours, according to the different natures of the several drugs, which had been applied to their different parts; and these colours, so wonderfully produced from a tincture of only one colour, could not afterwards be discharged by washing; and he considers it as admirable, that the dyeing liquor, which, if cloths of different colours had been put into it, would have confounded them all, should thus produce, and permanently fix several colours, being itself only of one colour. Pliny, lib. xxxv. cap. 2.

This account contains a plan of description of one of the branches of calico-printing, that no one who is conversant with the present practice can entertain any doubt that the ancient Egyptians were acquainted with many of the principles of this very curious art. Our readers, who are desirous of further investigating this interesting subject, will find abundant and satisfactory information by consulting the following works:—Pisly's "Natural History," the 26th volume of "Recueil des Lettres Edifiantes," &c. Strabo, lib. xvi.; Delavay's "Experimental Inquiry into the Cause of Change of Colours, in opaque and coloured Bodies," Berthollet's "Elements of the Art of Dyeing," vol. i. p. 28; Beckman's "History of Inventions," in 4 vols.; Mr. Parker's "Chemical Essays," vol. ii. p. 65, &c.; and Dr. Bancroft "On Permanent Colours." In the above works, abundant testimonies will be found to shew that printed calicoes were not unknown to the ancients; and we have good reason also to suppose that the colours which they imparted to their cloths possessed a considerable degree of permanency, as we know that iron and alum were both employed by them as mordants. It is likewise well known that several ancient nations were acquainted with foda, indigo, indigo, the juice of the baccia, cochineal (or other plants similar to it), the celebrated Tyrian purple, and other materials, sufficient in the whole to enable them to give a great variety of colours and tints to their several productions.

Our object, however, in this communication, is to give a succinct account of the art of calico-printing as it is conducted at present, and we do not know that we can do better than to copy the greater part of the detail which has been given by Mr. Parkes in his "Essay on Calico-Printing," in the second volume of his "Chemical Essays," and which he has very politely allowed us to make use of in any way we think proper.

From this essay it appears, that calico-printing, as an art, is but of modern date in this country, though it has been practised in India, and other parts of the East, from time immemorial. From various accounts it appears, that formerly in India the cotton cloths when brought from the weavers, partly bleached, were worn next to the skin by the dyer and by all his family, during the space of eight or ten days, after which they underwent several macerations in water, with goat's dung, and were afterwards submitted to frequent washings, and as frequent dryings in the rays of an intense sun-light. Afterwards they were soaked for some time in the mixture of the acid extract of the yellow myrabolanum, and of curdled buffalo's milk. When thoroughly impregnated therewith, they were squeezed, dried by exposure to the sun, and then, by pressure and friction, they were made smooth enough for being drawn upon by the pencil with the different mordants.

The first of these mordants was an iron liquor, made by dissolving iron in a mixture of four palm-wine and of water in which rice had been boiled. This liquor was applied to the figures or spots intended to become black, and afterwards the aluminous mordant was applied, commonly by children, with the pencil, to the parts intended to be made red. The pieces were then exposed to the hottest sun-light, that the parts to which the mordants had been applied might be dried as much as possible; and then they were thoroughly soaked in pits of water, to cleanse them from the impure mordants, as well as from the buffalo's milk, &c.; and finally, they were dyed in water, with certain roots answering nearly in their effects to those of madder.

It was in this way the manufacture of printed cottons...
PRINTING ON CALICO.

was conducted by the Indians in former times. The following is an account of the modern Indian practice, in one particular branch of their manufacture, which Mr. Parkes says he procured from a gentleman who had spent some time in India, and who had taken pains to inquire into their manipulations.

This process relates to the method of printing the fine cotton chintz counterpanes, which the natives call pallampoores, and which are manufactured at Madras. These are woven in one piece, from two to four yards square, and are printed, or rather painted, with various designs, and in various colours. Their method is to draw a pattern first on sheets of paper sewn together, of the size of the intended pallampoor; and then to prick out the same in the paper with a sharp instrument. This done, the paper pattern is smoothly fixed upon the cloth, which is previously dampened, and a small muffin bag containing some kind of black powder is rubbed over the whole, in order to pass a part of the powder through the pin-holes, and completely mark out the pattern.

The pattern being thus sketched upon the cloth, the paper is removed; and when the outline of the various figures is drawn with a pencil, the piece is considered to be ready for receiving the colours.

One colour is then laid on with a brush made with a tough root of a particular kind of tree, or with the husk of the cocoa-nut; and when this is dry, the piece of cotton is given to a woman to wear, or to use in the family, till it be very much dirtied; in order that it might necessarily undergo a thorough washing, which is thought requisite to prove the goodnes and permanency of the colour. Another colour is then laid on in the same manner, and the piece is again submitted to the same trial of wearing and washing. The Asiatics may not be aware of it; but doubtless the long exposure to the air in these cases is the important point, as it is well known that the atmosphere is a prime agent in rendering many colours permanent, which, under a different treatment, would be heavy and fugitive. This is repeated for every colour that is employed; and when any one of these colours is found to be deteriorated by this treatment, it is printed afresh; and so are all the rest, till the workman is satisfied that all the colours are actually permanent.

This tedious process is adopted, however, only when the manufacturer means to warrant the article; but in all cases, even in those pieces which will not bear washing, the colours are laid on by a brush, as before mentioned.

Whether they are all substantive colours which are thus applied, or whether they use any species of mordants in their full work, we are unacquainted, as the artificers of India observe great secrecy, and are extremely jealous on this subject.

Such are the facts which we have been able to collect respecting the progress of calico-printing from the earliest ages; and all of the present state of the art among the Asiatics. The more difficult part now remains, viz. to give a brief detail of the most important processes of our own artificers. This, however, we shall endeavour to do with the utmost plainness, and shall not fail to suggest any improvement that may have occurred to us during our inquiries respecting this very interesting and varied branch of manufacture.

We have not been able to ascertain when calico-printing was introduced into this country, though there are various reasons for believing that it is an art, among us at least, but of modern date.

As the whole of this ingenious business, as it is now conducted, depends upon the proper application of a few compounds called mordants, it will be necessary, in the first place, to explain their nature and uses. In doing this, one or two preliminary remarks will assist us.

The colouring substances chiefly employed in this art are divided into two classes, viz. substantive and adjective. A substantive colour is one which is capable of itself of producing a permanent dye on wool or woollen cloth; such is the juice of the buccinum, used by the ancients for producing the imperial purple; such are also the woad and indigo employed by the moderns for producing a permanent blue; and we may add the metallic solutions, particularly those of iron, cobalt, gold, platina, and silver, which give various colours, according to the processes by which they are prepared.

It has been proposed to employ this valuable permanent colour for pencilling on fine muslins. In time of peace it might readily be procured in sufficient quantities, and would prove an important addition to the resources of the British calico-printer.

Dr. Bancroft tells us, that the first mention of indigo, as known in England, is in the Act of the 23d of Queen Elizabeth, chap. 9, where it is called Anse, or Blue Inde. Bancroft on Permanent Colours, p. 138.

By adjective colours are meant all those which are incapable of giving permanent dyes without the aid of certain intermediates, which form as it were a bond of union between them and the substances intended to be dyed.

These intermediates are what known by the term mordants, and are used for this purpose in very considerable quantities by the calico-printer of the present day.

Several expedients of this kind were employed by the ancients to produce fall, or, more properly, permanent colours, and this appears from the testimony of Aristotle and Pliny. The chief articles in use at present are, the acetate of iron, the acetate of alumina, and the various solutions of tin, all of which should be very carefully and correctly prepared.

We have already given some account of chemical mordants, in vol. xxiv. part 1, under the article MORDANTS; which see.

When piece-goods are designed to be dyed of one uniform adjective colour, they are first immersed in a solution of one of these mordants, then hung up to dry, and to absorb the oxygen of the atmosphere. When sufficiently exposed to the air, they are washed or dugged, to remove the superfluous mordant; that is to say, that part of it which is not chemically combined with the cloth; and the goods are then submitted to a bath of that particular kind of colouring matter which is to be imparted to them.

The dung of the cow is used in such large quantities by the calico-printer, that it has become an article of great expense. The proportion that is employed is usually about one bushel to one hundred gallons of water, though frequently a larger proportion would be more effectual. The brightness of the colours, and the purity of the whites, are always dependent upon the quantity of the dung employed.

Whenever it is meant that the colour should be partially inferted, the mordant is applied to those particular parts only; so that, when the piece is immersed in the colouring bath, no other place will receive the permanent stain. If a sufficient number of colouring substances should ever be discovered, that have no affinity for any thing but the chemical mordants, the business of calico-printing would be rendered much more easy and simple than it is at present. For though the whole texture of the cloth will be coloured, yet...
yet having in itself no affinity with the vegetable with which the decoction is impregnated, the whole of the colouring matter will be easily removed by exposure to the air, and the ground of the piece restored to its original whiteness; while those parts to which the mordant was applied, will remain and fix the colours in a way which will be more fully explained hereafter.

Formerly all calico-printers were bleachers; but in the neighbourhood of London these are separate and distinct trades, and the printer either purchases bleached goods for printing on his own private account, or receives the cloth from his customers in a white flate; and, when printed, he returns the identical pieces, and is paid so much per yard, according to the number of colours, for printing them.

In our opinion every printer should bleach his own goods, for it is impossible always to rely with confidence on the care of those who bleach for hire; and every printer knows that good bleaching is absolutely a necessary preliminary in the production of good printing. Indeed, this is now pretty generally acknowledged in the north of England; for most of the opulent houses in Lancashire and in Scotland, which produce fine work, are bleachers as well as printers.

Oxymuriate of lime is the agent generally employed in bleaching; but it appears to us that some other article might be introduced with advantage. For, as the goods are washed in dilute sulphuric acid when they are taken from the oxymuriate of lime, a sulphate of lime is always formed, which becomes fixed in the fabric, and, acting as a mordant when the pieces come into the madder-copper, occasions an indelible stain, which in very fine goods often impairs their beauty. If oxymuriate of soda were employed, the sulphuric acid would form a soluble salt with the soda, easily removable by washing.

No people have taken more pains to excel in bleaching than the Irish, and their credit is established accordingly. The German linen, we believe, is generally better than theirs; but the Irish has always the preference in foreign markets, owing to their superiority in bleaching and finishing.

A very minute account of the various processes in bleaching has been already given in our 4th vol. part ii. under the article BLEACHING; which see.

By whatever means the bleaching is performed, the printer commences his part of the business in the following manner.

The goods are first drifted by hanging them off the whole of the nap which is attached to them. This is effected by the following contrivance:—Ten pieces are generally wired together, and wound upon a roller, from whence they are passed over a hot iron, nearly in the form of half a cylinder, and received upon another roller; from thence they are returned to the iron, which is still kept red, or nearly at a white heat. The use of repeating this process is to remove the nap more effectually than it would be done by passing it only once over.

The next operation is that of fleaping, which consists merely in soaking the pieces for twenty-four hours in a vessel of weak alkaline ley, at a temperature of about 105°. These operations of hanging and fleaping are going on at one and the same time, which effectually prevent any accident that might otherwise arise from the effects of the hot iron.

The goods are then boiled or else boiled in a solution of potash (some workmen prefer to have this alkali in a pure caustic flate); they are then well cleaned by thorough washing in wash-wheels, or in floks, to ensure their being entirely divested of the alkali. The intention of thus treating them with potash, is to remove any grease or impurity that may be attached to them, which would otherwise endanger the evenness and uniformity of the colours. This process is called ashing.

By some observant calico-printers it has been imagined, that the rendering of the ley caustic is apt to impair the texture of the cloth; and we doubt not but that this has often been the case. Under the eye of the master, however, we are sure that it might be employed with advantage and safety.

It may be remarked, that in weaving calicoes the workman generally greases the reeds, in order to make them move easier. Tallow is also employed for greasing the warp, and this has a baneful effect on all goods which are designed for printing. Wherever this grease is in the cloth, it becomes fixed by the operation of fleaping; and if it be not taken out before bleaching, it will not come out afterwards by the usual process of ashing and foursing; for, when the pieces are submitted to a blue vat to be dyed of a uniform self-colour, all those greasy places will be found to have taken the dye in a very imperfect manner. If the calico-manufacturers themselves would make a point of preparing the oleaginous matter for the weavers, and would furnish them with nothing but pure vegetable oils, such as those of rape, linseed, &c., it is very likely that these inconveniences would not occur; for the flax from vegetable is not so indelible as that from animal oil. To cleanse such goods, various expedients have been adopted, but we apprehend nothing but a solution of caustic alkali can be depended upon. To prove the effect of any method which may be tried, it is a good way to run the pieces through water, and then to pass them from the water over a roller, as to give the superintendent an opportunity of examining every inch of the surface; and if any part remains greasy, it will be seen at once, for that part will continue dry, while all the rest of the cloth is wet.

There is another way in which the goodnefs of bleaching might be proved. Let a few of the unfused pieces be run once or twice through a madder-copper, at the temperature of about 180°. This will inevitably mark any part that may be imperfectly bleached; whereas, if the operation has been properly performed, they will come out to little stained, that an intelligent workman, who has been used to a madder-copper, will at once be satisfied that they contain no impurity that can form a permanent mordant.

The next process is one with diluted sulphuric acid. A quantity of soft water having been poured into a leaden vessel, oil of vitriol is gradually added to it, in the proportion of about twenty pounds of oil of vitriol to every hundred gallons of water, which by weight is in the proportion of about one to forty.

When this mixture has been well stirred, it is ready for use. Sometimes it is employed in this flate, at others it is heated to 90° or upwards of Fahrenheit, according to the nature of the work to be done, and the goods are immerged in it. They are not suffered to lie in this solution, but are wound by means of a winch over a wooden cylinder, that every part of the cloth may be immerged in the fluid, and exposed alternately to the action of the atmosphere.

This operation is generally continued for about twenty minutes, and is designed to remove any iron-moulds or other stains which the cloth may have acquired. It has also the effect of neutralizing any portion of potash that may have been left in contact with the cloth. The process is called foursing.

After this operation it is necessary to wash the goods thoroughly, that no part of the acid may be left in them to injure their texture, and this is best effected by means of

PRINTING ON CALICO.
the waft-wheel. The calicoes are then to be regularly and thoroughly dried, which finishes these preliminary operations, known in the trade by the term preparation; so that those cloths which have passed through these manipulations are said to have undergone a preparation. Besides the ules already mentioned, there is another advantage attending these processes, viz. that the cloth which has undergone this preparation will bleach sooner, the colours will be brighter, and the whites more delicate, than they would have been had they not gone through these previous operations.

The next process is that of calendering. Here the goods are passed through a set of rollers, which gives them a gloss, and the appearance of their having been ironed. They are now fit for printing. For copper-plate printing, or cylinder work, the process of calendering is omitted.

In printing full colours, the artist usually proceeds in this way: he lays the piece of calico, which has been already softened by calendering, upon a strong thick table, which is previously covered with a woollen cloth. He then proceeds to apply one or more mordants, as the case may require, for fixing the intended colours. These mordants are applied by means of wooden blocks, with the patterns formed upon them. These blocks were formerly chosen of holly, and the cutting them was a separate branch of the buffens, and was called black-cutting. Of late years, however, a considerable improvement has been made in this part of the buffens by the introduction of brass or copper; that is, the pattern, instead of being actually cut in the wood, is now formed by means of slimmer pieces of one of those metals being firmly fixed to the block, so as to produce the pattern intended. This alteration was occasioned by the perishable nature of wood, on account of which every printer incurred great and unnecessary expense. The pattern when thus formed with copper, is not only more lasting, but it has also the advantage of giving greater sharpness and beauty to the impression. When it was customary to use wooden blocks, the patterns were not engraven in the wood, but the wood was cut away in such a manner as to leave the pattern in relief. It will be obvious that this must always be the case in block-printing.

When the mordant is ready, it is mixed up either with flour-paste, or with a thick aqueous solution of gum arabic, gum fenegal, or gum tragacanth, and is then spread upon a piece of superfine woollen cloth, strained tight upon a hoop. This is placed within another hoop, covered either with sheep-skin or oil-cloth. These hoops are both so broad as to give to each of them the appearance of a tamborine. That which is covered with the woollen cloth is called a fiefe, the other a cafe. The fiefe within its cafe is now placed in a small tub of gum-water, and is ready for use.

Flour is an article of considerable consumption with the printers for making paste. Some houses buy twenty barrels of American flour at once. Should it be much or four from keeping, it is of little consequence for their use; but they are careful to buy none but such as has been made with found wheat, for if it should be of no value for their purposes.

Gum tragacanth is much dearer than the other gums mentioned above; but notwithstanding this, it must be had for some styles of work, as no other will answer for any of those colours or mordants which are prepared with nitrous acid. A solution of gum fenegal would be coagulated in an instant by any of those preparations. Of late years, an article called British gum has also been much in use for the same purpose; so much so that the making of it has become a distinct trade. It is merely common starch pul-

verized, and then calcined till it assumes a cinnamon-brown colour.

When the apparatus is thus prepared, the mordant is applied by a brush to the surface of the fiefe. This is called tereing.

It should have been remarked, that when a colourless mordant, like the acetate of alunine, is employed, the workman generally mixes a little of the decoction of Brazil wood, or of any other fugitive dye, with it. This is called lighting; and is for the purpose of making the pattern more obvious to the workman, that he may see its progress, and the efficacy of the materials, as he proceeds in printing. The manipulation may be thus described.

Taking the block containing the pattern in one hand, the workman applies it gently to the surface of the fiefe, so that a sufficient quantity of the thickened mordant may adhere to the figures. When the block is thus charged, he applies it to the calico, and gives it a blow with a small mallet, either slightly or otherwise, according to the nature of the pattern.

This alternate application of the block to the fiefe and to the calico, is continued till the workman has gone over the whole piece. In this way, several different mordants are sometimes applied to the same piece of goods. This is indeed always necessary, when the finished piece is intended to contain a variety of colours, the different colours requiring different mordants to fix them and render them permanent.

The calico is now removed to a room called the flove, where a certain degree of heat is given to it by means of flues, which go round the room on the inside, near the floor. In this room, it is generally continued for at least twenty-four hours. This is when common red-liquor has alone been printed; but if citric acid or strong muriate of tin has been employed, less time is sufficient, and for the latter feldom more than half an hour is allowed. The intention of this is to evaporate the acids used in the preparation of the mordants, and which might otherwise injure the texture, and also to fix the dyes more firmly within the fibres of the cloth.

In this operation, an attention to temperature is of the utmost importance. In general the room is kept at about 90°; but an intelligent calico-printer varies this according to the nature of the work under operation. If iron-liquor has been employed in printing the goods, it is an excellent practice to keep them for several days exposed to the atmosphere, after their removal from the flove, as the blacks, pompadours, olives, and indeed every other colour prepared with that metal, will increase in intensity; the goods will clean better in the dung-veffils, as will be explained hereafter, and the colours will rise higher and brighter when they come into the copper of bark or madder. The iron in an acetoxy solution is in the state of the black oxyd; but by exposure to the air it acquires a further dose of oxygen, and the more nearly it is made to approach to the state of the red or peroxyd, the more it fits it becomes for a mordant in dyeing. It may be worth an experiment to discover whether the colours containing iron would not be better if they were suffered to be only a very short time in the flove, but were hung up instead for several days, exposed to a current of air at the temperature of the atmosphere; as the iron would thus acquire the oxygen flower, and consequently would be fixed more firmly within the cloth.

When the pieces have been properly flove, they are passed, by means of a winch, through water at various temperatures, with a little cow-dung mixed in it. This part
PRINTING ON CALICO.

part of the business was formerly conducted in a very uncleanly and negligent way, but of late years some printers have incurred a considerable expense in the construction of their dunging machines, with cocks for hot and cold water attached to them, and thermometers to regulate the temperature. Thosé erected by Mr. Wright, a very ingenious calico-printer, at Strines, near Difley, are the most complete of any we have yet seen.

The intention of the dung is to absorb and remove that portion of the mordant which is not actually combined with the cloth, and which otherwise might flake the white or unprinted parts.

We suspect the dung of the cow is serviceable in another way besides that of cleansing, though the printer may not be aware of the nature of its operation. To clean calicoes by immersion in a dung-vessel, may appear to be a strange phrase; but as this is the technical language of the trade, no other could be employed with propriety. It is acknowledged that madder, cochineal, and some other dyes, produce much better colours on woollen than on cotton cloths, owing to the former being of animal, and the latter of vegetable origin. We presume, therefore, that the dung imparts an animal matter to the fibres of the cotton, and that this animal matter acts as an additional mordant, and thus more powerfully affects the colouring particles of the dye, than the mordants alone would be capable of doing. Berthollet, who analysed the dung of the cow, found in it a substance partaking of the nature of bile.

If a piece of calico, prepared with the acetate of alumine, be divided into two parts, and the superfusible mordant removed from one of them by cow-dung and water, and from the other by water only, though both fluids were at the same temperature, it will be found, on passing the two portions through a decoction of weld or quercitron bark, that the yellow will be much more intense and bright in that which had been submitted to the action of the cow-dung. This is a satisfactory and decisive experiment.

The process of dunging is an operation that varies in time from five to forty minutes, according to the lye of work. The pieces are then taken to the river or wheel, to be more effectually washed; after this they are passed through tepid water, in order that the workman may be assured that every impurity is removed.

His next care is to provide a copper boiler of pure cold water, in which a sufficient quantity of madder is put, and a fire lighted underneath it. The calicoes, printed and rinsed as above, are now put into this boiler, and from the time they are immersed, the workman never ceases to turn the wheel, so as to pass every part of the goods repeatedly through the liquor, till the whole acquires a boiling heat. Indeed, this operation is sometimes continued for ten or fifteen minutes after the bath of madder actually boils, when the pieces are taken out and washed.

Madder is one of the most valuable drugs we have, for a variety of purposes in dyeing and calico-printing; as it is the agent by which the red and yellow permanent blacks are produced; also the finest purples, and every shade of red from a pale pink to a crimson. But perhaps it may not be generally known that this article improves by age. If a quantity of madder-roots be ground, and then packed tighly in a cask, so as to exclude the air, and are kept thus for six months, they will then dye a much better colour, and go much further than they otherwise would have done, had these roots been used as Iroon as they were ground.

This process, which is called madding, has the effect of imparting all the requisite colours to the goods, by means of one operation, which may be thus explained. While one mordant precipitates the colouring matter of the madder to a red, another precipitates a different portion of it to a purple, another precipitates it to a black colour, and so on of every possible shade, from a lilac to a black, and from a pink to a deep red.

If a portion of weld or bark be added to the madder, every shade from a brown to an orange may be produced; whereas, if weld or bark alone be employed, all colours between a dark olive and a bright lemon can be imparted to the cloth. These changes are all occasioned by the play of chemical affinities, and are due to the improved state of chemical knowledge.

Here it may be worth remarking, that whenever it is of consequence to produce the finest yellows or more delicate lemon colour, it is necessary to dry the pieces in the open air, as the flow would not fail to injure such colours; for flow-drying has always a tendency to convert a yellow to an orange. It is also necessary to be equally careful in the operation of dunging the mordants for these pale yellows; for, should this be done at a higher temperature than 96° or 100°, their beauty will certainly be impaired. There is another advantage in this, viz. by dunging at this low temperature, the dyeing may be completed even at 110° or thereabouts, which will give a much livelier colour than when a higher temperature has been employed.

The mordants generally used in calico-printing are acetate of iron for browns, blacks, blues, &c. and acetate of alumine for all the different shades of reds and yellows.

Formerly the acetate of iron was made by digesting old iron hoops in four beer, or in very weak vinegar; but of late years it has chiefly been made with the pyroligneous acid, [if wood be submitted to an intense heat, when inclosed in an iron vessel of any kind with a proper aperture to allow the vapour to pass, this vapour on being condened forms the acid in question, and is now known to be a kind of impure vinegar.] The wood in this cafe is converted into charcoal, of which a great deal is prepared by this process, particularly for the formation of gunpowder,] the oleaginous impurities of which tend, in some cases, to improve the mordant.

Blacks are also produced by the nitrate of iron [nitrate of iron was not applied to calico-printing till within the last fifty years. This discovery formed an important era in the trade, as it afforded the manufacturer the means of varying his styles of work in a multiplicity of ways and forms, which, till then, were entirely unknown] and gallic acid; the mixture is called chemical black. This nitrate of iron is made by dissolving metallic iron in a peculiar kind of aquafortis. Common aqua-fortis will not answer for this purpose; for, though it may dissolve the iron with rapidity, part of the metal is apt very soon to precipitate; which not only weakens the colour, but leaves the remainder so acidulous, that there is always a danger of such a preparation injuring the texture of the cloth.

It is, however, necessary to remark, that the black which is formed by this solution of iron, is produced in a different way from blacks in general; for, when common iron-liquor is used for this purpose, it is first printed on the calico; and when it has been sufficiently oxydized by exposure to the air, the goods are boiled in a decoction of madder, which renders such parts as had been printed with the acetate of iron an intense black. But the black from nitrate of iron and gall is applied at once to the cloth, and is not afterwards raised by dyeing.

The calico-printer by using a black ready formed is thus enabled to mix it with other colours, in cafes where by dyeing alone it could not be produced, as in conjunction with yellows and olives, raised by weld or quercitron bark.
The acetate of alumine is prepared by a mixture of the 
fulpate of alumine with acetate of lead, both in a state of 
solution; so that, on the theory of double decomposition, 
fulpate of lead is formed, which precipitates, while the 
acetate of alumine remains in solution.

Since the demand for this article has been increa®ed on 
account of the extension of the printing trade, it has been 
prepared from the pyroligneous acid by means of lime and alum.

The following is the method:

The pyroligneous acid is ®rst passed through a still, to 
divest it of a portion of the tar which is always dissolved in 
it; it is then saturated with lime or whiting; and lastly, the 
acetate of lime thus formed is decomposed by a heated solu-
tion of fulpate of alumine. The result of this double 
decomposition is fulpate of lime, which precipitates, and 
acetate of alumine, which is drawn from the sediment of the 
calcareous fulpate, and preferred for nfe.

And here it may be nece®sary to caution the manu-
facturer against a misfortune that may ®ll him if he be 
not convener with the chemical nature of the substances 
he employs.

Magnesian lime-lime abounds in Derbyshire, and in some 
of the adjacent counties; and should a maker of acetate of 
alumine employ such lime in his processes, the article which 
it would produce would in all probability be entirely un®t 
for the use of the calico-printer. But we must be more 
explicit.

In employing the common lime in conjunction with alum, 
a fulpate of lime will be formed, as established above, and 
this being nearly an in®nable salt, will precipitate. But here, 
fulpate of magnesia would also be formed, which being a 
®solable salt, would remain in solution, and increase the spe®c-
®c gravity of the liquor; a circumstance which would be very 
apt to occasion the deception which we are anxious should 
be avoided. If magnesian lime-lime be employed, the liquor 
will appear good by the hydrometer; but, as it will contain 
more Époine salt than acetate of alumine, it will be un®t 
for every purpose for which it was intended.

While speaking of acetate of alumine, we cannot avoid 
remarking that the pro®ce which has just been described for 
making this mordant, and which is followed invariably by 
many of the manufacturers in the North, is extremely im-
proper, on account of the lime which is employed in it, be 
the lime ever so good, as that earth is very prejudicial to 
every species of red dye. The true way of making it, 
though more expensive, is that which was originally pointed 
out by Berthollet, and which consists in decomposing ful-
pate of alumine by means of faechurum satimur, or acetate 
of lead.

In reverting to the remaining pro®cees of the print-work, 
it must be noticed, that when the goods have passed through 
the weld or madder-copper, they are usually carried to a 
boiler containing wheat-brain and water, in which they are 
winched for a considerable time, for the purpose of freeing 
the white grounds from the ¢ain which they had acquired 
from the madder or the weld. This process always impairs, 
in some measure, the intensity of the colours; ®branning has 
also the effect of giving a pink hue to all madder reds. But 
it is not generally known what a ¢egasus ¢nefulness may be 
ipated to madder-colours, by raising them with a mixture of 
bran and madder; that is, by mixing a portion of bran 
with the madder in the ¢rst infusae. Mr. Parkes tells us, 
that he has sometimes produced colours in this way whose 
brilliance has astonished him. The operation of the bran in 
producing this effect will be explained hereafter; but it is a 
necessary operation, as there is no other mode so convenient 
for removing the ¢ain which is always given to the white 
part of a print by the madder, the bark, or the weld, which 
has been used in dyeing it.

It frequently is the case, however, that goods will not 
bear to be su®ciently branned to clear the whites entirely 
by that one operation; [the temperature at which the opera-
tion of branning is performed, is very important. If bark 
yellows are dyed at 100°, it is customary to bring such goods 
at 115° or 120°, as it is a principle always to brann at a 
higher temperature than the goods are dyed at. Madder- 
work must be branned at a boiling heat;] such goods, 
therefore, are partially cleaned in the branning-copper, and 
are then laid on the grats for some days, till they become 
perfectly clean.

But within a few years a new method has been intro-
duced, which consists in immersing the pieces for a certain 
time in a very weak solution of one of the bleaching fahs, 
such as oxyburnite of potash, soda, or magnesium. [A Scotch 
houfe of great confucence had practised this method a con®dable time; and in the year 1812, a person visited 
Lancashire for the purpose of instructing the English printers 
in the method.] This simple proceed, which effects in a 
®ew minutes what would require more than as many days 
in gras-bleaching, is now much practiced, and promises very 
soon to supersede crofting entirely. This is a most im-
portant improvement, as some of the large printers formerly 
required as much land to spread out their goods upon, as 
would make a farm of a very considerable size.

Besides the kinds of calico-printing already mentioned, 
there are others which it will be proper to notice in this 
place. Of these, what is called ®®st-®ars, is now done in 
considerable quantities. It is conducted in the following 
maner:

A certain preparation of copper, mixed either with flour-
pate, with gum, or with pipe-clay and gum, is printed 
on the calico, in any shape or of any pattern that may be 
directed. [The sulphate, the nitrate, the muriate, and 
the acetate of copper, have all been employed for preparing the 
®®st-®ars; but the sulphate is the best for the purpose; 
unless a very concentred solution of the four fahs were 
prepared by successively dif®lving each of them in pure water.] 
When this is ®ciently dry, the goods are repeatedly 
®pped in the blue vat till they have acquired that depth of 
tint which may be required; and then, when they are washed, 
and ®pped through diluted sulphuric acid, those parts which 
had been printed with the preparation of copper, are found 
to be a good white; the preparation having efectually 
®®ed the operation of the indigo. [The art of making an 
indigo-vat consists in forming such a mixture of lime and 
sulphate of iron as shall most efectually deoxydize the 
indigo; as indigo has no a®nity for cloth in its natural or 
®xigenized state. Hence, those parts of a piece which are 
printed with a solution of copper will never be dyed blue in 
one of these vats; because the deoxydized indigo becomes 
®xogenated the moment it touches the copper, which parts 
with its oxygen to the indigo, and occasion it to become 
®noluble, and consequently incapable of forming a dye. 
Thus, whilst sulphate of iron has the power of deoxydizing 
indigo, sulphate of copper, or any other fah of that metal, 
is incapable of retaining its oxygen, whenever it comes in 
contact with that singular substance in a state of deoxydize-
ment; and it is a curious infuence of the different degrees of 
intensity by which oxygen is held by the different meta-
tals.] though all the other parts of the cloth have received 
a permanent dye. The various deep blue calicoes with 
white spots or white ®gures, which are now so com-
mon, are generally done in this way; and by a familiar 
management with subfrequent dyeing in madder, weld, or 
bark,
PRINTING ON CALICO.

In some particular styles of work, the operation of certain colors is facilitated by means of boiling out with wax; but this is too expensive a method to be adopted often in those cases, when it is the object of every manufacturer to finish his prints at the least possible expense. [In printing those filk handkerchiefs called Bandanas, a process called waxing is still followed. It consists in making a preparation of tallow and rosin very liquid by heat, and in printing it in that state with a block upon the filk. When such goods are passed through the blue vat, those parts which are covered with the tallow and rosin are preferred from the action of the indigo, and remain white, while all the rest is dyed a fast blue. The method afterwards taken to discharge a part of this blue, and produce yellow, orange, &c. will be mentioned hereafter.] Formerly this mode was very generally practised, and wax [in the East Indies wax is still used for preferring the whites in calico-printing] was confumed in very large quantities by this process. [A very singular-looking substance was discovered a few years ago near Stockport, which being handed about from one to another as an undescribed substance, created considerable interest in that neighbourhood. Every body supposing it to be a natural production, specimens of it were sent to a variety of persons in various parts of the kingdom, for their opinion and analysis, and among others a portion was sent to Mr. Parkes. However, after every one had been busily engaged in examination and conjecture respecting this unknown substance, it was announced, that some seventy or eighty years before a calico-work had flooded on the spot where the article was found, and that this was nothing more than a large heap of the refuse compound of flour, wax, and gum, above-mentioned.]

The reader will perceive that these refls are employed for the purpose of preferring certain parts of a piece white, and of giving other varieties to those goods in which blue is the predominant colour: but if the ground be to be white, and the piece is only to have one small object [a technical term, belonging to this branch of manufacture] in indigo blue, such as a single sprig, then a different management is necessary, and the colour is imparted by a process which is called pencil-blue.

Here the indigo is deoxidized by means of permanganate, which is a fulphuret of arsenic; and formerly, whatever objects were done with it were put in by means of a pencil: hence its name, pencil-blue. [Pencil-blue is composed of the following ingredients, viz. Ten ounces of indigo finely ground in water; twenty ounces of quick-lime in lumps; the same quantity of potash of commerce, or the impure subcarbonate of this alkali; and ten ounces of orpine. These proportions require one gallon of water, and the whole is to be thickened with gum fenegal.] See Colour.

Another kind of process remains to be noticed, called chemical discharge-work. Here the cloth is first dyed of some uniform colour, by means of a mixture of iron-liquor, and some one or more of the common vegetable dyeing substances; and calicoes thus prepared are laid to be dyed of self-colours. They are then washed and dried; and when properly pressed or calendered, they are fit for receiving any pattern whatever, according to the artist's taste or design.

This is generally effected by means of the mineral acids, which are previously composed for the purpose, by dissolving the iron which is contained in the dye, and which is always used in such quantity as to cover, or at least to disguise in a great measure, the other colour or colours which had been employed with it, and at the same time to act as a mordant in beautifying and fixing these colours.

Thus a piece treated with a decoction of Brazil-wood, and dried black by being padded [by the term padding is understood the operation of passing the pieces from a roller through a trough containing a solution of iron, or any other mordant. Bleaching is another term used in calico-printing, and is synonymous with padding] with iron-liquor, if, when dried, it be printed with a peculiar solution of tin, the ferruginous portion of the dye will be dissolved, and the printed part will instantly be converted from a deep black to a brilliant crimson.

In the same way an olive-coloured calico, dyed in a solution of iron and a decoction of weld, will as quickly be changed to a bright pale yellow; and the various drabs and flates of every shade which have iron in their composition, will undergo a sudden change by the same treatment; though the colour of the figures produced on them will depend on the materials with which the cloths were originally dyed. Even the deepcoloured colours, or strongest buffs, if produced by iron only, may, by a peculiar preparation of tin, be discharged; and such parts of the cloth as have been treated with this metallic solution will be restored to their pristine whiteness.

By similar management, calicoes dyed of a light blue in the indigo-vat, then run through fumach and coppers, and finished in a bath of quercitron bark and alum, may have figures of a bright green imparted to them. Here the green is originally formed by means of the indigo-vat and the bark, though it is covered by the iron of the coppers, which overcomes the other colours, till the solution of tin is applied, which removes the iron from those particular parts, and gives a brilliance to the remaining colours which they would not otherwise have possessed: the tin being a powerful mordant for the bark, by which the yellow of the green is produced.

Again, a good self-colour may be given to calicoes, merely by dyeing them in fumach and coppers, and then running them through an alkaline solution of anmotto; and here the figures produced by the application of a colourless solution of tin will be of a bright orange. But it is necessary to enumerate more inferences, as the workman accustomed to a dye-house will have little difficulty in varying these in a thousand ways, when he becomes acquainted with the nature of the solution of tin which he employs.

The whole of this, however, refers to that branch of discharge-work only, where all the purpoases are attained by dissolving the iron which makes a part of the colour that is intended to be discharged; whereas, the finer and more expensive work is done in a different way, and by a process which it will be necessary for us presently to describe.

In the mean time it may be proper to remark, that there is an objection to the particular kind of chemical discharge-work of which we have been speaking, namely, that it is not perfectly fast; that is, the goods produced in this way will not bear such frequent washing, as those which are done by the bath of madder or bark.

It is certainly an object of great national importance to give a permanency to the calico-printing of the country; [to this end great improvements have lately been made in the method of grinding madder-roots, by separating the inferior parts, and dividing the whole into two or three different qualities. Thus the printer is enabled to apply the finest, which in this way is made equal to Dutch crop-madder,
madder, to his best work, and the other is laid by for inferior purposes;] and a great deal of very excellent printing is now done in various parts of the kingdom, especially the bell chintz-work and other furniture patterns. But, in what is called fall-work, there is a great variety of qualities, and some of it little deserves the name of permanent.

The mention of permanent colours reminds us of a very valuable green which was invented a few years ago by a Mr. Iflet of London, and which deserves to be noticed by us. This colour, which was secured to him by his majesty's letters patent, was produced by printing ground indigo, mixed with a peculiar kind of solution of tin, and in that form the ground indigo, within the fibres of the calico by means of that process, which is well known to printers by the technical designation of china-blue dipping. [China-blue is produced thus: Indigo ground fine, and then thickened, is printed upon the cloth, and afterwards it is dissolved, and chemically united to the fabric, by alternate immersion in a solution of fulminate of iron and in lime-water. A description of this process has already been given very much in detail, in our eleventh volume, part ii. under the article Dipping, in Calico-Printing.] After this the goods are to be dyed in a copper of bark or weld, which converts the blue to a green, and the whites are to be cleaned by croft-bleaching, &c.

Upon this very ingenious process, Mr. Parkes has the following observation. "Having," says he, "formed a very high opinion of this invention, I procured several interviews with Mr. Iflet, soon after he obtained the patent, and from him I was fully informed of the whole process. — This I have since repeated for the purpose of verifying the detail in all its branches; and I am satisfied that it is one of the most beautiful and permanent colours that has ever been fixed upon cotton."

There is, however, another mode of producing very beautiful blues which has been much practised lately, and therefore deserves notice. This consists in printing some solution of iron, and then palling the goods through a very dilute and neutral solution of prussiate of potash. The prussian blue which is thus formed upon the cloth may be rendered tolerably permanent by a variety of expedients, and this by means of any of the yellow dyes may afterwards be formed to any shade of green or of olive.

In returning from these digressions we must not forget to revert to that other kind of discharge-work which we have engaged to describe, and which we will now attempt as concisely as is consistent with perspicuity and correctness.

Here, the agent which is employed is the citric acid, and this is used in various fluids or concentration according to the purpose to which it is to be applied, and the strength of the ground intended to be discharged. It is chiefly employed for the production of white figures upon self-coloured grounds produced by madder and madder dyes. For this purpose the acid, in whatever fluid of concentration it may be, is mixed with either gum or with pate, when citric acid is used for resin-work, it is always mixed, with gum fenuagli and pipe-clay. The clay gives it a greater body, and likewise acts mechanically as a retifier, to a proper consistency for the block, the plate, or the cylinder, and from thence it is transferred to the piece; and wherever it attaches, the mordant, whether iron or alumine, is discharged, and a delicate white airies is its head. [It should be understood, that the discharge is printed upon the mordants before the goods are dyed.] In using citric acid for this purpose, a portion of one of the mineral acids is sometimes mixed with it.

The acid here referred to is produced from the juice of limes or lemons, and formerly it was not employed by the calico-printer until it was reduced to the utmost point of concentration, and appeared in a crystalline form. Even then, it was not thought sufficiently pure, but was distilled again, and redissolved and recrystallized, till it became white and pellucid as any other pure salt in a crystallized state, and was then generally sold for 35s. the pound, at which high price it could only be employed on the best styles of work. Now, however, it is often used in the brown, or first state of crystallization; and some of the larger printers purchase lime juice, and concentrate it themselves; and in many cases, they use it largely both for discharge and resist work, without ever crystallizing it at all. More on this subject may be seen in Mr. Parkes's Essay on Citric Acid, in vol. iii. of the Chemical Essay, page 1—118.

This mention of discharge-work by citric acid, [Mr. Thomson, who has a print-work near Clicheroe, has taken out a patent for discharging the Turkey-red dye by means of the citric and oxymuriatic acids; and the work executed in this way has a very pleasing effect,] reminds us of another species of discharge, which is employed by the printers of Bandana handkerchiefs, and which we are under the promise of noticing before we conclude this memoir.

The agent which these printers employ is the nitrous, and sometimes the nitro-muriatic acid. It is used for the purpose of putting yellow figures upon blue silk handkerchiefs. The following is the process which is principally adopted.

Aqua-fortis, or nitro-muriatic acid, of such a strength as is suitable for the kind of blue which is intended to be discharged, is mixed either with gum tragacanth, or with flour paste, to a proper consistence, and in this form it is printed on the silk, by means of a common block, on which the intended pattern is cut. The confluence of this is, that wherever the acid attaches, there the original colour is discharged, and a yellow dye is produced in its place. The pieces are then steamed, by palling them over a vessel containing boiling water, which gives brilliancy to the colour and finishes the operation.

If a stronger dye than the usual yellow, or even a deep orange be desired, all that is necessary is to immerse the goods, for a moment, in lime-water, or in a solution of lime and potash; and by varying the proportions of these ingredients a great variety of shades may be produced.

Recollecting, however, that this is a paper professedly on calico-printing, we must not deviate too far from the path we have preferred; otherwise, there are many processes in the printing of silks which are curious and interesting, on which we might copiously expatiate. The Bandana handkerchiefs which are printed upon cotton in imitation of India goods, are produced by a very different process, and which we have already described under the article Discharging of Colour, in vol. xi. part ii.

Having been speaking of yellows, it may be worth mentioning that there is a mode of producing yellows on calico which is not very frequently practised, and yet has a very good effect. The process is as follows:

A strong decoction of bark, thickened with gum tragacanth, is to be mixed with a portion of very pure nitrate of tin, and this, when printed, with the usual management, will produce a colour of brightnes and durability. We mention this the rather, because very many pleasing effects may be obtained by this method which cannot be produced in the usual way, by means of the acetate of alumine, and any of the yellow dyes that may be employed with it.

There is one very important advantage which this mode possesses,
Upon those parts of the calico which still remain white, any of the above mordants may be printed, according to the effect designed to be produced, after which all the preceding managements are to be repeated, except that instead of boiling in a decoction of madder, they are to be immerged for about half an hour, more or less, in a warm decoction of quercitron bark, the _Quecus nigra_ of Linnaeus; a most important dye-wood, introduced by Dr. Bancroft, and which is found to give out a much brighter colour to tepid water, than it does when treated with boiling water, or with water nearly approaching to that temperature.

The effect produced upon these prints by an immersion in a lukewarm decoction of this American bark, will be quite different from that produced by the madder; upon those parts of the cloth where the mordants have been printed which before produced a black, a dark olive only will be apparent, and instead of pompados will be drabs, and instead of reds we shall have yellows, which will vary in intensity according to the strength of the aluminous mordant.

Again, a further variety may be given to these prints, if the yellow mordant, or acetate of alumine, be applied to any of the colors which have already been dyed with madder; but this must be done before the pieces are immersed in the decoction of bark. This application will convert the reds and pinks into different shades of oranges, and the lilacs into cinnamon colours. By means of these different processes an endless variety may be given to the goods, and a calico-printer of taste will never be at a loss how to produce a pleasing effect, whatever may be the patterns which he has to imprint upon the cloth. This second immersion in the dyeing vessel will, however, give a yellow tinge to the remainder of the whites, but a short exposure on the grafts will obliterate it.

When chintz furniture-prints are designed to have as much variety of colouring as possible, a part of the remaining white is often coloured blue or green, or of any shade between those colours, by a still different process. This is done with what is called pencil-blue, which is a preparation that has already been described. The blue is given by putting in the prepared indigo with a pencil; and the green is produced by pencilling some of the same colour over certain parts of the pattern which has already been dyed yellow. When these colours have been imparted, the printing is laid to be finished, and the pieces are hung up to dry for at least twenty-four hours, after which they are rinsed thoroughly in cold water; and when they have been dried with care, they are properly calendered and put up for sale.

Nothing now remains but to notice an improvement which has been made of late years by the introduction of cylinder-printing, and which has the advantage of superior accuracy and neatness, as well as of great expedition.

The machines which effect this are rather complicated and expensive; but they are so contrived that the cylinders on which the patterns are engraved, furnish themselves with colour during their revolutions; are kept clean by a steel knife, or _dator_ as it is called, passing over their surfaces the moment they have charged themselves with the strengthened colour; and they have such a pressure given to them, either by means of screws or levers, which can be tightened or slackened at pleasure, that the whole surface can be made to deposit its colouring matter with the greatest certainty and exactness on the cloth, while this rolls over it in succession, from one end of the piece to the other.

These cylinders, which are made of copper, are from eighteen to forty-two inches in length, according to the width of the calico to be printed, and three and a half to five

**Vol. XXXIX.**
five inches in diameter; and these maclie rollers have the patterns encafed upon their surfaces, in the same way as a pattern is cut upon a flat plate of copper, that is intended to be employed in copper-plate printing. As these cylinders are made with plates of copper hammered into a circular form and joined by brazing, great loss has sometimes been sustained by the engraving giving way upon the brazed joint. To obviate this, a patent has been lately obtained for boring the copper cylinder from the solid metal in the modern way of boring cannon.

Many of these machines are now contrived to as to carry two of these cylinders, each of which has a trough of colour attached to it, by which means two different colours may be printed on the same calico, at one and the same time.

Mr. Adam Parkinfe of Manchefer has lately invented a machine capable of printing at one time, by means of one cylinder and two surface-rollers, or by two of the former and one of the latter, three distinct colours.

These machines have not only the excellence of printing more correctly than can possibly be done by means of the block, but the saving of time and labour which they afford is great indeed. A piece of calico which would take a man and a boy three hours to print with one colour, or six hours to finish with two colours, may by this means be done in three minutes, or three minutes and a half, and then much more completely than could even have been imagined before the introduction of this invention.

Beside these cylinders there are others which are called surface-machines, which contain cylinders of wood, and which have the pattern formed upon their surfaces in relief, exactly similar to the blocks already described. These are employed in particular styles of work, especially in light ground-work, and for certain kinds of relief and discharge work.

In light work, the white grounds are apt to be foiled by the cylinders; hence surface-machines were contrived, and these are not liable to the same objection. Cylinder-machines are more commonly employed in those styles which are full of colour and leave but little white.

It must be obvious to every one who is acquainted with the subject, what an astonishing facility these machines have afforded to the production of printed calicoes; and also what an advantage they give to the British printer in foreign markets.

But we cannot conclude without expressing our fears, that even these facilities may eventually be the means of doing a serious injury to the trade, and of destroying that confidence in the goodness of British prints, which has hitherto been generally felt in every market on the continent, and also in every part of the New World, wherever they have been introduced. We refer to that mode of printing which has lately been adopted, and which conveys in precipitating the colouring matter from logwood, and from other fugitive dyes, and in printing these on the cloth, without any mordant or previous preparation whatsoever. Thousands of pieces of this sort have been finished at the low rate of one penny the yard, including every expense of colour, paste, and printing. These articles, it will scarcely be credited, are dried up immediately from the printing-machines, and are shipped abroad, without even being washed off.

To wash off is a technical phrase. It means the soaking and rinsing the pieces in water, in order to dissolve and remove whatever gum or paste had been employed with the colours in printing them.

Such goods, wherever they go, must produce great dis-
satisfaction; for they will neither endure the rays of the sun nor moisture. The first shower of rain to which they may be exposed, will not fail to wash out the pattern, and reduce them to a worse state than that of plain white calicoes.

In the reign of queen Elizabeth, an act was passed to restrain the use of logwood in dyeing, on account of the fugitive nature of its colour; and if this degrading kind of printing be continued, the interference of the legislature will again become necessary, or the foreign trade will, from this cause alone, be entirely lost to the country.

PRINTING, Cylinder. See the preceding article.

PRINTING on Porcelain. The art of printing, particularly as it applies to books, has, from its inestimable benefits and vast importance, excited at once the profound admiration and gratitude of the world; and this ineffaceable discovery has been claimed by several individuals, alike anxious for the honour of giving mankind at large the advantage of a rapid and economical diffusion of delight and instruction. The first idea of types was very probably given by the Roman potters, who were in the habit of stamping their names in raised characters on their vases, &c. The letters on this plan were, in fact, models of the types used by the first printers; and it appears singular that the idea of adapting such models by the medium of ink, to the common purpose of multiplying words and sentences, should not have come into use until about the year 1442.

It will appear, on consideration, still more singular, that after the introduction of engraving on wood and copper, (which was in use at the same time with letter-press printing,) the art of transferring impressions of ornamental designs, from the copper-plate to the surface of porcelain or pottery, was not discovered till about the year 1760.

The Royal Porcelain Works in Worcefter, belonging to Mr. B. Flight, Barr, and Barr, are the only establishment that claims the honour of inventing this admirable and ingenious process. We can find no mention of this art in the annals of this or any other country prior to this period. It was practised with great success for many years in the works alluded to; and besides the demand for home consumption, large quantities were exported to Holland. In the year 1788, his present majesty Geo. III., and his royal highness the prince of wales, the prince of wales, and the prince of wales, visited the Worcefter Porcelain Works, and particularly noticed this ingenious branch of the art of decoration. The royal party were much gratified by the compliment paid them, in the striking off impressions from two copper-plates with the likenesses of the king and queen, which had previously been engraved by direction of the proprietors, in order to exemplify the nature of the operation. The secret of the printing was, about the year 1781, conveyed from the works at Worcefter into the potteries of Staffordshire, and has proved of infinite service in extending this branch of national commerce, and affording employment to the numerous population in that part of the country. The common British blue and white printed earthen-ware is now held in high esteem in foreign countries, from its cleanly and neat appearance, besides its being in general use at home. This art is certainly belted confined, as in the present day, to the inferior fabrics, such as earthen-ware, as the material on which the print is made is reasonable, and can be rendered at a price which suits the convenience of the consumer for all common purposes. The method, as invented and adopted by the original proprietors of the Worcefter Porcelain Works, is as follows:—The engraved copper-plate having first
first been warmed on the stove, is prepared to receive the colour, which, being previously mixed with oils of a proper consistency, is then rubbed into the engraved lines, and the superfluous quantity of colour is carefully cleared from the surface of the plate. The paper, which is very thin, and manufactured for the purpose, is then laid on the plate, and delivered to the pressman, who places it on a plank covered with warm flannels, and being fixed between two iron cylinders, it is drawn through by turning a wheel, exactly on the plan practised in taking off copper-plate prints. The paper bearing the clear-coloured impression is now removed from the copper-plate and delivered to the printer, who fixes the piece of porcelain in a vice, to keep it steady; and the printed paper is then rubbed with a wooden tool, covered with flannel, till the impression is completely transferred to the surface of the biscuit, or unglazed porcelain. The operation of rubbing on the impression being completed, the porcelain, with the paper left on the surface, is thrown into a tub of cold water, and in a short time the paper delivers itself, and leaves the print. The ware is now placed out to dry, and is afterwards carried to the kiln, where the impressions are burnt in. It is then dipped in the vitreous substance called the glaze, is burnt a second time, and the colour, which is the oxys of cobalt, (and most generally used,) comes out a neat blue, perfectly secured under the glaze.

An improved method of printing, comparatively of very recent invention, was introduced under the direction of the late Martin Barr, Esq., and is now carried on in the Porcelain Works at Worcester, and is much admired for the excellence of the engravings, and the great beauty of the impressions. On this plan, the printing-press and stove are not necessary, as the engraved plate is charged with a prepared oil by the printer, who cleans the surface of the engraving with the hand; and instead of paper, a bat of glutinous consistency is cut out and laid on the copper-plate, and is so ductile as to adapt itself to the form of any vessel intended to be printed; and by the simple pressure of a fluffed leathern ball with the hand, produces a perfect impression of the subject in oil on the smooth side of the bat. The ware being rubbed dry and clean, the bat is now gently pressed with the leathern ball on the glazed surface of the porcelain, and when removed the impression appears complete, but only in oil. The colour, in form of a powder, is then lightly moved over the oil impression with a piece of carded cotton, and the print completely cleared of all that is superfluous. The porcelain is afterwards carried to the enamellers, who fill the design by adding some decorations in gold; and it is then passed through the enameling kiln, where the oil is evaporated by the fire, and the colour, which is always a mineral preparation, unites firmly with the glaze, and becomes perfectly durable as the tints laid on with the camel's-hair pencils by the painters. The great advantage of this plan is, that the engraving can be executed much finer for the smooth surface of the glazed porcelain, than for the coarser blue and white prints, (which are laid on the rough unglazed surfaces,) as the glaze is capable of receiving the finest touch the artist can put into his engraved plate. Mellers, Flight, Barr, and Barr, the proprietors of these works, have in consequence introduced beautiful engravings of figures from the antique, Besides designs in landscapes, flowers, hills, &c. which reflect no small degree of credit on this branch of the art of printing. Considerable quantities have been exported to the East and West Indies; and where economy is the object of the consumer, this style of decoration suits very well, however deficient in richness of effect and elegance, to the more elaborate production of enamelled designs, executed in these interesting and highly respectable works.

PROFESSOR, i. 2, for venus r. venus.

PROJECTIONS OF THE SPHERE, ORTHOGRAPHIC. PROB. I. 1. 8, for IC and FG, r. 1C.

PROMEROPS, in Ornithology, a genus of birds of the order Pice; the characters of which are, habit as in the genus Upupa; feet formed for walking; tail lengthened, and in most species conuated. Dr. Shaw enumerates and describes the following species: viz. Cereus, or blue P. with black bill and legs; the Upupa indica, or blue promerops of Latham; a native of India: Cafer, or brown P. white beneath, with rufescent breast, and very long tail; the Upupa P. or Cafer P. of Latham, and the Upupa P. or Merops cafer of Linnaeus; a native of Africa, and common about the Cape of Good Hope; Stelatus, or brown P. beneath white, with black undulations and very long tail; Upupa papuensis, or New Guinea brown P. of Latham; native of New Guinea, inhabiting large woods: Superbus, or black P. with violet and green glofs, foliated golden shining scalular feathers, and very long tail; the Upupa superba and great P. of J. Latham, a magnificent species, exceeding all the rest in the splendour and elegance of its plumage; a native of New Guinea: Paradisaeus, or chefnut P., the Upupa paradisea of Linnaeus and Latham, and crested P. of the latter: Mexicanus, or grey P. with green and purple glofs, blueish wings, yellowith belly, and very long tail; Upupa mexicana, or Mexican P. of Latham; a native of Mexico, frequenting mountainous regions, and feeding on various kinds of insects: Aurantius, or orange-coloured P., with tail of moderate length and even at the top; the Upupa auranta, or orange P. of Latham; native of Guiana, frequenting the small islands in the mouth of the river Berbice; Fernandez describes the supposed female of this species under the name of Cocbitobia: Erythrogramus, or black P. with green and purple glofs, red bill and legs, and long tail with the feathers spotted with white near the tip; the Upupa erythrogramus, or red-billed P. of Latham; an highly elegant species, an inhabitant of Africa.

PROPERTY, LITERARY. (See Literary Property.)

The state of literary property has been considerably improved since the article on this subject appeared in the body of this work. The act of 54 Geo. III. c. 156. an absolute term of twenty-eight years copyright has been vested in the author of every book that shall be published after the passing of that act, and in his assigns, and if the author shall survive that period, the copyright is also secured to him for his life. On books that were published before this statute was made, the second contingent term of fourteen years granted by the former acts on this subject, was made absolute in such authors as were then alive, and a life interest was also added if they survived this extension. On this last subject, the court of King's Bench has decided in a recent case, that if the book had been the property of the public at the time the act passed, which was on the 29th July 1814, the benefit granted by the act to the authors of books published before that time, were not meant by the legislature to apply in such instances.

The same act continued the obligation of delivering eleven copies of every book, and of its maps, plates, &c. to the eleven libraries therein mentioned, being the British Museum, Sion College, the Bodleian Library at Oxford, the Public Library at Cambridge, the Library of the Faculty of Advocates at Edinburgh, the Libraries of the four universities of Scotland, Trinity College Library, and the King's Inn
Library at Dublin. This delivery has been felt to be a severe burden, and several petitions have been presented to parliament by authors as well as publishers of books to be relieved from it. These petitions were in the seessions of 1818 referred to a committee of the House of Commons, which examined many witnesses on the subject, and made a report to the House of the following import:

That it is the opinion of this committee, that it is desirable that so much of the copyright act as requires the gratuitous delivery of eleven copies should be repealed, except in so far as relates to the British Museum, and that it is desirable that a fixed allowance should be granted in lieu thereof, to such of the other public libraries as may be thought expedient.

That if it should not be thought expedient by the House to comply with the above recommendation, it is desirable that the number of libraries entitled to claim such delivery, should be restricted to the British Museum, and the libraries of Oxford, Cambridge, Edinburgh, and Dublin universities.

That all books of prints, wherein the letter-press shall not exceed a certain very small proportion to each plate, shall be exempted from delivery except to the Museum, with an exception of all books of mathematics.

That all books in respect of which claim to copyright shall be expressly and effectually abandoned, be also exempted.

That the obligation imposed on printers to retain one copy of each work printed by them shall cease, and the copy of the Museum be made evidence in lieu of it.

PURPURIC ACID, in Chemistry. The name of an acid principle recently discovered by Dr. Prout; produced by the action of nitric acid upon the lithic or uric acid. The beautiful purple sub stance produced by the action of the nitric acid and heat upon lithic acid, has been long known to chemists. This purple sub stance is a compound of the acid in question and of ammonia. This acid, which may be likewise forms from the lithic acid by chlorine and iodine, possesses the remarkable property of forming beautiful purple compounds with the alkalies and alkaline earths. Hence the name of purpuric acid has been adopted by Dr. Prout, which was suggested by Dr. Wollaston.

Purpuric acid may be separated from the purpurate of ammonia above-mentioned, by the sulphuric or muriatic acids. It usually exists in the form of a light yellow or cream-coloured powder. It is exceedingly insoluble in water, and consequently possesses no taste, nor affects limus paper, though it readily decomposes the alkaline carbonates by the assistance of heat. It is soluble in the stronger mineral acids and in alkaline solutions, but not in dilute acids in general. It is insoluble in alcohol. When exposed to the air it assumes a purple colour, probably by attracting ammonia. Submitted to heat it is decomposed, and yields carbonate of ammonia, prussic acid, and a little fluid of an oily appearance.

The alkaline purpurates, as before observed, all form solutions of a beautiful purple colour. They are capable of crystallizing, and their crystals possess some remarkable properties. The purpurate of ammonia crystallizes in quadrangular prisms, which when viewed by transmitted light appear of a deep garnet-red, but by reflected light two of the opposite surfaces appear of a beautiful green, while the other two retain their natural red colour. This curious property seems to be possessed by the other alkaline purpurates. The metallic purpurates are in general remarkable for their solubility, and the beauty of their colours. The purpurate of zinc is of a beautiful gold-yellow, the purpurate of tin of a pearly-white. The other purpurates are all more or less of a red colour.

Dr. Prout thinks it probable, that this acid forms the basis of many animal and vegetable colours. The pink colour of the sediment in the urine of feverseems to be owing to the purpurate of ammonia. Dr. Prout also thinks, that some of its faults might be used as paints, and also for dyeing, as they appear to possess strong affinities, especially for animal substan ces. See Philosophical Transactions for 1818.

QUARANTINE, that space of time (usually forty days, as the term manifestly implies) which vessels and persons are restricted from having intercourse with other vessels or persons, or with the shore, on their arrival from places subject to the plague or other infectious diseases or distemper, or having held communication with ships coming from such places, or on board of which any infectious disease shall have appeared during the voyage.

The public health is a matter of the highest importance, and whoever is sensible of the havoc which the plague and other infectious diseases formerly made in this country, (see Plague,) and considers the prevalence of such diseases in some parts of the globe, how easily they are communicated, and how long the poisonous contagion lies dormant without losing its malignity, will readily advert to the strong necessity that exists for rigorous precautions being adopted, to prevent its introduction into these kingdoms.

Of such common concern, indeed, is the health of large and trading communities, that the chief magistrates (says Blackstone) have the guardianship of the public health, and are empowered to issue such ordinances as may be deemed necessary, either to prevent the introduction of infection from neighbouring or remote countries, or for separating those actually infected by removal, or by cutting off communication with their abode.

In this country, a Board of Health has been instituted, to inquire into the nature of the infection of the plague, and the best mode to counteract its effects; and public ordinances have been made from time to time upon this subject; formerly by proclamation, but latterly by parliament. And such has been the anxious solicitude to frame the laws and orders to obtain the ends desired, that they have at various times undergone laborious revision, and such further regulations and amendments have been introduced as by experience were found to be necessary. Nor has the care and anxiety of the British government been wanting for their confuls and public functionaries abroad are instructed to convey, with the utmost promptness, intelligence of the appearance of any epidemic distemper in the places where they reside, or in such as are in their vicinity. Government is thereby enabled to issue necessary directions, for subjecting ships and persons arriving from thence, to a more rigid examination and seclusion than might otherwise have been adopted. Governors and commanders have similar local powers and instructions, and are empowered to make such orders, either to regulate or entirely cut off communication with suspected places and vessels as they shall deem necessary. In sea-ports, vessels and their cargoes and crews are subjected, on arrival, to examination; where the two former are aired and purified for a necessary time, and the latter retained a certain number of days, in which time, it is supposed, any infectious disease they might retain, would make its appearance.

In inland places, restraints are likewise imposed for similar purposes, and intercourse thereby cut off by similar means, (usually a cordon of troops drawn round the infected place,) which taking possession of the roads, rivers, and watercourses, effectually prevents infected persons entering the place, as well as others from escaping.

All these measures, though they may appear arbitrary, are founded upon sound policy; and however irksome they may be found by those who are subjected to their operation, yet if they reflect for a moment what dread is created at the very apprehension of approaching persons afflicted with diseases of an infectious or putrid nature, or having even the possibility of harbouring contagion; and what dreadful and painful consequences are known to follow from an unguarded or indiscreet exposure, in such cases they will refrain from hastily rushing into society, without submitting to such salutary precautions which are so absolutely necessary, or at least to satisfactory to their fellow-citizens. No doubt the time is tedious, and the places appointed may be but little calculated to afford comfort to or reconcile "lex detentus;" but when they reflect that thousands may be swept away in a few days, by the introduction of such a malady, it is hoped they will submit with less impatience. One thing which makes the necessity less apparent is, that from the length of time since England has been afflicted with such a calamity, and from the success of the measures that have been adopted to prevent its introduction, persons in general have no actual knowledge, and still less fear of its dreadful effects, and they perceive with indifference, as it were, an object at a distance, which on nearer approach would almost paralyze their senses.

That persons and commerce may be as little impeded as the nature of circumstances will admit, a certificate is always obtained by persons coming from places where any of these disturbing maladies are of frequent occurrence; by this means, the general safety is more strongly secured, as well as less impediment given to the trader and the traveller; because when it declares the country free from any infectious disease or distemper, no further detention is generally required, than is necessary to transmit the case to the consideration of those who are intrusted with the general safety. If on the contrary the certificate states, that an infectious distemper does prevail at such place at the time of their departure, or if no certificate is brought, the examinations are more minute, and the purifications are of longer duration.

It is not intended in this article to say anything of the nature of infectious diseases; they will be found in the previous work under the heads Epidemical Diseases, Plague, Yellow
QUARANTINE.

Yellow Fever, Contagion, &c. to which the reader is respectively referred. A succinct account only will follow of such enactments and orders as have been made with the view of securing the performance of quarantine, and that the necessity and value of these regulations may be more generally known.

Much pains and inquiry have been instituted for considering the most effectual means for preventing the introduction, and, of the steps most necessary to be adopted, in case of the sudden appearance of the plague, both with regard to the treatment of the persons and their homies, as well as their dealings and communication with each other; whereby such instructions can on any emergency be immediately issued, as must check the extension and deprive the malady of half its inveteracy and of half its terrors.

Besides this, so much more air has been admitted to large and manufacturing towns than formerly, so much more cleanliness secured by underground drainage, as well as among the lower classes, that in addition to their better condition generally, in point of food, and the treatment of febrile complaints being better understood, its recurrence or virulence must be considerably lessened. Apprehensions and false alarms will, at times no doubt, be created among weak and credulous persons, and it will be most judicious in the local magistracy, immediately to institute rigid inquiry into the rumour, and either to take prompt measures to contradict it, and thereby prevent unnecessary alarm, or to adopt such speedy steps as will secure those deemed infected from having intercourse with others who are in health, until his majesty's privy council can issue such directions as the case may require, which they are specially authorized to do by 45 Geo. III. c. 10. sect. 12. So much is the privy council on the alert in this respect, that it directed, and deemed prudent for the safety of the community, to have three vessels funk a few years ago, having cargoes of skins from Mogadore on board, under very strong suspicion of their harbouring the plague.

It will not here be necessary to make an enumeration of the many acts that have been passed respecting quarantine, since they were all repealed, (except so much of the 39 & 40 Geo. III. c. 85. as repealed the former acts) by the 45 Geo. III. which passed 12th March 1805, and which embraces many of the former provisions and enactments. Three other acts have passed subsequently, (46 Geo. III. c. 98. 50 Geo. III. c. 20. and 51 Geo. III. c. 45.) making further provisions and amendments; and several general orders in council have been published in the London Gazette, by authority of, and in furtherance of those laws; and which have equal force with the laws themselves. Indeed but for the levying of duties, and the infliction of pecuniary penalties and capital punishments, it is conceived acts of parliament would have been unnecessary, for by the common law the king is invested with the care of the public health, and his edict must of necessity have been binding on the subjects residing in or trading to this country. But to return: the 45 Geo. III. c. 10. in the first place, declares what ships, persons, and goods, are liable to the performance of quarantine. They are.

1. All ships and vessels (including his majesty's ships of war) arriving from or having touched at any place, from which his majesty shall declare it probable that the plague, or any other infectious disease or distemper may be brought, and all persons, goods, wares or merchandize, packets, packages, baggage, wearing apparel, books, letters, or any other articles whatsoever, on board the same. (Act, sect. 10.)

2. All ships, vessels, and boats, receiving any person, goods, wares or merchandise, packets, packages, &c. out of such ships, whether they came or were put on board the same, either before or after the arrival of such ships at any port in Great Britain, or the islands of Guernsey, Jersey, Alderney, Sark, or Man, and whether they were bound to Great Britain or not. They are likewise deemed to be liable from the time of the vessels leaving such infected place, or from the time when such person or goods went or were received on board such vessel. (Act, sect. 10.)

3. Ships and vessels importing certain goods, more especially liable to retain infection, (to be set forth in any order in council,) and which may be carried from infected places into other countries, and from thence imported into Great Britain, are liable to all such regulations and restrictions as are made concerning quarantine. (Act, sect. 11.) For the goods, see Clas. 1 and 2.

4. Ships and vessels coming from any place in Europe, without the frights of Gibraltar or America, (where there is not a regular establishment of quarantine,) having on board any goods enumerated in the first clas, the produce of Turkey, or Africa within the frights, or West Barbary, and all ships and boats receiving such goods out of such ships, are, together with all persons, (and pilots,) goods, &c. to perform quarantine, as ships coming from the Mediterranean with clean bills of health (which is fifteen days.) Order in council, 5th April 1805, sect. 5.

5. But by order of the prince regent in council, 26th April 1817, ships which have failed from ports deemed liable to infection, to others which are not liable to infection, and afterwards arriving here, shall not be liable to perform quarantine, if they come in ballast, or with a cargo taken in at the last-mentioned port, if the master shall make oath that all the goods of the first and second classes were landed or otherwise discharged at the latter port forty days at least before her arrival in Great Britain, and that no plague, &c. existed on board at any time from the commencement of the outward voyage to the termination of the homeward one; and provided also, that the goods taken on board at the port not liable to infection are not the growth, &c. of any country declared liable to infection; or if any goods of Clas. 1. taken in at a place not deemed liable, shall be the produce of any country deemed liable, then on proof according to the 43d section of order in council of 5th April 1805, that such goods have performed quarantine at one of the foreign lazarets.

6. Ships and vessels also arriving from any place whatsoever, under any alarming or suspicious circumstances as to infection, are liable to such regulations and restrictions as are made by any order of his majesty (act, sect. 11.), or by any three of the lords of the council, in case of any unforeseen emergency on any ship arriving with any infectious diseases on board, or if any infectious distemper has appeared in the course of the voyage, although he shall not have come from any place from whence his majesty has declared it probable the plague, &c. may be brought. (Act, sect. 12.)

And all such ships and boats, and all persons, (including pilots,) goods, wares, &c. who have been imported or put on board such ships, boats, &c. as well as on board the receiving ship, shall be obliged to perform quarantine in such places and manner, and for such time, as shall be directed by his majesty's order in council, published in the London Gazette; and that until they have performed and been duly discharged from quarantine, they shall not come or be brought

[Note. — This is deemed to relate to the outward as well as the homeward voyage. By 5 Geo. III. c. 25. sect. 3. letters are to be given to the superintendant, who is to dispatch the same in the usual manner, after due precaution.]
brought on shore, or go and be put on board any other ship, &c., in order to go on shore, though such ship may not be bound to Great Britain, unless by directions and permission of his majesty in council. And all ships and boats, perfons, pilots, masters or commanders, goods, wares, or merchandise, coming from such restricted or any infected place, shall be subject to all the rules, regulations, and provisions of the act, and any order in council, and to all pains and penalties, &c., of that act for any breach or disobedience to it, or of any order in council made under its authority. Sect. 10. of the act.

By 46 Geo. III. c. 98. his majesty, or any of the lords of the council, as often as they shall apprehend that the yellow fever, or other highly infectious distemper, prevails in America, or the West Indies, may require every vessel coming from or having touched at those places, to come to anchor at certain places to be appointed by the commissioners of the customs, for the purpose of having the state of health of the crew ascertained before the shall be permitted to enter any port in Great Britain; but the ship shall not be deemed liable to quarantine, unless it shall be afterwards specially ordered under that restraint. Sect. 6.

Shortly after the passing the act of the 45 Geo. III., and under its immediate authority, an order in council was issued, dated 5th April 1805, which declared what places his majesty judged it probable the plague, or other infectious distemper or disease, may be brought from. They are by vessels coming from or through the Mediterranean, or from the West Barbary on the Atlantic ocean, and also by the importation of certain goods being the growth or produce of Turkey, or Africa within the freights of Gibraltar or West Barbary, from any port in Europe without the freights, or on the continent of America. And by further order, dated 7th November 1805, it was declared, that an infectious disease might be brought by vessels coming from or having touched at any port in the states of Pennsylvania or New York, but this order has since been annulled.

The Goods deemed most liable to retain infection are set forth in three tables, by sect. 33, 35, and 38 of the order in council, and are as follow:

**Class I.**—Apparel; artificial flowers; ball, or any article made thereof; beads, bracelets, or necklaces, in strings; beds, bed-ticks; books; brooms; brushes; burdets; cambric; canvas; carmenian wool; carpets; cordage not tarred; cotton wool, yarn, or thread, all articles wholly made of or mixed with cotton, silk, wool, thread, or yarn; down; feathers; f1ax; furriers' w1aive; goat's gold or silver in thread, cotton, hair, silk, or wool, or any other substance heretofore enumerated; grogram; hats, caps, or bonnets of Irish, chip, cane or any other material; hemp; hoes; horns and horn tips; hair of all sorts; leather; linen; liquor of any kind, in bottles or flasks; lute-strings, catlings, or harp-strings; maps; mattresses; mats and matting; mohair yarn; nets, new or old; paper; packthread; parchment; pelts; plating of ball, chip, cane, flaw, or horse-hair; quills; rags; sails and sail-cloth; silks; vzvz.; crapes and taffianies, silk and knubs, raw silk, thrown or organize silk, waffle silk, wrought silk, f1ims, hides, and furs, and parts or pieces of f1ins, hides, and furs, whether unbled, or in part or wholly tanned, tawed, or dressed; f1oanges; flaws, or any article made or mixed with flaw, flockings; thread; tow; vellum; whisks; wool, whether raw or anywive wrought; yarn of all sorts.

**Class II.**—Senna; jilap; gum arabic; gum tragacanth; myrrh; opium; scammony; antimony; castor-hares; alum; juniper-berries; pomegranates, flowers and seeds; sal nitre; sal ammoniac; madder; f1umach; gall; tobacco; coffee; wood in raisings; cork.

**Class III.**—Grain; pulses, and other seeds in bulk; grain, and other seeds in sacks or casks, or baskets of rush mat; dried fruits in baskets, or packages made of articles enumerated in the first class, or in packages of wood and oil in barrels.

Where vessels are to perform quarantine depends upon circumstances; for if the plague, &c., appears on board any ship within the freights of Gibraltar, she is to go to one of the foreign lazarets (at Malta, Ancona, Venice, Messina, Leghorn, Trieste, Genoa, or Marseille), but if it appears without the freights, then she is to go to the harbour of St. Helen's-Tean and North Wither, (two of the islands, called the Scilly islands,) or such places as his majesty shall appoint. (Sect. 13. of the act.) And immediate intelligence shall be given to the commissioners of the customs, and to the privy council, so that measures may be taken for the comfort and support of the crew and passengers, and such precautions used as the case may require; and the ship is to remain there, and none of the crew or passengers are to go on shore, or have any communication with any other vessel, and any person who shall not act conformably hereto, or any directions of the privy council, are to suffer death without benefit of clergy. If the vessel cannot make the island or other places appointed, or shall be forced by f1ire of weather to go up either of the Channels, the shall not enter any port in Great Britain, or the islands of Guernsey, Jersey, &c., but shall remain in the open road till the master receives direction from the privy council. Sect. 13. of the act.

The next regulation is, that ships not having the plague on board, coming through the Mediterranean, or West Barbary, without clean bills of health, (except ships of war, transports, or other vessels in the actual service of government, which are to go to the Motherbank near Portsmouth, in a place marked out with yellow buoys,) and all ships receiving goods out of them, are to perform quarantine at Stangate Creek, and no where else. (Order, sect. 4.) But by order 15th July 1813, ships not having the plague actually on board, (except king's ships, &c.) coming from or through the Mediterranean, or West Barbary, without clean bills of health, bound to the western ports of Great Britain, may perform quarantine at Milford Haven.

The 46 Geo. III. c. 98. sect. 7. authorizes his majesty or the privy council to prohibit (by proclamation or publication in the Gazette) any person, ships, or boats from going within the limits of any station which may be appointed for the performance of quarantine by ships without clean bills of health, under the penalty of 500l. By orders in council, dated 21st July 1806, and 6th September 1811, it was ordered, that no ship or boat (except quarantine and custom-house boats) should go, but on cafes of emergency, within the place at the Motherbank set out with yellow buoys for ships not having clean bills of health; and that ships with clean bills of health ordered to the Motherbank are to go within the compacts of the yellow buoys, but separate from his majesty's ships and ships without clean bills.

The two west buoys are placed to the caulkward of Wooton Creek, and the two north ones near the line of Wight, with another buoy midway between them, and a red buoy as a mark for a burying-place.

By sect. 2. of the order of 5th April 1805, ships (king's ships as well as others) with clean bills of health, Bound to London, Rochefort, Faversham, or any creeks or places belonging to or within any or either of the above ports, are to perform quarantine at Stangate Creek.
[Note.—In the case of ships coming from Turkey, and obliged to perform quarantine before their entry into the port of London, it is usual for the consignee to send down persons at his own expense to pack and take care of the goods; and where a consignee had omitted to do so, and the goods were damaged by being sent loose to shore, it was held that he had no right to call upon the master for a compensation. Durnage v. Julliffe, before lord Kenyon, chief justice, at Guildhall, M. T. 1789.]

Ships bound to Leigh, and the ports and creeks extending from thence to, and including Berwick,

— bound to Carlisle, and the ports and creeks extending from thence to, and including Beaumaris, and the Isle of Man,

— bound to Sandwich and Dover, and the ports inclusive,

— bound to Poole and Scilly, and the ports inclusive,

— bound to Bridgewater and Swan-sea, and the ports inclusive,

— bound to St. Ives and Aberystwyth, and the ports inclusive,

— bound to Jersey, Guernsey, Sark, or Man, or any part of them,

— bound to Leith, and all the ports or creeks extending from thence along the eastern coast of Scotland, as far as and including Aberdeen,

— bound to Glasgow, and all the ports or creeks extending along the western coast of Scotland, as far as and including Wigtown,

— bound to Inverness, and all the northern coast of Scotland, as far as and including Stornoway,

— bound to Dumfries and Kirkcudbright, and all the ports and creeks on the south-west coast of Scotland,

— bound to any port or place on the coasts of England and Scotland, not within any of the before-mentioned limits,

Vessels liable to quarantine, and having on board, which are bound to any of the above ports, and have passed the place appointed to perform quarantine, either from the master's ignorance of being liable, or by force of weather, or other unavoidable circumstances, may, on proof of oath that it was unintentional, and not with the view of avoiding the regulations of quarantine, repair (and shall be compelled to go) to any other place at the discretion of the quarantine officer, &c. keeping the proper signal flying during the whole time. Order, fect. 6.

When any country or place is known or suspected to be infected with the plague, &c., then, whenever any ship shall attempt to enter any port in Great Britain, or the islands of Guernsey, &c., she shall be visited by the superintendent of quarantine, or proper officer of customs; and the master, upon being directed, (for which purpose he or the pilot is to bring to, under penalty of 100l.) shall give a true answer in writing to all such questions and interrogatories as shall be put to him; and if he refuses to make a true discovery in any of the particulars, or if he shall give a false answer, (though not upon oath,) he shall forfeit 200l. (Act, sect. 18.) If it appears by such answers that the ship is liable, the superintendent shall direct her to repair forthwith to the proper place, and the shall not enter any other place, (except from farts of weather or damage,) and she may be compelled, by all necessary means, (either by firing of guns upon her, or any other kind of necessary force,) to go to the proper place. (Order, sect. 8.) And if the master does not cause such ship to be conveyed to the place appointed, he shall forfeit 500l. 45 Geo. III. c. 10. sect. 21.

Vessels not bound to this country are not to touch or attempt to enter any port in Great Britain, or the islands belonging thereto, although they may be ports appointed for performing quarantine (except for orders, or in consequence of farts of weather, or loss or damage at sea;) and then the masters are to answer the preliminary questions, and to conform to all such directions, as they shall receive, as well with respect to their continuance at such ports, and departing and repairing to any other place, as to all other regulations, &c. touching quarantine; and if they do not comply, they may be compelled to put to sea; to which the commander, or other officer of his Majesty's ships of war, may be called in. Order, sect. 7, and 45 Geo. III. c. 15. sect. 19.

The duration of quarantine depends upon circumstances; as the country from whence the ship arrives, the kind of goods she brings, the production of a bill of health, or otherwise. And the commencement is to be taken for ship and goods (where the cargo consists of goods of Clafs I. and II.), and goods non-enumerated, when the whole of the two former are removed. (Order, sect. 35.) But if there are no goods of those classes, then from the time of the vessel's arrival at the quarantine station. (Sect. 12.) And for ships without bills of health, but with cargoes not enumerated in the two classes, and not deemed infectious, from the day the quarantine guardians are put on board. Order, sect. 40.

The lords of the council may issue orders for shortening the time of quarantine performed by particular ships, persons, or goods, &c., or for wholly releasing them, absolutely or conditionally, as they shall think fit. 45 Geo. III. c. 10. sect. 12.

The duration for ships performing quarantine is as follows:

Ships having the plague on board, and arriving under any alarming or fulpicious circumstances, the time is left to the discretion of the privy council. 45 Geo. III. sect. 12 and 13.

Ships coming from or through the Mediterranean or West Barbary with clean bills of health, having on board goods of Clafs I. and II., fifteen days. Order, sect. 12.

Ships arriving without clean bills of health, thirty days. Order, sect. 57—49.

Ships arriving from places in Europe without the freightes, or on the continent of America, where there is not a quarantine establishment, bringing goods of the 1st Clafs, the produce of Turkey, or Africa within the freightes, or West Barbary, to perform quarantine for fifteen days. Order, sect. 5.

Ships bringing touched, &c., suspected bills, to perform quarantine for twenty days. Order, sect. 41.

The time for passengers and the crews of vessels performing quarantine is to be governed by the nature of the cargoes of the respective vessels, and whether they come with or without bills of health.
The duration for goods performing quarantine to be as follows:

- Goods of the 1st Class, coming without clean bills of health, forty days at the lazaret. Order, sect. 33.
- Goods of the 2d Class, coming without clean bills of health, thirty days. Order, sect. 35.
- Goods remaining after those of the 1st and 2d Class are removed to a floating or land-lazaret, are to perform quarantine for thirty days, and are to be afterwards fumigated. Order, sect. 37.
- Goods arriving from or through the Mediterranean, or West Barbary on the Atlantic ocean, in ships not having the plague on board, without clean bills of health, to be removed to the floating lazaret at Stangate Creek, and perform quarantine for thirty days. Order, sect. 14.
- Goods coming from those places with clean bills of health are to be aired one week in the same ship; except goods of Clafs 1. and 11., which are to be removed to the lazaret, and be aired for fifteen days. Order, sect. 13.
- Goods coming in ships with suspected bills of health to be treated as ships coming without bills of health, except that they are to perform ten days less quarantine. Order, sect. 41.

Dried fruits having been shifted from baskets and packages made of articles in Clafs 1., or considered fufceptible, if all the persons on board are in health may be delivered in twenty days. Order, sect. 38.

Dried fruits in wood, may be delivered in ten days. Order, sect. 38.

Oil in barrels, the bungs being tarred, and the barrels brufted and dipped in fea-water, may be delivered in ten days. Order, sect. 38.

Grain, pufe, and feed in bulk, or in facks, or cafsks, or mats, when shifted, and passed through a fieve, may be delivered in ten days. Order, sect. 38.

And the packages, when made of fufceptible articles, are to be fent to the lazaret to perform quarantine, according to the nature of them, or be defroyed at the option of the owner. Sect. 38.

Formerly the 42d clause in the order in council required "the production of a declaration on oath for goods of the 1st Clafs," when brought from places without the frefhips of Gibraltar, or on the continent of America, &c. to affcrtain their growth, and that they were not the produce of Turkey, &c., but that clause has been fuppfed by order of 8th Aug. 1810; and they may be admitted without performing quarantine, on the matter making oath that no infectious disorder prevailed at the place from whence they failed, or on oath of the importer that they are not the produce of Turkey, or of any place in Africa within the frefhips, or West Barbary: but whenever that declaration is produced, the oath of the importer or of the importer is not required. Order in Council, 27th Oct. 1818.

Veffels having performed quarantine at any of the foreign lazarets, and producing proper documents to prove that fact, are not required to do fo again: nevertheless, fuch part of the cargo as confils of articles in Clafs 1. are to be taken out and perform quarantine in the usual manner for fifteen days (Order, sect. 43.) But no goods are to be landed or removed therefrom until the fmall has given notice to the quarantine fuperintendent, or officer of customs, in order to be laid before the privy council. Landing or removing them before directions are given, or contrary thereto, subjects the matter to the penalty of 2000 £. 45 Geo. III. sect. 22.

Having thus flated what ships and goods are liable and required to perform quarantine, and the time for which they are to perform it, we fhall proceed to flate the manner of doing it, which is to be by opening and airing in the manner directed by order in council (Aô, sect. 29.), according to the nature of the goods, and the articles of which the packages are made.

Goods of the 1st Clafs, unaccompanied with a clean bill of health, undergo two performances, one probationary, the other of longer time and greater precaution. The hatches of the veffel are first to be opened, and as many of the bales as can be ranged upon the deck are to be taken from the hold, (as soon as the pilot and passengers are removed,) and the ends opened, and the contents handled by the sailors, under directions of a quarantine guardian for fix days; and after this, any further parcels are only required to be fo opened and aired for three days, unlefs any fupplicious circumftances arise, and then the time may be extended to four, fix, or eight days, fo as to complete in the whole twenty-one days, or even a longer time if necessary, and then they are to be conveyed to the lazaret. Order, sect. 32.

In the second performance, or expurgation at the lazaret, all bales of cotton are to be opened from one end to the other, and fo much removed as admit the handling and removing the remainder. Rags, raw wool, goats' wood, Car- menia wool, and hair, are to be taken out and ranged in heaps of four feet high, and often ruffaged. Bales of flilk to be opened on one fide, from end to end, the cords loofened, and the flilk aired for twenty days; and then the other fide to be opened in like manner for five days more. Cottons, yarn, thread, flufs, and linen, are to be piled in rows or pyramids, and turned every four days, and completely spread out and fuppfed on cords for several days. Paper, books, parchment, fponges, and flockings, are to be un-packed and feparated, fo as to admit thorough airing. Feathers, fraw-batts, artificial flowers, coral beads in frifings, and brushes, fpread out in the fame manner. Carpets, furs, hides, and fkins to be unbaked, and each piece spread and fuppfed on cords in the open air, and frequently turned; and all goods packed with fraw, cotton, or articles flated in Clafs 1., shall be entirely taken out of the fame, opened, and handled, and carefully aired, as well as all other goods in that clafs, for which no directions are given. Order, sect. 33.

Goods of the 2d Clafs, unaccompanied with clean bills of health, though less liable to infection, are to be carried to the lazaret, and be unpacked, opened, and aired as much as possible; and by moving them as much as practicable from time to time, fo as to admit free ventilation for thirty days. Order, sect. 35 and 36.

Goods not mentioned in those clafs, and remaining on board the importing ship, are to perform quarantine for thirty days, by being frequently swept and shifted, fo as to admit free ventilation; at the end of which time, if all the persons on board, and those employed in the expurgation on shore, are well, the ship, goods, crew, and passengers, are to be fuppfed and difcharged. Order, sect. 37.

There are other regulations and enactments on this subject which it is necessary to notice, and though they relate to the first arrival of the ships, and take effed from that time, yet being rather regulations to ascertain the nature of the voyages, and the flate of the crews, and the goods accompanying the cargo, than any part of the performance of quarantine, this is conceived a proper place to introduce them.

It is manifest, that without the earliest information of the arrival of veffels from countries infected with the plague, &c. and of the kind of goods of which their cargoes are compofed, many of the above-mentioned fentury regulations would be useflefs, either by perfons quitting veffels immediately
QUARANTINE.

Matners knowing any place from which they came, or at which they touched, to be infected with the plague, or any infectious disease, or having any person on board infected with it, and who shall refuse or neglect to disclose the same when examined by the superintendmt of quarantine, or officer of customs, and permitting to hoist the proper signals, shall be guilty of felony, and suffer death. 45 Geo. III. c. 10. f. 19.

Matners of vessels ordered to perform quarantine are to deliver to the master of customs, or quarantine superintendent at the quarantine station, (and which they are required to demand,) their bills of health, manifest, log-book, and journal, under penalty of 100l. 45 Geo. III. c. 10. f. 20.

Matners of ships liable to quarantine, although the plague, &c. shall not have then appeared, who shall quit the ship, or suffer any seaman or passenger to quit the same, till they have performed quarantine, (unless by licence or order in council,) shall forfeit 500l. And if any person coming in, (or any pilot or other person who may go on board, whether before or after her arrival at any port in Great Britain,) shall afterwards quit her before the shall be regularly discharged, all persons (by necessary force) may compel each person to return on board; and every person for quitting such ship shall forfeit 200l. and be imprisoned six months. 45 Geo. III. c. 10. f. 21.

Such of the passengers and crew of ships not furnished with clean bills of health as may be defective of performing quarantine in a separate vessel, (to be hired at their own expense,) may, if the superintendent and medical attendant see objection thereto, do so, and may quit the ship before the hatches are opened and go on board such ship, (a guard being there placed at their expense) for thirty days (Order, fect. 28.) but their baggage, apparel, and books, for which they have not immediate occasion, shall be sent to a floating lazaret to be aired, and before any passengers or crew shall be discharged, they, their clothes, and effects, shall be fumigated (Order, sect. 31.) but passengers and the crews continuing on board the ship in which they arrived are to remain under quarantine till the ship be discharged. Order, sect. 28.

Pilots may quit the ship and be removed to the hospital ship, after the quarantine guardians are placed on board, provided they come from ships having no suspicious sickness on board; but if otherwise, they are to be sent to the pelthoue, or other place appointed for persons so affected, and they are to continue under quarantine until the probationary airing of the goods is finished, when, if they continue well, they are to be fumigated and discharged. But such pilots are not to have communication with any other person, except under the regulations usual in like cases. Order, sect. 37.

If any pestilential accident occurs among the ship's crew or passengers during the probationary airing, (at whatever stage it may happen,) the quarantine of the crew, passengers, and pilot, (if any shall have been on board,) and the goods, is to recommence, and the sick are to be sent to the hospital, or pelthoue, or place provided for persons so afflicted, the external guard to be doubled, and notice immediately given to the privy council. Order, sect. 29.

If any peron falls ill, and a medical man is on board, he shall confer with the medical man who comes alongside, the latter keeping ten feet to windward; but if no medical man

...and other accidents) to forfeit 100l. (43 Geo. III. c. 15. f. 17;) and not requiring such paper, 100l. by 46 Geo. III. c. 98. f. 2.

Matners knowing any place from which they came, or at which they touched, to be infected with the plague, or any infectious disease, or having any person on board infected with it, and who shall refuse or neglect to disclose the same when examine...

...by the superintendmt of quarantine, or officer of customs, and permitting to hoist the proper signals, shall be guilty of felony, and suffer death. 45 Geo. III. c. 10. f. 19.

Matners of vessels ordered to perform quarantine are to deliver to the master of customs, or quarantine superintendent at the quarantine station, (and which they are required to demand,) their bills of health, manifest, log-book, and journal, under penalty of 100l. 45 Geo. III. c. 10. f. 20.

Matners of ships liable to quarantine, although the plague, &c. shall not have then appeared, who shall quit the ship, or suffer any seaman or passenger to quit the same, till they have performed quarantine, (unless by licence or order in council,) shall forfeit 500l. And if any person coming in, (or any pilot or other person who may go on board, whether before or after her arrival at any port in Great Britain,) shall afterwards quit her before the shall be regularly discharged, all persons (by necessary force) may compel each person to return on board; and every person for quitting such ship shall forfeit 200l. and be imprisoned six months. 45 Geo. III. c. 10. f. 21.

Such of the passengers and crew of ships not furnished with clean bills of health as may be defective of performing quarantine in a separate vessel, (to be hired at their own expense,) may, if the superintendent and medical attendant see objection thereto, do so, and may quit the ship before the hatches are opened and go on board such ship, (a guard being there placed at their expense) for thirty days (Order, fect. 28.) but their baggage, apparel, and books, for which they have not immediate occasion, shall be sent to a floating lazaret to be aired, and before any passengers or crew shall be discharged, they, their clothes, and effects, shall be fumigated (Order, sect. 31.) but passengers and the crews continuing on board the ship in which they arrived are to remain under quarantine till the ship be discharged. Order, sect. 28.

Pilots may quit the ship and be removed to the hospital ship, after the quarantine guardians are placed on board, provided they come from ships having no suspicious sickness on board; but if otherwise, they are to be sent to the pelthoue, or other place appointed for persons so affected, and they are to continue under quarantine until the probationary airing of the goods is finished, when, if they continue well, they are to be fumigated and discharged. But such pilots are not to have communication with any other person, except under the regulations usual in like cases. Order, sect. 37.

If any pestilential accident occurs among the ship's crew or passengers during the probationary airing, (at whatever stage it may happen,) the quarantine of the crew, passengers, and pilot, (if any shall have been on board,) and the goods, is to recommence, and the sick are to be sent to the hospital, or pelthoue, or place provided for persons so afflicted, the external guard to be doubled, and notice immediately given to the privy council. Order, sect. 29.

If any peron falls ill, and a medical man is on board, he shall confer with the medical man who comes alongside, the latter keeping ten feet to windward; but if no medical man
man is on board, and it is necessary to visit the sick, the visit shall be made at the ship's boat by the medical attendant in his own boat, keeping to windward ten feet; and if medical aid cannot be administered on board, the sick is to be carried to the pell or hospital ship. Order, sect. 23.

Persons under circumstances to induce a suspicion of having any pestilential disorder, to be removed to the pell or hospital ship; but if it is not infectious, they may be removed to a more commodious apartment in the lazaret, there to complete the remainder of their quarantine. Order, sect. 24.

If any pestilential disorder shall actually discover itself in any ship or lazaret, the person is to be removed with all possible care and dispatch, under the special directions of the superintendent or medical attendant to the pell-house, and a proper attendant is to be affixed to him, and he shall be visited at a due distance; but if a nearer approach is necessary, some person is to be specially appointed for that purpose. Order, sect. 25.

Passengers and crews may have the assistance of any medical person they may choose from the shore; but if any persons communicate by contact with the sick, they shall perform the like quarantine as the sick. Order, sect. 26.

Persons liable to perform quarantine, and others having had intercourse with them (whether in ships or lazarets), are to be subject to the orders of the superintendent or officer of customs, who are required to enforce obedience to all such orders, and to call in others to their assistance; and they may compel such persons to repair to the lazaret or ship, and cause all goods liable to quarantine to be conveyed there also; and persons refusing to go, or, who being there, shall escape, shall be compelled by force to return, and persons refusing or neglecting to return, and persons escaping, shall suffer death without benefit of clergy. (45 Geo. III. ch. 10, sect. 23.) And may be seized by any constable, headborough, tythingman, or peace officer, or any other person, and be carried before a magistrate or justice of the peace, or such justice may issue his warrant for their apprehension and conveyance to their ship, or to any ship performing quarantine, or to any lazaret from which they have escaped, or for confining them in safe custody (but not in a public gaol) under such restrictions, as to having communication with other persons, as the justice may think proper, (calling to his aid medical advice) until they can be safely removed to some place appointed for quarantine, or until directions can be obtained from the privy council. 45 Geo. III. ch. 10, sect. 24.

Persons not infected with the plague, &c. entering the lazaret whilst any person is performing quarantine, are to perform it also, and are not to return without licence or order in council; and, if they shall actually escape before it has been fully performed, they shall suffer death, without benefit of clergy. 45 Geo. III. sect. 27.

Persons on board ship, or lazaret, may have communication with others by letter, to be collected by a boat, which is to go round at a fixed hour daily, and they are to be dipped in vinegar and put into the fumigating-box, and the covers slit open (Order, sect. 16); but letters to persons on board are to be taken by the quarantine superintendent only, and no conference is to be had by persons not under quarantine with persons who are under quarantine (except by permission of or in the presence of the quarantine superintendent or his attendant), nor from any ship, unless the superintendent's boat be present, and then at the distance observed by the superintendent. And to prevent improper or clandestine communication, there is to be a night-watch and row-guard at all the quarantine stations; and the boats belonging to any floating-lazaret are to be locked to the same; and the boats of the ships performing quarantine are to be taken away, and no use made of them, but for removing goods, from such ship, or upon occasions of necessity, till they are given up when the ship has done performing quarantine. Order, sect. 17.

Affliction and necessaries for ships under quarantine to be found by the superintendent and to be carried to the windward side, and delivered by means of buckets. (Order, sect. 18.) Quarantine guardians are to prevent any goods being delivered from ships without clean bills of health but by an order in writing from the superintendent, such order to be entered in a book and the original returned; and nothing to be conveyed from one ship under quarantine to another, nor any personal intercourse allowed. And a guardian is to go with the lighters and boats, to prevent communication during the transit of the cargo, and to take care that no remnants of cotton, or things of Classes I. and II., remain in them. And before leaving off work they are to collect and deliver all such articles into the lazaret. Sect. 19 of the Order.

The duty of the quarantine superintendent and officers of the customs may partly be collected from what has gone before; but it is necessary here to observe, that they are, on a ship's arrival, to go off and put the following preliminary questions:—What is the name of the ship? Master? From whence? Where bound? At what port has she touched on the homeward voyage, or what ships spoken with? Whether the plague, or any infectious disease, existed at the time of leaving the port the ship loaded at? What kind of goods the cargo is composed of, and what country are they the produce? and whether she brings a bill of health?

If the ship is deemed liable to quarantine, she is then to be directed to the proper quarantine port, where, on arrival, the superintendent is to go to the windward side, (taking medical advice with him, if necessary,) and to see all the officers, crew, and other persons, mulled on the gangway, and is to put further questions to them. They are in substance the same as above, except more particular as to the places the vessel touched at during the whole voyage; the respective dates of her arrival at every place, and dates of her departure; the number and conditions of the crew for the voyage, whether any have been sick or died, and the nature of the disease; whether their bedding and clothes were destroyed, or any peron employed about them taken ill; if so, when, and what kind of disease; whether any letters or parcels have been received out of any other ship on the passage; of what kind and where delivered, and into what vessel or boat; what persons she has had; and any particulars respecting British ships loading at the same port from whence she came; their names; where bound, &c. and what British ships were at the places at which she touched; whether any person employed in loading the cargo was taken ill, or any sufferance of the kind; whether the cargo had been long warehoused, or packed, handled, or brought on board by any person affected with the plague; did the touch at the isle of Rhodes, Morea, or any and what part of Africa; if so, where? and had the any communication with the shore at those places, or with any ship coming from such places; if so, in what manner, and when, and whether the crew of such ship was healthy.

The answers to all these questions are to be taken in writing, and the master to make oath to them, and is to deliver the log-book, manifest, and ship's papers, (which are to be dipped in vinegar and fumigated,) and make oath to the truth of the contents of the former, or in what particular it is not correct; and whether any particular entry was
was made soon after the fact, and if not, for what reason; and also to make oath to all the other papers. Sect. 10 of the Order.

If any suspicious circumstances appear in the answers to the above questions, or from any other circumstance, the proper officer is immediately to transmit such answers to the privy council and the commissioners of the customs, and without regard to the bill of health, whether clean or otherwise, is to order such ship to a station distant from all other vessels, and put her under special guard, the more effectually to prevent communication with her. Order, sect. 11.

Ships coming without clean bills of health are to have two quarantine guardians placed on board as soon as the examinations are ended, and the shall have arrived at her proper station. Order, sect. 15.

Guardians are to take care that, after the cargoes are discharged into the lazaret, the holds and between decks are completely swept, and the sweepings burnt. (Order, sect. 20.) And they are to search all lockers and chests, &c. of passengers and crews, so that no goods in Lift i and 2, or any thing liable to infection, remains undelivered, except what the superintendent or medical man declares requisite for daily use; and they are to see all such chests, clothes, and the bedding of the ship daily opened and aired. (Order, sect. 21.) They are also to make daily reports of the state of health of every person on board, and whether the regulations are regularly complied with; and, in case of any impediment, are to give notice to the master, and then to the superintendent, who shall remove the same. Order, sect. 22.

Persons landing or removing any goods, wares, or merchandise, packets, packages, baggage, wearing-apparel, books, or letters, from any ship liable to quarantine, or knowingly receiving the same, are to forfeit, for every offence, not more than 500l., nor less than 100l. And persons clandestinely conveying them (or concealing them for that purpose) from any ship actually performing quarantine, or from the lazaret, are to be adjudged guilty of felony, and suffer death without benefit of clergy. Act, sect. 31.

Officers of customs, or other persons embezzebling goods, or guilty of any other breach or neglect of duty, in respect of the ships, persons, and goods performing quarantine, shall lose their office or employment, and be rendered incapable to hold the same, or receive a new grant thereof, and shall forfeit 100l. And if they shall defeat their duty, or wilfully permit any ships, persons, or goods, to depart, or be conveyed out of the lazaret, ship, or other place, unless by permission under an order in council, and if they, or any person authorized to grant certificates of ships having performed quarantine, shall knowingly give a false certificate thereof, they shall suffer death without benefit of clergy; and if they shall wilfully damage any goods under their direction, they shall pay treble damages and costs of suit to the owner. 45 Geo. III. c. 10. sect. 26.

Perfons forging, counterfeiting, interlining, or altering, any certificate required by this act, or any order in council touching quarantine, or procuring it to be done, or publishing it as true, shall suffer death without benefit of clergy. 45 Geo. III. c. 10. sect. 30. and 46 Geo. III. c. 98. sect. 8.

After goods have been duly opened and aired, proof thereof shall be made by the oaths of the master of the lazaret or vessel, and one of the guardians or officer of the customs, and the superintendent, shall give a certificate of such proof having been made, and such goods shall not be liable to any further restraint, either at that or any other port. 46 Geo. III. c. 98. sect. 5.

Ships and persons having performed quarantine, proof is to be made by the oaths of the master, and of two other persons belonging to the ship, before the principal officer of customs or justice of peace, at the port where quarantine was performed, or, if at the islands of Guernsey, &c. before two jurats, that such ships or persons have duly performed quarantine, and that they are free from infection. And, upon producing a certificate from the superintendent to that effect, the collector or justice, &c. is required to give a certificate thereof, and thereupon such ships and persons shall not be liable to farther restraint. 45 Geo. III. c. 10. sect. 28.

All forfeitures and penalties incurred against this act may be recovered in any of his majesty's courts of record, or by suit in any of his majesty's courts in the islands of Guernsey, &c. one half to them who shall sue, and the other to his majesty, to be applied towards defraying the expenses of erecting and maintaining the lazaret. 45 Geo. III. c. 10. sect. 34.

Actions to be commenced in the name of the attorney-general, or of some officer of the customs, and the former may stop proceedings if he thinks proper, as well as to the officer's share as to the king's moiety. Sect. 35 and 36.

Offences against this act, not being felony, and disobedience to any order in council, for which no specific penalty is provided, may be tried before any two justices of the peace for the county, riding, &c. where such offence happens; and if any person shall be convicted he shall be liable to such penalty, not exceeding 50l. for any one offence, or to such imprisonment, not exceeding three months, as shall, in the discretion of the two justices, be judged proper. Such penalty to be applied as directed by sect. 34-45 Geo. III. c. 10. sect. 38.

Offences contrary to this or any act hereafter to be passed, or of any order in council, notified by proclamation, or published in the Gazette, may be tried in any county within England or Scotland, or in the proper courts in the islands of Guernsey, &c. No attainer of felony to work corruption of blood or forfeiture of goods, &c. 45 Geo. III. c. 10. sect. 39 and 42.

In any prosecution for offences against this act, or any act which may hereafter be passed, concerning quarantine, or for any breach of any order in council notified in the Gazette (which is to be a sufficient notice by 45 Geo. III. c. 10. sect. 33.), the answer to any questions or interrogatories put to the master of a ship, may be given in evidence as to the place from which such ship came, or the places at which she touched in the course of the voyage; and where any ship shall have been directed to perform quarantine, the having been so directed shall be evidence that she was liable, unless satisfactory proof shall be produced by the defendant that the ship did not come from or touch at any such place as is stated in the said answer; or that such ship, although directed to perform quarantine, was not liable. And where any ship shall in fact have been put, and shall actually be performing quarantine, such ship shall, in any prosecution, be deemed to be liable, without proving in what manner, or from what circumstances, such vessel became liable. 46 Geo. III. c. 10. sect. 40.

By the 43d section, offenders may plead the general issue, and if the plaintiff is nonsuited, or discontinues his action after the defendant has appeared, or if judgment has been given upon any verdict or demurrer against the plaintiff, the defendant may recover treble costs, and have the like remedy at law as the defendant hath in other cases.

Actions
Actions to be brought within the space of two months after the offence is committed.

Whenever any person is charged with an offence against this or any other act, or in disobedience of any order in council concerning quarantine, and the same shall appear to any judge of the court of King's Bench by affidavit or certificate of an information being filed against such person, he may issue his warrant under his hand and seal, and cause him to be brought before him or a justice of the peace, that he be bound with two sufficient sureties to appear and answer such offence; and if such person shall refuse or neglect to become bound, he may be committed to goal till he does so give bail, or be discharged by order of the court of King's Bench. The recognizance to be returned and filed in court, and remain in force until such person is acquitted, or until he has received judgment. (Act, sect. 41.) And if he is detained for want of bail, the protector may cause a copy of the indictment to be delivered to him, or the gaoler, &c. with notice thereon indorsed, that if he does not in six days enter an appearance and a plea of demurrer, an appearance and plea of not guilty will be entered in his name; and upon affidavit being made of such notice, &c. being delivered, the protector may cause an appearance and plea of not guilty to be entered, and such proceedings shall be had as if the defendant had appeared and pleaded not guilty; and if upon a trial the defendant is acquitted the judge may direct his discharge. Act, sect. 43.

Where any examination or answer shall be taken on oath, the persons authorized to take such examinations and oath shall be deemed to have full powers to administer such oath; and if any person swears falsely, or procures others to do so, he shall be deemed guilty of perjury or subornation of perjury. 45 Geo. III. c. 10. sect. 37. and 46 Geo. III. c. 98. sect. 10.

The king may issue directions if the plague breaks out in Great Britain.—The lords of the privy council, in case any infectious disease breaks out in Great Britain, or the islands of Guernsey, &c. may make such order, and give such directions in order to cut off all communication between any person infected, and the rest of his majesty's subjects as shall appear to them expedient for that purpose. 45 Geo. III. c. 10. sect. 12. And if it shall happen that any part of Great Britain or Ireland, or the isles of Guernsey, &c. or France, Spain, Portugal, or the Low Countries, shall be affected with the plague or other infectious disease, his majesty may by proclamation restrain all small boats, and vessels under 20 tons, from falling out of the ports of Great Britain or the islands, until bond is given by the master, with sufficient sureties for 30£., that such vessel or boat shall not go or touch at any place mentioned in such proclamation, and that the master, crew, or passengers, shall not go on board any other ship at sea, nor receive any person on board at sea from any other ship, nor receive any goods out of any ship. And if any vessel for which such security is required, shall fail before security is given, the shall be liable to forfeiture, and the master and every mariner shall forfeit 50£. 45 Geo. III. c. 10. sect. 32.

By the flat 1 James I. c. 31, if any person infected with the plague, or dwelling in any infected house, be commanded by the mayor or constable, or other head officer of the town or vill, to keep his house and shall disobey it, he may be enforced by the watchmen appointed on such occasions to obey such necessary command, and if any hurt ensue the watchmen are thereby indemnified. And further, if such person goes abroad and continues in company, if he has no plague fore upon him, he shall be punished as a vagabond by whipping, and be bound to his good behaviour. But if he has any infectious sores upon him uncorrected, he then shall be guilty of felony. Blackstone, vol. iv. c. 13.

Having thus far given the laws and regulations concerning this matter, we shall relate the duties payable by ships performing quarantine, with the exceptions provided by the act; and also the best methods of fumigating ships and houses. It must be apparent, that the nature of the quarantine establishments and maintaining lazarets incur considerable expences, to defray which the duties are to be applied (Act, sect. 8.); and the law 45 Geo. III. c. 10. sect. 3, declares, that it is reasonable the importers should defray the same; and sect. 6. enacts, that the ship-owners may recover of the importers such sums as the tonnage of their goods shall bear to the proportion of the tonnage of the ships. These duties are to be paid upon the ships clearing inwards, and to be computed according to the 26 Geo. III. c. 60. 45 Geo. III. c. 10. sect. 5. They are to be levied and recovered as duties of customs, and although not raised for the purpose of contributing to the revenue, the amount is to be carried to the consolidated fund.

Sect. 7.

A Table of tonnage duties payable on ships and vessels, which ships or vessels, or the cargo of which, or any part thereof, shall have performed quarantine in Great Britain, or the isles of Guernsey, Jersey, Alderney, Sark, or Man. 45 Geo. III. c. 10. sect. 3.

1. For every ship which shall have arrived from any part of Turkey, or from Africa within the freight of Gibraltar, or in the West Barbary on the Atlantic Ocean, with a clean bill of health, the ton 15 0
2. Do. without a clean bill of health, the ton 3 0
3. For every ship which shall have arrived from any place whatsoever (except from any part of Turkey, &c.) with a clean bill of health, the ton 10 0
4. Do. without a clean bill of health, the ton 7 6
5. For every ship which shall arrive with any part of the cargo consisting of goods the growth of Turkey, or any place in Africa within the freight, or in the West Barbary, and which shall have arrived from any place whatever, the ton 7 6
6. For every ship which shall have arrived under such circumstances as shall induce his majesty, or the lords of the council, to subject such ship to the like quarantine as ships coming from Turkey with clean bills of health, the ton 15 0
7. Ships arriving under such circumstances as shall induce his majesty to subject such ship to the like quarantine as ships coming from Turkey without clean bills of health, the ton 1 0

Exempted from the said Duties.

Ships of war, transports, and other vessels employed in the service of government.

Ships or vessels not bound to Great Britain or the islands, and having put in in distress. (Although they should perform quarantine. Opinion of the attorney-general.)

Ships or vessels obliged to perform quarantine only on account of having goods enumerated in the first class of board,
QUARANTINE.

The stronger and better fumigations are the nitrous or marine acid, and the oxymuriatic acid vapour, the former of which is made thus: half an ounce of nitre reduced to powder and vitriolic acid (oil of vitriol) in equal quantities, mixed in small pots, and placed in various parts of the room.

Oxymuriatic acid, which is most powerful, is prepared thus:

- Manganese - - - - 2 parts.
- Common salt - - - - 4 parts.
- Vitriolic acid, specific gravity 1.85 3 parts.
- Water - - - - 1 part.

To a small quantity of the mixture of the manganese and salt, (fuppofe three ounces,) the whole of the water is to be added, (half an ounce,) and to this, in a pot large enough to prevent the ebullition from flowing over, add the vitriolic acid from time to time. This will keep up for twenty-four hours a discharge of the oxygenated muriatic acid, of which the smell is not unpleasant, and the vapour gives no annoyance to either the sick or the attendants.

Where houses or hospitals are highly infected with the plague, it will be necessary for them to undergo a stronger fumigation of sulphur, but that being attended with danger should only be done by persons properly acquainted with the manner of doing it; they should afterwards be whitewashed, and the floors well scoured.

It may be flated once for all, that the great object of quarantine laws is the separating of those affected, or suspected to be infected with an infectious diftemper, from those who are not, and nothing would be fo falutary or abso- lutely necessary, wherever the plague breaks out, as instantly separating of the sick from those who are well; and this is best done by removing them to a proper place, rather than suffering them to remain with their family, which too frequently by that means becomes infected also.

Whatever is requisite to be done by way of fumigation will be found at large under that head; the following precautions are, however, proper to be known.

The clothes of the sick should at all times, when changed, be removed by tongs, and not by handling, and should be put into cold water and boiled for an hour, and afterwards be well washed in washing machines, and then fumigated; or they may be baked in an oven; but the safer mode would be to have them destroyed, especially if not valuable.

Those who attend about the perfon of the sick, as well as the medical men, should remain as short a space of time as is consistent with their duty, and to avoid as much as possible all contact with his perfon or his bedding, clothes, &c. And they might be furnished with gloves made of oiled flilk, as well as drawers of the same article. The cup or glass out of which he drinks should be immediately plunged into water or vinegar, as well as any article he touches or ufed. Whatever he leaves of his meals should be burnt or wholly destroyed. The excrementitious discharges should also be received into cold water, and infantly removed out of the room. If the sick die, he should be immediately wrapped in oiled cloth or a tarpaulin, and be speedily buried at the depth of six or seven feet; which should be performed, without baffle, in the night time, without toll of bell, to prevent the alarming of others.

With respect to the bed and bedding upon which the sick has died, it would be best to have it burnt immediately; at all events, it must on no account be used till it has been baked in an oven for twelve hours (being rolled up and removed in a cart with every possible care, that it be as little handled as possible). It should be afterwards exposed to the open air for at least fourteen days before it is again ufed.

Furniture
Furniture consisting of chairs, bedsteads, &c. should be scoured and fumigated with sulphur and saw-dust for twenty-four hours, first removing every person out of the apartment, as no living creature can exist in the fumes for any length of time.

Houses and apartments should be fumigated in like manner, and be afterwards purified by the admixture of as much air as is practicable, and also by scraping and washing the walls with lime-water, and the floors with plenty of cold water.

And lastly, we cannot inculcate too much the fact, that the best preventive of infectious disease, and the surest mode of diminishing the effects of its contagion, is by the free admixture of pure air, even in the room of the sick, who, to admit of its free circulation, should not have bed or window curtains, and by the greatest attention to cleanliness. By the removal of the rest of the inhabitants from the sick house to a place of observation, for the space of twenty days, and by the sick being also confined for an equal length of time, having persons appointed to prevent his escape, and to have a nurse assigned to him. Articles necessary for his support must be delivered by means of baskets or planks, as well as those received from the house, and all money received in payment to be dipped in vinegar.

Large assemblies should not be permitted to meet while towns are infected, and the theatres, churches, and markets should be closed; and if these precautions are strictly adhered to, we are confident that if the contagion cannot be wholly prevented, its spreading may be greatly confined, and its malignity considerably lessened.

**QUARTZ.** See Quartz, and Mineralogy, Addenda.

**QUASSIN,** in Chemistry, the name which has been given to a bitter substance extracted from quassia. See Bitter Principle.

**QUEEN ANNE's.** Add—It contains 16,648 inhabitants, of whom 6381 were slaves in 1810.

**QUEMAKO,** a township of Somerset county, in Pennsylvania, having 1392 inhabitants.

**QUERCITRON.** See Quercus Tinctoria, and Printing on Calico.

**QUILOA.** At the close, add—An island of Quiloa was visited by captain Beaver in 1812. He describes this island, which has been the seat of royal residence, since the foundation of the kingdom, at least 700 years, as being about fix miles long and three broad; low and fertile, extending longitudinally across the mouth of a deep bay, having at either end an opening for two arms of the sea, and thus containing a peninsula which projects from the main land, forms two safe and magnificent harbours, capable of containing, in perfect security, the largest fleets. Of the ancient splendour and magnificence that subsisted when the Portuguese first visited this island, not a vestige remains. The present city, if it deserves the name, consists of a number of scattered huts from the borders of the sea to the shore. Here captain Beaver found the deputy of the Imam of Muscat, who controls the miserable Moors or Arabs who are in possession of the sea-coast, with his half a dozen of soldiers, situated in a round tower, mounting three guns, which pointed directly to the king's house, and at the distance of a musket-shot from it. By these means, he keeps the king of the extensive kingdom of Quiloa in awe, and levies a tribute in slaves, ivory, gold-dust, and many other articles exported from this part of the coast. The Moorish king is only the nominal sovereign both of the islands and of the shores of the continent.

**QUINCUNX,** l. 21, add—The notion, however prevalent, that plants thus fet have greater scope than when set at the same distance without alternation, is perfectly imaginary: thus below it is evident, that the square mode becomes a quincunx when viewed angularly, and the quincunx, in like manner, becomes a square; and the distance of the plants is the same in both.

**QUINTAL, col. 2, l. 3,** add—The Cahilian quintal is divided into 4 ararobis, or 100 lbs.; the lb. into 2 marcs, or 16 oz.; the marc into 8 drachmas, 16 adarmes, or 576 grains. The merchants commonly reckon 100 lbs. Cahilian weight equal to 102 lbs. avoirdupois; but the more accurate proportion is as 123 to 125.

**QUIRA,** or Quiri, in Geography, a province of the ancient kingdom of Colchis enclosed by the end of the Moctian hills. It is a pleasant and fruitful country, and, from the ruins that still remain, we may conclude, that it was formerly flourishing and populous in an extraordinary degree. The residence of the prince of Quira is Titi-zighi or Ighina (the ancient Pityus), situated on the shores of the Black sea, with a secure and spacious harbour. The only considerable river of Quira is the Boa, which rises 30 vergas from Titi-zighi, and after a course from E. to W. empties itself into the Black sea.

**QUIRILIA,** the only river of consequence in Imeritia, or, as it is now called, Iberia. It rises in the Sosami ridges and being increased by the snow-streams which descend from the Georgion side of the Caucasus, enters the Phasis, in the neighbourhood of Cottis.
RACOON, in Geography, a township of Gallia county, in Ohio, having 395 inhabitants.

RADIATION of Heat, a property of heat or circumstance belonging to it, which has been lately investigated and successfully illustrated by professor Leflie of Edinburgh. There are two modes in which heat is discharged from bodies. A portion is communicated to the contiguous matter, and is slowly diffused through it. Another portion, when the body is placed in an aerial medium, is discharged with rapidity, darts through the air to a distance, and even at that distance, when intercepted, produces a heating effect. This forms what is called the "radiation of heat." Mr. Leflie has discovered the important fact, that different kinds of matter, at the same temperature, discharge very different quantities of heat by radiation. From a metallic surface, the quantity is comparatively small; from a vitreous surface, it is much greater; and it is still more so from a rough spongy surface.

The power of different surfaces in discharging different portions of heat, in this mode, at the same temperature, Mr. Leflie attributes to the more or less close contact which they admit with the external air; a vitreous surface, for example, admitting of a closer proximity of the air than a metallic surface does, and thereby communicating to it, in a given time, a larger portion of heat. And on the same principle he explains the fact, that those surfaces which are most powerful in this discharging heat, are also most powerful in arresting and absorbing it; the closer contact into which the heated air comes with the surface on which it impinges, favouring the transfer of its heat; while a surface, to which the heated air does not approach so closely, will in a great measure reflect it with little loss of heat. Hence the discharging and absorbing power are proportional to each other; while the reflecting power is the reverse.

Some important practical applications resulting from these differences are suggested by the author.

A vessel with a bright metallic surface is the best fitted to preserve liquors either long warm, or as a conservatory to keep them cool. A silver pot will emit far less heat as much as heat as one of porcelain; and even the very slightest varnishing of gold, platinum, or silver, which communicates to the ware a certain metallic gloss, renders this new kind of manufacture about one-third part more retentive of heat. The addition of a covering of flannel, though indeed a slow conductor, far from checking the dissipation of heat, has directly the contrary tendency; for it prevents to the atmosphere a surface of much greater propulsive energy, which it would require a thickness of not fewer than three folds of this loose substance fully to counterbalance. The cylinder of the steam-engine has lately been mott advantageously sheathed with polished copper.

The progress of cooling is yet more retarded, by surrounding the heated vessel, on all sides, at the distance of near an inch, with a cafe of planished tin; and the addition of other cafes, following at like intervals, augments continually the effect. With an obstruction of one cafe, the rate of refrigeration is three times slower, with two cafes it is five times slower, with three cafes it is eleven times slower, and so forth, as expressed by the succession of the odd numbers. By multiplying the metallic cafes, therefore, and disposing them like a neat at regular intervals, the innermost could be made to retain the same temperature with little variation for many hours or even days. Such an apparatus would obviously be well calculated for various culinary and domestic purposes.

In the conveyance of heat by means of steam, the surface of the conducting tubes should have a metallic lustre. On the contrary, if it be intended by that mode to warm an apartment, they should be coated on the outside with soft paint, to facilitate their discharge of heat. For the same reason, metallic pots are more easily heated on the fire, after their bottoms have become tarnished or smoked. If a bright surface of metal be slightly furrowed or divided by fine fluting, it will emit heat sensibly faster, because the prominent ridges, thus brought closer to the general atmospheric boundary, will excite the pulsations with augmented energy.

For the experiments which led to this discovery, and the conclusions deduced from it, we refer to his "Essay on Heat," and to a "Short Account of Experiments and Instruments depending on the Relations of Air to Heat and Moisture." 8vo. Edinb. 1814. See Heat. See also Dew, Rays of Heat, and Refractibility of Radian Heat.

RADMOR, in Geography, a township of Ohio, in Delaware county, having 347 persons.

RAJAFOOT, denotes literally the son of a king, and is used as the name of a warlike race of Hindoos.

RALEIGH, col. 5. l. 20. r. 1601.

RAM of M. Montgolfier. Add—See Water.

RAMA, or RAMAH. Add—This was a common name applied to many places in the Holy Land; and it is suggested (see Clarke's Travels, vol. iv. p. 432.), that the modern village of Bethoor and the modern Rama are the places
places mentioned by St. Jerom, where he says, “Rama et Bethoron et relique urbes nobiles a Salomone conscripte parvi viculi demonstrantur.” Rama was a village in the time of Jerom, and the situation of Bethor is distinctly marked in the Apocrypha, with reference to the plain of Rama. (I Maccab. iii. 16. 24.) (However, the prophecy of Jeremiah (xxxii. 15.) applied by St. Matthew (ii. 17.) to the murder of the Innocents by Herod is not believed to refer to the place now mentioned, but to another Rama, noticed by Eusebius.) The origin of Rama has been ascribed to the Moslems under Solomon, son of Abdolemec, who is stated to have built the town with materials from the ruins of Lydda, distant three miles from Rama. But that this is an error may be evinced by reference to the writings of St. Jerom; who speaks of its vicinity to Lydda, and calls it Arimath, from a prevalent opinion that it was the native place of Joseph, who buried our Saviour. Jerom’s testimony, preceding the Mahometan conquest of the country, is sufficient to prove that the city existed anterior to the invasion of Palestine by the Moslems. Nevertheless it is possible that Rama, from having been a small village, might have become a large town under their dominion; nor does there seem much reason to doubt, that this Rama was the village mentioned with Bethoron by St. Jerom, as the only remains of the two cities so named, which were built by Solomon. According to Rada, the oldest writer who mentions Rama is Bernard the monk, who visited the Holy Land in the 9th century. Oriental geographers describe it as the metropolis of Palestine; and it is said that St. George, the tutelar saint of our ancestors in England, suffered martyrdom in this place; though others say, that his relics repos’d in a magnificent temple at Lydda or Diopolis. Its distance from Jerusalem, usually estimated at a day’s journey, is described as equal to 36 or 37 miles by Phocas; who distinguishes Armathem, the native place of the prophet Samuel, from Ramola or Rama, with which Adrichomius seems to have confounded it; and places the church of St. George within the latter city; which position, although disputed by Rada and other authors, not only seems to coincide with the testimony given by the Alexiad of Anna Comnena, but also with the evidence afforded by Bernard the monk, who mentions a monastery of St. George near to Ramula. There is not a part of the Holy Land more fertile than the plain around Rama; it resembles a continual garden; but cultivation had been neglected at the time of the arrival of Dr. Clark, the traveller now cited, owing to the dreadfull plague with which the whole country had been afflicted. Rama and Lydda were the two first cities of the Holy Land that fell into the hands of the Chirilians when the army of the Crusaders arrived. Rama was then in its greatest splendour; a fenced city, abounding in all the luxuries of the East. It was exceedingly populous, and was adorned with stately buildings, and well fortified with walls and towers. The count of Flanders having been dispatched by the princes and generals of the Christian army, with five hundred cavalary, to reconnoitre the place, and to summon the city to surrender, found the gates open: the inhabitants, alarmed by the sudden approach of so powerful an army, had abandoned their dwellings and all their property during the preceding night. In consequence of this, a general rendezvous of the Christian forces took place in Rama, where they remained during three entire days, regaling themselves in the abundance the place afforded. During this time, Robert of Normandy was elected bishop of Rama and Lydda, to which bishopric all the revenues of the two cities and their dependencies were annexed; the whole army joining in thanksgiving to St. George the Martyr, the patron saint of Diospolis and Rama, to whom the auspicious commencement of the enterprise was attributed. Hence probably originates the peculiar confederation in which St. George was held by the inhabitants of England, during the early periods of its history.

RAMSURY. By the returns of 1811, the parish of Ramsbury contained 398 houses, and 2095 persons; viz. 1028 males, and 1067 females: 248 families being employed in agriculture, and 85 in trade, manufactures, and handicraft.

RAMSDAL, dele.

RANOLDPH. Add—In 1810, their number was 1170; l. 3 of next article, infert—including 798 slaves.

RANOLDPH, a county of the Illinois (dele Indiana) territory, containing four townships; viz. Kamas, United States’ Saline, Shawnee, and the residue of Randolph county, and 12,282 inhabitants, containing 168 slaves. Allo, a township of Montgomery county, in Ohio, containing 936 inhabitants.

RAPIDES. Add—This is one of the best tracts in Louisiana. No town, except Alexandria, on the right bank of the Red river, has been found, (says Mr. Darby, 1816,) in the parish of Rapides. This place is a thriving little village, and banding at the head of conftant boat navigation, is of considerable commercial importance. The staples of the parish are, cotton, timber, beef, pork, and maize; the four fird being the principal.

RATE, l. 8, for Ireland r. India; in Ireland six, legal interest charged by all private banks, though the interest charged by the bank of Ireland for money advanced is 5 per cent.

Rate of a Ship, &c. col. 2, l. 39, add—About ten years ago, an additional lieutenant was appointed to the line of battle ships. Ships of 50 and 38 guns have four lieutenants: l. 5 from bottom, after lieutenants, infert—ships of 20 guns, and all ships upon the establishment of floopes of war, have two lieutenants. Col. 3, l. 14, add—See Ship.

Rate of Ship of War, add—By an order of council, the operation of which commenced Jan. 1, 1817, the following regulations were fixed with regard to rates in the navy; viz.

1st rate. All three deckers.
2nd rate. All of 80 guns, and upwards, on two decks.
3rd rate. All of 76, and under 80 guns.
4th rate. All of 70, and under 70 guns.
5th rate. All of 56, and under 50 guns.
6th rate. All of 24, and under 50 guns.
7th rate, 900, 850, and 800 men.
8th rate, 700 or 650 men.
9th rate, 650 or 600 men.
10th rate, 500 or 550 men.
11th rate, 450 or 450 men.
12th rate, 300 or 280 men.
13th rate, 175, 145, or 125 men.

RAVA, in Geography, a town of the Persian empire, in the pahalic of Bagdad, situated between Kerkea (the Roman Circeum) and Amal (the Amathus Armiliarius), and confiding of about 200 stone houses in the midle of extensive ruins. On the opposite side of the river are the remains of a castle, erected on the summit of a rock.

RAYUN, a town of Peria, in the province of Kerman, which, like Tchroot and Mahim, is surrounded by numerous gardens.

READING, a township of Fairfield county, in Ohio, having 789 inhabitants.

REALIZE, r. Realize, or Realize.
RED ANTIMONY-ORE. See MINERALS, Addenda.

REDSTONE. Add—the township situated in Fayette county contains 1224 inhabitants.

REEL. See MANUFACTURE OF Cotton.

REFRACTION. The following laws have been deduced by MM. Dalong and Petit from their experiments on the cooling of bodies. See HEAT.
1. If the cooling of a body in a vacuum surrounded by a medium whose temperature is constant could be observed, the velocity of cooling would decrease in a geometrical progression, while its temperature would decrease in an arithmetical progression.

2. When the temperature of the medium surrounding a vacuum remains constant, the velocity of cooling for excesses of temperature in arithmetical progression decreases as the terms of a geometrical progression diminished by a constant number. The ratio of this geometrical progression is the same for all bodies, and is equal to 1.0077.

3. The velocity of cooling of a body in a vacuum for a constant excess of temperature increases in a geometrical progression, the temperature of the surrounding medium increasing in an arithmetical progression. The ratio of that progression is still 1.0077 for all bodies.

4. The velocity of cooling arising from the simple contact of a gas is entirely independent of the nature of the surface of a body.

5. The velocity of cooling arising from the simple contact of a fluid varies in a geometrical progression, the excess of temperature varying at the same time in a geometrical progression. If the ratio of this second progression be 2, that of the first is 2.35, whatever may be the nature of the gas or its elasticity.

This law may be also expressed by saying that the quantity of heat removed by a gas is in every case proportional to the excess of temperature of a body raised to the power of 1.233.

6. The cooling power of an elastic fluid diminishes in a geometrical progression, while the tension diminishes in a geometrical progression. If the ratio of this second progression be 2, the ratio of the first is 1.366 for air, 1.301 for hydrogen, 1.431 for carbonic acid, and 1.415 for olefiant gas.

This law may be also expressed in the following manner. The cooling power of a gas, ceteris paribus, is proportional to a certain power of the pressure. The exponent of that power is 0.45 for air, 0.315 for hydrogen, 0.37 for carbonic acid, and 0.50 for olefiant gas.

REVOLUTION, French. At the close, add—On the 4th of June 1815, the king (Louis XVIII.) came to the two chambers to make a declaration of the constitutional charter; and on the occasion delivered a speech distinguished by its dignity and propriety. On the 11th of March 1815, however, Buonaparte, having escaped from Elba, landed in France, and by rapid and uninterrupted marches hasted to Paris, and resumed his power, March 22, 1815, but his fate was finally determined by the battle of Waterloo; and he made his second abdication, in favour of his son, on the 23rd of June 1815; and on the 8th of the following month, the foreign troops entered the capital. Disappointed in his views of settling either in America or in England, he surrendered himself, with a suite of forty persons, to captain Maitland of the Beauforton, July 15, 1815; and at Torbay he was transferred to the Northumberland, which conveyed him to the island of St. Helena, debarred by the allied sovereigns to be the place of his future abode. Here he arrived Oct. 16, 1815.

Upon his departure from Paris, Louis XVIII. was again reforde and fixed by the allied powers on the throne of France.

With respect to the events that have occurred since this article was written, such as the famous battle of Waterloo (see WATERLOO), the total defeat of Buonaparte, his deposition from the government, his removal to the capital, his confinement in the island of St. Helena, the re-establishment of Louis XVIII., the withdrawal of the allied troops, and the measures adopted for the secure and permanent sovereignty of France, under the present dynasty; they are so recent, and our limits are so restricted, that we must refer the reader to documents of access of a minute detail and more ample information.

RICCIÓ, DOMENICO, called Bucia-Sorci, in Biography, an eminent painter, was born at Verona in 1494, and became a disciple of Giovanni Francesco Caroto, under whose instruction in design and colouring he laid the foundation of his subsequent celebrity. For further improvement he studied the works of Giorgione and Titian at Venice; and his proficiency was such, that his works have been generally admired and fought after, on account of the beauty of his colouring and the attitudes of his figures. Under the patronage of cardinal Gonzaga, by whom he was invited to Mantua, he became a competitor in the exercise of his art with two of the most celebrated masters of his time, Paolo Veronese and Paolo Farinati. In the church of St. George at Verona is a picture by Riccio, which represents the gathering of the mima in the wilderness, and which is accounted a fine composition, and distinguished by the force of its colouring. This matter died in 1567, at the age of 73 years.

RICHBOROUGH. The parish of Asf, in which this hamlet is situated, contained, in 1811, 334 houses, and 1685 persons; viz. 868 males, and 817 females.

RICHFIELD, a township of Geauga county, in Ohio, having 329 persons.

RICHLAND, l. 3, add.—It contains 927 persons, of whom 523 were slaves in 1810. At the close, add—Allo, a township of Belmont county, in Ohio, having 283 persons.—Allo, a township of Clinton county, in Ohio, having 783 inhabitants.—Allo, a township of Fairfield county, in Ohio, having 881 inhabitants.—Allo, a township of Guernsey county, in Ohio, having 227 inhabitants.

RICHMOND, in America, col. 2, l. 27, add—of whom 3178 were slaves in 1810: 154, add—of whom, in 1810, 2115 in the county, and 1321 in the town of Augusta were slaves. At the close, add—Allo, a township of Kentucky, in Madison county, having 366 inhabitants, including 102 slaves.

RINSING, an operation in calico-printing, for an account of which, as well as of damping, see PRINTING, Calico. RIO, &c. col. 2, l. 15, r. Helen.

RIOT, l. 20, after pillory, infert.—(now abolished).

RIVERHEAD, in Geography, a village, or liberty, in the parish of Seven-Oaks, and county of Kent, which, in 1811, contained 184 houses, and 1012 persons; viz. 474 males, and 538 females.

ROAD, col. 23, l. 11 from the bottom, r. 1°, 1°, 32°, and 22 yards; l. 9, for 6300 r. 7272; l. 7, for 255,150 rd. 294,516.

ROANE. Add—of whom 670 were slaves in 1810.

ROARING, a disease of horses, well known to jockeys and dealers in these animals. It takes its name from a jingling noise which the horse makes in breathing whenever he is put into a brisk motion. It usually accompanies broken wind, or at least is the forerunner of it. Mr. Ryder says, that it is owing to the extravasation of lymph, and its coagulation on the inside of the trachea, or wind-pipe, which thus obstructs respiration; and if this account of it be jult, it seems to resemble the cough in children. The principal cause is sudden or violent and long-continued exercise. At its commencement, blistering the whole length of the wind-pipe may be of use; but when the disease continues for a length of time, it becomes incurable.

ROBERTSON, in Geography, a county of West Tennessee, containing 7270 inhabitants, of whom 1608 were slaves in 1810.

RODSEON, l. 3, add—of whom 1340 were slaves in 1810.

ROCKBRIDGE, l. 4, add—of whom 1724 were slaves in 1810.

ROCKCASTLE. Add—of whom 163 were slaves in 1810.

ROCK-CRYSTAL. See Mineralogy, Addenda.

ROCKDALE, in Geography, a township of Crawford county, in Pennsylvania, having 401 inhabitants.

ROCKHAM, l. 17, add—of whom the slaves in 1810 were 2114; l. 23, add—of whom 1491 were slaves.

ROCKLAND, a township of Berks county, in Pennsylvania, having 1026 inhabitants.

ROMANO, GIULIO, l. 14 from bottom, for sagacious r. falacious.

ROME, in Geography, a post-town of the district of Maine, in the county of Kennebec, with 785 inhabitants.

ROMILLY, Sir SAMUEL, Knight, in Biography, a no less distinguished as a patriot and philanthropist, than for his legal knowledge and practice, has every claim which prominent talents and character can give him to honourable notice in those biographical sketches which this work contains. Descended from a race of ancestors, whose attachment to civil and religious liberty constrained them to sacrifice their property, to abandon their native land, and to seek an asylum from persecution in this country, it was referred for him to maintain and perpetuate the honour of the family from which he derived his origin. Of his family and its emigration, it will be sufficient to transcribe the following account given by himself in an address to the citizens of Britain, when they invited him to become a candidate for representing them in parliament. "It has been published in this city that I am a foreigner, and that if you elect me, you will lend a foreigner to represent you in a British parliament. Gentlemen, I was born and educated, and have passed my whole life in England, with the exception of a short interval, which was spent in visiting foreign countries. My father too was born and educated in England, and spent his whole life in it; my grandfather, it is true, was not an Englishman by birth, but he was an Englishman by choice. He was born the heir to a considerable landed estate at Montpelier, in the south of France. His ancestors had early imbibed and adopted the principles and doctrines of the reformed religion, and he had been educated himself in that religious faith. He had the misfortune to live soon after the time when the edict of Nantes, the great toleration act of the Protestants of France, was revoked by Louis XIV., and he found himself exposed to all the vexations and persecutions of a bigoted and tyrannical government, for worshipping God in the manner in which he believed was most acceptable to him. He determined to free himself from this bondage; he abandoned his property, he tore himself from his connections, and fought an asylum in this land of liberty,
where he had to support himself only by his own exertions. He himself embarked in trade; he educated his sons to useful trades; and he was contented at his death to leave them, instead of his original patrimony, no other inheritance than the habits of industry he had given them; the example of his own virtuous life; an hereditary detestation of tyranny and injustice; and an ardent zeal in the cause of civil and religious freedom. To him I owe it, among other inestimable blessings, that I am an Englishman. Gentlemen, this is my origin; and I trust that I need not blufh to own it."

The father of Sir Samuel was an eminent Jeweller, and realized a handsome fortune; his mother, whose maiden name was Garnault, was defended from a family of French refugees; and he being the youngest of nine children, of whom three only attained to maturity, was born in Frith-street, Soho, in the city of Westminster, on the 1st of March, 1757.

In early life he manifested those powers of the understanding, and those affections of the heart, which, under proper direction and auspicious culture, augured his future advancement to eminence of situation and character. "He was remarkable," says one of his biographers, "for the benevolence of his disposition, his deep and generous sensibility, his high sense of honour, the quickness of his apprehension, and the extraordinary maturity of his judgment;" combining "great vivacity and a constant flow of animal spirits, with a powerful imagination, a retentive memory, and the strongest and most durable affections; he possessed a correct taste in literature and the fine arts, and retained through life a keen relish for the beauties of nature. It was his good fortune, at an early age, to form an intimacy with the Rev. Mr. Hoght, a young gentleman resembling himself in taste and disposition, and afterwards his brother-in-law; to whom he was much indebted, as he himself had the modesty and gratitude to acknowledge, for giving direction to his talents, and a steady impulse to his exertions.

Thus liberally endowed by nature, and aided by the counsel of an intelligent and affectionate friend, he overcame a variety of obstacles which prevented themselves in the way of his progress and advancement; and having chosen the profession of the law for the exercise of his talents, he soon exhibited those powers and that persevering application, which, without the advantages of a patrimonial estate, and an education at a public school or university, ensured his future eminence. Having enrolled his name in one of the inns of Court, and previously acquired some notion of business in the "Six Clerks' Office," connected with the court to which he directed his views, he was called to the bar in 1783; and from the reputation he gained as an "equity draughtsman," he soon rose to the higher departments of his profession. Upon the removal of Thurlow, Scott, and Mitford, from the chancery court, Mr. R. became a leader, and was retained in almost every cause. "His indefatigable industry, his unwearied patience, his comprehensive acquirements, his deep knowledge of the law, his correct notions of the practice of the court, were all calculated to give due weight to arguments fetected with skill, propounded with modesty, and enforced by a skilful eloquence."

Railed to an independence by his own exertions, it was natural for a person of his disposition to seek a domestic establishment; and accordingly in the summer of 1797, whilst he was upon a visit at the seat of the marquis of Lansdowne, he met with a daughter of Francis Garbett, esq. of Knaik-court, in the county of Hereford; a young lady, whose youth and beauty and other amiable qualities engaged his affection, and determined his choice; and to whom he was married in the following year. This connection opened to his views the prospect of a growing family, and of course induced him to apply to the business of his profession with additional ardour and affability. Accordingly when Mr. Fox and lord Grenville assumed the reins of government in the year 1806, he was nominated solicitor-general, after some fulsnee about committing to his custody the great seal, and received the honour of knighthood.

It is recorded to the honour of Sir Samuel, as well as to that of his colleague Sir Arthur Pigott, the attorney-general, that, though the prefs, according to the language of lord Chatham, was become, during their time, a "chartered libertine," and political contention had arrived at its height, yet with a kind of triumph over all provocations which afforded the administration of this period, no prosecution for libel occurred. Indeed, the mind of Sir Samuel was occupied about a much higher object, which was the reform of the English fystem of jurisprudence. His first attempt with this view was an amendment of the bankrupt laws, and though he did not succeed to the extent of his wishes, so as to render the freethink of debts of persons liable to the bankrupt laws, who might die indebted, affect for the payment of their simple-contract debts, for which he was allowed to bring a bill into the house of commons in 1807, which bill was laid on a division; he nevertheless obtained an act by means of which the debts of traders have been more effectually secured, for the benefit of the public. About this time he acted as a manager at the trial of the late vicount Melville, for high crimes and misdemeanors in his office as treasurer of the navy, which terminated in an acquittal. On occasion of the abolition of the slave-trade, which conferred immortal honour on this short-lived administration, Sir Samuel delivered a speech which made great impression on the house; and it is said that one passage of it, which he uttered with an uncommon degree of animation, was honoured by three distinct plaudits. On the dismissal of the ministry, of which he formed so distinguishing a part, he vindicated and applauded their conduct, during the year of their existence; expressing in terms of cordial approbation their decisive measures with regard to the abolition of the slave-trade, and the emancipation of Ireland, as well as their refusal to give the king a pledge not to renew the Roman Catholic question; and depreciating the return of lord Melville to office, notwithstanding his acquittal, as no one had moved for refeeding the vote against him.

The attention of Sir Samuel, both in and out of office, was much occupied concerning the state of our criminal code, and the adoption of measures for reforming it. He lamented, in common with many other enlightened patriots, that the loss of life should be annexed to a greater variety of actions in England than in any other country in the world, and that criminals of very different descriptions should be subject, by the administration of our laws, to the same kind and degree of punishment. To rectify this anomaly in our jurisprudence appeared to Sir Samuel Romilly to be an object of great importance, in its connection, both with the equity and humanity of legislation, and the prevention of crimes. Accordingly on the 18th of May 1808, he moved for leave to bring in a bill for the repeal of certain objectionable laws; and in this bill he introduced a clause for granting compenination to persons who were unjustly accused and tried. He soon after published a pamphlet, intitled "Observations on the Criminal Law of England, as it relates to capital Punishments, and to the Mode in which it is administered." In this pamphlet, which passed through three editions, he explained his views, and pursued his refutation of the theory of Dr. Paley. "The certainty of punishment,"
of the peculiar August and Surry, Vice-chancellor great their order your am but find any prominent new and state You were an passion. except committed. “If,” says the biographer whose article we are citing, “the king of France has relaxed on his part, and declared the trade in human beings to be annihilated, so far as concerns his own dominions, it is to sir Samuel Romilly, and those who supported him on this occasion, that we are to attribute the change.”

The subject of this memoir soon afterwards distinguished himself by his opposition to the appointment of a new judge and tribunal for facilitating public business and alleviating the labours of the lord-chancellor. This he considered and represented as an innovation, from which neither the chancellor, nor the tutors of his court, nor the public in general, would eventually derive any advantage. In a pamphlet under the title of “Objections to the Project of creating a Vice-chancellor of England,” he announced to the public his opinions on this subject, “the general result of which was, that the new division of chancery into two courts, and the creation of an intermediate court of appeal between it and the house of lords, would tend greatly to enhance the expense of suits already grievously and oppressively high,” to multiply the buncels of the court, and to protract the final decision of causes. “The remedy,” he adds, “my lord, which I have to propose, is a very simple one, but I am much afraid, confidering the force of several expreffions which I find scattered in your lordship’s pamphlet, that you will think me disrespectful even in mentioning it. You have, however, really left me no choice. You have imposed upon me the necessity of being deficient in what you will think due respect, in order to avoid the reproach of being deficient in what you have made my duty. The remedy, then, my lord, seems to be, That the house of lords, like all inferior tribunals, should, when they are pressed with an unequal quantity of business, sit on a greater number of days and at unusual hours, in order to dispatch it.”

His bill, and as some have thought his brief speech, was delivered, at the close of the late parliament, against the “Alien-bill?,” and so powerful were his arguments, that, on his suggestion, the amendments introduced by the lords were thrown out. In this speech, the eloquent senator details and reprobates the measures adopted and purfued by the parliament just expiring, and he closes with the following reflection: “who our succcissors may be, I know not, but God grant that this country may never see another parliament so regardles of the liberties and rights of the people, and of the principles of general justice, as this parliament has been!” However the political opinions of persons may differ, they must concur in admiring the integrity and ardour of the speaker; and considering it as the last speech which he ever delivered in the national senate, the perusal of it cannot but otherwise than awful and impressive.

No man ever devoted his time and talents to important and useful purposes with greater affinity and zeal than sir Samuel Romilly. His professional practice, which was very extensive, demanded a great portion of his time and attention; and yet whenever the public interest required his attendance in the house, he never abdented himself on account of any personal engagements. His practice and his parliamentary duties occupied the whole of the day from the morning dawn frequently till midnight; and his publications were the productions of those hours that ought to have been devoted to rest and sleep. It is not at all surprising that talents like his, and so employed, shoud command general notice and respect. In a former parliament many enlightened and respectable members of the city of Britol directed their views to him, and wished for such a representotive; but other interets prevailed against his abilities and character, and the influence of his friends. At the last general election, he was proposed as a fit representative for Weftminster, his native city; and he was chosen in the most honourable manner, without trouble, expense, and solicitation, by a decided majority, and amid the applause of an immense body of electors. But a circumstance occurred which rendered the closing period of his life gloomy and distressing, and which disappointed the expectations of his constituents. Lady Romilly, to whom he was affectionately attached, and with whom he had enjoyed a high degree of coniubial felicity, had been for some time in a state of declining health, and his mind was agitated by very disquieting and depressing apprehensions on her account. During their residence at their country-house at Tanhurst, in Surry, in August 1818, her complaint feems to have abated, and with the flattering hope that her convalescence would be confirmed by the mild air of the Isle of Wight, they accepted an invitation from Mr. and Mrs. Nash, to spend the remainder of the vacation at their hospitable castle at East Cowes, whither they removed in the month of September. Here lady Romilly’s disorder recurred with circumstances of peculiar aggravation; and Dr. Roget, the nephew of sir Samuel, was summoned to her relief. Her complaint, however, was irrecoverable; and after various fluctuations, which excited alternate hope and alarm, she died of a dropy in the chest, in the night of the 29th of October. During the progress of her disorder to its fatal termination, sir Samuel’s mind was kept in a state of constant suspension and anxiety, until at length his sympathy with the amiable sufferer and an apprehension of the uncertain issue of her complaint, disordered his whole frame, deprived him of sleep or scared him with frightful dreams; and it is laid, that on one occasion, after having been in a state of great distress, he intimated to a friend, that he felt a burning faintness in his head; and this feems to have been the only occasion on which he made a complaint of this kind. Alarmed about himself, he sought relief, and tried a variety of medicines without any permanent effect. He frequently expreffed his surprize, that his want of sleep did not interfere with his bodily health, that his appetite and digestion continued in full vigour, that no indication of fever existed, and that he felt no uneasy faintness in his head. In conversing with Dr. Roget and Mr. Dumont he dwelt much on this apparent anomaly, and drew from it the most ominous prefiguration, as to the probability of its ending in infancy—an apprehension which unfortunately took deep root in his mind. Although in all other respects he was perfectly in possession of his faculties, yet on this subject his imagination
A striking instance of this feeling appears in one of the testamentary papers written by him about this time, in which he gave particular directions as to the management of his property, the care of his children, and the custody of his person and estate, in the event of his becoming a lunatic. It may be remarked also, that the circumstance of his losing sight, in a great measure, of the primary cause of his grief, and of fixing his attention so much upon his own feelings, was so opposite to his natural disposition, as in itself to constitute a strong feature of aberration. Other circumstances, which occurred on his interviews with his friends, confirm the same observation.

On the morning after lady Romilly’s death, when Dr. Roget informed him of the event, he received the intelligence with calmness and resignation, and without any effusion of grief; and prepared to quit the scene of his forrows at the suggestion of his friends without hesitation or demur. At Marcol-green, where they lodged in their way to London, we learn from Dr. Roget, who paffed the night in the fame room with him, that, although he was in general reflfets, yet, at intervals, he enjoyed tranquill sleep; nor did he betray, at any period, the smallest sign of impatience or irritability. As he approached London, however, on the following day, his agitation increased, and he once complained to his daughter that his head was disturbed. After his arrival at his own house in town, he ate his dinner with his usual appetite; he then went for Dr. Marcot, who inquired particularly concerning the state of his head, and was informed by Sir Samuel, “that he had no head-ache, nor any uneafy fenfation whatever in his head.” “Our symptoms were those of a high degree of nervous irritation, unaccompanied by fever or any inflammatory action; but they were of a nature to excite considerable alarm as to the state of his mind. Though he refrained from giving vent to his feelings, it was evident, from his manner and from the expressions which dropped from him, that he depairied of his recovery, in spite of every endeavours to inspire him with hope and comfort.” To the use of all means that were recommended for allaying his extreme irritation he objected; alleging, “that he could not possibly pass a wretched night, and that if he were to ufe any medicinal prescription, it would only have the effect of taking away all his confidence in the powers of medicine.”

During the greatest part of the night, Dr. Roget, who slept in the fame room, reports that he was perfectly tranquil and apparently asleep; though in the morning Sir Samuel affurred him, that he had never, for an instant, dropped asleep.

The next morning the reflfets returned, and was attended with symptoms of fever; the tongue became white during the night, and the pulse at one time rose to 130 in a minute. Upon consulting Dr. Marcot, it was proposed, at his fuggiflion, to apply ice to the head, and to have recourse to cupping; but before these measures were adopted, Dr. Bahington was sent for, and before he arrived the excitement had fubfided, and Sir Samuel was much relieved by a copious perspiration. Upon consultation it was agreed, that the measures propofed by Dr. Marcot, in extifiting circumstances, would not be expedient; and other medicines of an active nature were prefcribed. Thofe were taken by Sir Samuel without reluctance; and he continued tranquil and apparently asleep till about two o’clock. His daughter remained at the fide of his bed, who obferved upon his awaking, that he became reflfets and agitated. Upon being asked whether Dr. Roget fhould be called, he replied in the negative; but upon a fcond inquiry, he faintly afented. During the fhort interval of Mifs Romilly’s abfence, a fudden paroxysm had feized him, hurried him from the bed, and armed his hand againft his own life. The razor with which he had inflicted the fatal wound was in his hand when Dr. Roget entered his apartment. Before he exprefed, as his biographer proceeds in the relation of the melancholy catastrophe, he made figns that he wifhed to write, but though fupplied with pen and ink, nothing intelligible could be collected from his attempts. He then defilled from making them, and joining his hands, appeared from the movements of his lips and eyes, to be absorbed in fervent prayer. It is hardly necessary to flate, that the jury summoned on the coroner’s inquest brought in a verdict, “that the deceased had destroyed himself in a state of temporary mental derangement.”

Sir Samuel and his lady were interred at the fame time, in the fame grave, at Knill, the seat of her ancestors, in Herefordshire. The funeral, agreeably to the instructions of his will, was private; being attended only by his nearest relations and most intimate friends. Six fons and one daughter survived to lament the irreparable losfs which they fuffered. The calamitous event, which thus afwiftly terminated the life of Sir Samuel Romilly on the 2d of November, 1818, in the 62d year of his age, made a deep impression, not only in the circle of his family and friends, but through the country in general. So highly was he respected and esteemed, that, on this melancholy occasion, “the folicitors fupended their practice; the counsel abandoned the courts; while the judge forfook the bench, after he had fded a torrent of tears!” The following ftringular circumstance is mentioned by his biographer, viz. that in the parish church of St. Bride, Fleet-freet, there is a fimple unadorned tablet placed against the wall, with an inscription on it to the memory of Mr. Isaac Romilly, F.R.S., who was the uncle of Sir Samuel, and who died in 1759 of a broken heart, feventy days after the deceaf of a beloved wife. For the materials and authentic documents that have furnifhed this article, we refer to the “Annual Biography and Obituary for the Year 1819,” vol. iii.

ROMNEY, in Geography, a town of Grafton county, in New Hampshire, containing 765 inhabitants.

ROOFS, in Rural Economy. Add—Roofs of iron have lately been introduced with advantage. Mr. T. Pearfall of Bath has contrucfed several in the neighbourhood of Bristol and London; and on a comparison of a roof of this kind with that of timber, he obferves, that the iron-roof is fixed on the walls complete for the covering; that the strength and durability of the iron must be allowed to be superior to thofe of wood; and that the prevention of fire should not be forgotten. By his fatement, the whole expence of fuch a roof, erected over a brick-kiln near Bristol, 29 feet 3 inches in length, and 18 feet 6 inches in fpam, appears to have been 18l. 6s. 11d.

ROSMOND, col. 2, l. 17, r. if it cannot be, &c.

ROSS, in Ohio, l. 1, r. 16. Add—Alfo, a township of Butler county, in Ohio, having 1321 inhabitants.

ROSSO of Florence, in Biography, called by the French Maitre Roux, was born in 1496, and without regular tuition arrived at a considerable degree of eminence in the art of painting. The works of Michael Angelo were his favourite studies, whose flile he endeavoured to imitate without ferially following it. Hurried away by a lively imagination and great command of the pencil, he could not attach himfelf to the fudy of nature, or the antique, fo feadily as he ought; hence, though his works exhibit great brilliancy of invention,
invention, grandeur in their mass, gaiety of colour, and taste in the management of the draperies, they are frequently wild and extravagant in composition and effect.

He exhibited his talents early in life, and painted when very young a large picture of the Assumption of the Virgin for the church of La Nunciata at Florence, which was distinguished by the novelty and intrepidity of its style. He painted several other pictures there, and then went to Rome, where reputation had already forerun him. In that city, he painted an altar-piece for S. Maria della Pace, and the Decollation of St. John for the church of St. Salviani. He remained there till it was sacked in 1527, and then fled to Votterra, where he painted a fine picture for the oratorio of St. Carlo. He went afterwards to Venice, and there painted for Areitin his celebrated picture of Mars and Venus; but not being sufficiently employed in Italy, he accepted an invitation from Francis I. of France, who then emulated the character of an encourager of art and science. By this munificent monarch, Roffo was employed both as an architect and painter, and the building and decoration of the palace of Fontainbleau were intrusted to his care, and he was gratified with a handsome pension, and lived in affluence and ease, as he was not only an able artist, but a man of literary acquirements, and of polished and agreeable manners.

The unhappy termination of the life of Roffo affords a lesson to those whose minds are inclined to indulge fictitious fantasies. He had lived in friendship with one Francesco Pellegrini, a Florentine painter, who was in the habit of visiting him occasionally. Soon after one of his visits Roffo’s house was robbed of a considerable sum, and he rashly suspected Pellegrini to be the thief. He accused and prosecuted him, but he having endured examination and the torture, to which he was cruelly put to extort confession without any sign of guilt, was declared innocent. As soon as he was released, the unfortunate Florentine published a jilt and severe unatatement of his cafe, and appealed for justice; to this Roffo had nothing to plead, and to avoid the infamy and remorse to which he had been guilty of much necessarily subject him, he put an end to his existence by poison in 1541, at the age of 45. The greater part of his paintings at Fontainbleau was destroyed by his rival and successor Primaticcio, to make room for his own productions.

ROSS-SHIRE, col. 2, l. 2, for 13,280 r. 12,829; and after inhabitants, add—viz. 27,640 males, and 33,213 females; 7490 families being employed in agriculture, and 2499 in trade, manufactures, and handicraft.

ROSTRATA. See Whales.

ROT, Dry, l. 2, add—See Boletus. Col. 7, at the close, add—Mr. Robert M’William, in a valuable ‘‘Eléfay on the Origin and Operation of the Dry-Rot, with a View to its Prevention or Cure;’’ to which are annexed, Suggestions on the Cultivation of Forest-Trees, and an Abstract of the several Forest Laws, from the Ridge of Canute to the present Time,’’ 1818, has demonstratively shown, that the common practice of felling oak in the spring is an error which ought not to be avoided; and that the fanning of timber is not less important as a means of preventing this disease. This ingenious author considers fungi as a proximate cause of the dry-rot; and as to the origin of fungi, he knows of no found argument against its having been created, like other vegetables, at the beginning of all things. After many investigations and researches, the cause of vitality has not been satisfactorily ascertained. Dr. Darwin, in his Speculations on the Origin of Microscopic Beings, adopted the incomprehensible doctrine, that their vitality is spontaneous. Buffon, Raynur, Prieftley, Ellis, Ingen-
culation of atmospheric air, and the application of heat may be useful as an auxiliary in promoting such a circulation. He observes, that even atmospheric air itself must be applied with some discretion: for if in its passage through any part of a building which is damp and already affected it should become impregnated with noxious gases, and be charged with any of the volatile seeds of fungi, it may do more harm than good. It is necessary, therefore, in limine, to remove the infected materials, the discovery of which requires a penetrating eye.

Water is likewise a powerful agent in preventing and remedying the ravages of the rot; and many instances have occurred that prove the antifeptic properties of water acting on wood entirely submerged in it. But when water is applied as a subliming for air in cellars, vaults, &c. care must be taken that it does not flagrate, but flow regularly through the drains; in which case it will carry off with it much of the carboonic acid gas, which is so essential a pabulum to fungi.

The charring of timber is of very ancient use, and against external infection is an admirable preservative; but when the principles of decomposition are within, it is of very little advantage in resiling them. Paint, when the timber is properly seasoned and dry, is likewise very beneficial. For other interesting particulars relating to this subject, we must refer to the author's Essay.

ROVING. See Manufacture of Cotton.
ROUM. For Kala r. Kela.
ROWEN. Add—of whom 3757 were slaves in 1810.
ROXBURGHSHIRE, l. 23, for 6518 r. 6423; after inhabitants, add—viz. 17,113 males, and 20,117 females: 3763 families being employed in agriculture, and 2487 in trade, manufactures, or handicraft.
RUBY, SPINEL. See Mineralogy, Addenda.
RUDGELEY. In 1811, the parish contained 453 houses, and 2213 persons: viz. 1089 males, and 1124 females: 101 families being employed in agriculture, and 277 in trade, manufactures, and handicraft.
RUMFORD, l. 1, for Cumberland r. Oxford. Add—
It has 629 inhabitants.
RUSCOMB MANOR, a township of Berks county, in Pennsylvania, having 932 inhabitants.
RUTHERFORD. Add—of whom 979 were slaves in 1810. Add—Allo, a county of West Tennessee, having 10,265 inhabitants, of whom 2791 were slaves in 1810.
RUTILE. See Mineralogy, Addenda.
RUTLAND, in America, l. 7, r. 17 townships.
RYE, Chemical Composition of. This grain has been analyzed by Einhoff; according to whom 100 parts of good rye-meal consist of:

S.

Sabine, in Geography, a river of Louisiana, being a temporary boundary between the United States and the Spanish internal provinces, and part of the permanent western limits of the State of Louisiana. This river discharges itself into the gulf of Mexico, in N. lat. 29° 23' and W. long. 93° 57', or 10° 57' W., from Washington city. The depth of water at its mouth is not more than four feet on the bar in ordinary tides. This river about 12 miles from its mouth expands into a wide shallow lake, 10 or 12 miles wide and 25 long, with a bearing N.E. and S.W. At the extremity of this lake, it receives both the Sabine and Netches. A line of sea-shell banks is formed along the shore of the lake between the two rivers, and on the point on the left shore of the Sabine, an increased mount of these shells is found, covered with dwarf trees. About 15 or 20 miles above the lake, wood presents itself in larger bodies, and the wood rives by a flow gradation; and as we advance the woods enclose the river on both banks, the stream becoming contracted to the width of 150 yards, and continuing with little variation as high as the Alabama villages, where it shrinks to 70 or 80 yards in breadth, and it prefers this breadth to N. lat. 32°. The source of the Sabine has not yet been precisely ascertained; nor have any settlements of civilized people, a single family excepted, been yet made on the Sabine. The western branch of the Sabine is called Netches; which see.

S. ALC LACTIC Acid, in Chemistry. This acid has been recently analyzed both by Gay Lussac and Thenard, and
by Berzelius. According to these chemists, it is composed of

Which coincide nearly with 5 atoms hydrogen + 6 atoms carbon + 8 atoms oxygen; according to which, the weight of its atom will be 131.25.

SACO, in Geography, a town of Maine, in the county of York, having 2492 inhabitants.

SADDLE RIVER. Add—Alto, a township, containing 2174 inhabitants.

SADSURY. Add—Alto, a township of Lancaster county, in Pennsylvania, having 843 inhabitants.—Alto, a township in Crawford county, in the same state, having 540 inhabitants.

SAHLITE. See Sahlite, and Mineralogy, Addenda.

SAL SEDATIVUS, &c. add—after Sedative SALT, under Salts.

SALEM, l. 9, add.—This county contains nine townships, and 12,761 inhabitants, including 29 lakes in 1810; l. 24 r. 12,693; l. 52, for two r. three; l. 54, and a third in Mercer county, having 470 inhabitants.

SALEM, New, a town of Hampshire county, in Massachusetts, containing 2107 inhabitants.

SALFDORD. Add—the upper contains 838, and the lower 558 inhabitants.

SALINE, a township of Gallia county, in Ohio, having 262 inhabitants.

SALINES. Add—This town appears from the entrance into Salines bay covered with that white fog, so much dreaded, and so well known in Italy by the name of mal-aria. Whenever this phenomenon occurs, the heat upon the island is excessive. Salines, and the towns situated on the E. and N.E. coasts of the island, are subject to such dangerous temperature, that in the months of June and July, persons fall victims to the afflicting malady called by the French Coup de soleil (a sun-flower), if they venture out at noon without an umbrella. The great heat experienced upon the eastern coasts of Cyprus is owing to two causes: to the situation of the island with respect to the Syrian, Arabian, and Lybian deserts; and to its mountainous nature, preventing the cooler winds, the well and north-well, from the low shores to the east and north-east.

See Cyprus.

SALISBURY, a township of Gallia county, in Ohio, containing 460 inhabitants.

SALIVA. Chemical Composition of. According to the experiments of Berzelius, 1000 parts of human saliva consist of

The peculiar animal matter is soluble in water, insoluble in alcohol, and is precipitated by bicarbonate of lead. Hence it appears to be a species of mucus. What Berzelius has termed mucus, Dr. Botfield and Dr. Thomson appear to consider as coagulated albumen.

SALMO Alpinus. Dr. Shaw suggests, that this is the girt char of Pennant, and the next species or Salvelinus is his red char. Taimen, I. penult. r. 3.5 feet. Kund- scha, l. 3, r. 2 or 3. Lavenetus, add—See Gwinad. Dr. Shaw supposed that the gwinad of Pennant is the S. Wartmanni; r. Leucithys. Edentulus, or tooth-lefs, silver-olive, salmon, with compressed yellow head, lanceolate red fins, and forked tail: a native of Surinam, where it is highly esteemed as food; r. Astomus.

SALT, col. 3 l. 31, r. fishery for fishery. Col. 4 l. 7, r. fishery for fishery.

SALT, Laws relating to, col. 7 l. 20, add—Mr. Parkes informs us, that he has made inquiry of one of the most considerable salt-importers, who informs him, that they pay only 5s. 6d. city-duty on the cargo, whether it be five tons or forty tons of the salt imported.

SALTS, Superintendence of Potash, l. 8, infert—See Tar- trate.

SALTS, in Chemistry. It may be proper to observe here, that a large proportion of the numbers representing the weights of the atoms of bodies given under our article Salts in the Cyclopaedia require correction; for which purpose we refer our readers to the tables appended to Atomic Theory, and to the different articles in the Addenda, where they will find the most recent determinations.

SALT CREEK, in Geography, a township of Muskingum county, in Ohio, containing 389 inhabitants.—Alto, a township of Pickaway county, in Ohio, containing 810 inhabitants.

SALT-LICK TOWN, l. 1, add—in the county of Pennsyl- vania, having 994 inhabitants.

SAM, col. 2 l. 24 from bottom, for fiction r. friction.

SAMBORNTOWN, l. 2, r. Stratford.

SANDERSFIELD, a town of Berkshire county, in Massachusetts, containing 1648 inhabitants.

SANDHURST, near Baghot, in Hampshire. The royal military college, part of which is now established at Sandhurst, consists of a junior and junior department. The junior department was established at High Wycombe, in the year 1799, (but has recently been removed to Farnham, in Surrey) for the purpose of instructing officers in the scientific parts of their profession, with a view of enabling them better to discharge their duty when acting in the command of their regiments, and at the same time qualify them for being employed in the quarter-master and adjutant-general’s department.

No officer can be admitted into this department until he has completed the twenty-first year of his age, and actually served with his regiment as a commissioned officer for three years abroad, or four years at home. Applications for admission must be made to the governor through the colonel or commanding officer of the regiment to which the individual belongs. Every candidate, previous to admission, must undergo such examination as may be deemed requisite.

The students pay into the funds of the college such sum annually as is determined by the supreme board of commissioners. The present subscription is thirty guineas per annum. They are subject to the rules and discipline of the army, as if serving with their regiments.

The studies pursued at this department are as follows:—Mathematics in all its branches; fortification; gunnery; castlemetation; military drawing and surveying; the recom-
SANDSTONE, l. to, r. to be visible. In other sandstones, the grains, &c.

SANDY CREEK. Add—Alto, a township of Mercer county, in Pennsylvania, containing 327 inhabitants.

SANDY LAKE, a township of Mercer county, in Pennsylvania, having 403 inhabitants.

SANGUISORBA. Addafter Dr. Prout, in his "Chemical Essays," (vol. v. p. 12.) informs us, on the authority of a tanner, that there is more of the tanning principle in the plant called burnet than in oak-bark. His informant suggested, that it might be cultivated for cattle, which (he says) are fond of it, and ploughed up every three years in order to collect together the root for the purpose of tanning.

SANSANDING. Add—Sansanding is called Badoo, and in Park's last million to Africa is represented as a small town, consisting of 300 huts; another Badoo, N. of this, is called Sansanding. Sansanding is said to contain 11,000 inhabitants; it has no public buildings, except the mosques, two of which, though built of mud, are not inelegant. The market-place is a large square, strewed with articles of merchandise, and crowded with people. Some of the stalls contain nothing but beads; others, indigo in balls; others, wood-ashes in balls; others, Hussa and Jimmie cloth. Here are also, amulets, Phal, copper and silver rings and bracelets, amber, filks from Morocco, tobacco and salt, yellow leather, &c. &c. Park's Last Million to Africa, p. 216.

SAP, Chemical Composition of. Add—Dr. Prout has examined the sap of the common vine. He found its f.p. gr. did not differ from that of common water. It did not affect litmus paper, and contained fo little of solid matter, that 200 parts of it evaporated to dryness left only one part of residuum, of which about half was carbonate of lime, and the rest a peculiar vegetable matter insoluble in alcohol, with traces of an alkali.

SAPHIES, an African term which denotes certain charms or amulets, which the negroes constantly wear about them. These saphies are prayers, or rather sentences from the Koran, which the Mahometan priests write on scraps of paper, and fold to the simple natives, who regard them as perfecting very extraordinary virtues. Some of the negroes wear them to guard themselves against the bite of snakes or alligators; and in this case, the saphie is commonly inclosed in a snake's or alligator's skin, and tied round the ankle. Others have recourse to them in time of war, to protect their persons against hostile weapons; but the common use to which these amulets are applied is to prevent or cure bodily diseases; to preserve from hunger and thirst, and generally to conciliate the favour of superior powers under all the circumstances and occurrences of life.

Similar charms or amulets are common in all parts of Africa, under the different denominations of domini, grigi, fetiches, &c. &c.

SAPPHIRE. See Mineralogy, Addenda.

SARASWATI, l. 1, 2. 34 from bottom, for creature r. creative. Col. 3, l. 8, for Jayatri r. Gayatri. Col. 5, l. 11 from bottom, for painted r. pointed.

SARKFOOT. Add—In 1811 the parish of Graneley contained 533 houfe, and 1749 perpons; viz. 797 males, and 952 females.

SAROS, l. 4, add—Beroeus used this period, and also Nero and Sosoph (which fæe), in chronological calculations, and fixing the epochs of his history of Babylon. Ancient authors, however, are not agreed as to the number of years contained

...
SAVANNAH, *penurious* sort—the slaves in the county being 7557, and in the town 2195.

SAUCON, Lower and Upper, two townships of Northumberland county, in Pennsylvania, the former containing 1074, and the latter 1456 inhabitants.

SAVING-BANKS, or Banks for Savings, are institutions which, under this appellation, are of recent origin, and which have been established for the purpose of ameliorating the condition of the lower classes of mankind. Many schemes, of various denominations, have been proposed with a view partly, or wholly, to this object. One of the most ancient of this kind is the institution of male *Friendly Societies*, which was established about a century ago, and which, to a certain extent, counteracted the prejudice of poor-rates, and the growth of those baneeful habits of dependence which poor-rates are adapted to produce. (See *Friendly Societies*.) These societies, though they partake of the nature of insurances on life and property, by promising certain advantages in the event of certain calamities or contingencies, are, however, preferable to common insurance offices, inasmuch as the members infuse each other, and retain all the profits in their own hands for the general advantage. In these societies, there is also a beneficent principle that influences those who form them, and induces them to feel and express a solicitude for each other's welfare. Neverthelefs, the benefits derived from them by individual members are often distant, and in their nature uncertain; so that those who have regularly contributed to them for forty or fifty years have not received a sufficing from their funds. In the year 1772, baron Maferes published "A Proposal for establishing Life Annuities in Parishes, with a View to the Benefit of the Indigent Poor;" and this was accompanied with the fuggellions of some alterations by the Rev. Dr. Price. The ingenious baron recommended to the nation, to obtain a law for enabling the parish-officers in England to grant, upon purchase, to the labouring inhabitants life-annuities, payable out of the parish-rates. The plan was approved by persons of the most distinguished character at that period, and a bill was brought into the house of commons by Mr. Dowdwell, under the auspices of Mr. Burke, Mr. George Savile, Lord John Cavendish, Mr. Dunning, Mr. Thomas Townshend, and others, for carrying it into effect. The bill was passed, but it miscarried in the house of lords at the second reading. However defirable and excellent this plan might appear in theory, it was not likely to prove effectual; because, for the purchase of the proposed annuities, a sum of money, of great amount to the purchaser, was demanded at once; and it was out of his power to procure it. A scheme somewhat resembling that of a saving-bank was published in 1797 by Mr. Bentham, in Young's "Annals of Agriculture." One part of his plan comprehended an institution which he denominated "A Frugality-Bank." Into this bank he proposed to receive the deposits of the poor, not for the mere purpose of yielding an interest, and being withdrawn when wanted, but to form or purchase an annuity for old age, when the ability for earning would be destroyed or impaired. He suggested, however, that this superannuation annuity should, either wholly or in part, be converted into any other species of benefit adapted to the exigencies of the owner. E. gr. It might be changed into an annuity for an exiling wife, in the event of widowhood, or into an annuity during the nonage of a certain number of children; or it might serve as a pledge for money borrowed; or part of it might be sold for raising a marriage-fund; or it might be simply withdrawn. As no attempt was made for the accomplishment of Mr. Bentham's plan of a frugality-bank, it remained without effect. It is needless to mention, or to detail, the various particulars of a plan submitted to the public by Mr. Bone in the years 1805 and 1806; as it comprehends a great number of objects which lay beyond the attainment of the poor.

It was still a matter of regret that, notwithstanding various schemes that had been suggested, no plan had been devised for securing to the labouring classes a place of safe deposit for the fruits of their industry, so as to encourage them to save, in the years of active exertion, a portion of their gains as they might be able to spare from their present necessities, so that they might have a resource in the season of misfortune, or in the decline of life; and more especially to afford them the advantage of receiving regular interest for their small savings, on a scale advancing to a certain extent, in proportion to the amount and continuance of their deposits. Of the first establishment of an institution that may properly be called a saving-bank, we have an account in N° 84, of "The Reports of the Society for bettering the Condition of the Poor." From this report it appears, that a female benefit-club was established on the 22d of October, 1798, at Tottenham, near London, under the patronage of a number of ladies. This institution comprehended within its general design and plan two other objects, viz. a fund for loans to prevent the use of pawnbrokers' shops, and a "bank for the earnings of poor children." "Children of either sex," says Mrs. Priscilla Wakefield, an ingenious and benevolent lady, whose pen was employed in the instruction of the public, and whose heart was actuated by a generous concern for benefitting those by whom she was surrounded, "or of whatever age, whether belonging to a member or not, are permitted to bring any sum above a penny to the monthly meeting of the Kewraders, to be laid up in the funds of the society; where their small earnings may accumulate in security, until wanted for an apprentice-fee, clothing, or going to service, or some other important purpose." It is added, "although the children receive no addition to the pittance they deposit in the fund, yet it answers several purposes; it stimulates them to earn and to save that which would probably be idly spent, as of too small importance for care; it often encourages their parents to lay by a little store for them, which they would not have thought of doing, had they not been invited by this opportunity of placing it in safety. It habituates the children to industry, frugality, and foresight; and by introducing them to notice, it teaches them the value of character, and of the esteem of those who, by the benefactions of Providence, are placed above them; and in many instances, it may supply a resource when it is essentially requisite. The success has already exceeded expectation; above sixty children bring their little treasure monthly." The success of this children's bank gave rise to a more extensive plan in the same place in 1834, called "The Charitable or Benefit Bank." This was begun for the express purpose of providing a safe and profitable place of deposit for the savings of labourers,
labourers, servants, &c., and opened once a month for
receipts and payments. The books were at first kept
by a lady; six wealthy individuals were appointed to
act as trustees, each of whom agreed to receive an
equal part of the sums deposited, and each to be respon-
sible to the amount of 100/ for the repayment of the
principal with interest. Any sum above 10 was to be
received, and, to encourage perseverance, interest at
the rate of five per cent. was to be allowed for every 20s. which
should remain a year with the trustees. For every addi-
tional 100, it was agreed that a new trustee should be
chosen; and thus the loss to the trustees in fulfilling their
engagement, with the fluctuation of interest, could not be
considerable. The benefits of the institution were to be
confined exclusively to the labouring classes; but the re-fi-
dence of the depositors was not restricted. One great
advantage attending this plan is, that it holds out to the
lower classes fixed advantages, and prefers their private
property from that fluctuation of value to which the public
funds are liable. This was the first distinct "Bank for
Savings," publicly let on foot for the benefit of the lower
classes; it was founded by Mrs. Wakefield, and remained
for some time under her inspection and management.
Mrs. Wakefield was succeeded in the labour of conducting
it by Mrs. Powell, who has appointed a treasurer, to whom,
the says, I account after every monthly meet-
ing, that I may not be responsible myself for the money
lodged in my hands; and I have the purchases made in the
funds placed in the names of two trustees." This excel-
 lent female adds, that the benefits resulting from this in-
itiation are incalculable, as it has enabled many to save sums
which have made them comfortable for life, who would
otherwise have spent the money at an ale-house, or lent it to
their friends. "I keep," says Mrs. Powell, "the whole
of the accounts myself; and carry on the business on so
 easy and simple a plan, that I have nothing to relate. I
merely receive and pay principal and interest the first
Monday in every month, for an hour and a half. I have
no assistance whatever, except that I lend any money I have
to the treasurer, and now and then compare my cash-book
with my own. The only care I have is to keep the re-
spective accounts correct. I have a ledger, a cash-book,
an interest account, and a walle-book. — I call a meeting of
the trustees once a year to audit my accounts, and those of
the treasurer, which are the counterpart of mine." In
July 1817, an act was passed for the protection and encour-
gement of banks for savings in England; and the several
provisions and arrangements of this useful act are minutely
detailed in the last edition of Mr. Roche's excellent "Tract
on Saving Banks." Societies similar to those of the banks
for savings have become of late years very numerous both
in England and Scotland; and in England and Wales many of
them have opened accounts with the bank of England
under the late act of parliament.

Although some few institutions of the same and others of
a similar kind had been established soon after the commence-
ment of the present century, yet their increase was slow and
inconsiderable until the year 1810; when the Rev. Mr.
Henry Duncan, availing himself of one of the provisions of
Mr. Bone's plan already mentioned, published an account of
it, and proposed that the gentlemen of Dumfriesshire should
establish banks for savings in the different parishes of the
county. Whist his zeal was applauded, his recommenda-
tion was disregarded. However he steadfastly persevered, and
determined to make the experiment in his own parish; and
denominated his new establishment "The Parish Bank
Friendly Society of Ruthwell." He so far succeeded,
Your committee have the satisfaction of seeing the institutions for the secure and profitable deposit of the earnings of the industrious, which was heretofore projected, are now by the spontaneous exertions of individuals, in actual and successful operation; and from the growth of the system of saving-banks, they are inclined to expect very beneficial results, not only in affording to the industrious poor a secure depot for their savings, but in familiarizing them with a practice, of which the advantage will be daily more apparent. Both the above cited reports are justly entitled from the testimony of individuals, which is annexed to them.

We shall here subjoin an extract from the third report of the "Edinburgh Society for the Suppression of Beggars," 1815. "To improve permanently, and effectually to better the condition of the poor, can be accomplished only by encouraging among them habits of industry, sobriety, prudence, and forethought. The very general adoption of the plan of instituting savings banks shows, that the genuine and enlightened principles of benevolence are beginning to be well understood, and will be zealously acted upon whenever a proper opportunity occurs; for no scheme seems better calculated for the comfort of the poor than this simple plan for enabling the poor man to lay up in the day of health for the hour of sickness. It relieves from want without checking industry; it secures independence without inducing pride; it removes those painful misgivings which render the apprehensions of poverty so appalling, and often paralyze the exertions which might ward off the blow; it leads to temperance and the restraint of all the disorderly passions, which a wanton expenditure of money nourishes; it produces that sobriety of mind, and steadiness of conduct, which afford the best foundation for the domestic virtues in humble life. The effects of such an institution as this upon the character of the people, were it to become universal, would be almost inappreciable. But it would be endless to cite authorities for establishing a principle so universally acknowledged by all whose observation and experience render them competent judges. We are therefore the more surprised to find it alluded to in the part of the Supplement to the Encyclopaedia Britannica recently published, that "taken by themselves, it is at least a doubt whether savings banks may not produce as great a quantity of evil as good." See Annals of Banks for Savings. London. Richardson, &c. 1818.

SAUSSURITE. See Mineralogy, Addenda.

SAYBROOK. Add—In 1810 it contained 3994 inhabitants, including 5 sexes.

SCALE of Chemical Equivalents. The description of this ingenious and useful instrument, contrived by Dr. Wolflon, has been omitted in its proper place; but its importance demands that it should be introduced here.

The author states, that he does not offer this instrument as an attempt to correct the tables that have been formed by others, but as "a method by which their results may be advantageously applied, in forming an easy approximation to any object of our inquiries."

"The means (to use Dr. W.'s own words) by which this is effected, may be part underlaid by inspection of the plate, (Chemistry, Plate XXI., figs. 5, 6.), in which will be seen the list of substances intended to be estimated, arranged on one or other side of a scale of numbers in the order of their relative weights, and at such distances from each other, according to their weights, that the series of numbers placed on a sliding scale can at pleasure be moved, so that any number expressing the weight of a compound may be brought to correspond with the place of that compound in the adjacent column. The arrangement is then such, that the weight of any ingredient in its composition, of any re-agent to be employed, or precipitate that might be obtained in its analysis, will be found opposite to the point at which its respective name is placed."

In order to shew more clearly the use of this scale, the plate exhibits two different situations of the slider, in one of which oxygen is 10, and other bodies are in their due proportion to it; so that carbonic acid being 27.54, and lime 35.46, carbonate of lime is placed at 63. In the second figure, the slider is represented drawn upwards, till 160 corresponds to muriate of soda, and accordingly the scale then shews how much of each substance contained in the table is equivalent to 100 of common salt. It shews with regard to the different views of the analysis of this salt, that it contains 46.6 dry muriatic acid and 53.4 of soda, or 39.8 soda and 13.6 oxygen: or if viewed as chloride of sodium, that it contains 60.2 chlorine and 39.8 sodium. With respect to re-agents it may be seen, that 283 nitrate of lead containing 191 of litharge employed to leparate the muriatic acid, would yield a precipitate of 237 muriate of lead, and that there would then remain in solution nearly 146 nitrate of soda. It may at the same time be seen, that the acid in this quantity of salt would ferve to make 232 corrosive sublimate, containing 815.5 red oxide of mercury, or would make 91.5 muriate of ammonia, composed of 62 muriatic gas, (or hydro-muriatic acid,) and 29.5 ammonia. The scale also shews, that for the purpose of obtaining the whole of the acid in distillation, the quantity of oil of vitriol required is nearly 84, and that the rediaum of this distillation would be 122 dry sulphate of soda, from which might be obtained by crystallization 277 of Glauber's salt, containing 155 water of crystallization. These and many more such inferences appear at once by bare inspection, as soon as the weight of any substance intended for examination is made by motion of the slider, correctly to correspond with its place in the adjacent column.

"With respect to the method of laying down the divisions of this scale, those who are accustomed to the use of other sliding rules, and are practically acquainted with their properties, will recognize upon the slider itself the common Gunter's line of numbers (as it is termed), and will be satisfied that the results which it gives are the same that would be obtained by arithmetical computation." See Gunter's Scale.

This scale may be had at the different mathematical instrument-makers; and we need fearlessly add, that the numbers laid down upon it differ a little from those recently determined by Dr. Thomson. These differences, however, are in general very trifling; but should any one prefer using the new numbers, they will find them stated in the tables appended to Atomic Theory.

SCAPOLITE. See Mineralogy, Addenda.

SCILLER-SPAR. See Mineralogy, Addenda.

SCHOOLS, Military, the principal institutions of this kind in our country, where officers may be formed for the profession by acquiring sound knowledge both in theory and practice, are the Royal Academy of Woolwich, the institution at Sandhurst near Windon, and the academy at Portsmouth.

SCHUYLKILL. Add—Alto, a township of Berks county, containing 353 inhabitants.

SCIOTO. Add—Alto, a township of Pickaway county, having 216 inhabitants.—Alto, a township of Ross county, having 840 inhabitants.
SCOTLAND, col. 22, l. 29, for extent r. extinct.
SCOT'S, l. 2, infert—those of the town included.

SEDATIVUM Sal. Add after SALT—under the article SALTS.
SEEING, col. 3, l. 5, add—Dr. Wells, in his "Essay on fingle Vision with two Eyes," has reduced the principal opinions upon this subject into two classes. The first class comprehends those of Galen, Alhazen, Rohault, Dr. Briggs, and Dr. Isaac Newton; all of whom have regarded the question as equivalent to the following one: Why should the mind be affected with only one perception from two impressions upon the external organs of sight, since either of those impressions is of itself sufficient to produce a similar perception? To this question they reply, that the two impressions are united before they are communicated to the mind, and they only differ concerning the manner in which such an union takes place. Against the opinions now stated by Dr. Wells objects, that they must be considered as mere conjectures, founded upon certain supposed changes in the brain and nerves, the exclusion of which, from the nature of the parts, it is impossible either to demonstrate or to refute by experiments; and that no one of them, though admitted to be true, is yet sufficient to explain the phenomenon on account of which it was framed. To the second class, Dr. Wells refers the opinions of those who maintain, that an object is seen fingle by both eyes, because it is seen by each of them in the same external place; and who profess to point out some law, or constant rule of vision, from which this sameness of place is to be derived as a necessary consequence. This view of the question, as our author imagines, was first suggested by Agulionius, and it has been since adopted by Dechales, Dr. Porterfield, Dr. Smith of Cambridge, and Dr. Reid of Glasgow.
Agulionius, who has been followed in the same train of reasoning by Dechales and Dr. Porterfield, begins with defining the terms horopter and plane of the horopter. If a line be drawn through the point of the mutual interection of the optic axes, parallel to the interval between the eyes, this from its office is denominated the horopter; and a plane, supposed to pass through this line perpendicular to the plane of the optic axes, is called by Agulionius the plane of the horopter. According to his statement, it is a law of our constitution, that all bodies which we see with one glance or look, whatever are their real places, appear to each eye to be situated in this plane; and upon this supposition he shows why some should be seen single with two eyes, and others double. For according to a recent opinion, which he has advanced, and which other writers on vision have not contradicted, the two lines of direction in which an object is seen with both eyes, can meet each other only in one point, and therefore all bodies which are really situated in the plane of the horopter, must necessarily appear single, as the lines of direction in which any one of them is perceived by the two eyes, coincide in that plane, and no where else; and all bodies which are not situated in the plane of the horopter must necessarily appear double, since, in this case, the lines of their visible directions intersect each other, either before or after they pass through it. To this reasoning Dr. Wells replies, that if the visible places of all bodies were contained in the plane of the horopter, they would appear of magnitudes proportional to the angles which they subtended at the eye; e. g. a finger held near to the face would seem as large as the part of a remote building which it might conceal from the sight. But this is contrary to experience, and therefore no reasoning that depends upon it can be admitted.
If it be asked, says Dr. Smith, why, in seeing with both eyes, we do not always see double, because of a double refraction, it is sufficient to reply, that in the ordinary use of our eyes, in which the pictures of an object are constantly painted upon "corresponding places or points" of the retinas, the predominant sense of feeling has originally and constantly informed us that the object is single. What he means by "corresponding points," he thus explains: When the optic axes are parallel, or meet in a point, the two middle points of the retinas, or any points which are equally distant from them, and lie on the fame sides of them, either towards the right hand or left hand, or upwards or downwards, or in any oblique direction, are called "corresponding points." Accordingly our idea of the outwards place of an object is connected with both these refects; as is manifest by its appearing in two places when its pictures are not painted upon corresponding places of the retinas, which is only a direct consequence arising from our general habit of seeing. If it be asked why, in order to produce single vision, all men agree in directing their eyes toward the object in such a manner as to receive its pictures upon corresponding points of the retinas, hence all those who have connected the refects of any other two points with the information of its unity from seeing? To this objection, urged by Dr. Reid, the reply may be made in Dr. Smith's own words (vol. 1. p. 46.): "When we view an object obliquely, we have acquired a habit of directing the optic axes to the point in view; because its pictures falling upon the middle points of the retinas, are then distinct from if they fell upon any other places; and since the pictures of the whole object are equal to one another, and are both inverted with respect to the optic axes, it follows that the pictures of any collateral point are painted upon corresponding points of the retinas."
Dr. Wells is of opinion, that Dr. Smith's hypothesis for the solution of this celebrated question is liable to other objections
objections not so easily repelled. Admitting the fact respecting corresponding points to be true, it may be observed, that if we are taught by feeling to see objects single, notwithstanding a sensation in each eye, the information of the former sense ought to be uniform, or else one set of visual appearances would be associated with different reports from feeling, and no certain mark would be afforded us which of them we should trust. Feeling, as Dr. Smith allows, is not always the predominant, but sometimes the inferior sense; and its informations are not confiant and original, but variable and derived. When a difference occurs between the informations of the two senses, it is natural to enquire what rule have we for determining which is most worthy of credit. But supposing that the sense of touch to have originally and confidently informed us that objects are single, it would not follow that we are hence taught to see them also single. For, since the place where an object seems to either eye to poffefs, manifestly depends both upon its apparent distance and its apparent direction from that eye, if visible place be, in the language of Dr. Smith, only an idea of real or tangible place, visible direction must bear the fame relation to tangible direction; whence it follows, that we can never have a more accurate knowledge of the direction, in which an object may lie from any part of our bodies, by touch than by touch. Whereas the contrary is proved by facts. Moreover whatever be the direction in which an object may appear to either eye, it cannot be seen in the place by both, except at some point common to the two directions. Accordingly Dr. Smith says, that when an object is perceived single with both eyes, it is seen at the mutual interection of the two visual rays; the visible direction of any object coinciding, according to him, with the visual ray, or the principal ray of the pencil which flows from it to the eye. Should we then even allow, that all we know by sight of the places of bodies has been borrowed from feeling, it will still be easy to shew, that the rule of vision for each eye, which he has derived from such experience, that of our seeing objects in the directions of their visual rays, is inconsistent with much of the phenomena of sight with two eyes; and, consequently, that he has left unremoved the chief difficulty of his subject, which was to explain the single appearance of objects to both eyes, from those laws, or rules of vision, which affect each of them singly. For it is a well-known fact, that if two bodies of the same shape, size, and colour, be placed, one in each optic axis, they appear but as one body, provided they be at equal distances from the eyes. Agreeably to the theory of our seeing objects in the direction of their visual rays, this cannot happen, except the united body appear at the interection of the optic axes. Dr. Smith, accordingly, maintains that it does. In the first place, Dr. Wells appeals to experiments for a direct proof that it does not; and, in the second, he observes, that, as the two bodies in the optic axes appear as one, whether they be situated within or beyond the concurrence of those lines, and as a right line joining the bodies, and extended both ways, appears at the same time to the light as a right line, it follows, upon admitting the fact which he has denied, that all objects in the plane of the optic axes which are seen in one position and state of the eyes, however near to us, or however remote they may in reality be, must appear to be equally distant, or rather in a line drawn through the concourse of the optic axes, parallel to the interval between the eyes, and named by opticians the horopter. Again, if a right line be made to pass through any part of the plane of the optic axes, at right angles to it, the portions above and below this plane are perceived to be in the same right line with the point which is situated in it, and the whole appears perpendicular to the plane. But the point in the plane is seen, by the last article or proposition, in the horopter; the whole, therefore, of the perpendicular line must be seen in a plane passing through the horopter at right angles to that of the optic axes; or, in other words, in the plane of the horopter, in which consequently all bodies will have their visible places. But this was the very opinion of Aguiolius, to which he was probably led by a similar train of reasoning; though, as a teacher, he might choose rather to ground it immediately upon a original law of our constitution.

Dr. Reid agrees with Dr. Smith in his general principle, but differs from him in maintaining the property to be original by which any two places in the retinas exhibit only one object, while Dr. Smith derives it altogether from custom. They differ also with respect to the meaning of a term; Dr. Smith calling corresponding points, such as have the position just mentioned, whether they represent objects single or not; whereas Dr. Reid says, that those points correspond, whatever their position may be, which represent objects single; and he appears to Dr. Wells not always to attend to the double use of the same term, when he speaks of the opinions of Dr. Smith.

Could it be flown, says Dr. Wells, that the places of the two retinas, which represent an object single when each receives its picture, are not the centres, or such others as are similarly situated, an obvious inference would be, that the single appearance of the object is not occasioned by a property in those places, bestowed upon them for this special purpose by nature; it being reasonable to expect, that such a property should be found, if anywhere, in those parts of the retina which are the most like to each other.

Anatomists have commonly taught, that the centres of the spheres, to which the cornea, the ball of the eye, and the two portions of the crystalline belong, are all placed in the same right line, hence called the optic axis, and that this being produced both ways, passes through the centres of the cornea and retina, considered as surfaces. Opticians, on their part, observe, that an object appears single to both eyes, when the axes of each is accurately directed to it; from which they infer, that the centres of the retinas agree in suggesting but one object, though each receives its picture. — Again; since it is known by experience, that, while any object is seen single, to which the optic axes are turned, others at the same distance from the eyes likewise appear so; and since the pictures of these lateral objects fall upon points in the two retinas, equidistant from their centres, and both upon the same side, that is, both to the right or left of the centres, or both above or below them, opticians conclude, that every two places of the retinas, which are similarly situated with respect to the centres, must also agree in exhibiting but one object, though pictures are received by both.

But the whole of this reasoning, says Dr. Wells, is built upon a circumstance in the fabric of the eye, which has been flown by some of the most eminent anatomists not to have place. For Varolius long ago observed, that the crystalline is not situated in the middle of the eye, but more inwardly; and the accurate Zinn has more lately mentioned, that if the eye be divided into a right and left half, the centre of the crystalline will be found in the inner portion. Haller confirms this fact; and Winflow's observation, that the centres of the pupil and iris do not coincide, but that the former is nearer to the nose than the latter, is connected with it; since both Zinn and Haller agree, that
the centre of the pupil is placed in the axis of the crystalline, while that of the iris is evidently in the common axis of the cornea and globe. Now, a consequence of this position of the crystalline is, that, contrary to what is universally maintained, no ray of light whatever can pass unobstructed to the retina from the atmosphere, or any other medium differing in refractive power from the aqueous humour.

If, then, the line joining the centres of the cornea and globe of the eye be what is called the optic axis, and if it be true, that objects appear single when we direct both these axes to them, it must be evident, to such as are acquainted with the common rules of optics, that the pictures of those objects do not fall upon the centres of the retinas, but more internally; and, therefore, that the centres and all the other points of those membranes, which by the present system are supposed to represent objects single, do in fact exhibit them double.

Admitting, however, that objects are represented single, when their pictures fall upon the centres of the retinas, or upon any other two points which are equally distant from the centres, and both upon the same side, it appears to Dr. Wells, notwithstanding, to be in violation of all analogy, to ascribe this effect, with respect to the points at least, on the right and left sides of the centres, to any peculiar property which they possess from nature. For when anatomists find, in a new species of animals, organs similar in structure to those of others they are already acquainted with, they immediately conclude, that they are also similar in regard to their use. In animals of the same species, they believe with certainty, that the organs they see in one have the same properties as the corresponding organs of another; and, if it be possible, they attribute with greater certainty the same properties to two organs of the like kind, which are found in the same individual. Such is the influence of the rule, that resemblance of property is implied by resemblance of structure. Now it is an universal fact, that if an animal be divided into a right and left half, the corresponding parts of those organs which exist in pairs are found at equal distances from the plane of partition. Thus, for instance, in respect to the eyes, the optic nerves penetrate their outward coat at the same distance from this plane. Their muscles, blood-vessels, and every other of their component parts and appendages, are arranged in the like manner; those nearest to the dividing plane, or the innermost, in the one, being similar in structure to the innermost in the other, the outermost to the outermost, and the intermediate to the intermediate. It is surely, therefore, natural to expect, that such parts should also be similar in their properties; and we in fact find this similarity to exist, wherever it can be clearly ascertained what the properties are. Every person, for example, admits, that the internal straight muscle of the right eye performs the same office, with respect to that eye, as the other internal straight muscle does with respect to the left eye. What judgment are we then to form of the opinion of Dr. Reid, which attributes the same original properties, or rather the joint possession of one original property, to places in the retinas situated at unequal distances from the general plane of partition; which makes an external point in one to correspond, in use, with an internal point in the other, and this too by a principle implanted by nature? If such things exist, they may, at least, be said to stand opposed to a most extensive analogy.

To these arguments, à priori, against the opinion of Dr. Reid, Dr. Wells adds others derived from a consideration of its consequences: but our limits oblige us to refer for these to the author's own account. If objects, it may be said, appear single neither from custom, nor from an original property of the eyes, have we not an effect without a cause, and must there not be something wrong in the facts or reasoning which lead to such a conclusion? Dr. Wells replies: Since visible place contains in it both visible distance and visible direction, it is not necessary that the single appearance of an object to both eyes, should depend altogether either upon custom, or an original principle of our constitution; for its visible distance to each eye may be learned from feeling, and its visible direction be given by nature; in which case, the unity of its place to the two eyes, will be owing to neither of those causes singly, but to a combination of both; and this Dr. Wells regards as a sufficient reply.

Dr. Wells proceeds to propose and illustrate his own theory for the solution of the question, why objects are seen single with two eyes; or, in other words, why they appear in the same place to both? The visible place of an object being composed, as he conceives, of its visible distance and visible direction, it becomes necessary, for fluowing how it may appear the same to both eyes, to explain in what manner the distance and direction, which are perceived by one eye, may coincide with those which are perceived by the other. He begins with a consideration of the distance. In judging of distance by sight, no person has ever observed, that while an object seemed to one of his eyes at a certain distance, it has appeared to the other to be at a different distance, and from this circumstance alone has been seen double; or, to express the same thing in another way, that while the visible appearance of an object to one eye, covered the visible appearance of the same object to the other eye, the two appearances did not seem entirely to coincide, and make one, but were seen separate by the two eyes. Hence it follows, that the difficulty in finding a true and sufficient cause: for the union of the two visible places of one or two objects to two eyes, must therefore conflict altogether in fluowing, in what manner the two apparent directions may coincide, consistently with the attending phenomena.

From the time of Kepler's discovery of the fact and manner of vision, there have been, says our author, only two theories offered respecting the apparent directions of objects. One is, that they are perceived in the direction of lines passing from their pictures on the retina, through the centre of the eye; the other, that their apparent directions coincide with their visual rays. But both of these theories are inconsistent with the phenomena of single vision with two eyes. For according to neither of them can an object, placed at the concourse of the optic axes, be seen single, unless we have a most accurate knowledge of its distance; nor will either admit two objects to be seen as one, which are situated in the optic axes, whether on this side, or beyond where they meet, unless the united object be referred by sight to their very point of intersection; both of which conclusions are contradicted by experience. It is evident, therefore, that some other theory of visible direction is required, which shall not be liable to these objections.

Dr. Wells's theory is illustrated in the following propositions, which we can merely state without enlargement: 1. Objects situated in the optic axis do not appear to be in that line, but in the common axis; i.e. in a line drawn from the middle of the visual bafe, through the point of intersection of the optic axes, or parallel to them, if they be parallel to each other. 2. Objects, situated in the common axis, do not appear to be in that line, but in the axis of the eye, by which they are seen. 3. Objects, situated in any line drawn through the mutual intersection of the optic
optic axes to the visual bafe, do not appear to be in that 
line, but in another, drawn through the fame intefion, 
to a point in the visual bafe diftant half this bafe from the 
foimilar extremity of the former line, towards the left, if the 
objects be feen by the right eye, but towards the right, if 
feen by the left eye. In the aplication of the theory 
which Dr. Wells has endeavoured to embafli in the pre-
ceding propofitions, he obferves, that, if the fefion be 
concerning an object at the concourfe of the optic axes, it is 
feen fingle, becaufe its two foimilar appearances, in regard 
to fize, fame, and colour, are feen by both eyes in one and 
the fame direction, or, if you will, in two directions, which 
coincide with each other through the whole of their extent. 
It therefore matters not, whether the diftanfe be truly or 
fallly estimated; whether the object be thought to touch 
our eyes, or to be infinitely remote. And hence we have a 
reason, which no other theory of visible direction affords, 
why objects appeared fpingle to the young gentleman men-
tioned by Mr. Chefelden, immediately after he was 
beathing, and before he could have learned to judge of 
diftanfe by fight.

When two foimilar objects are placed in the optic axes, 
one in each, at equal fiftances from the eyes, they will 
appear in the fame place, and therefore one, for the fame 
reafon that a truly fingle object, in the concourfe of the 
optic axes, is fpingle here. Again, as the two visible 
directions coincide in every point, it is not necefsary that 
the united aparence fould be judged to be at any par-
ticular diftanfe; that it fould be referred, for infance, 
to the concourfe of the optic axes, where the two other 
theories of visible direction are obliged to place it, in oppo-
sition to the plainel obfervation.

Objects, any where in the horopter, will be fpingle, 
becaufe their apparent directions to the two eyes will then 
completely coincide. And for a contrary reafon, thofe 
placed in any other part of the plane of the optic axes will 
appear double. To make these things evident, let a line 
pafs through the point of interfeftion of the optic axes and 
any given object, to the visual bafe, which is to be produced, 
if necefsary; and let it be called the line of the object's real 
pofition. Take afterward, in the visual bafe, or its pro-
duction, two points, one on each fide of the line of the real 
pofition, and both distant from its termination there, half 
the visual bafe. Lines drawn from these points, through 
the point of interfeftion of the optic axes, must confequently 
contain the two visible poftitions of the object. But when 
this is fpitted in the horopter, the line of real poftion will 
coincide with the horopter, and will not therefore reach the 
visual bafe, unlefs at an infinite diftanfe from the eyes. For 
which reafon, the two lines, containing the visible poftitions 
of the object, muft fall upon the visual bafe at a like 
diftance, and muft confequently be regarded as coinciding 
with each other. When the object is not in the horopter, 
the two lines of visible diftanfe will be found, by the 
fame means, not to coincide.

SEGO, col. 2, l. 13; r. Manfong; l. 17, r. San-
fanding.

SELENIUM, in Chemistry, the name of an elementary 
substance recently discovered by Berzelius, and confe-
idered by him as a kind of semi-metal. This subfance was 
first miftaken for tellurium. It was obtained from a ful-
phuric acid manufactory at Gripsholm, where pyrites from 
the mines of Fahlun were employed, and which of courage 
contained the subfance in queftion. It also exists in the 
foame mines combined with copper. Selenium has the 
properties of a metal combined with thofe of sulphur to fo 
great a degree, that it is difficult to know under which 
head to clas it, and in short whether it might not be 
rather considered as a new species of sulphur. In its me-
tallic flate it has a brilliant metallic luftre externally, with a 
tinge of red. The fracture is vitreous, like that of sulphur, 
but with a very brilliant luftre of a grey colour. It be-
comes fo at a temperature of 212°, and at a higher tem-
perature it melts; and at a temperature about equal to that 
at which mercury boils it may be brittle. When in a 
galeous flate, it is yellow, like sulphur. When fublimed 
in a large vefsel, it is deposited in the form of flowers of 
a cinnebar colour, but not oxidized. During its cooling, it 
preferves for some time a certain degree of fluidity, fo that 
it may be moulded between the fingers, and drawn into 
threads, which are transparent, and of a red colour 
when held between the eye and the light; but by reflected 
light they exhibit a brilliant metallic luftre. It burns 
with an azure-blue flame when heated with a candle, and 
exhales a strong odour of horfe-radish.

Selenium combines with metals, and generally produces 
a reddifh flate. The alloys are commonly grey, with a 
metallic luftre. The feleiniuret of potaffium diffoles in 
water, without evoking any gas, and produces a red-
coloured solution, which has the tale of hydrofulphuret of 
potaff. When muriatic acid is poured upon this feleiniuret, 
a feleiniuretted hydrogen gas is difengaged, which is fofule 
in water, and precipitates all metallic folutions, even thofe 
of zinc and iron. This gas has the odour of fulphuretted 
hydrogen gas when it is diluted with air, but if it be 
breathed at length it produces a painful fenfation in the 
nofe, and a violent inflammation, ending in catarh, which 
continues for a considerable time.

Selenium combines with the alcalies both in the humid 
way and by fufion. These combinations are red. The 
feleinites of barytes and lime are also red, but they are 
infofile. It also diffoles in melted wax, and in the fat 
oils; the folutions are red, but have no hepatic odour. 
There exift alfo feleiniuretted hydrofeleniurets of the alcalies 
and of the earths.

Selenium diffoles in nitric acid by the affifance of heat; 
the folution evaporated and fublimed yields a mafs crys-
tallized in needles, which is a very strong acid. It has a 
pure acid flavour, and forms peculiar falths with the alcalies, 
earths, and metallic oxyds. The felenic acid is fofule in 
water and in alcohol: its combinations with potaff and 
ammonia are deliquefcent; the latter is decomposed by fire, 
water is given out, and the felenium is reduced. The 
feleinites of barytes and lime are fofule in water. The 
felenic acid mixed with muriatic acid is decomposed by 
zinc, and the felenium is precipitated in the form of a red 
powder; by fulphuretted hydrogen gas an orange-yellow 
precipitate is formed.

Such is a brief fummary of the properties of this curious 
subfance. From the final quantities in which it has 
hitherto been found, we believe no experiments have been 
made to atern the weight of its atom, &c.

SELKIRK, l. 23 from bottom, for 440 r. 439.

SELKIRKSHIRE. In 1811 this fhire contained 
1080 houfes, and 589 perfons; viz. 2750 males, and 
3139 females: 500 families being employed in agriculture, 
and 363 in trade, manufactures, and handicraft.

SENÉCA. Add.—Allo, a county of New York, con-
taining 16609 inhabitants, of whom 101 are flavés.—Allo, 
a town of Guernfey county, in Ohio, having 300 inhabitants.

SEPOT, a term used in India to denote a native folder.

SETRA-WOLLIES. See KAJAAGA.

SERICA. Add.—(See Thibet.) Hugh Murray, efq. 
in his "Ancient Geography of Eastern and Central Asia," 
4 N published
SERMON, col. 4, l. 38, for Buller r. Butler.

SERPENTARIUS, or Snake-eater, in Ornithology, a genus of birds allied both to Vultur and Falco, but most nearly to the former. The characters are, beak vulturine, tongue pointed, and legs very long. It includes one species, viz., the S. Africana, or ah-coloured snake-eater, with the hind-head crested, the tail uncused, and the middle tail-feathers lengthened. This is the V. Serpentarius or Secretary vulture of Latham, and the Falco Serpentarius of Gmelin's Linnaeus. The most accurate description is that of La Vaillant, who, in his African travels, had an opportunity of observing it in its native regions. We refer to the 7th volume of Shaw's Zoology. It is an inhabitant of dry open plains in the lower parts of Africa.

SERPENTES.—Ater, l. 1, r. is white with black bands.

SEVIER, l. 2, r. 4595, and 204.

SHAPLEIGH. Add—containing 2362 inhabitants.

SHARON. Add after Portland—containing 944 inhabitants.—After Litchfield, having 2506 inhabitants.—After Bolton, having 1800 inhabitants.—After Norwich, having 1363 inhabitants. Add.—Alfo, a town of Hillsborough county, New Hampshire, having 416 inhabitants.—Alfo, a township of Franklin county, in Ohio, having 450 inhabitants.

SHARP, Granville, col. 3, l. 33, for taken up on r. taken upon.

SHAT-UL-ARAB, l. 16, r. Bamihere and Mefene; l. 20, r. Hafar.

SHENANGO. Add.—Alfo, a township of Mercer county, having 634 inhabitants.—Alfo, a township of Beaver county, having 670 inhabitants.

SHEPELY. Add—The largest parish in this island is that of Minfier, which in 1811 contained 842 houses, besides 20 that were not finished, and 5318 persons; viz., 2596 males, and 2722 females; 87 families being employed in agriculture, and 1163 in trade, manufactures, or handicraft.

SHILLINGSTONE, or Shilling Okeford, a parish in the west division of Shalford, in the county of Dorset, which in 1811 contained 75 houses, and 335 inhabitants; 163 males, and 222 females. On the right of the village are two high hills, called Hood and Hawkledon, on which are the remains of an ancient Roman encampment.

SHOES, col. 3, l. 29 from bottom, for felt r. left.

1. S. robi. Sall-trec. Roxb. l. 212. Found on the flarks of the northern mountains of India. A majelic tree, whose timber is much valued, and now in value to the teak, (see Tectona,) being stronger, though far lefs durable. Leaves alternate, falked, ovate, entire, acute, smooth, from four to eight inches long. Panicles downy, axillary and terminal, of numerous, pale yellow, flarly flowers, not an inch wide. Capfule accompanied by five oblong, ribbed, unequal wings, formed of the calyx. This genus is nearly allied to Diptercarpus; see that article.

SHORT Creek, in Geography, a township of Jefferson county, in Ohio, having 1890 inhabitants.

SHORT-SIGHTEDNESS, l. 21, add.—For Mr. Ware's observations on this subject, see Spectacles.

SHREWSBURY, in America, l. 8, add—of whom 577 are slaves. At the end, add.—Alfo, a township of Lycoming county, containing 294 inhabitants.

SID, l. 3, add—but the statute for this purpose has been repealed.

SHUKUSU, r. or Shukanu.

SHUSTER, l. 24, for magnitude r. magnificence.

SIBH, a district of the Persian empire, in the province of Mekran, containing an extensive plain, governed by a chief, who resides in a small town of the same name. The country, almost destitute of water, though a river, nearly dry, flows through the centre of the plain, is, generally speaking, barren, if we except some groves of date-trees which gradually grew in the bed of the river.

SIDNEY, Sir Philip, in Biography, the eldest son of Sir Henry Sidney, by a daughter of the duke of Northumberland, was born at Penhurst in Kent, in the year 1554. He was named Philip in compliment to the king of Spain, the husband of queen Mary. In very early life he manifested a sedulous studious disposition; and he judiciously improved every advantage for gaining knowledge, which he enjoyed, first at Shrewsbury school, and afterwards at Oxford, where he was entered at Christ Church college in 1569, and also at Cambridge. At the age of 18, the queen, according to the then existing custom, granted him a licence to travel abroad; and he first visited Paris, where he was introduced, by his maternal uncle, the earl of Leicester, to sir Francis Walsingham, the English ambassador. Charles IX. who was then king of France, wishing to shew respect to Leicester, and probably with the pernicious design of lulling his security, the Protestant party in France; formerly to the horrid massacre of St. Bartholowmew's, appointed Sidney one of the gentlemen of his bed-chamber. When the fatal day arrived, Sidney, together with several of his countrymen, found a refuge in the house of the English ambassador. Soon afterwards he purposed his tour to Germany; and at Frankfort formed an intimate acquaintance and friendship with Hubert Languet, than refident for the elector of Saxony, whose communications were singularly useful to our young traveller. After visiting Vienna, Hungary, Venice, and Padua, in company with his friend Languet, he returned through Germany and Flanders, and arrived in England in 1575, with those accomplishments, and with his moral principles in untainted purity, which rendered him the admiration and delight of his countrymen. In the following year, being only in the 22d year of his age, he was dispatched as ambassador to the court of Vienna, to concile with and congratulate the new emperor Rodolph II.; and entered with a commission to engage the Protestant princes of Germany in a league with each other, or with England. He was also entrusted to demand the repayment of the sum advanced by Elizabeth to the elector palatine. In the discharge of these several trusts, he acquitted himself with singular reputation, and with satisfaction to all the parties concerned in the objects of his embassy. After his return, he received no other honorary recompenence besides the office of cup-bearer to the queen. With a temper somewhat irascible, and a high sense of honour, blended in some degree with the spirit of chivalry, few characters in that age were so unexceptionable as that of Sidney. Of his disinterested patriotism, we have a striking instance in his remonstrance addressed to queen Elizabeth on her projected marriage with the duke of Anjou; and such was the efficacy in which he was held by the queen, that she did not manifest her displeasure against Sidney, though others suffered.
SIDNEY.

After the spirit of chivalry, he exhibited his skill in military manoeuvres at a tournament held, in 1585, in honour of the queen; and in the same year, he offered his rank as a gentleman, against an infult offered him at a tennis-court by Vere, earl of Oxford. In order to compose his mind, which had been thus disquieted, he retired to the house of his brother-in-law, the earl of Pembroke, at Wilton, and engaged in the composition of his well-known romance, called "Arcadia," which was not published till after his death. In 1581 his name appears as one of the knights of the shire for the county of Kent, and as one of the committee for drawing up acts, with a view to the security of the kingdom against the Pope and his adherents. His "Defence of Poetry," written about this time, contributed more to his literary reputation than Arcadia. Of this treatise one of his biographers says, that it may be considered as the earliest piece of criticism in the English language worthy of attention, and reckoned by some the best written of his works. In a simple and unaffected style, it displays much learning and judgment, and a true relish of the excellencies of that art, which he undertakes to patronize and illustrate." In the year 1585, he married the only daughter and heiress of Sir Francis Walsingham, a lady, as it is said, of great beauty and merit. On occasion of being nominated by the prince palatine of the Rhine his proxy at the installation of the garter in 1584, he received from the queen the honour of knighthood; an honour which she was not lavish in conferring. When Sir Francis Drake was projecting a secret naval expedition, Sir Philip Sidney wished to join him, and with this view to equip a land and naval armament against the Spanish settlements in America; but the queen interposed, and absolutely prohibited the execution of his design. Of his nomination as a candidate for the vacant crown of Poland, upon the death of Stephen Bathori in 1583, we shall say nothing; as one of his biographers has related several particulars, which render the fact very improbable. In the year just mentioned, Sir Philip had a seat in the privy council; and Queen Elizabeth determined to affix the Low Countries in their revolt, on condition of their putting into her hands some cautionary towns, indulged his martial disposition by appointing him governor of Flushing. As soon as he had taken possession of his charge, he was made colonel of all the Dutch regiments, and captain of a band of Englike soldiers. He was soon joined by his uncle Leicester, as general of the auxiliary forces, and Sir Philip was appointed general of the horfe, under his command. It soon appeared that Leicester was unfit for the trust reposed in him; his nephew was dissatisfied, and endeavoured to allay the discontents which prevailed among the subordinate commanders. Sir Philip in his first exploit, which was the surprize and capture of Axell, in July 1586, without the loss of a man, was singularly successful; but in the month of September he fell in with a convoy sent by the enemy to Zutphen, and having one horfe shot under him, he mounted another; and while charging the foe with great vigour, he received a musket bullet above the knee, which broke the bone and penetrated deep into the thigh. On his way from the field to Leicester’s camp, whither he was conveyed, he found himself faint and thirsty, and called for water; but as he was preparing to drink, he observed a fodor in the agonies of a mortal wound; he regained the draught to him, with an expression which entails permanent honour on his memory: ‘This man’s necessity is still greater than mine!’ Upon his arrival at Arnhem a mortification ensued, and on the 17th of October, after exhibiting the most unaffected piety, exemplary comporture, and self-possession, he expired with tranquillity at the early age of 32 years. His death was universally regretted by his enemies as well as friends, and abroad as well as at home. The queen directed his body to be brought to London, and after lying in state, he was interred with all the solemnity of a public funeral in St. Paul’s cathedral; and although no monument was erected over his remains, James, king of Scotland, composed an epitaph to celebrate his memory, and both universities furnished some collections of verses to record his fame. But his name will ever live in the records of history, as one of those who have reflected the highest honour on his country.” Of his “Arcadia,” we shall merely observe, that it was one of the earliest specimens of grave or heroic romance; that it was left in scattered fragments of MS., which his father collected and published; and from this circumstance, it was denominated “The Countess of Pembroke’s Arcadia.” It became very popular, and was translated into foreign languages. Lord Orford (Horace Walpole) speaks of it very contemptuously; but Dr. Zouch has more candidly and more justly appreciated its value. Biog. Brit. Zouch’s Mem. of Sir Philip Sidney. Gen. Biog.

SIDNEY, or SYDNEY, ALGERNOS, the second son of Robert, earl of Leicester, by Dorothy, eldest daughter of Henry Piercy, earl of Northumberland, was born in 1621 or 1622, and carefully educated under his father’s inspection. In early life he was desirous to the military profession, and in 1641 he had a commission in his father’s own regiment of horse, when he was appointed lord-lieutenant of Ireland. During the rebellion in that kingdom entered immediately into active service, and had many opportunities of exhibiting his courage. In 1643, upon the commencement of the war in England between the king and parliament, he obtained permission to return. He and his brother, upon their landing, were intercepted, and placed under guard: and the king, conceiving (justly, as the event proved) that they had been taken by their own contrivance, was much offended; and not without reason, for they both joined the parliamentary army. In 1644, the earl of Manchester appointed Algernon to the command of a troop of horse in his own regiment; and in the following year, Fairfax promoted him to the colonelcy of a regiment of horse. Having been present in several actions, he was entrusted with the government of Chichester. In 1646 he accompanied his brother to Ireland, and was advanced to the post of lieutenant-general of the cavalry and governor of Dublin. For his services in that kingdom he received the thanks of parliament, and returning to his own country was made governor of Dover. Although he was nominated in 1648 a member of the high court of justice for the trial of the king, he was neither present when sentence was pronounced, nor did he sign the warrant for his execution. This part of his conduct, it is supposed, was owing to the particular request of his father; for it appears, from his general conduct, that his principles would not induce him to condemn this act. When he was afterwards a voluntary exile in Denmark, and charged by his father with the violence of his political sentiments, his father writes to this purpose: “It is said that the university of Copenhagen brought their album to you, defying you to write something therein, and that you did ferebire in albo these words:

“Manus hsec, inimica tyrannis, Enfe petit placidam sub libertate quietem,”

and put your name to it; also, that a minister, being there in company with you, said, ‘I think you were none of the late king’s judges, nor guilty of his death.’ ‘Guilty!’ said you; ‘do you call that guilt? Why, it was the juftest and bravest action that ever was done in England, or any
where else?” Confidently with the sentiments avowed on this occasion, Sidney actually opposed the designs of Cromwell; and he afterwards refused to act under him and under his successor Richard. During this period he passed a retired life at Penshurst, and employed himself, as it is said, in writing his Difcourses on Government. But when the Long Parliament regained its power, Sidney having been engaged in the establishment of a republic, to which form of government he was ardently attached, became an active partisan, and was nominated one of the council of state. He also accepted the office of one of the commissioners for mediating a peace between Denmark and Sweden, and was actually engaged in this embassy at the period of Charles II.’s restoration. Although he was solicited by general Monk and others to return to England, he could repose no confidence in the royal party, but remained in exile for fourteen years, finding that the few supplies which he received from home were insufficient to support him in a manner suitable to his birth and rank. He was, however, treated with respect and civility in various places, and particularly at Rome; and he employed his many leisure hours in making addition to the ample stock of knowledge which he had already acquired. In 1677 his father, being advanced in life, was anxious to see him, and employed his interest in obtaining the king’s permission for his return, to which permission was annexed a pardon for all his past offences. When he afterwards joined in cabals against the court, he incurred the cenfure of those who were dispoled to take offence; and Mr. Hume has charged him with acting counter to the moral principles of gratitude and with a breach of faith: others, however, have vindicated him, alleging that unconscious of guilt he might consider the royal permission to return, after so long an absence, as a reparation of injustice rather than an act of clemency, and that personal obligation ought not to influence his public conduct, when he conceived the great interests of his country in danger. At the time of his return, parliament was urging the king to commence a war with France; but Charles, being a pensioner of the French court, wished from selfish motives to avoid it; but as he was actuated by no found principles, it was apprehended that he would appear to concur with the wishes of the nation, that he might have a plea for raising supplies, for his own personal gratification, in the prosecution of his pleasures or his designs to render himself arbitrary. The English patriots were averse from war, and some of their leaders intrigued with Barillon, the French ambassador, for preventing it. In the list of those persons in England who were at this time pensioners in France, the name of Sidney appears. When this discovery was made by Sir J. Dalrymple’s publication of Barillon’s papers, the friends of liberty were affrighted and grieved; and they hesitated in admitting this dishonourable charge. In vindication of Sidney some have suggested, that Barillon falsified his accounts of the money with which he had been entrusted; whilst others have satisfied themselves with that perfunctory of Sidney’s honour and integrity which was founded on his general conduct, and with the assurance that he always adopted and pursued those political measures which appeared to him, in all circumstances considered, most beneficial to his country. Upon his father’s death, he joined the opposition party without disgrace, and offered himself for a seat in parliament; but he was twice defeated by the influence of the court. Thus exasperated, and apprehending the liberty of his country to be in danger, as well as dreading a popish successor, the ardour of his mind urged him to associate with the duke of Monmouth and his party; and in the history of the Rye-house plot he was charged with being one of six who were promoting an insurrection. But the part which he was supposed to have taken in a conspiracy for affalinating the king was the plea for arresting him, together with Russell and several others, in June 1683. When lord Russell was sacrificed, the next victim selected by the court was Sidney; and he was brought to trial for high treason, before that judge whose infamous character is indelibly recorded in the page of history, chief-justice Jeffreys. Lord Howard, who was a disgrace to the title he bore and to that rank in society with which he was connected, was the only direct evidence against him; but the law required two witnesses for conviction on a charge of treason. In order to supply this defect, the attorney-general produced some passages from his papers, found in manuscript in his closet, in which the writer maintained the lawfulness of refting tyrants, and his preference of a free to an arbitrary government; and without decisive proof that they were written by him, or that they were even communicated to any living person, this kind of evidence was admitted, in defiance of law and common sense, as equivalent to the testimony of a second witness. His defence was of no avail, and a servile jury pronounced him guilty. From respect to his family, the disgraceful part of his sentence was omitted, and exchanged for beheading. On the 7th of December he was executed on Tower-hill, at the age of about fifty-one years, delivering to the heralds a paper which proved the injustice of his condemnation, and offering a prayer for that “old cause” in which he had been from his youth engaged. This paper was afterwards printed, and made great impression on the public mind. It is given at full length in the Memoirs of his Life. He suffered with the firmness, as it is said, of an old Roman. After the revolution one of the first acts was the revocation of his attainted, and his name has been held in high esteem and veneration by all the avowed friends of free government. The following sketch of his character is given by bishop Burnet. “He was a man of most extraordinary courage, steady even to obstinacy, sincere, but of a rough and boisterous temper that could not bear contradiction. He seemed to be a Chriftian, but in a particular form of his own; he thought he was to be like a divine philosopher in the mind, but he was against all public worship, and every thing that looked like a church. He was still to all republican principles, and an enemy to everything that looked like monarchy. He had fludied the history of government in all its branches beyond any man I ever knew, and had a particular way of intimating himself into people that would hearken to his notions, and not contradict him.” Of this character, it is said, in the Notes to the Memoirs of his Life, that it was roughly and inaccurately drawn. Sidney’s “Difcourses on Government” were first printed in 1698, fol. reprinted in 1704 and 1750, and in 4to. 1772 at the expense of Thomas Hollis, &c., with his letters, trial, and memoirs of his life prefixed. Lord Orreys says of them, “they are admirably written, and contain great historical knowledge, and a remarkable propriety of diction; so that his name, in my opinion, ought to be much higher eulogized in the temple of literature than I have hitherto found it placed.” Biog. Brit. Gen. Biog. Memoirs, &c. prefixed to Hollis’s edition.

SIFEEED ROOK. See Rood.

SILENI, I. 20, for faccho r. Jaccho; I. 33, for second r. sixth.

SILICA, SILICON, in Chemistry. From the recent experiments of Berzelius and Stromeyer, the basis of silicon does not appear to be a metal as formerly supposed, but a substance analogous to boron and carbon; hence it has been named
named silica. Little is known, however, of the nature of this substance, except that it is dark-coloured, and will bear a considerable heat without undergoing change, and that it decomposes water, and is converted into silica when brought in contact with that fluid. It is also capable of combining with iron, and probably other metals. Dr. Thomson estimates the weight of the atom of silica, from the experiments of Berzelius and Stromeyer above-mentioned, at 10, and of silica at 20. The same chemist also considers silica to be an acid, and proposes for it the name of silicic acid, in which case its compounds must be denominated silicates.

SILVER, in Chemistry. Dr. Thomson, from the most recent experiments on this metal and its salts, estimates the weight of its atom at 137.5, that of oxygen being 16. See Atomic Theory.

SILVER ORES. See Silver, and Mineralogy, Addenda.

SILURES, col. 2, l. 32, r. Wilk or Ulk.

SIMIA FattuEUS, l. 1, for talles r. long-tailed.

SITACA. Add—twelve geographical miles below Bagdad, and nearly opposite to the embouchure of the Dealla river.

VOL. XXXIII.

SITTINGBOURNE, a town and parish of Kent, 40 miles from London, in the road to Canterbury; contained, in 1811, 230 houses, and 1562 persons; 633 being males, and 729 females.

SKIDDAW, l. 15, after sea, add—which differs little from 3017 feet, the barometrical measurement of Mr. W. Allen, according to the method proposed by him. H. Englefield. (See Trans. of the Geol. Soc. vol. iv. part 2.)

SLATE-SPAR. See Mineralogy, Addenda.

SLAVE, col. 2, l. 40, for Almighty r. A mighty.

SLAVETRade, Abolition of the, col. 2, l. 12, for principled r. principled.

SLIDING-RULE. Add—Mr. Bevan has lately published in the Philosophical Magazine an ingenious modification of the sliding-rule. By the inversion of the slides all the usual operations are performed, together with the extraction of the square root, and factors of any given number are found by simple inspection. At the same time, the instrument is reduced to half its usual size.

SMITH, in Geography, l. 2, add—of whom 2201 are slaves.

SNORING. Add—See Larynx.

SNOW, col. 2, l. 3 from bottom, r. earth, and of bodies on its surface, is prevented from escaping by radiation to the heavens during still or dewy nights. The cause of this additional cold does not, indeed, constantly operate; but its presence, during only a few hours, might effectually destroy plants, which now pass unhurt through the winter. Moreover, while low vegetable productions are prevented, by a covering of snow, from becoming colder than the atmosphere in consequence of their own radiation, the parts of trees and tall shrubs, which rise above the snow, are little affected by cold from this cause: for their outermost twigs, now that they are dilute of leaves, are so small, that they will very seldom become more than 2° colder than the atmosphere. The larger branches too, which, if fully exposed to the sky, would become colder than the extreme parts, are, in a great degree, sheltered by them; and, in the last place, the trunks are sheltered both by the smaller and larger parts, not to mention that the trunks must derive heat, by conduction through the roots, from the earth kept warm by the snow. In a similar way is partly to be explained, the manner in which a layer of earth or thaw preserves vegetable matters in our own fields, from the injurious effects of cold in winter. It may be remarked, however, that a thick covering of snow, while it renders the surface of the earth warmer than it would otherwise be, must occasion the lower atmosphere to be colder, by preventing the passage of the heat of the ground to the air, either by radiation or conduction. Wells's Hist. p. 258. See Dew and Heat.

SNOWDON, l. 17, after sea, add—according to Mr. W. Allen's barometrical measurement, 3595 feet.

SOAP-STONE. See Mineralogy, Addenda.

SODA. See Sodium. Add—under NATRON, l. 5, r. Natron, from an erroneous apposition of its being the nature of nitre, has been by many. Col. 2, l. 35, dele vegetable alkali. Col. 4, l. 33, for a further account of barilla, see CARBONATE of Soda. Under the article Leathier, l. 17, for a species of salt-petre r. a CARBONATE of Soda; which see.

Soda, Sodium, in Chemistry. From the most recent and correct experiments, the weight of the atom of soda has been estimated by Dr. Thomson at 30, and consequently the weight of the atom of soda at 40, that of oxygen being 16.

SODAIC Powders, denote powders which are used as a substitute for soda-water. Professor Brande, in his course of chemical lectures at the Royal Institution, took occasion to observe, that though these powders produce an effervescence when dissolved, arising from the disengagement of carbonic acid, the solution is very different from soda-water, both in its constituent parts and its properties. These powders consist of an alkaline carbonate, either of potash or soda, and a concrete acid, reduced to powder. The acid, though cold as the citric, is in reality the tartaric acid, produced from the substance known as cream of tartar. When the powders are dissolved, the tartaric acid unites with the alkali, and the carbonic acid, or fixed air, immediately escapes, occasioning a momentary effervescence. A salt is formed in the solution, called by chemists the tartrate of potash, or soda: if the former alkali has been used, and the acid is in excess, the salt formed is nearly insoluble, and has a harsh taste, and an irritating effect on the stomach. Thus, a quantity of alkaline tartrate is taken into the fyltem, which rather tends to increase than remove obstructions, and in many infirmities must be highly injurious. Soda-water, if prepared in the best manner, should contain a very small portion of carbonate of soda, which has a tendency to correct acidity on the stomach; it should contain also about eight times its own bulk of carbonic acid gas, part of which is in a state of loose combination with the water. A considerable quantity of this gas, however, appears to be united by a stronger chemical affinity, and will remain in the water some hours after it is poured out. This gas, acting as a solvent of all the different earths, and various other substances, gives to the soda-water a more dilute and deodorant efficacy, than is possessed by common water; and to this cause we may ascribe the good effects of soda-water in removing bile and calculous concretions. The carbonic acid, in its concentrated form, as it exists in soda-water, is a more powerful solvent of metallic substances than is generally supposed. On which account the manufacture of soda-water, in vessels of copper, or other metals, ought carefully to be avoided, and too great caution cannot be observed by those who are in the habit of drinking
drinking soda-water, to have it free from any metallic impregnation, or improper admixture.

SODALITE. See Mineralogy, Addenda.

SOMERSET, I. 6, r. 14725.

SOON'TAARS, a wild and unlettered tribe of Hindoos, who inhabit the district of Ramgar, the latest civilized part of the Company's possessions, and who have reduced the detection and trial of persons suspected of witchcraft to a system. For an account of their practices, we refer to the fourth volume of the Asiatic Researches, p. 343. See Bekaars.

SORBIC Acid, in Chemistry. This acid was so named by Mr. Donovan in his discoverer, because obtained from the berries of the mountain ash (formerly denominated forbus aucuparia, but now aper aucuparia). The juice of the ripe berries is to be strained and mixed with a filtered solution of acetate of lead. The precipitate is then to be separated by a filter, and washed in cold water. A large quantity of boiling water is then to be poured upon the filter, and allowed to pass through the precipitate into jars. After some hours this liquid becomes opaque, and deposits crystals of great luster and beauty. These crystals are to be boiled for half an hour with 2½ times their weight of sulphuric acid, specific gravity 1.000, supplying water as fast as it evaporates, and taking care to keep the mixture constantly stirred. While still hot a stream of sulphured hydrogen is to be sent through the resulting liquid, which will precipitate the lead, and leave the forbie acid in solution in the water.

Sorbic acid thus obtained is a transparent colourless inodorous fluid, soluble in alcohol, and in any portion of water. It does not crystallize, nor is it volatile. Its taste is exceedingly acid, and it does not appear to undergo much change when kept. The forbyates of potash, soda, and ammonia, are crystallizable salts, containing an excess of acid. The forbie acid combines with lead in three proportions. The subforbyate is a hard mass or a gritty powder. The forbyate is a white powder, which by solution in forbie acid may be obtained crystallized in beautiful silvery crystals. The supersorbic has a sweet taste, and is soluble in water. The other forbyates are little known, and do not seem to be very interesting.

There appears to be a great resemblance between the forbie and malic acids. Indeed it has been asserted that they are identical. The malic acid having recently been obtained in a more pure state than formerly, has enabled chemists to investigate its properties more completely, and in this pure state it is said in no circumstance to differ from forbie acid.

SOOS, a Chaldian period of 60 years, which doubled gave the return of the lunar months to within the 20th part of a month. By multiplying this cycle as many times as are necessary to obtain the precise returns of the sun and moon to the same points of the heavens, astronomers found a period of 600 years, called the Nero; which fee.

SOUND, for Roberts r. Roberts.

SOUTHAMPTON, in Geography, a township of Cumberland county, in Pennsylvania, having 700 inhabitants.

SOUTH-END. In 1811, the parish of Prittlewell with Milton contained 285 houses, and 1541 persons; 759 being males, and 782 females.

SOUTHWARK, East, a township of Pennsylvania, in Philadelphia county, having 726 inhabitants.

SOUTHWARK Bridge, an elegant structure designed by Mr. Rennie, and forming a communication between the city of London and the borough of Southwark, in nearly a straight line between Guildhall and the Bank-side. It consists of three grand arches; the centre arch being 240 feet in span, and each of the side arches being 210 feet. The arches are composed of cast-iron, and the piers and abutments of stone. The elevation of the arches was 287,000l., and that of the piers, on the supposition that London Bridge should be rebuilt, was conjectured to amount annually to 50 or 60,000l. The first stone of this bridge was laid in 1815, and it was opened for passengers and carriages in February 1819.

SOWANS, a nutritious article of food prepared in Scotland from the husks of oats, by a process not unlike that by which common farl is made. The husk of the oat after having been separated by the sieve still retains a considerable portion of farinaceous matter. It is mixed with water, and allowed to remain till the water becomes sour. The whole is then thrown upon a sieve; the milky water paffes through loaded with farl matter, which soon malates. The four liquor is poured off, and an earthy equal quantity of fresh water added. This mixture when boiled forms a very nourishing article of food, and the portion of the four water which still adheres to the farl gives the whole a pleasant acidity.

SPANGLES, plaitettes, Fr. are small thin round leaves of metal, pierced in the middle, which are fewed on garments, &c., as ornaments. They are prepared by first twilling wire round a rod into the form of a fire and then cut into single spiral rings, like those used by pin-makers in forming heads to their pins; and these rings being placed upon a smooth anvil are flattened by a flat stroke of the hammer, so that a small hole remains in the middle, and the ends of the wire which lie over each other are closely united. The smaller spangles were first made in the French gold and silver manufactory, and imitated in Germany, for the first time, in the beginning of the 18th century. Beckmann's Hist. of Inventions, vol. ii.

SPARROW, in Agriculture. Add.—It has been suggested, however, that the millchief done by sparrows may be fully compensated by their usefulness in destroying caterpillars; a single pair has been found to consume 40,000 in one season, in feeding their young. We may here add, that in a district in which great pains had been taken to extirpate the moles every vegetable was for a considerable time destroyed by cockchaffers, which grubs had been thus preserved by the short-fighted policy of the farmers.

SPARTA, I. 13, for country r. city.

SPARTA, col. 2, 1. 3, containing 179 inhabitants.

SPAVIN. Add.—In healing the blood spavin, Mr. Denny recommends repeated blistering, and afterwards a compres of folded linen, moistened in the following lotion, and confined by a long bandage: Take 4 oz. of sal ammoniac, 2 oz. of acetated ceruse, 2 quarts of vinegar, and 4 of water, mix them. The usual method of treating the bone spavin is by blistering and firing.

SPECIUM, col. 15, l. 23 from bottom, for cord r. card.

SPEECH. See Larynx.

SPERMACETI, Chemical Properties of. See Cetio Acid.

SPERMADICTION, in Botany, from σπερμα, seed, and δίκτυος, a net, because of the reticulated tunic of the seeds.—Roxb. Coromand. v. 3. 32.—Clas and order, Pen- tendria Monogynia. Nat. Ord. Rubiaceae, Jaff.

1. S. fuscoleus,
STAPHYLMUS, 1. 5, add—The larvae are subter-
aceous, and much resemble the complete animals; 1. 15, add—Mr. Marsham, in his "Entomologia Britannica," enumerates no fewer than 87 British species.

STARCH, Chemical Composition of. Starch has been analyzed by three different experimentalists. The following were the results:

<table>

Berzelius employed potato starch. The other experiments were made with the starch of wheat. 

Kirchhoff, a Russian chemist, found, that by boiling starch with dilute sulphuric acid it is converted into sugar; and M. T. de Saussure has recently discovered, that this change takes place spontaneously when boiled starch is exposed for a considerable length of time to the action of the air.

STATISTICS, a term applied to the topography of a country, and comprehending its population, policy, manufactures, trade, and a variety of other circumstances.

STEARIN, in Chemistry. A name given by Chevreul to a substance exuding in animal tallow and fats. It may be separated by alcohol, or simply by pressure. Braconnot used the following method: The oil if fluid was congealed, and in this state was subjected to strong pressure between folds of blotting paper. The clair (see LAIRN) was imbibed by the paper while the stearin remained behind in a fold of fat.

Stearin thus obtained is white, brittle, and resembling, like wax in appearance. It crystallizes in small needles. It has little or no smell. It is tasteless, and produces no effect on vegetable juices. It melts, as obtained from different fats, between 189° and 192°; that from the fat of the duck being most readily melted, and that from human fat the least. It is soluble in water, and combines with the alkalies, forming soaps.

STUBEN, 1. 15, add—of whom, in 1810, 87 were slaves.

STIPPLING, 1. 7 and 9, r. pecks.

STIRLINGSHIRE. In 1811, this shire contained 8910 houses, besides 55 unmanned, and 58,174 persons (including 803 local militia); 27,745 being males (militia included), and 50,429 females: 3425 families being employed in agriculture, and 5912 in trade, manufactures, and handicraft.

STIRRUP. At the close, add—The Roman manners required that young men and expert riders should be able to vault on horseback without any assistance. (Virgil, Æneid, l. 12. 288.) In many public places, particularly highways, stones were erected, to which a rider could lead his horse, that he might mount with greater facility. Such stones Gracchus caused to be raised (Plutarch, de Vit. Gracchi); and they were to be found in many cities in the 16th century, especially near the council-house, for the convenience of the members of the council, who at that time did not ride in coaches. It was usual also to have portable foils, which were placed close to the horse when persons wished to mount: and this gave rise to the barbarous practice of making conquering generals and prisoners foop down, that the victor might more easily get on horseback, by flapping upon their backs as upon a foil. In this ignominious manner was the emperor Valerian treated by Sapor, king of Perse. Some horses were so taught, that they knelled until the rider mounted; and warriors had on their spear or lance a step or projection on which they could rest the foot until they got on horseback. (Strabo, lib. iii. Sil. Ital. lib. x.) See ÁNABATHRA and ÆNABOLEUS. The first certain account of stirrups, says Beckmann, (History of Inventions, vol. ii.) is in a book written by Mauritus, respecting the art of wars, about the end of the 6th century. Euflatius, the commentator on Homer, informs us, that in his time, i.e. the 12th century, stirrups had not become very common; but on a piece of tapestry, of the eleventh century, cauffed to be engraved by Montfacon, the saddles of all the horses appear to have stirrups. However, after they became common, it was thought to be an evidence of superior dexterity to ride without them.

STRONTIAN, STRONTIUM, in Chemistry, the name of an elementary substance or earth, the description of which has been omitted.

Strontian is always found in nature combined with the carbonate or sulphoric acids. (See STRONTIANITE and CELESTINE.) It may be obtained pure from those minerals precisely in the same manner as barytes and lime.

Strontian thus obtained is in porous masses of a greyish-white colour. Its tafte is acid and alkaline, and it converts vegetable juices to green. Its fp. gr. according to Halleufratz, is 1.647. It does not act strongly on animal bodies as barytes, nor is it poisonous.

Sir H. Davy, led by analogy, subjected it to galvanic influence, and thus succeeded in separating its oxygen and obtaining frontium, the metallic basis of strontian. This metal is white, much heavier than water, and bears a close resemblance to barium in its properties: when exposed to air or thrown into water, it rapidly absorbs oxygen, and is converted into frontium.

Dr. Thomson, from the recent experiments of Stromeyer...
and others, fixes the weight of the atom of frontian at 65; from which the composition of its salts may be readily estimated.

The salts of frontian require to be briefly noticed. They are in general more soluble than the salts of barytes, but less so than the salts of lime. Most of them are capable of being crystallized. They are precipitated by the sulphates, phosphates, and oxalates. Succinate of ammonia precipitates barytes, but not frontian. When a piece of paper is dipped into a solution of a salt of frontian, it burns with a red flame. The salts of frontian are not precipitated by the prussiate of potash, nor are they poifonous.

**Nitrates of Strontian.**—This salt crystallizes in six-sided pyramidal dodecahedrons with their apexes truncated, so as to have the appearance of hexagonal plates with bevelled edges. Sometimes in eight-sided prisms. It is perfectly transparent. It has a strong pungent cooling taste. Its fp. gr. is 3.260. It is soluble in its own weight of water at 60°, and in little more than half its weight of boiling water. It is insoluble in alcohol. It is not altered by exposure to air. It degrades on hot coals. When a crysal of nitrate of frontian is put into the wick of a candle, it communicates a beautiful purple flame.

**Muriate of Strontian.**—This salt crystallizes in long slender hexagonal prisms. Its taste is sharp and penetrating. Its fp. gr. is 1.4402. It is soluble in less than its weight of cold water, and in any quantity in boiling water. It is soluble in about twenty-four parts of cold alcohol. The crysals do not deliquesce on exposure to the air, except in very damp weather.

**Carbonate of Strontian.**—This, when precipitated, is a white powder without taste or smell, and soluble in about 1.536 parts of boiling water. Its fp. gr. is about 3.66, and it is not altered by exposure to the air.

**Sulphate of Strontian.**—This salt is tasteless, soluble in 3840 parts of boiling water; readily soluble in sulphuric acid when affixed by heat, and possesses other properties very analogous to the sulphate of barytes.

**Phosphite of Strontian.**—This salt is likewise tasteless, insoluble in water, and not altered by exposure to the air.

**Oxalate of Strontian.**—This is soluble in little more than twice its weight both of cold and hot water. It may be crystallized, and the crysals are not altered by exposure to the air. It renders vegetable colours green.

The other salts of frontian do not in general possess any remarkable properties. The oxalate, tartrate, succinate, and citrate of frontian, are all more or less soluble in water; the oxalate being the least soluble, and the citrate the most. The molate of frontian is more soluble in water than the malate of barytes.

STROUD, in Geography, a parish of Kent, part of which is included within the jurisdiction of the city of Rochester (see Rochester); and the other part, in 1811, contained 242 houses, and 1394 persons; 718 being males, and 676 females.

**Style, in Painting,** is the manner in which a painter conceives and executes the subjects he adopts; or, in other words, in which he combines the various qualities of a picture. Style is properly divisible into four distinct kinds, viz. the grand or sublime, the beautiful, the natural, and the mean. There are indeed several varieties of style which have obtained specific appellations; but they will be found upon examination to combine, in different ways, the qualities peculiar to those above-mentioned; and are justly regarded as vicious in their nature: such are the ornamental and the artificial styles of art, which divert the attention of painters from the more pure application and exercise of their art, and lead them to adopt fictitious means of attracting attention, by contrail and affectation, by glitter, and an idle display of skill in workmanship, to the neglect of nature and just expression, and sometimes even of common sense.

The object and aim of the grand style is to captivate the imagination. It is the only proper one for the representation of grand and elevated ideas; of subjects which reprezent the actions of deities, or of heroes, or which relate to the higher qualities of the mind of man: the only medium whereby the art of painting can embody such ideas as the cultivation of those qualities inspires, and by which alone it can at all pretend to rival the grandeur and effect of heroic poetry. Its characteristics are simplicity and fulness of form and colour; and it is obtained, by adopting only essential parts, avoiding those which are nothing to specific character, and fixing solely upon those general forms which particularly distinguish one race of beings, or one class of natural objects or of actions from another, giving them their greatest possible degree of elevation, even to the verge of extravagance, in modulation of line, and fulness of form. This selection of form and of action requires an appropriate chiaro-oscuro, arranged and combined in broad and simple masses, and painted with a serious tone of colour; in fact, such a combination of the prime qualities of the art, as will most effectually unite in the production of one unmingled emotion.

The grand style does not admit attempts at illusion, or too close an imitation of natural objects; which, when carried to excess, necessarily disturbs that singleness or simplicity of effect required where the object is to produce an elevated tone of thinking. It is not dependent upon size, but may be exhibited on a small scale as effectually as on a large one: witness many of the beautiful bronzes and gems of the ancients, and the effect, as described by Statius, of the statue of Hercules made by Lygippus, which "though not more than a foot in height, filled the imagination in a manner equal to the Hercules Farnese." Raphael's small picture of the vision of Ezekiel is also an effective influence of the truth of this assertion.

**Style, for that word alone is adopted as signification of the grand in art, can only be acquired by those who have made themselves well acquainted with the just proportions and varieties of nature. Its aim being to represent her works with the greatest degree of sublimity commixed with truth, all attempts to produce it without real knowledge must necessarily lead to error, and a species of bombast, instead of expression, yields only deformity. Of this, the works of Gottzius, of Spranger, and the Germans who followed them, are sufficient evidence. And yet such is the rarity of perfection in form among the human or the animal race of beings, that an artful whole aim is to produce grandeur of style must draw largely upon his imagination; and while he touches the verge of impossibility, will find that the difficulty he has to overcome is in uniting the principle on which he depends with propriety. Even Michael Angelo, great and glorious as he was among those who have made it their principal object, has not unfrequently allowed himself to be misled by the wish to aggrandize, and give his contours only redundancy for style; and for the sake of a flowing and varied line, has sometimes given forms of action to masses which ought to have been represented tranquil.

Of this style, as far as relates to form, the best among the sculptures of the ancients afford the fairest examples, particularly the torso of the Belvidere, the head of Jupiter, the Laocoon, the Apollo, the figures on Monte Cavallo, &c. &c.; and it is a striking feature in the works of Phidias.
STYLE.

dias, though with a chastened impulse, as may be seen in the Elgin marbles. Indeed it appears to have been so perfectly understood among the artists of ancient Greece, that it spread generally in a greater or less degree through all their productions, at least in those of sculpture; and from the few remains of painting left to us, it appears not improbable that the professors of that art were no less masters of its principles. In latter times, among the moderns, the Florentine school made it their principal object of attention; and in the works of Leonardo da Vinci, Fra. Bartolomeo, and more particularly of Michael Angelo, it reached in quality nearly to a level with the taste of those from whom it was adopted. Raphael attempted it in imitation of M. Angelo, and sometimes succeeded, but it evidently was not congenial to his feeling, which inclined to the beautiful and graceful, more than to the sublime; and hence it is that his pictures of the Godhead rarely impress us with sentiments of an exalted nature.

The beautiful style differs from the grand, in that it requires less force of contrast in form and action, and greater softness of colour and effect. Whatever is graceful and animated, void of superfluous parts, and yet essentially characteristic and pleasing in arrangement, combines to form the beautiful. Flowing lines, graceful contrasts, both in form and colour, softened lights and shades, and rich and harmonious colouring, are its principles: on them it depends, and every departure from them necessarily diminishes its quality. It is the fit medium for every subject whose character is adapted to afford pleasure.

As the grand style confits in an elevated view of nature, a conception of perfection almost super-human, built upon the possibilities of creative power, acting upon known and natural forms; so the beautiful also must be sought in the regions of imagination, guided by the knowledge of existing objects, and supported by felection from the varieties of nature. Therefore, in order to comprehend the character of beauty as applied to art, we must consider the perfection of that art, not as consisting in mere imitation of visible objects, but as requiring a separation and choice of parts, an ideal perfection, which, though it belongs to the works of nature in all classes of beings, yet is not to be found entire in any given object. Raphael, when he was painting his Galatea, said in a letter to his patron count Baldasfare Castiglione, "that not being able to find perfect beauty upon earth, he was obliged to have recourse to ideal excellence framed in his own mind." But Zeuxis took another method to produce the concurrence of perfections recognised in his Helen; viz. by felection and combining the various beauties of the most beauteous among the virgins of Agrigentum: thus surpassing the works of nature, with materials furnished by herself.

Beauty, it will be easily conceived, is not confined to one given line, or set of lines or colours, in uniform or in contact with each other. There is necessarily one general form of the male among men and animals, and one of the female; distinct in their character, and yet each having its appropriate degree of beauty: so there is also a distinction of form among different creatures of the same species. Apollo, Hercules, and a Gladiator, have each distinct qualities which must be maintained in their representatives, whilst grace and beauty are given to their forms and actions: and it would be as great an absurdity to soften each to the merely beautiful, and thus render them similar in form and character; as it is ignorance and gross to trust to that which is characteristic alone for a graceful and agreeable effect.

Though these, which we have specified, be the distinct separations between the grand and the beautiful styles in art, yet either may be rendered more perfect by the addition of the other; and when expression is superadded, then is exhibited the most perfect display of the power of art: and it is this union of the beautiful and characteristic with the grand, which connotes that mental and energetic application of the art of painting which elevates it above the mechanical arts, and entitles it to the highest pretensions, as it is addressed to the noblest faculties. This is that beau-ideal so much the theme of praise and exultation among the connoisseurs; so universally felt when exhibited, so little understood, and so often the foundation of the grossest follies and deceptions among both artists and amateurs. The former, pursuing the practice of it in theory, often become the dupes of their own imaginary fancies; the latter more often impose themselves upon the world as men of worth by the mere cant of its dictum, and are screened from discovery by the general want of information concerning the principles and proper objects of art.

In this happy combination of beauty and grandeur the Greeks still remain unrivalled, as far as relates to sculpture, and perhaps single figures in pictures, but we have very little ground for conjecture how far they were able to conduct the principle in extended compositions in painting. Among the moderns, perhaps Parmigianio in his latter and more perfect works, as his Moses and his Vision of St. Jerome, has effected more than any other painter this definable union: and most likely had he lived much longer the world would have seen the perfection of the art from his hands; more particularly if he had cultivated expression in the school of Raphael, as successfully as he had the other branches of the art in those of Correggio and M. Angelo. The name of Correggio, says Mr. Fuseli, 'is the synonyme of whatever is graceful and agreeable in painting;' to him we are principally indebted for chiaro-oscuro, and that luminous and harmonious tone of colour, which fascinates and delights the eye by its unity, blended with richnefs and variety. He may be regarded as the father of the beautiful in modern art, as M. Angelo is of the grand and sublime.

That kind of style which is termed natural is, as its name imports, a mere imitation of the common forms of nature, without that felection which we have pointed out as necessary to the higher styles of art. Of this we have many capital instances among the smaller antique bronzes of Fauns, Nymphs, &c. and in many of the works of Titian in his second manner. Most of the principal portrait painters have almost necessarily adopted it, though that branch of the art admits, when highly practised, of that felection of parts which constitutes the beautiful, and of being treated with dignity and even sublimity, as many of the works of Sir Joshua Reynolds, of Titian, and of Vandyke, sufficiently prove. In a lower degree, the Dutch and Flemifh masters have most successfully wrought in this style, as Jan. Steen, Oltade, Teniers, Rembrandt, Metz, Terburg, &c. and compensated for the want of higher qualities, by the perfection of their arrangements and execution, and the exactness of their imitations.

Of what is mean in style, it is hardly necessary to speak: examples of it may be found in all early effays; but in none more abundantly than among the works of the artifts of the German and Flemifh schools of the 16th century. Even in those of Albert Durer, mezzafins is a never-failing alloy; amidst all the brilliancy of imagination, and activity of mind, they display; deforming actions and expressions otherwise well worthy of eleeon, and extending through every part of the compositions, be it of figures, drapery, or background.

Of the four species of style above enumerated, all others are
and others, fixes the weight of the atom of frontian at 65; from which the composition of its salts may be readily
eliminated.

The salts of frontian require to be briefly noticed. They are in general more soluble than the salts of barytes, but less
so than the salts of line. Most of them are capable of being
crystallized. They are precipitated by the sulphates, phosphates,
and oxalates. Succinate of ammonia precipitates barytes, but not frontian. When a piece of paper is dipped into
a solution of a salt of frontian, it burns with a red flame.
The salts of frontian are not precipitated by the prussiate of
potash, nor are they poisonous.

*Nitrates of Frontian.—This salt crystallizes in six-sided
pyramidal dodecahedrons with their apexes truncated, to os
have the appearance of hexahedral plates with bevilled
edges. Sometimes in eight-sided prisms. It is perfectly
transparent. It has a strong pungent cooling taste. Its
f.p. gr. is 3.006. It is soluble in its own weight of water at
60°, and in little more than half its weight of boiling
water. It is insoluble in alcohol. It is not altered by ex-
oposure to air. It degrades on hot coals. When a crys-
tall of nitrate of frontian is put into the wick of a candle, it
communicates a beautiful purple flame.

*Murcuric Acid of Frontian.—This salt crystallizes in long slender
hexagonal prisms. Its taste is sharp and penetrating. Its
f.p. gr. is 1.4402. It is soluble in less than its weight of
cold water, and in any quantity in boiling water. It is
soluble in about twenty-four parts of cold alcohol. The
crystals do not deliquece on exposure to the air, except in
very damp weather.

Carbonate of Frontian.—This, when precipitated, is a
white powder without taste or smell, and soluble in about
10.56 parts of boiling water. Its f.p. gr. is about 3.66, and
it is not altered by exposure to the air.

Sulphate of Frontian.—This salt is tafteless, soluble in
38.40 parts of boiling water; readily soluble in sulphuric
acid when asifted by heat, and poses the other properties
very analogous to the sulphate of barytes.

Phosphates of Frontian.—This salt is likewise tafteless,
insoluble in water, and not altered by exposure to the
air.

*Acetate of Frontian.—This is soluble in little more than
twice its weight both of cold and hot water. It may be
crystallized, and the crystals are not altered by exposure to
the air. It renders vegetable colours green.

The other salts of frontian do not in general possess any
remarkable properties. The oxalate, tartrate, succinate, and
citrate of frontian, are all more or less soluble in water; the
oxalate being the least soluble, and the citrate the moft. The
malate of frontian is more soluble in water than the malate
of barytes.

STROUD, in Geography, a parish of Kent, part of which
is included within the jurisdiction of the city of Rochester
(see Rochester); and the other part, in 1811, contained
242 houses, and 1394 persons; 718 being males, and 676
females.

STYLE, in Painting, is the manner in which a painter
conceives and executes the subjects he adopts; or, in other
words, in which he combines the various qualities of a pic-
ture. Style is properly divisible into four distinct kinds,
viz. the grand or sublime, the beautiful, the natural, and
the mean. There are indeed several varieties of style which
have obtained specific appellations; but they will be found
upon examination to combine, in different ways, the quali-
ties peculiar to those above-mentioned; and are justly regarded
as vices in their nature: such are the ornamental and the
artificial styles of art, which divert the attention of painters
from the more pure application and exercise of their art, and
lead them to adopt fictitious means of attracting attention,
by contrast and affection, by glitter, and an idle display of
skill in workmanship, to the neglect of nature and just ex-
pression, and sometimes even of common sense.

The object and aim of the grand style is to captivate
the imagination. It is the only proper one for the representa-
tion of grand and elevated ideas: of subjects which rep-
resent the actions of deities, or of heroes, or which relate to
the higher qualities of the mind of man: the only just
medium whereby the art of painting can embody such ideas as
the cultivation of those qualities inspires, and by which alone
it can at all pretend to rival the grandeur and effect of heroic
poetry. Its characteristics are simplicity and fulness of
form and colour; and it is obtained, by adopting only
essential parts, avoiding those which have nothing to spe-
cific character, and fixing solely upon those general forms which
particularly distinguished one race of beings, or one class of
natural objects or of actions from another, giving them their
greatest possible degree of elevation, even to the verge of
extravagance, in undulation of line, and fulness of form.
This felection of form and of action requires an appropriate
chiaro-oscuro, arranged and combined in broad and simple
shapes, and painted with a serious tone of colour; in fact,
such a combination of the prime qualities of the art, as will
most effectually unite in the production of one unmingled
emotion.

The grand style does not admit attempts at illusion, or
too close an imitation of natural objects; which, when car-
ried to excess, necessarily disturbs that singleness or sim-
licity of effect required where the object is to produce an
elevated tone of thinking. It is not dependent upon fire,
but may be exhibited on a small scale as effectually as on
a large one; witness many of the beautiful bronzes and
gems of the ancients, and the effect, as described by Stat-
ius, of the statue of Hercules made by Levyppus, which
"though not more than a foot in height, filled the imagi-
nation in a manner equal to the Hercules Farnebo." Rap-
hard's small picture of the vision of Ezekiel is also an
effective instance of the truth of this assertion.

STYLE, for that word alone is adopted as signification of
the grand in art, can only be acquired by those who have
made themselves well acquainted with the just proportions
and varieties of nature. Its aim being to represent her
works with the greatest degree of sublimity commixed with
truth, all attempts to produce it without real know-
ledge must necessarily lead to error, and a species of bombast,
instead of expression, yields only deformity. Of this, the
works of Gottzius, of Spranger, and the Germans who
followed them, are sufficient evidence. And yet such is
the rarity of perfection in form among the human or the
animal race of beings, that an artifical whole aim is to pro-
duce grandeur of style must draw largely upon his imagi-
nation; and while he touches the verge of impossibility, will
find that the difficulty he has to overcome is in uniting the
principle on which he depends with propriety. Even Michael
Angelo, great and glorious as he was among those who
have made it their principal object, has not unfrequently
allowed himself to be misled by the wish to aggrandize,
and given his contours only redundancy for style; and for
the sake of a flowing and varied line, has sometimes given forms
of action to muscles which ought to have been represented
tranquil.

Of this style, as far as relates to form, the belt among
the sculptures of the ancients afford the fairest examples,
particularly the torso of the Belvidere, the head of Jupiter,
the Laocoon, the Apollo, the figures on Monte Cavallo,
&c. &c.; and it is a striking feature in the works of Phi-
dias,
dias, though with a chastened impulse, as may be seen in the Elgin marbles. Indeed it appears to have been so perfectly underfoot among the artists of ancient Greece, that it spread generally in a greater or less degree through all their productions, at least in those of sculpture; and from the few remains of painting left to us, it appears not improbable that the preceptors of that art were no less masters of its principles. In latter times, among the moderns, the Florentine school made it their principal object of attention; and in the works of Leonardo da Vinci, Fra. Bartolomeo, and more particularly of Michael Angelo, it reached in quality nearly to a level with the taste of those from whom it was adopted. Raphael attempted it in imitation of M. Angelo, and sometimes succeeded, but it evidently was not congenial to his feeling, which inclined to the beautiful and graceful, more than to the sublime; and hence it is that his pictures of the Godhead rarely impres us with sentiments of an exalted nature.

The beautiful style differs from the grand, in that it requires less force of contrast in form and action, and greater softness of colour and effect. Whatever is graceful and animated, void of superficial parts, and yet essentially characteristic and pleasing in arrangement, combines to form the beautiful. Flowing lines, graceful contrasts, both in form and colour, softened lights and shades, and rich and harmonious colouring, are its principles: on them it depends, and every departure from them necessarily diminishes its quality. It is the fit medium for every subject whose character is adapted to afford pleasure.

As the grand style consists in an elevated view of nature, a conception of perfection almost super-human, built upon the possibilities of creative power, acting upon known and natural forms; so the beautiful also must be sought in the regions of imagination, guided by the knowledge of existing objects, and supported by feeling from the varieties of nature. Therefore, in order to comprehend the character of beauty as applied to art, we must consider the perfection of that art, not as consisting in mere imitation of visible objects, but as requiring a separation and choice of parts, an ideal perfection, which, though it belongs to the works of nature in all classes of beings, yet is not to be found entire in any given object. Raphael, when he was painting his Galatea, said in a letter to his patron count Baldassare Catiligione, “that not being able to find perfect beauty upon earth, he was obliged to have recourse to ideal excellence framed in his own mind.” But Zeuxis took another method to produce the constellation of perfectness recognized in his Helen; viz. by selecting and combining the various beauties of the most beautiful among the virgins of Agrigentum: thus furnishing the works of nature, with materials furnished by herself.

Beauty, it will be easily conceived, is not confined to one given line, or set of lines or colours, in union or in contact with each other. There is necessarily one general form of the male among men and animals, and one of the female; distinct in their character, and yet each having its appropriate degree of beauty: so there is also a distinction of form among different creatures of the same species. Apollo, Hercules, and a Gladiator, have each distinct qualities which must be maintained in their representatives, whilst grace and beauty are given to their forms and actions: and it would be as great an absurdity to soften each to the merely beautiful, and thus render them similar in form and character; as it is ignorant and gross to trull to that which is characteristic alone for a graceful and agreeable effect.

Though these, which we have specified, be the distinct separations between the grand and the beautiful styles in art,
are necessarily composed; but there have been some few remarkable aberrations from the ordinary course of art, by painters of uncommon talent, which bid defiance to all classification, and stand alone in their respective spheres. Such are those of Rubens and Rembrandt, of Titian and Salvator Rosa, compounds of all that elevates and degrades; in which the grand and the mean, the beautiful, the natural, and the deformed, go hand in hand; the evil counterpoised by the good, and the whole rendered engaging, in spite of defects, by the skilful display of the master hand which wielded the materials. Such examples, great though they are, ought not to serve as excuses for inattention to settled principles. Who shall say, that if Rubens had been more correct in form, his works would have been less engaging; or, that if Titian had been more pure and true in expression, his productions would not have been more interesting. (See the article Picture.) Combinations which will justify such expectations have been formed, and we have seen them in our own great Sir Joshua’s productions, where fine form, rich and full-toned colour, and jull chiaro-fofeuro, have been blended in skilful and free execution.

Eff. Ch. Pouche nearly globular, beaked with the avolished style; valves hemispherical, prickly; cells single-fed.

Colyedons folded together.

SUFFOLK, col. 6, l. 13, add—In 1811 Suffolk contained 37,227 houses, besides 155 then unperfified, and 234,211 persons; viz. 111,988 males, and 122,223 females: 26,406 families being employed in agriculture, and 15,180 in trade, manufactures, or handicraft.

SUGAR-Loaf, in Geography, a township of Luzerne county, in Pennsylvania, having 282 inhabitants.

SULLIVAN, l. 26, inf.—including 43 slaves in 1810.

SULPHUR, in Chemistry. According to the most recent determinations, the weight of the atom of sulphur is 32, and of sulphuric acid 50; from which data the composition of the compounds of this substance can be accurately ascertained. See Atomic Theory.

SULPHUR Island, l. 8, add—The sulphur is collected by a few individuals resident on the island solely for that purpose; sent to the Great Loo-choo, and thence exported to Japan and China. N. lat. 27° 50'. E. long. 128° 11'. Ellis’s Journal of an Embassy to China. 1818.

SULPHURETTED CHLORIC Acid. See Cyanogen.

SULPHURIC Acid. It is stated in our article on this subject, that sulphuric acid cannot exist without water; and that the sulphuric acid prepared at Northaulen from green vitriol probably differs from common sulphuric acid by containing less water. The fact is, according to Dr. Thomson, that the latter, when most concentrated, contains no water whatsoever, and consequently a perfectly anhydrous sulphuric acid can exist.

SULPHURIZED MURIATIC Acid, in Chemistry. The fulblance described under this name in the Cyclopaedia is a chloride of sulphur. See Chlorine. See also the original article Sulphur.

SULTANABAD. For Tashisr r. Tushish.

SURABHI, col. 2, l. 44, for proscribe r. prescribe.

SURRY, in Virginia, l. 4, r. 6855.

SURYA, col. 5, l. 24, for drawn r. driven.

SUTURE, 1, 3 and 4, from bottom, r. thus—out number. As well as meritorious suffering for religion’s sake, suicide is in some cases legal, and even commendable.

SUTTON, a village and parish of Surry, in the second division of Wallington hundred, which in 1811 contained 121 houses, and 538 persons; viz. 310 males, and 328 females.

SWADHA, l. 5, for Galaka r. Golaka.

SWIMMING Bladders of Fish, Nature of the Air contained in. We may introduce here the curious experiments made by Biot on this subject. This gentleman and Mr. Laroche found in general a mixture of azote and oxygen, but no hydrogen or carbonic acid in the swimming bladders of fish; the air-bladders of those fishes living near the surface of the water containing little oxygen, and those of fish brought from a great depth the most. The following table exhibits the proportion of oxygen in 100 parts of the air in the different fish examined.

</table>

The depth at which the fish in the preceding table are caught increases gradually, as well as the proportion of oxygen, from the beginning to the end of the table. The trigla lyra is always caught at a very great depth. M. Laroche found, that fishes taken at a depth greater than 150 feet, furnished at a mean about .70 oxygen, while the mean result furnished by the fish caught at less depths was only .29. The fame law holds with respect to fresh-water fish. M. Biot’s experiments were made near the Balearic islands.

TELFAIR, in Geography, a county of Georgia, containing by the census of 1810, 744 persons, of whom 218 were slaves.

TELINGA, a name formerly called the Kalinga, and by the Europeans Gentoo, an Indian language occupying the space to the E. of the Mahatta, near Ciacaco, its northern, to within a few miles of Pulicat, its southerm boundary, with the intervention of a stripe of small dimension. This space was divided into the Andra and Kalinga countries; the former S., the latter N. of the river. At the period of the Mahometan conquest, the southerm part of these united provinces seems to have been known to that people by the name of Telingana, and Warrakul is the capital of the whole.

TELLURIUM, in Chemistry. Add—This metal has the property of combining with hydrogen, forming a gaseous compound, to which the name of telluriumed hydrogen gas has been given. This compound was discovered by Sir H. Davy, and its properties were afterwards investigated by Berzelius.

Telluriumed hydrogen may be formed by mixing together oxyd of tellurium, potash, and charcoal, and exposing the mixture to the action of a red heat. It is then put into a retort, diluted sulphuric acid is poured on it, and the head of the retort is plunged into a mercurial trough. A gas comes over, which may be collected in glass jars previously filled with mercury. This gas is transparent and colourless, and possessesthe mechanical properties of common air. It has a strong peculiar smell, something like sulphurised hydrogen. It burns with a blueish flame, and oxyd of tellurium is deposited. It is soluble in water, and gives that liquid a claret colour. Davy was not able to determine whether it reddens vegetable blues, but in other respects it is
T E H

poffesses the properties of an acid, combining with alkalies, and precipitating most metallic solutions like sulphuretted hydrogen. Chlorine gas immediately decomposes it. The other properties of this gas have not been satisfactorily examined. From the experiments of Ritter, there appears to be a solid compound of tellurium and hydrogen.

Tellurium seems also to have the property of combining with carbon.

TEMPATION, col. 2, l. 28, r. eminence.

TERRITORY, Missouri, col. 2, l. 5 add—It was first discovered by Sebastian Cabot in 1499, and in 1512 visited by John Pontio de Leon, a Spaniard, who endeavoured to form a settlement. In 1684 M. de la Sella, a Frenchman, discovered the mouth of the Mississippi, and built Fort Louis; but being assassinated, it was again abandoned. In the year 1698, captain Ibberville failed to the Mississippi, formed a settlement, and named the country Louisiana. About twenty-two years afterwards, M. de la Suire also failed up the Mississippi, and proceeded to the distance of 2280 miles from its mouth. In 1762 France ceded it to Spain; in 1800-1801 Spain ceded it back to France; and by a treaty of April 30th, 1803, the French government sold it to the United States for the sum of fifteen millions of dollars, payable in fifteen years at the rate of one million annually. TEWKESBURY, in Geography, a town of Huntingdon county, in New Jersey, containing 1308 persons, of whom 66 were slaves in 1846.

THEOPHILANTHROPISTS, a sect which sprung up, flourished, and became extinct in France during the period of the Revolution. It has been said, that the "temple of nature," opened in Margaret-Street, London, in 1776, by the late deceased David Williams, an active member, if not the founder of the society for the relief of decayed and indigent authors, for worship on Deistical principles, sung by the unbelievers of France, the idea of a ritual and liturgy of deism, which was first carried into execution in the year 1796. The resemblance of the principles of some members of the sect to those of Robespierre, and of its ceremonies to the worship of the goddes of Reason, has led some persons to represent the Theophilanthropists as partisans of the tyrant, and their meetings as Jacobinical clubs; but the abbe Gregoire (ubi infra) has laboured to vindicate them as a body from this charge. The first person who planned the celebration of the rites of natural religion appears to have been D'Aubermnil, a romantic enthusiast, who wished to revive a part of the doctrines of the ancient Magi. In his work intituled "Culte des Adorateurs," which is a rhetoric, a liturgy, and a treatise of morals, eight days are appointed for labour, and the ninth for rest; but the temples were to be constantly open, and the sacred fire kept burning in them with the most religious care. The priests, whose costume was prescribed, were to offer to the Deity grain and fruits of different kinds, salt and oil, and, turning to the four cardinal points, to pour libations and make apotheoses to the elements. The twelve signs of the zodiac were to be painted on the walls of the temple, (or asylum, as it was denominated,) and under each thirty butterflies, to represent the number and shortness of our days. Sacred dances were to be performed at different periods; the elderly men leading off with the matrons, the young men and the virgins following. At funerals a libation was to be poured out to the manes of the deceased, and the eldest of his relations was to throw water on the fire, addressing the element in a prepared formula. D'Aubermnil proposed to denominate his followers "Theoanthropophiles," which appellation was afterwards changed to "Theophilanthropes." As the churches had all become national property, the Theophilanthropists applied to the civil authorities for the use of them jointly with the Catholics; and their request was granted, on condition that each party should remove the emblems and decorations of its own worship, while that of the other was performed. We shall not detain our readers with describing their ritual, the dregs of their orators, or the circumstances attending their worship, and their marriage-festivals, nor shall we detail their moral leissons, or give specimens of their hymns and sacred poetry. This sect did not subsist for a long time; the zeal of its partisans began to decline in the provinces; and it appears, from the registers of a society at Bourges, that their first meeting was held in the cathedral, Feb. 29, 1798; and that on the 18th of Augst, 1800, their number being reduced to seven or eight, they dispersed, and the Theophilanthropic church of Bourges became extinct two years and a half after its first formation. In about five years, the whole sect had quietly disappeared; the last trace of it being that Chemin, who wrote a work defending their principles, made use of their manual as a school-book in a seminary at Paris, where he taught Latin. See Abbe Gregoire's Histoire des Sectes Religieuses, &c. 2 vols. 8vo. Paris.

THOMPSON'S Pond, and Shaker Settlement, in Geography, a township of America, in the district of Maine, and county of Cumberland, having 191 inhabitants.

THORINA, in Chemistry. The name of an earth recently discovered in Sweden by Berzelius.

This celebrated chemist first detected thorina in the Gadalinic of Koravec, and afterwards in the dehydrates of cerium, and the double fluoride of cerium and yttria, both minerals found at Falun.

Thorina may be obtained from the minerals containing protoxyd of cerium and yttria in the following manner. Precipitate the iron by means of the succinate of ammonia. Thorina when alone is precipitated by this salt, but this is not the case when it is mixed with the other bodies that exist in the fluorides of cerium and yttria. After the iron is removed, precipitate the cerium by means of sulphate of potash. Ammonia now precipitates the thorina mixed with yttria. Dissolve them in muriatic acid. Evaporate the solution to dryness, and pour boiling water on the residue, which will dissolve the greatest part of the yttria, but not the whole. Redissolve the residue in muriatic or nitric acid, and evaporate till it becomes as exactly neutral as possible. Then pour water upon it, and boil it for an instant, the thorina precipitates, and the solution contains a diffigerated acid. If we saturate this acid, and boil it a second time, an additional portion of thorina is precipitated.

Thorina when separated by the filter has the appearance of a gelatinous semi-transparent mass. When washed and dried it becomes white, absorbs carbonic acid, and diffuses with effervescence in acids. Though calcined it retains its white colour. After a violent heat it is difficultly soluble in muriatic acid. The solutions in this acid are yellowish, but become colourless when diluted.

The neutral solutions of thorina have a purely astringent taste, which is neither bitter, sweet, salin, nor metallic; a property in which it agrees with zirconia, and differs from all other earths.

Thorina is little soluble in the alkalies or alkaline earths. It
It has not yet been reduced to the metallic state. It is insubfible per se before the blow-pipe, but with borax it melts into a transparent glafs. It differs from alunina by its infusibility in hydrate of potash; from yttria by its purely aftragent tafke without sweetnefs; and by the property of its solutions polfles of being precipitated by boiling, when they do not contain too great an excefs of acid. It differs from zirconia by the following properties: 1. After being heated to redness, it is still capable of being divided in acids.

2. Sulphate of potash does not precipitate it from its folutions, while it precipitates zirconia from a solution containing even a confiderable excefs of acid. 3. It is precipitated by oxalate of feric acid whifh is too acid with zirconia.

Sulphate of thorina cryftrallizes readily, while sulphate of zirconia, fuppofing it free from alkali, forms when dried a gelatinous transparent mass, without any tendency to cryftrallization.

Thorina combines with the different acids. The sulphate of thorina is fubtle, and yields transparent crysfs, which are not altered by expofure to the air, and which have a flippy tafte.

The nitrate and muriate of thorina do not cryftrallize. The carbonate of thorina is very readily formed, the earth having a very great affinity for this acid. None of the other farts of thorina known appear to be capable of cryftrallization.

THORN, in Geography, a township of Fairfield, in Ohio, having 437 inhabitants.

THORNBURY, a township of Chester county, in Pennsylvania, having 200 inhabitants.

THORNTON, a town of Grafton county, in New Hampshire, containing 704 inhabitants.

THRIPS, col. 2, under VARIEGATA, l. 13, add.—The Thrips phyfapus has been fuppofed to do much injury to wheat, rye, &c. by causing the young flowers to decay, and thus preventing the growth of the embryo grain. Some, however, have diſputed this opinion, conterminating that the thrifs does not attack itself to fuch of the cerealia as are in a perfectly healthy state, but rather to fuch as are difeafed, by having the germina covered with the duft of a very minute fungus, often growing on wheat, &c. and belonging to the genus Acidum or Lycoperdon, and which appears in the form of a flatfh, smooth, irregular exudation of a yellow colour in various parts of the plant. (See on this Subjeft, vols. iii. iv. v. of the Transations of the Linnaean Society.) The ingenious Mr. Kirby, however, feems convinced, that the thrifs is in reality an infect highly injurious to corn, by deriving its nourifhment from the embryo grain. Shaw's Zool. vol. vi.

TIC DOLEUREUX, in Medicine, an extremely painfule difeafe of the nerves of the face, communely, if not ex- clusively, affecting fome branch of the fifth pair of nerves, and most frequently the infra-orbital branch, where it paffes through the foramen, so named in the check.

The complaint commences with flight and almofl imperceptible attacks of pain, and generally without any warning; though fome patients feel in the affected part peculiar and inexplicable fentiations preceding its approach, from which they announce with horror the coming enemy; the patient at the fame time enjoying a good or an indifferent fate of health. The pain, however, soon becomes moft acute, shooting and darting along the various ramifications of the affected nerves. It generally continues from a quarter to half a minute, and never exceeds the fpace of one minute. It returns at intervals more or lefs frequent; there being fometimes feveral paroxysms in a few minutes, and at other times there are intervals of from fifteen to thirty minutes, or longer. There is no determinate period; we always find the utmost irregularity even in the fame patient.

The pains vary in their degree of intensity, at one time exciting the moft piercing cries, and diftacted writhings and motions in the miserable patient; while at another, they are more bearable. When at the acme of their violence, the parts affected are often convuluted, and fometimes various contortions and grimaces are observable. Thife are to be distinguished from the convulsive twitchings of the muscles, with which the diseafed nerves communicate, and which are occafioned by irritation from the exceflive pain; while the contortions and grimaces are voluntary, being called by the patient's writhing and twifling from the agony of his torture, and may be prevented by a firm refolution to reft the impule of shrinking from the attack.

The pain does not always confine itself to the feat of the difeafe, but darts with the rapidity of lightning to the neighbouring parts, shooting in different directions like radii from a centre. It rarely gives warning of its approach, and often the first fign of an attack, is the patient's staring up in a flate little short of phrenzy. In this condition, fome patients beat the part with violence, or forcibly rub it with fome rough fubftance till excoriation takes place; and in fome instances, they have fucceeded in diminifhing the intensity of the pain.

The pains are more frequent during the day than in the night, probably from there being fewer caufes of irritation; and they are more frequent during converfation than in fience, and flill more fo, at the time of malinfinition, when the attacks often fuccefs each other with fuch rapidity as to appear like one continued paroxysm, with fearfully one interval of ceffation. The eye at times is red, inflamed, and watery, as we sometimes obferve in feveretooth-ach.

In other cafes, it is particularly dry, and in fome patients a copious flow of saliva succeeds a paroxysm. In general, only one fide of the face is affected with this dreadful malady. But as there are cafes recorded in which both fides suffered at the fame time, we cannot lay it down as a certain characterifte of the difeafe. Fouquet obferved at Montpellier two women who had both cheeks affected at the fame time; and Pujol knew a lady, who, for feveral months, had the pain in one cheek, which after a while was free from pain; but the other cheek was immediately attacked in the correffponding place, the pain continuing for two months, and then refuming its former position.

When the difeafe continues for a great length of time with increasing violence, the patient can neither obtain reft by night nor by day. His appetite fails; and, as may be expected, there is some degree of fevernefs. But this rarely happens, and only in cafes of the utmost feriety. The complaint ufually terminates without any apparent caufe, leaving the patient for a time to enjoy the comforts of life. But whoever has had one attack may with conliderable certainty anticipate another; and though he is to-day well, and free from all pain, to-morrow's day may uher in a renewal of his torment. So varied is the duration of this affecion, and fo limited is our knowledge of it, that we can affign no determinate or even probable period for its continuance; and unless a cure is effected it returns at intervals more or lefs frequent, and with increased violence, till the great final catastrophe, which, however, it does not seem to accelerate. For though Dr. Banfch is faid to have died of it, we can place little reliance on the report, and fubfquent cafes and obfervations do not corroborate such a fuppofition.

Hartenkeil,
TIC DOULEUREUX.

Hartenkell, Hildebrand, and Baldinger, and some other
Germans, relate cases of what they call tic douleureux; and
which, though in some particulars, they resemble that
affection, in others differ most materially. The first of
these writers describes it as having been very prevalent at
Saltzburg. But the pain was periodical, recurring gen-
erally once in twenty-four hours; and sometimes, though
rarely, once in twelve hours; often remaining for several
hours at a time, and then suddenly departing. These
causes of the disease seem to be a certain period of life, when the
functions are impaired, and the whole corporal
frame to feel the first signs of approaching decay. We
rarely find it commence before the fiftieth year, though
two or three cases of an earlier date are recorded. Women
do not seem to be more liable to the complaint than men;
though Dr. Fothergill, having a great proportion of female
patients, imagined they were more predisposed to it; as
likewise did Pujol, from their greater sensibility. The
latter author (in his Essay, p. 14.) says, "we generally
observe in such people as are subject to tic douleureux an
excess of mobility, which renders them more or less dif-
posed to hysterical and hypochondriacal affections.
Experience, however, teaches us, that people very far removed
from excess of sensibility are equally liable to the disease;
that women are not more liable to it than men; and that
the predisposing period of life is that when the sensibility
or mobility of fibre is most defective.

The exciting causes are, cold applied to the face in a
stream, whether of air or water; particularly when the
patient is fatigued by previous exhaustion. Exposure
to a stormy, damp, moist, and tempestuous
weather, frequently excites an attack; also external injuries,
as blows or contusions on the face. Pains of the
mind, as excess of anger or of grief.

The disease being once established in the styptom, the
lightest causes in some individuals will bring on a paroxysm;
such as eating, drinking, and talking, or indeed any motion
of the facial muscles, or the gentlest touch with a hand-
kercbief, or any other sub stance to the nose, lips, cheek, &c.
of the affected side. Shaving is an operation most particu-
larly flinmed and dreaded by the unhappy patient; and
often cannot be endured till after a considerable interval of
time. Blowing the nose is absolutely impracticable; or, if
attempted, a most pungent and disfiguring torture attends
the performance. M. André, in a work entitled "Observa-
tionees sur les Maladies de l'U'rite," mentions a very
oblit rate case of tic douleureux, which he attempted to
cure by destroying the nerve that he supposed to be the
seat of the disease. He began by laying it bare, and was
sufficiently to find, that every time he touched the denuded
nerve, he immediately excited symptoms of the disorder;
the paroxysm ceasing in the usual time, and recurring when-
ever the nerve was touched. This fact is very clear and
decisive as to the part affected by the disease, and hence
we readily perceive, why the least touch or motion on the
surface of the skin produces a paroxysm.

When the pain has continued with frequent accidents for
a length of time, a most distressing eczema is sometimes
witnessed. The patient, whose health at the time is
generally good, after defiling from eating and drinking,
till the keenest of his appetite, and the intensity of his
thirst, are too irrefrangible urgent to be longer unrelieved,
attacks whatever food is placed before him with maniac
fury and hurried precipitancy; his countenance suffused
with crimson, and convulsed and contorted with pain.
This horrid conflict does not last long; he soon throws
down his knife and fork with desperate violence, obliged to
folicit a cessation of pain by a flate of inaction.

Treatment of Tic Douleureux.—Of the inefficacy of most
medicines in the cure of this cruel disease, we have
abundant and melancholy proof. Those which have been
found to procure ease are, opium, cica, zinc, frimonium,
belladonna, argentinum nitrum, and arsenic. But the
influences in which a cure was effected by their use are very
rare; indeed some practitioners, from painful experience,
deny their efficacy. All manner of topical applications, from
blistering to the smocking entails torn
from living pigeons, have been in vain applied, and baths
and bleeding of all sorts.

M. Watton, professor of chemistry in the central school
of Vaucluse, relates two cases of tic douleureux arising
from venereal causes. The first was of an officer in the
French army, aged thirty; the other that of a lady, aged
forty. They were both completely cured by a course of
mercury. These cases, in some respects, differed from the
tic douleureux, but had its most disquieting character-
tistic darting pains in the direction of the nerves.
We learn nothing more from them, however, than that
the symptoms of the tic douleureux are excited by
the existence of a venereal taint in the habit, then
will depart when that taint is overcome by the action of mercury; but
it is found from experience, that in ordinary cases, the
symptoms are not in the least relieved by the use of mercury.
Recourse has next been had to electricity, to magnetism,
to actual cantery, and finally, to the section of the affected
nerves. Electricity sometimes procures temporary ease,
but as frequently increases the pain; though Mr. Blunts
in the Medical Journal, relates the case of a lady afflicted
with tic douleureux being cured by electricity. The
pain was chiefly seated in the right temple, and the symptoms
are so well described as not to be disputed. She was
electricised twice in the day for several minutes each time;
first with fsparks, then with shocks, after having previously
endured a long and ineffectual course of powerful medi-
cines. Immediately after the second application of electricity
she ventured to eat, and performed that necessary
operation without any inconvenience. The pains after-
wards recurred very slightly; the electricity was con-
tinued, and in the course of a short time, the became
entirely free from the complaint. The decided success of
this, though a solitary case, in such a dreadful disease,
authorises us to hope, that future trials may be made of
the application of electricity, which under the direction
of an able practitioner is often a very powerful instrument in the
cure of disease, and much oftener fails from want of care and
affinity in the application, than from inefficiency in itself as
an agent.

The mode of destroying the affected part of the nerves by
caulis has been adopted by some practitioners, and failed
to be attended with success. But, till more experience has
better established the utility of such a cruel operation, we
cannot recommend its use; it has not been had recourse to
in this country; and some cases are related in which it did
not succeed, and others in which deformity of the face was
the consequence. M. André, however, has tried it, and
recommends its general use. In his work will be found
an account of the method of operating.
The fection of the affected nerve was thought of and tried many years ago in the cure of this disease; and of late years, from a temporary success, some practitioners have confidently asserted, that the cure was effectual and radical; but more recent experience has destroyed the validity of such assertions.

So long back as the year 1786, Veillard published a thesis, in which he decided this question in the negative. "Utrum in pertinacius capitis, facieiisque doloribus, aliquid prodeel poife sectio ramorum nervi quiunti paris?" Now it is not likely, that he should have treated this important question superficially, but that he would rather collect all the information that at that time could be obtained upon the subject. He mentions two cases where the disease returned after the division of the nerves; and others, in which bad consequences ensued after the operation. Marechal, about the middle of last century, operated twice without success. Pujol was so convinced of its uncertainty, that he would not venture upon it. He has seen the muscles paralyzed, and the face distorted in consequence of the operation. Sabatier relates, that Ritah, surgeon to the king of Poland, performed the operation with success; but the patient, after being free from the complaint for some time, was again attacked with his former pains.

Modern practice seems also to confirm our scepticism in the permanent success of dividing the nerves. We see that what was at first hoped to be the most decisive cafe in its favour, the operation performed, and the account of it ably recorded by Dr. Haighton, is now not to be relied upon. Mr. A. P. Cooper has frequently performed the operation with similar present success, but only what permanency time only can determine.

There is a cafe related by Darwin, in the Zoönomia, of a gentleman who first had the second branch of the fifth pair of nerves divided; then the first branch; and thirdly, the remaining third branch. But the patient was not yet relieved. He then had several incisions made across the side of the nose, and offa nasi, through the malleus muscle to the jaw-bone, through the parotid gland. And last, some more twigs from the second branch of the fifth pair, passing into the cheek, and lying between the pterygoideus internus muscle, and the upper part of the lower jaw. These operations were performed by Mr. Cruikshank and Mr. Thomas. The patient, it seems, at length escaped alive and cured. De Haen has divided the suborbital nerve, as have also Morcau and Guerin, without any bad consequences. For the best method of operating, see Dr. Haighton's paper in the medical records.

It appears then, that as yet we know of no certain and radical cure for this painful affection. The section of the nerves promises the fairest; but when it is had recourse to, the patient should be warned of the possibility of the complaint returning, and not amused with the certainty of its being completely cured. Admitting, however, that the disease may return in the course of a few years, the operation is so simple, it is attended with little inconvenience or danger, and the relief in general so complete and instantaneous, that there can be little hesitation on the part of the practitioner in recommending its being performed, when the least of the disease is accurately ascertained.

Lentin declares, he has had the misfortune to treat, in the course of twenty-seven years, fourteen patients attacked with this painful malady, without radically curing one; and calls upon all practitioners to make public any means they may have found to succeed, either in performing a complete cure, or even a partial relief of the symptoms. The only remedies from which he experienced any good effects, were the tincture of thornapple, Datura Stramonium Lin-zei, and the sulphureous baths of Meunendorf.

A French writer relates a method of taking nutriment for those patients who feel an appetite, but dare not indulge in it, on account of the extreme pain; and that is, to fiuck through a small tube, as a quill, reed, &c. foup, broth, milk, or any nourishing fluid, so gently as not to excite any pain.

TILE-ORE. See Copper, and Mineralogy, Addenda.

TIN, CRYSTALLIZED, a kind of manufacture said to have been accidentally discovered in France by M. Baget, called metallic watering, or mairé métallique. It depends upon the action of acids, either pure or mixed together, and in different degrees of dilution, on alloys of tin. The variety of dents and refemblies mother-of-pearl, and reflects the light in the form of clouds. The procés is this:—First, diffuse four ounces of muriate of fods in eight ounces of water, and add two ounces of nitric acid. Second mixture; eight ounces of water, two ounces of nitric acid, and three ounces of muriatic acid. Third mixture; eight ounces of water, two ounces of muriatic acid, and one ounce of sulphuric acid. One of these mixtures is to be poured warm upon a sheet of tinned iron, placed upon a vessel of flone ware: it is to be pour'd in separate portions, until the sheet is completely watered; it is then to be plunged into water, slightly acidaed, and washed. The watering obtained by the action of these different mixtures upon tinned iron, imitates very closely mother-of-pearl and its refenions; but the designs, although varied, are quite accidental. By heating the tinned iron to different degrees of heat, itars, fern-leaves, and other figures, are produced; and by pouring one of the above mixtures, cold, upon a plate of tinned iron, at a red heat, a beautiful granular appearance is obtained. The metallic waterings will bear the blow of a mallet, but not of a hammer; hence the invention may be used for embossed patterns, but not for those which are punched. Different colours and shades may be given by varnishes, which, when properly polished, will set off the beauty of the watering.

When the tin is upon copper, the crystallization appears in the form of radiations or itars. M. Lewis Felix Vallet obtained a patent for an invention of this kind, upon delivering the following specification, Feb. 5th, 1813. The procés of giving the new ornamental surface on metals or metallic compositions, consists in employing those acids and saline compounds and subfances which chemically act upon tin, and which, when employed in the manner to be stated presently, give to the metals or metallic compositions to which they are applied the appearance of a crystalline surface variously modified. To produce this effect, the metal or metallic composition ought to be previously tinned, or covered with a thin coat of tin. If the metal be pure tin, it requires no previous preparation. All greases remaining on the tinmed surface in consequence of tinning is to be taken off with a solution of potash, soap, or any other alkaline subfances. The tin or tinned surfaces should then be washed with pure water, dried, and heated to a temperature which the hand can bear. When the surface has thus been cleaned and heated, any of the acids which act upon tin, or the vapours of those acids will cause the desired appearance of crystallization; but I give the preference to the following composition, which may conveniently be laid over with a brush or a sponge.

Take one part by measure of sulphuric acid, dilute it with five
five parts of water; take also one part of nitric acid, and
dilute it with an equal bulk of water, and keep each of the
mixtures separate. Then take ten parts of the sulphuric
acid diluted in the manner before directed, and mix it with
one part of the diluted nitric acid, and then apply this
mixed acid to the tin, or to the tin plate surface with a
pencil or sponge, as above directed, and repeat the applica-
tion of the said composition for several times successively,
or until the refult you expect proves satisfactory. When
this has been done, the crystaline surface may be covered
with a varnish or japan more or less transparent or colour-
less, or coloured, and lastly polished in the usual manner.
Mr. Shaw, of Brunswick-square, purchased this patent,
and tin-plates were made under its protection, at the manu-
factory of Mr. Burwell, at Battersea. But the process
being generally known among chemists, the manufacture
decayed, and the patent, for which a considerable sum was
paid, became of little value.

TIN-PLATES. Add—The manufactory for tinning iron-
plates was established at Pontypool by Mr. John Han-
bury, where he resided until his death in 1734; and the
invention of the art has by some persons been erroneously
ascribed to him. His monument may be seen in Trevelli
church.

TIOGA, in New York. Add—By the census of 1810,
the number of its inhabitants was 7899, including 61 slaves.

TIOGA, a county of Pennsylvania, including two town-
ships, and 1857 inhabitants.—Allo, a township of the said
county, having 803, the other Dalmore, having 884 inhab-
abitants.

TISBURG, including the Elizabeth islands, in Duke's
county, Massachusetts, contains 1202 inhabitants.

TITAN, in mineralogy.

TITICACA. Add—See Cusco.

TOBACCO, l. 3, for 1560 r. 1784. See Drake.

TOBACO, a township of Cumberland county, in
Pennsylvania, having 7599 inhabitants.

TOBY. Add—Allo, a township of Armflrong county,
in Pennsylvania, having 611 inhabitants.

TOLERATION, l. 18, add—The late abbé Gregoire,
in his " Histoire des Séces Religieuses, &c." observes, that
" we must not confound civil and religious toleration. The
latter supposes that truth and error are indifferent; which
truth can never be, for it is only one; and this being the
caste religious toleration would be an affront to God, who
is truth itself. Civil toleration is that which grants to
every one the power of publicly exercising the mode of
worship to which he is attached—an inalienable right of
every member of society, and which, incorrectly denomi-
nated toleration, ought to be called liberty of worship. It
has been already observed, and cannot be too often re-
peted, that the only authority which the civil magistrate
possesses over religious associations is to see that they neither
uffer molestation nor molest one another." Col. 6, l. 113,
add—and extended to Ireland by 57 Geo. III. c. 70.

TOLLAND. Add—Allo, a town of Massachusetts,
in the county of Hampton, having 798 inhabitants.

TOOLAVA, an Indian language, which extends from
Nilifuram to Scodahaor, S. of Goa.—Allo, the name of
a country considered as a subdivision of Kérela, which
extended from Coouro, round Cape Comorin, to the river
Tumbapura in Tinnaverry.

TOOME, a river of Hindooistan, which is a
southern branch of the Kistvaen; which fee.

TOPASSE, an Indian denomination of native black
Christians, the remains of the ancient Portuguese.

TOPHANIA, or TOFFANIA, the name of a woman
who resided at Palermo, and afterwards at Naples, and
who rendered herself infamous by preparing and adminis-
tering poison. She sold these drops, which from her ac-
quired the name of Aqua Tophania, Aqua della Tofana. It
was called also Acqueta di Napoli, or only Acqueta; but
she distributed her preparation, by way of charity, to
fugitive wives as wished to have other husbands. From four to
fix drops were sufficient to destroy a man; and it has been
asserted, that the dose could be so proportioned as to
operate in a certain time. As she was watched by the
government, she fled to an ecclesiastical asylum; and when
Keslyer was at Naples in 1730, she was then living; her
life being secure under that protection. It was her prac-
tice to distribute her poison in small glass phials, upon
which was this inscription, " Manna of St. Nicholas of
Baris," and ornamented with the image of that saint, whose
reputation prevented its being particularly examined by the
custom-house officers. About the year 1709, Tophania
fled from one convent to another; but she was at length
feized and thrown into prison. Her imprisonment, as she
was under ecclesiastical protection, excited the indignation
of the clergy, who endeavoured to raise an insurrection
among the people; but they were appeased upon Topha-
ния's confession, that she had poisoned all the springs in
the city. Upon the rack she acknowledged her wickedness;
her protectors fled, and she was strangled; and in order
to infligate the archbishop, her body was thrown down, at night,
into the area of the convent from which it was taken. Her
abstinent did not die with her; but her poison was secretly
prepared and administered at Naples after her death. It
was afterwards presumed, from the effects of her poison,
that it was a preparation of arsenic. Keslyer. Beckmann,
Hist. Invent. vol. i.

TORPEDO, a kind of destructive machine, invented
by Mr. Fulton, to whom we owe the construction of the much
more useful naval machine, viz. the fleet-boat. Add—This
submarine mine, however it may give celebrity to the
ingenuity of the inventor, will, we truill, for the sake of humanity
and the honour of naval conflicts, never be adopted in any
civilized nation.

TERROR, or TOUBE, a river of the south of France,
in the department of Gex, with its source in the Alps. Add—It
was a boundary of Savoy and the Duchy of Burgundy, and
passed into the county of Savoy, and afterwards into the
province of Dauphiny, where it is joined by the Arve.

TORRES VEDRAS. Add—This ancient town lies
about seven leagues from Lisbon, and is situated in a small
plain, about three leagues from the sea, on the river Zigan-
dra. It owes its name to the circumstance of there being
the ruins of many old towers in its neighbourhood. The
principal one, or castle, has been repaired, and serves as a
point of defence to the works thrown up at this important
pale, which covers two great roads leading to Lisbon from
this point, one by Mafra, the other by Eunzarra dos Cas-
valeiros. Although this may be a sufficient description of it
in a geographical point of view, we do not think it should
be omitted to be here stated, that the celebrated position
occupied by the duke of Wellington to cover Lisbon in the
fall of the year 1810, took its name from this town, which
formed one of the principal points of the line of defence,
which was carried across from the Tagus to the sea, pre-
fenting a contour of about forty miles, of such an imposing
nature as to render unavailing all the efforts of an almost
overwhelming French army, under one of their most dif-
tinguished marshals, to expel the Anglo-Portuguese from

Vol. XXXVI.
the Peninsula. This line of defence (with another about five miles in its rear), stretched from the Tagus at Alhendra to the sea where the Zigranda falls into it, being a direct line of about twenty-six miles. The whole of this most extensive, varied, and gigantic position, was beleaguered and formed under the duke of Wellington's direction, with the most unwavering exertion by those able and scientific engineers the late Sir Richard Fletcher and colonel Chapman, and with the retreat of the French from before it, may be said to have commenced the series of achievements which finally ended in the triumphs of the British army in the heart of France.

TORKINGTON, l. 1, after Connecticut, add— in the county of Litchfield, containing 1586 inhabitants.

TORSK. See GADUS BROCHNE.

TORTURE. At the close, add—Torture was abolished in Sweden by order of the king in 1786; in Poland, in 1776; in France by edict, Aug. 16, 1780; in Spain, Aug. 1814; and in Austria, in 1776.

TOURACOC. See CUCULUS and OPÆTIUS.

TOWIACHES, 1. i., infert.— (see Panis); l. 5., after towns, add—N. lat. 39° 20'; W. long. 97°.

TOWNSEND, l. 1, add—in the county of Middlesex, containing 1246 inhabitants.

TOWNSHIP, Upper, Middle, and Lower, three townships of Capemay county, in New Jersey; the first having 1652, the second 1106, and the third 852 inhabitants.

TRACHYMENE, in Botany, from τραχύς, rough, and μένη, (as we presume,) a membrane, alluding to the roughness of the covering of the seeds.—Rudge Tr. of Linn. Soc. v. 10. 300.—Cliffs and order, Pentandria Dignas. Nat. Ord. Umbelliferae.

1. T. inefia. Smooth Trachymene, or Botany-bay Carrot. Rudge as above, t. 21. f. 2.—Stem nearly naked, smooth. Umbels terminal.—Sent, many years since, under the above English name, from Port Jackson, by Dr. White. We have heard that the root is eatable, and like a carrot. The herb is smooth, two or three feet high. Stem round, slender, alternately branch, each of the long, terminal, naked, simple branches bearing a few, simple umbel, scarcely an inch broad, of numerous, white or reddish, uniform, equal flowers. Leaves of the involucrum awl-shaped, shorter than the umbel, combined at the base. Fruit somewhat heart-shaped, broader than long, mucratic all over, when quite ripe, with crowded, blunt tubercles. One seed is often abortive. The leaves are chiefly radical, flaked, smooth,坚ate, with wedge-shaped, three-cleft, notched segments. See Fischera.

2. T. pilosa. Hairy Trachymene.—Stem leafy, hairy, as well as the leaves; and foot-tulks. Umbels laterad.—Gathered by Mr. Menzies, in King George's Sound, on the west coast of New Holland. Whole herb rough with short shaggy hairs. Umbels on stout flaks, from the forks or sides of the stem. Tubercles of the fruit acute, bristle-pointed. See Fischera.

TRAETH COCH, for REDWAPHE or REDWATA.

TRELLECH, or TRELLICK. Add—In 1811 the town contained 23 houses, and 121 persons; viz. 58 males, and 63 females. The parish of this name, in the upper division of Ragland hundred, consists of the parish contained, the town division, and the Grange division: the former contained 191 houses, and 568 persons; 275 being males, and 293 females; and the latter included 20 houses, and 134 persons; 74 being males, and 60 females.

Vol. XXXIX.

TRENTON, l. 6, r. 3000.

TREVETHIN, a populous parish of the county of Monmouth, in the upper division of Abergavenny hundred, which, including Pont-y-Pool, contained, in 1811, 466 houses, and 2423 persons; viz. 1211 males, and 1212 females: 123 families being employed in agriculture, and 280 in trade, manufactures, or handicraft.

TRICHECUS—ROSMARUS, r. Jonbione.

TRIDACTYIUS, a species of Bradypus; which see. See also Sloath.

TSCHUTSKI. See Chukstskia.

TURCOMANIA. Add—See Armenians.

TURNER, l. 2, add—and county of Oxford, having 1179 inhabitants.

TURNSTILE, in Fortification, a kind of barrier, which consists of two or three pieces of timber, formed crossways, and making four or six rays like the spokes of a wheel; the frame is put on a post in the middle of a passage to turn horizontally, so that two of its rays always stretch across the passage, and prevent more than one person at a time from passing the same way.

TUSKARAWA, r. Tuskarawa.

TWEDDELL, JOHN, in Biography, an accomplished scholar, whose early fate has been much lamented by all the lovers of literature and the arts, was the eldest son of Francis Tweddell, esq. of Threewood, in the county of Northumberland, was born on the 18th of June 1759; and after passing through the usual course of preparatory education, was entered at Trinity college, Cambridge, where he distinguished himself by such proofs of original genius as are, perhaps, without example, even in the records of that learned society. As a candidate for university honours, his "Prolusiones Academice" atted his success to have been equally brilliant and extraordinary, and supercede the necessity of particular illustration. Mr. Tweddell was elected a fellow of Trinity college in 1792, and soon afterwards entered himself a student of Lincoln's Inn, where he kept his terms, and continued to reside until the year 1795, when he left England to commence his travels on the continent of Europe—and met with that untimely fate which has mixed his ashes with those of the sages and philosophers of Greece. He visited Switzerland, Germany, most parts of the Russian empire, and particularly the Crimea, where his intercourse with professor Pallas was of the most intimate kind, and had so endeared him to that amiable scholar, that the admiration with which he spoke of him partook of the tenderness and affection of a father. From the borders of the Euxine, where his researches were both diligent and productive, he proceeded to Constantinople; and after spending some part of the summer of 1795 under the hospitable roof of Spencer Smith, esq. the English minister, he took his departure for the Grecian islands; and having traversed the provinces of Macedonia and Thessaly, arrived at Athens; where, after a residence of several months, he reached the period of all his learned labours, on the 25th of July 1799.

Mr. Tweddell, independent of the advantages which his own merit secured for him in the countries which he visited, professed recommendations and facilities of a superior kind for conducting his learned pursuits; and his industry keeping pace with his talents and opportunities, his collections and manuscripts are known to have been extensive and singularly valuable. Perhaps no traveller of modern times has enjoyed in an equal degree the means of investigating the antiquities of Greece.

His remains were interred in the beautiful Doric temple of Theseus at Athens; and his grave was simply a small oblong
oblong heap of earth, like those over the common graves in all our English church-yards, without a stone or inscription of any kind; and his body was carelessly deposited at about three or four feet beneath the surface. The part of the temple which has been buried is now converted into a Greek church, dedicated to St. George; but the building is occasionally open and liable to the intrusion of animals, who sometimes seek such retreats, Dr. Clarke and his companions, in their travels to Athens, obtained leave to take up the coffin, and to have it properly covered; and a Greek epitaph, composed by Mr. Walpole in 1805, has been inscribed on a large block of Pentelic marble from the Parthenon, for recording the merits of the deceased. The completion of this monument has been owing to the exertions of lord Byron, and Dr. J. F. Lee, of St. John's college. Cambridge. Clarke's Travels, vol. vi.

TWIGGS, I. 2, adds—of whom 642 were flaves in 1810.
TWIST, and TWISTING. See MANUFACTURE of COTTON.

V and U.

VAMANAVATARA, col. 3, l. 11, for admirer r. advier.

VANDELLUS, VANDEL, in Ichthyology, a genus of fishes of the order Thoracici, confidered by Dr. Vandelli of Coimbra as nearly allied to the genus Trichurus; the characters of which are, body extremely long, sword-shaped, gill-membrane five or fix-rayed, and teeth tubulate, those in front large. This fish is the beautiful vandell, with forked tail, which occurs, very rarely, in the Mediterranean and Atlantic seas, and sometimes near Lisbon.

VANDER WEYDE, ROGER, called Roger of Bruges, in Biography, an historical and portrait painter, was born at Bruges about the year 1455, and became the disciple of John Van Eyck, who, at a short period before his death, discovered to him the secret of painting in oil. From this he distinguished himself by many grand compositions in a large size, and was confidered as one of the first Flemish artists who improved the national taste, divesting it in some degree of the Gothic, and manifef ting grace in the aims of his heads, as well as correctness in his delign. He painted the portraits of several princes, and of many persons of eminence, and obtained a considerable degree of fame and fortune. His paintings in the town-hall of Bruges have been much commended; one of which is formed on the subject of Trajan's justice, executed on one of his fiders, on the complaint of a mother, whose son had been murdered by him; and that of another is Archambant, prince of Brabant, flabbing his nephew, who was his next heir, when he himself was near dying, for having ravished a maid of that country.

VAN UTRECHT, ADRIAN, was a native of Antwerp, where he was born in 1599, and learnt the art of painting: at first painting peacocks and other fowl for his amufement, in which he so much excelled that he was encouraged to prosecute this branch of his art. The subjects to which his attention was principally directed were fruit, birds, flowers, dead game, and objects of still life; imitating and copying nature, and distinguishing by correct drawing, and the colouring of nature. He was deemed next to Snyd in that style of any of the artists in the Low Countries; and though he was very industrious, he could not execute one half of the orders which he received. His manner of pencilling was peculiarly delicate, and gives an uncommon transparency to his colours. Most of his works were engraved by the king of Spain, so that they became scarce, and they now produce very high prices. This artist died in 1651, at the age of 52 years.

VASSALBOROUGH. Add—containing 2063 inhabitants.

VATICAN. Add.—The Vatican, depofiled during the French revolution, can again boast of polishing the Apollo, the Laocoon, the Antinous, and all those fine examples of the exquisite taste and delicate sentiment of that refined people, the Greeks. The Transfiguration of Raphaelle, the St. Jerome of Domenichino, and the St. Peteroilla by Guercino, since their return from Paris, have been placed in a room by themselves, but inconveniently dark.

VAUXHALL BRIDGE, a bridge over the Thames, extending from Millbank to Smith's tea-gardens, which nearly adjoin Vauxhall Gardens, and connecting the roads branching from that spot to Hyde Park Corner by a straight road and street across Tothill-fields to Eaton-square, Pimlico, and Grosvenor-place. This bridge, constructed by Mr. J. Walker, consists of nine arches of equal span in squares of cast-iron, on piers of rusticated stone, formed of fragments, united by means of Parker's cement. The total width is 80 feet, the span of the arches 78 feet, the height 25 feet, and the clear breadth of the road-way 36 feet. The estimated cost of this bridge was above 300,000l.

VELOCIPEDE, ACCELERATOR, or SWIFT-WALKER, a machine originally invented by theon Charles de Drais, master of the woods and forests of his royal highness the grand duke of Baden, who, in his account of its nature and properties, says, that on a well-maintained post-road, it will travel up hill as fast as an active man can walk; that on a plain, even after a heavy rain, it will move six or seven miles an hour; that, when roads are dry and firm, it runs on a plain at the rate of eight or nine miles an hour, which is equal to a horse's gallop; and that on a defcent, its motion is equal to that of a horse at full speed. This machine, the theory of which is founded on the application of a wheel
wheel to the action of a man in walking, consists of two wheels, one behind the other, connected by a peron, on which is placed a saddle for the seat of the traveller. The front wheel is made to turn on a pivot, and is guided in the same manner as a Bath-chair. On a cushion in front, the fore-arm is reeled, and by so doing the machine and the traveller are kept in equilibrium.

The management is as follows:—The traveller, having placed himself on the saddle, with his elbows extended, and his body a little inclined forward, must rest his arms on the cushion, and preserve his equilibrium by pressing lightly on that side which appears to be rising. The rider (if it may be so called) must be held by both hands, which are not to rest on the cushion, but to extend somewhat beyond it; that they may be at full liberty, as they are no less essential to the conduct of the machine than the arms are to the maintenance of the balance of it, for which purpose sufficient dexterity will be soon acquired by attention and practice; then, placing lightly the feet on the ground, long but very slow steps are to be taken in a right line, at first care being taken not to turn the toes out, left the heels should come in contact with the hind wheel. Dexterity in managing the equilibrium and direction of the machine should be acquired before any attempt is made to accelerate the motion of the feet, or to keep them elevated while it is in rapid motion. This machine will run for a considerable distance while the rider is inactive, and with the same rapidity as when his feet are in motion; and in defeat it will surpass the best horses in a great distance, without being exposed to the risks incident to them, as it is guided by the mere gradual motion of the fingers, and may be instantly stopped by the feet. The saddle, as well as the cushion, may be raised or lowered at pleasure, so as to suit the height of different persons. The inventor proposes to construct these machines to carry two persons, and to be impelled by each alternately, or by both at once; and with three or four wheels, with a seat for a lady; besides the application of a parasol or umbrella: he also proposes to avail himself of a fail, with a favourable wind.

The velocipede has been introduced into this country under letters patent, by Mr. Johnson, a coach-maker in Long Acre, by whom it has been much improved, both in lightness and strength.

VENICE, col. 5; l. 10 from bottom. Add—At the last census, taken about the year 1815, the population was stated to be about 100,000; and it is said to be decreasing.

VENETIAN, l. 7, add—and LARYNX.

VOL. XXXVII.

VERMILION, col. 2, l. 20, add—The painter's vermillon is a factious cinnamon, made by subliming a compound of sulphur and mercury.

VERNON, in Geography, a town of Tolland county, in Connecticut, containing 827 inhabitants.

VESICULA FELLIS. See LIVER for GALL-Bladder.

VESTIS ANGELICA, for Angelica.

VIENNA, in Geography, a township of Trumbull county, in Ohio, including 234 inhabitants.

VIOLIN. Add—The art of holding the bow, and of placing and moving it on the strings, is the most difficult and important to incipient practitioners on the violin, which they have to encounter; as upon that depend the force, sweetness, and penetrating power of the tone. They must pay great attention not to press too hard upon the string, so as to make it curve and deviate from a right line; for then the tone would be harsh and coarse. Neither must the bow be laid too lightly on the strings, as the tone would then whistle and be too feeble. The juft point of accuracy in this particular is, to place the hair on the strings in such a manner, that every part of it is in contact with whichever may be wanted. The bow must not act too near the bridge, nor too distant from it, as only dull and unpleasant sounds would be produced.

</tbody>
</table>

Total $151,400,000

Their present value has not been ascertained, but it appears that the exports of their manufactures amounted in 1811 to a total of $1,553,000, including those for domestic materials at $1,321,000, and those from foreign materials at $232,000; and in 1816 to $1,755,000, including $1,415,000 of the former kind and $340,000 of the latter.

The manufactures from foreign materials were, spirits from molasses, refined sugar, chocolate, gunpowder, brass and copper, with medicines. The manufacture of wool is rapidly extending, as are also those of iron and hemp, and especially the latter, and also that of cotton. The manufacture of gunpowder nearly supplies the home market, which is also the case with regard to coarse earthen-ware, window-glass, glass bottles, and decanters. About a million of barrels of salt are manufactured annually; and salt-petre is largely manufactured in Virginia, Kentucky, Massachusetts, East and West Tennessee. Sugar from the maple-tree is produced in Ohio, Kentucky, Vermont, and East Tennessee, to the amount of nearly 10 millions of pounds annually. West Tennessee and Vermont afford abundance of good copperas: 25 millions of gallons of ardent spirits are annually distilled and consumed in the United States: 400 water and horse mills, working 190,000 spindles, are employed in spinning cotton. The fulling-mills amount to 2000, and the number of looms exceeds 490,000; and the number of yards of cloth, manufactured from wool, cotton, and flax, is about 100 millions. They have 500 gunpowder-mills, 600 furnaces, forges, and bloomeries, and 200 paper-mills.

In the state of Vermont, the chief manufactures are those of iron, lead, pipe-clay, marble, distilleries, maple-fugar, flour, and wool. In Massachusetts, the principal manufactures are, duck, cotton, woollen, cut-nails (by a machine invented in Newbury port, which is capable of cutting two hundred thousand in a day), paper, cotton and wool cards,
playings-cards, shoes, silk and thread lace, wire, stuff, oil, chocolate and powder mills, iron-works, and flitting-mills, and mills for sawing timber, grinding grain, and falling cloth, distilleries, and glases. In Rhode Island, are manufactured cotton, linen, and tow cloth, iron, rum, spirits, paper, wool and cotton cards, flaxen, sugar, machines for cutting screws, and furnacces for cutting hollow ware. In Connecticut, are manufactured silk, wool, card-teeth (bent and cut by a machine to the number of 860,000 in an hour,) buttons, linen, cotton, glases, stuff, powder, iron, paper, oil, and very superior fire-arms. In New York, are manufactured wheel-carriages of all kinds, the common manufactures, refined sugar, potters’-ware, umbrellas, musical instruments, glases, iron, and steam-boats. In New Jersey, are numerous tanneries, leather manufactories, iron-works, powder-mills, cotton, paper, copper-mines, lead-mines, stone and slate quarries. In Pennsylvania, there are valuable collieries on the Lehigh river, distilleries, rope-walks, sugar-houses, hair-powder manufactories, iron founderies, shot manufactories, steam-engines, mill machinery, type-founderies, improvements in printing, and carpet manufacture. In Delaware, there are cotton and calico cloth and powder manufactories, fulling, stuff, filling, paper, grain and saw mills. In Maryland, are iron-works, collieries, grist-mills, glass-works, stalls, paper-mills, and cotton. In Virginia, are lead mines, iron-mines, copper-mines, salt collieries, and marble quarries. In Kentucky, are manufactured cotton, wire, paper, and oil. In Ohio, ship-building is carried to a great extent. In North Carolina, the pitch-pine affords excellent pitch, tar, turpentine, and lumber; also iron-works, and a gold-mines, which has furnished the mint of the United States with a considerable quantity of virgin gold. In South Carolina, are gold, silver, lead, black-lead, copper and iron mines, and also pellicid flames of various hues, coarse cornelian, variegated marble, nitrous stone and sard, red and yellow ochres, potters’-clay, fullers’-earth, and a number of dye-stuffs, chalk, crude alum, sulphur, nitre, and vitriol. In Georgia, the manufactories are indigo, silk, and fag. In Louisiana, are manufactured cotton, wool, cordage, shot, and hair-powder.

But the most extraordinary, and perhaps the most important manufacture in the United States, is that of steamboats; the first application, if not invention, of which is ascribed to Mr. Fulton. It was in the year 1807 that the first steam-boat plied between the cities of New York and Albany; but since that time this mode of navigation has been successfully used in many other rivers of the United States besides the Hudson; so that steam-boats now ascend the Mississippi and Ohio rivers, hitherto nearly unnavigable, except in the direction of their currents. The following table shews the cheapness, as well as expedition, of travelling since food as well as conveyance is included.

The net amount of revenue received in 1815 was $35,966,106, being from customs $37,656,486; internal duties $5,903,225; direct tax $5,723,122; public lands $1,287,959; paper and currency $275,282. The report of the secretary of the treasury for the year 1816 states, that on the 12th of February 1816, the whole of the public debt, funded and floating, was $124,930,682; but on the 1st of January 1817 did not exceed $189,748,272, reducing the debt from Feb. 12th, 1816, to Jan. 1st, 1817, $13,882,420.

The American capital, consisting of personal property $2,200,000,000, and of real property $5,000,000,000, amounts to $7,200,000,000; the income, $300,000,000; expenditure, $450,000,000; national debt, $1,000,000,000. The salaries of the principal officers of the federal government are as follows:

- President, per annum - - $25,000 = 525l.
- Vice-president, ditto - - $500 = 1125l.
- Secretary of State, ditto - - $500
- Treasury, ditto - - $500
- War, ditto - - $450
- Navy, ditto - - $450
- Ministers plenipotentiary, ditto - - $900 = 182l. 10s.
- Members of Congress, per day - - $8

For the revenue of the United States we can only collect a few particulars. We observe in general, that the national debt at present does not amount to 120 millions of dollars. Its sinking fund consists of an annual appropriation of $8,000,000, arising from the interest of the debt redeemed, amounting in 1813 to $1,932,107; for the sales of public land, equal in that year to $830,671; and from the duties on imports and tonnage. The revenue of the United States, previous to the late war against England, were derived from duties and taxes on imports, tonnage of ships and vessels, spirits distilled within the United States, and stock, pollage of letters, taxes on patents, dividends on bank-stock, stuff manufactured in the United States, sugar refined here, sales at auction, licences to retail wines and distilled spirits, carriages for the conveyance of persons, stamps, paper, direct taxes, and sales of public lands. The revenues have been chiefly derived from duties on imports and tonnage. Internal taxes have been laid at different periods by the Washington administration, but were all discontinued by an act passed April 1802, under the auspices of Mr. Jefferson. The following statement exhibits the estimated receipts and expenditures of the United States at different periods.

Brided observes, that the population of the whole United States has hitherto doubled itself in less than twenty-five years. The New England states, he says, of course do not retain their proportion of this increase, because large bodies of these people migrate annually to the western country, which has therefore increased much faster than the states to the southward. Kentucky, e. g., has increased 80 per cent. in ten years; Tennessee, 95; Ohio, 180; Louisiana, 110; Indiana, 109; Mississipi territory, 190; Illinois territory, 700; Michigan territory, 200; Missouri territory, 700; while of all the Atlantic states, the greatest increase is only 44 per cent., the population growth of New York; and the least is, that of Virginia, only 20 per cent.; so that in a few years the states will range, if the future be like the past, as to their aggregate population in the following order, viz. New York, Pennsylvania, Virginia, Kentucky, Ohio, North Carolina, Mississipi, South Carolina, Tennessee, Maryland, Georgia, New Jersey, Connecticut, Vermont, Louisiana, New Hampshire, Indiana, Missouri, Mississipi, Illinois, Delaware, and Rhode Island.

Voltaism, l. 13.—The general conclusion deduced by Galvani from his experiments was, that the animal body possesses an inherent electricity of a specific kind, which is connected with the nervous system, and conveyed by means of the metals into the muscles, so as to throw them into convulsions. From his discoveries he formed, with a preci- pitation that led him into error, a theory of muscular motion, according to which the body contains an apparatus analogous to the Leyden phial, its different parts being in different states of electricity, and the metals forming a connection between them, by which the electricity is equalized. Fowler, in his "Effay on Animal Electricity," published in 1813, concludes, that the galvanic influence is not referable to electricity, because, for the production of the former, the presence of two different metals appears to be necessary, while electricity, as proceeding from the electrical machine, is excited by the action of an electric upon a conductor. He also endeavors to show, says Dr. Bollock, the ingenious historian of galvanism, that electricity and galvanism are not, in all cases, conducted by the fame substances; and he also made some curious observations upon the effect of galvanism on animals not furnished with distinct limbs, such as worms of various kinds. In the same year, 1793, professor Volta's communications appeared in the Philosophical Transactions of London, who adds to his luminous account of Galvani's discovery many curious experiments and observations of his own. He attempted, and with complete success, says Dr. Bollock, to overthrow Galvani's opinion, that the animal body bears an analogy to the Leyden phial, its different parts being in opposite states of electricity. He suggested, that for the production of the effect it was essential to have two different : metals, and hence he was led to conclude, that the muscular contractions are produced by small portions of electricity that are liberated by the action of the metals upon each other. This action of the metals upon each other is described as destroying their electrical equilibrium; and by establishing a communication between them, their equilibrium is restored. This destruction of equilibrium he considers as a new law of electricity discovered by himself; and the animal is supposed to have no further concern in it, than as being a peculiarly sensitive electricometer, and affording a very delicate test of the presence of this disengaged electricity in its passage from one metal to the other. He also established another point, viz. that the nerve is the organ on which the galvanic influence immediately acts; but he found that if a part of a muscle be laid upon two different metals, and these be made to communicate, a contraction is produced. He also confirmed the fact, previously noticed by Fowler, but by independent experiments, that snails and worms could not be made to contract; but that many of the insects, as butterflies and beetles, were subject to the influence of the metals. For an account of Dr. Wells's experiments and observations, we refer to his paper in the Phil. Tranf. for 1795. Professor Volta, prosecuting his inquiry into the nature of galvanism, was led to introduce a new principle into his theory. Having before stated that two metals were essential to the extraction of the electric influence, he informs us, that their metallic nature may be dispensed with, provided that the substances differ in their power of conducting electricity. Accordingly he divides conductors into the two classes of dry and moist; the first including metals and charcoal; the latter, essentially conifiing of water, holding various substances in solution. In order to form a galvanic circuit, it is necessary that a body from one of these classes be placed between two bodies from the other class; and thus the equilibrium is destroyed, which is again restored when the two are united by a conductor. (See Galvanism.) For further particulars we are under a necessity of referring to Dr. Bollock's very valuable "Account of the History and present state of galvanism," 8vo. London, 1819.

At the close, add—It is natural to conclude, that galvanic electricity would be applicable to medical purposes. Accordingly we find, that about the year 1824, it was extensively
tensively employed, more especially in those diseases in which common electricity had been found useful. But the expectations that were formed concerning the efficacy of this powerful agent were generally disappointed. Flattering accounts, however, says Dr. Bollock, (*ubi supra*) of its success in different nervous disorders, in paralytic affections, in deafness, in some kinds of blindness, in the recovery of persons apparently drowned or suffocated, and even in hydrophobia and insanity, were published. But the credit of the proposed remedy was not permanent; and it therefore sunk into disuse. Of late it has again been brought into notice by Dr. Philip of Worcesters, who has made trial of it, with beneficial effect, in spasmodic asthma. Bollock's Hill.

**URFE, Honoré D'B.,** count of Chateauneuf, and marquis of Villomerie, in *Biography,* was the fifth son of James D'Urfe, a noble family of Forez, originating from Swabia, and born in 1567 at Marseilles, in which city he was educated, and also in the Jesuits' college at Tournon. Although he was first inclined to be a knight of Malta, he was diverted from this purpose by his objection to celibacy; and he afterwards obtained a dispensation to marry the wife of his brother Anne, who was separated from her on account of impotence, and became an ecclesiastic. His view in this marriage was to secure the property of his wife, who was a rich heiress, to his own family; but as he had no children by her he was disappointed in his mercenary purpose, and the connection was unhappy. Thus frustrated in his selfish views, he retired to Piedmont, and devoted himself to letters. He was the author of several publications; but his name has been celebrated as a romance writer, on account of his "À la France," which was published in five separate volumes, at successive periods, and continued as a performance of general perusal for fifty years. This romance exhibits a picture of human life in its various conditions, and displays ample invention and acquaintance with men and characters under the disguise of pastoral fiction, from which, however, the author often deviates; he furnishes a history of his courtship of Diana de Chateaume-Ronat, his brother's wife, whom he married, and of the gallantries of the court of Henry IV. Although it was at a former period much read, it is now trifling for instruction and too tedious for amusement. It was often republished, but the last edition is said to be that of Paris in 1753, in 10 vols. 12mo. by the abbé Souchaise. D'Urfe died at Villefranche in 1625. His brother Anne was also a writer, and published some poems.

WEB

The editor seems to have been a man of some learning, as well as knowledge in music, as he dedicates the work, in a Latin copy of verses, to the earl of Essex, then at the summit of favour with queen Elizabeth, and addresses Luca Maranzio, from whom most of the madrigals were taken, in another.

WEARE, l. 2, r. Hillborough.

WEBB, senior, in Biography, a favourite author of English catches and glees, and one of the most successful candidates for prizes at the catch-club during the most brilliant period of its institution in 1762. See CATCH, and CATCH-CLUB.

WEBB, DANIEL, esq. author of an elegant and ingenious tract, entitled "Observations on the Correspondence between Poetry and Music," 1769, 12mo. This author had acquired considerable reputation by two former dissertations in dialogue; the first, "An Inquiry into the Beauties of Painting," the second, "Remarks on the Beauties of Poetry," which had rendered the public willing to receive favourably a third work from the same pen. Much learning, extensive reading, and a classical taste, were manifested in this production, "On the Correspondence between Poetry and Music." It is, however, more metaphysical and less intelligible than his former tracts. The author seems to have conceptions difficult to bring forth, and out of the reach of common language to express. He seems to concur with Roussel, that "music cannot narrate, nor precisely express or paint any particular passion;"

but it can awaken sensation and sentiments near the truth, and, with the affinities of poetry, can be pointed to a determined affection or passion. It can soothe affection, it can supplicate, it can animate and move our courage, excite hilarity, and generate ideas of grace, innocence, and content, without the interpretation of poetry; but having nothing to imitate in nature, like poetry and painting, imagination must assist in finding similarities.

The speculations of Mr. Webb are not always free from obscurity, though his language (when not deformed by his fondness for hath) is accurate and elegant. He says, that "music cannot give pain, like poetry and painting," but extreme harsh dissonances allowed to be occasionally used in counterpoint, give pain to the ear, as intense as painting and poetry to the eye and the mind. The author's chief illustrations are from Milton; and the work seems more intended to throw the beauties of Milton, than the analogies between poetry and music. The expression of music arises more immediately from rhythm than from the arrangement or combination of sound, and many of its imitative beauties, perhaps all, are ideal. Mr. Webb's ideas in general are delicate, refined, and beautifully expressed. But he never ventures to instance a musical composition or single passage which reminds us of practical music; and it does not clearly appear what kind of music he most approves, or indeed what it is that he honours with the name of music.

Mr. Webb was one of the first in our country who ventured to say, that counterpoint and complications of parts in dissimilar motion was an enemy to melody and expression; he quotes Algarotti's "Saggio sopra l'Opera in Musica," in confirmation of his opinions; but Roufeau preceded both, in his "Lettre sur la Mus. Fran." published in 1751, when he first developed his idea of "Unité de Mélodie." Mr. Webb's observations, indeed, abound with deep reflections and belle paroles; but we have not yet discovered what benefit lyric poetry or vocal music can derive from such discussions.

WEIDEMAN, ——, came to England about 1726. He was long the principal flageo player, and composer, and master for the German flute. He was a good musician, and played so well on the organ, that we remember Handel, at a rehearsal of an oratorio in Covent Garden theatre, desiring him to touch a new organ just finished by the elder Byfield, that he might judge of its effects in different parts of the theatre, in which he was obeyed by Weideman with considerable abilities. But in his productions for the German flute, he never broke through the bounds of that mediocrity to which his instrument deemed confined.

WEIGEL, ——, an excellent performer on the violoncello, whom we heard in 1772, at Vienna, in a grand concert given to all the first people of that imperial city, and by the best performers that could be selected. Gluck and his niece, a pupil of Millico, and an enchanting singer, were there, and the fungi, sometimes to her uncle's accompaniment on the harpsichord only, and sometimes with more instruments, in so exquisite a manner, that we could not conceive it possible for any vocal performer to be more perfect.

Between the vocal parts of this delightful concert, some admirable quartets, by Haydn, were executed in the utmost perfection; the first violin by Startzler, who played the adagio with uncommon feeling and expression; the second violin by Ordonitz, a good performer in the emperor's band; the tenor by count Brühl, one of the four sons of the great Saxon minstrel, an admirable dilettante, and fine performer on several instruments; and the violoncello by Weigle, the subject of the present article. All the performers
formers in this concert, finding the company attentive, and in a disfavour to be pleased, were animated to that true pitch of enthusiasm, with which, when musicians are themselves inflamed, they have a power of communicating to others their own order, and of letting all around in a blaze: so that the contention between the performers and hearers on this occasion was only who should pleae, and who applaud the mod.

WELLS, SYLVESTER LEOPOLD, a famous performer on the lute, born in Silesia, travelled into Italy in 1708, in the suite of prince Alexander Sobiesky, who dying at Rome, he was obliged to make his lute bear his expenses back into Germany, going first to Breslaw and afterwards to Dresden, where he was engaged in the service of the king of Poland, and became the most celebrated lutenist at that time in Europe. Germany has produced many eminent musicians of the name of Wells; as John Adolphus Faulmann, son of Sylvester Leopold, a lutenist likewise; C. Wells, a performer on the German flute, who visited London in 1783, an ingenious and curiously musician, who had improved his instrument, and had many curiously peculiarities in his performance.

WELDON, JOHN, an eminent musician, was born at Chichester, learned the rudiments of music of Mr. John Porter, organist of Eton college, and afterwards received instructions from Henry Purcell. He was for some time organist of New college, Oxon. But in 1701 he was appointed a gentleman extraordinary of the Chapel royal; and in 1708 succeeded Dr. Blow as one of his majesty's organists. In 1715, upon the establishment of a second composer's place in the king's chapel, Weldon was the first who filled that station, of which he seemed conscientiously determined to fulfil all the duties; for before he had long been in possession of this office, he gave proofs of his abilities and diligence in the composition of the communion service, as well as the several anthems required by the conditions of his appointment.

He was likewise organist of St. Bride's church in Fleet-street, and of St. Martin's-in-the-Fields.

Besides many favourite songs and solo anthems of the time, Weldon composed two full anthems, which are inserted in Dr. Boyce's second volume; the first is rather too familiar and common; but the second, "Hear my crying, O God," in six parts, is a very pleasing and masterly composition; particularly the first movement. In the second movement, the words up upon are unfortunately expressed by notes that succeed each other too rapidly for their easy utterance. The passages of the third and fourth movements seem much worn by forty or fifty years use; however, the pauses at the end of the last strain have a fine effect.

Six of his solo anthems were published about the year 1730: we say about that period, as musical chronology is become a very difficult study. The late Mr. Walsh, finding that old music-books were like old almanacs, ceased very early in this century to ascertain the time of their birth by dates, which have ever since been as carefully concealed as the age of antiquated virgins.

Weldon's powers of invention and of harmonic combination seem very much limited. His anthems had the advantage of being sung in the Chapel royal by a celebrated singer, Mr. Richard Ellford; but now, let who will execute them, they must appear feeble and old-fashioned, unless the embellishments of George L.'s time are changed for those in present use. The truth is, that the fund of original conception or science, which alone can render old music valuable to the curious, long after the style in which it was written is become antiquated and forgotten, was never very considerable in Weldon's productions. His first anthem, "O Lord rebuke me not," remained long in favour, when well sung in our cathedrals, from its resemblance to the style of Purcell; and the natural and easy flow of the voice is heard in "Turn thee, O Lord, and deliver my soul," which has so much of a peculiar song and roundel in it, that it is remembered with pleasure by the musical parts of a congregation, who are more likely to bear it in mind than more serious parts of the service.

The productions of Weldon appear fitly after those of Crofts; and Dr. Green's after Handel's: yet Green compared with Weldon is a giant; that is, a Handel.

There is a vice of which composers of small resources are often inadvertently guilty, for want of a sincere and judicious friend to tell them of it; and that is, eternal repetition of the same passage, a note higher or a note lower, which the Italians call rofalia. This certainly originates in the want of ideas, and yet it may be avoided by attention, though the sheet would not fall fo fast. Weldon has indulged himself in these repetitions to a tiresome degree in several of his anthems; but in the ritornel to "Have Mercy upon me, O God," he has iterated the fame poor passage a note lower seven times successively!

His song for two voices, "As I saw fair Clara walk alone," was in great favour some years ago; and his air in the Judgment of Paris, "Let Ambition fly thy Mind," is a melody so natural and pleasing, that, like an ever-green in vegetation, it will always be fresh and in season. And there is no air in greater favour than this at present, in the English opera of "Love in a Village," to the words, "Hope the Nurse of young Defire."

This composer died in 1736, and was succeeded in the king's chapel by the late Dr. Boyce.

WELLS, l. 1, r. L. and E.

WELLS, in Geography, a township of Rutland county, in Vermont, having 1040 inhabitants.

WELSH Music. If incredulity could be vanquished with respect to the account which Gervais Cambrensis gives of the state of music in Wales during the 12th century, (see Gervais Cambrensis,) it would be by a Welsh MS. formerly in the possession of Richard Morris, esq. of the Tower, which contains pieces for the harp that are in full harmony or counterpoint; they are written in a peculiar notation, and supposed to be as old as the year 1100; at least, it is the antiquity of many of the songs mentioned in the collection. But whether the tunes and their notation are coeval with the words, cannot easily be proved; nor is the counterpoint, though far from correct or elegant, of so rude a kind as to fortify such an opinion.

Some part of "this MS," according to a memorandum which we found in it, "was transcribed in the time of Charles I., by Robert ap Huw, of Bodwigen, in the isle of Anglesea, from William Penlyn's Book." The name of William Penlyn is recorded among the successful candidates on the harp, at the eisteddfod, or feession of the bards and minstrels, appointed in the ninth year of queen Elizabeth, at Caerwys in North Wales, where he was elected one of the "Chief bards and teachers of instrumental song." The title given to these pieces is "Muficae neu Beroraieth;" and a note in English informs us, that the manuscript contains "the music of the Britons, as set down by a congregation, or meeting of makers of music, by order of Gryffydd ap Cynan, prince of Wales, about the year 1100, with some of the most ancient pieces of the Britons, supposed to have been handed down to us from the British bards."

This music is written in a notation by letters of the alphabet, somewhat resembling the tablature for the lute;
but without lines, except a single line to separate the treble from the base.

In the notation, double $\text{f}$ seems the lowest; then the first seven letters of the alphabet are written thus, $g$, $a$, $b$, $f$, $e$, $c$, and the next septenary thus, with a dash over each letter, $g$, $a$, $b$, $c$, $d$, $e$. If these letters represent the same sounds as at present, we find some such chords as are admitted in modern harmony; but others frequently occur that are mere jargon.

Many of the bases, or accompaniments to the melodies, begin with the chord of C inverted, $\text{f}$. These chords and melodies are lessons for young practitioners on the harp, and are said to be the exercises and trial-pieces which were required to be performed by the candidates for musical degrees, and for the silver harp. Among the first twenty-four lessons of this kind, some few are easy to decipher, as No XI. and XVII., which we shall give here as specimens of this notation, explained in modern musical characters.

After twenty-four lessons, or measures, as they are called, of this kind, there follow twelve variations on a ground base.

This counterpoint, however artificed it may seem, is too modern for such remote antiquity as is given to it. The falsc 5th, from B to F, in the first example, has not been long allowed in harmony; and the unprepared 7th, from B to A, in the second example, is a crudity that has been but very lately tolerated.

That the ancient inhabitants of Wales were great encouragers of poetry and music, cannot be disputed, as many specimens of Cambro-British verisimilitude of undoubted antiquity still subsist; and that these poems, as well as those of ancient Greece and Rome, were originally sung and accompanied with instruments, is very natural and reasonable to believe; but that a rude and uncivilized people, driven into a mountainous and barren country, without commerce or communication with the rest of Europe, should invent counterpoint, and cultivate harmony, at a period when it was unknown to the most polished and refined inhabitants of the earth, still remains a problem of difficult solution.

Dr. Burney gives a farther account of this curious MS. in speaking of national music, and the establishment of musical games or contests in Wales, before any other music seems to have been much cultivated in the rest of the island, except the ecclesiastical or Gregorian chant, which the Britons, driven into the mountains of Wales by the Saxons, seem to have been very unwilling to receive from the Roman missionaries that were sent over to convert their conquerors. The British annals and songs ascribe with great resentment the slaughter of the monks at Bangor, by Ethelbert, king of Kent, to the instigation of Aulfin the monk, on account of their having refused to submit to the jurisdiction of pope Gregory, and the regulations he proposed.
WES

WELWIN, or WELWYN. In 1811, the parish contained 192 houses, and 1120 persons; viz. 567 males, and 563 females.

WEMYSS. In 1811, the parish contained 565 houses, and 3691 persons; viz. 1057 males, and 2634 females. This parish includes Buckhaven, E. and W. Coallows, Kirkland, Methil, E. and W. Wemyss, and the rest of the parish, containing 116 males, and 117 females.

WENDLING, J. BAPTIST, in Biography, an eminent performer on the German flute, in the service of the Elector of Hanover.

WENTWORTH. In 1811, the parish contained 178 houses, and 941 inhabitants.

WESTBURY, Westmoreland. In 1811, the township contained 256 houses, and 1086 persons; viz. 542 males, and 544 females.

Wigram, Gentleman. In 1811, this parish, containing five townships, viz. Felwell, Hylton, Monk-Weremouth, Monk-Weremouth Shore, and Southwick, contained 832 houses, and 6504 persons; viz. 2037 males, and 2567 females. The township of Monk-Weremouth contained 220 houses, and 1091 persons; viz. 457 males, and 634 females; and that of Monk-Weremouth Shore contained 458 houses, and 4264 persons; viz. 1815 males, and 2449 females.

WESTERLEY. Add-in Washington county, containing 1512 inhabitants.

WESTHAY, a town of Rutland county, in Vermont, having 679 inhabitants.

WESTMINSTER ABBEY. Its happy construction for music at the commemoration of Handel in 1754, appeared to be such as not only to overtop all the predictions of ignorance and fanaticism, but the conjectures of theory and experience. By some it was predicted that an orchestra so numerous could never be in tune; but even tuning to the noblest organ was for once grand, and producible of pleasing f安东尼ons. By some it was thought that, from their number and diaphane, they would never play in time; which, however, they did most accurately, and without the measure being beaten in the usual clumsy manner. By others it was prophesied that the band would be so loud, that whoever heard this performance would never hear again; however the sound of these multiplied tones arrived as mild and benign at the ears of the audience as they could from the feeble efforts of a few violins in a common concert-room. And, lastly, that from the immense size of the building, no single voice had the least chance of being heard by those who had places remote from the orchestra; but luckily this was so far from being true, that not a vocal breathing, however feeble by nature, or softened by art, was inaudible in any part of the wide-extended space, through which it diffused itself in all directions.

There was, doubtless, great propriety in saluting their majesties at their entrance with the Coronation Anthem, yet we could not help wishing that this performance, so different from all others, had opened with some piece in which every voice and every instrument might have been heard at the same instant; as such an effect might then have been produced as can never be obtained by gradation. Indeed the most sudden and surprising effect of this stupendous band was, perhaps, produced by simultaneous tuning; as all the fiend-like-instruments performed this air à double cordes, and these strings being all open, their force was more than equal to that of two fling-fling-strings upon two different instruments.

It is but justice to Madame Mara, in speaking of the effects of a single voice in this immense building, to record that she had not only the power of conveying to the remotest corner of this expanded structure, the softest and most artificial inflections of her sweet and brilliant voice, but of articulating every syllable of the words with such neatness, precision, and purity, that it was rendered as audible and intelligible as it could possibly have been in a small theatre by mere declamation.

The happy contrivance of Westminster Abbey for cherishing and preferring musical tones, by a gentle augmentation without echo or repetition, was demonstrated by no part of the commemoration performance more clearly than in that of Miss Abrams, whose voice, though sweet, of perfect intonation, and good quality, was not regarded as theatrical, but such as the Italians denominate bela voce de camera, yet in the solo air, which she sung with her usual taste and expression, her voice was rendered more audible in every part of that immense building, than it had ever been in any concert-room in London.

Giardini, the composer of the powerful tone of Fister's hautbois, which could even rival that of his own violin with all its force and sweetness, used to say that Fister had an impudence of tone, but it never produced a more full, rich, and sweet effect than in the solo parts of Handel's fourth hautbois concerto, which he performed with such taste and propriety, as must have convinced all those who heard him that his excellence was not confined to his own very original and ingenious productions. Indeed, one of the Commemoration wonders seems to have been the perfect manner with which the sweet and grateful tone of his single instrument filled the stupendous temple of our holy religion, in the performance of this concerto.

WEST PENN, in Geography, a township of Northampton county, in Pennsylvania, having 947 inhabitants.

WESTPHAL, in Biography, an eminent music merchant of Hamburg, one of the greatest publishers in Germany during the middle of the last century.

WHIFF. Add—See Pleuronectes puniatus.

WHITE, John, in Biography, a Quaker, at whose shop in Newgate-street ladies were furnished with straw hats. This worthy man was a great collector of ancient rarities, as well as natural productions of the most curious and extraordinary kind; no one of which, however, was more remarkable than the obliging manner with which he allowed them to be viewed by his friends and examined by strangers. Among his old books and MSS. he was in possession of a very scarce and valuable music-book, which once appertained to Dr. Robert Fayrfax, an eminent English composer during the reigns of Henry VII. and Henry VIII.; it was afterwards in the possession of general Fayrfax, and upon his demise became a part of the Thoreby collection, at the sale of which it was purchased by honest John White.
WODFORD, in Geography. In 1811, the parish contained 379 houses, and 1914 persons; viz. 891 males, and 1023 females.

WODFORD, in Lincolnshire. In 1811, the parish contained 179 houses, and 821 persons; viz. 379 males, and 442 females.

WODFORD, in Norfolk. In 1811, the parish contained 112 houses, and 494 persons; viz. 254 males, and 240 females.

WITCHCRAFT. Add—Dr. Henry More published a curious tract, entitled "Antidotes against Atheism," in which he undertakes to prove the being of a God from the existence of witches, and the power which they possess.

See his biographical works.

WITHERITE, col. 2, l. 9, add—The known repositories of this substance are very limited; but it has been observed by Mr. Aikin, in great abundance, in the lower part of a lead-mine in Shropshire, where it occurs in irregular masses, which weigh from forty to two or three hundred pounds, imbedded in heavy fpar. The miners call this substance "yellow fpar;" not that this is its real colour by day-light, but its transparency is so considerable, that if a lighted candle be placed behind a mass of it, the whole will glow with a yellowish light, by which circumstance the miners distinguish it from "heavy fpar." This latter from the looseness of its texture, being in large masses quite opaque. The colour of the witherite is white, with a slight tinge of yellow; its fracture is hard, iridescent, approaching to straight foliated; it is for the most part massive. Mr. Aikin observed only one specimen that presented any indications of a regular crystalline form. In other particulars it agrees with the usual description of this substance. 100 parts of this witherite yields, Carbonate of barytes - - 96.3

- of fluorites - - 1.1

Sulphate of barytes - - 0.9

Silis - - - - 0.3

Alumine and oxyd of iron - - 0.25

99.95

WITTENA-GEMOTE, l. 14 from the bottom, r. concomitantes.

WODANUM, in Chemistry, the name of a metal recently discovered by Lampadius. This metal was obtained from a species of pyrites, named by Breithaupt Wodan-kis, or wodon pyrites, formed at Topfchau, in Hungary, and which had hitherto been considered as an ore of cobalt. The specific gravity of this mineral is 5.102. Its lustre is metallic. Its colour dark tin-white, paling into grey or brown. Hitherto it has only occurred mafive, and in that state it is full of cavities. Its fracture is uneven. It is brittle and easily frangible, and in hardnefs furpafles fluor fpar, but is inferior to apatite. This mineral contains about 20 per cent. of the new metal united with sulphur, arsenic, iron, and nickel.

Wodanium has a bronze-yellow colour similar to that of cobalt glance, and its specific gravity is 11.470. It is malleable. Its fracture is hackly; it has the hardnefs of fluor fpar, and is strongly attracted by the magnet. It is not tarnished by exposure to the atmosphere at common temperatures, but when heated it is converted into a black oxyd.

The solution of this metal in acids is colourlefs; or at leaft has only a slight wine-yellow tinge. Its hydrated carbonate is likewise white. The hydrate of it precipitated by caustic ammonia is indigo blue.

Neither the alkaline phosphates nor arseniates occasion any precipitate when dropped into a faturated solution of this metal in an acid, neither is any precipitate produced by the infusion of nut-galls. A plate of zinc throws down a black metallic powder from the solution of this metal in muriatic acid. Prussiate of potash throws down a pearl-grey precipitate, &c.

Nitric acid diffolves with facility both the metal and its oxyd, and the solution yields colourlefs needle-form cryftals, which readily diffolve in water.

Such at present is all we know of this metal, and the ore containing it. The name wodanum has been given from the old Saxon divinity, Woden.

WOODVILLE, in Geography. Add—Dr. Woodville, always anxious for the promotion of science, and no lefs disposed to serve the friends whom he esteemed, favoured the editor with several botanical articles for the Cyclopaedia.

WOOLCOTT, in Geography, a town of Orleans county, in Vermont, having 124 inhabitants.

WOOLLET, William, in Biography, a very eminent engraver, was born at Maidstone, in Kent, Aug. 27, 1735, and educated in his native town. In early life he exhibited specimens of his graphic talents, which being seen by Mr. Tuney, an engraver, occasioned his being taken by him as an apprentice. His advancement in his profession was very rapid, and so distinguished, that he contributed in a very high degree to the perfection of landscape-engraving. He was also singularly successful in the exercise of his art on historical subjects and portraits. So established and so permanent has been his fame, that the best impressions of his prints, particularly those of "Niobe" and "Phaeton," "Cebanod and Amelia," "Clytie and Aletes," "The Fidler," "Vandyke's Portrait of Rubens," "The Death of General Wolfe," and "The Battle of the Boyne," whenever they occur in collections, are highly appreciated.

The world was deprived of this eminent artist at the age of 50. His death, which occurred at his house in Upper Charlotte-street, Rathbone-place, May 23, 1783, was announced to the public with the following tribute of respect to his memory: "To say he was the first artist in his profession would be giving him his least praise, for he was a good
a good man. Naturally modest and amiable in his disposition, he never cenfured the works of others, or omitted pointing out their merits: his patience under the continual torments of a most dreadful disorder upwards of nine months was truly exemplary; and he died, as he had lived, in peace with all the world, in which he never had an enemy. He has left his family inconsolable for his death, and the public to lament the loss of a man whose works (of which his unflaming temper never baulfed) are an honour to his country. An elegant monument was erected to his memory in the cloisters of Westminster-abbey.

WOOLWICH, col. 3. l. 11. — The cadets, who are instructed at the royal military academy, were sent for some years to the military college, then at Marlow, now at Sandhurst, as a preparatory school; but that plan, being found attended with disadvantages, was abandoned. The institutions at Woolwich and Sandhurst are now therefore entirely independent; and we may add, that they are different in their nature, and are intended for very different purposes. The institution at Woolwich is confined solely to the instruction of young gentlemen intended for the artillery and engineer service; that at Sandhurst is supplementary, and designed for the instruction of such as are destined for any other branch of the military service of Great Britain. The education at Woolwich is free of expense, except the little that is incurred by the purchase of the first uniform. The cadets at Sandhurst pay a certain sum annually, bearing an allotted proportion to the rank of their parents, and being only free, as we conceive, in cases where the cadets are orphans, or their fathers in bankrupts.

Z INJAN, in Geography, a town of Perä in the province
of Irak, distant 21 miles, and bearing about N.W. by
W. of Suzann. This is a large and prosperous town, capital
of the extensive district of Khumfah, under the government
of one of the king's sons. From hence to the banks of the
Kizibozian, or golden stream, the distance is 71 miles over
an uneven country, full of deep ravines.

ZOLLIKOFER, George Joachim, in Biography, an
eminent German divine and popular preacher, was born at
St. Gall in Switzerland, Aug. 7th, 1730. His father,
who was a practitioner in the law, much esteemed for his
integrity and piety, took great care of his education, and
by his own counsel and example directed the course of his
moral conduct; nor were any of his efforts for the pro-
cracy of his son in knowledge and virtue unavailing. As
he was intended for the clerical profession, he was removed,
at an early age, from the gymnasium of his native town,
first to Bremen, and afterwards to the university of Utrecht,
where the theological professors were held in high estima-
tion. Our young student, however, soon discovered that
a college education was ill adapted to his aspiring mind; as,
in his opinion, it was very unfavourable to all exertions
of genius and originality of thought, by levelling the distinc-
tions of nature, by restraining the intellectual capacities to
a blind veneration for authorities, and preposterously mis-
leading the judgment so as to take the means of instruction
for its end. Pusillanimous a native vigour of mind, which dif-
tinguished him through the whole course of his life, he
resolved, whilst he attended the public lectures with the rest
of the scholars, to cultivate his talents and to pursue his
inquiries in his own way. Instead of paying implicit de-
ference to systems and summaries of theology, drawn up
in technical and scholastic phraseology, he made scripture
and reason his guide, and, as he says in a letter to a friend,
"I privately applied myself to the Bible, together with a
close investigation of ecclesiastical history; for I found it
impossible for me to submit to the trammels of the schools,
where derivative doctrines are uniformly transmitted, with-
out examination, by the successive tutors from generation
to generation, &c." In the other sciences, as well as in
theology, he expresses his dissatisfaction with the means
of instruction that were then adopted and invariably practiced
in the public schools. "The little which I know," as
this modest man was heard to say, "I was obliged to teach
myself, chiefly after I arrived at years of maturity; for
indeed I had but a miserable education." This is not the
language of pride and pedantry; as his attention was
directed to a variety of researches, which, in his youth, the
state of education in Germany would furnish him with no
extraordinary advantages; and as he is known to have
excelled in various departments of general literature and
science, besides theology. His attainments in natural his-
tory and natural philosophy were very considerable; with
the histories, ancient and modern, of the several nations of
the world he had cultivated an extensive acquaintance,
and in the ancient and modern languages, particularly the
Latin, French, and English, he was no ordinary proficient;
having made the works of the best poets, orators, and phi-
losophers, the subjects of his particular study. Of Cicero
he is said to have been a great admirer; and his eloquence
was formed upon the model of that of this celebrated
Roman orator. "Oh, my beloved Zollikofer!" says Zim-
mermann (on Solitude), "what delightful experiences I am
constantly feeling of the truth of those lessons you delivered
at Leipzic; those truly useful doctrines, which, disregard-
ing a cold and barren theology, inculcate wise and virtuous
precepts, that warm and amend the heart. On quitting
your auditory, the man of business forgets his vexations,
pours his anxieties into the bosom of friendship, furrenders
his feelings to the charms of consolation, until his heart is
dilated with new hopes and his inquietudes are so far suf-
fended as to enable him to sustain their return with fortu-
tude, or to dispel them with courage. The industrious man
abandons his recondite and laborious researches, escapes
from the labyrinth, and finds in the innocent and simple
satisfactions of his family and dependants more real content
and happiness than even art and science could afford them."
"—"Men, in short, of every cast and character, here find by
degrees the mind's blest calm, and learn to put on the pure
spirit of the gospel of Christ."

Soon after he had finished his academical course, he
settled, as a preacher, at Murten in the Pays de Vaud;
and in a little while removed to a more considerable place at
Monstein in the Grisons, and afterwards to Ichenburg. But
neither of these places afforded sufficient range for his
talents and zeal; and therefore in the year 1758, at the
age of twenty-eight, he accepted an invitation to be one of
the German preachers at the church of the evangelically
reformed at Leipzic. In this connexion he availed himself
of the opportunity which his moderate labours afforded
him, of giving that perfection to his discourse which was
the object of his wishes. Accordingly, the universal appro-
bation which he received on the part of his numerous con-
gregation from his first settlement constantly augmented
from
ZOLLIKOFER.

from day to day, and adhered to him to the very last hour of his addressing them. A considerable number of young members of the university eagerly preffed to hear his discourses, learning from him, by example, how a subject should be studied and discussed, in order to contribute, in any remarkable degree, to the advancement of wisdom and virtue among mankind by the oratory of the pulpit.

It is therefore natural to hope, that Zollikofe's genius will continue to operate not only throughout his native country, but likewise over many provinces of Germany, by means of thes he styles, who are thus prepared for differentiating truth, and virtue, and happiness among their fellow-creatures to the latest posterity.

Several volumes of his excellent discourses have for some years been in the hands of the public, and are in high and deserved repute wherever the German language is understood, by all persons to whom religion and virtue are objects of serious concern; to which the number of editions through which they have passed, and which are continually published, bear ample testimony, as well as the taste and judgment of the times with regard to compositions of this nature. A German writer says, that "Zollikofe was one of the first pulpit orators of his time. His sermons were distinguished by clearness of ideas and warmth of feeling. In regard to form, they were the most complete productions of the kind which had appeared, at that time, in Germany. The diction is copious and varied; the periods harmonious, and the whole acquires great animation from the connection of the ideas and the transitions." Of his theological creed we can form no decided opinion. His discourses are practical, and not controverfal; and it must be allowed that whatever were his sentiments on disputed topics, they are adapted to inform the understanding, to improve the heart, and to regulate the temper and conduct. Some have suspected that he belonged to the modern German school of theologians. Professor Eichorn pronounces his eloquence in the following strain: "Zollikofe, on account of the philosophical colouring combined with popularity, which he knew how to give to his discourses, was an orator for the highest ranks. He unfolded the doctrines and principles of Christianity with philosophical accuracy; exhibited them in a concise and impressive manner, clothed in pure and simple language, without artificial ornament; and endeavoured to affect the heart by convincing the judgment."

Zollikofe, considering that psalmody and prayer form an essential part of public worship, undertook to make a collection of spiritual songs for the use of his congregation, on a plan more suitable to the purpose, and more edifying than the old one. In doing this he availed himself of the advice and afflance of his judicious friends, both in regard to the improvement of the forms, and to the proper selection of hymns from the modern poets, particularly Gellert, Cramer, and Klopstock. This performance appeared in the year 1766. His discourses and prayers for the use of public and family worship were published in 1777, and were followed in 1785 by his exercises of devotion and prayers for the private use of reflecting and sincere Christians. The Rev. W. Tooke, F.R.S. has done great service to the cause of rational religion, by the translation of 10 vols. 8vo. of Zollikofe's Sermons, and of his Devotional Exercises in 1 vol. 8vo.

Having said so much concerning the professional character and performances of Zollikofe, we cannot forbear adding a few particulars from the account that lies before us, with regard to his private and social disposition and conduct.

"In humility and retirement, he purified his path of life; never willing to shine, his only aim was to be useful; because in the exercise of that fierna virtue which he taught he found his supreme delight. The poor and destitute, especially those of his congregation, beheld in him a father and a friend; though his bounty was not by means confined to them, it also extended to those of other communions, relieving them either by his own donations or through application to others."—"His advice, his judgment, his intercourse with others, his admonitions, his consolation in misfortune, were at the service of all who applied for them, and he even went before their requests. Young men desirous of knowledge, eagerly sought his acquaintance, and all those who enjoyed that benefit have honestly confessed, that they derived from it material improvement both in heart and mind. Whatever he said was true; every word he uttered might be relied on as conveying the real sentiments of his heart; arrayed in the simple majesty of truth, he bought no other covering: and never did he commend or approve from complaisance any thing that was contrary to the conviction of his own mind, or that he saw could not be approved upon the strictest rules of morality. His gravity was attractive and engaging, charity itself was in its smiles, his conversation entertaining, often animated, his equal cheerfulness amiable and insouciant, and his raillery, in which he very rarely indulged, the mildest possible. To a very considerable compass of literary attainments and great brilliancy of imagination, were added in the character of Zollikofe, the most undeviating rectitude, the most amiable disposition, and the most prepossessing manner. The whole tenor of his life was one pure, uninterrupted, captivating harmony of virtue, and the sweet enjoyment of the felicities arising from it. Among his other satisfactions he had that of being universally esteemed, of necessity it could not be otherwise. That happy mixture of serenity and dignity with gentleness and affability; his own strict course of virtue combined with so much indulgence and candour towards the failings of others; his heartfelt and firm conviction of the great truths he taught, which manifested itself in all his actions, in the whole tenor of his conversation as well as in his discourses from the pulpit, without entertaining the slightest intolerance towards such as differed from him in opinion, or arrogating the smallest superiority over those who professed not the faculty of thinking for themselves, or of fully comprehending every truth; his unwearied zeal to lead his auditors to the rigorous exercise of virtue, in his demands however never disregarding the rights of humanity concerning what they could or could not do in these or other circumstances; his impartial estimation of mankind, justly discriminating the opinions and principles upon which they acted, carefully tracing out their good qualities, and heartily rejoicing in every advantageous discovery of that nature—let the reader contemplate all this as combined in the character of Zollikofe, and then pronounce, whether real undistinguished veneration, the general esteem of all ranks and classes of persons must not as insensibly have attended his wisdom and virtue as the shadow follows the substance. Even the wanton wit of those who, in the judgments they pass on the ministers of religion, are not ashamed to set aside the respect that is due from man to man, was awed into silence at the name of Zollikofe."

He was twice married, and in both connections he was truly happy, though both proved childless. For about a year before his death his faculties began to decline, and he wished to resign his office of preacher, and to retire to the place of his nativity in Switzerland; but at the request of his congregation, who for the sake of retaining him expressed their willingness to be satisfied with one discourse in a fortnight, he was induced to remain in his station. At length within a few weeks before his death he was obliged to devolve
devolve the charge of preaching on another person. His last illness was very painful; but he bore it with the patience of a philosopher, and the resignation of a Christian, looking by a steady eye of faith and hope beyond the grave to a world of retribution. He obtained a release on the 22d of January 1788, and was buried on the 25th. The whole of his numerous congregation, together with some hundreds of young students of the university, and numbers of his auditors of the Lutheran communion, attended his remains to the grave, with every token of unfeigned sorrow.

### ANALYSIS.

#### Palpable Arithmetic and Writing.

I. Fig. 1. Digits or Figures
2--8. Arithmetical Tables, &c. &c.

II. Fig. 7--9. Nepers's Bones. *See Miscellany, Plate I.*

### ALGEBRA.

**Palpable Arithmetic and Writing.**

I. Fig. 1. Cifloid.
2--9. Conchoid
10--20. Contraction

(The figure numbered 20 is not the proper one. The figure referred to is inferred in Geometry, Plate IX. fig. 2. Construction.)

II. Fig. 21, 22. Cotesian Theorem
23. Crown
24. Curve, Caustic
25. Dia-caustic
26. Characteristic, Triangle of a

Fig. 18. Element
3. 4. Cylinder. *(These figures are referred to in Geometry, Plate IV.)*

### ANALYSIS.

#### IV. Curvature

I. Fig. 1--16. Curve

(This Plate is numbered VI. and referred to as Plate VI. under the article Curve.)

V. Fig. 1--8. Cycloid

(Fig. 1--8. have also been engraved by mistake on a separate Plate, under the head CYCLOID.)

9--11. Epicycloid

VI. Fig. 1--10. Evolute

(This Plate is numbered V. and referred to as Plate VI. The reference in the article EVOLUTE, to fig. 35, in this Plate, should be to fig. 2.)

### VII. Fluxion

5. Analytic Function

(This is a wrong figure inferred by mistake. The proper figure is in Geometry, Plate IX.

6--8. Analytic Function

4 R 2
ANATOMY.

I. Organs of Sense

EYE. Plate I. Fig. 1—5. (Plate I.* fig. 1—5. The same in Outline)

II. Eye. Plate II. Fig. 1—11. (Plate II.* fig. 1—11. The same in Outline)

III. Eye. Plate III. Fig. 1—15. (Plate III.* fig. 1—15. The same in Outline)

IV. Eye. Plate IV. Fig. 1—5. (Plate IV.* fig. 1—5. The same in Outline)

(IV.) Eye. Plate IV. Fig. 4. (This is fig. 4. of the preceding Plate, on a larger scale, and therefore not numbered as a separate Plate.)

ANATOMY, COMPARATIVE.

I. & II. Fig. 1—3. Anatomy of Birds

III. Fig. 1. 2. Skeleton (Numbered Plate IX.)

I—III. Anatomy of the Horfe

IV. Stomach

Inteclines

The other Plates referred to in the several articles on Comparative Anatomy, comprized in the former part of the Cyclopaedia, including the articles FEATHERS, FISHES, HAIR, HORNS, INCUBATION, MAMMAL, &c. are unavoidably omitted. Dr. Mac CARTNEY, by whom these articles were furnished, has stated that "he has found it impossible to procure, within any reasonable time, the drawings required for those Plates, in conformation of his removal from London, and of the indispensible occupations attending the laborious duties of his present professorship in the University of Dublin;" the editor has deemed it preferable, upon the whole, in this dilemma, to omit these Plates altogether, rather than to give them in an imperfect and unconnected manner; especially as he could not have given them, even in this defective state, without charging the work with a heavy additional expense, and further delaying its completion to a distant and indefinite period. He has had the less difficulty in coming to this determination, in conformation of no reference to Plates having been made in any of the articles on Comparative Anatomy, since Dr. Mac CARTNEY's removal to Ireland deprived the editor of his assistance in this department.

ARCHITECTURE.

I. Fig. 1. Attic Bafe, Temple of Jupiter Olymplus at Athens

2. Temple of Minerva Polias at Athens

3. Doric Bafe, according to Vignola

BASSO RELIEVO—HOROLOGY.

Plate

Bark-Beds, and Pits. See Gardening, Plate I.

BASSO RELIEVO.

I. Fig. 1. An Egyptian Hieroglyphical Sphinx
2. A Hindu Bass-relief
3. A Persian Ditto
4. Jupiter with a Thunder and Trident

II. Fig. 1. Hercules and Apollo contending for the Tripod
2. Minerva fabduing Hercules

III. The Tomb-robe of Xanthippos

IV. Fig. 1. Capital of a Column in the Well-door of the Cathedral of Carrara

(This part of the Plate, fig. 1, is also in Architecture, Plate XL.)
2. Zethus and Amphion comforting Antiope, their Mother

(These Altars are referred to as Miscellany, Plate I. No. 1-5.

BLEACHING.

I. Fig. 1, 2. Bucking
3. 4. Oxy-chloric Acid

II. Fig. 1-7. Washing and Clearing

III. Fig. 1-4. Drying

IV. Fig. 1-7. Boiling Pan, &c.

BLOCK MACHINERY.

I. Fig. 1-4. Sawing Machine
II. Fig. 1-3. Crown Saw
4-9. Coating Engine

III. Fig. 1, 2. Riveting Hammer
3-7. Face-turning Lathe

IV. Fig. 1-4. Boring Machine
5-9. Cornering Saw

V. Fig. 1-6. Mortising Machine

VI. Fig. 1-5. Shaping Engine

VII. Fig. 1-5. Scoring Engine
6, 7. Machine for making Dead Eyes

BOATS.

I. Pahie, &c.
II. Life Boat

(See Ships, Plate VII.)

(Camp, Construction of

(Ther article has been superseded by the article
Whole Moulding, in Ship Building, to

which the reader is referred.)

Vol. XXXIX.

CANALS.

Plate XXXIII. Fig. 1. Graham’s Zenith Sector
2. Ramden’s Zenith Sector
3-6. Dollond’s Zenith Micrometer

Plate CAMP.

I. Plan of a Roman Consular Camp, according to Polybius

II. Plan of the Camp of a Roman Army, according to the Hyginian System of Castrametation

(This is referred to under Castrametation, as Plate of Castrametation, fig. 1-3.)

III. Plan of the Encampment of a Park of Artillery

(This Plate is headed Artillery, Encampment; and referred to under Castrametation as Castrametation, fig. 4.)

IV. Profiles of Lines of Circumvallation, according to Vauban

Lines of Circumvallation, with Camp
Plan of a Part of the Line of Circumvallation at Phillipsburg, in 1734
Plan of a Part of the Line of Circumvallation at Arras, in 1654

(This Plate is headed Circumvallation, Camp, V. It is referred to under Camp, as Military, Plate V. and under Circumvallation, without a name.)

V.-XII. Situations proper for the Encampment of Armies, and for Engagements

(The last four Plates, there being two subjects on each Plate, are referred to under Castrametation, as Castrametation, fig. 4, 5, &c.)

CANALS.

I. Fig. 1. Level Cutting
2, 3. Side-lying Ground
4, 5. Embanking
6-13. Deep Cutting
14. Puddling
15. Lining
16-18. Reservoirs

II. Fig. 19. Aqueduct Bridge at Kelvin, on the Forth and Clyde Canal. Plan

20. Transverse Section
21. Elevation

III. Cast Iron Aqueducts

Fig. 22. Mr. Telford’s, on the Shrewsbury Canal at Long
23, 24. Mr. Fulton’s

IV. Fig. 25. Embankment
26. Safety Gate
27. Weir
28, 29. Circular Weir
30. Pile Planks
31-35. Iron Railways
CASTING.

Plate IV. Fig. 40-42. Canal Bridges
(See Plate VI. to which the reference ought to have been made.)

V. Fig. 36, 37. Locks
38, 39. Gates

VI. Fig. 40-42. Canal Bridges

VII. Fig. 43. Swing Bridge
44-47. Rollers, &c. for Ditto
48-52. Navigators' Tools
Map of the Canals, Navigations, and Railways of Great Britain
(Given in the Atlas, Vol. VI. of the Plates)

CANDLE MAKING.
Fig. 1. Apparatus for Dipping
2. Wick Broach
3. Machine for cutting Cotton
4. Tallow Ciftern for Mould Candles
5. Mould Frame
6. Mould
7-12. Candle Sticks

CANNON.
I. Fig. 1. Whole-length Cannon
2. Caeable
3. Muzzle
4. Mortar
5. 6. Sea Ditto
7. Howitzer
8. Land Mortar
9. Sea Mortar
10. Howitzer
11. Mortar
12. Stone Mortar

II. Fig. 13-16. Cannon Boring

III. Fig. 17-21. Cannon Boring, &c.

CANTEENS.
I. Fig. 1. Canteen
2, 3. Cross-cutting Saw
4, 5. Tenating or Rebating Saws
6. Bung Stave
7. Boring Machine
8. Center Bit
9. Slider

II. Fig. 10. Frame
11. Screw Hoop
12. Truf Hoop
13. Screw Hoop applied to a Canteen
14. Turning the Chime
15. Turning the Head
16, 17. Shears
18. Punching the Hoops
19. Rounding the Ends of the Hoops

CASTING.
I. Fig. 1, 2. Open Sand Cafting
3. Trowel
4. Ramming Tool
5. Lifting Screw
6. Sand Cafting between Flasks

CHEMISTRY.

Plate I. Fig. 7-10. Method of Cafting Cog Wheels
11-13. Moulds, &c. for Loam Cafting

CASTMETATION. See Camp.

CHEMISTRY.
I. Fig. 1, 2. Cupalo Furnace
II. Fig. 1-5. Still
II. Fig. 1. Blaff Furnace (For fig. 4. read fig. 6.)
6-9. Iron Smelting Furnace
III. Fig. 10. Alcohol
10-13. Alembic
14. Aludel
IV. Fig 15-26. Furnaces for the Reduction of Antimony
V. Fig. 27, 28. Wolfe's Apparatus
VI. Ditto
VII. Fig. 1-4. Destillation
VII. Fig. 1-4. Blast Furnace
VIII. Fig. 1-4. Ditto
IX. Fig. 1-6. Ditto
(The reference to Plate IX. fig. 4. under this article as "the Ground-plan of arch, pillars, hearth, &c. of a Blast Furnace," should be to Plate X. fig. 4.)

X. Fig. 1-10. Blast Furnace
X. Fig. 1-3. Blowpipe (See Plate XIV. fig. 5-7.)

X. Fig. 1. Hope's Eudiometer
(See Plate XXI. fig. 1.)
2. Pepys's Eudiometer
(See Plate XXI. fig. 2.)

XI. Fig. 1-7. Blow-pipe

XI. Ancient Chemical Characters.

XI. XII. Blast Furnace Works, Plan and Section

XII. XIV. Blast Furnace Works

Fig. 1. Section of the Building
2. Dam Stone
3. Dam Plate
4. Tymp Plate
1. 2. Water Regulator

XIV. Blast Furnace Works

XIV. Gasometer and Blow-pipe

Fig. 1. Hydraulic Bellows
2. Air Holder
3. Bell
4. Gas Holder
5. Glas Blower's Lamp
6. Shoe Lamp
7. Double Blow-pipe
(Fig. 5, 6, 7, are referred to as Plate X. fig. 1, 2, 3.)

XV. Fig. 1, 2. Air Vault

XVI. Laboratory

Fig. 1. Stand with the Apparatus
2. Retort
3. Acid Holder
4, 5. Receiver
6. Bended Tube
7. Adopter
8. Receiver
10. Nooth's Apparatus
11. Dr. Hamilton's Apparatus
COMPOSITION.

Plate

XVI. Fig. 12. Part of Nooth's Ditto enlarged
16. Pneumatic Trough
17. Supporter
18. Eudiometer Tubes
19. Mercurial Trough
20. Glass Jar
21. Iron Ring Supporter
22. Volta's Eudiometer
23. Evaporating Vessel
24. Mattraps
25. Proof Glass
26. Precipitating Glass
27. Gas Bottle
28. Muffel
29. 30. Crucible
31, 32. Crucible Stands
33. Cupel
34. Separatory Funnel
35. Iron Retort

Laboratory

XVII. Fig. 9. Apparatus for the Absorption of Gases
13, 14. Simplified Gafometer
15. Pepys's Gafometer

XVIII. XIX. (No Plates of these Numbers)
XX. Fig. 1—3. Apparatus for the Diffusion of Pyrogenous Acid

XXI. Fig. 1. Hope's Eudiometer
(Referred to as Plate X., fig. 1.)
2. Pepys's (or Davy's) Improvement of Volta's Eudiometer
(Referred to as Plate X., fig. 2.)
3. Gay Lussac and Thenard's Apparatus
4. Berzelius's Apparatus for the Analysis of Organic Substances
5. Dr. Wollaston's Scale of Chemical Equivalents.

CHIARO-SCURO.

(See Composition, Plate II.)

CHIMNEY-SWEEPING.

(See Miscellany, Plate II.)

CLOUDS.

I. No. 1. Cirrus in different Forms
2. Cirro Stratus subsiding on Cumuli beneath
3. Cirrus as seen before Thunder
4. Cirro Cumulus as seen before Thunder
5. A Nimbus flanked by Cirro Stratus, and giving an electrical Discharge
6. A Range of Cumuli passing to Cumulo Stratus before Thunder

II. No. 1, 2. Cirro Stratus
3. Cirrus passing to Cirro Cumulus
4. Cirro Stratus, Cumulus, and Cumulo Stratus, grouped

COMPOSITION.

I. Fig. 1. The "Battle of the Standard," by Leonardo da Vinci

COTTON MANUFACTURE.

Plate

I. Fig. 3. The "Creation of Man," the "Transgression at the Tree of Knowledge," and "the Expulsion from Paradise," — Frescoes of Michelangelo in the Sistine Chapel

II. 2. "The Cartoon of Pisa," (or, according to Vafari, its chief Group,) by Michelangelo
5. "Paul preaching at Athens," from the Cartoon of Raffael;e at Hampton Court

CHIARO-SCURO.

1. The simple Principles of Chiaro-Scuro illustrated
2. The Conduct of Correggio in the Distribution of his Mafies of Light and Shade exemplified in one of his Compositions in the Duomo at Parma
3. An Example from Rubens
4. Rembrandt

CONICS.

I. Fig. 1. Ambigtenal
2, 3. Asymptote
4—10. Cone
(The reference to truncated cone, fig. 8, should be to fig. 9.)
12. No. 2. (See fig. 3.)
20. Abfiffe (See fig. 2.)
31, 32. Axis (See Geometry, Plate IX., fig. 5, 6.)
33. Asymptote (The figure thus referred to is in Geometry, Plate IX., fig. 4.)

II. Fig. 1—9. Conic Sections; lines harmonically divided
10—14. Conic Surfaces

III. Fig. 15—23. Sections
IV. Fig. 24—31. Ditto
V. Fig. 31, 32. Axis (See Geometry, Plate IX., fig. 5, 6.)
32—43. Conic Sections

VI. Fig. 44—55. Sections

VII. VIII. Fig. 1—13. Ellipse
VIII. IX. Fig. 14—26. Ditto
X. Fig. 1—12. Hyperbola
XI. Fig. 13—21. Ditto
XII. Fig. 1—16. Parabola

COTTON MANUFACTURE.

I. Fig. 1—6. Calico Printing
II. Fig. 1—5. Batting Machine
III. Fig. 1—5. Deviling
IV. Fig. 1—4. Carding Machine
V. Fig. 1—4. Drawing Frame
VI. Fig. 1, 2. Roving Can Frame
3, 4. Winding Block
(The number has been omitted on this plate.)

VII. Roving Frame
Horizontal Plan of the Machine called the Double Speeder
DIALLING.

PLATE

VIII.

Roving Frame, Double Speeder

Fig. 1-3. Elevation in Front
(This, like the preceding, is numbered Plate VII.)

IX.

Fig. 1-6. Water Spinning Frame

X.

Fig. 1-3. Throttle Spinning Frame

XI.

Fig. 1-5. Mule Spinning

XII.

Fig. 1, 2. Reeling

3-5. Machine for winding sewing Cotton into Balls

XIII.

Fig. 1, 2. Doubling Machine

3-4. Twisting Machine

Sections of Miers. Strutt's Cotton Mills at Belper

Fig. 1. Longitudinal Section

2. Crof Section

3. Section of the Wing

CRISTALLOGRAPHY.

(See Plates, Vol. V. Natural History)

CUTLERY.

1. Fig. 1. Two Troughs of a Grinding Mill
2, 2.* Tongs for preffing Knife-Handles
3. Preffing Vice
3. Spring Drill
(This is the only Plate of Cutlery)

CYCLOID.

Fig. 1-8. (By mistake these figures have been twice engraved. See Analysis, Plate V. fig. 1-8. to which the reference is made in the letter-prefix)

DIALLING.

1. Fig. 1. Declinater
1.* Ruler of the Declinater
2, 3. Declinater
4. Equinoctal Dial
5. Universal Equinoctal Dial
6, 7. Universal Dial
8-12. Horizontal Dial
13. Vertical South Dial
11. Fig. 14. Vertical North Dial
15. South Dial
16. East Dial
17, 18. Polar Dial
19. Dial on three Planes
20. Dials (primary)
21, 22. Vertical declining Dial
23. Inclined Dial
24. Universal Mechanical Dial
(For fig. 25, 26, see Plate IV.)

III.

Fig. 27, 28. Cylindrical Dial
29, 30. Portable Dial
31-33. Universal Dial on a Crofs

IV. Fig. 25, 26. (of Plate II.) Moon Dial
34, 35. Ring Dial
36. Tide Dial (See Miscellany, Plate XXV. fig. 10.)
36, 37. Dials constructed by a Globe
38-41. Dialling Cylinder
42. Dialling Scales

ELECTRICITY.

PLATE

DOCKS.

Docks at Liverpool, 1808
Docks at London, 1808

DRAWING.

I. II. III. Fig. 1, 2. Outlines of the Human Face
3. Shading, Hatchings
4, 5. Outlines of the Human Face
6. Shading, Hatchings

IV. Iffs Magna Mater

V.-VII. (No Plates of these Numbers)

VIII. From an original Drawing by G. Pouf

IX.

Ditto

X. Landscape from an original Drawing of Claude Lorraine

DRAWING INSTRUMENTS.

I. Fig. 1-11. Compasses
(For fig. 5, see Plate TURNING, fig. 29.)

I.* Fig. 1. Peacock's Delineator
2, 3. Mifs Edgeworth's Ditto
4, 5. Ramfden's Optigraph, by Jones
6, 7. Wollafton's Camera Lucida

II. Fig. 1, 2. Oval
3-6. Farey's Elliptograph
7. Douglas's reflecting Protractor

ELECTRICITY.

I.* Fig. 2. Teyler's Battery
(This Plate is referred to as Plate I. fig. 2.)

3. The Frame separate
(See Plate XV. fig. 7.)

4. The Whole Battery
(As this so nearly resembles the Battery represented in Plate I.* it has been deemed unnecessary to give it on a separate Plate.)

Bell (See Plate V. fig. 38.)

II. Fig. 4-9. Condenfers

III. Fig. 10-20. Difchargers
21-25. Cavallo's doubler

IV. Fig. 26-37. Electrical Experiments

V. Fig. 38-50. Ditto

VI. Electrical Configurations
(This Plate is not numbered)

VII. & XIV. (One Plate.) Fig. 51, 52. Electrical Experiments. Electrical Flyers
53, 54. Inflammable Air-Piftol
55. Volta's Inflammable Air-Lamp

Fig. 1, 2. (XIV.) Electrophorus

VII. Fig. 1, 2. Hawkfbee's Electrical Machine
3. Abbe Nollet's Machine
4. Dr. Watson's Ditto
5. Mr. Wilfon's Ditto

VIII. Fig. 6-9. Electrical Machines

IX. Fig. 10. Mr. Beccaria's Machine
11. Common Machine
12. Nairne's Ditto
18. Van Marum's Ditto
(Referred to as on Plate XI.)
PLATE

X. Fig. 13. Nairne’s Machine, with a Person electrifying his Shoulders
14. Ditto, his Leg
15. 16. Pearson’s Machine
18. (See Plate IX.)
XI. Fig. 22. Cuthbertson’s Electrical Machine (This is numbered Plate X.)
XII. & XIII. Fig. 1—12. Electrometers
13—15. (Plate XIII.) Ditto
XIII. Fig. 16—23. Electrometers
XIV. Fig. 1, 2. Electrophenus (On Plate VII. & XIV.)
XV. Fig. 1. Medical Electricity. Machine for electrifying the Teeth
2. 3. Thunder-House
4. 5. Torpedo
6. Bruh
7. No. 1, 2. Inside Connecting Frame of Tevler’s Battery (Referred to as Plate I. fig. 3.)

ENGINE.

I. Fig. 1—7. Salmon’s Weighing Machine (This is numbered Plate II.)
II. Fig. 1—3. Cutting Engine, by Hindley
III. Fig. 1—5. Ditto
6—12. Rope Engine, by Holtzapfell and Deycrien
IV. Cutting Engine, by Rehe
V. Fig. 1, Ditto, for Worm Wheels
2. Annular Wheels
3. Short Arbor
4. Engine for Racks
5. Cutter Arbor
VI. Fig. 1—6. Cutting Engine, by Rehe, for sharpening Cutters
VII. Ramden’s dividing Engine, Perspective View
VIII. Fig. 2—4. Ramden’s dividing Engine
IX. Fig. 5—14. Ditto
X. Engine for cutting the Screw of Ramden’s Circular dividing Engine
Fig. 1. Elevation
2. Plan
XI. Engine for cutting the Screw of Ramden’s straight Line dividing Engine
Fig. 1. Plan
2. Elevation
XII. Fig. 1—3. Ramden’s Engine for dividing straight Lines

ENGRAVINGS, EARLY BRITISH.

Fig. 1. From the front of King Alfred’s Jewel
2. Impression from the engraved Seal of Anfelm, the Primate
3. Engraved Balfson the Tomb of William de Fulbourn, in Fulbourn Church, Cambridgehire

FLAGs.
(See Heraldy, Plate VII.)

FORTIFICATIONS AND TACTICS.

PLATE

FARRIERY—Horse-Shoeing.

I. Concave Fore-shoe, or S. Bell’s Shoes
Racing Hind-shoe
Fore-shoe
Seated Fore-shoes
Froil-shoe
Shoe to prevent cutting
Hind-shoe
Fore-shoe with a Joint in the Toe (This is the only Plate of Farriery.)

FEATHERS.
(See above, under Anatomy, Comparative.)

FENCES.

XIX. (The Plate so entitled and numbered is Agriculture, Plate XIX.)

FORTIFICATION AND TACTICS.

I. II. & IV. Fig. 1. Angle at the Centre
1. Battion, &c.
2, 3. Cavalier
4. 5. Expense Magazine
(These figures have been omitted, as unnecessary in a Work of this nature.)
6—14. Field Fortification (See Plate III.)

(II.) Fig. 1, 2. Flank of an Army (The writer of this article in the Cyclopaedia died without furnishing the figures. They are not, however, essential to the understanding of the description.)
1. 2. Battery
(Fig. 1. on Plate II. is the figure referred to in the article Battery, as fig. 21. No. 2. Fig. 2 is the figure referred to as 23. No. 2.)
3. Battery on Barre, or Barbet (Fig. 3. is the figure referred to as Plate III. fig. 25.)

III. Fig. 1—4. Echellon.
5. Enfilade
6—14. Field Fortifications (Referred to as on Plate I.)

(IV. on Plate I.) Fig. 1—3. Breastwork. (These figures have been omitted, as the nature of Breastwork will be sufficiently understood by the view of the figures of Battery, on Plate II.)
4—10. Fort

V. Fig. 1—6. Constriction
VI. & VII. Fig. 7—14. Ditto

VIII. Fig. 15. Belidor’s Method (This figure is on the Plate marked Fortification, Plates VI. VII. VIII.)
(The articles in which these figures are referred to, were written by Mr. Glennie, and the descriptions were taken from an unpublished work of his own. He died without furnishing the figures.)

V. Fig. 1. 2. Irregular Fortification
3. Profile of a Fortification
4. Fortified Place

### MONOGRAMS OF THE ENGRAVERS OF THE LOW-COUNTRIES.

**Plate III.**

- John William Baur
- Gerard Lairesse
- John Ulric Kreuz
- Andrea Meyer
- J. J. Thourneyton
- Derick Meyer
- Rodolph Meyer
- Adrian Van Otride

**Plate IV.**

- Christian Louis Moyart
- Nicholas Berghem
- Peter Nolpe
- Nicholas Viftcher
- Peter Quaif
- John George Van Vliet
- Antonio Waterlo
- Henry Vanduer Borcht
- Peter Vanduer Borcht
- Theodore Van Keffel
- Abraham Genoels
- Herman Van Swanevelt
- John de Bifchop or Epifcopius
- Lewin Cryly
- Bartholomew Bremainburgh
- John Van Somer
- James Vanden Hayden
- Robert Van Audenarde
- A. F. Bargas
- John Van Hugtenbourg
- Peter Van Bleeck
- William Buteniveg
- John Vanden Bruggen
- William de Leeue
- John Von Londerfeil
- Herman Muller
- Peter Serwouters

### MONOGRAMS OF ITALIAN ENGRAVERS.

**Plate III.**

- J. Ant. de Brete
- Andrea Mantegna
- Nicolas da Moenda
- Agostino of Venice
- Domenico Beccafermi
- Jerome Moccet
- Leo Daris or Lion Davin
- Marc Antonio
- Marc of Ravenna
- Julio Bonalone
- Domenico Barbiere
- Nicholas Beatrice of Lorraine
- Lucas Penni
- Jean Baptifi Ghiff
- George Ghiff of Mantua
- Adam Ghiff

- Boldrini
- Martin Rota
- Antonio Fantuzzi
- J. J. Caragio
- Antonio Salamanca
- Galpar ab Avibus
- J. Baptifi Cavaleris
- Mario Kartaro
- Jaques Palma
- J. Baptifi Pagi
- Francefchi
- Cherubino Alberti
- Andrea Andreani
- Jean Louis Valfio
- Amiabil Caracci
- Antonio Tempefta
- Odoard Fialetti
- Louis Cefli
- Francifco Villamens
- Guido Reni

**Plate IV.**

- Simon Paffa
- Christopher Van Sicinom
- Hafncr John Bol
- Cornelius Van Sicinom
- John Sadeler
- Philip Galle
- Cornelius Cort
- Nicholas de Bruyn
- Affuerus Louderfel
- Jerome Wierix
- Abraham de Bruyn
- Zachary Dolendo
- Paul Morelfe
- Karl Van Sicinom
- James Matham
- James de Ghein the elder
- John or Hans Saenredam
- Bartholomew Dolendo
- William Saenredam
- Henry Hondius
- Abraham Bloemart
- Joif Hondius
- Lucas Vorfterman
- William Hondius
- David Teniers
- Cornelius Bleeker
- Michael Natalis
- Sheltius à Bolswert
- Efais Vandevelde
- Albert Flamen
- Adam à Bolswert
- Peter Molyn

MUSIC.

I.
Modern Time Table
Characters for Time

II.
Arpeggio
Ancient Musical Characters of the 14th and 15th Centuries
Arrangement of the Set of Keys on Keyed Instruments

II.
Thorough Bass, or Accompaniment

III.
Thorough Bass

IV.
Difallowances in Thorough Bass

V.
Counterpoint

VI.—VIII.
Fugues

IX.—XI.
Fundamental Basses

XII.
Regle de l'Oktave, in four parts

XIV.—XVI.
Counterpoint, preparation and resolution of Difcord

XV.
Double Counterpoint in the Oktave

XVIII.—XX.
Contrapunto doppio in genere Cromatico

XXI. XXII.
Modulation

XXIII.
Modulation

Rouffeu's regular Modulation in the Key of C major

Kirnberger's two essential Chords

Examples of the first Use of Difcords

XXIV.
Modulation

XXV. & XXVI.
Example of the pathetic Genus, in which are expressed its Successions in the Chromatic Scale ascending and descending

Acciacuscere (One Plate, numbered XXV.)

XXVII.
Fingering on Keyed Instruments

XXVIII.
Iteration in Fingering

XXIX.
Fingering of Semitonic or Chromatic Divisions

XXX.
Shakes

XXXI. & } Balloon

Scale of the Balloon

(One Plate, numbered XXXII.)

XXXIII.
Air upon Three Notes, by the late M. Rouffeu

MUSICAL INSTRUMENTS.

Plate XXXIV.—XLIV. (It was originally intended that these Plates should comprise selections from the works of Haydn and Mozart, and specimens of the national airs of several countries, viz. Italian, English, Scottish, Irish, Welsh, &c.; but as most or all of these subjects are easily accessible, it has been deemed unnecessary to insert them here as so heavy an additional expense)

XLV. Original Melodies to the Hymn of Offan in Temora

XLVI. (No Plate of this number)

XLVII. Euclidis Sectio Canonis

XLVIII. Canon in Ogni Modo

Canone Canticzando

Complete Set of Keys on the Piano Forte

MUSICAL INSTRUMENTS.

I. Ancient Musical Instruments

Fig. 1. Timbrel or Tambour de Basque

2. Citharifria, or female Minstrel

3. Double Litus

4. Pan playing on the Syrinx

5. A Bacchanal playing on two Flutes of the same Pitch, tibia pares

6. 7. Antique Theatrical Masques

8. A genuine ancient metallic Litus

II. Ancient Musical Instruments and Masks

Fig. 1. A Greek Barbiton or Harp

2. Mask of the Hercules furen of Eupides

3. Mask of Thais from Terence's Eunuch

4. A Figure from the Herculaneum Paintings

5, 6. Lyres from Sir W. Hamilton's Vases

Ancient Musical Instruments

III. Ancient Musical Instruments

Fig. 1—3. Group of Musicians performing an Epithalamium, from a Piece of Ancient Sculpture in the Ghigi Palace at Rome

4. The Tuba, or Trumpet of the Jubilee

5. Cupid playing on a double Flute, or tibia pares

6—10. From Egyptian paintings in the Tombs of the Kings of Thebes

Ancient Musical Instruments

IV. Ancient Musical Instruments

Fig. 1, 2. The Tefoduo, or Lyre of Amphinon, front and profile

3. Lyre of Terpsichore, in the Picture of that Mufe, dug out of Herculaneum

4. Psalterio from the Picture of Erato, dug out of Herculaneum

5. Trigonon, or Triangular Harp

6. Abyssinian Tefudo

7. Etruscan Lyre with seven Strings

8. Lyre in an ancient Picture dug out of Herculaneum, on which Chiron is teaching young Achilles to play

9. An Egyptian Sylfrum

10. An ancient Lyre richly ornamented

Indian Musical Instruments

V. Indian Musical Instruments

Fig. 1. From an original Indian Painting

2. The Been, an Indian Musical Instrument

VI. Pandean Minstrels in performance at Vauxhall

VII. Welsh Harps

Single Harp
MUSICAL INSTRUMENTS.

Plate VII.
Ancient Triple Harp
Modern Triple Harp
(For Guitar, referred to this Plate, see Plates IX. XIII. & XV.)

Plate VIII.
Fig. 1—5. Origin of the Bow
Ruskin Musical Instruments
Goudk Rebec with three strings
Gaita
Double Flutes of the Ancients
Rok, or Hunting Horn of Siberia
Rojok
Batalika, Guitar with two strings

Plate IX.
Fig. 1. Harp of Brian Boromh
3. Silver Prize Harp
4. Bell Harp

Plate XI.
Fig. 1. English Common Flute
2. German Flute
3. Improved Ditto, with additional keys
4. 5. Hautboys
6. B Fife
7. C Fife
8. English Flageolet
9. Gong
10. Tabour
11. Pipe

Plate XII.
Fig. 1, 2. Hunting Horns
3. Serpent
4. French Horn
5. Bugle
6. Sacbut or Trombone

Plate XIII.
Fig. 1. Arch Lute
2. Mandoline
3. Mandola

Plate XIV.
Fig. 1. Violin
2. Bow
3. Sordine or Mute
4. Violoncello
5. Violino Piccola, or Kit
6. Viol de Gamba of the 16th Century

NAVAL ARCHITECTURE.

Plate XV.
Fig. 1. Viol d'Amour
2. Mandore
3. Spanish Guitar
4. Lute

Chinefe Musical Instruments
Ching
King
(See Miscellany, Plate I. fig. 8, 9.)

Plate XVI.
Draught of a Ship of 74 Guns
Sheer Plan
Half-breadth Plan
Body Plan
Perpendicular View of the Stern
Disposition of the Frame of a Ship of 74 Guns
Frame
Profile of a Ship of 74 Guns, inboard work
Plans of a Ship of 74 Guns
Plan of the Gun Deck
Orlop
(Numeroed Plate VI.)
Plans of the Quarter Deck, Forecastle, and Upper Deck of a Ship of 74 Guns

Plate XVII.

Plate XVIII.
Fig. 1—12. A Ship of 76 Guns, laying off B

Plate IX.
Fig. 1—12. A Ship of 74 Guns, laying off C

Plate XII.
Fig. 1—8. A Ship of 74 Guns, laying off D

Plate XII.
An East Indiaman

Plate XIII.
Royal Sovereign Yacht

Plate XIV.
Fig. 1—3. Scale of Tons
4—8. Whole Moulding
3—6. Hill's Machine for drawing Ships' Bolts
(See also Mechanics, Plate XXII. XXIII.)

PLATES. VOL. IV.

NAVIGATION—WRITING BY CIPHER.

Plate I & II.
Fig. 2, 3. Meridional Parts
(Referred to as Plate II. fig. 8, 9.)
4—8. Tide
(Referred to as Geography, Plate I. fig. 10—14.)
7. Forestaff
(See Astronomical Instruments, Plate I. fig. 3.)

Plate II.
Fig. 1—3. Hadley's Quadrant, theory of
4. Sinical Quadrant
5, 6. Rhumb Line
7. Variation
8, 9. Ditto
(Referred to as Analysis, Plate XIII. fig. 1, 2.)
8, 9. Meridional Parts
(See Plate I. fig. 2, 3.)
OPTICS.

Plate (II.) Fig. 10. Nocturnal (See Astronomical Instruments, Plate I. fig. 6.)

II. & IV. Fig. 1—4. Rudder
5—18. Plain Sailing
Fig. 19. Great Circle Sailing
20—23. Parallel Sailing
24, 25. Mercator's Sailing
26—34. Great Circle Sailing

III. Fig. 1, 2. Traversing Sailing
3—6. Current Sailing
1—3. Naval Tactics
(Referred to as Naval Tactics, Plate I. fig. 1—5.)
5—10. Trigonometry
(Referred to as Trigonometry, Plate III. fig. 1—5.)

NOTATION.
Plate of Arithmetical Characters
(See Miscellany, Plate I. fig. 7.)

OIL MILL.
Smeaton's Oil Mill
1. Plan
2. Elevation

OPTICS.

I. Fig. 1. Aberration
2—4. Angle
5. Burroughs's Machine, Perspective View
(Referred to as Plate II. fig. 4 & 5.)
13. Altitude
(See Plate IV. fig. 11.)

II. Fig. 1—3. Parker's Burning Lens
4, 5. Burroughs's Machine
(See Plate I. fig. 5.)

III. Fig. 1—7. Camera Obscura

IV. Fig. 1, 2. Catoptric Cistula
2*—4. Dioptrics
5, 6. Dispersions of Light
8. Focus
(Referred to as Plate V. fig. 2.)
9. Looking Glasses
(Referred to as Plate IX. fig. 10.)
10—13. Shadow
14—16. Visible
17. Vision

V. & VI. (V.) Fig. 1. Virtual Focus
2. Eye
2. Focus
(See Plate IV. fig. 8.)
3—7. Grinding Machine

(VI.) Fig. 5—11. Lens

VI. Fig. 1. Heliohota
2. Bed of Horns
3. Horopter
4. Refraction
(This figure is not numbered)

VII. Fig. 1—12. Lens

OPTICS.

Plate
VIII. Fig. 1—12. Lens
IX. Fig. 1—9. Light
10. Looking Glasses
(See Plate IV. fig. 9.)

X. Fig. 1—3. Magic Lantern
4. Apparent Magnitude
5—11. Micrometer

XI. Micrometer
Fig. 1. Dr. Malkelyne's
2—4. Troughton's
5. Herfel's Lamp Micrometer
6. Ditto, the arm enlarged
7. & 8. Ditto, the lamp open with the weight W
9. Ditto, the lamp shut
(Figs. 7, 8, 9. are not numbered on the Plate)

XII. Microscope
(Referred to as Plate XII. fig. 1.)

XIII. Microscopes
Fig. 1. Marshall's
2. Culpepper's
3—4. Reflecting Microscope
5. Dr. Smith's Ditto
6—8. Solar Microscope
(For Mirror, see Plate XV.)

XIV. Compound Microscope
1—4. Adam's
5—11. B. Martin's

XV. Fig. 1. Incidence, Inclination
2—18. Mirror
18. Micas Volantes
19. 20. Centering Object Glasses
21. Opera Glasses
22. Optical Inequality
23—24. Parhelion
(Referred to as Plate XVII. fig. 8, 9.)

XVI. Microscope, (See Plate XVI.)

XVII. Fig. 1—8. Optometer, &c.
9. Optic Place
10. Pencil of Rays
(The reference to fig. 11, under Place, in Optics, should be to fig. 9.)
11, 12. Polyhedron
(Referred to as fig. 12, 13)
12. Polemofcope
13. Polyoptum
(Referred to as fig. 14.)
14. Reflection
15. Refractibility
(For Parhelion, see Plate XV. fig. 23, 24.)

XVIII. Rainbow, Refraction
Fig. 1—9. Rainbow
10—24. Refraction of Light

XIX. Fig. 1—15. Refrangibility of Light
XX. Fig. 1—4. Shadow
(See Optics, Plate IV. fig. 10—13.)
5—7. Visible
(See Plate IV. fig. 14—16.)
8. Vision, theory of
(See Plate IV. fig. 17.)
PLANEYRARY MACHINES.

PLATE

ORGAN.
I. Fig. 1—13. Detached Parts

WRITING BY CIPHER.

I.—III. Characters and Examples
PLATES. VOL. V.

NATURAL HISTORY.

GENERAL SYSTEMATIC ARRANGEMENT OF THE PLATES OF
NATURAL HISTORY,

INCLUDING THE THREE KINGDOMS OF NATURE, ACCORDING TO
THE SYSTEM OF LINNÆUS.

*"* The Arabic Numerals on the Left, denote the Number of the Plates, according to the Systematic Arrangement of them in the Catalogue.

PLATE ANIMALS.

CLASS MAMMALIA.

ORDER I. Primates.

Genus Homo

1* Homo Sapiens, Rational Man
   (See Plates Painting)
   Anatomical Structure
   (See Plates Anatomy)

2* Varieties of Homo Sapiens, Rational Man, according to Climate
   a Americanus, American Man
   b Europæus, European
   γ Asiaticus, Asiatic, (of Palestine)
   δ Afer, African
   (See Painting, Plate III.)

Genus Simia.

1. Lettered Mammalia, Order I. Primates, Plate I.
   Fig. 1. Simia Satyrus, Black Oran Otan, or Outang, Homo Sylvestris, var. Pongo
   2. — var. Jocko, Chefnut Otan, or Outang
   3. Simia Troglohyes, (Gmel.) Satyrus indicus Tulipii. Chimpanzee
   4. Simia Lar, (Gmel.) Long-armed Ape
   5. Simia Inuus, Barbary Ape
   6. Simia Sylvanus, Pigmy Ape

Genus Lemur.

2. Lettered Mammalia, Order Primates, Genus Lemur, Plate II.
   Fig. 1. Lemur Potos, Tarier Lemur
   2. Lemur caudatus, Tailfes Lemur, or Maucauco
   3. Lemur murinus, Murrine Lemur
   4. Lemur Catta, Ring-tailed Lemur, or Maucauco
   5. Lemur tardigradus, Loris Lemur
   6. Lemur volans, (Linn.) Flying Lemur, or Flying Colugo?
   * Genus Galeopithecus (Rufus) Audebert

Genus Vespertilio.

3. Lettered Mammalia, Genus Vespertilio, Plate III.
   Fig. 1. Vespertilio Vampyrus, Vampire Bat
   2. Vespertilio auritus, Long-eared Bat
   3. Vespertilio Spasma, Cordated Bat
   4. Vespertilio leporinus, Peruvian Bat
   5. Vespertilio Spetrum, Speëtre Bat

Order Brute.

Genus Bradypus.

4. Lettered Class Mammalia, Order Brute, Genus Bradypus
   Fig. 1. Bradypus tridactylus, Three-toed Sloth
   2. Bradypus didactylus, Two-toed Sloth

Vol. XXXIX.
NATURAL HISTORY.

Genus Myrmecophaga.

4. Fig. 3. Myrmecophaga didactyla, Two-toed or small Ant-Eater
4. Myrmecophaga tetradactyla, Four-toed Ant-Eater
5. Myrmecophaga jubata, Great Ant-Eater

Genus Ornithorinchus.

Fig. 6. Ornithorinchus paradoxus, Duck-bill
Platypus anatinus, (Shaw,) Duck-billed Platypus

Genus Manis.

5. Lettered Mammalia, Quadrupeds, Genus Manis
Fig. 1. Manis pentadactyla, (Linn.) Five-toed Manis, or S. short-haired Manis
2. Manis tetradactyla, (Schreb.) Four-toed Manis, or Long-tailed Manis

Genus Dasypus.

3. Dasypus hexadactylus, Six-banded Armadillo
4. Dasypus novemcincus, Nine-banded Armadillo
5. Dasypus duodecemcinus, (Schreb.) Twelve-banded Armadillo
Dasypus uncinus, (Linn. et Gmel.) Ditto

Genus Rhinoceros.

Fig. 1. Rhinoceros unicornis, One-horned Rhinoceros
2. Rhinoceros bicornis, Two-horned Rhinoceros

Genus Sukotyro.

(A doubtful genus not admitted by Gmelin)

7. Lettered Quadrupeds, Genus Sukotyro
Fig. 1. Sukotyro indicus, Sukotyro
(From Nieuhoff, the Dutch traveller, and Churchill's Collection of Travels)

Genus Elephas.

Fig. 2. Elephas maximus, Elephant

Order Feræ.

Genus Trichechus.

8. Lettered Quadrupeds, Claws Mammalia, Genus Trichechus
Fig. 1. Trichechus Rufus, Arctic Walrus, or Morfe
2. Trichechus Manatus, 2 borealis, Whale-tailed Manatus

Genus Phoca.

Fig. 3. Phoca Ursina, Ursine Seal
4. Phoca gristlandica, Harp Seal
5. Phoca Viulina, Sea Calf, or Common Seal
6. Phoca maculata, Kurile or Spotted Seal

Genus Canis.

9. Lettered Quadrupeds, Dogs, Plate II. of Order Feræ
Fig. 1. Canis familiaris, Shepherd's Dog?
2. Dingo, Australasian, or New Holland Dog
3. Canis familiaris, var. Pomeranian Dog
Canis 2 pomeranus, Ditto
4. Canis var. Sibericus, Siberian Dog
5. Canis var. Iceland Dog?
6. var. Aquaticus minor, Small Barbet, or Water Dog
7. var. Aquaticus, Great Barbet, or Water Dog

10. Lettered Quadrupeds. Plate III. Dogs, Genus XV. Canis
Fig. 1. var. brevipilis, King Charles's Dog
2. var. brevis, Bull-dog
3. var. Egyptius, Naked or Turkish Hound
4. var. fricoter, Dog
5. var. Spaniel
6. var. Shock
7. var. variegatus, Small Dane
8. var. Lion, Lion Dog
9. var. hybridus, Roquet

11. Lettered Quadrupeds, Plate V. Dogs, Genus XV. Canis
Fig. 1. var. Anglicus, Mastiff
2. var. Melufus, Bull-dog
3. var. Senior, or Harlequin Dog
4. var. Dalmatian Dog

12. Lettered Quadrupeds, Dogs, Plate IV. of Order Feræ, Genus XV. Canis
Fig. 1. Old English, or Tallot Hound
2. Beagle
3. Harrier
4. Blood Hound

13. Lettered Quadrupeds, Dogs, Plate V. of Order Feræ, Genus XV. Canis
Fig. 1. Stag Hound
2. Fox Hound
3. Larger Terrier
4. Smooth Terrier
5. Rough Terrier

14. Lettered Quadrupeds, Order Feræ, Genus Canis
(No number on the Plate)
Fig. 1. Canis Lupus, Wolf
2. Canis Hyæna, Striped Hyæna
3. Canis Mesomelas, Cape Jackal
4. Canis Vulpes, Common Fox
5. Canis Lagopus, Arctic Fox

Genus Felis.

15. Lettered Quadrupeds, Plate I. Genus Felis, Lions
Fig. 1. Felis Leo, Lion, Lioness, and Young
### PLATE

16. Lettered Quadrupeds, Plate II. Order 3; Genus Felis
   - Fig. 1. *Felis Tigris*, Tiger
   - 2. *Felis Pardus*, Panther
   - 3. *Felis Leopardus*, Leopard

17. Lettered Quadrupeds, Genus Felis, Tigers, Plate II.
   - Fig. 1. *Felis Puma*, Congourar
   - 2. *Felis Lynx*, Lynx
   - 3. *Felis Uncia*, Ounce
   - 4. *Felis Caracal*, Persian Lynx
   - 5. *Felis Onca*, Jaguar
   - 6. *Felis jubata*, Hunting Leopard

18. Lettered Quadrupeds, Plate III. of Order Feræ, Genus Felis
   - Fig. 1. *Felis pardalis*, Ocelot
   - 2. *Felis Tigrina*, Margay
   - 3. *Felis Serval*, Serval
   - 4. *Felis Catus*, Wild Cat
     - α *femur*, Tame or domesticated
     - β *femur*, Tortoiseshell Cat
   - 7. *Felis γ angorensis*, Angora Cat
   - 8. *Felis ε caeruleus*, Slate-coloured Cat, (Blue or Chartreux.)

### GENUS VIVERRA.

19. Lettered Quadrupeds, Order Feræ, Genus Viverra (No number on the Plate)
   - Fig. 1. *Viverra Zibetha*, Zibet, or Indian Musk Weasel
     - 2. *Viverra Fossa*, Fossa
     - 3. *Viverra Ichneumon*, Ichneumon Weasel
     - 4. *Viverra Najus*, Brazilian Weasel
     - 5. *Viverra Ciretta*, Civet Weasel, or Civet-Cat, African Musk Weasel

20. Lettered Quadrupeds, Order Feræ, Genus Mysleta (No number on the Plate)
   - Fig. 1. *Mysleta Lutris*, Sea Otter, Greater Otter
   - 3. *Mysleta Foina*, Martin
   - 4. *Mysleta Zibellina*, Sable, or Fisher Weasel

### GENUS Ursus.

21. Lettered Quadrupeds, Order Feræ, Genus Ursus (No number on the Plate)
   - Fig. 1. *Ursus Americanus*, American Bear
     - 2. *Ursus maritimus*, (Gmel.) Polar Bear
     - 4. *Ursus Malea*, (Schreb.) Glutton
     - 5. *Ursus Metas*, Badger

### GENUS Didelphis.

22. Lettered Quadrupeds, Genus Diadelphis, &c. (No number on the Plate)
   - Fig. 1. *Didelphis Opus* (Gmel. Schreb.) Virginian Opossum
     - Didelphis Virginia (Shaw) Ditto
     - 2. *Didelphis petaurus* (Shaw) volans, New Holland Flying Opossum
     - 3. *Didelphis Murina*, Murine Opossum

### PLATE

22. Fig. 4. *Macropus Kanagurta, a. male, b. female*

### GENUS MACROPUS.

23. Lettered Quadrupeds, Order Feræ, Genus Talpa, &c. (No number on the Plate)
   - Fig. 1. *Talpa Capensis*, Cape Mole
     - 2. *Talpa longicaudata*, Long-tailed Mole
     - 3. *Talpa Europæa*, European Mole

### GENUS SOREX.

24. Lettered Quadrupeds, Order Glires, Genus Hystrix (No number on the Plate)
   - Fig. 1. *Hystrix erithaca*, Common or crested Porcupine
     - 2. *Hystrix prehensilis*, Brazilian Porcupine
     - 3. *Hystrix cristata*, Canadian Porcupine (white variety)

### GENUS CAVIA.

25. Lettered Quadrupeds, Order Glires, Genus Castor (No number on the Plate)
   - Fig. 1. *Castor Fiber*, Common Beaver

### GENUS MUS.

26. Lettered Quadrupeds, Order Glires, Genus Arctomys, &c. (No number on the Plate)
   - Fig. 1. *Arctomys Citillus*, (Schreb.) Variegated Marmot
     - 2. *Arctomys Empeira*, Canadian Marmot

### GENUS SCIURUS.

27. Lettered Quadrupeds, Order Glires, Genus Sciurus (No number on the Plate)
   - Fig. 3. *Sciurus Petaurista*, Taquan, or Taguan flying Squirrel, Sailing Squirrel (Penn.)
     - 4. *Sciurus getulus*, Barbary Squirrel
     - 5. *Sciurus vulgaris*, Common Squirrel

**NATURAL HISTORY.**
NATURAL HISTORY.

**Plate**

**Genus Myoxus.**

26. Fig. 6. *Myoxus Myocardium* (Schreb.), *Mus arcellinarus* (Linn.) Common Dormouse. — (Donov. Brit. Quadr.)

**Genus Dipus.**

27. Lettered Quadrupeds, Order Glires, Genus Dipus (No number on the Plate)

Fig. 1. *Dipus Jaculus*, Common Jerboa (or Gerboa)
2. *Dipus Sagitta*, Arabian Jerboa
3. *Dipus cafer*, Cape Jerboa

**Genus Lepus.**

Fig. 4. *Lepus timidus*, Common Hare

**Genus Hyrax.**

Fig. 6. *Hyrax Catapha*, Cape Hyrax

**Order Pecora.**

**Genus Camelus.**

28. Lettered Quadrupeds, Order Pecora, Genus Camelus (No number on the Plate)

Fig. 1. *Camelus Dromedarius*, Arabian Camel or Dromedary
2. *Camelus Bactrianus*, Bactrian Camel

**Genus Moschus.**

29. Lettered Quadrupeds, Genus Mofchus (No number or order on the Plate)

Fig. 1. *Mofchus moschiferus*, Thibet Musk
2. *Mofchus pygmeus*, Guinea Musk
3. *Mofchus javanicus*, Java Musk

**Genus Cervus.**

4. *Cervus Alices*, Elk

30. Lettered Quadrupeds, Genus Cervus (No number or order on the Plate)

Fig. 1. *Cervus Tarandus*, Rein Deer
2. *Cervus Elaphus*, Stag or Hart
3. *Cervus Axis*, Spotted Axis

**Genus Camelopardalis.**

4. *Camelopardalis Giraffa*, Giraff, or Camelopard

**Genus Antilope.**

31. Lettered Quadrupeds, Genus Antilope (No order or number on the Plate)

Fig. 1. *Antilope Rupicapsa*, Chamois
2. *Antilope Cervicapra*, Antelope
3. *Antilope pygmeus*, Royal Antelope, or Pigmy Antelope
4. *Antilope Grimming*, Guinea Antelope
5. *Antilope Gnu*, Gnu

**Plate**

**Genus Capra.**

32. Lettered Quadrupeds, Genus Capra (No order or number on the Plate)

Fig. 1. *Capra Ibes*, Ibes Goat
4. *Capra Aegagrus*, (var. mormbica) Syrian Goat
5. *Capra Aegagrus*, (var. angorenis) Angora Goat

**Genus Aries.**

33. Lettered Quadrupeds, Genus Ovis, Aries (No order or number on the Plate)

*Aries, Ovis*, Common Sheep
var. South Down Polled Sheep of the improved breeds. From the Stock of the late Duke of Bedford, Woburn

34. Lettered Quadrupeds, Genus Ovis, Sheep (No order or number on the Plate)

*Aries, Ovis*, Common Sheep
Fig. 1. var. Norfolk Breed
2. Hereford Breed

**Genus Bos.**

35. Lettered Quadrupeds, Genus Bos, Taurus (No order or number on the Plate)

*Bos, Taurus*, Ox
Fig. 1. var. Scottish Wild Ox, the Bull
2. The Cow and Calf

36. Lettered Quadrupeds, Genus Bos, Taurus (No order or number on the Plate)

*Bos, Taurus*, Common Ox
var. Long-horned or Lancashire Breed

**Order Belluae.**

**Genus Equus.**

37. Lettered Horses, Plate I. (No order on the Plate)

*Equus Caballus*, Horse
Fig. 1. var. Shetland Poney
2. var. English Cart Horse

38. Lettered Quadrupeds, Order VI. Belluae, Genus Equus (No number on the Plate)

*Equus Caballus*, Horse
var. Suffolk Agricultural Punch Horse
var. Suffolk Mare and Foal, from the Stock of the late Duke of Bedford

39. Lettered Quadrupeds, Genus Equus (No order or number on the Plate)

*Equus Caballus*, Horse
Fig. 1. var. Race Horse, Royalist
2. var. The Hunter Skylark
Plate

Genus Hippopotamus.
40. Lettered Quadrupeds, Genus Hippopotamus (No number on the Plate)
   Fig. 1. Hippopotamus amphibius, Hipppopotamus

Genus Tapir.
Fig. 2. Tapir Americanus, Tapir

Genus Sus.
41. Lettered Quadrupeds, Genus Sus (No number on the Plate)
   Fig. 1. Sus Scrofa, (ferus a) Wild Hog
   2. Sus Babyrufis, Babyrufa
   3. Sus Æthiopicus, Æthiopian Hog
   4, 5. Sus Scrofa, (domesticus 6) Domesticated Hog

Order Cete.
Genus Monodon.
42. Lettered Mammalia, Order Cete, Genus Monodon, &c. (No number on the Plate)
   Fig. 1. Monodon Monoceros, Narwhal, or Narval
   (Sometimes Sea Unicorn, or One-toothed Monodon, so rarely having two teeth, that only a single example of the kind is known. Donov. Muf. Vide Donov. Brit. Quadrupeds)

Genus Balæna.
Fig. 2. Balena Myftecetus, Great Myftecete, or Common Whale
   3. Balena Boops, Pike-headed Whale

Genus Physeter.
43. Lettered Mammalia, Order Cete, Genus Physeter (No number on the Plate)
   Fig. 1. Physeter macrocephalus, Blunt-headed Cachalot
   2. Physeter, var. gibbosus, (Schreb.) Gibbous Cachalot

Genus Delphinus.
Fig. 3. Delphinus Phocena, Porpoise
   4. Delphinus Delphis, Dolphin

ORNITHOLOGY.

CLASS II. AVES.

Order Accipitres.

Genus Vultur.
44. Lettered Division I. Land Birds, Plate II. (No number on the Plate)
   Fig. 1. Vultur Gryphus, Megallanic Condur, or Condor

Genus Falco.
   2. Falco Chrysaetos, Golden Eagle
   3. Falco gentilis, Falcon Gentil
   4. Falco fahbbuto, Hobby

Genus Strix.
44. 5. Strix Bubo, Great Horned Owl, or Eagle Owl

Order PICÆ.
Genus Psittacus.
45. Lettered Division I. Land Birds, Plate I. Order Picæ
   Fig. 1. Psittacus Macron, Red and blue Macaw
   2. Psittacus Alexandri, Alexandrine Parrot
   3. Psittacus Æflorus, var. Amazon Parrot
   4. Psittacus garrulus, var. Ceram Lory
   5. Psittacus Moluccensis, Great red-crested Cockatoo
   6. Psittacus Banksii, Bankfian Cockatoo
   7. Psittacus pullarius, Ethiopian Parrot

Genus Ramphastos.
46. Lettered Division I. Land Birds, Plate II. Picæ (No number on the Plate)
   Fig. 1. Ramphastos picirurus, Brasilian Toucan
   2. Ramphastos Aracari, Green Toucan, or Aracari

Genus Buceros.
Fig. 3. Buceros Rhinoceros, Rhinoceros Horn-bill

Genus Buphaga.
Fig. 4. Buphaga Africana, African Beef-eater

Genus Crotaphaga.
Fig. 5. Crotaphaga Ani, (major) greater Ani Bird

Genus Glaucopsis.
Fig. 6. Glauc opin cinereus, Cinereous Wattle Bird

Genus Corvus.
47. Lettered Division I. Land Birds, Picæ, Plate III.
   Fig. 1. Corvus Corax, Raven
   2. Corvus Pica, Magpie
   3. Corvus Carypatetis, Nut-cracker
   4. Corvus glandarius, Jay
   5. Corvus crìflatus, Crested Jay

Genus Coracias.
Fig. 6. Coracias Garrulus, Roller (Garrulous Roller, Donov. Brit. Birds)

Genus Oriolus.
48. Lettered Division I. Land Birds, Order II. Picæ, Plate IV.
   Fig. 1. Oriolus crìflatus, Crested Oriole
   2. Oriolus Baltimorea, Baltimore Oriole
   3. Oriolus Pëficus, Black and Yellow Oriole
   4. Neilt of ditto

Genus Cuculus.
Fig. 5. Cuculus canorus, Common Cuckow
NATURAL HISTORY.

PLATE 48. Fig. 6. Cuculus cupreus, Coppery Cuckow 7. Cuculus indicator, Honey-guide

GENUS GRACULA.

49. Lettered Division I. Land Birds, Order II. Picz, Plate V.
Fig. 1. Gracula Quiscalis, Purple Grackle 2. Gracula canus, Bald Grackle 3. Gracula Saudalis, Dial Grackle

GENUS PARADISEA.

Fig. 4. Paradisa Regia, King Bird of Paradise 5. Paradisa Apoletis, Greater Bird of Paradise 6. Paradisa aurea, Golden Bird of Paradise

GENUS Todus.

Fig. 7. Todus macrorhynchos, Great-billed Tody (This genus should be placed after Sitta.)

GENUS TROGON.

50. Lettered Division I. Land Birds, Order II. Picz, Plate VI.
Fig. 1. Trogon Curcurui, Red-bellied Trogon

GENUS BUCCO.

Fig. 2. Bucco Lathami, Buff-faced Barbet 3. Bucco Cayennensis, Cayenne Barbet

GENUS YUNX.

Fig. 4. Yunx Torquilla, Wryneck

GENUS PICUS.

Fig. 5. Picus pileatus, Pileated Woodpecker 6. Picus Carolinus, var. Caroline Woodpecker

GENUS SITTA.

Fig. 7. Sitta Europaea, European Nuthatch

GENUS ALCEO.

51. Lettered Division I. Land Birds, Order II. Picz, Plate VII.
Fig. 1. Alcedo cristata, Crested King's Fifer 2. Alcedo venosa, Venerated King's Fifer 3. Alcedo Alcyon, Belted King's Fifer 4. Alcedo Jacta, Sacred King's Fifer

GENUS GALBULA.

Fig. 5. Gallula paradisa, Lath. (Alcedo paradisa, Gmel.) Long-tailed Jacamar, Paradise Jacamar 6. Gallula viridis, Lath. (Alcedo Galbula, Gmel.) Green Jacamar

GENUS MEROPS.

52. Lettered Division I. Land Birds, Order II. Picz
Fig. 1. Merops Aurunculatus, Wattled Bee-eater 2. Merops Novus Zealandia, New Zealand Bee-eater

GENUS UPUPA.

Fig. 5. Upupa Pomeroys, Cape Hoopoe

PLATE 52. Fig. 4. Upupa Epops, Common Hoopoe 5. Upupa Erythropygus, Red-billed Hoopoe

GENUS CERTHIA.

53. Lettered Division I. Land Birds, Order Picz, Plate IX.
Fig. 1. Certhia paradisa, Great hooked-billed Creeper 2. Certhia obscura, Hook-billed Green Creeper 3. Certhia Coccinella, Hook-billed Red Creeper 4. Certhia Cortulata, Blue Creeper

GENUS TROCHILUS.

ORDER ANSERES.

GENUS ANAS.

54. Lettered Division II. Water Birds, Order III. Anseres, Plate I.
Fig. 1. Anas Atrata, Black Swan 2. Anas Olor, Tame Swan 3. Anas Cygnoides, Chinese Goose 4. Anas Zambensis, Spur-winged Goose

55. Lettered Division II. Water Birds, Order III. Anseres, Plate II.
Fig. 1. Anas Erythropeterus, Bernacle Goose 2. Anas Canadenensis, Canada Goose 3. Anas Spatulata, Grey-headed Duck 4. Anas Mephitica, Mulcovy Duck

56. Lettered Division II. Water Birds, Order III. Anseres, Plate V.

GENUS MERGUS.

57. Lettered Division II. Water Birds, Order III. Anseres, Plate IV.
Fig. 1. Mergus Mergus, Goofander 2. Mergus Eucullatus, Crested Merganer 3. Mergus Albellus, Smew, or Nun (White Smew, Donov. Brit. Birds)

GENUS ALCA.

Fig. 4. Alca antiqua, Ancient Auk 5. Alca Cirrata, Tufted Auk

GENUS APtenodytA.

Fig. 6. AptenodytA Patagonica, Patagonian Penguin
Genus Procellaria.

58. Lettered Division II. Water Birds, Order III. Aniferes, Plate VI. Obs. with six Birds.
- Procellaria capensis, Painted Petrel
- Procellaria fuliginosa, Sooty Petrel
- Procellaria pelagica, Stormy Petrel
- Procellaria gigantea, Gigantic Petrel

Genus Diomedea.

59. Lettered Division II. Water Birds, Order III. Aniferes, Plate VI. Obs. This is the Plate VI. containing five Birds, both being lettered and numbered alike
- Pelecanus Erythrorhynchos, Rough-billed Pelican
- Pelecanus Saula, Booby
- Pelecanus Aquilus, Frigate

Genus Pelecanus.

60. Lettered Division II. Water Birds, Order III. Aniferes, Plate VII.
- Phalocrocorax aterreus, Common Tropic Bird
- Phalocrocorax phoenicus, Red-tailed T. B.

Genus Columbas.

61. Lettered Division II. Water Birds, Order III. Aniferes, Plate IX.
- Larus parasiticus, Arctic Gull
- Larus cornix, Ivory Gull
- Larus marinus, Black-backed Gull

Genus Sterna.

62. Lettered Order Grallae, Plate I.
- Sterna cinerea, (Sterna Tchegrava, Lepechin) Calfion Tern
- Sterna flegata, Noddy

Genus Rynchops.

63. Lettered Order Grallae, Plate II.
- Rynchops nigra, Black Skimmer

Genus Phoenicopterus.

64. Lettered Order Grallae, Plate V.
- Phoenicopterus ruber, Red Flamingo

NATURAL HISTORY.

PLATE
57. Fig. 7. Aptenodyta papua, Papuan Penguin
8. Aptenodyta minor, Little Penguin

Genus Procellaria.

62. Fig. 2. Platala ajaia, Roseate Spoonbill

Genus Scolopax.

63. Fig. 3. Palamedea cornuta, Horned Screamer

Genus Myteria.

64. Fig. 4. Myteria Novo Hollandia, New Holland Jabiru

Genus Cancroma.

65. Fig. 1. Cancroma Cothlearia, Crested Boatbill

Genus Scopus.

66. Lettered Order Grallae, Plate III.
- Ardea Ciocia, White Stork
- Ardea Dubia, Gigantic Heron
- Ardea exilis, Minute Bittern
- Ardea Egretta, Great Egret
- Ardea Tigrina, Tiger Bittern

Genus Tantulus.

67. Lettered Order Grallae, Plate IV.
- Tantulus Loculatus, Wood Ibis
- Tantulus melaonotis, Black-faced Ibis
- Tantulus calvus, Bald Ibis

Genus Corrira.

68. Lettered Order Grallae, Plate II.
- Corrira noctuosa, Italian Courier

Genus Scolopax.

69. Fig. 5. Scolopax leucocyphala, White Headed Curlew
- Scolopax phalopus, Whimbrel

Genus Tringa.

70. Lettered Order Grallae, Plate V.
- Tringa leucopodia, White-winged Sandpiper
- Tringa pugnax, Ruff and Reeve
- Tringa lobata, Grey Phalarope

Genus Charadrius.

71. Fig. 5. Charadrius apricarius, Alwagrim
- Charadrius Himantopus, Long-legged Plover
- Charadrius spinatus, Spur-winged Plover
PLATE

Genus Recurvirostra.

68. Lettered Order Grallae, Plate VII.
Fig. 1. Recurvirostra americana, American Avocet

Genus Hematopus.

Fig. 2. Hematopus ostralegus, Oyster catcher (Pied Oyster Catcher; Donov. Brit. Birds.)

Genus Glareola.

Fig. 3. Glareola auffricaca, Auftrian Pratincole

Genus Fulica.

Fig. 4. Fulica Porphyria, Purple Gallinule
5. Fulica crílata, Crested Coot

Genus Vaginalis.

69. Lettered Order Grallae, Plate VIII.
Fig. 1. Vaginalis alba, White Sheath-bill

Genus Parra.

Fig. 2. Parra Jacana, Chefsnut Jacana
3. Parra finenflis, China Jacana

Genus Rallus.

Fig. 4. Rallus crex, Land Rail
5. Rallus variegatus, Variegated Rail

Genus Psophia.

Fig. 6. Psophia cripitans, Gold-breasted Trumpeter

Order Gallinæ.

Genus Otis.

70. Lettered Division I. Land Birds, Order 5. Gallinæ, Plate I.
Fig. 1, 2. Otis Tarda, Buffard—male 1. female 2.

Genus Struthio.

Fig. 3. Struthio Rhea, American Ostrich
4. Struthio cafuirius, Caffowary, or Emeu
5. Struthio Nova-Hollandiae, New Holland Caffowary

Genus Didus.

71. Lettered Division II. Land Birds, Order 5. Gallinæ.
Fig. 1. Didus Ineptus, Hooded Dodo

Genus Struthio.

Fig. 2, 3. Struthio Camelus, Ostrich—male 2. female 3.

Genus Pavo.

72. Lettered Division I. Land Birds, Order Gallinæ, Plate III.
Fig. 1. Pavo crílatus, Crested Peacock
2. Pavo crílatus (var. varíus), Variegated or Pied Peacock
3. Pavo crílatus (var. albus), White Peacock
4. Pavo bicalcaratus, Iris Peacock

Genus Meleagris.

73. Lettered Division II. Land Birds, Order 5. Gallinæ, Plate IV.
Fig. 1. Meleagris Gallopavo, American or Wild Turkey

Genus Penelope.

Fig. 2. Penelope crílata, Guan

Genus Crax.

Fig. 3, 4. Crax Alector, Curassow—male 3. female 4.
5. Crax Pausi, Cuhew

Genus Phasianus.

74. Lettered Division II. Land Birds, Order Gallinæ, Plate V.
Fig. 1, 2. Phasianus Gallus, Wild Cock—male 1. female 2.
3. Ditto, var. doméísticus, domefticated varieties, Rumpled Cock
4. Ditto, Silky Cock
7, 8. Game Cock—male 7. female 8.
9, 10. pufillius 5, Bantam Cock—male 9. female 10.

75. Lettered Division II. Land Birds, Order Gallinæ, Plate VI.
Fig. 11, 12. Phasianus Gallus, var. doméísticus, varieties, Malay Cock—male 11. female 12.

76. Lettered Division III. Land Birds, Order Gallinæ, Plate VII.
Fig. 1. Phasianus Colcheicus, Common Pheafant
2. Phasianus pitius, Gold Pheafant
3. Phasianus Nycthemerus, Silver Pheafant
4. Phasianus Argus, Argus Pheafant

Genus Numidia.

77. Lettered Division I. Land Birds, Order Gallinæ, Plate VIII.
Fig. 1. Numidia meleagris, Guinea Hen or Pintado
2. Numidia crílata, Crested Pintado

Genus Tetrao.

Fig. 3. Tetrao umbellus, Ruffed or Ruff-necked Grous
4. Tetrao abelata, Pin-tailed Grous
5. Tetrao Canadenfis, Spotted Grous
6. Tetrao paradoxus, Heterochitus Grous, or Paradoxical Grous

78. Lettered Division II. Land Birds, Order Gallinæ, Plate IX.
Fig. 1. Tetrao perdis, Common Partridge
2. Tetrao ferrugineus, Hackled Partridge

**Order Passeres.**

**GENUS COLUMBA.**

79. Lettered Division I. Land Birds, Order Passeres, Plate II.

- Fig. 1. *Columba chalcopera*, Bronze-winged Pigeon
- 2. *Columba ernestina*, Garnet-winged Pigeon
- 3. *Columba macroura*, Great-tailed Pigeon
- 4. *Columba nicobarica*, Nicobar Pigeon
- 5. *Columba curvirostra*, Hook-billed Pigeon
- 6. *Columba capensis*, Cape Turtle, or Cape Pigeon
- 7. *Columba coronata*, Great-crowned Pigeon

**GENUS ALAUDA.**

80. Lettered Division I. Land Birds, Order Passeres, Plate LXXX.

- Fig. 1. *Alauda capensis*, Cape Lark

**GENUS STURNUS.**

- Fig. 2. *Sturnus militaris*, Military Starling
- 3. *Sturnus undulata*, Undulated Starling

81. Lettered Division I. Land Birds, Order Passeres, Plate III.

- Fig. 1. *Turdus Orpheus*, Mocking Thrush
- 2. *Turdus Rex*, King Thrush
- 3. *Turdus perspicillatus*, Speckled Thrush
- 4. *Turdus crassirostris*, Thick-billed Thrush
- 5. *Turdus cyanurus*, Blue-tailed Thrush
- 6. *Turdus longirostris*, Long-billed Thrush

**GENUS AMPELIS.**

82. Lettered Division I. Land Birds, Order Passeres, Plate IV.

- Fig. 1. *Ampeus carunculatus*, Carunculated Chatterer
- 2. *Ampeus catinus*, Purple-breasted Chatterer
- 3. *Ampeus Pompadura*, Pompadour Chatterer
- 4. *Ampeus carinix*, Red Chatterer

**GENUS COLIUS.**

- Fig. 5. *Colius capensis*, Cape Cloy
- 6. *Colius erythropus*, White-backed Cloy

**GENUS LOXIA.**

83. Lettered Division I. Land Birds, Order Passeres, Plate V.

- Fig. 1. *Loxia lincola*, Linneated Grosbeak
- 2. *Loxia excaliduta*, Crested Dominican Grosbeak
- 3. *Loxia philippina*, Philippine Grosbeak
- 4. The pendulous Nell of the Philippine Grosbeak
- 5. *Loxia Cardinialis*, Cardinal Grosbeak
- 7. *Loxia fluvicola*, Fan-tailed Grosbeak

**GENUS FRINGILLA.**

85. Lettered Division I. Land Birds, Order 3. Passeres, Plate X.

- Fig. 4. *Fringilla ignita*, Fire Finch
- 5. *Fringilla flammea*, Crimson-crowned Finch
- 6. *Fringilla longicauda*, Blue-bellied Finch
- 7. *Fringilla Ptilurus*, Parrot Finch

**GENUS PHYTOTOMA.**

86. Lettered Order Passeres, Plate VIII.

- Fig. 6. *Motacilla cyanura*, Superb Wheat-ear

**GENUS MOTACILLA.**

87. Lettered Order Passeres, Plate IX.

- Fig. 1. *Motacilla biocolor*, Black and White Flycatcher
- 3. *Motacilla tyrannus*, Forked-tailed Flycatcher
- 5. *Motacilla fluvicola*, Fan-tailed Flycatcher

**GENUS PIPIRA.**

88. Lettered Order Passeres, Plate XX.

- Fig. 4. *Pipra rubicola*, Rock Manakin
- 5. *Pipra fritata*, Striped-headed Manakin
- 7. *Pipra punicota*, Speckled Manakin

**GENUS PARUS.**

- Fig. 1. *Parus macrocephalus*, Great-headed Titmouse
- 2. *Parus crista*, Crested Titmouse
- 3 Y
NATURAL HISTORY.

PLATE 88. Fig. 4. Hirundo effulenta, Efulent Swallow
5. The efulent Nest of this Swallow
6. Hirundo tahitica, Otaheite Swallow
7. Hirundo pelagia, Aculeated Swallow
3. Hirundo indica, Rufous-headed Swallow

PLATE 89. Genus Hirundo.

GENUS CAPRIMULGUS.

50. Lettered Division LAND BIRDS, Order Passeres, Plate LXXX.
Fig. 4. Caprimulgus longipennis, Leona Goatfucker
5. Capiimulgus grandis, Great Goatfucker

ELEMEHTARY PLATES TO ILLUSTRATE

THE CLASSIFICATION OF BIRDS.

Characters of the Feet in the different Orders and Genera.

ACCIPITRES.

Feet formed for affixing the Mandibles in seizing and tearing the prey, being armed with strong talus.

89. Lettered Ornithology, Elementary Plate I.
The Feet in Falco (Falco chryosastes, Golden Eagle); and Eagles, Falcons, Hawks
The Feet in Strix (Strix flammea, White Owl); striudula, brachyotos, pufferina (The Shrikes belong to this order)

PIGE.

* Feet formed for Perching.

90. Lettered Plate IV.
The Feet in Sitta (Nuthatch) European Nuthatch

92. Lettered Plate II.
The feet in Corvus (Crow) Common Crow
Paradisea (Bird of Paradise)
The same structure prevails in the feet of the genera Buphaga, Oriolus, Coracias, Upupa, Certhia, Trochilus, Cc.

** Feet formed for Climbing.

90. Lettered Elementary Plate IV.
The Feet of Picus (P. Martius, Great Black Woodpecker; P. Viridis, Green Woodpecker)
The Feet of Musophagus (Musophagae)
This structure is well exemplified in Pittaicus (Parrot), and Cuculus (Cuckow), which are familiar examples; and occurs in the genera Scythrops, Ramphalos, Trogon, Crotophaga, Galbula, Yunx, and Bucco.

PLATE

*** Feet formed for Walking.
90. Lettered Elementary Plate IV.
The Feet of Alesto (King's-fisher)
The other genera of Picus, which have the feet formed for walking, are Momotus, Buceros, Merops, and Todus.

ANSERES.

Feet formed for Swimming.

91. Lettered Ornithology, Elementary Plate III.
Feet in the genus Anas (Goose, Duck)
Alta (Ank)
Aptenodyta (Penguin)
Pelecanus (Pelican), two species
Columbus (Grebe), three species
Larus (Gull)

90. Lettered Ornithology, Elementary Plate IV.
Feet in the genus Steena (Tern)

GRAIL.

Feet formed for Wading.

91. Lettered Ornithology, Elementary Plate III.
Feet in the genus Phanieopterus (Flamingo)

89. Lettered Ornithology, Elementary Plate I.
Feet in the genus Platalea (Spoonbill) P. aja

90. Lettered Ornithology, Elementary Plate IV.
Feet in the genus Ardea (Heron)

89. Lettered Ornithology, Elementary Plate I.
Feet in the genus Ardea cinerea (Grey Heron)

91. Lettered Ornithology, Elementary Plate III.
Feet in the genus Recurvirostra, (Avocet)

89. Lettered Ornithology, Elementary Plate I.
Feet in the genus Tantalus (Ibis) T. igneus, Bay Ibis

91. Lettered Ornithology, Elementary Plate III.
Feet in the genus Tringa (Phalarope) T. lobata, Scallop-toed Tringa

89. Lettered Ornithology, Elementary Plate I.
Feet in the genus Charadrius (Plover, Long-legged P.)
Hematopus (Osier Catcher)
Glareola (Pratincole) P. auf-briaca

91. Lettered Ornithology, Elementary Plate III.
Feet in the genus Fulica (Gallinule)
Vignalis (Sheathbill)

90. Lettered Ornithology, Elementary Plate IV.
Feet in the genus Rallus (Rail)
PLATE
91. Lettered Ornithology, Elementary Plate III.
Feet in the genus Rallus (Rallus gallinule)

90. Lettered Ornithology, Elementary Plate IV.
Feet in the genus Parra (Jacana), two species

GALLINÆ.
Form of the Feet.

92. Lettered Ornithology, Elementary Plate II.
In the genus Otis (Buffard)
Struthio (Ostrich) S. camelus, Common or Black Ostrich
Struthio camelus, Cassowary
Cercoptis (Cercops)
Pavo (Peacock) Common P.
Phasianus (Pheasant) Common P.
Menura (Menura)

89. Lettered Ornithology, Elementary Plate I.
In the genus Tetrao (Grouse), T. urogallus, Great Grouse.
T. lagoopus, Ptarmigan.
T. tetrix, Black Game

PASSERES.
Structure of the Feet.

89. Lettered Ornithology, Elementary Plate I.
In the genus Colius (Coly)

90. Lettered Ornithology, Elementary Plate IV.
In the genus Alauda (Lark), A. arvensis, Sky-lark, A. obsoleta, Dulky Lark
Pipra (Manskin)

92. Lettered Ornithology, Elementary Plate II.
In the genus Parus (Titmouse)

90. Lettered Ornithology, Elementary, Plate IV.
In the genus Turdus (Thrufh)
Motacilla (Warbler)

89. Lettered Ornithology, Elementary Plate I.
In the genus M. Regulus (Gold-crested Wren)

CLASS AMPHIBIA.

93. Lettered Amphibia, Plate X.
Fig. 5. Testudo mydas, Elculent Green Turtle
6. Testudo imbricata, Hawkbill Turtle

LAND TURTLES.
Fig. 1. Testudo denticulata, Denticulated Tortoise
2. Testudo europaea, Green Speckled Tortoise
3. Testudo spatata, Spotted Tortoise
4. Testudo picta, Painted Tortoise

PLATE
94. Lettered Amphibia, Plate I.

Fig. 1. Rana Pipa, Surinam Toad—Female with her young nestling in collides on the back
2. Rana bicolor, Two-coloured Frog
3. Rana paradoxus, Paradoxical Frog, in the fifth-like former tad-pole plate
4. Rana arborescens, Tree Frog.

GENUS LACERTA.

95. Lettered Amphibia, Plate VIII.
Fig. 1. Lacerta Salamandra, Salamander
2. Lacerta Vittata, Forked Lizard
3. Lacerta Chamaeleon, Chameleon
4. Lacerta agilis, Green Lizard
5. Lacerta lennifera, Eight-lined Lizard

GENUS DRACO.

96. Lettered Amphibia, G. Lacerta, Plate IX.
Fig. 1. Lacerta seicnoides, Australafian Galliawfsp
2. Lacerta chalcedon, Chalcides Lizard
3. Lacerta apus, Apodal Lizard

GENUS SIREN.

97. Lettered Amphibia, G. Siren, Plate VI.
Fig. 1. Siren lacertina, Eel-shaped Siren
2. Siren angulina, Anguine Siren

ORDER II. SERPENTS.

98. Lettered Amphibia, G. Croatalus, Plate II.
Fig. 1. Croatalus horridus, Banded Rattle-snake
2. Croatalus Durissus, Striped Rattle-snake

GENUS BOA.

99. Lettered Amphibia, G. Boa, Plate V.
Fig. 1. Boa constrictor, Great Boa Serpent
2. Boa Phrygia, Embroidered Boa Serpent
3. Boa horridus, Garden Boa Serpent

GENUS COLUBER.

100. Lettered Amphibia, G. Coluber, Plate IV.
Fig. 1. Coluber nasica, Horn-naed Viper
2. Coluber cerastes, Cerastes Viper
3. Coluber naja, Nagoo or Spectacle Viper

GENUS ANGUIs.

101. Lettered Amphibia, G. Anguis, Plate III.
Fig. 1. Anguis Crotalus, Coral Slow Worm
2. Anguis atris, Black Banded Slow Worm
3. Anguis Jamaicae, Jamaicae Slow Worm

GENUS AMPHIBIANÆ.

102. Lettered Amphibia, G. Amphibianæ, Plate VII.
Fig. 1. Amphibianæ alba, White Amphibianæ
2. Amphibianæ fuliginis, Fuliginous Amphibianæ
Plate

Genus Cecilia.
102. Fig. 3. Cecilia tentacula, Eel-shaped Cecilia

Genus Hydrus.
103. Lettered Amphibia, G. Hydrus
Fig. 1. Hydrus colubrinus, Colubrine Hydrus
2. Hydrus bicolor, Black-backed Hydrus

Genus Langaya.
Fig. 3. Langaya nasuta, Snouted Langaya

Genus Acrochordus.
Fig. 4. Acrochordus dubius, Doubtful Acrochordus

Ichthyology.
Class Pisces.
Order Apodes.
Genus Munena.
104. Lettered Order Apodes, Plate I.
Fig. 1. Munena anguilla, Eel Munena, or Common Eel

Genus Synbranchus.
Fig. 2. Synbranchus marmoratus, Marbled Synbranchus

Genus Sphagebranchus.
Fig. 3. Sphagebranchus rostratus, Snouted Sphagebranchus

Genus Gymnotus.
Fig. 4. Gymnotus electricus, Electric Gymnotus

Genus Gymnotorhax.
Fig. 5. Gymnotorhax munena, Eel Gymnotorhax
6. Gymnotorhax catenatus, Chain Gymnotorhax

Genus Stomateus.
105. Lettered Order Apodes, Plate II.
Fig. 1. Stomateus cinereus, Ash-coloured Stomateus
2. Stomateus niger, Black Stomateus

Genus Stylephorus.
Fig. 3. Stylephorus chordatus, Chordated Stylephorus

Genus Trichius.
Fig. 4. Trichius argenteus, Silvery Trichius

Genus Sternoptyx.
Fig. 5. Sternoptyx diaphana, Diaphanous Sternoptyx

Genus Xiphias.
Fig. 6. Xiphias gladius, Sword-fish

Genus Anarichas.
Fig. 7. Anarichas lupus, Ravenous Wolf-fish

Plate

Order Jugulares.
Genus Trachinus.
106. Lettered Order Jugulares, Plate I.
Fig. 1. Trachinus major, Great Weever
2. Trachinus deors, Small Weever

Genus Uranoscopus.
Fig. 3. Uranoscopus lacera, Rough Stargazer

Genus Callionymus.
Fig. 4. Callionymus draco, Sordid Dragonet
5. Callionymus lyra, Gemmous Dragonet

Genus Gadus.
107. Lettered Ichthyology, Order Jugulares, Plate II.
Fig. 1. Gadus morhua, Cod-fish
2. Gadus carbonarius, Coal-fish
3. Gadus minutus, Poor
4. Gadus Taur, Tau Cod-fish

Genus Bleenius.
Fig. 5. Bleenius maris, Ocellated Blenny

Genus Kurtus.
Fig. 6. Kurtus indicus, Indian Kurtus

Order Thoracici.
Genus Cepola.
108. Lettered Ichthyology, Order Thoracici, Plate I.
Fig. 1. Cepola Tria, Ribband-fish

Genus Echneis.
Fig. 2. Echneis Remora, Mediterranean Sucking-fish

Genus Coryphiena.
Fig. 4. Coryphiena hippurus, Common Coryphene
5. Coryphiena pentadactyla, Five-spotted Coryphene

Genus Gobius.
Fig. 3. Gobius minutus, Spotted Goby

Genus Cottus.
Fig. 6. Cottus grinniens, Grunting Bull-head
7. Cottus cataphractus, Mailed Bull-head

Genus Scorpéna.
109. Lettered Ichthyology, Order Thoracici, Plate III.
Fig. 1. Scorpéna Scrofa, Hog Sea-Scorpion
2. Scorpéna boreida, Horrid Sea-Scorpion
3. Scorpéna antennata, Antennated Sea-Scorpion

Genus Zeus.
Fig. 4. Zeus gallus, American Zeus
5. Zeus ciliaris, Filamentous Zeus
6. Zeus inflictor, Infidious Zeus

Genus Nyphus.
Genus Pleuronectes.

110. Lettered Ichthyology, Order Thoracici, Plate III.
   Fig. 1. Pleuronectes zebra, Zebra Sole
   2. Pleuronectes argus, Argus Flounder
   3. Pleuronectes platessa, Plaice
   4. Pleuronectes bilineatus, Bilineated Sole

111. Lettered Ichthyology, Order Thoracici, Plate IV.
   Fig. 1. Pleuronectes punctatus, Dotted Flounder

Genus Chilotodon.

110. Lettered Ichthyology, Order Thoracici, Plate III.
   Fig. 5. Chilotodon bicolor, Two-coloured Chilotodon
   6. Chilotodon fuscatus, Banded Chilotodon

111. Lettered Ichthyology, Order Thoracici, Plate IV.
   Fig. 2. Chilotodon imperator, Imperial Chilotodon
   3. Chilotodon marginatus, Bordered Chilotodon
   4. Chilotodon arcatus, Bowed Chilotodon
   5. Chilotodon rostratus, Snouted Chilotodon
   6. Chilotodon teira, Teira Chilotodon

Genus Sparus.

112. Lettered Ichthyology, Order Thoracici, Plate VII.
   Fig. 1. Sparus fallax, Falcated Gilthead
   2. Sparus surinamensis, Surinam Gilthead
   3. Sparus fuscatus, Banded Gilthead
   4. Sparus chrysurus, Golden-tailed Gilthead
   5. Sparus annularis, Annulated Gilthead
   6. Sparus menta, Cackarel

Genus Scarus.

113. Lettered Ichthyology, Order Thoracici, Plate VIII.
   Fig. 7. Scarus viridus, Green Scarus

114. Lettered Ichthyology, Order Thoracici, Plate X. & XI.
   1. Scarus cretensis, Large-scaled Scarus

Genus Labrus.

113. Lettered Ichthyology, Order Thoracici, Plate VIII.
   Fig. 1. Labrus micropodius, Large-scaled Wrasse
   2. Labrus trichopterus, Hair-finned Wrasse
   3. Labrus malapterus, Soft-finned Wrasse
   4. Labrus maculatus, Spotted Wrasse
   5. Labrus punctatus, Dotted Wrasse
   6. Labrus nelsoni, Black-bellied Wrasse

Genus Sciaena.

114. Lettered Ichthyology, Order Thoracici, Plate X. & XI.
   Fig. 2. Sciaena diacantha, Two-spined Umbre, or Sciaena
   3. Sciaena cirrhosa, Cirrofe Sciaena
   4. Sciaena punctata, Dotted Sciaena
   5. Sciaena plumieri, Plumier's Sciaena

Genus Perca.

115. Lettered Ichthyology, Order Thoracici, Plate IX.
   Fig. 1. Perca brasilienensis, Brazilian Perch
   2. Perca flectis, Rock Perch
   3. Perca punctata, Dotted Perch
   4. Perca guttata, Guttated Perch
   5. Perca maculata, Spotted Perch
   6. Perca bimaculata, Bimaculated Perch

Genus Trachycithys.

116. Lettered Ichthyology, Order Thoracici, Plate XI.
   Fig. 4. Trachycithys australis, Australasian Trachycithys

Genus Gasterosteus.

117. Lettered Ichthyology, Order Thoracici, Plate XII.
   Fig. 1. Scomber sardus, (Scomber scomber, Linn.)
   Common Mackarel
   2. Scomber niger, Black Mackarel
   3. Scomber saurus, Saliens Mackarel
   4. Scomber ruder, Red Mackarel

Genus Mullus.

118. Lettered Ichthyology, Order Thoracici, Plate XIII.
   Fig. 1. Mullus furcatus, Surmullet

Genus Trigla.

117. Lettered Ichthyology, Order Thoracici, Plate XII.
   Fig. 2. Trigla carolina, Caroline Gurnard
   3. Trigla rhenus, Swallow Gurnard
   5. Trigla cataphractus, Mailed Gurnard
   4. Trigla punctata, Dotted Gurnard

Genus Lonchiurus.

117. Lettered Ichthyology, Order Thoracici, Plate XII.
   Fig. 5. Lonchiurus barbatus, Bearded Lonchiurus

Order Abdominales.

Genus Cobitis.

119. Lettered Ichthyology, Order Abdominales, Plate V.
   Fig. 4. Cobitis fuscus, Great Loche

Genus Anableps.

119. Lettered Ichthyology, Order Abdominales, Plate V.
   Fig. 5. Anableps tetraptebolalus, Four-eyed Anableps

Genus Silurus.

117. Lettered Ichthyology, Order Abdominales, Plate V.
   Fig. 1. Silurus clarius, Long-bearded Silurus

Fig. 1. Sciaena undecimalis, Eleven-spot Sciaena
   2. Sciaena lineata, Lineated Sciaena

Fig. 4. Trachycithys australis, Australasian Trachycithys

Fig. 3. Gasterosteus aculeatus, Stickelback
Genus Platystachus.

119. Fig. 6. Platystachus anguillaris, Eel-shaped Platystachus

Genus Loricaria.

Fig. 2. Loricaria costalis, Ribbed Loricaria
3. Loricaria flavs, Yellow Loricaria

Genus Salmo.

120. Lettered Ichthyology, Order Abdominales, Plate III.
Fig. 1. Salmo bimaculatus, Bimaculated Salmon
2. Salmo fischeri, Banded Salmon
3. Salmo tumidus, Barred Salmon
4. Salmo Odoco, Odoco Salmon
5. Salmo Guentheus, Yellow-finned Salmon
6. Salmo Frederici, Frederician Salmon
7. Salmo rhomboides, Rhombic Salmon

Genus Fistularia.

121. Lettered Ichthyology, Order Abdominales, Plate II.
Fig. 1. Fistularia chinensis, Chinese Tobacco-pipe Fish
2. Fistularia tabaccaria, Spotted Tobacco-pipe Fish

Genus Esox.

Fig. 3. Esox niger, Bony Gar Fish, or Sea Pike
4. Esox Belone, Sea Pike, or Gar Fish
5. Esox brasilensis, Brasilian Pike, or Gar Fish

Genus Elops.

Fig. 6. Elops Saurus, Saury Elops

Genus Argentina.

Fig. 7. Argentina Sphyraena, European Argentine

Genus Atherina.

122. Lettered Ichthyology, Order Abdominales, Plate I.
Fig. 1. Atherina Hepsetus, Common Atherine

Genus Mugil.

Fig. 2. Mugil Tang, Tang Mullet
3. Mugil cephalus, Grey Mullet

Genus Exocoetus.

Fig. 4. Exocoetus coclalaus, Mediterranean Flying Fish
5. Exocoetus exilis, Swallow Flying Fish
6. Exocoetus Macguiger, Atlantic Flying Fish

Genus Polynemus.

123. Lettered Ichthyology, Order Abdominales, Plate IV.
Fig. 1. Polynemus paradiceus, Paradice Polynemus
2. Polynemus decadasTLuus, Ten-fingered Polynemus

Genus Clupea.

123. Fig. 3. Clupea Thrissa, Thrissa Herring
4. Clupea najs, Nalal Herring

Genus Cyprinus.

Fig. 5. Cyprinus cultratus, Razor Carp
6. Cyprinus auratus, Golden Carp, var.
7. Cyprinus phoxinus, Minnow

Order Branchiostegi.

Genus Ostracion.

124. Lettered Ichthyology, Order Branchiopteri, Genus Ostracion, Plate V.
Fig. 1. Ostracion taurinus, Eared Trunk Fish
2. Ostracion trigus, Triangular Trunk Fish
3. Ostracion natus, Snouted Trunk Fish
4. Ostracion bicaudalis, Bicaudate Trunk Fish
5. Ostracion quadricornis, Four-horned Trunk Fish
6. Ostracion cornutus, Horned Trunk Fish

Genus Tetrodon.

125. Lettered Ichthyology, Order Branchiopteri, Genus Tetrodon, Plate V.
Fig. 1. Tetrodon hifpidus, Hifpid Tetrodon
2. Tetrodon ochutus, Osculated Tetrodon
3. Tetrodon lineatus, Lined Tetrodon
4. Tetrodon lagocephalus, Hare Tetrodon

Genus Diodon.

Fig. 5. Diodon Hystrix, Porcupine Diodon
6. Diodon orbicularius, Round Diodon

Genus Syngnathus.

126. Lettered Ichthyology, Order Branchiopteri, Plate VI.
Fig. 1. Syngnathus foliatus, Foliated Pipe Fish
2. Syngnathus acus, Great Pipe Fish
3. & 4. Syngnathus Hippocampus, Sea-Horse Pipe Fish

Genus Pegasus.

Fig. 4. & 4. Pegasus Draconis, Dragon Pegasus
5. & 5. Pegasus natans, Swimming Pegasus

Genus Centriscus.

Fig. 6. Centriscus luteus, Mailed Centriscus

Genus Balistes.

127. Lettered Ichthyology, Order Branchiopteri, Plate III.
Fig. 1. Balistes vetula, Old Wife
2. Balistes maculatus, Spotted Old Wife
3. Balistes aculeatus, Aculeated Old Wife
4. Balistes monoceros, One-horned Old Wife

Genus Cyclopterus.

128. Lettered Ichthyology, Order Branchiopteri, Plate IV.
Fig. 1. Cyclopterus Lumpus, Common Lump-fucker
Plate
128. Fig. 2. Cyclopterus ocellatus, Ocellated Lump-fucker
3. Cyclopterus lineatus, Lineated Lump-fucker

Genus Lophius.
Fig. 4. Lophius marmoratus, Marbled Angler
5. Lophius Hisfris, Harlequin Angler
6. Lophius rostratus, Beaked Angler
7. Lophius ptychus, Painted Angler

Order Chondropterygi.
Genus Acipenser.
129. Lettered Ichthyology, Order Chondropterygii, Plate I.
Fig. 3. Acipenser Sturio, Common Sturgeon
4. Acipenser ruthenus, Sterlet

Genus Chimera.
Fig. 2. Chimera monstrofa, Sea-monster
5. Chimera callorhynchus, Southern Sea-monster

Genus Pristis.
Fig. 1. Pristis Antiquorum, Common Saw-fish

Genus Squalus.
130. Lettered Ichthyology, Order Chondropterygii, Plate II.
Fig. 1. Squalus glaucus, Blue Shark
2. Squalus Catulus, Lesser spotted Shark
3. Squalus Squatina, Angel Shark
4. Squalus Zygera, Hammer-headed Shark
5. Squalus Zebra, Zebra Shark

Genus Spatularia.
Fig. 6. Spatularia renticulata, Reticulated Spatularia

Genus Raja.
131. Lettered Ichthyology, Order Chondropterygii, Plate VI.
Fig. 1. Raja diabolus, Demon Ray
2. Raja clavata, Thorn-back
4. Raja undulata, Undulated Ray
5. Raja torpeda, Electric Ray
6. Raja rhinobatos, Long-noised Ray

Genus Gastrobranchus.
132. Lettered Ichthyology, Order Chondropterygii, Plates III., IV., V.
Fig. 1. Gastrobranchus coecus, Hag-fish
2. Gastrobranchus Dombyei, Dombyean Hag-fish

Genus Petromyzon.
Fig. 3. Petromyzon marinus, Marine Lamprey
4. Petromyzon fluviatilis, River Lamprey
5. Ditto, the young, shewing the under surface

Plate
ENTOMOLOGY.
CLASS INSECTA.
Order Coleoptera.
Genus Scarabaeus.
133. Lettered Entomology, Order Coleoptera, Plate I.
Fig. 1. Scarabaeus Hercules
2. Scarabaeus Chorineus
3. Scarabaeus Thyius
4. Scarabaeus moleus
5. 6. Scarabaeus cornifex. male and female
7. Scarabaeus Foer

Genus Goliathus.
134. Lettered Entomology, Genus Goliathus, Plate I.

Genus Lucanus.
135. Lettered Entomology, Order Coleoptera, Plate IV.
Fig. 1. Lucanus cervus
2. Lucanus inermis

Genus Dermestes.
Fig. 3. Dermestes vingti-guttatus
4. Dermestes sex-dentatus
5. Dermestes brachypterus
6. Dermestes pedicularius
7. Dermestes pictipes

Genus Bostrichus.
136. Lettered Entomology, Order Coleoptera, Plate V.
Fig. 12. Bostrichus phaeseus
1. Bostrichus polygraphus
2. Bostrichus typographus
3. Bostrichus piniferda

Genus Melyris.
137. Lettered Entomology, Order Coleoptera, Plate XII.
Fig. 13. Melyris viridis

Genus Ptinus.
136. Lettered Entomology, Order Coleoptera, Plate V.
Fig. 4. Ptinus Scotius
5. Ptinus Imperialis
6. Ptinus sex-punctatus
7. Ptinus tegellatus
8. Ptinus pellicornis

Genus Hister.
Fig. 9. Hister unicolor
10. Hister planus

Genus Gyrinus.
Fig. 11. Gyrinus natator

Genus Byrrhus.
137. Lettered Entomology, Order Coleoptera, Plate XII.
Fig. 1. Byrrhus pilula

Genus *Forficula*.

Fig. 13, 14. *Forficula gigantea*

149. Lettered Entomology, Coleoptera, Plate III.

Supplementary Plate of the Order Coleoptera.

* This Plate, which we have placed as an Appendix to the Coleoptera tribe, was engraved and published in the Cyclopaedia before the Proprietors had determined to under-
and these, it must be allowed, were not chosen altogether with that due attention to accuracy which the intricacy of this branch of Natural History demanded. These insects were copied; we understand, from specimens in the very valuable cabinet of Mr. Francillon; but owing to the dispersion of that collection by public sale, the means of comparison has pulled away, and the death of the artist then employed, as well as of the zealous proprietor of that collection, has opposed a period to enquiry further. The far greater and more costly portion of the Francillonian Cabinet is indeed preferred, being incorporated in the princely cabinet of Alexander McLeay, Esq., a cabinet to which true science is never refused an easy access; but the insects in question having been removed from their respective situations, in Mr. Francillon's drawers, they can be no longer recognized as the specimens from which the figures in this plate are taken; and this, in some few instances at least, it must be confessed, is requisite to enable us to speak of them with certainty. We may observe, moreover, that very few names accompany the articles reprepented in this Plate of Mr. Edwards; and of these few there are certainly faulty. Hispa is doubtful (a true Hispa has been since given in Plate 141, fig. 8.). Bruchus is erroneous, and appears to be, with the exception of the antennæ, Attelabus Coryli; (a true Bruchus is infested by us in Plate 141, fig. 9.) and his insect named Attelabus, has much the appearance of Mylabris, except in having pectinated instead of moniliform antennæ: nevertheless this may be a Curculis, and allied to Apium. (See Plate 148, fig. 9.) Lampyrus is indifferent; Canthis uninterpretable. With these, and some few other exceptions, the Plate should be preferred, as it contains other insects infested, the repetition of whose figures has been purposely avoided in selecting the materials for the rest of the Plates of Coleoptera.

We believe Curculis, No. 1, to be Curculis bispinoseus; No. 3, to be Curculis Imperialis, the Brazilian or Diamond Beetle; No. 4, Curculis vitata, of Jamaica; Cerambyx, No. 3, Cerambyx marginatus; Necydalis, No. 2., N. cerulea; Lampyrus, fig. 1., L. vulgaris, male (having wings); No. 2, the female (beingapterous, or without wings); Elater, No. 1., E. ocellatus, West Indies; No. 2, is uncertain, but is, no doubt, an Elater, placed on its back, to show the situation of the pointed sternum in that genus, by striking which upon the breast, the insect is enabled to spring up with instantaneous velocity when laid down in that position.
NATURAL HISTORY.

Plate

Order Lepidoptera.

Genus Papilio.

154. Lettered Entomology, Order Lepidoptera, Plate I.

Fig. 1. Papilio Helcer, Eq. Tr. 1. Upper figure on the left hand.
2. Papilio Eclusi, Eq. Tr. 2. Right-hand side, middle figure.
3. Papilio Deiocus, Eq. Actib. 2. Left-hand side, middle figure.
4. Papilio Agamemnon, Eq. Actib. 2. Lowell figure on the left hand.
5. Papilio Machaon, Eq. Actib. 3. Lowest figure on the right hand.
7. Papilio Mecystas, Eq. Actib. 5. Butterfly with erect wings, in the middle of the Plate.

Genus Sphinx.

155. Lettered Entomology, Order Lepidoptera, Plate VII.

Fig. 1. Sphinx rustica. The largest figure in the lower part of the Plate.
2. Sphinx vitis. The largest figure in the upper part of the Plate.
3. Sphinx Elba. Shewing the natural erect position of the wings in this family of Sphinxes, when they are at rest. Placed on the left hand, towards the middle of the Plate.
4. Sphinx fusiformis, (Sesia, Fabricius). Upper figure on the left hand.
5. Sphinx crysos, (Sesia, Fabricius). Lowest figure in the Plate on the left side.
6. Sphinx tipus, (Sesia, Fabricius). Smallest figure in the Plate, and placed in the centre, in a flying position.
7. Sphinx Polymena, (Zygena of Fabricius, Donov. Inf. China). Right hand, towards the middle of the Plate.
8. Sphinx fausta, (Zygena fausta, Fabricius). Bottom figure of the Plate on the right hand.

Genus Phalæna.

156. Lettered Entomology, Order Lepidoptera, Plate I.

Phalæna

Fig. 1. Phalæna Atlas (Bombyx fam.), with wings expanded.

157. Lettered Entomology, Order Lepidoptera, Plate II.

Fig. 1. Phalæna Saturnus (Bombyx).

158. Lettered Entomology, Order Lepidoptera, Plate I.

Plate

Order Neuroptera.

Genus Libellula.

158. Lettered Entomology, Order Neuroptera, Plate I.

Fig. 1. Libellula indica.
2. Libellula grandis, (Ephne genus, Fabr.)
3. Libellula clavata, (Ephne, Fabr.)
4. Libellula linearis, (Agrion genus, Fabr.)
5. Libellula virgo, (Agrion, Fabr.)

Genus Ephemera.

Fig. 7. Ephemeræ varia

Genus Phryganea.

Fig. 8. Phryganea varia

Genus Hemerobius.

159. Lettered Entomology, Order Neuroptera, Plate II.

Fig. 1. Hemerobius chryops.

Genus Myrmeleon.

Fig. 2. Myrmeleon Libellulides.
3. Myrmeleon Americanus, (Acalaphus Americanus, Fabr.)
4. Myrmeleon barbarus, (Acalaphus barbarus, Fabr.)

Genus Panorpa.

Fig. 5. Panorpa communis
6. Panorpa coa

Genus Raphidia.

Fig. 7. Raphidia ophiogis

Order Hymenoptera.

Genus Cynips.

160. Lettered Entomology, Order Hymenoptera, Plate XI.

Fig. 1. Cynips quercus folii

Genus Tenthredo.

Fig. 2. Tenthredo bimaculata
3. Tenthredo femorata
4. Tenthredo fulvicornis

Genus Sirex.

Fig. 5. Sirex gigas
6. Sirex juvenus
Plate

Genus Sphex.

Fig. 8. Ichneumon flavicornis
9. Ichneumon perfunctorius

Genus Scolia.
161. Lettered Entomology, Order Hymenoptera, Plate III.
Fig. 2. Scolia flavifrons

Genus Thynnus.
Fig. 3. Thynnus emarginatus

Genus Leucopsis.
Fig. 4. Leucopsis dorfigera

Genus Tipula.
Fig. 7. Chalcis flavipes

Genus Chrysis.
Fig. 8. Chrysis flendiida
9. Chrysis amethystina
10. Chrysis faetcula
11. Chrysis ignita

Genus Vespa.
162. Lettered Entomology, Order Hymenoptera, Plate XIII.
Fig. 1. Vespa cinata
2. Vespa tricolor
3. Vespa arcurata
4. Vespa faetcula

Genus Apis.
Fig. 5. Apis felina
2. Apis violacea
7. Apis aemula

Genus Formica.
Fig. 8. Formica gigas
9. Formica bengalensis
10. Formica tibamata

Genus Mutilla.
Fig. 11. Mutilla Americana, (female)
12. Mutilla bengalensis
13. Mutilla rubra

Plate

Order Diptera.

Genus Oestrus.
163. Lettered Entomology, Order Diptera, Plate II.
Fig. 1, 2. Oestrus equi
3. Oestrus bovis
4. Oestrus ovis

Genus Tipula.
Fig. 5. Tipula ruosea
6. Tipula bicornis
7. Tipula variegata
8. Tipula cornuta
9. Tipula punctata
10. Tipula atroca
11. Tipula plumosa
12. Tipula pellicornis

Genus Diopsis.
Fig. 13. Diopsis ichneumonea

Genus Musca.
164. Lettered Entomology, Order Diptera, Plate IV.
Fig. 1. Musca grigga, hair of the antennae naked
2. Musca bidentata
3. Musca bifaceta
4. Musca cuparia
5. Musca vibrans
6. Musca fucularia
7. Musca fisciflora
8. Musca onopordinis
9. Musca felissa
10. Musca faetcula
11. Musca Chameleon, (Stratiomys Chameleon, Fabr.)
12. Musca morio
13. Musca clavicornis, (Ceria clavicornis, Fabr.)
14. Musca foetidis, (Rhagio foetidis, Fabr.)
15. Musca triangularis
16. Musca analis, (Bibio analis, Fabr.)
17. Musca tenax, (Sympus tenax, Fabr.)
18. Musca pendula, (Sympus, Fabr.)
19. Musca florea, (Sympus, Fabr.)
20. Musca lurida
21. Musca vespsiformis
22. Musca noctula
23. Musca bilineata
24. Musca uliginofa, (Nemotelus uliginofus, Fabr.)

Genus Tabanus.
165. Lettered Entomology, Diptera, Plate IV.
Fig. 1. Tabanus bovinus
2. Tabanus tropicus
3. Tabanus bicornis
4. Tabanus phoebe
5. Tabanus rupestris
6. Tabanus caecutenus

Genus Culex.
Fig. 7. * Culex pipiens, natural size and magnified
NATURAL HISTORY.

Genus Empis.

**Genus Tænia.**

179. **Lettered Vermes, Order Intestina, Plate V.**

Fig. 1. *Tænia folium*, grouped into folds in order to include the whole animal, which is of extreme length, within the limits of the Plate. Found in the human body.

2. The head, natural size, of a specimen twenty feet in length.

3. Head magnified.

7. Two joints retaining the external skin, and shewing the alternate disposition of the ocula along the edges of the joints as they usually appear.

8. Two joints shewing their lateral disposition when they occur on both the margins of each joint, which sometimes happens.

4. A portion of the joints of the natural size, divided of the outer skin, and disclosing more fully the alternate lateral ocula, together with the alimentary canals, as they communicate from one joint to the other.

5. The middle system of vesels illustrated in another portion of four joints.

6. Another portion deprived of the outer coating, and displaying all the canals in their relative situation. Vide Carlisle in Linn. Trans. v. 2. *Tænia lata.* Carlisle in Linn. Trans. 2. *Tænia oculis lateralisbus solitariis,* Linn. Ameo. Acad. 2.?

10. A portion of several joints exhibiting the ocula, which are disposed in a single feries down the center of the joints.

11. Another portion divided of the outer coating, and shewing the fylferm vesels down the center within, and also the lateral alimentary canals. Found in the intestines of mankind.

9. *Tænia canina,* head, and a portion of the body, confining of the five first joints. Found in the dog.

**Genus Gordius.**

180. **Lettered Vermes, Genus Gordius, Plate IV.**

Fig. 1. *Gordius aquaticus.*

**Genus Lumbricus.**

Fig. 2, 3. *Lumbricus terrestris.*

**Genus Hirudo.**

Fig. 4. *Hirudo muricata.*

5. *Hirudo geometra.* The smaller figures at No. 1. denote the eggs and natural size of the animal: No. 4. magnified shews the animal affixed by the broad pedal-like tail with the body extended horizontally: No. 3. the same contracting into an arched form: No. 2. when most contracted, arched, and elevated, preparatory to walking, which it does somewhat in the manner of the larve of the Geometra tribe of moths, or as usually defribed as if measuring the ground like a pair of compasses.

**Genus Planaria.**

Fig. 6. *Planaria crenata.* No. 1, 2, 3, 4, 5, shews various positions and contractions of this animal.

**Genus Siphunculus.**

**Genus Limax.**

Fig. 8. *Limax aerter.*

**Genus Onchidium.**

181. **Lettered Vermes, Order Mollusca, Plate VII.**

Fig. 1, 2. *Onchidium typha.*

**Genus Laplifia.**

Fig. 2. *Laplifia depilans.*

**Genus Doris.**

Fig. 3. *Doris argo.*

4. *Doris radiata.*

5. *Doris papillosa.*

**Genus Aphrodita.**

Fig. 6. *Aphrodita aculeata.* No. 6. small, upper surface, right-hand figure.

No. 6. ditto, under surface, left-hand figure.

No. 6. large size.

7. *Aphrodita humilis.*

**Genus Nais.**

182. **Lettered Vermes, Genus Nais, Plate V.**

Fig. 1, 2, 3, 4. *Nais serpentina,* highly magnified, the natural size being three quarters of an inch in length, or not exceeding that of the cluther shewn on the duckweed, fig. 5.

5, 6, 7, 8, 9, 10, 11. *Nais vermicularis,* highly magnified, natural size one-tenth of an inch.

12, 13. *Nais proboscidea,* highly magnified, natural size three-fourth of an inch.

**Genus Actinia.**

183. **Lettered Vermes, Genus Actinia, Plate II.**

Fig. 1. *Actinia diaphana.*

2. *Actinia cerasus.*

**Genus Holothuria.**

184. **Lettered Zoology, Class Vermes, Plate I. of Mollusca.**

Fig. 1. *Holothuria elegans.*

2. *Holothuria pentactae.*

3. 4. Arca sinuosa, No. 1. the outside, lower figure, No. 2. inside, the upper figure
5. 6. Arca nodosa, No. 1. outside, lower figure. No. 2. inside
7. Arca nebulosa

Genus Ostrea.

Pecten, or Scallops.

196. Lettered Conchology, Genus Ostrea, Plate XII.

Fig. 1. Ostrea Jacobae
2. Ostrea subfuscita
3. Ostrea nodosa
4. Ostrea lineata
5. Ostrea obtusa
6. Ostrea varia, various sizes
7. Ostrea obsoletus, nat. size (Donov. Brit. Shells)

Genus Mytilus.

193. Lettered Conchology, Genus Mytilus &c. Plate XI. B.

Fig. 6, 6. Mytilus edulis, var. purpureus, (Donov. Brit. Shells) inside and outside

Genus Pinna.

197. Lettered Conchology, Genus Pinna, Plate VII.

Fig. 1. Pinna nigra, inside and outside, small size
2. Pinna muricata, shelling the byssus or beard
3. Pinna rubra, ditto
4. Pinna fragilis

Univalves.

Genus Argonauta.

198. Lettered Conchology, Order Univalve, Plate IV.

Fig. 1. Argonauta argo, Paper-filer Shell
2. Argonauta vitrea, called the Glassy Nautilus, a shell of unusual rarity

Genus Nautilus.

199. Lettered Conchology, Genus Nautilus &c. Plate XI. A.

Fig. 3. Nautilus pompilius, Great Nautilus.
4. No. 1. the largest of the ordinary size; No. 2. young, No. 3. section of the young shell, shelling the chambers and the siphunculus

Genus Conus.

200. Lettered Conchology, Genus Cyprea, Plate XIV.

Fig. 1. Cyprea tigris, upper and under surface
2. Cyprea aurora, Aurora or Orange Cowry of the South Seas
3. Cyprea argus
4. Cyprea Arabica
5. Cyprea annulata, upper and under surface
6. Cyprea saxifara
7. Cyprea maculata
8. Cyprea vespa
9. 9. Cyprea moneta, upper and under surface
10. 10. Cyprea pediculus

Genus Bulla.

199. Lettered Conchology, Genus Bulla, &c. Plate XI. A.

Fig. 6, 6. Bulla nigeria, No. 1. the outside, No. 2. the lower figure, shelling the mouth

Genus Voluta.

201. Lettered Conchology, Genus Voluta, Plate I.

Fig. 1. Voluta torminata
2. Voluta porphyria
3. Voluta oliva
4. Voluta pallida
5. 5. Voluta pometis, No. 1. the back, No. 2. shelling the mouth
6. Voluta episcopalis
7. Voluta Ethipica
8. Voluta indica

Genus Buccinum.

202. Lettered Conchology, Order Voluta, &c. Plate II.

Fig. 1. Buccinum harpa
2. Buccinum patulum
3. Buccinum maculatum
4. Buccinum frigillatum

Genus Strombus.

203. Lettered Conchology, Order Univalve, Plate III.

Fig. 5. Strombus echiura
6. Strombus fugilis
7. Strombus lentiginosus
8. Strombus urceus

Genus Murex.

204. Lettered Conchology, Order Univalve, Plate III.

Fig. 1. Murex hostellum
2. Murex longicauda
3. Murex muricatus
4. Murex tulipa

Genus Trochus.

205. Lettered Conchology, Order Univalve, Plate III.

Fig. 5. Trochus niloticus
6, 6. Trochus perspicuus. No. 1., right-hand figure, shelling the convex surface; No. 2. left-hand, the concave surface or under side
7. Trochus pisula
8. Trochus turritus

Vol. XXXIX.

5 A
PLATE

GENUS Turbo.

199. Lettered Conchology, Genus Bulia, &c. Plate XL A.

Fig. 7, 7. Turbo trilineatus, (Donov. Brit. Shells) smallest figure shews the natural size
8, 8. Turbo fissiformis, (Donov. Brit. Shells) ditto

GENUS Helix.

Fig. 9, 9. Helix bentina

GENUS Nerita.

Fig. 10, 10. Nerita carena, the figure on the left hand exhibits the carinated umbilicus

GENUS Haliotis.

204. Lettered Conchology, Genus Haliotis Plate VI.

Fig. 1, 1. Haliotis Afinum. The lower figure shews the outside or upper surface of the shell, as the animal moves; the upper figure exhibits the hollow of the shell, when deprived of the animal
2. Haliotis tuberculata
3. 4. Haliotis fuscina, outside and inside
5. Haliotis levigata

GENUS Patella.

* Shell valved within.

205. Lettered Conchology, Genus Patella Plate (blank)

Fig. 1, 1. Patella equestris. The upper figure shews the outside of the shell, which is rugose; the lower one the inside, which is smooth, and furnished with an internal lip or valve in the hollow center
2, 2. Patella fornicate. The figure on the left hand exhibits the outside; that on the right hand the inside, with the broad inner lip or valve
3. 3. Patella fragata. No. 1., the lower figure, shews the frigate outer surface; No. 2., the upper figure, the concave hollow beneath, with the inner lip or valve

* * Shell at the Apex perforated.

4. 5. Patella fissa
5. Patella fissaflora
6. Patella greta
7. Patella ranaeta
8. Patella lobata
9. Patella nimbofa. The upper figure shews the outside surface; the lower one the hollow cavity, or inside

*** Apex of the Shell entire.

206. Lettered Conchology, Genus Patella Plate XVI.

Fig. 1. Patella granatina. The upper figure shews the outside; the lower one the concave, or inside

PLATE

206. Fig. 2, 2, Patella Auricula, two varieties. The figure in the middle of the left-hand margin shews the outer surface; the others the concavity
3. Patella vulgata, var.
4. Patella frigata
5. Patella foigata
6. Patella virgata
7. Patella anatina

GENUS Dentalium.

207. Lettered Conchology, Genus Dentalium Plate (blank)

Fig. 1. Dentalium elephantium

GENUS Serpula.

Fig. 2. Serpula trigeret, various examples adhering to a Peclen, (Offrea)
3. Serpula trigeret, ditto, adhering to the valve of a Mytllus
3. Serpula vermicularis, intermixed with S. trigeret
4. Serpula vermicularis, detached
5. Serpula filiformis
6. Serpula reticulata
7. Serpula papillofa
8. Serpula tortuofa
9. Serpula anguina
10. Serpula penis

GENUS Teredo.

208. Lettered Conchology, Genus Teredo Plate X.

Fig. 1. Teredo navalis, exhibiting the manner in which the timbers of ships' bottoms are sometimes perforated by this destructive creature
2. Teredo navalis, a single shell detached from the timber, is shewn at the bottom of the Plate

GENUS Sabella.

Fig. 3. Sabella Belgica
4. Sabella albepicta

ELEMENTARY PLATES OF CONCHOLOGY.

UNIVALVES.

209. Lettered Conchology, Elementary Plate I.

Fig. 1, 1. 1. The part denominated the Bafe of an univalve shell, illustrated by examples selected from different Genera, as in Dentalium, Turbo
2, 2, 2. the Apex, as in Dentalium and Patella
3. 3. the Front, as in Turbo, Buccinum
4. 4. the Back, as in Turbo, Helix
5, 5. the Sides, as in Turbo, Buccinum
6, 6, 6. the Body, as in Helix, Mures
7. 7. the Belly, as in Nerita
8. the Whorl, as in Turbo
9, 9, 9. the Spire, as in Turbo, Mures,
10, 10. the Sutures of the Spire or Whorl, as in Mures, Turbo

NATURAL HISTORY.
NATURAL HISTORY.

210. Lettered Conchology, Elementary Plate II.

Fig. 11. The part denominated the Pillar or Columnella, as in *Murex*.  
12, 12, 12. the Aperture, as in *Murex*, *Helix*, *Nerita*.  
13, 13, 13. the Lip, as in *Voluta*.  
14. the Beak, as in *Murex*.  
15. the Canal, as in *Murex*.  
16, 16. the Umbilicus, as in *Trochus*, *Nerita*.  

211. Lettered Conchology, Elementary Plate III.

Fig. 17, 17. The part denominated the Operculum, as in *Trochus*, *Murex*.  
18. the Involute Spire, as in *Nautilus*.  
19, 19, 19. the Chambers, as in *Nautilus*, the Chambered Patella, and the Ammonite, (found fossil).  
20. the Siphunculus, as in *Nautilus*.  
21. the Epidermis, as in *Turbo*.  

BIVALVES.

Fig. 22. The part denominated the Base of a Bivalve Shell, as in *Venus*.  
23. the Summit, as in *Patella*.  
24, 24. the Beak, as in *Chama*, (Cor.). *Mytilus*.  
25. the Sides, as in *Venus*.  

212. Lettered Conchology, Elementary Plate IV.

Fig. 26. The part denominated the Margin, or Limb, as in *Tellina*, (cornua).  
27, 27. the Disk, as in *Venus*, *Tellina*.  
29, 29. the Posterior Slope, as in *Macra*, *Tellina*, *Venus*.  
30. the Lunule, as in *Venus*, *Tellina*, (a. & b.).  
31, 31. the Cartilage, or Hinge, as in *Tellina*, *Venus*.  
33, 32. the Ears, as in *Patella*, (Offrea, Linn.).  
33, 33. the Ligament Perforation, (Aperture in the upper valve of the Shell through which the ligament of the animal passes, by which it adheres to extraneous substances, as in *Anomia*).  

213. Lettered Conchology, Elementary Plate V.

Fig. 34, 34. The Length and Breadth of a Bivalve Shell, as in *Solen*, *Mytilus*.  
35. the Inside of a Bivalve Shell, as in *Mytilus*, (rugosus).  

Plate 213. Fig. 37. The part denominated the Cicatrix, Impression of the Spaces to which the animal-inhabitant of the Shell adheres.  
38, 38. the Byssus, or Beard, as in *Mytilus*.  

MULTIVALVES.

Fig. 39, 39. The part denominated the Base of a Multivalve Shell, as in *Leptes*.  
40, 40. the Ligament, as in *Leptes*, (anatlera).  
41, 41. the Operculum, as in *Leptes*, (Balanus vulgaris).  

* Vide article Conchology, which these Elementary Plates are intended to illustrate.  

ORDER 4. ZOOHYTES.

GENUS TUBIFORA.

214. Lettered Zoophytes, Genus Tubifora, Plate I.

Fig. 1. *Tubifora mylula*.  

GENUS MADREPORE.

* Consisting of one Star.  

Fig. 2. *Madrepore fungites*.  
3. *Madrepore plicus*.  
4. *Madrepore Agathyrsus*.  
5. *Madrepore foliaceus*.  

*** With numerous united Stars.  

215. Lettered Zoophytes, Plate II.

Fig. 1. *Madrepore labyrinibica*.  
2. *Madrepore phrygia*.  
3. *Madrepore grya*.  
4. *Madrepore avrolata*.  

**** Aggregated distinct Stars and porous tuberculate prominent Undulations.  

Fig. 5. *Madrepore australis*.  

***** Ramose, with distinct Stars, and tuberculated porulea Undulations.  

Fig. 6. *Madrepore porites*.  

GENUS ISIS.

216. Lettered Zoophytes, Genus Isis, Plate I.

Fig. 1. *Isis Hippuris*.  
2. *Isis coccinea*.  

GENUS ANTIPATHES.

Fig. 3. *Antipathes sulphureus*.  
4. *Antipathes Myriophylla*.  

GENUS GORGONIA.

217. Lettered Zoophytes, Genus Gorgonia, Plate II.

Fig. 1. *Gorgonia tepida*.  
2. *Gorgonia cerotophyta*.  
3. *Gorgonia americana*.  
4. *Gorgonia espiritualia*.  
5 A 2.
PLATE 218. Lettered Zoophytes, Genus Gorgonia, Plate I.

Fig. 1. Gorgonia nobilis, Red Coral, or Noble Coral
2. Part of the branch of Gorgonia Nobilis magnified, and exhibiting the animals
3. Gorgonia umbraculum
4. Portion of a branch magnified
5. Gorgonia reticulata
6. Portion of a branch magnified

Genus Alcyonium.

219. Lettered Zoophytes, Genus Alcyonium, Plate III.

Fig. 1. Alcyonium gorgonoides

Genus Spongia.

220. Lettered Vermes, Order Zoophytes, Genus Flustra, Plate VIII.

Fig. 1. Flustra foliacea
2. Flustra bombycina
2. A portion of a branch magnified to shew the cells
3. Flustra carbasca
3. Magnified to shew the cells
4. Flustra verticillata
4. Magnified to shew the cells

Genus Flustra.

221. Lettered Vermes, Order Zoophytes, Genus Tubularia, Plate I.

Fig. 1. Tubularia magnifica, Magnificent Tubularia, or Animal Flower
The figures in this Plate display the animal in its young and full-grown state, and exhibit likewise the full expansion of the tentacula

Genus Tubularia.

222. Lettered Zoophytes, Genus Corallina, Plate VI. & VII.

Fig. 1. Corallina officinalis
2. One of the branches magnified
3. Corallina squamata
4. A branch magnified
5. Corallina incrustata
6. Corallina opunlia
7. Corallina cornutula
8. A branch magnified

Genus Sertularia.

223. Lettered Vermes, Order Zoophytes, Genus Sertularia, Plate VIII.

Fig. 1. Sertularia fruticosa
1. A branch magnified

PLATE 223. Fig. 2. Sertularia quadridentata
2. A branch magnified
3. Sertularia pinifer
3. A branch magnified
4. Sertularia filicina
4. A branch magnified

Genus Hydra.

224. Lettered Vermes, Order Zoophytes, Genus Hydra, Plate V.

Fig. 1. Hydra viridis, Green Polype
2. Hydra grifida, Grey Polype
3. Hydra fusca, Brown Polype
4. 5. 6. Clusters of the different species, as they live at the roots of aquatic plants immersed in water
8. Those marked with a star are magnified.

Order V.

Infusoria.

Genus Brachionus.

225. Lettered Animalcules, Clas Vermes, Plate I.

Fig. 1-6. Brachionus urceolaris, in various states of expansion and retraction
7. Brachionus fritatus
8. Brachionus tripus
9. Brachionus uncinatus
10. Brachionus quadridentatus

Genus Vorticella.

226. Lettered Vermes Infusoria, Plate II.

Fig. 1. Vorticella polypina
12. Vorticella polypina, a cluster magnified
13. Vorticella anaftatica, the group shewing the manner in which they aggregate in clusters; and also figures of the single-headed, double-headed, and quadruple-headed, separate
14. Vorticella pyralia, a cluster
15. Vorticella opercularia, a group, shewing the fleshtiform animal expanded
16. Vorticella umbellaria
17. Vorticella digitalis
18. Vorticella nebulifera

Genus Trichoda.

227. Lettered Vermes Cercaria, Plate IX.

Fig. 8, 9. Cercaria Lernna, in the entirely expanded position it assumes when moving, and two others
9. Cercaria inequata, extended and subretracted

Genus Cercaria.
PLATE 226. Fig. 10. Cercaria lupus  
11. Cercaria podura

Genus Kolpoda.
Fig. 12. Kolpoda pyrum

Genus Paramecium.
Fig. 13. Paramecium oviferum  
14. Paramecium chrysostri  
15. Paramecium marginatus

Genus Vibrio.
Fig. 16. Vibrio angustilcula  
17. Vibrio glutinis, the smaller figures denote the  
natural size  
18, 19. Vibrio aniger, in two positions  
19. Vibrio olor  
20. Vibrio lunula  
21, 22. Vibrio pacilifer, variously connected

Genus Leucophra.
Fig. 22. Leucophra cornuta

Genus Enchelis.
Fig. 23. Enchelis punctata  
24, 25. Enchelis retrograda, two figures  
25. Enchelis trunca  
26. Enchelis caudata

Genus Volvox.
Fig. 27. Volvox globator  
Obst. All the Vermes infusoria are microscopic objects

Addenda to the Zoology.

PLATE 227. Fig. 14. a, a, The three masses of luminous sub-
stance, which are applied to the three last 
rings of the abdomen  
b, b, The arrangement of the cellular or interstitial substance on the other abdomi-
nal rings, which give the pale colour to the 
whole belly of the insect
15. Diffusion of the common Glow-Worm, ex-
ploiting the facts of luminous matter in situ,  
on the last ring of the belly.  
a. The fac on one side  
b. One of the facts of the Glow-Worm taken  
out and very highly magnified.  
a. The external part of the face, composed of an  
ter weaving of a spiral fibre.  
b. The luminous substance seen at one end

17. Elater nothilus, with a portion of the  
shell of the thorax removed to uncover  
one of the organs of light, of which there  
are two, one being situated on each side,  
at the posterior part of the thorax.  
a. The yellow transparent spot of the thorax  
b. The oval mass of luminous substance  
surrounded by an irradiation of the  
interstitial substance.  
c. The ends of the muscles which are on the inside of the  
thorax

18. The luminous apparatus of the elater nothilus,  
considerably magnified.  
a. The radiated appearance of the interstitial  
substance around the oval mass of luminous  
substance.  
b. The arrangement of that  
substance when it passes down between the  
muscles.  
c. The ends of the muscles of the back.  
d. The shell of the thorax

19. Elater ignitus.  
a. The yellow part of the  
thorax.  
b. The small mass of luminous  
substance, seen on removal of the shell of the  
thorax

Obst. The preceding objects were those appointed by  
Dr. Macartney for the explanation of his article  
Luminous Animals, which will be found placed  
under the leading article, Light.

In addition to those, we have, ourselves, conceived  
the propriety of introducing another figure of the  
Nereis genus, that of Vianelli being, confes-  
edly, very doubtful. This animal is, therefore,  
not merely introduced by us as a species highly  
phosphorescent, under certain circumstances, in  
common with most others of its tribe, but in order  
laterwise to convey a more accurate idea of the  
Nereis genus, than the figure copied from Via-
elli will afford. The species we have introduced,  
is the Nereis carulae of some authors, fanguinea  
of others, and is, beyond any doubt, a genuine  
Nereis of the Linnean Syllem.

The figure by Vianelli, is contained in a small tract  
written in the Italian language, entitled "Nuove  
scoperte intorno le luci notturne dell' acqua marina;"  
and which, besides being most evidently depicted  
from a very mutilated object, is entirely different  
from that included in the third volume of Ame-
nitates Academicae, which Linneaus himself gave  
very shortly afterwards as the same animal: and  
even this latter, like that of Vianelli, if we mis-
take not, must have been delineated likewise from
an imperfect animal. We have, indeed, a strong suspicion, that the animal represented by Vianelli, cannot be of the Neris genus.

In conclusion of this note, it may not be amiss to add, that no animal has been more indefinitely described than the Neris noctilucia. The only specific character assigned to it in the last edition of Systema Naturae cura Gmelin, is Corpores vis conficientes, which being applicable to every minor species, can be no criterion of the individual kind that author had intended; and the same vague character occurs again in Mull. Zool. Prod. n. 2623. In the twelfth edition of Linn. Syll. Nat. the body of Neris noctilucia is described as consisting of twenty-three joints, which is the number represented in the Plate inserted in Ameis. Acad. t. 3, but this distinction is totally at variance with the subject of Vianelli’s tract; for in that figure there are no more than about eleven joints in the body, instead of the twenty-three which Linnaeus has described.

**BOTANY.**

Illustration of the Twenty-four Linnean Classes, according to the Number of the Staminæ.

228. Lettered Botany, Plate II.

Fig. 1. Clas 1. **Monandria**, one stamen, as in *Salicornia*, *Callitrichis*, &c.

2. 2. **Diandria**, two stamens, as in *Veronica*, &c.

3. 3. **Triandria**, three stamens, as in *Hordeum*, *Agrostis*, &c.

4. 4. **Tetrandria**, four stamens, as in *Ilex*, &c.

5. 5. **Pentandria**, five stamens, as in *Borago*, *Primula*, &c.

6. 6. **Hexandria**, six stamens, as in *Allium*, *Erisippermum*, *Ornithogalum*, &c.

7. 7. **Heptandria**, seven stamens. Tiennials, *Dianthus*, *Rheum*, *Petrocarpa*, *Pancopia*, and *Josefa* are of this class.

8. 8. **Octandria**, eight stamens, as in *Epilobium*, *Ceratiola*, &c.

9. 9. **Enneandria**, nine stamens, as in *Butomus*.

10. 10. **Decandria**, ten stamens, as in *Sedum*.

11. 11. **Dodecandria**, twelve stamens, as in *Sempervivum*; above twelve, and less than twenty stamens, as in some other genera.

12. 12. **Koandria**, twenty or more stamens inserted in the calyx, as in *Mefphlous*, *Pyrus*, and some other fruit-bearing plants, including *Fugaria*, *Riber*. &c.

229. Lettered Botany, Plate III.

Fig. 13. Clas 13. **Polyandria**, many stamens, and inserted into the receptacle or base of the flowers, as *Papaver* (poppy), *Trollius* (great butter-cup), *Ranunculus*, &c.

230. Lettered Botany, Orders, Plate IV.

Fig. 1. **Monogynia**, one style or stigma (with five stamens), as in *Salix*, *Cytisus*, *Anchusa*, *Borago*, &c.

2. 2. **Diogynia**, two styles (with ten stamens), as in *Grifolspermum*, *Melites*, *Scleranthus*.

3. 3. **Triogynia**, three styles (with ten stamens), as in *Silex*, *Stellaris*, &c.

4. 4. **Tetragynia**, four styles, with four stamens, as in *Rupia*, *Potamogeton*, *Sagina*, &c.; with five stamens, as *Parnassia*, &c.; with six stamens, as in *Papaver*. &c.

5. 5. **Pentagynia**, five styles (with ten stamens), as in *Oxalis*, *Scuriana*, *Lycbius*, &c.

6. 6. **Hexagynia**, six styles, as in *Butomus*.

7. 7. **Heptagynia**, seven styles (with seven stamens), as in *Suaea*.

8. 8. **Decagynia**, ten styles (with ten stamens), as in *Neurada* and *Phyllocaes*.

9. 9. **Dodogynia**, twelve styles (with twelve stamens), as in *Sempervivum*.

10. 10. **Polygynia**, many styles, as in the 1st, 2d, 3d, and 4th. order of Clas Syngenea.

11. 11. **Gynofermes**, naked seeds, as in *Ajuga*, *Teucrium*, *Satureja*, &c.
NATURAL HISTORY.

Plate
230. Fig. 12. Angelospermia, seeds inclosed in a pericarpium or seed-velvct, as in many genera, Anterbinum, Cybarla, &c.

231. Lettered Botany, Orders, Plate V.

Fig. 13. Siliquoloa, pericarpium a filicula, as in Thalaspi (shepherd’s purse), Draba, &c.
14. Siligula, pericarpium a filique, as in Raphanus, Sinapis, Brastica, &c.
15. Polygonum Equalia, flowers compound, all the florets hermaphrodite, as in Leontodon, Hieracium, &c.
16. Polygonia Superfusa, florets of the disk hermaphrodite, those of the radius female, as in Bellis (garden daily), Tussilago, Senecia, &c.
17. Polygramia Vereoptera, flowers of the disk male, those of the radius female, as in Calendula, Chryogenum
18. Polygramia Fragiflora, florets of the disk hermaphrodite, those of the radius neuter, as in Gentaeas, Sclerocarpus, Radbeckia.
19. Polygramia Segrega, many partial cups contained in the common calyx, which separate and surround the floecula, as in Echinops, Gundelius, Spharatus, &c.
20. Triiactia, have the polygamy or parts of fructification on three different plants, as in Ficus, and also Ceratonia.
21. Felices, fructification doriferous (on the back of the leaf), as in Asplenium, Adiantum, Trichomanes, &c.
22. Musci, anthers without filaments; female flowers distinct and without pifiilum: feeds a naked corculum without cotyledon or tunic. With or without a calyptra or veil, as in Bryum, Hypnum, Buskium, &c.
23. Hepaticae, herbaceous frondose in general, the fructification originating from what is at the same time both stem and leaf, as in Marchantia, Jungermanla, &c.
25. Fungii, mushrooms, as in Agaricus, Boletus, &c.

Class Cryptogamia.

Addenda to the Musci, in Illustration of the Fringes of Musci.
* Furnished with single Fringes.

232. Lettered Botany, Plate Fringes of Musces.

Fig. 1. Tetraphis. Fringe of four teeth, as in Mnium pellucidum. These are cret, acute, firm, polished, and permanent.
2. Oxypleurum. Fringe of eight teeth, as in Bryum albidum. Capule without an apophysis.
3. Spiactium. Fringe of 16 teeth, dilated at the base, approaching each other in pairs.
7. Conostomum. Fringe of 16 tapering teeth, approaching each other in pairs, and all cohering at the points, as in Bryum tetragonum, Dickson, Grimmia conostoma, Smith Engl. Botany.
8. Dietramus. Fringe of 16 flat, somewhat inflected teeth, cloven half-way down.
9. Trichostomum. Fringe of 32 linear (straight) teeth, approaching each other in pairs, sometimes joined at the base in pairs.
11. Syntrichium. In some species of Tortula the teeth are united into a cylinder at the base, pierced with numerous holes, upon which some recent botanists have founded this new genus.

* * The following Genera are furnished with a double Fringe, some few Species of Orthotrichium and one of the Buxbaumiae perhaps excepted.

Fig. 2. Orthotrichium. Capule terminal. Outer fringe of 16 teeth; inner of 8 or 16 linear ones, sometimes altogether deficient. Veil furrowed.
23. In Buxbaumia folios the outer fringe is scarcely perceptible; it is represented at fig. 16.
22. Polytrichum. Outer fringe of 32 or 64 flat inflexed teeth; inner, a transverse orbicu
Apetalous

Vide article Fringe of Mosses, by Sir J. E. Smith.

Class Cryptogamia.

Addenda in Illustration of the Genera of Fungi.

Obf. The importance of the Syſtem of Tournefort, the outline of thefe classifcation is here laid down, will be felt underflood by thoſe who are aware of the attachment of the French Botanifs, even of the latest times, to the method of this early author: a botanif, whose labours preceded thoſe of Linnaeus by nearly half a century.—It has been truly obferved, that Tournefort is to the French in the science of botany, the foundation-stone upon which all their fylltems areedified. This pre-dilefion in favour of their own fylltems, to the exclusion of that the Swedish naturalif laid fdown upon the sexual organs of plants, may yet havfe revolution; but that in the prefent time is more than can be well expected. As the botanical department of this Cyclopaedia has been almoft from the commencement allotted to one of the moft able profeffors in the science, it is very far from the intention of the writer of the prefent article to enter into the comparative merits of the prevailing fylltems of this time, the Linnaean in Britain, under the auspices of its many learned advocates, and that of the French, founded on a "natural method" not very different from that of Tournefort, and as improved by Juffieu and Guertner. We only wish to offer some apology for the great number of plates devoted to the fylltem of the celebrated corollift M. Tournefort than to the sexual fylltem of Linnaeus; the latter being a naturalift whom from adopion we may almoft deem our own, and we muſt confefs with all his imperfections our moft favourite author.

The great talents of one of our ablefl and moft experienced Botanifs at this period, we are well aware have been directed to the advancement of a "natura

Plate

Vegetable Anatomv.

18. A horizontal fection of a bulbous root, shewed

* Robert Brown, Efq. who, without rejecting the sexual organs as useful auxiliaries, regards more particularly the germination of plants, with the number and form of the Cotyledons, as essentially characteristic in a fylltem founded on a natural clasfification.
Plate 245. — Ing the concentric layers of which it is composed.

Fig. 20. Perpendicular section of a bulbous root.

MINERALOGY.

246. Inscribed Natural History, Plate I.

View of Mount Aetna, from Spallanzani's Work.

This is a general view of Mount Aetna, the adjacent country and the sea; and is intended to shew the effects occasioned by the eruption of the volcanic matter at different times. A points out the loftiest summit of the Mount. H is Nicolosi, and marks the Mount Rosso or Red Mountain, formerly a plain, but in 1699, a new vertex opened in it, and discharged the dreadful torrents of lava which overflowed the land, till reaching the sea, it formed the promontory of lava in the sea extending as far as letter Y. G, near this new opening of Aetna, is the mountain Montpeliere or Montpilier.

Various other interesting spots are marked in the plate, for which consult the article AETNA, Mount.

247. Inscribed Natural History, Plate II.

A View of the Crater of Mount Aetna.

A A A. One edge of the lava of 1787, which overflowed from the upper crater. B B the circumference of the crater, with its cleft C C through which the internal part is discernible. D the flat bottom of the crater. E the aperture in the bottom through which the larger column of smoke F F arose. G G is that part of the edge of the crater from which its internal part is best seen. H H is the smaller column of smoke to the north-east. Vide article Mount AETNA for further explanation.

248. Inscribed Natural History, Plate IV.

View of the Crater of Mount Vesuvius. Drawn by the same hand, and at the same time as the preceding.

249. Mineralogy, Plate II.

Bafalt. The Mountain of Aifa, called La Coupe, or the Col d'Aifa, near the village Entrague, in the Viverrais, above the torrent of Volant.

This plate affords an example of the formation of bafaltic columns, and illustrates the hypothesis of the Huttonian system, according to which the bafaltic matter has been originally of volcanic origin, and while in a state of fusion cast out of the crater of the mountain. In its progress this lava has formed a wavy channel down the mountain side. According to St. Fond, this is the most remarkable and best characterized crater in all the Viverrais. The ends of the columns may be distinctly seen before the bafalt reaches the river.

GEOLGY.

250. Geology, Plate I.

Fig. 1. The upper figure in this Plate exhibits the dip, dyke, fault, slip, trouble, &c. described and referred to in the article Coal.

251. Geology, Plate II.

Fig. 1—10. Sections of various Strata.

252. Geology, Plate III.

Fig. 1. Strata : being a sketch of the arrangement of the strata through England, by Mr. R. Bakewell. Lat. 54° 35' to 54° 45'.

2. Section of the strata through part of Dorsetshire and Devonshire, by Mr. R. Bakewell.

3. Perpendicular strata.

4. Horizontal strata.

5. Inclined strata, consisting of greywacke clay-flate, compact felspar, porphyry finte, trap, clink-flone and granite, valley of Long Sleddale, Westmoreland.

6. Undulate strata: shewing the wavy structure of the beds of slate, called shillet, in Devonshire.

253. Geology, Plate IV.

Fig. 1. 1. Metallic veins exemplified, with a "rider, &c.; and also the interfeftion (or "cutting-off") of metallic veins.

2. Columnar and amorphous bafalt, interfefted by bafaltic dykes.

3. Lime-flone broken and intected in bafalt, being in a bafaltic rock on the coast of Antrim. Whifflone dykes, or bafaltic veins, passing through chalk, and changing it into marble—under figure 4. (See article Geology. Suppl. Vol. XXXIX.)

Addenda to the Geological Illustrations.

254. Plate Ichthyologie, or Ichthyological Remains.

Mineralized remains, or impressions of fishes, on black shillet slate, found at Illeben, in Germany.

255. Fossils, Extraitous, Plate I.

Fig. 1. Mineralized remains of an encrinus, Encrinus Illiformis, or "flone lily," in relievo, on a flab of stone.

2. Transverse fection of the lily-head.

3. The lily-head half broken through transversely.

4. Bottom of the lily-head, shewing the peduncle by which it is connected to the main stem of the encrinus.

CRYSTALLOGRAPHY.

256. Lettered Crystallography, Plate I.

Fig. 1—7. Various forms of the crysals of adaman-
tine fpar.

262. Lettered Crystalization, Plate VII.

Fig. 27. The Octahedron, regularly formed.

Plate

62. Fig. 5. The Hexahedral prism, or equiangular six-sided prism
12. The Rhomboidal dodecahedron
14. The Pyramidal dodecahedron, or double six-sided pyramid

37. Crystallography, Plate II.

Fig. 17—21. Mechanical division of an hexahedral crystal of calcareous spar, and extraction of the primitive crystal, or nucleus

22, 23. Mechanical division of the dog's-tooth spar, erroneously fig. 6, 7. Plate I.

Fig. 24. Rhomboids of calcareous spar, a secondary crystal, with the primitive nucleus.

50. Crystallography, Plate V.

Fig. 56. The base of the six-sided prism, divided by sections parallel to each of its sides, and producing the triangular prism, the ultimate form obtained by mechanical division

39. Crystallography, Plate IV.

Fig. 48, 49. The cube divided by sections parallel to the sides, and producing a series of smaller cubes, considered as the form of the integrant molecule

37. Crystallography, Plate II.

Fig. 26. The primitive rhomboid of the tourmaline, with its division. This crystal is divisible both in the direction of the six faces, and in that of the short diagonals; by which latter sections the rhomboid is reduced to fix tetrahedrons, surrounding the nucleus, as here represented

Decrement of the Edges of the Crystals.

24. & 258. Crystallography, Plates II. & III.

Fig. 27, 28. The rhomboidal dodecahedron, which figure may be formed from a cubic nucleus, by the superposition of decreasing laminae.

21. Crystallography, Plate III.

Fig. 29. Congeries of cubes, confiding of integrant molecules, forming the cubic nucleus, with the pyramids raised on three of the faces

22. Crystallography, Plate II.

Fig. 27. The form of the crystal, produced by the combination of these integrant molecules, when complete

Decrement in Breadth and Height.

23. Crystallography, Plate III.

Fig. 30. A crystal of iron pyrites, with twelve pentagonal faces, in which the two kinds of decrement are combined

Plate

258. Crystallography, Plate III.

Fig. 31. The cubic nucleus of this variety is shewn

32. The formation of the crystal by decrements

33. Decrement of the dog’s-tooth spar, (the metamorphic crystal of Häiyl) represented complete in Plate 257. fig. 22. The present figure supposes the hypothesis of a decrement by two ranges in breadth. It represents the upper pyramid of this crystal placed on the upper planes of the primitive nucleus, which being partly visible, dislopes more clearly the progressive effects of the decrement by two ranges

34. A secondary crystal, which is a rhomboid much more obtuse than the nucleus, is represented as surrounding the nucleus in the variety of calcareous spar, called by Häiyl, equiaxe.

The nucleus (presumed to be the primitive rhomb of carbonate of lime) progressively divided to explain its structure.

The face at letter A, fig. 35, shews the same face of the rhomb as is represented in fig. 34, but symmetrically divided, and the same shews the gradual division of the rhomb, by mechanical separation down to letter I d.

258. Crystallography, Plate III.

Fig. 36. Decrements on the angles of a crystal, shewn in the regular octahedron formed on a cube

259. Crystallography, Plate IV.

Fig. 37. The arrangement of the integrant molecules on one of the triangular faces of the octahedron

259. Crystallography, Plate IV.

Fig. 38. Rhomboid crystal

39. Another example of the decrements on the angles, exemplified in the division of the rhomboid, fig. 38., which differs somewhat from that of the cube, producing a very obtuse rhomboid, encircling the nucleus; found among the secondary crystals of olivite, iron ore.

Further illustration of the different variations, of which the decrements of the rhomboid, both of the superior and inferior angles, are susceptible. The rhomboid is shown at fig. 45; the divisions at fig. 46, 47.

Intermediate Decrements.

Fig. 48. A parallelopiped undergoing a decrement, by two ranges on the angle of its base

49. A crystal, in which all the three decrements round the same solid angle are intermediate

50. Another example of intermediate decrement in one of the faces of a cubic nucleus, taking place on the angles, by the subtraction of double molecules

51. The cubic nucleus, marking the decrements parallel to the lines k m, &c. by subtrac-
NATURAL HISTORY.

Plate 259.

52. A polyhedral crystal of thirty faces, produced by the cessation of decrement, before the formation of the pyramid round each face of the nucleus.

53. Example of intermediate decrements on the two lateral angles of a rhomboid, (as at fig. 47.), the decrements taking place by ranges of double molecules, producing in the complete result a fold of twelve faces, disposed fix and fix towards each summit, as in one variety of calcareous fpar, or double-pointed dog’s-tooth fpar.

Compound secondary Forms of Crystals.

Fig. 54. A secondary crystal, an icosahedron bounded by eight equilateral triangles, and twelve isosceles triangles. Occurs in iron pyrites.

Fig. 55. A calcareous fpar (Analogue of Haüy’s), composed of twenty-four trapezoidal faces, fix of which are vertical, and twelve others disposed fix and fix. The different trapezoidal faces are shown in the figure.

260. Crystallography, Plate V.

Fig. 56. The end of the regular six-sided prism, which, for its molecule, presents us with the triangular, or three-sided prism.

57. A cubic nucleus divided into its cubic molecules.

59. Superior face of the second lamina, A.

Ditto, further mechanical division of the integrant molecules, B.

Ditto, ditto, C.

58. Explanation of vacuities on the edges of a crystal, given by Haüy.

60. An oblique prism with rhomboideal bafes, so situated that the faces A D, a d', and C D, c d', are vertical; and B D are the acute angles of the base, and that the latter proceed in an ascending direction from A to C.

Interflet this prism into halves, by means of a plane passing by the diagonals, drawn from B to D, and from b to d', so that the half situated on the left remaining fixed, the other is reversed without being separated, and the figure presented will be as shown at fig. 61.

62. Another example of grouping, in which crystals are interfolded into each other, is extremely common. This combination is illustrated by a cube, and M N r, an equilateral triangular facet, produced by a decrementation of one range round the angle A.

63. A second cube modified in the same manner, and affixed to the other by its corresponding facet, will afford the double crystal represented.

Plate

To illustrate the Notation of Crystals.

Fig. 64. Represents an oblique paralleloped, its faces of which have angles of different measures.

65. The effect of decrement shewn.

66. An oblique paralleloped.

67. Primitive molecules.

68. Bibinary fpar of Haüy.

69. Primitive form of a rectangular prism, which has oblique-angled parallelogram bases, one of which is longer.

70. The oblique prism, with rhomboideal bafes.

71. The rectangular prism, with rectangular bases.

72. The rectangular prism, with rhomboideal bases.

73. The rectangular prism, with square bafes.

74. The cube.

75. The most common variety of chrysoberyl, cymohane, the nucleus of which is regular paralleloped, as represented fig. 71.

76. The prism.

261. Crystallography, Plate VI.

Fig. 77—84, &c. Several figures inserted to illustrate the manner in which the symbol employed in the definition of crystals by Haüy, and other crystallographers are expressed.

86. Octahedron, with scalene triangles.

87. Octahedron, another variety.

88. The regular octahedron.

83, 84. The primitive octahedron, composed of eight isosceles triangles similar, four in each.

85. The tetrahedron when become a prim form.

86. The regular six-sided prism.

87. The same, in which three fold angles, taken alternately, are replaced by faces, while the intermediate angles remain untouched.

88. Rhomboideal dodecahedron, in which each fold angle is composed of three planes, and may be assimilated to a summit of obtuse rhomboid.

89. Primitive form of the tournaline.

90. One variety of the tournaline.

Steam Safety Lamp

* * * By attending to the above classification, the whole of those Plates of Natural History, which the proprietors have allotted to this Cyclopaedia, may be readily reduced to numerical order, and be by that means, it is presumed, more easily distinguished when required for reference than by the original plan, in which the plates of each section were lettered separately from the rest. They now follow each other, not only in numerical order throughout their whole extent, but also in the order of the Linnaean System, as nearly as the number of plates appropriated to the respective Sciences would conveniently allow. The miscellaneous nature of some few plates, which it has been lately thought desirable by the proprietors to introduce, renders it impossible to place them strictly in the order of system.

ERRATA

ON THE

PLATES OF NATURAL HISTORY.

Some few errors having been committed by the writing engravers in lettering the names upon the plates of Natural History, which it will be very desirable to correct, the reader is requested to observe, that wherever the names upon the plates are found at variance with those inserted in this printed index, the preference is to be invariably given to the latter; and that the names upon the plates may be corrected by a reference to this index. The following errors occur to us in passing over the plates for the purpose of composing the present classification.

ANCIENT AND MODERN ATLAS.

PLATE

I. Ancient Geography—Imperium Car. Mag. ad finem faculi post Chrift. VIII.

A few copies, only, of this Map were published with the parts of the Cyclopaedia. The proprie-
tors having afterwards determined to engrave the maps on a larger scale, it was cancelled, and a
Map of the World, as known to the ancients, substituted in its stead as the first of the Ancient
Atlas.

GEOGRAPHIA ANTIQUA.

TABULA

I. Orbis Veteribus Cognitus
II. Populi, Urbes, &c. in Gracia, Thraña, et Asia, quorum meminit Homerus
III. Britannia Romana, cum Hibernia et insulis adja-
centibus
IV. Peloponnesus, quae ante Aepia, Pelagia, et Argos, antequam Romanæ ditionis fuit, &c.
V. Hellas, sive Graecia Propria, Thesfalia et Epirus, antequam Romanæ ditionis fuerunt
VI. Macedonia et Thracia, antequam Romanæ ditionis fuerunt
VII. Asia Peninsularis, cum Insulis adjacentibus
VIII. Ægyptus, provincia Romana Imperialis
IX. Lybia, vel Africa, ora borealis
X. Italia Regio Alpina, quæ vulgo dicitur Gallia Cifalpina
XI. Italia Media, vel Italia propria pars borealis, ante diviſionem ab Augusto factam
XII. Italia Ulterior, cujus pars Australis Magna Graecia, ob Græcorum colonias, dicta, ante
 diviſionem ab Augusto factam
XIII. Sicilia, provincia Romanorum, cum Insulis ad-
 jacentibus
XIV. Italia in regiones undecim ab Augusto descripta,
cum Insulis Corfica et Sardinia
XV. Imperium Romanum
XVI. Hispania Romana
XVII. Galliae, sicut ab Augusto divisa, pars meridionalis
XVIII. Galliae, sicut ab Augusto divisa, pars septen-
 trionalis. Additur, Gallia Qualis fuit inueute
 feculo quinto Ærae Christianæ in 17 provincias
divertita
XX. Rhaetia et Noricum, provincia Romanorum

TABULA

XXI. Germania Magna, quae nunquam Romanis paruit
XXII. Terra Filiorum Israelis, antequam in duo Regna
divertita fuit, cum Terra Philiflaorum, parte
Phenices, &c. Etiam, Judæa et Regiones
finitima circiter initium Ærae Christianæ.

INDEX
INDEX OF THE PLATES.

Containing a List of all the Subjects represented on the Plates, arranged in alphabetical order, and classed under the several Sciences or Departments to which they pertain; together with References to the particular Plate and Figure where each Subject is delineated.

The Roman Numerals denote the Plate; the Arabic Numerals, the Figure.

AGRICULTURE.

Barn, Common, i. 1.
Double, i. 2.
Dutch moveable, i. 5.
Improved, i. 3.
Open, i. 4.
and Threshing Machines, ii. 1—6.
with moveable floor, and racks for feeding cattle, ii. 7.

Berne Machine, xxxvii. 1.
Bevertone Plough, xxxi. 1.
Blighting Stones, implements for, iii. i.
Borers, Draining, xxxvii. 2.
Break Plough, or Faring Spade, xxxii. 3.
Calf Pens, iv. 1, 2.
Chert, iii. 3—9.
Cattle Sheds, iv. 3—6. v. 1—8.
Chaff-cutter, by M'Dougall, vii. 3.
Salmon’s, as made by Rowntree, vii. 1, 2.
Charles’s, Mr., Machine for levelling Land, xxxi. 1, 2.
Cheepe Prefs, viii. 1, 2.
Cheeshire Faring Plough, xxxii. 1.
Churns, by Hartland, viii. 3—4.
by Rowntree, viii. 5—7.
Coppinges, Mr., Malt Kiln, xxxvi. 8.
Corn and Mixed Farm Buildings. See Farm.
Cottage Bed Room, ix. 5.
Fire-place, ix. 1, 2.
Staircase, ix. 3—4.

Cottages, Farm, vi. 1—4.
Ornamental, vii. 1—9.

Couch Grafs Drag, Amos’s, ix. 7, 8.
Rake, by the same, ix. 9, 10.

Cultivators, x. 1—5.
Curd-cutter, iv. 7.
Cyder Mill, x. 1, 2, 5.
Prefs, x. 3, 4.

Dairy Houfes, xii. 1—7.
at Woburn, xi. 6, 7. xiii. 1, 2.

Dairy Farm Buildings. See Farm.
Drill Machine, by Salmon, xxv.

Duckett’s Skim Coulter, xxx. 5.

Embarkments, x. xi.

Earth Buildings. See Fré.

Fan Machine, xxxvi. 3.
Farm Buildings, Grafs and Dairy Farms, xxxi. 1—5.
Corn and Mixed Farms, xiv. 1—5.

Farm Cottages. See Cottages.

Houses, xx. 1—6.
Yards, Angular and Circular, Plans of, xvii. 1, 2.
Square, Plans of, xvi. 1, 2.

Vol. XXXIX.
INDEX OF THE PLATES.

AGRICULTURE.
Quarries, Draining, xxxviii. 1—5.
Quendon Barrow, for carrying water, xxxviii. 6, 7.
Rawson’s, Mr., Kiln, xxxvi. 2.
Roger's, Mr., Bean Cultivator, x. 3.
Rotherham Plough, xxx. 1.
Rumford's, Count, Lime Kiln, xxxvi. 1.
Stark’s Potatoe Set Scoop, xxxix. 5.
Small’s Chain Plough, xxx. 2.
Somerville’s, Lord, Plough, xxx. 3.
Double Furrow ditto, xxx. 6.
Stone Lifting Machine, xxxvi. 4.
Stones, Implements for Blasting, iii. 1.
Suffolk Iron Plough, xxx. 4.
Threshing Machines. See Barn.
Water, Machine for raising, xxvi. 5.
by Sargeant, xxxvi. 6.
Weston’s, Mr. C., Double Cultivator, x. 4.

ALGEBRA.
Arithmetic, Palpable
Writing, Ditto.
Neper’s Bones, Miscellany, i. 6.

ANALYSIS.
Circle of Circles, Magic, xi. 7.
Cissoid, i. 1.
Conchoid, i. 2—7.
Construction, i. 8—20. GEOMETRY, ix. 2.
Cotesian Theorem, ii. 21, 22.
Crown, ii. 23.
Cuneus, Parabolic, xiii. 3.
Curve, ii. 18. 24—26. iv. 1—16.
Harmonic, ix. 4. No. 2—8.
Logistic, xi. 4.
Caulic, ii. 24.
Diacauitc, ii. 25.
Curvature, iii. 1—13.
Cylindroid, v. 1—8. See also Plate CYLINDROID.
Cylinder, ii. 3—4.
Epicylindroid, v. 9—11.
Evolute, vi. 1—10.
Fluxion, vii. 1—4.
Function, Analytic, vii. 5—8. GEOMETRY, ix. 3.
Geometry, Analytic, viii. 1—10.
Gyraton, ix. 1—4. No. 1.
Harmonic Curve, ix. 4. No. 2—8.
Helicoid, x. 1.
Inclifion, x. 2—7.
Hyperbrom, ix. 1—17.
Lemnifate, xi. 1.
Logarithmic, Atmospheric, xi. 2.
Curve, xi. 3.
Logistic Curve, xi. 4.
Spiral, xi. 5.
Magic Circle of Circles, xi. 7.
Square of Squares, xi. 6.
Locus, xii. 1—23.
Maxima and Minima, xiii. 1—2.
Parabolic Cuneus, xiii. 3.
Parallelogram, Analytic, xiii. 4.
Progression, xiii. 5.
Quadratic Equation, xiii. 6.

ANALYSIS.
Quadratrix, xiii. 7—9.
Quadrature, xiii. 10—20.
Ratio, xiii. 21.
Rectification, xiv. 1—5.
Sections, following, xiv. 6.
Solidity, xiv. 7—10.
Square of Squares, Magic, xi. 6.
Subtangent, xiv. 11.
Superficies, xiv. 12—15.
Tangent, xiv. 16—21.
Tangent, GEOMETRY, ix. 14—19.
Variation, NAVIGATION, i. ii. 8, 9.

ANATOMY.
Cranium, xix. xx.
Ear, Anatomy of, v.—vii.
Eye, Anatomy of, i.—iv.
Myology, viii.—xvi.
Osteology, xvii.—xix.
Skeleton, xvii. xviii.
Vindexa, xxxi.—xxiv.

ANATOMY, COMPARATIVE.
Birds, i.—iii.
Horse, i—iv.

ARCHITECTURE.
Abacus, xxx.
Amphitheatre, ii.—v.
Annulet, xxx.
Arch, vi. 1—7.
Oblique, xxxix.
of Adrian, ix. 1.
Constantine, x. 1.
Severus, ix. 2.
Titus, x. 2, 3.
Afragal, xxx.
Attie Bafe, i. 1, 2.
Bafe, Attic, i. 1, 2.
Doric, i. 3.
Ionic, i. 4.
Basilica, xi.
Basilica, Roman, from Vitruvius, ii.
of St. Peter’s, ancient and modern, xxxv.
Baths of Caracalla, xxxvi. xxxvii.
Titus, painting from, xxv.
Bead, xxxi.
Bridge, Wooden, at Walton, xxxiv.
Bridges, xxxii.—xxxiv. xxxvii. xxxix. lxv.—lxvii.
Cantiliver, xxxi.
Capital, Doric, i. 5, 6.
Egyptian, xxvi.
Ionic, i. 7.
Capitals, Corinthian and Composite, xxxvii.
Caracalla, Baths of, xxxvi. xxxvii.
Circus of, xii.
Carpentry, xlii.—xliv. lviii.—lxviii.
Geometrical principles of, lxxxix.—lxxviii.
Carrara, west door of the Cathedral of, xl.
Cavetto, xxxi.
Centre, lxv.—lxvii.
INDEX OF THE PLATES.

ARCHITECTURE.

Chimney, viii. & xli.
Circus of Caracalla, xii.
Composite Capitals, xxvii.
Corinthian Ditto, xxvii.
    Order from the Temple of Jupiter Stator, in
    Rome, xxix.
Corona, xxi.
Cyma, xxi.
Cymatium, xxi.
Doors, xiii. xxiv.
Doric Base, i. 3.
    Capital, i. 5. 6.
    Order, xviii. a.
from the Agora, at Athens, xviii. 5.
    Parthenon, xiii.
    a Temple at Selinus, xv. 5.
    a Temple at Delos, xv. i.
    Agela, xv. 3.
    the Temple of Philip, at Delos, xv. 2.
    Jupiter, at Selinus, xv. 4.
    according to Sir W. Chambers, xvi.
    from the Temple of Jupiter Panellenius, in
    Agina, xvii. 4.
    from the Temple of Concord, at Agrigentum,
    xvii. 3.
    from the Temple of Minerva, at Athens,
    xvii. 5.
    from the Temple of Thefeus, at Athens,
    xvii. 2.
    from a Pseudo-diportal Temple, at Paflum,
    xvii. 1.
    from the Temple of Marcellus, at Rome,
    xvii. 1.
    from an Hexathy Temple, at Paflum,
    xvii. 2.
    from the Temple of Jupiter Nemueus, near
    Argos, xviii. 3.
    from the Temple of Juno Lucina, at Agrigentum,
    xviii. 4.

Echino, xxi.
Egyptian Capitals, xxvi.
Facia, xxi.
Fillet, xxi.
Hindoo Temple in Bahar, xx.
Hollow, xxi.
Joinery, xxii.—xxiv.
Ionic Base, i. 4.
    Capital, i. 7.
    Order, from the Temple of Minerva Polias, at
    Priene, xxviii.
Latopolis, Portico at, xxx.
Liftel, xxi.
Modillion, xxi.
Mouldings, xxi.
Ogee, xxi.
Pandrofus, Temple of, at Athens, xix.
Pannel, xxi.
Portico at Latopolis, xxx.
    Eastern, of the Parthenon, at Athens, xxxi.
Roofs, xiii.—xlvii. lxvii. lxix.
Scotia, xxi.
Soffit, xxi.
Talon, xxi.
Titus, Baths of, xxxv.

ARCHITECTURE.

Torus, xxi.
Trochilos, xxi.
Tuscan Order from the Church in Covent-Gardea, xiv.

ARMOUR.

Bronzes, Ancient, i.—iii.
Carthaginian Armour, iii. 11—14. 16. 18. 19.
Croupie, or Buttock Armour, v. 2.
Danish Armour, iv. 3. 4.
Egyptian Armour, ii. 1. 2.
Greek Armour, ii. 3—10. 14. 18.
Henry the Eighth's Armour, v. i.
Norman Armour, iv. 5.
Plate Armour of Sir Thomas Beauchamp, iv. 6.
Roman Armour, iii. 12. 15. 20.
Saxon Armour iv. i. 2.
Sword, Bras, in the British Museum, iii. 11. 19.
Tilting Armour of Robert Dudley, Earl of Leicester, v. 5.
    Half Habit of Prince Henry, v. 4.

ARTILLERY.

Aries, or Battering Ram. i.
Catapulta, ii.
Carriages, i.—v.

ASTRONOMY.

Aberration, i. 1, 2.
Altitude, i. 5—6.
    Parallax of, i. 8.
    Refraction of, i. 7.
Anomaly, i. 9.* 10.*
Arc, i. 11.*
Area, i. 12.
Argument, i. 13.
Armillary Sphere, iii. 14.
Ascending Nodes, xxii. 4.
Ascencion, iii. 15—17.
Axis, iii. 18. 19.
Azimuth, iii. 20. 21.
Chronology, iii. 22.
Comet, iv. 23—36.
Comets, Parabolic Orbits of 79, xii.
Commutation, v. 37.
Configuration, xx. 4.
Copernican Sphere, xx. 7.
    Sytem, xx. 15.
Crepusculeum, v. 38—42.
Culmination, i. 3. 4. v. 43.
    Day, v. 43.
    Declination, v. 44. 45.
Degree, vi. —viii.
Demicrrofs, v. 46.
Depth, ix. 68.
Depreftion, ix. 61, 62.
Deviation, ix. 63.
Diameter, ix. 64—66.
Dichotomy, ix. 67.*
Double Star, ix. 67.
Earth, ix. 68—70, x. 71.
Eclipfareon, Ferguson's, x. 74.
Eclipse, x. 75—77, xi. 78—89, xi. No. 2. 90—99.
    Hindoo Computation, xii. 90.

5 C 2
INDEX OF THE PLATES.

ASTRONOMY.

Eclipse, Mr. Pond's Machine for, xii. 100.
Elliptic, xii. 101—103.*
Egyptian System, xx. 16.
Elevation, xii. 102.
Elliptic, xii. 103.
Elongation, xii. 104.
Epicycle, xii. 105.
Equal Altitude, xii. 106.
Equation of the Center, xii. 107.*
Equator, xii. 109.*
Equinox, xii. 110.
Evection, xii. 107—109. (one figure)
Excentric, xiii. 110—113.
Galaxy, xiii. 114, 115.
Geocentric, xiii. 116.
Globe, xiv. 117—121.
Ferguson's Celestial, xv. 122.

Heat, xvi. 138.
Heliocentric Latitude, xvi. 139.
Hemisphere, Horizon, Tropics, xvi. 140.
Northern, i.
Southern, ii.
Horizon, xvi. 140, 141.
Horodidical Quadrant, xix. 8.
Hour, xvi. 142.
Jupiter, xvi. 143—146.
Satellites of, xxi. 3.
Latitude, xvi. 147.
Heliocentric, xvi. 139.
Reduction, xvi. 148—xix. 10.
Longitude, xvii. 1.
Magnitudes, proportional, of the primary Planets, ii. 10.
of the Sun, as seen from ditto, ii. 11.
Mars, xvii. 2.
Meridian Line, xvii. 3, 4.
Moon, xvii. 5—15.
Moon's Parallax, xvii. 8—14.
Nodes, xviii. 2.
Orion, Constellation of, i.
Paracentric, xviii. 3.
Parallax, xviii. 4—7.
of Altitude, i. 8.
of the Moon, xviii. 8—14.
of Venus, xviii. 15.
Particula Exfors, xix. 1.
Penumbra, xix. 2, 3.
Planet, xix. 2, 3—5.
Preceletion of the Equinoxes, xix. 7.
Prodhaphareis, xix. 7.*
Ptolemaic Armillary Sphere, xx. 6.
Pythagorean System, xx. 15.
Quadrant of Altitude, xiv. 120—xix. 9.
Quadrant, Horodidical, xix. 8.
Reduction, Latitude, xvi. 148, xix. 10.
Refractions, xxi. 11.
of Altitude, i. 7.
Retrogradation of Planets, xix. 12.
the Sun, xix. 13.
Saturn's Ring, xix. 14—16.
Solar System, ii.
Sphere, Armillary, iii. 14.
Sphere, Copernican, xx. 7.

ASTRONOMICAL INSTRUMENTS.

Alfrald's, i. 1.
Back staff, i. 2.
Bird's Quadrant, Graduation of, xviii. 2.
Bifedtion, of an Arc, xxi. 5.
Borda's Circle, iv. 4—9.
Brewster's, Dr., Patent Telescope, xxx. 4.
Cavendish's, Mr., method of graduating Circles, xviii. 4.
Quinqueleftions, xviii. 5.
Chaulme's, Due de, method of graduating Circles, xviii. 3.
Circle, Borda's, iv. 4—9.

Collector, without reflection, vi.
Graduated, with 2 and 3 verniers, iv. 1—4.
Mayer's, ii. 1—3.
Mendoza's, iv. 5.
Mural, x.
Portable, ix.
Repeating, without reflection, vii.
Wollaston's, viii.

Clavius's method of graduating a Circle, xxi. 1, 2.
Cole's Quadrant, xvi. 2.
Mr., Equal Altitude, xvii. 3.
Cros's Staff, i. 3.
Davis's Quadrant, i. 2.
Dial, Star, i. 6.
Dollond's Portable Equatorial, xi. 3.
Dollond's, Portable, xvi. 2.
Dollond's, Portable, xx. 2.
Dollond's, Portable, xiii. 2.
Dollond's Portable Equatorial, xi. 3.
Dollond's, Portable, xvi. 2.
Dollond's, Portable, xx. 2.
Dollond's, Portable, xiii. 2.
Dollond's Portable Equatorial, xi. 3.

Earl of Hay's, xvii. 4, 5.
Equatorial Instruments, portable, Dollond's, xi. 3.
Fayrer's, xi. 3.
Nairne's, xii. 1.
Ramden's, xi. 2.
Made by ditto for Sir G. Shuckburgh, xv.
Short's, xi. 1.

Equatorial, Universal, by Troughton, xiv.
Equatorial Instrument, Troughton's, at Armagh, xvi.
INDEX OF THE PLATES.

ASTRONOMICAL INSTRUMENTS.

Equatorial Sector, Graham’s, xiii. 1.

Sifflon’s, xvii. 1, 2.

Equatorial Stand of a Telescope, by Smeaton, xiii. 5.

Fayrer’s Equatorial Instrument, xi. 4.

Fore Staff, i. 3.

Graduation of Circles, xvii. i—xx.

Bird’s Method, xviii. 2.

Cavendish’s Method, xviii. 4.

Duc de Chaulnes’s Method, xviii. 3.

by Clavis, xx. 1, 2.

Graham’s Method, xviii. 1.

by Maferchoni, xxi. 3—5.

Troughton’s Method, xix. xx.

Graham’s Equatorial Sector, xiii. 1.

Quadrant, Graduation of, xviii. 1.

Mural Quadrant, xxi. 4.

Zenith Sector, xxxiii. 1.

Gunter’s Quadrant, xxii. 3.

Hadley’s Octant, xxii. 1.

Herschel’s, Dr., 40-feet Reflecting Telescope, xxxi.

Hay’s, Earl of, Equal Altitude Instrument, xvii. 4.

Maferchoni’s Method of graduating a Circle, xxi. 3—5.

Mayer’s Circle, ii. 1—3.

Mendoza’s Circle, iv. 5.

Microscope, Object Glafs, Dollond’s, xii. 4.

Microscope, Compound, Theory of, xxiv. xxv.

Nairne’s Portable Equatorial, xii. 1.

Newton’s Quadrant, i. 7.

Nocturnal, i. 6.

Object Glas Micrometer, Dollond’s, xii. 4.

Octant, Hadley’s, xxxiii. 1.

Pearson’s, Rev. Dr., Rotative Roof for an Observatory, xxii. 5, 6.

Quadrant, i. 4.

Cole’s, xxxiii. 2.

Davis’s, i. 2.

Elton’s, i. 8.

Graham’s Mural, i. 4.

Gunter’s, i. 3.

Newton’s, i. 7.

Ramond’s, i. 5.

Troughton’s, i. 6.

Bird’s, Graduation of, xviii. 2.

Graham’s, Graduation of, xviii. 1.

Ramond’s Astronomical Circle, v.

Portable Equatorial, xi. 2.

Equatorial Instrument, made by, for Sir Geo. Shuckburgh, xv.

Quadrant, xxi. 5.

Refraction Apparatus, xii. 2.

Zenith Sector, xxxiii. 2.

Rotative Roof, Pearson’s, xxi. 5, 6.

Smeaton’s, xxxii. 1—4.

Short’s Portable Equatorial, xi. 1.

Sifflon’s Equatorial Sector, xvii. 1, 2.

Smeaton’s Equatorial Stand of a Telescope, xiii. 5.

Micrometer, xiii. 3.

Mr., Rotative Roof for an Observatory, xxi. 1—4.

Support for a Telescope, xxx. 8.

Star Dial, i. 6.

Telescope, Theory of the, with respect to Aberrations, &c. xxv.

Telescope, Achromatic, principles of, xxviii. xxix.

Dr. Brewter’s patent, xxx. 4.

ASTRONOMICAL INSTRUMENTS.

Telescope, Dr. Herschel’s 40-feet Reflecting, xxxi.

Telescopes, Reflecting, Theory of, xxvii.

chiefly Reflecting, xxx.

Reflecting, Theory of, xxiv. xxv.

Troughton’s English Reflecting Circle, iii. 1, 2.

Mural, x.

Portable Circle, ix.

Repeating Circle, without reflection, vii. 1, 2.

Method of graduating a Circle, xix. xx.

Universal Equatorial Instrument, xiv.

Equatorial Instrument at Armagh, xvi.

Quadrant, xxxi. 6.

Transit Instrument, xxxi.

Wollaston’s Circle, viii.

Zenith Micrometer, Dollond’s, xxxii. 3—6.

Sector, Graham’s, xxxiii. 1.

Ramond’s, xxxii. 2.

BASSO RELIEVO.

Altars, Pagan, iv. No. 1—5.

Carrara, Basso Relievo on a Capital in the Cathedral of, iv. 1.

Hercules and Apollo contending for the Tripod, ii. 1.

Hindu Basso Reliefs, i. 2.

Minerva subduing Hercules, ii. 2.

Sphinx, Egyptian Hieroglyphical, i. 1.

Xanthippus, Tombstone of, iii.

Zethus, Antiope and Amphion, Basso Relievo of, iv. 2.

BLEACHING.

Boiling Pan, &c. iv. 1—7.

Bucking, i. 1—3.

Drying, iii. 1—4.

Oxi-muriatic acid, i. 4.

Washing and Clearing, ii. 1—7.

BLOCK MACHINERY.

Boring Machine, iv. 1—4.

Cooking Engine, ii. 4—9.

Cornering Saw, iv. 5—9.

Crown Saw, ii. 1—3.

Dead Eyes, machine for making, vii. 6, 7.

Lathe, Face Turning, iii. 3—7.

Rivetting Hammer, iii. 1, 2.

Sawing Machine, i. 1—4.

Scoring Machine, vii. 1—5.

Shaping Engine, vi. 1—5.

BOATS. SEE SHIPS.

CAMP.

Caftremation, v. xxii.

Circumvallation, lines of, iv.

Encampment of a Park of Artillery, iii.

Roman Confular Camp, according to Polybius, i.

Roman Camp for Three Legions, and according to the Hyginian system, ii.

CANALS.

Aqueduct Bridge at Kelvin, ii. 19—21.
INDEX OF THE PLATES.

CANALS.

Aqueduc, Cast Iron, Fulton's, iii. 23, 24.
Mr. Telford's, on the Shrewsbury Canal, iii. 22.
Barrow, vii. 48.
Bridges, vi. v.
Deep Cutting, i. 6.
Embarking, i. 4, 5.
Embankment, iv. 25.
Grafting Tool, vii. 50.
Level Cutting, i. 1—3.
Lining, i. 15.
Locks, v. 36—39.
Navigator's Tools, vii. 48—52.
Pile Planks, iv. 30.
Puddling, i. 14.
Rail Ways, Iron, iv. 31—35.
Referoirs, i. 16—18.
Safety Gate, iv. 26.
Scoop, vii. 52.
Shovel, vii. 51.
Swing Bridge, vii. 43—47.
Weirs, iv. 27—29.

CANDLE MAKING

Apparatus for dipping Candles, 1.
Mould Candles, 4.
Candlelicks, 7—12.
Mould, 6.
Frame, 5.
Wick Broach, 2.
Cutter, 3.

CANNON.

Boring Cannon, Machinery for, ii. iii.
Cannon, whole length, i. 1.
Cafeable, i. 2.
Howitzer, i. 7, 10.
Mortar, 1. 4, 11.
Land, i. 8.
Sea, i. 5, 6, 9.
Stone, i. 12.
Muzzle, i. 3.

CANTEENS.

Boring Machine, i. 7.
Bung Stave, i. 6.
Canteen, i. 1.
Center Bit, i. 8.
Cros Cutting Saw, i. 2, 3.
Punching the Hoops, ii. 18.
Rounding the ends of the Hoops, ii. 19.
Screw Hoop, ii. 11.
Shears, ii. 16, 17.
Slider, i. 9.
Tenating or Rebating Saw, i. 4, 5.

INDEX OF THE PLATES.

HOROLOGY.

Escapement, xxxi.—xxxvi.
Remontoir, xlii.
Amant’s, xxxiii. 4.
Anchor, xxxiii. 5.
Bennet’s dead beat, xxxii. 7.
Berthoud’s, xxxiii. 1.
for Chronometers, xxxiv. 4—8.
Betheune’s, xxxiii. 3.
Cumming’s, xxxiii. 6.
Duplex, xxxv. 5.
Goodriche’s, xxxvi. 3.
Graham’s dead beat, xxxii. 4, 5.
Horizontal, xxxii. 2.
Grignon’s dead beat, xxxii. 6.
Harrifon’s, xxxiii. 5.
Hooke’s, xxxvi. 8.
Huygens’s, xxxvi. 7.
Le Roy’s, xxxiii. 8.
Improved, xxxiv. 1—3.
Margett’s, xxxv. 3.
Maffey’s, xxxvi. 5.
Mudge’s, xxxiii. 7.
for Chronometers, xxxv. 1.
Nicholfon’s, xxxvi. 2.
Robins’s, xxxv. 4.
Smeaton’s, xxxiii. 2.
Sully’s, xxxii. 1.
Thiout’s, xxxvi. 8.
Tompion’s, xxxv. 7.
Troughton’s Escapement, xxxvii.
Compensating Pendulum, Mercurial, xl. 4.
Rhomboidal, xl. 2.

HOROLOGY.

Prior’s Striking part of Clock-work, xxvi. 2, 3.
Recordon’s Renovator, xliii. 1, 2.
Regnault’s Compensating Pendulum, xl. 5.
Reid’s Astronomical Clock by, xxii.
Reid’s Compensating Pendulum, xl. 7.
Remontoir Escapements, xlii.
Ritchie’s Compensating Pendulum, xl. 9.
Robins’s Escapement, xxxv. 4.
Smeaton’s Escapement, xxxiii. 2.
Sully’s Escapement, xxxii. 1.
Thiout’s Escapement, xxxvi. 8.
Time Keeper, Mudge’s, xiii.
Tompion’s Escapement, xxxv. 7.

Ward’s Compensating Pendulum, xl. 6.
Watch, with Alarum, xlv. 9—14.
Common, xlv. 1—8.
with Mufic, xliii. 4—9.
Repeating, xlv. 1—6, xlvii. xlvii. 6.
Rolling, xlv. 15—18.

HYDRAULICS.

Archimedes’ Screw, xiv. 11—13.
Contracted Vein, i. 1—4.
Counterpressure, i. 5.
Discharge of Fluids, i. 6—17.
Diving Bell, Dr. Halsey’s, ii. 18.
Spalding’s, ii. 20.
Triewald’s, ii. 19.
Machine, Klingert’s, ii. 21—27.
Dredging Machine used on the Thames, iii. 1, 2.
Eddy, iii* 3.
Fire Engine, iii. 4.
Newham’s, iii* 5—11.
Rowntree’s, iv. 1—6.
Floating, vii. 1, 2.
Fluids, i. v. vi.
Discharge of, i. 6—17.
Fountain, vii. 7.
Hieron’s Crown, viii. 5.
Hydromancy, viii. 3, 4.
Hydrometer, ix. 1.
Clark’s, ix. 2, 3.
Defagulier’s, ix. 4.
De Luc’s, ix. 5.
Nicholfon’s, ix. 6.
Hydrosstatic Balance, x. 7, 8.
Defagulier’s, x. 9.
Martin’s, x. 10.
Hydrosstatic Bellows, x. 11.
by Fergucon, x. 12—14.
Hydrosstatical Paradox, x. 15, 16.
Instrument, Bradford’s, xii. 14.
Hygrometer, xii. 13.
Anderfon’s, xii. 8.
Fergucon’s, xii. 12.
Forler’s, xii. 11.
Hale’s, xii. 11.
Hooke’s, xii. 9, 10.
Kater’s, xii. 12.
De Luc’s, xiii. 5, 6, 8, 9.

Cylindrical, Cylindrical, ii. 2.

Cylindrical, ii. 2. No. 2.

Plano Cylindrical, ii. 1.

Masonry, Greek, i. 6.

Incert, i. 2.

Isodum, i. 3.

Pleudidum, i. 4.

Reticulated, i. 1.

Roman Emplection, i. 5.

## MECHANICS.

Acceleration, i. 1, 2.

Angle of Elevation, i. 3, 4.

Angular Motion, ii. 1.

Axis in Peristrephiochi, i. 5-7.

Balance, ii. 8-11.

Affay, ii. 13.

Bent Lever, ii. 12.

Ballast, ii. 14.

Boring Cyliniders, Dixon's Machine for, xxiii. 1, 2.

Water Pipes, ii. 2-4.

Crab, ii. 5.

Cylinder, Double, ii. 6, 7.

Jack, for raising Weights, ii. 8, 9.

Smoke, ii. 10.

Lever, ii. 11-13.

Projectiles, ii. 14-17.

Capstan, iii. 15-21.

Center of Friction, iv. 21.

Gravity, iv. 22-29.

v. 30-40. vi. 41-51.

Gyration, vii. 52-54.

Motion, vii. 55.

Oscillation, viii. 56-60, viii. 61-66.

Percussion, viii. 67-69.

Position, ix. 70-73.

Preffure, ix. 74, 75.

Rotation, ix. 76-80.

Central Forces, x.

Centrifugal Forces, x.

Machine, xi. 93.

Centripetal Forces, x.

Centrobaryc Method, xi. 94-99.

Chains, xii. 1-9.

Clay Mill, xii. 10, 11.

Coach, xiii.

Coal Measuring, xiv.

Cocks, Water, xiv.

Collusion, xv. 1-24.

Colour Mill, xxv. 1-6.

Comb Making, xv. 1-7.

Composition of Motion, xvi. 1, 2.

Condenser of Forces, Frony's, xvi. 10, 11.

Cone, Double, xvi. 7.
MECHANICS.

Cork Screw, xvii. 1—4.
Corking Machine, xvii. 5.
Coupling Box, xv. 6—8.
Crane-necked Carriage, xiii. 1.
Crane, various, xxi.

by Brathwaite, xx. 3, 4.

Dixon, xx. 5.
Ferguson, xviii. 2, 3.
Smeaton, xix. 2, 3.
White, xx. 1, 2.
Cylinders, Dixon’s Machine for boring, xxiii. 1, 2.

of Motion, xxii. 3.

Bolts, Ships’, Hill’s Machine for drawing, xxiii. 1, 2.

Drilling Machines, xxiv. 10, 11.

Drills, xxiv. 1—9.

Dynamics, M'Dougal’s, xxvi.* 1.
Salmon’s, xxvi.* 2.

Expanding Riggers, Mr. Farey’s, xxvi. 8—11.
Mr. A. Flint’s, xxvi. 5—7.

Flour Mill, Dr. Barker’s, xxxiii. 3.

Common Breech Mill, xxxiii. 1.
Portative or Hand Mill, xxxiii. 4.
designed by Smeaton, xxiv.

Fly Prefs, xxvii. 1—9.

Force, xxviii. 1—20.

Friction, xxix. 1—3.

Fulling Mill, xxiv. 4—6.

Jacob’s Contrivance for the Fore-wheel of a Coach, xiii. 2.

Inclined Plane, xxiv. 16—21.

Lead Pipes, Machine for casting and drawing, xl.

Logwood Mill, xxxi. 1—7.

Mechanical Powers, xxx. & xxxvi. 16, 17. xxxii. 1—17.

Motion, xxxiv. 1—11.

Diagonal, xxxiv. 2—5.

Perpetual, xxxiv. 11.

Percussion, xxxiv. 12—15.

Pile-driving Machine, xxxv. 1—7.

Engine, Valuée’s, xxv. 8, 9.

Piles, Bramah’s Machine for drawing, out of the Ground, xxxv. 15.

Pulley, xxx. & xxxvi. 11—13.

Refraction, xxx. & xxxvi. 14.

Rotation, xxxvii. 1—16.

Screw, xxxviii. 1—4.

Machine for trying, xxxviii. 5.

Solid of the leaf refraction, xxx. & xxxvi. 15.

Spring, xxxviii. 6—10.

Steel-yard, xxxviii. 11.

Throwing Mill, Salmon’s portable, xxvii.

Wedge, xxx. 1—5.

Weight, xxx. 6, 7.

Wheel, xxx. 8—13.

MILITARY MANŒUVRES.

Manœuvre, first to the fourth, i.

fifth to the ninth, ii.
tenth to the thirteenth, iii.
fourteenth to the sixteenth, iv.
fifteenth to the nineteenth, v.

Inspection, or Review, vi.

INDEX OF THE PLATES.

MILL WORK.

Bevilled Wheels, i. 5, 6.
Cog Wheels, i. 1—3.
Comical Wheels, i. 7.
Shafts, &c. ii. iii.

MISCELLANY.

Æolus Harp, xxv. i.

Altar of Burnt-offering, i. 4.

Incense, i. 3.

Altitude of the Sea, i. 1, 2.

Arithmetical Characters, Ancient, i. 7.

Ark of the Covenant, i. 5.

Bee-hive, Thorley’s, xx. 1.

White’s, xx. 2—4.

Button-making, ii.

Chimney, by Dr. Franklin, xiv. 1—7.

Chimney cleaning Machine, Smart’s, ii. 1—6.

Ching, Musical Instrument, i. 8.

Chuviole, Hawkins’s, xiv. 1—6.

Coinage, iii. 1—3.

Copying Machines, iii. 1—3.

Crowth, xxv. 2.

Crystallography, iii. 21, 23.

Dumast, iv. 11.

Diagonal Motion, v.

Automaton, vii.

dividing and cutting Engine, vi. 18—20.

Diaper, xiii. 8.

Diaper Loom, viii. 1, 2.

Dimity, iv. 10. xii. 5, 7.

Discharging Prefs, viii. 1—4.

Dissimilar Spots, weaving, xii. 10.

Dornock, iv. 9. xii. 6.

Dramatic Machinery, ix. & x. x. & xi.

Draper, xx. 8, 9.

Draught and Cordine Looms, xii.

Draw Loom, viii. 3.

Drowned, Perfous apparently, Apparatus for reforing, xv. 1—5.

Eufel, Painter’s, xii. 1.

Efeutcheon, secret, for a key-hole, Marshal’s, xii. 1—8.

Extinguishers, self-acting. xii. 9.

Hawkins’s, xii. 10.

File-cutting, xiii. 1—7.

Filters, xiii. 8—10.

Filtration, xxv. 3.

Fire Escape, Malere’s, simplified by Forster, xii. 12.
orignial Suspension, xii. 13.

Fire-places, by Dr. Franklin, xiv. 1—7.

Flood-gate, by Smeaton, xv. 5, 6.

self-acting, by Farey, xv. 7.

Foundry of Bella, xv. 1.

Types, xv. 2, 3.

Fountain Pen, xv. 4.

Gage, Hale’s Aquo-mercual, xvi. 2.

Hooke’s Sea, xvi. 1.

Rain, xvi. 10.

of the Royal Society, xvi. 11.

Sea, i. 1, 2.

Gas Lights, Clegg’s Apparatus for, xvii. 1—3.

Cooke’s Apparatus for, xvii. 5.

Dr. Stanchile’s Apparatus for, xvii. 4.

Gem Engraving, Apparatus for, xviii. 1—18.

PLANETARY MACHINES.

Cometarium, i.

by W. Jones, ii. 1—3.

Dial for the Equation of the Sun's Center, ix. 1.

Sun's Declination, ix. 2.
of mean High Tides, ix. 8.

for the Moon's Equation of the Center, ix. 4.

Heliocentric Latitude, ix. 5.

Horizontal Diameter and Parallx, ix. 7.

Parallx, ix. 6.

Reduction of the Equinox to the Equator, ix. 3.

Dials, graduated for showing Planetary Phenomena, ix.

Equation Mechanism of a Planet's Orbit, by Huygens, iii. 1.
### PLANETARY MACHINES.

Equation Mechanism of a Planet's Orbit, by Priestley, iii. 2.
by Pearon, iii. 3—5. iv. 1—6.

Jovilabe, by Janiers, xii. 5.

Orrery for equated Motions, v.
mean Motions, viii. viii.

Janvier's vi.

Planetarium, Common, x. 1.
Pearson's for the Royal Institution, x. 2—5.
equated Motions, xi. 1, 2.

Satellitian, by Pearson, xii. 2—4.
Roemer, xii. 1.

### PLANING.

Bramah's Planing Machine, i. ii.

### PLATED MANUFACTURE.

Die Stamp, 1.
Furnace, 12.
Punches, embossing, 11.
Rollers, grooved for Beads, 8—10.
Swage, Bit, 3.
Common, 4.

### PNEUMATICS.

Aëoliule, i. 1.
Aërolation, i. 2—4. 9—12. ii. 5—8.
Air Gun, iii. 14—25.
Air Pump, iv. 24—32. v. 33—44. vii. 48—55. viii. 56.

Air Pump, Cuthbertson's viii. No. 2. 58—66.
Nairne's, vi. 46, 47.
Smeaton's, vi. 45.
Anemometer, vii. No. 2. 69.
Aræometer, vii. No. 2. 70, 71.
Atmosphere, viii. No. 2. 72.
Bacchus, viii. No. 2. 73.

Bifloire Caché, Coimé's, vii. 8.
Blifourry, vii.
Bone Nippers, ii.
Brufh for cleaning the Teeth of the Trephine, vii. No. 2, 11.
Capule, Cline's Instrument for dividing, x. 2.
La Faye's Cyiltome for dividing, x. 3.
Minute Steel Tenaculum, for extracting Bits of,
x. 1.
Cataract, Instruments for the Extraction of, x. xi.
Catheters, Female, iii. 13, 14.
Male, iii. 16—19.
Cauftic Cafe, iii. 7.
Cornea, Sciflars for enlarging the Wound of, x. 4, 5.
Couching, Instruments for, xii.
Director, iii. 10.
Elevator for raifing depressed Portions of a Fractured Scull,
viii. 2.
Common, viii. No. 2. 5.
Petit's, improved by Louis, viii. 49.
Tripod, viii. 3.
Eye Probe, iii. 6.
Fistula Lacrimalis, Instruments for, x.
Forceps for taking up the Mouths of Vessels, ii.
Common, iii.
INDEX OF THE PLATES.

Surgery.

Forceps for Lithotomy, vi. 10–12.
Spring, for extracting the Circle of Bone, &c. in Trepanning, viii. No. 2. 1.
Wenzel's, for extracting Bits of Capsule, &c. xi. 18.
Fracture of the Clavicle, iv.
Leg, v.
Goret, Abernethy's, vi. 9.
Blunt, vi. 6.
Cline's Cutting, vi. 8.
Hawkins's Dito, vi. 7.
Hook, Silver, used in Couching, xi. 1.
Pellier's Dito, Ditto, xi. 2.
Lancet, iii. 5.
for puncturing the Lachrymal Sac, x. 13.
Lenticular, viii. No. 2. 7.
Knife for Extraction of the Cataract, Richter's, xii. 12.
Ware's, xi. 14.
Wenzel's, xi. 13.
Wathen and Phipps', xi. 10, 11.
enlarging the Wound of the Cornea, xi. 15, 16.
Lithotomy, Blizzard's, vii. 7.
Burn's, vii. 4.
A. Cooper's, vii. 6.
Gibson's, x. 14.
Hunter's, vii. 5.
Lithotomy, Instruments for, vii. 7.
Needles, Aneurism, ii.
for sewing up Wounds, iii. 1–3.
for Couching, xi. 3–5. 19.
Hey's ditto, x. 7–9.
Probe, Common, iii. 9.
Eye, iii. 6.
Rasputory, viii. No. 2. 8.
Saw, Hey's, with curved edges, viii. No. 2. 6.
Large straight, viii. No. 2. 10.
Small ditto, viii. No. 2. 9.
Old Conical, viii. 5.
Scalpel, ii.
Scalpel for Trepanning, viii. No. 2. 4.
Scissors, iii. 11.
for enlarging the Wound of the Cornea, x. 4, 5.
Scoop, for Lithotomy, vii. 2.
Screw, for regulating the dilatance to which the blade shall move out, in Lithotomy, vii. 9.
Sound, for Lithotomy, vi. 1.
Spatula, iii. 4.
Splints, v.
Staffs, for Lithotomy, vii. 2–5.
C. Bell's, vii. 3.
A. Burn's, vii. 4.
Stiles, Ware's, x. 11.

Combs, i. 1.
Cartwright’s Combing Machine, ii. 1—3.
Gilpin’s Combing Machine, i. 4.
Roving Frame, i. 6.
Spinning Frame, i. 7.
Stove, i. 3.

WRITING BY CIPHER.
Characters and Examples, i. 1—iii.

* * As only a few of the Plates relating to Natural History are referred to in the articles of the Cyclopaedia which they are intended to illustrate, it has been deemed unnecessary to incorporate the subjects of them in the Index. The systematic arrangement and minute analysis of them in the annexed Catalogue will, it is conceived, be found ample sufficient for every purpose of reference and consultati

THE END.

New-Street-Square, London.
DIRECTIONS TO THE BINDER.

In making up the Plates of the Cyclopaedia into volumes, the first business of the binder must be to arrange the Plates in their several classes, as Agriculture, Algebra, Analysis, &c., and in the order in which they are numbered. He must, however, observe, that some of the Plates are wrongly numbered: which those are, and to what place in the series they must be transferred, he will easily learn from the Catalogue. In some instances he will find two or three Plates numbered alike; and, in others, Plates on which the number has been omitted: in these cases again, he will readily ascertain, from an inspection of the Catalogue, where, and in what order, they are to be placed. In every case, the Catalogue must be his guide, and to this he must rigidly adhere in the arrangement and disposition of the whole of the engravings.

---

ERRATUM,

The following Plate has been accidentally omitted, both in the Catalogue and in the Index. The Binder is required to place it immediately after the other Plate of Architecture numbered XV.

ARCHITECTURE, Plate XV.
Doric Order.
Fig. 1. From the temple of Corinth
2, 3. a Hypaethral Temple at Paestum
4. the Temple of Minerva at Sunium
5. at Syracuse
